C. nivalis, usnic acid (Z. 1904). *C. stuppea* protolichesteric acid (Z. 1904). *C. aculeata* or *Cornicularia aculeata*, protolichesteric acid (Z. 1904); lichenin and lichenic (fumaric) acid. *C. pinastri*, pinastric acid $C_{10}H_8O_3$ (Z. 1895). *C. glauca* (*Platysma glaucum*), lichenin (Berzelius). *C. juniperina*, chrysocetraric acid $C_{19}H_{14}O_6$, usnic and vulpic acids (H. 1898). *C. pinastri*, chrysocetraric, usnic and vulpic acids (H. 1898; Z. 1899). *C. fahlunensis*, cetraric acid (Z. 1898).

Candelaria concolor, callopismic acid or ethylpulvic acid $C_{20}H_{16}O_5$, dipulvic acid $C_{32}H_{22}O_9$ (Z.); calycin, and stictaurin $C_{18}H_{12}O_5$ (H.; Z. 1899). According to Hesse, 1898, dipulvic acid is a mixture of calycin and pulvic anhydride. *C. vitellina*, stictaurin (Z. 1899), calycin and pulvic anhydride (Z. 1899).

Cladina silvatica, usnic acid and cetraric acid (Z. 1898). *C. alpestris*, usnic acid (Z. 1898). *C. rangiferina*, cetraric acid and atranorin (Z. 1898) and usnic acid (H. 1898). *C. pyxidata*, parellic acid (H. 1898). *C. coccifera*, cocellic acid $C_{20}H_{22}O_7$ (H. 1898). *C. uncialis*, *d*-usnic and thamnolic acids $C_{20}H_{18}O_{11}$ (Z. 1902).

Cladonia amaurocraea, usnic acid (Z. 1898). *C. alcicornis*, usnic acid (H. 1902). *C. deformis*, usnic acid (Z. 1900). *C. cyanipes*, usnic acid (Z. 1900). *C. Floerkeana*, cocellic and thamnolic acids (H. 1900). *C. rangiformis*, atranorin, rangiformic acid $C_{20}H_{33}O_5{\cdot}OMe$ (H. 1898). *C. uncinata* (no usnic acid, see Knop, Annalen, 1844, 49, 120); but uncinatic acid $C_{23}H_{28}O_9$ (H. 1900). *C. destricta* (*C. uncialis*), usnic acid and starch (Knop, Annalen, 49, 119); *l*-usnic acid (Salkowski, Annalen, 1901, 319, 391). *C. incrassata*, *l*-usnic acid (S.). *C. glauca*, squamatic acid (Z. 1902). *C. strepsilis*, thamnolic acid and strepsilin (Z. 1903). *C. thamnolis*, thamnolic acid $C_{20}H_{18}O_{11}$, and strepsilin. *C. destricta*, *l*-usnic acid (Z. 1903); *l*-usnic and squamatic acids and cladestin (H. 1904). *C. macilenta*, usnic acid and starch (Knop, *l.c.*); rhizonic acid (Z. 1903). *C. squamosa*, var. *ventricosa*, squamatic acid (Z. 1904). *C. squamosa*, var. *denticollis*, squamatic acid (Z. 1907). *C. fimbriata*, var. *simplex*, fumaroprotocetraric acid and fimbriatic acid (Z. 1907). *C. fimbriata*, var. *cornuto-radiata*, fumaroprotocetraric acid (Z. 1907). *C. pityrea*, var. *cladomorpha*, fumaroprotocetraric acid (Z. 1907). *C. silvatica*, var. *condensata*, *l*-usnic acid (Z. 1907). *C. verticillata*, var. *subcervicornis*, fumaroprotocetraric acid (Z. 1907), atranorin and cervicornin. *C. chlorophæa*, fumaroprotocetraric acid. *C. gracilis*, var. *chordalis*, fumaroprotocetraric acid (Z. 1907). *C. crispata*, var. *gracilescens*, squamatic acid (Z. 1907). *C. coccifera*, cocellic acid $C_{20}H_{22}O_7$ (H. 1895). *C. incrassata*, *l*-usnic acid (Z. 1905). *C. rangiferina* usnic acid (Rochleder and Heldt, Annalen, 48, 2); lichenin (Schmidt, *ibid.* 51, 29); cladonic acid (*β*-usnic acid) $C_{18}H_{18}O_7$ (Stenhouse, *ibid.* 155, 58); *d*-usnic acid (no *l*-usnic) and silvatic acid $CO_2Me{\cdot}C_{18}H_{34}O_3{\cdot}COOH$ (H. 1907); atranorin and fumaroprotocetraric acid (Z. 1906). *C. rangiferina*, var. *vulgaris*, atranorin and protocetraric acid (H. 1898). *C. rangiferina*, var. *silvatica*, *d*-usnic acid (Z. 1906); usnic and protocetraric acids (H. 1898). *C. pyxidata*, lichenin (Schmidt, Annalen, 51, 29); emulsin (Hérissey, J. Pharm. Chim. 1898, [vi.] 7, 577).

Cornicularia aculeata, rangiformic acid (H. 1902).

Chiodecton sanguineum (*C. rubrocinctum*), chiodectonic acid $C_{14}H_{18}O_5$.

Cyphelium trichiale, var. *candelare*, calycin (Z. 1906).

Darbishirella gracillima, parellic acid (H. 1898).

Dendographa leucophæa, protocetraric acid (H. 1898); erythrin and orcinol (Ronceray, Bull. Soc. chim. 1904, [iii.] 31, 1097).

Dimelaena oreina, zeorin and usnic acid (Z. 1897).

Diploicia canescens (*Catolechia canescens*), diploicin, m.p. 225°, catolechin, m.p. 214°–215°, and atranorin (Z. 1904).

Diploschistes scruposa, diploschistessic acid $C_{15}H_{16}O_7$ (Z. 1906).

Endocarpon miniatum (α) *vulgare*, phytosterol and an acid (H. 1898).

Evernia divaricata, divaricatic acid (H. 1900) $C_{21}H_{23}O_6{\cdot}OMe$, and usnic acid (Z. 1897); no usnic acid (H.). *E. furfuracea*, usnic acid (Rochleder and Heldt, Annalen, 48, 9); no usnic acid, but erythric acid (Z. 1897), or rather olivetoric acid $C_{27}H_{36}O_8$ (Z. 1900), physodic acid, physodylic acid $C_{23}H_{26}O_8$, and furevernic acid (H. 1907); atranorin, evernuric acid $C_{22}H_{24}O_8$, and furevernic acid, but no erythric or olivetoric acids (H. 1906); emulsin (Hérissey, J. Pharm. Chim. 1898, [v.] 7, 577). *E. prunastri*, evernic acid, atranorin (Z. 1897); evernic acid, usnic acid, and atranorin, and chrysocetraric acid (H. Annalen, 1895) $C_{19}H_{14}O_6$. *E. thamnodes*, divaricatic acid, usnic acid (Z. 1897; H. 1900). *E. vulpina*, vulpic acid and atranorin (H). *E. illyrica* (Dalmatia), divaricatic acid and atranorin (Z. 1904). *E ochroleuca*, usnic acid (Knop, Annalen, 49, 122).

Everniopsis Trulla, salazinic acid and atranorin (Z. 1897).

Gasparrinia medians (*Physcia medians*) calycin, rhizocarpic acid (H. 1898); pulvic lactone (H. 1903). *G. sympagea*, parietin (Z. 1905). *G. elegans* (*Physcia elegans*), physcion (H. 1898). *G. murorum*, physcion (H. 1898). *G. decipiens* physcion (H. 1898). *G. cirrhochroa*, chrysophanic acid (Z. 1897).

Graphis scripta, salazinic acid (H. 1900).

Gyalolechia aurella, calycin (Z. 1895), callopismic acid (Z. 1897), stictaurin (Z. 1899).

Umbilicaria pustulata (Hoffm.) (*Gyrophora pustulata*), gyrophoric acid $C_{36}H_{36}O_{15}$ (Stenhouse, Annalen, 70, 218) $C_{16}H_{14}O_7$ (H.). *G. hirsuta*, gyrophoric acid (Z. 1898). *G. deusta*, gyrophoric acid (Z. 1898). *G. polyphylla*, umbilicaric acid $C_{25}H_{22}O_{10}$ (Z. 1898); umbilicaric acid and gyrophoric acid (H. 1898, 1901). *G. hyperborea*, umbilicaric acid (Z. 1898). *G. deusta*, umbilicaric acid (Z. 1898). *G. vellea*, gyrophoric acid and gyrophorin, m.p. 189° (Z. 1899). *G. spodochroa*, var. *depressa*, gyrophoric acid (Z. 1900). *G. polyrrhiza*, umbilicaric acid, lecanoric acid, gyrophoric acid (Z. 1905).

Hæmatomma ventosum, divaricatic acid $C_{22}H_{26}O_7$, m.p. 149° (Z. 1898); *d*-usnic acid, divaricatic acid, and an acid resembling alectoric acid (H. 1900). *H. coccineum*, var. *leiphæmum*, leiphæmin, m.p. 193°, atranorin, zeorin (Z. 1902). *H. coccineum*, var. *abortivum*, coccic acid $C_{12}H_{16}O_{10},3H_2O$, m.p. 262°–264°, atranorin, hæmattomin $C_{10}H_{16}O$ or $C_{20}H_{32}O_2$, m.p. 143°–144°, and hæmatommidin, m.p. 194°–196° (Z. 1903); no zeorin (H. 1907). *H. coccineum*, var. (?), lecanoric acid (H. 1907). *H. coccineum*, var. (?) (from Wildbad), coccic acid, atranorin, zeorin, hydrohæmatommin $C_{10}H_{18}O$, m.p. 101° (H. 1906). *H. coccineum*, *l*-usnic acid, zeorin, atranorin, porphyrillic acid, hymenorhodin, and leiphæmin (Z. 1906). *H. leiphæmum*, atranorin, zeorin, leiphæmin, leiphæmic acid $C_{22}H_{46}O_5$, m.p. 114°–115° (Z. 1903). *H. porphyrium*, atranorin, zeorin, porphyrilic acid, leiphæmin, hymenorhodin (Z. 1906).

Pertusaria dealbata, Nyl. f. *corallina*, Cromb. (*Isidium corallinum*) ('white crottle'), calcium oxalate (Braconnot, Ann. Chim. Phys. [ii.] 28, 319).

Lecanora atra, atranoric acid (atranorin) $C_{19}H_{18}O_8$, and a yellow crystalline substance (Paternò and Oghaloro, Gazz. chim. ital. 1877, 7). Hesse (Ber. 10, 1324) considers the atranoric acid to be hydrocarbonusnic acid, and the yellow substance to be cladonic acid. Obtained from certain districts it contains lecanorol (Z. 1897) $C_{27}H_{30}O_9,H_2O$. *L. varia*, psoromic acid and *l*-usnic acid (Z. 1905). *L. grumosa*, atranorin and lecanorol (Z. 1897). *L. cenisea*, atranorin and roccellic acid $C_{17}H_{32}O_4$ (*cp.* Schunck and Hesse, *Roccella tinctoria*). *L. sordida*, atranorin, zeoric acid (Z. 1897). *L. sordida*, var. *glaucoma*, atranorin and parellic acid (H. 1898). *L. sordida*, var. *Swartzii*, atranorin, thiophanic acid $C_{12}H_6O_{12}{\cdot}H_2O$, m.p. 242°, roccellic acid, lecasteric acid $C_{10}H_{20}O_4$, m.p. 116°, and lecasteride $C_{10}H_8O_5$, m.p. 105° (H. 1898). *L. campestris*, atranorin (Z. 1897). *L. badia*, stereocaulic acid (Z. 1897). *L. effusa*, atranorin and usnic acid (Z. 1897). *L. subfusca*, atranorin (Z. 1897; H. 1900). *L. epanora*, zeorin and lepanorin, m.p. 131°–132° (Z. 1900). *L. glaucoma* (*L. sordida* α-*glaucoma*) (from Tyrol), atranorin, thiophanic acid, roccellic acid (Z. 1903). *L. sulphurea*, usnic acid (Z. 1903). *L. parella* ('light crottle'), parellic acid, lecanoric acid (Schunck, Annalen, 54, 257, 274; 41, 161). *L. tartarea* (Linn.) (*Patellaria tartarea*, *Parmelia tartarea*), erythric acid, synonymous with Nees. v. Esenbeck's 'remarkable resin' (Brandes' Archiv. Apoth. 16, 135), with Heeren's erythrin, and with Kane's erythrilin (Schweigger's, J. Ch. Phys. 59, 313). Schunck found crustaceous lichens belonging to *Lecanora*, &c., collected on the basalt rocks of the Vogelsberg in Upper Hessia to contain lecanoric and erythric acids (Annalen, 41, 157). In a specimen from Norway, Stenhouse (*ibid.* 70, 218) found gyrophoric acid. *L. ventosa*, usnic acid (Knops, *ibid.* 49, 122).

Rhizocarpon geographicum, Dl. (*Lecidea geographica*) usnic acid (Knop, *l.c.*). *Lecidea candida* (*Psora candida*), calcium oxalate (Braconnot, Ann. Chim. Phys. [ii.] 28, 319). *L. cineroatra*, lecidic acid $C_{22}H_{27}O_4{\cdot}COOMe$, m.p. 147°, and lecidol, m.p. 93° (H. 1898). *L. sudetica*, salazinic acid (Z. 1899). *L. confluens*, confluetin, m.p. 147°–148° (Z. 1899). *L. grisella*, gyrophoric acid (H. 1900). *L. aglæotera* (*L. armeniaca*, var. *lutescens*), roccellic and cetraric acids (Z. 1904).

Lepraria latebrarum, leprarin, m.p. 155°, roccellic acid (Z. 1897), and atranorin (Z. 1900); *d*-usnic, hydroroccellic, lepraric, and talebraic acids (m.p. 208°) and atranorin (H. 1903). *L. flava*, calycin, pinastric acid, calyciarin (Z. 1905). *L. xanthina* (from Vorarlberg), physcion (H. 1906). *L. latebrarum* (Baden-Baden), atranorin, leprariaic acid, oxyroccellic acid, and neobraic acid (H. 1906). *L. candelaris*, calycin (Z. 1906). *L. chlorina*, calycin (Z. 1895).

Lepra candelaris (*Lepraria flava*), calycin

$$C_{18}H_{11}O_4{\cdot}OH,$$

m.p. 240°–242° (H. 1898).

Leprantha impolita (*Arthonia pruinosa*), lecanoric acid, lepranthin $C_{25}H_{40}O_{10}$, m.p. 183°, lepranthaic acid $C_{20}H_{32}O_2$, m.p. 111°–112° (Z. 1904).

Mycoblastus sanguinarius, caperatic acid and atranorin (Z. 1899).

Menegazzia pertusa (*Parmelia pertusa*), atranorin and farinacic acid (capraric and pysodic acids absent) (H. 1907).

Nephroma arcticum, zeorin, nephrin, and *d*-usnic acid (Z. 1909). *N. antarcticum*, zeorin and *d*-usnic acid (Z. 1909). *N. parile*, zeorin and mannitol (Z. 1909). *N. resupinatum*, mannitol (Z. 1909). *N. lævigatum*, mannitol (Z. 1909). *Nephromium lævigatum*, usnic acid and nephrin $C_{20}H_{32},H_2O$, m.p. 168° (H. 1898). *N. tommentosum*, usnic acid and nephrin (H. 1898). *N. lusitanicum*, nephrin and nephromin $C_{16}H_{12}O_6$, m.p. 196° (H. 1898).

Ochrolechia androgyna (*Lecanora subtartarea*), gyrophoric acid and calyciarin (Z. 1905). *O. pallescens* var. *parella* (from Auvergne), parellic acid and ochrolechiasic acid $C_{22}H_{14}O_9$, m.p. 282° (H. 1906); but no lecanoric acid (*see* Schunck, Annalen, 1845, 54, 274) (Z. 1898). *O. tartarea*, gyrophoric acid (Z. 1898)

Pannaria lanuginosa, hydroxyroccellic acid $C_{17}H_{32}O_5$, m.p. 128°, and pannaric acid $C_9H_8O_4$, m.p. 224° (H. 1901).

Parmelia aleurities, atranorin (Z. 1897). *P. tiliacea*, atranorin and parmelialic acid, m.p. 165° (Z. 1897); the latter is in reality lecanoric acid (H. 1898 and 1900). *P. perlata*, atranorin and hæmatommic acid (Z. 1897); usnic acid, lecanoric acid, and perlatin (H. 1900); imbricaric acid (Z. 1902); no lecanoric acid (H. 1903); atranorin and perlatic acid $C_{27}H_{27}O_9\cdot OMe,2H_2O$ (H. 1904). *P. perlata* from certain sources: (*a*) atranorin, (*b*) atranorin, usnic, and vulpic acids, (*c*) atranorin and lecanoric acid, (*d*) atranorin and perlatin $C_{19}H_{14}O_5(OMe)_2$ (H. 1898). *P. saxatilis*, var. *sulcata*, atranorin and stereocaulic acid (Z. 1897); protocetraric acid only (H. 1900), not protocetraric but pannatic acid (H. 1904); usnic acid (Schmidt, Annalen, 51, 29). *P. saxatilis*, var. *panniformis*, atranorin, protocetraric acid, and usnetic acid $C_{24}H_{26}O_8$ (not $C_9H_{10}O_3$), m.p. 192° (H. 1900). *P. saxatilis retiruga*, atranorin, protocetraric acid, and saxatic acid $C_{25}H_{40}O_8$, m.p. 115° (H. 1903). *P. physodes* (or *P. ceratophylla*, var. *physodes*) is known as 'dark crottle,' and is employed for dyeing a brown colour on homespun woollen yarn. Contains physodin and two colourless substances (Gerding, Brandes, Arch. Pharm. [ii.] 87, 1), ceratophyllin (H. Annalen, 119, 365); atranorin, physodalic acid, and physodalin (Z. 1897 and 1898); evernuric acid, physodylic acid, capraric acid, and atranorin (H. 1907). *P. parietina*, chrysophanic acid (Rochleder and Heldt, 48, 12); identical with Thomson's (Edin. New. Phil. Jour. 37, 187), parietin, also (H. 1895) physcion $C_{16}H_{12}O_5$, physcianin $C_{10}H_{12}O_4$, m.p. 143°, and physciol $C_7H_8O_3$, m.p. 107°. A variety of *P. parietina* growing on sandstone rock and not on trees like that of Rochleder and Heldt, contained vulpic acid (chrysopicrin) Stein (J. pr. Chem. [i.] 93, 366). *P. caperata* ('stone crottle'), emulsin (Hérissey, J. Pharm. [vi.] 7, 577); capraric acid $C_{22}H_{18}O_8(COOH)_2$, m.p. 240°, usnic acid, caperatic acid $COOMe,C_{18}H_{33}O_2(COOH)_2$, m.p. 132°, and caperin $C_{36}H_{60}O_3$, m.p. 243° (H. 1898), *d*-usnic acid (H. 1900). *P. caperata* from *Castanea vesca*, usnic, capraric and caperatic acids (H. 1904). *P. conspersa*, usnic acid, zeorin, and atranorin (Z. 1898); usnic acid and salazinic acid (H. 1898); *d*-usnic acid and conspersaic acid, m.p. 252° (H. 1903). *P. acetabulum*, atranorin (Z. 1898); atranorin and salazinic acid (H. 1901). *P. excrescens*, zeorin and atranorin (Z. 1898). *P. perlata*, var. *exrescens*, atranorin (Z. 1898). *P. Nilgherrensis*, atranorin (Z. 1898). *P. perforata*, zeorin and atranorin (Z. 1898); lecanoric acid (H. 1900). *P. olivetorum*, atranorin (Z. 1898); lecanoric acid, but no erythric acid (H. 1900); olivetoric acid $C_{27}H_{34}O_8$, m.p. 141°-142° (Z. 1902); atranorin, olivetorin, m.p. 143°, and olivetoric acid $C_{21}H_{26}O_7$ (H. 1903). *P. pertusa*, physodalic acid (Z. 1898). *P. fuliginosa*, atranorin and lecanoric acid (H. 1898). *P. fuliginosa*, var. *ferruginascens*, lecanoric acid (Z. 1899). *P. pulverulenta*, unknown acid (H. 1898). *P. ciliaris*, everninic acid and atranorin (?) (H. 1898). *P. omphalodes* (*P. saxatilis*, var. *omphalodes*). Under the name of 'black crottle' this lichen is employed for dyeing a brown colour in the outer Hebrides (Lewis and Harris); contains stereocaulic acid (Z. 1899). *P. tiliacea*, var. *scortea*, lecanoric acid (Z. 1899). *P. verruculifera*, lecanoric acid (Z. 1899). *P. glomellifera*, glomelliferin, m.p. 143°-144° (Z. 1899 and 1902). *P. incurva*, usnic acid (Z. 1900). *P. Borreri*, lecanoric acid (Z. 1900). *P. sorediata*, diffusin (Z. 1900); lecanoric acid (H. 1900). *P. tinctorum*, atranorin (H. 1900). *P. tinctorum* (E. Africa), atranorin and lecanoric acid (H. 1906). *P. tinctorum* (Madras cinchona bark), atranorin and lecanoric acid (H. 1904). *P. glabra*, lecanoric acid (H. 1902). *P. lacarnensis*, imbricaric acid (Z. 1902). *P. sinuosa*, *d*-usnic and usnaric acids (Z. 1902).

Parmelia cetrata (Java cinchona bark), cetrataic acid $C_{29}H_{24}O_{14}$, m.p. 178°-180° (H. 1903). *P. olivacea*, oliveacein $C_{17}H_{22}O_6\cdot H_2O$, m.p. 156°, and oliveaceic acid $C_{16}H_{19}O_5\cdot OMe$, m.p. 138° (H. 1903). *P. revoluta*, atranorin and gyrophoric acid (Z. 1905). *P. pilosella*, atranorin and pilosellic acid, m.p. 245° (Z. 1905). *P. Mougeotti*, *d*-usnic acid (H. 1906).

Peltigera apthosa, peltigerin $C_{21}H_{20}O_8$ (or $C_{16}H_{16}O_6$), m.p. 170°-180°, and mannitol (Z. 1909). *P. malacea*, peltigerin, zeorin, and mannitol (Z. 1909). *P. horizontalis*, peltigerin, zeorin, and mannitol (Z. 1909). *P. polydactyla*, peltigerin, mannitol, polydactylin, m.p. 178°-180°, and peltidactylin, m.p. 237°-240°. *P. venosa*, peltigerin. *P. scabrosa*, peltigerin. *P. propagulifera*, peltigerin and zeorin. *P. lepidophora*, peltigerin. *P. praetextata*, mannitol. *P. rufescens*, mannitol. *P. spuria*, mannitol. *P. canina*, caninin (Z. 1909); emulsin (Hérissey, J. Pharm. Chim. [vi.] 7, 577).

Pertusaria amara (*P. communis β-variolosa*, *Variolaria amara*), emulsin (Hérissey, *l.c.*); cetraric acid, pertusaric acid $C_{24}H_{38}O_6$, m.p. 103°, pertusarin $C_{30}H_{50}O_2$, m.p. 235°, pertusarene $C_{60}H_{100}$, m.p. 286°, and pertusaridin (H. 1898); salazinic acid and picrolichenin (Z. 1900); orbiculatic acid $C_{22}H_{36}O_7$ (H. 1901). *P. lactea*, lecanoric acid and variolaric acid, m.p. 285° (Z. 1902). *P. lactea* (sterile Auvergne), lecanoric acid and ochrolechiasic acid (H. 1906). *P. corralina* (*P. ocellata β-coralline*), ocellatic acid $C_{20}H_{15}O_{11}\cdot OMe$, m.p. 208° (H. 1901). *P. rupestris* (*P. communis β-areolata*), areolatin $C_{11}H_7O_6\cdot OMe$, m.p. 270°, areolin, m.p. 243°, and gyrophoric acid $C_{16}H_{14}O_7$ (H. 1903). *P. glomerata* (Wildbad), porin $C_{42}H_{67}O_9OMe$, m.p. 166°, and porinic acid $2[C_{11}H_{12}O_4],H_2O$, m.p. 218° (H. 1903). *P. Wulfenii* (*P. sulfurea*, *P. sulphurella*, *P. fallax*), thiophanic acid (Z. 1904). *P. lutescens*, thiophanic acid (Z. 1904).

Placodium gypsaceum, squamaric acid and usnic acid (Z. 1898); parellic acid, but no usnic acid (H. 1901). *P. chrysoleŭcŭm*, usnic acid (Z. 1898). *P. saxicolum*, var. *vulgare*, usnic acid and zeorin (Paternò, Atti. R. Accad. Lincei, 1876, [ii.] 3); zeorin, but no atranorin (H. 1898), *d*-usnic acid (H. 1900). *P. saxicolum*, var. *compactum*, atranorin (H. 1901). *P. melanaspis*, atranorin (Z. 1898). *P. Lagascœ*, psoromic and usnic acids (Z. 1897).

Placodium crassum, atranorin (trace), *l*-usnic acid (H. 1901). *P. circinatum* (*a*) *radiosum*, salazinic acid (H. 1902).

Physcia ciliaris, emulsin (Hérissey, J. Pharm. Chim. [vi.] 7, 577). *P. endococcina*, zeorin and atranorin (Z. 1895), rhodophyscin and endococcin (Z. 1905). *P. caesia*, zeorin and atranorin (Z. 1895); atranorin and zeorin (H. 1902). *P. stellaris*, *f. adscendens*, atranorin (Z. 1895). *P. parietina*, atranorin and placodin, m.p. 245° (H. 1899). *P. medians*, vulpic acid and calycin (Z. 1895), calycin and callopismic acid (Z. 1897). *P. pulverulenta*, var. *β-pityrea*, atranorin (Z. 1895).

Physcia tenella, atranorin (Z. 1895). *P. aipolia*, atranorin (Z. 1895).

Cetraria glauca (*Platysma glaucum*) atranorin and caperatic acid (Z. 1899). *Cetraria cucullata* (*P. cŭcŭllatum*), lichenostearic acid and usnic acid (Z. 1899). *P. diffusum*, diffusin, m.p. 135°–136°, and usnic acid (Z. 1899).

Pleopsidium chlorophanum, rhizocarpic acid (Z. 1895).

Pseudevernia ericetorum, atranorin, physodalin (Z. 1905).

Psora ostreata, lecanoric acid (Z. 1899).

Pulveraria chlorina, calycin, vulpic acid, and lepraric acid, m.p. 228° (H. 1898). *P. latebrarum*, atranorin, parellic acid, latebride, m.p. 128°, and pulverin, m.p. 262° (H. 1898). *P. farinosa*, oxyroccellic acid, and pulveraric acid, m.p. 234° (H. 1898).

Raphiospora flavovirescens, rhizocarpic acid (Z. 1895).

Ramalina calicaris, var. *fastigiata*, contains large quantities of starch (lichenin) and a small quantity of saccharic acid (Berzelius, Scherer's Annalen, 3, 97), usnic acid (Rochleder and Heldt, *ibid.* 48, 9). *R. calicaris*, var. *fraxinea*, lichenin and usnic acid (R. and H. *l.c.*); *a*-usnic acid (Hesse, Annalen, 117, 297). *R. ceruchis*, usnic acid and usnaric acid (H. 1898). *R. armorica*, atranorin, armoricaic acid, m.p. 240°–260°, armoric acid $C_{18}H_{18}O_7,H_2O$, m.p. 226°–228° (H. 1907). *R. cuspidata*, cuspidatic acid $C_{16}H_{20}O_{10}$, m.p. 218° (H. 1900). *R. farinacea*, *d*-usnic acid and ramalic acid $C_{30}H_{26}O_{15}$, m.p. 240°–245° (H. 1903). *R. subfarinacea*, *d*-usnic acid and salazinic acid (Z. 1907). *R. minuscula*, *d*-usnic acid (Z. 1907). *R. Kullensis*, *d*-usnic acid, kullensisic acid $C_{22}H_{18}O_{12}$ (Z. 1907). *R. obtusata*, *d*-usnic acid, ramalinellic acid, m.p. 169°, and obtusatic acid (Z. 1907). *R. Landroënsis*, *d*-usnic acid and landroënsin (Z. 1907). *R. pollinaria*, ramalic acid $C_{16}H_{13}O_3OMe$ and evernic acid (Z. 1897); usnic acid, atranorin, evernic acid, and ramalic acid (H. 1898). *R. fastigiata*, emulsin (Hérissey, J. Pharm. Chim. 1898, [vi.] 5, 577). *R. fraxinea*, emulsin (Hérissey, *ibid.*). *R. polymorpha*, usnic acid (Z. 1897). *R. scopulorum* (*see* Thomson, Annalen, 53, 252), *d*-usnic acid, scopuloric acid $C_{19}H_{16}O_9$, m.p. 260° (Z. 1907). *R. thraŭsta*, usnic acid (Z. 1900). *R. yemensis*, *d*-usnic acid (H. 1902).

Reinkella birellina, roccellic and oxyroccellic acids (H. 1898).

Rhizocarpon geographicum f. contiguum, parellic acid, rhizonic acid $C_{19}H_{20}O_7$, m.p. 185°, rhizocarpic acid $C_{28}H_{22}O_7$ (H. Ber. 1898, 31, 663), rhizonic acid is $OMe{\cdot}C_{17}H_{14}O_2(OH)_2COOH$ (H.). *R. geographicum f. lecanorinum*, rhizocarpic acid (Z. 1895); parellic acid, rhizocarpinic acid, m.p. 156°, rhizocarpic acid

$$COOH{\cdot}C_{24}H_{16}O_3{\cdot}COOEt,$$

m.p. 177°–178°. Parellic acid

$$COOMe{\cdot}C_{17}H_{11}O_3(COOH)_2,$$

m.p. 262°–265°, is the same as Zopf's psoromic acid, and the squamaric acid and zeoric acid of other writers (H.). *R. geographicum f. geronticum*, parellic and rhizocarpic acids, but not rhizocarpinic acid (H. 1909).

Rhizoplaca opaca (*Lecanora chrysoleuca*, *β-opaca*, *Parmelia rubina β-opaca*, *Squamaria chrysoleuca β-opaca*), usnic acid, placiodilic acid (previously termed placiodĭlin), and rhizoplacic acid $C_{21}H_{40}O_5$, m.p. 94°–95° (Z. 1905), usnic acid and placiodilic acid $C_{17}H_{18}O_7$, m.p. 156°–157° (Z. 1906).

Roccella fuciformis (*R. tinctoria*, var. *fuciformis*). This well-known 'orchella weed' is imported from Angola, Zanzibar, Madagascar, Ceylon, and Lima for the purpose of manufacturing archil and cudbear. It contains erythric acid (Heeren's erythrin, Kane's erythrilin) and roccellic acid (Schunck, Pharm. J. [iii.] 39, 164; Annalen, 61, 64; Kane, Trans. Roy. Soc. 1840, 273; Heeren and Schweiggers, J. Pharm. Chim. 59, 346). Stenhouse (Annalen, 149, 288) examined a Lima weed in 1848, and found it to contain lecanoric acid, but this was probably *R. tinctoria* and not identical with the *R. fuciformis* examined by him in 1869, and in which he found erythric acid. Compare Hesse (Annalen, 117, 329, and 139, 22) who found Lima weed to contain erythric acid, but not lecanoric acid. Stenhouse considers the *R. Montagnei* from Angola, in which he found erythric acid to be identical with *R. tinctoria*, var. *fuciformis*, examined by Schunck. A stunted variety of *R. fuciformis*, examined by Menschutkin and Lamparter, contained *β*-erythrin. In a better growing specimen erythrin was obtained (Lamparter, Annalen, 134, 243). A variety of *R. fuciformis*, probably from the west coast of Africa, contained erythric acid and a bitter substance picroroccellin (Stenhouse and Groves, *ibid.* 185, 14). More recently Hesse (1898) has found the weed to contain erythric acid and oxyroccellic acid.

Roccella Montagnei, erythric acid and oxyroccellic acid (H. 1898); orcinol (Ronceray, Bull. Soc. chim. 1904, iii. 1097). *R. fruticosa*, eyrthric acid (erythrin) (H. Ber. 1904, 37, 4693). *R. phycopsis* (Crete), erythrin, oxyroccellic acid, oxalic acid, and erythritol (H. 1906). *R. peruensis* (*R. fructectosa* and *R. cacticola*), erythrin, oxyroccellic, and roccellic acids (H. 1898), erythrin, erythritol, and oxalic acid (H. 1906). *R. portentosa*, lecanoric acid (H. 1898). *R. decipiens*, lecanoric acid (H. 1898). *R. sinensis*, lecanoric acid (H. 1898).

Roccella tinctoria. This lichen used largely for the manufacture of orchil and cudbear, is imported from the Cape of Good Hope, the Cape Verd Islands, and Chile (Valparaiso Weed). Formerly it seems to have been imported also from Lima (Stenhouse). It contains lecanoric acid (Stenhouse's α- and β-orsellic acid) and roccellinin. The latter is, however, probably a decomposition product of the former (Stenhouse, Annalen, 68, 55; 149, 288; Phil. Mag. [iii.] 32, 300). According to Hesse (1898) it contains erythrin, oxyroccellic acid, roccellic acid, and lecanoric acid, whereas Ronceray (Bull. Soc. chim. 1904, [iii.] 31, 1097) detected in this lichen the presence of lecanoric acid and orcinol (*cp.* Hesse, Ber. 1904, 37, 4693).

Roccellaria intricata, zeorin and roccellaric acid, m.p. 110° (H. 1898).

Squamaria elegans (*Gasparrinia elegans*), chrysophanic acid (Thomson, Phil. Mag. [iii.] 25, 39); physcion (H.).

Solorina crocea, soloric acid, m.p. 199°–201° (Z. 1895).

Sphærophorus fragilis, sphærophorin, m.p. 138°–139°, and fragilin (Z. 1898), sphærophorin $(C_{14}H_{16}O_4)_n$, or $C_{28}H_{34}O_8$, sphærophoric acid, m.p. 206°–207 , and fragilin (Z. 1905).

Sphyridium placophyllum, atranorin (Z. 1898).

Stereocaulon alpinum atranorin, and stereocaulic acid, m.p. 200°–201° (Z. 1895). *S. corallöides*, atranorin and psoromic acid (Z. 1895), usnetic acid, atranorin, and an acid not psoromic acid. Zopf's stereocaulic acid from *S. alpinum* is usnetic acid (H. 1900). *S. incrustatum*, atranorin and psoromic acid (Z. 1895). *S. vesuvianum*, psoromic acid (Z. 1895). *S. denudatum*, var. *genuinum* atranorin (Z. 1895). *S. tomentosum*, atranorin (Z. 1895). *S. pileatum*, atranorin and stereocaulic acid (Z. 1895 and 1899). *S. condensatum*, atranorin (Z. 1895). *S. paschale*, atranorin (Z. 1895). *S. virgatum* f. *primaria*, atranorin (Z. 1895). *S. ramulosum*, atranorin (Z. 1895). *S. salazinum*, salazinic acid, which blackens at 260°–262° (H. 1900).

Sticta fuliginosa, trimethylamine (Z. 1897). *S. aurata*, stictaurin a derivative of pulvic acid (Z. 1899). Stictaurin has the formula $C_{18}H_{12}O_5$ (H. 1900). *S. desfontainii*, calycin and ethylpulvic acid (H. 1900). *S. pulmonaria*, stictaic acid $C_{18}H_{11}O_8(OMe.)$, m.p. 264°, stictinic acid, (Knop and Schnedermann, J. pr. Chem. 1846, 39, 365), and not protocetraric acid (H. 1900). This lichen is known as 'hazel crottle.'

Stictina gilva, stictinin, m.p. 160°–161° (Z. 1905).

Thamnolia vermicularis, thamnolic acid, m.p. 202°–204° (Z., Chem. Zentr. 1893, ii. 54). According to Hesse this has the formula $C_{19}H_{15}O_{10}\cdot OMe$ (1898 and 1900).

Thallœdema candidum, probably lecanoric acid (H. 1898).

Thalloschistes flavicans, parietin (Z. 1905) (Brittany); physcion and acromelin (H. 1907).

Tornabenia chrysophthalma, physcion (H. 1907). *T. flavicans*, var. *crocea*, physcion (H. 1907). *T. flavicans*, var. *acromela* (*Physcia acromela*), acromelin $C_{17}H_{16}O_9$, m.p. 242°, and acromelidin $C_{17}H_{20}O_9$, m.p. 162° (H. 1907). *T. flavicans*, var. *cinerascens*, physcion and acromelin (H. 1907).

Umbilicaria pustulata (*Gyrophora pustulata*), gyrophoric acid $C_{18}H_{18}O_7$ (?) (Stenhouse, Annalen, 70, 218; Z. 1898; H. 1898).

Urceolaria lichens, collected from the basalt rock of the Vogelsberg in Upper Hessia, contain lecanoric and erythric acids (Schunck, Mem. Chem. Soc. 1, 71).

Urceolaria scruposa, var. *vulgaris*, atranorin and lecanoric acid (H. 1898, 1904, 1907); patellaric acid (Z. 1902). *U. cretacea* (*U. scruposa*, var. *gypsacea*), lecanoric acid, but no atranorin, zeorin, or parmelialic acid (H. 1898; *cp.* Zopf, 1897).

Usnea barbata (*Lichen barbatus*, *Parmelia barbata*), usnic acid (Rochleder and Heldt, Annalen, 48, 8; Stenhouse, *ibid.* 155, 51) and lichenin (Berzelius, Scherer's Annalen, 3, 205; Hesse, Annalen, 137, 241; Ber. 10, 1324), usnic and barbatic acids (H. 1898); emulsin (Hérissey, J. Pharm. Chim. [vi.] 7, 577). *U. barbata* f. *dasypoga*, usnic acid and usnaric acid $C_{30}H_{22}O_{15}$, m.p. 240°–260° (H. 1898), *d*-usnic, usnaric, and alectoric acids (H. 1900); barbatic, usnic, and usnaric acids, but no alectoric acid (Z. 1902); alectoric acid (H. 1903). *U. barbata*, var, *ceratina*, usnic acid $C_{18}H_{16}O_7$, m.p. 195°–196°, and barbatin (H. Annalen, 1895, 284, 157). *U. barbata α-florida*, *d*-usnic, usnaric, and parellic acids, and usnarin (H. 1902). *U. ceratina*, usnic acid, barbatic acid and barbatin (H. 1898). *U. ceratina* (Black Forest), barbatic and usnic acids (Z. 1902), *d*-usnic acid, barbatic acid, and barbatin (H. 1903) (Java cinchona bark), *d*-usnic, usnaric, and parellic acids and ceratin (H. 1903). *U. ceratina β-hirta*, Bolivian, *d*-usnic, usnaric, plicatic, and barbatic acids (H. 1903). *U. barbata* (β·) *hirta*, *d*-usnic, usnaric, and barbatic acids, and usnarin (H. 1902), atranorin (H. 1906). *U. barbata* (β-) *hirta*, (St. Thomas), *d*-usnic and usnaric acids, and santhomic acid $C_{11}H_{14}O_4$, m.p. 166° (H. 1902). *U. hirta*, usnic acid (Knop, Annalen, 49, 103), usnic acid, alectoric acid, hirtic acid, m.p. 98°, and hirtellic acid (m.p. 215° decomp.) (Z. 1903). *U. cornuta*, *d*-usnic and usnaric acids (Z. 1902). *U. longissima*, barbatic and usnic acids (Z. 1897; H. 1898). *U. longissima* (from Amani), ramalic acid, *d*-usnic acid, and dirhizonic acid $C_{18}H_{16}O_5(OMe)_2$, m.p. 189° (H. 1906). *U. florida*, usnic acid (Knop, Annalen, 49, 103); usnic acid and hirtellic acid (Z. 1904). *U. schraderi*, *d*-usnic acid and usnaric acid (Z. 1905). *U. microcarpa*, *d*-usnic acid and usnaric acid (Z. 1905). *U. articulata*, var. *intestiniformis* (Indian cinchona bark), *d*-usnic acid, barbatic acid, and articulatic acid $C_{18}H_{16}O_{10}$ (?) (H. 1907). *U. plicata*, *d*-usnic acid, usnaric acid, usnarin, and plicatic acid $C_{20}H_{33}O_8(OMe)$, m.p. 133° (H. 1900). *U. scrŭposa*, atranorin and lecanoric acid (Z. 1902).

Pertusaria dealbata, Nyl. (*Variolaria dealbata*, *Lichen dealbatus*), variolarin (Robiquet, Annalen, 42, 236; 58, 320). Schunck found crustaceous *Variolaria* collected on the basalt rocks of the Vogelsberg in Upper Hessia, to contain lecanoric and erythric acids.

Xanthoria parietina (*Parmelia parietina*, *Physcia parietina*), atranorin and physcion (H. 1898). *X. lychnea*, physcion (H. 1898). *X. candelaria* (*X. controversa*, *X. lychnea*, var. *pygmœa* *X. parietina*, var. *lychnea*), parietin, m.p. 202° (Z. 1904). A. G. P.

LICKNER'S BLUE. A silicate of cobalt and potassium. A variety of smalt COBALT.

LIDDITE *v.* EXPLOSIVES.

LIEBERMANN'S REACTION *v.* PHENOL AND ITS HOMOLOGUES.

LIEBIGITE. *Calcium uranium carbonate* v. Uranium.

LIÈGE BLACK. *Blue black* v. Pigments.

LIEN, LIENADEN v. Synthetic drugs.

LIGHT CARBURETTED HYDROGEN. *Marsh gas* v. Methyl.

LIGNIN DYNAMITE v. Explosives.

LIGNITE v. Fuel.

LIGNOCERIC ACID $C_{23}H_{47}COOH$, m.p., 80·5° is found in the solid paraffin obtained from beechwood tar (Hell and Hermanns, Ber. 1880, 1713) and in earth nut oil (Kreiling, *ibid.* 1888, 880).

LIGNUM COLUBRINUM v. Nux vomica.

LIMA WOOD. A variety of Brazil wood (*q.v.*).

LIME v. Calcium; also Cements.

LIME, BISULPHITE OF, v. Calcium.

LIME BURNING v. Calcium.

LIME, HYDRAULIC, v. Cements.

LIME, SUPERPHOSPHATE OF, v. Calcium; also Fertilisers.

LIME-OIL v. Oils, essential.

LIMESTONE (*Kalkstein*, Ger.; *Calcaire*, Fr.). A rock composed essentially of calcium carbonate ($CaCO_3$) in the form of the mineral calcite. Owing, however, to the frequent presence of mechanically admixed impurities and to variations in texture, the rocks of this class exhibit wide differences in character (v. Marble, Chalk, Lithographic stone, Marl). A snow-white crystalline limestone—*i.e.* a statuary marble—is quite compact, and is pure calcium carbonate, consisting, in fact, of a granular aggregate of calcite. With the admixture of clayey material there may be a gradual passage through argillaceous limestone to calcareous mudstone or to an incoherent marl. Other limestones, containing mechanically admixed impurities of various kinds, are described as silicious, sandy, carbonaceous, bituminous, ferruginous, and phosphatic limestones. In dolomitic or magnesian limestones there is an isomorphous replacement of lime by varying amounts of magnesia. The majority of limestones are bedded rocks of sedimentary origin, and are composed of the calcareous remains of marine organisms. As a general rule the compactness of a limestone is a measure of its geological age; the harder and more compact varieties belonging to the Silurian and Carboniferous Systems, whilst those of the Jurassic, Cretaceous and Eocene Systems are less coherent. Although limestones often resemble some other kinds of rocks in their appearance, they can always readily be recognised by the fact that they easily yield to the knife and effervesce with cold dilute acid (those containing much magnesium effervesce only with hot acid). In addition to their extensive application as building stones, limestones are much used for making lime in the manufacture of mortars and cements of various kinds (v. Cements); as fluxes in smelting; and as fertilisers, either in the powdered form or burnt as lime.

Howe, Geology of Building Stones, 1910. On economic questions much has been written in the geological survey publications of the United States. L. J. S.

LIMESTONE, MAGNESIAN, v. Calcium, Magnesium, and Dolomite.

LIMNITE (λιμνή, a marsh). A hydrated ferric oxide, perhaps $Fe_2O_3,3H_2O$, but passing into limonite (*q.v.*).

LIMOGES ENAMELS v. Enamels.

LIMONITE or **Brown Iron-Ore.** A hydrated ferric oxide $2Fe_2O_3,3H_2O$ of importance as an ore of iron (Fe, 59·9 p.c.). It is not crystallised, and often occurs as rounded, stalactitic, or mamillated forms with an internal radially fibrous structure. The surface of such masses is sometimes black and lustrous (German, Glaskopf), but here, as in all other instances, the streak of the mineral is of a very characteristic brownish-yellow colour. Concretionary (pisolitic) and earthy or ochreous masses are also of common occurrence. The sp.gr. varies from 3·6 to 4·0, reaching the higher value in the compact, fibrous material. Limonite is of abundant occurrence in nature as the final product of weathering of all iron-bearing minerals. Pseudomorphs of limonite after crystals of iron-pyrites and other minerals are well known. As an earthy ochreous deposit it separates from the waters of chalybeate springs, and in peat-bogs and at the bottom of pools and lakes. Such deposits are known as bog-iron-ore (*q.v.*), lake-ore, &c., and the name limonite (from λειμών, a meadow) means, in fact, meadow-ore. The brown iron-ores extensively mined in Northamptonshire, the north of Spain, Luxemburg, Lorraine, and western Germany (here a pisolitic or bean-ore known as 'minette'), and many other places, occur as beds in sedimentary rocks. Ochreous limonite is used for making paint, and in the manufacture of linoleum, brown paper, &c. L. J. S.

LINADIN v. Synthetic drugs.

LINAMARIN v. Glucosides.

LINARIN. A glucoside found in the flowers and leaves of *Linaria Vulgaris* (Mill.) (Klobb, Compt rend. 1907, 145, 331).

LINNÆITE. Native cobalt sulphide Co_3S_4.

LINOLENIC ACID, LINOLIC ACID v. Oils, Fixed, and Fats.

LINSEED. The seeds of *Linum usitatissimum* (Linn.). There are two chief varieties, with white and blue flowers respectively. The plant requires moist heat, but is not suited to great heat and drought or to frosty conditions. It therefore does best on the seacoast or plains and hills where the rainfall is abundant or dews and fogs frequent, and in damp soils rather than in dry ones. It is grown in many countries, but the chief sources of the linseed of commerce are Russia and India.

The average composition, as given by König, as the mean of 61 analyses, is—

Water	Protein	Fat	Nitrogen free substances	Crude fibre	Ash
9·0	22·8	34·4	22·8	6·8	4·2

All the constituents are liable to considerable variation, *e.g.* protein 16–31 p.c., fat 22–40 p.c. The 'protein' of linseed is almost wholly albuminoid in nature, not more than 2–4 p.c. of it being in other forms (a small portion as a glucoside). Linseed contains a characteristic mucilage (about 6 p.c. of its weight), which exists mainly in the membranes of the outer cells and causes the seeds when macerated with water to swell up so much as to burst the cell-walls. When linseed is boiled with water, the mixture thickens owing to the solution of this mucilage.

Linseed is very largely consumed, being used as a food for young calves (as a partial substitute for milk), and in enormous quantities in the preparation of linseed oil, so important in the preparation of varnishes, paints, and linoleum, the by-product linseed cake or linseed meal, also forming an important cattle food, valuable not only for its nutritive value, but also on account of its richness in the manurial substances, nitrogen, phosphoric acid, and potash.

The ash of linseed contains—

K_2O	Na_2O	CaO	MgO	Fe_2O_3	P_2O_5	SO_3	SiO_2	Cl
30·2	2·1	8·1	14·3	1·1	40·5	2·3	1·2	0·2

Of pure linseed cakes there are two types, viz. those from which the oil has been *expressed*, and those from which the oil has been *extracted* by the use of volatile solvents; the former are richer in fat and more digestible, the latter richer in albuminoids and ash. The following average compositions are given by Kellner—

	Water	Protein	Fat	*N*-free extract	Crude fibre	Ash
Expressed cake	11·0	33·5	8·6	31·7	8·7	6·5
Extracted ,,	10·2	37·4	3·8	32·7	9·1	6·8

It was shown by Jorissen (Bull. Acad. Roy. Belg., 1883, 3, 5, 750) that linseed contains a cyanogenetic glucoside. This glucoside, named *linamarin* by Jorissen, has been shown to be identical with *phaseolunatin* (*a*-dextrose ether of acetone cyanohydrin) which occurs in the beans of *Phaseolus lunatus* (Linn.) (Dunstan, Auld and Henry, Proc. Roy. Soc., 1906, B. 78, 145). This substance is present in young linseed plants, in linseed, and also in linseed cake. In the latter, to the extent of yielding 0·03 to 0·04 per cent. of hydrocyanic acid, but the enzyme which hydrolyses the glucoside, and which is present in the seed, is destroyed by the high temperature employed in expressing the oil, and is therefore absent from the cake (Dunstan and Auld, J. Soc. Chem. Ind., 1908, 428). Pure linseed cake is therefore not *likely* to act as a poison, but *might* do so if prepared by cold pressure, or if fed along with any foodstuff containing the enzyme necessary for the hydrolysis of the glucoside. H.I.

LINSEED GUM *v.* Gum.

LINSEED OIL, flax seed oil, is obtained from the seeds of the flax plant, *Linum usitatissimum* (Linn.), a native of Central Asia. The principal countries where it is grown in considerable quantities to yield oil seed are the Argentine, India, the United States, Canada, and Russia. Notable quantities of seed are also produced in Morocco. Attempts are being made to grow linseed oil in Australia and in the Transvaal Colony.

Two qualities of Russian seed are recognised in the trade, known, according to their source, as Baltic and Black Sea seed; hence the terms 'Baltic linseed oil' and 'Black Sea linseed oil.' The oil expressed from Indian seed is known as 'East India oil.' The Baltic linseed yields the best drying oil; this is explained by the fact that the Baltic seed is the purest, whereas in Black Sea seed 5 p.c. (and more) of hemp seed and (or) ravison seed are usually present. Indian seed is always mixed with mustard, rape, and cameline seed, owing to the plants yielding the latter being grown along with the flax plant. It has been proved that when the Indian linseed is carefully separated from the foreign seeds and then expressed, the oil possesses as good drying properties as does best Russian oil. During latter years, more attention having been paid in India to this growing industry, the quality of seed has improved. Argentine seed, yielding the (River) Plate oil (La Plata oil), being badly harvested, contains much chaff and admixed fibres; if more care were exercised, La Plata oil also would more regularly approach Baltic oil in drying properties. The United States, who until recently had been importing East Indian seed, have so considerably increased the home production that they rank occasionally (*i.e.* when the harvest is plentiful) amongst the exporting countries. Canada also is exporting considerable quantities of linseed.

The proportion of linseed oil in the seed varies with the origin of the seed and also with the seasons. It may be accepted that linseed contains from 32 to 42 p.c. of oil, according to the origin. On a large scale the quantity of linseed oil obtained from good seed does not exceed 35 p.c.

On cold-pressing, a golden-yellow coloured oil is obtained, having a pleasant taste, so that it can be used as an edible oil. Considerable quantities are being expressed for this purpose in Russia, Hungary, Germany, and India. In some parts of Germany the oil is used either as such, or (as 'Leinoelschmalz') in admixture with tallow or (and) lard for edible purposes. By far the largest quantities of oil are, however, employed in the arts. In that case the seed is crushed between rollers and then heated to about 160°F. in the mixing kettle; subsequently the seed is expressed while still warm. The oil so obtained has a yellowish-brown hue, and is somewhat turbid, due to traces of moisture and mucilaginous matter. The press cakes retain about 10 p.c. of oil; they are used as one of the most valuable and wholesome cattle foods.

On storing the oil, the moisture and the mucilaginous matter gradually settle out, and the oil hereby acquires a higher value, especially for some technical uses, as in the making of varnish. Such oil, sometimes kept for years, is known as 'tanked oil.' The suitability for varnish-making purposes is ascertained by heating rapidly the linseed oil in a test tube. Oil from which gelatinous matter separates is considered unsuitable. Seed pressed in a comparatively fresh ('green') state yields oil containing larger quantities of 'mucilage' than seed three to six months old. The gelatinous matter ('mucilage' or 'spawn' or 'break') contains phosphates and traces of sulphates.

The bulk of linseed oil is at present produced by expression. The main reason for this is that the hot-pressed cake is valuable as cattle food, whilst linseed meal obtained by extraction with solvents could only be used as manure, at any rate in this country. Occasionally linseed has been extracted with solvents, as it was thought that the oil so obtained, being richer in unsaturated acids, and containing less of the mucilaginous matter, would be more suitable for the paint and varnish trades. This has, however, not been borne out in practice, extracted oil having been found unsuitable as a paint oil. Moreover, the oil obtained by extracting with carbon disulphide, light petroleum, &c., possesses an inferior colour and a more unpleasant smell than expressed oil. Therefore it would only be profitable to extract damaged seed, which cannot be used for proper cattle food.

A rapid method for removing the impurities in the crude oil is to refine it, which is done on a large scale by treating crude linseed oil with 1–2 p.c. of a somewhat concentrated sulphuric acid. The charred mass carries down with it the bulk of impurities contained in the crude oil. For the manufacture of the best and finest kinds of linseed oil ('artists' oil'), the refined oil is subjected to 'sun-bleaching,' by exposure in shallow zinc trays under glass to the action of sunlight. Powdered lead placed in the trays accelerates the bleaching process. Recently a proposal has been made to bleach linseed oil by exposure to the Cooper-Hewitt mercury lamp. Dark linseed oils intended for soft soap are usually bleached in the soap works by treatment with a small amount of caustic potash. The soap which is formed carries down with it the colouring matters.

The chemical composition of linseed oil is not yet fully known. It may, however, be stated broadly that linseed oil contains about 10 p.c. of solid fatty acids, amongst which palmitic acid and arachidic acid have been identified. In addition thereto the oil contains a high proportion of linolenic acid and linolic acid. The proportion of oleic acid which Hazura gave as amounting to about 5 p.c., may possibly, according to later statements, have to be raised to 15 p.c. The '*iso*linolenic acid,' which Hazura stated to occur in linseed oil does not appear to be a chemical individual (according to the researches of Rollett, who doubts the existence of a β-linolenic acid, which Erdmann and Bedford state is obtainable from linolenic acid).

Linseed oil has a higher specific gravity than any fatty oil that would be used to adulterate it, with the exception of tung oil. Hence, in the trade a specific gravity lower than 0·93 is considered to indicate adulteration with other fatty oils or mineral oils.

The higher the specific gravity of a linseed oil, the more suitable it is for the purposes of the paint and varnish manufacturer. This is also expressed in a general way by the magnitude of the iodine value. Linseed oil has, with the exception of perilla oil, the highest value of all known fatty oils. Hence the iodine test is the most characteristic one for identifying a sample. The iodine value of linseed oil should not fall below 170 (La Plata and North American oils), although much higher iodine values reaching as high a figure as 205 have been recorded. Thus Indian oils usually absorb from 183 to 192 p.c., and Baltic oil from 190 to 200 p.c.

When the price of linseed oil is high adulteration is practised to a very considerable extent. For the methods devised for detecting these adulterants the reader is referred to Lewkowitsch's Chemical Technology, vol. ii. 50–60.

Linseed oil (provided its price is not excessively high) is very extensively used as stock material for soft soaps; for this purpose those oils are especially employed which have a comparatively low iodine value. The presence of mucilage forms no objection in the soapery.

A further important application of linseed oil is found in the manufacture of boiled oil for paints, varnishes, lithographic varnishes, and for the manufacture of linoleum. No other drying oil approaches the properties of linseed oil, the drying oil *par excellence*. Hence linseed oil is also the best oil for making putty. Linseed oil is further largely used in the preparation of plastic masses.

Boiled oil is obtained by heating linseed oil with driers to a temperature of about 150°C. The process is carried out by introducing the oil into a cylindrical vessel provided with a heating coil and agitating gear, so as to produce an intimate intermixture between oil and drier while they are heated to the desired temperature.

According to the quality and the amount of drier added, and the length of time during which the oil is heated ('boiled'), pale or dark oils are produced. The former are known in commerce as 'pale boiled oils,' the latter as 'double boiled oils.' The temperature of 'boiling' can be reduced even to 120°C. when 'liquid driers' (solutions of lead linoleate, &c., in linseed oil) are used. They are merely dissolved in the oil and the operation is assisted, if required, by a current of air.

This last process yields somewhat inferior drying oils to those obtained by boiling at 150°C. with lead oxide, &c. It has, however, been inferred therefrom that in order to obtain a quickly drying oil it suffices to prepare a solution of metallic salts in oil. This view has even led to the preparation of 'boiled oils' in the cold, by merely adding to linseed oil a solution of lead linoleate or manganese linoleate, and carefully intermixing it with the oil. (An oil having the properties of a 'boiled' oil can also be prepared by carefully grinding linseed oil with manganese borate in the cold.) These 'boiled oils' are, therefore, identical with the product which painters used to prepare themselves from raw linseed oil by grinding it with a drier. Such oils naturally do not dry so rapidly as do the oils prepared at a higher temperature; they behave more nearly like raw linseed oil as regards the time required to 'dry.'

With regard to the employment of other oils in the manufacture of boiled oils and the adulterants of boiled oils (*cp.* Lewkowitsch, Chemical Technology, vol. ii. 109 *et seq.*).

Linseed oil is also used in the manufacture of 'vulcanised oils,' and for extracting indiarubber from 'waste rubber.' By heating linseed oil with sulphur, the official *oleum lini sulf.* is prepared. J. L.

LIPASE, the enzyme which hydrolyses fats to glycerol and fatty acids, is of considerable importance in animal physiology and in germinating seeds. It is used industrially in the manufacture of glycerol and fatty acids, and is concerned in the phenomenon of rancidity. The knowledge of it, however, is still in a somewhat fragmentary state. It was first discovered by Reynolds Green (Proc. Roy. Soc. 1890, 48, 370) in the germinating seed of *Ricinus communis*

(Linn.), and has since been found in many other seeds, usually in the germinating rather than in the resting stage; it also occurs in mould fungi and in yeast. Lipoclastic enzymes are present in most animal tissues, the liver being the most active. The enzyme appears to cling to the solid particles of tissue cells.

Vegetable lipase is very sparingly soluble in water, and it is doubtful whether active filtered extracts of the enzyme can be obtained. It has been shown by Connstein and others (*see* summary in Asher and Spiro's Ergebnisse der Physiologie, 1904, 3, 194) that *Ricinus* lipase is effective only in the presence of acid, and that it acts preferentially on the natural fats, other ethereal salts being but little attacked by it.

Animal lipase, on the other hand, is quite active in hydrolysing simple esters and acts on the natural fats with difficulty, though this is perhaps due to the difficulty of securing a satisfactory emulsion (*cp.* H. E. Armstrong, Proc. Roy. Soc. 1905, 76B, 606; 1906, 78B, 376; Kastle and Loevenhart, Amer. Chem. J. 1900, 24, 491).

According to Tanaka (Chem. Soc. Abstr. 1910, i. 800) lipase is present in castor oil seeds in the form of an insoluble zymogen which is readily converted by dilute acid into the insoluble enzyme, the acid acting merely to liberate the enzyme which, when once liberated, is active in a neutral medium. It is inactive in alkaline solution.

The action of lipase is accelerated by manganese sulphate and by bile salts. All acids are effective in activating the enzyme, action depending on the amount rather than on the concentration of the acid.

Animal lipase may be separated by dialysis, or filtering, into two substances which are inactive singly, but the original activity is restored when they are mixed; the activity of the filtrate is not destroyed by boiling (Magnus, Zeitsch. physiol. Chem. 1904, 42, 149; Rosenheim and Shaw-Mackenzie, J. physiol. 1910, 40). Lipase also exercises synthetic activity (Kastle and Loevenhart, Amer. Chem. J. 1900, 24, 491; Hanriot, Compt. rend. 1901, 132, 212).

The ferment process is used for the preparation of soap-stock fatty acids (Connstein, Eng. Pat. 22111, 1902). The ground seeds were made into an emulsion with oils and dilute acetic acid, but the original process was abandoned on account of the losses due to the formation of a middle layer between the fatty and aqueous layers. According to Lewkowitsch (Chemical Technology of Oils, Fats, and Waxes, 1909, 3) it is now customary to prepare a 'ferment' by grinding decorticated seeds with a large quantity of water and filtering. The creamy liquor is allowed to ferment spontaneously when a creamy emulsion containing the active enzyme rises to the top. The oil is emulsified by air currents in lead-lined vessels with 40 p.c. of water, 5–8 p.c. of the ferment and 0·2 p.c. manganese sulphate, the last substance serving to accelerate the change (Eng. Pat. 25680, 1905). After several days the mixture is warmed to 80°C., and 0·3–0·45 p.c. sulphuric acid (50 p.c.) is added; it is then allowed to settle. Three layers are formed—a bottom aqueous layer containing glycerol, an upper fatty layer and a middle layer consisting of an emulsion, which is allowed to accumulate, and on renewed treatment separates into three layers. The temperature of hydrolysis is maintained above 20°C. and below 42°C.; it should be slightly above the melting-point of a fat. The products so obtained are much lighter in colour than those given by the older processes of hydrolysis.

Rancidity.—The presence of lipase in oily seeds leads to the formation of small quantities of fatty acids, particularly in presence of moisture. Commercial fats of both vegetable and animal origin, if they have not been submitted to a sufficiently high temperature to kill the enzyme during their manufacture, are likely to contain traces of lipase, and this in presence of moisture may cause the formation of free fatty acids. When the fatty acids are further exposed to oxidation, particularly in presence of light, rancidity takes place (*see* further on this point, Lewkowitsch, *l.c.* 1, 35) (*v.* FERMENTATION).

E. F. A.

LIQUATION. 'When an ore or metallic mixture containing ingredients differing sensibly in fusibility is exposed to a degree of heat sufficient only to melt the most fusible which may flow away from the unmelted mass, this process is termed liquation' (Percy's Metallurgy). In certain cases a mixture of two metals can be roughly separated in this way. For instance, if an alloy of lead and copper be heated to a temperature a little above the melting-point of lead, the lead trickles out, leaving a porous mass behind. The lead contains 2–3 p.c. of copper. The copper contains 25 p.c. of lead. This process is used commercially to separate antimony sulphide from the ore, by heating in earthenware pots with a hole in the bottom, through which the melted sulphide flows.

At the Schemnitz silver works impure lead is purified by melting it on the bed of a furnace, the lower end of which is connected with a large iron pot, heated independently, and into which the lead trickles. Fresh lead is thrown into the furnace from time to time; the melted lead flows into the pot and leaves less fusible alloys behind. The lead in the pot is then made hot, skimmed and poled. The purification of a metal by this means depends upon the formation of less fusible alloys between the metal and the foreign metals present. Pattinson's process (*v.* LEAD) for desilverising lead depends on the formation of such alloys, but in that case the solidified alloys are fished out of the melted lead by a ladle, instead of allowing the lead to flow away from them.

LIQUEFACTION OF GASES. The readiness with which many liquids can be converted into vapours similar in many respects to ordinary gases, suggests the possibility of an intimate relationship between the gaseous and liquid states of matter. Van Helmont, to whom we owe the introduction of the term 'gas,' in the latter part of the 16th century, distinguished between 'gases' and 'vapours,' saying that only the latter could be reduced to the liquid state. Boerhaave (1731) in his Elements of Chemistry (Eng. ed., 249), comments on the impossibility of liquefying air either in the sharpest frost or under pressure. Dalton clearly foresaw the result of subjecting gases to low temperatures and high pressures when he said: 'There can scarcely be a doubt entertained respecting the reducibility of all elastic fluids of whatever kind into liquids; and we ought not to despair of effecting it in low temperatures and by strong pressures exerted upon the unmixed gases.'

The statement in Fourcroy's Chemistry, 2, 74, that Monge and Clouet liquefied sulphur dioxide is one of the earliest recorded references to the liquefaction of a substance commonly recognised as a gas. Shortly afterwards, in 1805-1806, Northmore (Nicholson's Journal, 1805, 12, 368; 1806, 13, 233) succeeded in liquefying chlorine, hydrogen chloride, and sulphur dioxide, by compressing the gases into a strong glass receiver. These results, however, did not attract much attention, and no further work on the liquefaction of gases appeared until 1823.

The discovery of the production of liquid chlorine by heating chlorine hydrate in a closed glass tube, led Faraday to undertake a systematic study of the liquefaction of gases. The method employed in his first series of experiments (Phil. Trans. 1823, 113, 189) was simple. Into the sealed limb of a bent glass tube were placed materials for generating the gas. The other limb of the tube was then sealed and cooled in a freezing mixture of ice and salt. The end containing the reacting substances was heated to generate the gas; the pressure steadily increased as the gas was produced, and ultimately the gas liquefied in the cold limb. In this manner Faraday succeeded in liquefying sulphur dioxide, hydrogen sulphide, 'euchlorine,' cyanogen, ammonia, carbon dioxide, and nitrous oxide, the experiments on the last two gases being often accompanied by violent explosions.

The first experimenter to utilise the evaporation of a liquid under reduced pressure in order to produce low temperatures was Bussy (Ann. Chim. Phys. 1824, 26, 63). By the rapid evaporation of liquid sulphur dioxide he reached temperatures sufficiently low to liquefy chlorine, ammonia, and cyanogen. This method of producing low temperatures soon came into general use.

In 1834 Thilorier (Ann. Chim. Phys. 1835, 60, 427, 432; Annalen, 1839, 30, 122) prepared liquid carbon dioxide on a large scale by what was essentially the method of Faraday, using, however, a wrought iron generator and receiver connected by a copper tube. Moreover, he succeeded in freezing this liquid by allowing it to escape through a jet into a specially constructed drum-shaped box. Solid carbon dioxide has proved of service to subsequent experimenters. A mixture of solid carbon dioxide and ether, often called *Thilorier's mixture*, is even to-day a very valuable refrigerant; by evaporating it under reduced pressure, temperatures as low as −110°C. can be obtained.

In Faraday's second research on the liquefaction of gases (Phil. Trans. 1845, 135, 155) the gases were subjected to the simultaneous influence of high pressure and low temperature. The former was applied by means of two air pumps, and the latter was produced by means of a cooling bath of Thilorier's mixture boiling under diminished pressure. The gases were condensed in suitably shaped tubes of green bottle-glass, the pressures were measured by means of small air gauges inserted in the tubes, and temperatures were recorded by an alcohol thermometer. In these experiments, ethylene, silicon fluoride, phosphine, and boron trifluoride were liquefied, and hydrogen bromide, hydrogen iodide, sulphur dioxide, 'euchlorine,' hydrogen sulphide, ammonia, cyanogen, and nitrous oxide were solidified. Faraday was, however, unable to liquefy hydrogen, nitrogen, oxygen, nitric oxide, or carbon monoxide, although he predicted that, if the temperature could be sufficiently reduced, these gases would pass into the liquid state.

The work of Natterer (J. pr. Chem. 1844, 31, 375; 1845, 35, 169; 1852, 56, 127; Pogg. Ann. 1844, 62, 132; 1855, 94, 436; Wien. Ber. 1850, 5, 351; 1851, 6, 557, 570; 1854, 12, 199), which began in 1844 and extended over several years, placed at the disposal of experimenters a method for obtaining extremely high pressures. Natterer was the first observer to prepare liquid nitrous oxide in quantity. He repeatedly endeavoured to liquefy hydrogen, oxygen, nitrogen, and carbon monoxide, modifying his apparatus from time to time until the gases were subjected to the enormous pressure of 3600 atmospheres. Even the application of Thilorier's mixture to the gases at this pressure failed to effect their liquefaction.

Critical phenomena and the relation between the liquid and gaseous states.—The classical work of Andrews (Phil. Trans. 1869, ii. 575; also *ibid.* 1876, ii. 421) marks an era in the development of the subject of the liquefaction of gases. The relative values of temperature and pressure in effecting liquefaction had, up to that date, not been understood. As early as 1822, Cagniard de la Tour (Ann. Chim. Phys. 1822, 21, 127; 1823, 22, 411) had performed a series of experiments on heating volatile liquids in closed glass vessels. He showed that such a liquid as ether could be converted wholly into vapour, notwithstanding the existence of an enormous pressure, in a volume less than twice the volume of the liquid from which it was produced. He also observed that there was a definite temperature, independent of the actual amount of ether present, above which the liquid meniscus could not be observed, an indication that ether cannot exist as liquid above a certain temperature. Similar results were obtained with a number of other liquids, but their significance was not generally recognised at the time. Faraday, however, realised that the reason why he was unable to liquefy certain gases was that they were probably in the same condition as the ether vapour in Cagniard de la Tour's experiments when heated above the temperature at which the liquid meniscus disappeared, in which case he added that 'no compression, without the conjoint application of a degree of cold below that we have as yet obtained, can be expected to take from them their gaseous state.' It is curious, therefore, that Faraday made no attempt to realise the Cagniard de la Tour's state with any of the gases he had succeeded in liquefying.

Andrews found that on compressing carbon dioxide in a glass capillary tube at temperatures below 30·9°C., the volume diminished more rapidly than would be indicated by Boyle's Law, until at a certain pressure, depending on the temperature, liquefaction commenced. The pressure then remained constant while the volume was being diminished, until liquefaction was complete. After this, a large increase in pressure again became necessary in order to diminish the volume further. At temperatures above 30·9°C., however, he could obtain no indications of liquefaction at all, whatever pressure was applied. On partially liquefying carbon dioxide, and slowly raising the temperature, the surface of demarcation between the liquid and gas became fainter, lost its curvature, and finally disappeared at 30·9°C. 'The space was then occupied by a homogeneous fluid which exhibited, when the pressure was suddenly diminished or the temperature slightly lowered, a peculiar appearance of moving or flickering striæ throughout the entire mass.'

From these results on carbon dioxide and from analogous results for nitrous oxide, Andrews concluded that there is a perfect continuity between the gaseous and liquid states, and that for each gas there is a definite temperature above which it cannot be condensed to the liquid state. This temperature he called its *critical temperature.* The 'Cagniard de la Tour point,' to which Faraday frequently referred, and the 'absolute boiling-point' of Mendeleeff, correspond to the same temperature. The pressure required to effect liquefaction at the critical temperature is called its *critical pressure.*

Andrews was able from his results to draw a rational distinction between a 'vapour' and a 'gas' by defining them as gaseous substances respectively below and above their critical temperatures.

As a result of the work of Andrews it is clear that the general nature of the isothermals for a gas over a range of temperature, including the critical point, is similar to that shown in Fig. 1. Each isothermal below the critical point consists of three distinct parts, the middle portion being horizontal. The abscissæ of its extremities, *e.g.* v_v and v_l on the T_0 isothermal, represent the specific volumes of the substance, if the diagram refers to unit mass, as saturated vapour and as liquid under its own vapour pressure at T_0 respectively; intermediate volumes correspond to mixtures of liquid and vapour.

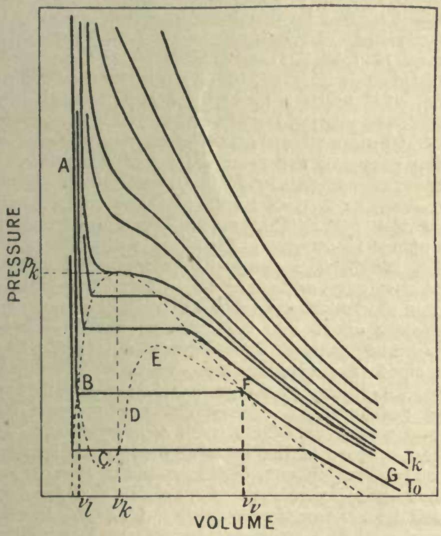

Fig. 1.

The theory of Andrews, that the change from gas to liquid is continuous, and that there is no essential difference between the two states, was adopted by Van der Waals, who, in 1879, put forward an equation to represent the behaviour of any fluid that does not change its molecular complexity on passing from the gaseous to the liquid state (Van der Waals, Die Continuität des gasformigen und flüssigen Zustandes).

The characteristic equation for a perfect gas

$$pv=RT$$

(where p, v, and T denote pressure, volume: and absolute temperature respectively, and R is a constant) represents the behaviour of ordinary gases accurately only over a small range of pressure, and at temperatures sufficiently removed from the critical point. As p increases, at constant temperature, from atmospheric pressure to one or two hundred atmospheres, the compressibility is initially greater than Boyle's Law indicates, the product pv diminishing as p increases (Regnault, Mém. de l'Acad. 21, 329; Amagat, Ann. Chim. Phys. 1880, [v.] 19, 345; 1881, [v.] 22, 353; 1883, [v.] 28, 456, 464; 1893, [vi.] 29, 68). The value of pv reaches a minimum, and afterwards increases with increase of pressure, so that at extremely high pressures all gases are much less compressible than is expressed by Boyle's Law (Natterer, *l.c.*; Amagat, *l.c.*). The initial diminution in the value of pv for a gas becomes less marked with rise of temperature, and at a sufficiently high temperature it is not observed. In the cases of hydrogen, helium and neon, this temperature, although considerably above the critical point, is much below the ordinary temperature, and the values of pv for these gases at this temperature steadily increase with rise of pressure from atmospheric pressure upwards (Regnault, Amagat, *l.c.*; Wroblewski, Monatsh. 1888, 9, 1067; Witkowski, Bull. Acad. Sci. Cracow, 1905, 6, 305; Kamerlingh Onnes and Braak, Comm. Phys. Lab. Leiden, 1907, No. 97; Burt, Trans. Faraday Soc. 1910, 6, 19).

These results can be represented fairly accurately by the equation of Van der Waals,

$$(p+\frac{a}{v^2})(v-b)=RT$$

the magnitudes of the (small) constants a and b (which may be deduced from the experimental values for p, v, and T) depending respectively upon the extent to which the molecules of the gas attract one another and upon their actual volume. This equation, besides representing the behaviour of compressed gases fairly accurately, also gives some account of the relationship between the liquid and gaseous states.

The equation represents the isothermals of a gas over a range of temperature including the critical point as being of the form shown in Fig. 1, with this difference, that those isothermals below the critical isothermal have the horizontal portions replaced by wavy curves, as indicated in the diagram by BCDEF on the isothermal for T_0°. The passage from vapour to liquid is thus represented as a continuous process. The portions BC and EF of the curve correspond with the conditions of superheated liquid and supersaturated vapour respectively, but the portion CDE of the curve, where p and v increase or decrease together, cannot be experimentally realised. At the critical point the specific volumes of vapour and liquid are identical, and the wavy portion of the curve therefore vanishes. Therefore the tangent at the critical point is horizontal, *i.e.* $dp/dv=0$. Since, moreover, the curvature of the critical isothermal changes sign at the critical temperature, $d^2p/dv^2=0$. These two relations give

$$2av_k^{-3}=\mathrm{RT}_k(v_k-b)^{-2} \text{ and } 3av_k^{-4}=\mathrm{RT}_k(v_k-b)^{-3}$$

the suffixes denoting critical values; whence

$$v_k=3b \text{ and } \mathrm{T}_k=8a/27b\mathrm{R}.$$

Substituting in the original equation, $p_k=a/27b^2$. The critical constants for carbon dioxide, calculated by Van der Waals from these formulæ, were $\mathrm{T}_k=32{\cdot}5$°C., $v_k=0{\cdot}0069$, $p_k=61$ atmos., in good agreement with the experimental values 30·9°C., 0·0066 and 70 atmos. respectively. The critical constants for hydrogen were determined by Wroblewski (Monatsh. 1888, 9, 1067) in a similar manner from his observations on the compressibility of the gas at low temperatures; his results agree remarkably well with the experimental values (Dewar, Chem. News. 1900, 81, 136) and afford a good instance of the utility of Van der Waals' theory. For further information concerning Van der Waals' equation, see Nernst's Theoretical Chemistry.

Liquefaction of the so-called 'permanent gases.'—The liquefaction of the five or six gases which Faraday and others had been unable to liquefy, and which had been called the 'permanent gases,' was, in the light of Andrews' researches, seen to depend upon the production of extremely low temperatures, since the lowest temperatures previously obtained had been above their critical points.

The first successful attempts to effect their liquefaction were made in 1877. On December 24th of that year, at the meeting of the French Academy, it was announced that Louis Cailletet of Chatillon-sur-Seine had liquefied both oxygen and carbon monoxide, whilst Raoul Pictet of Geneva had succeeded in liquefying oxygen (Compt. rend. 1877, 85, 1214, 1217, 1220).

The method used by Pictet (Compt. rend. 1877, 85, 1214; Ann. Chim. Phys. 1878, [v.] 13, 145; Arch. des Sci. Phys. et Nat. 1878) is essentially that devised by Faraday. Oxygen was generated by heating potassium chlorate in a wrought-iron flask. A long steel tube, provided at one end with a stop-cock, was attached to the flask. The accumulation of oxygen in the retort and tube created a pressure of 500 atmospheres. The tube was cooled to −120° to −140°, which is below the critical temperature of oxygen, by surrounding it with a copper cylinder through which liquid carbon dioxide, boiling under reduced pressure, was circulated. The liquid carbon dioxide was obtained by compressing the gas to 4–6 atmospheres, and cooling it externally by means of liquid sulphur dioxide, boiling under diminished pressure at −65°C. The elaborate apparatus employed was so designed that both sulphur dioxide and carbon dioxide could be liquefied, evaporated and re-liquefied repeatedly, so as to produce *continuous cooling*. The oxygen liquefied in the cooled tube, and when the stop-cock was opened, issued as a liquid jet with great violence, since the pressure employed was far in excess of that actually necessary for liquefaction.

The simple apparatus employed by Cailletet (Ann. Chim. Phys. 1878, [v.] 15, 132) is shown in Fig. 2. The gas is introduced into a glass tube, TTP, the narrow end of which consists of a stout capillary tube. By means of a metal collar, A, and the nut E′, the tube is screwed into a strong steel cylinder, B, partially filled with mercury. To compress the gas, water is forced into the steel cylinder by a hydraulic pump, through the copper tube U, which is fastened by the screws R and E into the apparatus; a pressure of several hundred atmospheres can thus be applied. A glass jacket M, and a bell-jar C, supported on the plate S, surround the capillary tube. The tap r serves to run off any liquid refrigerant in the jacket M.

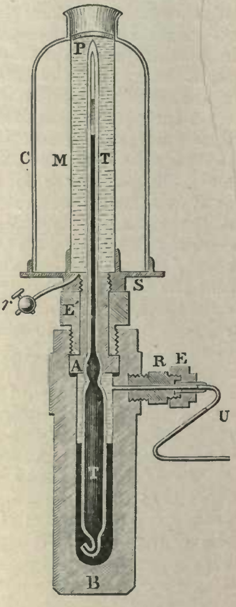

FIG. 2.

With this apparatus Cailletet liquefied acetylene (Compt. rend. 1877, 85, 851) and nitric oxide (*ibid.* 85, 1016), the latter condensing at −11° under a pressure of 104 atmospheres. Methane was not liquefied at 7° under a pressure of 180 atmospheres; but by suddenly releasing the pressure, the temperature of the gas was reduced sufficiently for liquefaction to occur, and a fine mist of liquid methane was formed in the tube. This method was successfully applied to oxygen and carbon monoxide (*ibid.* 85, 1213). The gases were compressed to 300 atmospheres, and cooled to −29°. The pressure was then suddenly released, when the resultant cooling effect was sufficient in both cases to produce partial liquefaction, a mist being formed of minute liquid droplets.

The theory of the process is simple. When a gas expands against external pressure, it performs work. This work is accomplished at the expense of the internal energy of the gas, and a diminution in the internal energy means a fall in temperature. To obtain the greatest fall in temperature possible, it is essential to perform the expansion with great rapidity in order that there may be no appreciable time for the gas to acquire heat from its surroundings. The fall in temperature experienced by a perfect gas when it expands adiabatically from an initial pressure p_1, at absolute temperature T_1, to a final pressure p_2, is given by $T_1 - T_2$, where

$$\frac{T_1}{T_2} = \left(\frac{p_1}{p_2}\right)^{\frac{k-1}{k}}$$

(k denoting the ratio of the specific heats of the gas). In the case of air, where $k=1\cdot41$, if p_1, p_2, and T_1 were 100 atmospheres, 1 atmosphere, and 273° abs. respectively, the final temperature T_2 should be 71·5° abs., or −201·5°C. Although this numerical result is necessarily somewhat inacccurate, owing to the fact that air under the above conditions deviates considerably from the laws of a perfect gas, it is sufficient to indicate that the adiabatic expansion of a gas is capable of producing extremely low temperatures. In Cailletet's experiments, expansion occurred practically under adiabatic conditions.

By this method Cailletet also succeeded in liquefying air and nitrogen, and obtained indications of the liquefaction of hydrogen (Compt. rend. 1877, 85, 1270). He also prepared liquid ethylene, first obtained by Faraday, in large quantities, and recommended its use as a refrigerant (Compt. rend. 1882, 94, 1224; 1883, 97, 1115; Ann. Chim. Phys. 1883, [v.] 29, 153). By cooling compressed methane and oxygen with this reagent boiling under diminished pressure, Cailletet obtained liquid methane and oxygen in the static form (Compt. rend. 1884, 98, 1565; 1885, 100, 1033).

A period of great activity in connection with the liquefaction of gases followed the publication of the successful pioneering experiments of Pictet and Cailletet, the subject being taken up by Wroblewski and Olszewski in Cracow, by Dewar at the Royal Institution in London, and by Kamerlingh-Onnes at Leyden. The Polish physicists occupied themselves mainly in determining the physical constants of liquefied gases. To obtain low temperatures, they acted upon Cailletet's suggestion, and employed liquid ethylene, which boils at −102°C., as a refrigerant. They compressed oxygen, nitrogen, and carbon monoxide in a stout glass tube by means of a modified Cailletet pump and cooled the gases to −136° by the rapid evaporation under diminished pressure of liquid ethylene, previously cooled with Thilorier's mixture. Under a pressure of 22·5 atmospheres, oxygen readily liquefied. The liquefaction of the other two gases was only effected by compressing them to 150 atmospheres at −136°, and then slowly reducing the pressure, when a further cooling effect was obtained. In each case a transparent liquid, with a well-defined meniscus, was obtained (Wied. Ann. 1883, 20, 243; Compt. rend. 1883, 96, 1140, 1225; Monatsh. 1883, 4, 415). The later work of these investigators was published separately. Wroblewski, who reached the temperature of −152°C. by rapidly evaporating liquid ethylene, obtained considerable quantities of liquid oxygen; he solidified nitrogen and carbon monoxide, and obtained temperatures below −200° by the rapid evaporation of the corresponding liquids; studied the utility of liquid methane as a refrigerant; obtained indications of the liquefaction of hydrogen; and at the time of his death was engaged in a study of the compressibility of hydrogen over a wide range of pressure and at very low temperatures (Wroblewski, Compt. rend, 1883, 97, 166, 309, 1553; 1884, 98, 149, 304, 982; 99, 136; 1885, 100, 979; 1886, 102, 1010; Wied. Ann. 1883, 20, 860; 1885, 25, 371; 1885, 26, 134; 1886, 29, 428; Monatsh. 1885, 6, 204).

The independent investigations of Olszewski, in which he solidified ethylene, carbon monoxide, nitrogen, and methane; liquefied oxygen in quantity and used the liquid as a refrigerant; obtained indications of the liquefaction of hydrogen and determined the physical constants of these and other gases, were summarised by himself in 1895 (Phil. Mag. 1895, [v.] 39, 188; 40, 202; *cf.* Compt. rend. 1884, 98, 365, 913; 1884, 99, 133, 184, 706; 1885, 100, 350, 940; 1885, 101, 238; Monatsh. 1884, 5, 124, 127; 1886, 7, 371; 1887, 8, 69; Ann. Phys. Chim. 1889, [ii.] 37, 337; 1895, [ii.] 56, 133).

The work of Dewar at the Royal Institution, from 1880 to 1895, led to the production of liquid air, oxygen, &c., in large quantities by using a liquefying plant constructed of metal and utilising liquid ethylene as refrigerant (Proc. Roy. Inst. 1886, 550; *cf. ibid.* 1884, 148; Phil. Mag. 1884, [v.] 18, 210). Dewar commenced a study of the properties of matter in general at low temperatures, and in this connection he made a most valuable contribution towards the manipulation of liquefied gases by introducing a vessel in which they could be kept with the minimum of loss by evaporation. The *Dewar flask* (Fig. 3) is simply a double-walled flask of convenient shape, from the space between the walls of which the air has been exhausted. The contained liquid is thereby separated from the atmosphere by a vacuum-jacket except at the mouth of the flask. Evaporation of liquid air and similar liquids in these flasks takes place only very slowly, since the heat radiated across the vacuous space is only one-seventh of the total heat which would reach the inner vessel were the jacket to contain air. If desired, the flasks may be silvered on the inside, thus increasing their efficiency.

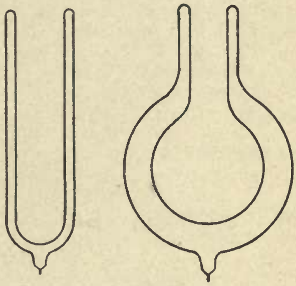

FIG. 3.

The method of self-intensive refrigeration (*so-called regenerative process*).—The experiments of Wroblewski, Olszewski, and Dewar on the production of low temperatures, previously described, involved no new principle; the 'cascade' method of lowering the temperature by stages, originated by Pictet, had been employed, and at times combined with Cailletet's expansion method. In 1895 a new principle, that of producing cold by self-intensive refrigeration, was introduced almost simultaneously by

Hampson and Linde. Briefly, it consists in continuously supplying the gas to be liquefied to an apparatus in which it may be cooled by expansion, and utilising each portion of gas, after it has been expanded and cooled, in lowering the initial temperature of the gas about to be expanded, until the cumulative effect of the cooling process is sufficient to produce liquefaction. For this purpose, the highly compressed gas at the ordinary temperature is passed downwards through a long copper spiral tube, expanded through a throttle valve, and the issuing gas passed upwards over the exterior of the copper tube.

For a description of Linde's liquefying plant *v.* the Engineer, October 4, 1895; J. Soc. of Arts, 1897, 1091; *cf.* also Eng. Pat. 12528, 1895; Ann. Phys. Chem. 1895, [ii.] 57, 328; Ber. 1899, 32, 925).

The general arrangement of Hampson's air-liquefying plant is indicated in Fig. 4. Air is drawn into the compressor through the large purifier, containing slaked lime to absorb carbon dioxide, and compressed in two stages to 150–200 atmospheres. The compressor is water-cooled to remove the heat generated by compressing the air. The air is then forced through a separating vessel, in which most of the water used as lubricant separates out, and afterwards through the high-pressure purifier containing potassium hydroxide, in which the remaining water and carbon dioxide are completely absorbed. The purified air then enters the liquefier; that which passes out is usually returned through the low-pressure purifier to the compressor, and used again. The purifiers do not then have to be very often refilled.

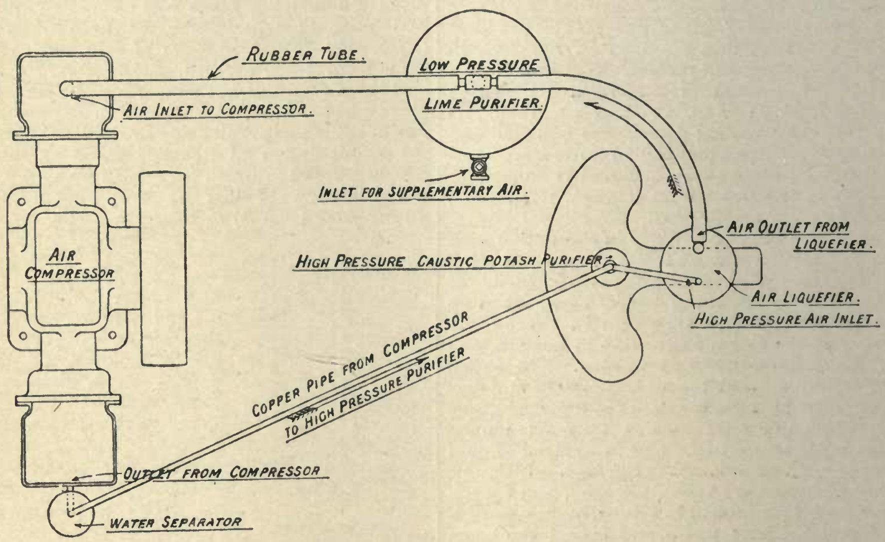

FIG. 4.

The Hampson liquefier, manufactured by the British Oxygen Co. (Eng. Pat. 10165, 1895; 7773, 1898; J. Soc. Chem. Ind. 1898, 17, 411), is shown in section in Fig. 5. In designing it, the following points were kept in view: the necessity for having a large, exposed surface of material of high thermal conductivity between the compressed and expanded air, the thickness of the material being diminished as far as possible; the desirability of having both compressed and expanded air in small masses in close contact with the conducting material, and of reducing the total mass and volume of this heat interchanger to the smallest possible amount, in order to minimise the mass of metal to be cooled down with the gas, and prevent, as far as possible, any access of heat from the surroundings. The liquefier consists of four copper coils, B, wound co-axially about a spindle, D, and joined at their lower ends to a valve, C, which may be opened or closed by turning the hand wheel E attached to the top of the spindle. A metal chamber, G, soldered directly to the casing of the coils, serves to collect the liquid air. The whole is enclosed in a metal chamber and the space between this jacket and the casing of the coils is filled with non-conducting material.

The purified air, the pressure of which is indicated by the gauge O, enters the liquefier through A, travels down the coils and is allowed to escape through the valve C. The released air immediately expands down to approximately atmospheric pressure, and travels back over the exterior of the coils B, finally passing back into the compressor or directly into the atmosphere. The expanded air acts with a self-intensifying cooling effect on the compressed air which is passing down through the coils, and in from 6 to 10 minutes part of the air begins to liquefy and collect in G. This receiver is emptied by turning the wheel T, which opens the valve P, when the liquid flows down the hollow spindle R into a vacuum receiver. A gauge H, connected by the tube J with the receiver G, indicates the amount of liquid in G. About 1½ litres of liquid air per hour can be obtained with an ordinary Hampson apparatus, and no auxiliary refrigerant is required. The interchanger acts so perfectly that the air which leaves the apparatus is only about 1° colder than that which enters it. About 5 p.c. of the air passing through the apparatus is liquefied.

In the liquefying machines of Hampson and Linde, the work done against atmospheric pressure as the gas flows along after expansion is not performed by the gas at the expense of its internal energy; the necessary energy is continuously supplied by the compression pump. A steady stream of gas at high pressure is pumped continuously into the coils of the liquefier, and after passing through the valve, is converted into a steady stream of gas at low pressure. There is a slight thermal effect due to the performance of external work, but its magnitude only depends upon the extent to which Boyle's Law is in error in representing the compressibility of the gas. It may be calculated from a knowledge of the specific heat of the gas and its compressibility, and at ordinary temperatures amounts to a slight cooling effect with all gases except hydrogen, helium, and neon. The main thermal change, however, is due to free expansion of the gas, and work is done in increasing the mean distance between the molecules of the gas in opposition to the forces of molecular attraction. This is performed at the expense of the internal energy of the gas. The subject was studied experimentally by Joule and Thomson (Phil. Trans. 1853, 143, 357; 1854, 144, 321; 1862, 152, 579) for a number of gases, and a slight cooling effect was found to be the net result in each case at ordinary temperatures except for hydrogen. The fall in temperature was proportional to the fall in pressure (up to 6 atmospheres), and varied approximately as the inverse square of the absolute temperature. At 17·1°C. the fall in temperature for air is 0·255°C. per atmosphere.

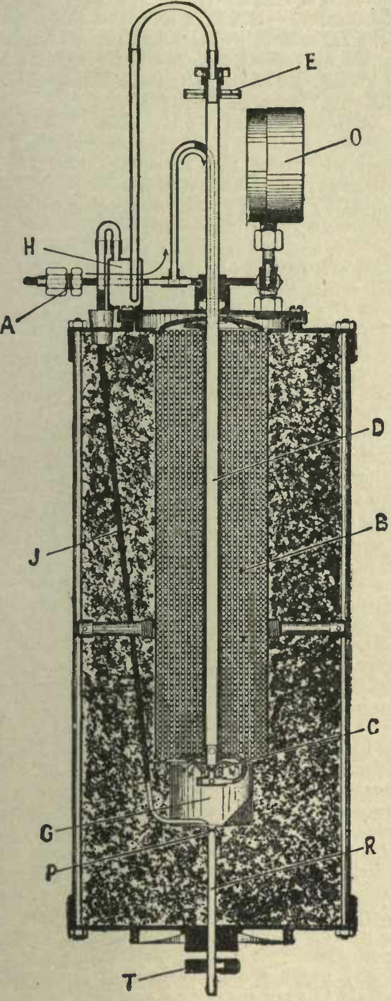

Fig. 5.

There is a temperature at which the thermal effect produced by free expansion (the Joule-Thomson effect) is zero. According to Olszewski (Phil. Mag. 1902, [vi.] 3, 535) this is −80·5°C. for hydrogen, and below this temperature hydrogen is also cooled by free expansion. The 'inversion temperatures' in the case of air and nitrogen are considerably higher than ordinary temperatures, and appear to vary with the initial pressure of the gas (Olszewski, Bull. Acad. Sci. Cracow. 1906, 792).

To liquefy hydrogen (and helium) it is therefore necessary to cool the gas strongly before applying the self-intensive cooling process. It was by this means that Dewar (Chem. News, 1900, 81, 136) first succeeded in collecting liquid hydrogen. Travers (Phil. Mag. 1901, [vi.] 1, 411) and Olszewski (Bull. Acad. Sci. Cracow, 1902, 619; 1903, 241) have since described modified Hampson liquefiers for preparing liquid hydrogen, in which the hydrogen is cooled by liquid air and then allowed to expand through a specially constructed valve. By cooling helium to the temperature of liquid hydrogen and then applying the self-intensifying process, Kamerlingh-Onnes (Compt. rend. 1908, 147, 421; Proc. K. Acad. Wetensch. Amsterdam, 1908, 11, 168) succeeded in obtaining helium in the liquid state.

The hydrogen liquefier designed by Travers and manufactured by the British Oxygen Company, is shown in Fig. 6. Pure dry hydrogen at 150–200 atmospheres pressure, enters the lower end of the coils A and is cooled by the cold hydrogen returning to the gas-holder. It then passes into the top of the coils in the chamber B, which is filled with liquid air, and by the time it has reached the bottom of the coils it is cooled to −190°C. The cold gas has its temperature lowered to below −200°C. as it passes through the coils in chamber C, which is connected by the pipe D to a vacuum pump, and in which liquid air is boiled under diminished pressure. The hydrogen then expands through the valve F at the end of the regenerator-coil E. The cooling-effect is self-intensified in the usual way, the cooled gas passing upwards over the coils E, and the outsides of the chambers B and C, finally cooling the coil A as it passes out of the apparatus. The coils B, C, and E are enclosed in a large, silvered vacuum-jacket. Liquid hydrogen collects in the vacuum vessel K, which is enclosed in a special box, hinged at LL to the supporting column and provided with glass windows.

Claude's process for liquefying gases.—The cooling effect produced when a gas expands with the performance of external work is much greater than that which is produced by the free expansion of the compressed gas. Mechanical difficulties for many years prevented this cooling effect from being intensified by rendering the process continuous, but it has now been effected by Claude. The process, as worked by Claude for the liquefaction of air, consists in compressing the air to 40 or 50 atmospheres and dividing it into two portions. One of these is expanded in a cylinder to 4 or 5 atmospheres, performing external work and thereby becoming cooled, and this cold air is then used to cool the other part, which can be thereby liquefied. This method, when applied on a large scale, needs less power than the Linde process; moreover, it may be used as a means of producing a low temperature preparatory to applying the ordinary self-intensive refrigeration method (Claude, Compt. rend. 1900, 131, 500; 1902, 134, 1568; 1905, 141, 762, 823; Eng. Pat. 27658, 1902; Fr. Pat. 322107, 1902; Linde, J. Soc. Chem. Ind. 1911, 30, 744). For further information concerning Linde and Claude's processes, *v.* OXYGEN.

Literature.—Hardin's Rise and Development of the Liquefaction of Gases; Sloane's Liquid Air and the Liquefaction of Gases; Ewing's Mechanical Production of Cold; Travers' Study of Gases; Preston's Theory of Heat; &c.

LIQUEURS and **CORDIALS.** The general characters of these beverages have already been described under the heading CORDIALS AND LIQUEURS (vol. II.), the former term being usually applied to British preparations and to such as have only one characteristic flavouring ingredient, and the latter to the foreign varieties which are usually of a more complex character. The term *liqueur* is also applied to certain wines and spirits remarkable for their bouquet as 'Tokay,' 'Liqueur brandy,' &c. *Bitters* are generally classed commercially with liqueurs and cordials, and contain one or more ingredients supposed to possess tonic and medicinal properties.

In ancient times, liqueurs consisted merely of wine flavoured with spices (as cinnamon) and sweetened with honey, and in the Middle Ages various aromatic herbs (as absinth, hyssop, &c.) were employed in a similar manner, the product being known as 'wine of herbs.' The 'liquori' of Italy were, however, the true prototypes of the modern liqueur, as the Italians were the first to extract the aromatic principles of the roots, leaves, flowers, fruit, and seeds of plants by means of spirit. Sometimes gold or silver leaf in a finely divided state was added to the liqueur, not only to give lustre, but also because of certain medicinal virtues these metals were supposed to possess.

At the present time, France is *par excellence* the home of the liqueur, and some of the most celebrated varieties have originated at certain monasteries which formerly derived considerable revenues from their manufacture and sale, *e.g.* *Benedictine*, *Chartreuse*, *Trappistine*, &c. Other countries have their special preparations as *Anisette d'Hollande* and *Crême de Genièvre* (Holland), *Allasch* and *Kümmel* (Russia), *Alkermes* (Italy), *Maraschino* (Dalmatia), and the various *Cocktails* of the United States of America.

The number and variety of liqueurs and cordials is very great but the best known are comprised in the following list:—

Absinth
Advocaat
Alkermes
Allasch
Angostura (bitters)
Anisette
Benedictine
Brandy (cherry, &c.)
Chartreuse
Clove cordial
Cocktails (American)
Crême de Menthe
Curaçoa
Gin (sloe, &c.)
Kirsch
Kümmel
Maraschino
Noyau
Parfait Amour
Peppermint cordial
Ratafias
Trappistine
Vermouth
Whiskey (cherry, &c.)

In the manufacture of liqueurs, the purity and good quality of all the ingredients used is a matter of the first importance. The spirits should be highly rectified spirits of wine as free as possible from fusel oil and free acid; the sugar of the finest white crystals or sugar-candy made into a clear syrup with distilled or pure soft water; glycerol (when employed) should be highly refined and colourless; and all the flavouring ingredients (*e.g.* flowers, fruits, rinds, roots, seeds, &c.) should be sound and well-dried.

The simplest method of manufacture, adopted for the commoner kinds of liqueurs, is that of merely adding essential oils to the spirit, and then the necessary amount of sugar syrup or glycerol.

The essential oils should be recently distilled and dissolved in from 5 to 10 times their weight of alcohol before being added. The particular flavour required can thus be better attained and cloudiness or milkiness of the finished liqueur avoided.

The finer qualities, however, are made by macerating the flavouring ingredients in spirit of about 85° to 90° alcohol by volume and distilling the infusion. The distillation was formerly conducted in copper stills heated by direct fire, then double-bottomed coppers were employed, and subsequently a water-bath added, but now steam-jacketed stills only are used in the largest liqueur factories. The middle portion of the distillate is used for the finest liqueurs, the first fractions being rough and the last inferior in character. Syrup is added and sometimes glucose or glycerol to give density and impart a 'velvety' character to the liqueur, and the whole is heated, well mixed and diluted with water, after which filtration and 'fining' may be found necessary.

Liqueurs are often classified in France according to the proportions of spirit and sugar used, *e.g.* 'crêmes,' 'huiles,' or 'baumes,' which are heavily sweetened to a thick oily consistency, and 'eaux,' 'elixirs,' and 'extraits,' which are perfectly limpid and less highly sweetened. As a rule, the same proportions are employed for the same quality of liqueur. The following grades may be taken as typical:—

	Ordinaire	Demifine	Fine	Surfine
Alcohol at 85°	25 litres	28	32	36
Sugar	12½ kilos	25	37½	50
Water	67 litres	57	46	34

It will be observed that in the superior grades the proportions of alcohol and sugar are increased with a corresponding diminution in the proportion of water.

The flavouring ingredients are extremely numerous and varied in character and their nature and proportions used are jealously guarded by the manufacturers as trade secrets.

The essential principles are extracted by *infusion* with hot spirit (if the aromatic principle is not too volatile), the ingredients being first moistened with boiling water; or by *maceration* with cold spirit which may require hours, days, or even many months, according to the solubility of the essential principles; by *digestion* or prolonged infusion or maceration in hermetically closed vessels when the aromatic principles are extracted only with difficulty by cold alcohol; or by *distillation* when only the natural essential oils or other volatile flavouring constituents are required. The following plants should always be distilled by steam: *absinth, anise, balms, caraway, citronella, fennel, juniper, hyssop, lavender, melilot, mint, orange, rose, sage,* and *thyme.*

Aromatic tinctures for use in flavouring liqueurs are sometimes prepared by a kind of fractional filtration. The ingredients in a finely divided state are made into a paste with spirit and placed in a large funnel plugged with cotton-wool. Alcohol is poured in and the extract allowed to filter through drop by drop. The first portions are the purest and strongest, those following decreasing in flavour until the latter becomes too weak or even foreign in character.

Careful *mixing* is essential to the successful manufacture of liqueurs. Two separate vessels should be employed, the one for the essences or flavouring ingredients dissolved in about three-quarters of the total amount of alcohol required by the formula, and the other containing the syrup together with the rest of the alcohol. In this way the danger of the aromatic principles being thrown out of solution on the addition of the syrup is obviated, and the process of clarification expedited. The admixture should always be made in the cold to avoid loss of the flavouring principles, and the vessels may be hermetically sealed and provided with a scale or gauge rod to indicate the quantity of the ingredients admixed. The liqueur should rest for some days after mixing, and any defects, detected by taste, remedied before colouring, clarifying, or filtering.

Filtration, when necessary, should be conducted as quickly as possible. The older methods with cotton, paper, or wool in copper or tin filters are slow and result in loss of spirit and flavour. A better method is to use paper-pulp brought to the consistency of thick soup with some of the liqueur to be cleared. This is added to the bulk of the liqueur and the whole passed through a hair sieve. Natural clearing is best if time permits.

Clarification or '*collage*' with 'fining' materials is best avoided if possible, but is often necessary. The principal materials and the proportions used are as follows: *albumen*, white of egg (one egg for every 10 litres); *gelatin* (30 grams per 100 litres); *isinglass* (10 grams per 100 litres); *milk* (1 litre boiled in 100 litres, with 15 grams of alum). Animal or vegetable carbon, alum, nitre, and various 'filtering powders,' as 'Poudre Lebœuf,' are also employed. For coloured liqueurs, which are apt to suffer by this treatment, filtration is preferable to 'collage.'

Liqueurs containing various flavouring ingredients improve by keeping, as time is required for the intimate blending of the various substances in solution. The effect of this 'maturing' is artificially brought about in ordinary liqueurs and those intended for immediate use by a process known as *tranchage*, which consists either in heating in a water-bath to about boiling-point, or by successive coolings with ice. The object is to suppress the penetrating flavour of the new spirit and to give a smooth uniform character to the product so that none of the different flavouring ingredients can be individually recognised. Tranchage should be carried out *before* the colouration, clarification, or filtration of the liqueur.

The place of *storage* of liqueurs should be kept at a uniform temperature of 15° to 20° and the liqueurs protected from strong light or direct sunshine, as this affects the colour, frequently causing it to change or to be precipitated.

Bitters are considered to be tonic and stomachic and to improve the appetite when taken in moderation. They are prepared by maceration without distillation. The substances most commonly used are cascarilla, gentian, orange peel, quassia and wormwood. The best known preparations are *Angostura, Khoosh, orange,* and *peach bitters.* A fundamental principle in most bitters is gentian. A bitter made according to the following formula, which represents the proportions necessary to make 20 gallons, may be taken as typical: 6 lbs. gentian; 5 lbs. cinnamon; 5 lbs. caraway seeds; 1 lb. juniper berries; ½ lb. cloves. Macerate in spirit of about 90° (or 60 p.c.) for 10 or 12 days; strain, filter, add a syrup consisting of 10 lbs. of sugar to 13 gallons of water, and colour with cochineal.

English bitters may be made by digesting 5 ounces of the outer rind of dried orange peel, 6 ounces of cinchona bark, 6 ounces of gentian, 8 ounces of *Carduus benedictus,* 8 ounces of centaury, 8 ounces of wormwood, and 4 ounces of orris root, with 12 gallons of spirit about proof strength, filtering and sweetening with 12 lbs. of sugar.

In the following brief description of the best known liqueurs and cordials, the formulæ given are not intended, in the case of proprietary articles, as *Angostura, Chartreuse,* &c., to represent the exact composition or mode of preparation of the liqueurs originally known under these names, and the manufacture of which is carefully preserved as trade secrets, but only to serve as a guide to the preparation of a more or less successful imitation or substitute in each instance.

Absinth (*v.* article ABSINTH in vol. I.).

Angostura. A well-known bitter originally in possession of the Capuchin Friars' Mission on the river Carony in South America, and called after the ancient name of a city in Venezuela, now Ciudad Bolivard.

The essential bitter principle is extracted from the bark of a plant belonging to the order *Rutacea,* genus *Galipea.* It has valuable febrifuge properties. The following formula is taken from the Scientific American Cyclopædia, 1903: 4 oz. gentian root; 10 oz. each of calisaya bark, Canada snake root, Virginia snake root, liquorice root, yellow bark, allspice, dandelion root, and Angostura bark; 6 oz. cardamon seeds; 4 oz. each of Tolu balsam, galanga, and Turkey rhubarb; 1 lb. each of orange peel and alkanet root; 1½ oz. each of caraway seed and cinnamon; ½ oz. cloves; 2 oz. each of catechu, coriander seed, nutmegs, and wormwood; 1 oz. mace; 1½ lb. red sanders wood and 8 oz. turmeric. The ingredients are pounded and macerated for 15 days in 50 gallons of proof spirit, 30 lbs. of honey added, and filtered.

Advocaat, a spirit made in Holland from spirit and yolk of eggs and sweetened with sugar. The average strength is about proof.

Alkermes, a liqueur originally made at Florence and highly esteemed in the South of Europe. The original formula for the Alkermes de S. M. Novella is as follows: Bay leaves and mace, 1 lb. each; nutmegs and cinnamon, 2 oz. each; cloves, 1 oz. all bruised; cognac brandy, 3½ gallons; macerate for 3 weeks with frequent agitation. Distil over 3 gallons; add 18 lbs. of clarified spirit of kermes and 1 pint of orange flower water, mix well and bottle.

Allasch, a superior kind of kümmel (*q.v.*) flavoured with caraway seeds, bitter almonds, angelica root, anise, iris root, and orange peel. It is usually supersaturated with sugar which crystallises out in the finished liqueur. Strength about 25 u.p. or 43 p.c. alcohol by volume.

Anisette. The principal varieties, differing somewhat in the flavourings used, are *Anisette d'Amsterdam* and *Anisette de Bordeaux.* This liqueur may be made as follows: 4 oz. aniseed; 1 oz. each of coriander and sweet fennel seeds bruised; ½ gallon of rectified spirits and 3 quarts of water. Macerate 5 or 6 days, distil over 7 pints and sweeten with 2½ lbs. of pure sugar. The alcoholic strength of anisette is usually about 52 p.c. of proof spirit or approximately 30 p.c. of absolute alcohol by volume.

Benedictine, so called from a monastery of this order in the north of France where the liqueur was first made. It is now produced on a large scale by a company at Fécamp, at a uniform strength of 75 p.c. proof spirit or 43 p.c. of alcohol.

This liqueur may be prepared by the following formula: cloves, 2 grams; nutmegs, 2 grams; cinnamon, 3 grams; balm, peppermint, freshly gathered angelica and genepi of the Alps, each 25 grams; calamus, 15 grams; cardamoms (small), 50 grams; arnica flowers, 8 grams. The materials are crushed and macerated for 2 days in 4 litres of alcohol at 85°; 3 litres of water added and the whole distilled, taking over 4 litres. A cold syrup made with 4 kilos. of sugar and 2 litres of water is added, the mixture brought up to 10 litres with water, coloured, and filtered.

Brandy (apricot, cherry, ginger, lemon, orange, peach, raspberry, &c.) by macerating the fresh fruits often for prolonged periods or mixing the juice with brandy, and sweetening with sugar syrup. Frequently essential oils are used, as ginger-brandy oil, essence of lemon, &c., and plain spirit instead of grape brandy. *Gin* and *whiskey* are similarly used for the preparation of fruit liqueurs, as sloe gin, cherry whiskey, &c., and, as in the case of brandy liqueurs, plain rectified spirit is commonly employed instead of gin or whiskey.

Chartreuse (*see* vol. i.).

Cocktail, a compounded drink much used in America. The spirit basis is brandy, gin, whiskey, or other spirits, and the different varieties, depending upon the kind of flavouring used, are very numerous and sold under fanciful names. A bottle of brandy cocktail may be made as follows: one-half brandy; one quarter water; and a wineglassful each of bitters, curaçoa, and gum syrup. Whiskey and gin cocktails may be made by the same recipe, substituting these spirits for brandy. The strength is usually from 50 to 75 p.c. of proof spirit.

Clove cordial may be prepared by the following formula. Bruised cloves, 1 oz. or essential oil, 1 dram to every 4 gallons of proof spirit. If distilled, this should be done over a quick fire. The necessary deep colouring is sometimes obtained by means of poppy flowers or cochineal, but more commonly with brandy colouring or red sanders wood. The cordial is improved by the addition of 1 dram of bruised pimento or 5 drops of the oil for every ounce of cloves. It is sweetened with about 3 lbs. of sugar to the gallon.

Crême de menthe is one of the most popular liqueurs in the United Kingdom and is typical of the class of 'crêmes,' which are highly sweetened and usually flavoured with only one characteristic ingredient, *e.g.* crême d'anis, cacao, café, menthe, noyau, orange, thé, vanille, &c.

The inferior grades are made by flavouring plain spirit with essential oils without distillation whilst the superior qualities are produced by macerating the flavouring ingredients (which sometimes include small quantities of others besides the principal one characteristic of the liqueur) with alcohol and subsequent distillation, sweetening, and colouring.

The following recipe for Crême de Menthe is given by De Brevans (The Manufacture of Liquors and Preserves, New York, 1893): peppermint, 600 grams; balm, 40 grams; cinnamon, 20 grams; sage, 10 grams; orris root, 10 grams; ginger, 15 grams. These are distilled with 5 litres of alcohol at 85°, the distillate sweetened with 3·75 kilos of white sugar, and made up to 10 litres.

Curaçoa, so called from the principal island of the Dutch West Indies where the peculiar oranges used for the manufacture of this liqueur, and known as 'Curaçoa apples,' are obtained. These are used before ripening and are exceedingly bitter.

The liqueur is now made chiefly in Amsterdam. The dried peel is rasped to a finely divided condition, macerated for several days in dilute spirit and distilled. A tincture made from various spices as cinnamon, mace, or cloves is often added to the distillate, which is then sweetened with syrup and coloured as desired with Brazil wood, saffron, or caramel. The flavour is said to be improved by the addition of about 1 p.c. of Jamaica rum. The alcoholic strength varies from 50 to 75 p.c. of proof spirit, the average being about 60 p.c. proof or approximately 35 p.c. of alcohol by volume.

The following formula is given by De Brevans: rasped skins of 18 or 20 oranges; cinnamon, 4 grams; mace, 2 grams; alcohol at 85°, 5 litres; white sugar, 1·75 kilos. Macerate for 14 days, distil without rectification, and colour with caramel.

Kirsch (see KIRSCHWASSER).

Kümmel, a liqueur made chiefly in Russia and to some extent in the other countries on the shores of the Baltic. The principal flavouring ingredient is caraway seeds. The inferior grades are, as usual, made from plain spirit and essential oils, and the superior qualities by maceration with spirit followed by distillation.

The following formulæ indicate the quantities necessary to make 20 gallons:—(*a*) inferior quality: 7 gallons of spirits of wine; ¼ lb. essential oil of caraway seed; 7½ drachms of fennel seed oil; 15 drops of bitter almond oil; syrup made with 40 lbs. of sugar in 12 gallons of water. When fined with alum or soda solution, it is ready for use. (*b*) Superior quality: 4 lbs. caraway seeds; ¼ lb. fennel; 2 oz. of Florentine iris root. These are macerated with 10 gallons of spirits of wine and 8 gallons of water, and distilled. The first part of the distillate is set aside because of its rough character, and about 8 gallons are then distilled over for making the fine kümmel, the last fraction of 3 or 4 gallons being used for the inferior grades. To the middle fraction a syrup made with 60 lbs. of sugar in 10 gallons of water is added, and the whole well mixed in an open heated vessel. The liquor is then cooled and made up with water to 20 gallons. It may be fined with isinglass and stored to mature and mellow.

The strength of kümmel varies considerably, viz. from about 60 to 100 p.c. of proof spirit, the average being 75 p.c. proof equivalent to 43 p.c. of alcohol by volume.

Maraschino. This liqueur was originally made at Zara in Dalmatia from the wild *marasca* cherry. The juice was fermented, distilled, flavoured with the bruised kernels and sweetened with honey. Other flavouring ingredients are now commonly used, as cherry leaves, kirschwasser, peach kernels, orris root, raspberries, vanilla, &c.

Imitation maraschino may be made from plain spirit flavoured with bitter almonds, raspberry juice and orange flower water, or with essential oils as neroli, noyau, jasmine, and vanilla.

The strength varies from 55 to 75 p.c. of proof spirit, average 69 p.c. proof or 39 p.c. of absolute alcohol by volume.

Noyau is distilled from brandy macerated with or distilled from bitter almonds, sometimes with the addition of other flavourings as cinnamon, coriander seed, ginger, mace, and nutmeg. The almonds are occasionally replaced by apricot or peach kernels or by oil of bitter almonds or its substitute nitrobenzene. The flavour is due chiefly to the presence of prussic acid and the liquor should therefore be used sparingly. It is frequently coloured pink.

Parfait amour may be made by flavouring spirit with the peel of 4 lemons, 1 drachm of essence of vanilla, and 3 lbs. of sugar to the gallon, colouring with cochineal. The essences of lemon, cloves, and mace are also employed in some varieties of this liqueur. The average strength is 60 p.c. of proof spirit or 34·5 p.c. of alcohol by volume.

Peppermint cordial (known also as 'Eau des Chasseurs' or 'Sportsman's cordial') is prepared from oil of peppermint, plain spirit, and sugar. The following is a recipe for making 100 gallons: English oil of peppermint, 5 oz., is added to 3 pints of rectified spirits of wine, well shaken, and placed in a cask capable of holding 100 gallons. 36 gallons of perfectly colourless and flavourless spirit at proof strength are poured in, and the whole well shaken for 10 minutes. A solution of pure sugar, 2¾ cwt. in about 35 gallons of pure soft water (preferably filtered rain water) is added, and the contents of the cask well rummaged for 15 minutes. Sufficient water to make the quantity up to 100 gallons and containing 5 oz. of alum in solution is next added, and the whole again well agitated for a quarter of an hour. The cask is then bunged down and allowed to rest for a fortnight.

On a small scale, peppermint cordial may be prepared by taking a pint each of peppermint water and gin or plain spirit of about 20 u.p. and adding ¾ lb. of sugar. Peppermint water is prepared by macerating peppermint flowers in about 4 times their weight of water containing about 5 p.c. of salt.

Ratafia. This term is applied to liqueurs or cordials the basis of which is the juice of fruits, obtained either by maceration or simple pressure. One of the most important is Ratafia de Cassis, made from black currants, but other pulpy fruits, especially apricots, cherries, gooseberries, oranges, peaches, raspberries, and strawberries are also commonly used. Various other flavourings as spices, ginger, orris root, &c., are occasionally added to give variety of flavour. The following formula for the preparation of cherry ratafia may be taken as typical: 20 litres of cherry juice; 20 litres of alcohol at 85°; 13·5 kilos. of sugar, and 4 to 8 litres of bitter almond water.

Trappistine. Originally prepared at one of the Trappist monasteries in Italy. Recipe: large absinthe, 20 grams; angelica, 40 grams; mint, 80 grams; cardamon, 40 grams; balm, 30 grams; myrrh, 20 grams; calamus, 20 grams; cinnamon, 4 grams; cloves, 4 grams; mace, 2 grams; alcohol at 85°, 4·5 litres; white sugar, 3·75 kilos. The method of preparation is similar to that described for Chartreuse (*v.* vol. I.). After macerating for 2 days, distil and rectify. Add syrup and colour green or yellow.

Vermouth. The principal varieties of vermouth are the French and Italian, the basis in each case being white wine flavoured with various herbs. Inferior kinds are made from brandy or other spirit sweetened and flavoured with essential oils. The French variety is less sweet and stronger in bitter principles, particularly wormwood, than the Italian.

The following recipe by Ollivero may be used for Italian vermouth: 100 litres of white wine of Picardy; coriander, 500 grams; rinds of bitter oranges, 250 grams; orris root, powdered, 250 grams; elder flowers, 200 grams; red cinchona, 150 grams; calamus, 150 grams; 125 grams each of large absinth, holy thistle, (*carduus benedictus*), elecampane (roots), little centaury, and germander; Chinese cinnamon, 100 grams; angelica root, 65 grams; 50 grams each of cloves, galanga, and nutmegs; and 30 grams of cassia. Digest for 5 or 6 days, draw off the liquor, size with fish glue and allow to stand for 15 days.

—	Specific gravity	Alcohol by volume	Alcohol by weight	Extract	Cane sugar	Other extractives	Ash
Absinthe .	0·9116	58·9	—	0·18	—	0·32	—

Kümmel .	1·0830	33·9	24·8	32·02	31·18	0·84	0·058

The strength of vermouth is usually between 23 and 30 p.c. of proof spirit, the average being 27 p.c. or 15·5° of alcohol by volume.

The table in the preceding column, by König, shows the results of analysis of some of the best known liqueurs and cordials.

J. C.

LIQUEUR DE FERRAILLE. *Ferric acetate* *v.* Acetic acid.

LIQUID STORAX *v.* Balsams.

LIQUORICE. The root of *Glycyrrhiza glabra* (Linn.). Cultivated chiefly in Spain, Russia, Italy, and to a small extent in Germany and England. It requires deep, fertile soil. Wild plants supply a considerable quantity in Asia Minor, and in some portions of Russia. The Spanish product is generally preferred to the Russian, since the latter is somewhat bitter.

The following analyses are given by König—

	Water	Protein	Fat	Glucose	Saccharose	Other *N*-free extract	Fibre	Ash
Spanish liquorice	8·8	12·9	3·7	7·4	2·1	43·0	17·7	4·4
Russian ,,	8·7	9·3	3·1	6·0	10·4	38·4	18·8	5·4

Liquorice owes its characteristic sweet taste to the presence of *glycyrrhizin* (the calcium and potassium salts of glycyrrhizic acid) which is present to the extent of about 8 p.c. To extract this, the roots are treated with cold water, the liquid boiled to precipitate albuminoids, filtered, and dilute sulphuric acid added, when the glycyrrhizic acid is precipitated in pale yellow flocks, which soon become a dark brown, sticky mass. This is then washed until free from acid and dissolved in dilute ammonia. By evaporation to dryness of this liquid, the "glycyrrhinum ammoniacale" is obtained, which serves as a sweetening agent in the preparation of medicines, in porter-brewing, and also as a sweetmeat.

Liquorice also contains a yellow colouring matter, and from 2 to 4 p.c. of asparagin, malic acid, starch, a little tannin and other substances.

H.I.

LIQUORICE ROOT. *Radix Glycyrrhizæ.* (*Réglisse*, Fr.; *Süssholzwurzel*, Ger.) The root of the underground stems of the *Glycyrrhiza glabra* (Linn.), a plant inhabiting the south of Europe and Central Asia (*cf.* Bentl. a. Tim. 74). Liquorice, or its solid aqueous extract, the 'Spanish juice' of commerce, has long been a favourite demulcent in throat affections, and is used as a laxative. It finds also a considerable employment in porter-brewing.

The root was examined chemically by Pfaff (Syst. Mat. Med. 1, 187), Robiquet in 1809 (Ann. Chim. Phys. 72, 143), also by Trommsdorff (Taschenbuch, 1827, 1) and others (*cf.* Gm. 17, 56). It was found to contain *glycyrrhizin* or *liquorice sugar*, the most important constituent, together with an *acrid oil*, *asparagin*, *malic acid*, *starch*, traces of *tannin*, and other substances common to plants.

Glycyrrhizin has been further studied by Vogel (J. pr. Chem. [i] 28, 1); Lade (Annalen, 59, 224); Gorup-Besanez *ibid.* 118, 236); Roussin (J. Pharm. Chim. 12, 6); Habermann (Ber. 10, 870; Annalen, 197, 105); Sestini (Gazz. chim. ital. 8, 454); and more recently by Tschirch and Cederberg (Arch. Pharm. 245, 97) and Tschirch and Gauchmann (*ibid.* 247, 121). It consists of the potassium and calcium salts of a tribasic acid, *glycyrrhizic acid* $C_{44}H_{64}O_{19}$. Glycyrrhizic acid melts at 205°, it has a sweet taste and is optically inactive. A hexa-acetyl derivative has been obtained, m.p. 210°. Glycyrrhizic acid does not reduce ammoniacal silver solution or Fehling's solution. When fused with potash it yields acetic and oxalic acids; distilled with zinc dust, naphthalene; and when oxidised with potassium permanganate, phthalic acid. If glycyrrhizic acid is boiled for 5 hours with water containing 3 p.c. of sulphuric acid, air being excluded, *glycyrrhetic acid* $C_{32}H_{48}O_7$ (hitherto known as *glycyrrhetin*) is precipitated. It can be obtained crystalline from acetic acid, melts at 210°, is monobasic, and forms a diacetyl derivative melting at 219°. The solution from which this acid has separated contains glycuronic acid.

The drug contains about 2 p.c. of glycyrrhizic acid, also 0·2 p.c. of a fatty substance with a bitter taste, and dextrose. Mannitol is present in the liquid from which the crude glycyrrhizic acid has been precipitated with sulphuric acid but it is not present in the original drug.

By distilling Spanish liquorice root, Haensel (Pharm. Centh. 40, 533) obtained 0·03 p.c. of an ethereal oil; the Russian roots yield 0·035 p.c. These oils are not identical, for whilst the Russian oil is dextrorotatory, the Spanish is lævorotatory.

For the technical analysis of liquorice extracts, *see* Py (Pharm. Chim. [vi.] 5, 280); Trubeck (J. Amer. Chem. Soc. 22, 19); Hafner (Chem. Zentr. 1900, i. 68; ii. 501). A. S.

LITHARGE *v.* Lead.

LITHIA MICA *v.* Lithium.

LITHIUM. Sym. Li. At.w. 6·94 (Hagen, Mallet, Troost, Diehl, Stas, Dittmar, Richards and Willard). This metal occurs in combination with silica, alumina, and the alkali metals in *lepidolite* or *lithia mica*, *petalite* (containing phosphates of lithium, iron, and manganese), *spodumene*, *triphylene*, and *amblygonite*, usually to the extent of 3 to 6 p.c. (J. Soc. Chem. Ind. 18, 877). Also in psilomelane, in a hexagonal variety of zinc sulphide, schalenblende, and in many radioactive minerals particularly carnotite (Gleditsch, Compt. rend. 145, 1148; 146, 331); Ramsay, *ibid.* 146, 456; McCoy, Nature, 1907, 79).

Lithium is widely distributed. It occurs as chloride in most spring waters and in sea water. A mineral spring at Wheal Clifford, near Redruth, contains 26 grains per gallon (Miller, Brit. Assoc. Trans. 1864, 35); Phillips has found 34 grains per gallon in a salt spring in Huel Seton copper mines in Cornwall. It is found in most plants, especially in the leaves (Tschermak, Chem. Zentr. 1899, ii. 1127). The ash of tobacco has been found to contain 0·44 p.c. of lithium chloride (Fruehot, Compt. rend. 78, 1022). The presence of lithium in excess appears to be generally injurious to plants. It also occurs in all the organs of the human body, particularly the lungs (Herrmann, Pflügers Archiv. 109, 26).

Lithium was first isolated by Brandes, but first prepared in quantity by Bunsen (Pogg. Ann. 94, 107). The metal cannot be obtained by ignition of the carbonate with carbon, or of the hydroxide with iron, but is obtained by the electrolysis of a mixture of equal weights of lithium and potassium chlorides (Guntz, Compt. rend. 117, 732). Ruff and Johannsen (Zeitsch. Elektrochem. 12, 186) recommend a mixture of lithium bromide with 10–15 p.c. lithium chloride, using a carbon anode and two iron rods, 4 mm. diameter, as cathode, the current required being 100 ampères and 10 volts. According to Borschers (Chem. Zentr. 1895, ii. 13), lithium can be obtained from its ores by making the solution of the chlorides of the alkalis and alkaline earths slightly alkaline, evaporating in an iron vessel, fusing the residue thus obtained with ammonium chloride and electrolysing the mass with a current of 1000 amperes per square metre of cathode surface and 5 volts. The upper rim of the iron crucible is kept cool by a current of cold water, the surface thus being protected from the atmosphere by a thin layer of solidified metal. The metallic globules are then placed in a paraffin bath at 130°–200° when the pure metal rises to the surface. Lithium can also be formed by heating the hydroxide with magnesium in a tubulated iron retort when the metal distils over (Warren, Chem. News, 1896, 6); or by the electrolysis of lithium chloride in pyridine solution (Kahlenberg, J. physical. Chem. 1899, 3602).

The statement that traces of lithium are formed in the degradation of copper by radium emanation (Cameron and Ramsay, Chem. Soc. Trans. 1907, 1593) lacks confirmation (Perman, *ibid.* 1908, 1775; Curie and Gleditsch, Compt. rend. 147, 345).

Properties.—Lithium is a silver-white metal which tarnishes and oxidises less rapidly than potassium or sodium. It is softer than lead, but less tenacious. Its sp.gr. is 0·589 to 0·598 (Bunsen), lower than that of any known solid. It melts at 180° (Bunsen), 186° Kahlbaum, Zeitsch. anorg. Chem. 23, 220), and volatilises at a bright red heat in a current of hydrogen, forming *lithium hydride* LiH (Guntz, Compt. rend. 122, 244). At a temperature somewhat above its melting-point it burns with an intense white light. When heated, it burns in chlorine, bromine, iodine, and sulphur vapour, and in carbon dioxide. In water it oxidises, but does not fuse. It absorbs nitrogen even in the cold, being the only metal that does so (Deslandres, Compt. rend. 121, 886; Guntz, *ibid.* 245).

By nitric acid it is rapidly oxidised, often with fusion and ignition. In dilute sulphuric acid and in hydrochloric acid it dissolves quickly; solution is slow in strong sulphuric acid. At a temperature below 200° it attacks silica, glass, and porcelain. Like other alkaline metals it dissolves with formation of a blue solution in liquefied ammonia gas, a similar result being obtained when it dissolves in methylamine (Moissan, Compt. rend. 128, 26). When gently heated to 400° in a current of ammonia, *lithamide* $LiNH_2$ is formed (Titherley, Chem. Soc. Trans. 1894, 517; Moissan, Compt. rend. 127, 685; *ibid.*, 133, 715).

At the ordinary temperature, lithium with dry ammonia gas forms a liquid which, when rapidly evaporated at 70°, yields a brownish red solid, *lithium ammonia* $LiNH_3$ (Moissan, *l.c.*).

Lithium forms an amalgam with mercury

(Kerp and Böttger, Zeitsch. anorg. Chem. 25, 1) and alloys with antimony, tin, and lead of the type Li_3M (Lebeau, Compt. rend. 130, 502; *ibid.* 134, 231, 284). These alloys have higher melting-points than the constituents and are powerful reducing agents. It also forms compounds with arsenic (Lebeau, *ibid.* 129, 47) and with silicon (Moissan, *ibid.* 134, 1083; Wallace, Zeitsch. anorg. Chem. 63, 1).

Detection.—Lithium salts produce a fine, crimson colour in the blowpipe flame. They are usually colourless, and when in strong solution give a precipitate on addition of carbonates or sodium phosphate, in presence of ammonia. In presence of sodium, lithium can be detected by making the solution alkaline with ammonia, then adding $\frac{1}{10}$ of its volume of sodium hydrogen phosphate, after which enough alcohol is added to produce a heavy permanent precipitate. On boiling, the solution will become perfectly clear if lithium is absent, for lithium phosphate is insoluble in boiling alcohol (Benedict, Amer. Chem. J. 32, 480).

Estimation.—The estimation usually entails the separation from potassium and sodium. For this separation Mayer's process is most satisfactory (Annalen, 98, 193). The solution containing the alkalis as chlorides is treated with sodium phosphate (*absolutely* free from alkaline earth phosphates), and sufficient sodium hydroxide to keep the solution alkaline, and evaporated to dryness. Sufficient water is added to dissolve the soluble salts, the solution heated gently and filtered after 12 hours. The precipitate is washed with a mixture of 1 part of water and 1 part of ammonia (of which liquid 3920 parts dissolve only 1 part of lithium phosphate); the filtrate and first two washings are evaporated and taken up as before, any residue of lithium phosphate being added to the bulk of precipitate. The precipitate, dried at 100°, has the composition Li_3PO_4.

Kahlenberg and Krankopf (Amer. Chem. J. 30, 1104) recommended the following method. The solution of mixed chlorides is evaporated to dryness and the residue is boiled with pyridine. The solution is decanted through a small filter and the residue is again treated with pyridine several times. The pyridine filtrates are now distilled and the lithium chloride residue is converted into sulphate by evaporation with sulphuric acid and weighed as such. According to Schieffelin and Lamar (Amer. Chem. J. 24, 392) a good way of estimating lithia in lepidolite is to dissolve the alkali chlorides obtained in the usual way in about 10 c.c. of hot water, a drop of hydrochloric acid is added, then a little ammonia and ammonium oxalate; the solution is filtered and the filtrate evaporated until it commences to crystallise (about 1–2 c.c.). A drop of water and of hydrochloric acid is added, then 15 c.c. of amyl alcohol, it is then concentrated to half its volume, cooled and filtered into a platinum dish, the residue is washed with amyl alcohol, until the washings are free from lithium, the amyl alcohol extract is evaporated below the boiling-point and the residue converted to sulphate.

For methods of estimating lithium in mineral waters, compare Carnot (Compt. rend. 107, 336); Waller (J. Soc. Chem. Ind. 1890, 1066); Razoli (Gazz. chim. ital. 31, i. 40).

Extraction of salts.—Finely powdered lepidolite or petalite 10 parts, is mixed with barium carbonate 10, barium sulphate 5, potassium sulphate 3, and ignited at the highest temperature of a wind furnace. Two layers are thus produced, the lower of barium silicate and sulphate, the upper of white sulphate of potassium and lithium. It is lixiviated with water and treated with barium chloride to convert the alkalis into chlorides and to precipitate the sulphuric acid as barium sulphate. The solution is evaporated to dryness and digested with a mixture of equal parts of absolute alcohol and ether, in which the lithium chloride dissolves with only a trace of potassium and sodium chloride (Troost, Compt. rend. 43, 921).

According to Müller (Annalen, 85, 251), *triphylene* is dissolved in hydrochloric acid, the iron oxidised to ferric chloride by the addition of nitric acid, the phosphoric acid precipitated by a persalt of iron, the mixture evaporated to dryness, and extracted with water. Manganous and lithium chlorides are thus dissolved; the former is precipitated with barium sulphide, the excess of barium being removed by the addition of ammonium carbonate or sulphuric acid. The solution is evaporated with oxalic acid and the residual oxalate ignited to carbonate.

The finely ground and sifted lepidolite is made into a thin paste with concentrated sulphuric acid, in a warm brick trough, and digested and stirred until it commences to agglomerate. It is then calcined in a reverberatory furnace, and, while warm, well lixiviated with water and filtered. The lye is mixed with sufficient potassium sulphate to convert all the alumina into alum, and the solution decanted from the alum meal. The remaining alumina is precipitated by milk of lime, the alkalis are converted into chlorides by addition of barium chloride, and the solution evaporated to dryness. The chlorides of lithium and calcium are extracted with absolute alcohol, the alcohol evaporated, and the calcium precipitated by ammonium oxalate, and any heavy metals removed by a little ammonium sulphide. The solution is evaporated to dryness in a silver basin (*v.* A. W. Hofmann, Dingl. poly. J. 219, 183, and Felsinger, *ibid.* 222, 385).

Powdered amblygonite or other lithium ore is intimately mixed with powdered sodium bisulphite and the mixture heated in cast-iron retorts, the hydrofluoric acid and silicon fluoride disengaged being collected. The mass is then transferred to a refractory earthen vessel and heated to redness. The product is lixiviated, filtered, and aluminium, copper, and iron are precipitated by a very small proportion of sodium carbonate. After filtration it is again treated with sodium carbonate when lithium carbonate is precipitated. The insoluble residue of the lixiviated product is said to be rich in phosphorus and can be used as a manure (J. Soc. Chem. Ind. 1906, 884).

Finely powdered lepidolite is mixed with 10 p.c. more than its weight of sulphuric acid and heated with frequent stirring for 8 hours at 112°–340°; 97–99 p.c. of the ore is thus decomposed. The mass is leached with water and the silica separated. The solution is now treated with sufficient potassium sulphate to convert the aluminium sulphate to alum and allowed to stand for 6 days when precipitation is complete, the decanted liquor is treated with whiting, boiled, and the alum precipitated as alunite by adding aluminium hydroxide. The last traces of alumina are removed by again treating the filtrate with whiting. The solution is then boiled, made alkaline with slaked lime and concentrated. Copper sulphate and magnesium and iron oxides are removed in the usual way and the solution consisting of lithium sulphate is added to a solution of potassium carbonate, when lithium carbonate is precipitated, and is washed and dried (Schieffelin and Cappon, J. Soc. Chem. Ind. 1908, 549).

According to Wadman (*ibid.* 1907, 469; 1908, 122), pure lithium carbonate can be obtained by heating the ore with an alkaline sulphate such as K_2SO_4. The solution of sulphates thus obtained is now treated with sufficient ammonia to render the potassium sulphate insoluble and to precipitate iron, aluminium, and magnesium hydroxides. The precipitate is removed and the lithium precipitated as carbonate.

According to Zell (J. Soc. Chem. Ind. 1909, 1126), a pure lithium compound can be obtained by heating a lithium ore in the presence of carbon in an atmosphere of acetylene. Volatile lithium hydrogen carbide is thus formed and is decomposed by water into lithium hydroxide and acetylene.

Lithium oxide Li_2O may be prepared by ignition of the metal in air or oxygen (Holt and Sims, Chem. Soc. Trans. 1894, 443); in solution, by precipitation of the sulphate with barium hydroxide solution. A purer product is obtained by heating lithium hydroxide or its hydrate LiOH, or $Li(OH)\cdot H_2O$, in a platinum crucible in a current of dry hydrogen for about an hour at 780° (Forcrand, Compt. rend. 144, 1321). Lithium carbonate heated similarly at 780°–800° also yields pure lithium oxide (Forcrand, *l.c.* 1402). It is yellowish white and spongy, less soluble than the oxides of potassium and sodium. It melts below redness, and, as it corrodes platinum powerfully, should be fused in a silver vessel. The hydrated oxide may be obtained in small crystalline grains.

By mixing lithium hydroxide (Forcrand, Compt. rend. 146, 802) with hydrogen peroxide and then adding an equivalent volume of absolute alcohol, the compound

$$Li_2O_2\cdot H_2O_2,3H_2O$$

is formed which, when placed in a vacuum over phosphorus pentoxide, yields *lithium peroxide* Li_2O_2 (Forcrand, Compt. rend. 130, 1465).

Lithium chloride LiCl may be prepared by combination of lithium and chlorine, or by dissolving the carbonate or oxide in hydrochloric acid. When formed at low temperatures the crystals contain two molecules of water; at temperatures above 15° anhydrous octahedral crystals are produced, which are very hygroscopic; various hydrated chlorides are known (Bogorodsky, Chem. Zentr. 1894, ii. 514). It dissolves in absolute alcohol and in a mixture of alcohol and ether. At 0° 100 parts of water dissolve 63·7 parts, and at 100° 145 parts of the chloride.

Lithium chloride is more volatile than potassium chloride; less so than sodium chloride. Below a red heat it volatilises, losing a little hydrochloric acid and producing an equivalent amount of lithium oxide.

Lithium dissolves in the chloride, but the subchloride Li_2Cl could not be obtained (Guntz, Compt. rend. 1895, 121, 945; Ann. Chim. Phys. 1907, 10, 13). At −18° the chloride absorbs ammonia rapidly, forming a series of compounds with 1, 2, 3, and 4 molecules of ammonia (Bonnefoi, Compt. rend. 124, 771; *ibid.* 127, 367). With ethylamine and methylamine, it behaves similarly (Bonnefoi, *l.c.* and Compt. rend. 129, 1257). Lithium bromide (Bonnefoi, *ibid.* 130, 1394; Bogorodsky, *l.c.*), lithium iodide (Thirsoff, J. Russ. Phys. Chem. Soc. 25, 467; Bogorodsky, *l.c.*), and their double salts with other metallic halides (Kurnakoff and Sementschenko, Zeitsch. anal. Chem. 1899, 335; Dobroserdoff, J. Russ. Phys. Chem. Soc. 32, 774; Bogorodsky, *l.c.* 515; Duboin, Compt. rend. 141, 1015; Chassevant, *ibid.* 115, 113); also lithium fluoride (Poulenc, Bull. Soc. chim. [iii.] 11, 15; Wells and Foote, Amer. J. Sci. 1897, 466) have been prepared.

Lithium sulphate Li_2SO_4 is prepared by dissolving the carbonate or oxide in sulphuric acid. It forms monoclinic plates, soluble in alcohol and water. It produces a double sulphate with potassium sulphate, but does not form an acid sulphate or an alum.

Lithium carbonate Li_2CO_3 is prepared by the addition of a hot concentrated solution of lithium chloride to an ammoniacal solution of ammonium carbonate. It is a white powder, which decomposes at 600° (Lebeau, Compt. rend. 136, 1256), is reduced by heating with aluminium (Franck, Chem. Zeit. 1898, 22, 236), and is more fusible than the potassium and sodium salts. It is quite insoluble in absolute alcohol (Kobbe, Pharm. Zeit. 34, 312) and only slightly soluble in water but more readily so in aqueous solution of the alkalis, particularly ammonium salts (Geffcken, Zeitsch. anorg. Chem. 1905, 43, 197).

Its solubility in cold is greater than in hot water. The solubilities given by different observers are not concordant. According to Bevade (Bull. Soc. chim. [ii.] 43, 123), the solubility in 100 parts of water is as follows:—

Temperature	0°	10°	20°	50°	75°	100°
Parts . .	1·539	1·406	1·329	1·181	0·866	0·728

The solubility increases after continued boiling. *V.* further Draper (Chem. News, 55, 169) and Flückiger (Arch. Pharm. [iii.] 25, 509).

The commercial salt usually contains about 98·5 p.c. of lithium carbonate. Lithium forms a very soluble *urate*; for this reason the carbonate and citrate are administered to remove uric acid from the blood in gouty affections (Kebler, Amer. J. Pharm. 1898, 600).

Lithium carbide Li_2C_2, is obtained by heating lithium carbonate with sugar carbon in an electric furnace (Moissan, Compt. rend. 122, 362); or by heating lithium and carbon together in a vacuum (Guntz, *ibid.* 126, 1866); or in a stream of carbon di- or monoxide (Guntz, *ibid.* 123, 1273; Moissan, *ibid.* 127, 911). It is a powerful reducing agent; burns in fluorine, chlorine, bromine, iodine, oxygen, and combines with sulphur and selenium; it is not attacked by concentrated acids but readily by water, forming acetylene and lithium oxide.

Lithium nitride Li_3N is prepared by heating lithium in an iron dish very gently in a slow stream of nitrogen (Ouvrard, Compt. rend. 1892, 114, 120; Guntz, *ibid.* 123, 995). It is a brownish red or black spongy substance, difficult to obtain quite pure and is readily decomposed by water or when heated with hydrogen.

Lithium azoimide LiN_3,H_2O, formed by neutralising a solution of lithium hydroxide with azoimide, HN_3, crystallises in colourless, lustrous, hygroscopic needles which explode between 115–298 (Dennis and Benedict, Zeitsch. anorg. Chem. 1898, 17, 18; Curtius and Rissow, J. pr. Chem. 1898 [ii.] 58, 261).

Lithium citrate $Li_3C_6H_3O_7$ is prepared by the addition of 100 parts of lithium carbonate to a solution of 186·5 parts of citric acid (Umney, Year-book of Pharmacy, 1875, 559). It may be produced as a white, anhydrous, neutral, non-deliquescent powder, or in crystals containing 4 molecules of water. It is soluble in 25 parts of cold water. The commercial salt usually contains salts of potassium, sodium, and calcium, and frequently lithium carbonate or citric acid, and powdered lepidolite or petalite (C. Thompson, Pharm. J. [iii.] 13, 783; Dott, *ibid.* 1905, 440). The following salts of lithium are employed in medicine:—

Benzoate, caffeine sulphonate, dithiosalicylate, formate, guaiacate, hippurate, and iodate in uric acid diathesis; bitartrate, theobromine salicylate, potassium tartrate and acetate as diuretics; glycerophosphate in neurosthenia; borosulphite, sulphoichthyolate, and sozoiodolate as antiseptics (J. Soc. Chem. Ind. 1898, 736; Kebler, Amer. J. Pharm. 1899, 57).

According to Vulpian (J. Soc. Chem. Ind. 1889, 476) lithium salicylate is of greater effect than sodium salicylate in gout and in acute articular rheumatism.

Lithium quinate is used in the treatment of gout and analogous diseases (Johnson, J. Soc. Chem. Ind. 1899, 1051). According to Dumesnil (J. Pharm. Chim. 1906, 326), lithium theobromine, prepared by adding excess of theobromine to lithium hydroxide solution, is 4 or 5 times as active therapeutically as the same weight of theobromine.

Lithium salts react with casein giving readily digestible compounds suitable for medical purposes (Abel, J. Soc. Chem. Ind. 1899, 398).

Lithium oxalate (Foote and Andrew, Amer. Chem. J. 1905, 153), thymate (J. Soc. Chem. Ind. 1906, 714), and the double salts of lithium and the acid salts of piperazine with oxalic, tartaric, and citric acids (*ibid.* 1897, 758), are also very useful products.

Double urinates (Melikoff and Pissarjewsky, Ber. 30, 2902; Coninck and Chauvenet, Bull. Belg. Roy. Acad. 1905, 51, 182); lithium phosphates and arsenates (Schulten, Bull. Soc. chim. [iii.] 1, 479; Ouvrard, Compt. rend. 110, 1333; Rammelsberg, Chem. Zentr. 1891, ii. 790; Quartaroli, Gazz. chim. ital. 1907, i. 598); zirconates (Ouvrard, Compt. rend. 112, 1444; Venable and Clarke, Amer. Chem. J. 1896, 434); borates (Reischle, Zeitsch. anorg. Chem. 4, 169; Chatelier, Compt. rend. 124, 109); alumino silicates (Weyberg, Centr. Min. 1905, 646); platinocyanides (Reynolds, Proc. Roy. Soc. 1909, 82, 380), and tungstates (Feist, Ber. 21, 133) have been prepared. Lithium tungsten bronze, LiW_5O_{15} (Hallopeau, Compt. rend. 127, 512) is prepared by the electrolysis of lithium para-tungstate.

Z. K.

LITHOFRACTEUR *v.* EXPLOSIVES.

LITHOGRAPHIC STONE. A fine-grained limestone of uniform texture, breaking with an imperfect conchoidal fracture, and free from spots and veins. It must be compact enough to take a good polish and yet sufficiently porous to absorb the grease of the draughtsman's crayon; whilst being a limestone it can be etched with cold dilute acid. The only stones possessing these properties in a high degree are those from the large quarries at Solenhofen and Pappenheim in central Bavaria. Here the rock is a thin-bedded limestone of Upper Jurassic age. Two qualities are distinguished—a yellowish-drab and a bluish-grey, the latter being rather harder and more serviceable. They consist of 81–96 p.c. $CaCO_3$, 1–18 p.c. $MgCO_3$, with small amounts of alumina, ferric oxide, silica, &c. The quality of the stone depends, however, on physical characters rather than on chemical composition. Many attempts have been made to find lithographic stone at other localities, more particularly in the United States (*v.* G. P. Merrill, The Non-metallic Minerals, 2nd edit., New York, 1910).

L. J. S.

LITHOMARGE. (*Steinmark*, Ger.) An amorphous substance, resembling clay in composition (hydrated aluminium silicate with some iron) and in most of its physical properties, but firmer and more compact. It occurs on a large scale in the basaltic lavas of Antrim, where it is associated with bole, bauxite, and aluminous iron-ore. Some of the Irish lithomarge is of lavender colour, with white specks of bauxite, whilst other varieties are brown or blackish. The substance is known to the workmen as 'marge.' It may have resulted from the alteration of the basalt, and appears to resemble some of the steatitic laterites of India. Where peaty water comes in contact with the lithomarge, it occasionally deposits manganese oxide in considerable quantity (*v.* P. Argall, Journ. Geol. Soc. Ireland, 1886, 16, 102; G. H. Kinahan, *ibid.* 307). Lithomarge occurs in several Cornish mines; a fine yellowish variety, with purple veins, being found at Cook's Kitchen, near Redruth. Closely allied to lithomarge is the *teratolite* of Saxony, formerly reputed to possess such powerful medicinal qualities that it was described by old writers as *terra miraculosa Saxoniæ.*

L. J. S.

LITHOPONE. A pigment prepared by strongly heating a mixture of zinc sulphide and barium sulphate, obtained by mixing solutions of barium sulphide and zinc sulphate. Is a variable mixture of zinc oxide, zinc carbonate, zinc sulphide, and barium sulphate. The usual process of manufacture is to heat heavy spar with carbon, dissolve the mass in water and mix with a solution of zinc vitriol. The precipitate is washed, dried, and ignited, mixed with 2–3 p.c. of sal ammoniac and again ignited. While hot it is thrown into water, dried, and finely ground. Its value depends upon the amount of zinc sulphide present. For methods of analysis (*v.* J. Soc. Chem. Ind. 1902, 1145).

LITMUS. *Tournesol en pain.* This colouring matter is well known to the chemist, since white paper impregnated with its solution in a slightly acid or alkaline condition has long been employed, under the name of red and blue litmus-paper, to indicate the presence, in any solution, of alkalis or acids respectively. Alkalis change the colour of red litmus-paper to blue, acids turn blue litmus-paper red. In alkalimetry litmus tincture has, until recently, been the most generally adopted indicator. This use depends upon the fact that the free colouring matter of litmus is red, whereas its alkali salts are blue.

Commercial litmus has the form of small pale blue cubes, composed essentially of gypsum and chalk mixed with but comparatively little colouring matter, which is largely present in the form of a lake.

It is said to be prepared, chiefly in Holland, from various species of lichens, *e.g. Lecanora tartarea, Roccella tinctoria*, &c., the same, indeed, as are used in the manufacture of orchil (*q.v.*). Under the combined influence of ammonia and atmospheric oxygen the proximate principles contained in these lichens yield *orceïn*, the alkali salts of which are purple (orchil); but if potassium or sodium carbonate is present at the same time, the reaction proceeds further, and ultimately *azolitmin* (the colouring matter of litmus), the alkali salts of which are blue, is produced.

According to Gélis (J. Pharm. Chim. 24, 277; Revue Scient. 6, 50), litmus may be prepared as follows. Orchil-weed is ground and mixed with half its weight of potassium carbonate, and then repeatedly moistened with urine saturated with ammonium carbonate or with an aqueous solution of this salt; the mass soon acquires a brownish-red colour (3 days), which gradually becomes purple (20–25 days), and finally blue (30 days), yielding a litmus of the best quality in 40 days. The pulpy mass is mixed with chalk and gypsum, then moulded in the form of cubes, and dried in the shade.

By modifying the action of air and ammonia upon orcinol, through the addition of sodium carbonate, De Luynes also succeeded in obtaining the colouring matter of litmus (Compt. rend. 59, 49; Dingl. poly. J. 174, 61; Chem. Zentr. 1865, 127; J. 1864, 551). A mixture of 1 part orcinol, 25 parts cryst. sodium carbonate, 5 parts water, and 5 parts ammonia solution, was heated to 60°–80° for 4–5 days with frequent agitation. On diluting the blue solution thus obtained and acidifying slightly with hydrochloric acid, the colouring matter was precipitated. On washing and drying, it assumed a metallic lustre. It is sparingly soluble in water, but readily soluble in alcohol and in ether.

In making a litmus solution to be employed as indicator, the commercial litmus is extracted with boiling water, the filtered solution is slightly acidified with acetic acid, then carefully neutralised with ammonia, and boiled to expel any excess of the latter. Kept for any lengthened period in stoppered bottles, the solution becomes decolourised in consequence of a reductive fermentation; on exposure to air, however, the original colour is restored. This defect is prevented by saturating the solution with sodium chloride (Reichelt). (Compare also Bellamy, J. Pharm. Chim. [v.] 18, 433.) A dry litmus-extract may be prepared according to Vogel in the following manner (*ibid.* 45, 64, 70; Chem. News, 1864, 205). Twenty grams powdered commercial litmus are twice digested, each time with 150 c.c. cold distilled water. The second solution, which is alone employed, is divided into two equal portions, one of which is slightly acidified with nitric acid and then mixed with the other. The purplish solution thus obtained is evaporated to dryness on the water-bath, and the granular amorphous mass is kept in a stoppered bottle ready for dissolving in water when required.

For the employment and characteristics of litmus as an indicator *v.* R. T. Thomson (J. Soc. Chem. Ind. 6, 198); also art. ACIDIMETRY, vol. i.; Marsh (Chem. News, 61, 2); Berthelot (Ann. Chim. Phys. [vii.] 25, 39); Ronde (Pharm. Zeit. 41, 736); Lescouer (Compt. rend. 123, 811); Lüttke (Zeitsch. anal. Chem. 31, 692); Foerster (*ibid.* 28, 428); Glaser (*ibid.* 38, 273).

Litmus exhibits a characteristic absorption spectrum. Ether extracts it from an acid solution, and forms a yellow liquid, which absorbs the more refrangible end of the spectrum to a point midway between D and E. If the solution is coloured blue by adding a drop of ammonia, an absorption-band is formed, commencing at D, where it is extremely black, and gradually diminishing to E. A blue aqueous commercial solution shows a well-marked absorption-band at D. Addition of acid changes the colour to red, the band at D disappears, and the spectrum now resembles that of œnolin, the colouring matter of red wine (A. H. Allen, Com. Org. Analysis, 325). (Compare also Vogel, Praktische Spectralanalyse, 1877, 269.)

Our knowledge of the chemistry of the colouring matters contained in litmus is very meagre. Gélis (J. Pharm. Chim. 27, 477) extracted from it several colouring matters in the following manner. After extracting commercial litmus with water, the insoluble residue is boiled with dilute caustic alkali and the filtered solution is precipitated with basic lead acetate. The blue precipitate is washed by decantation until it begins to dissolve and colour the wash-water. It is then decomposed with hydrogen sulphide, exposed to air until free from excess of H_2S, collected on a filter and digested with dilute ammonia to extract the colouring matter. On adding acid to the filtered solution the main portion of the litmus colouring matters is thrown down as a red flocculent precipitate. The filtrate from this contains a very small quantity of colouring matter (α).

On extracting the dried red precipitate with ether and leaving the orange solution to spontaneous evaporation, it yields a bright-red residue (β) containing crystalline needles. This product is insoluble in water, but readily soluble in alcohol, also in alkalis with a violet colour. The portion insoluble in ether is dissolved in alcohol, and on allowing the blood-red solution to evaporate spontaneously it yields a large quantity of a reddish-purple product (γ) having a bronze lustre. This represents the colouring matter most abundant in litmus.

The residue, which is insoluble in water, in alcohol, and in ether, contains another product (δ) which is soluble in alkalis, from which it may be precipitated by acids. The three products β, γ, and δ, appear to contain nitrogen.

A more detailed examination of litmus was made in 1840 by Kane (Royal Soc. Trans. 1840, 298; Ann. Chim. Phys. [iii.] 2, 129; Annalen, 39, 57; J. Pharm. Chim. 1841, 569), who isolated from it the chief and characteristic colouring matters *azolitmin* and *erythrolitmin*, together with *erythroleïn* and *spaniolitmin.*

According to Kane, finely powdered commercial litmus is extracted with boiling water. Most of the colouring matter remains in the form of an insoluble lake in the residue, to which hydrochloric acid is added till effervescence ceases and the mixture is strongly acid. The insoluble matter mixed up with liberated colouring-matter is collected on a filter, washed free from acid, dried, and extracted with boiling alcohol. The alcoholic solution is filtered from an insoluble reddish-brown mass (impure azolitmin) and then evaporated to dryness, and the residue is digested with warm ether until it becomes no longer coloured. On distilling the filtered ethereal solution, *erythroleïn* is left as a purple semi-fluid oily substance. That portion of the alcoholic extract which is insoluble in ether consists of *erythrolitmin.*

The above-mentioned impure azolitmin is purified, either by dissolving it in a large quantity of boiling water and evaporating the solution to dryness, or by dissolving it in very dilute ammonia, evaporating the solution to dryness, neutralising any residual ammonia by dilute hydrochloric acid, and washing with alcohol until free from ammonium chloride and excess of hydrochloric acid. The residue represents purified *azolitmin.*

The colouring matter contained in the deeply coloured solution obtained in the first instance by boiling the commercial litmus with water and filtering, is isolated as follows. The solution is precipitated with neutral lead acetate, the purple precipitate thus obtained is well washed, suspended in water, and decomposed with hydrogen sulphide. The mixture of lead sulphide and liberated colouring matter thus obtained is well washed and digested with warm dilute ammonia ; the filtered deep-blue solution is evaporated to dryness, the residue is moistened with hydrochloric acid, washed free from ammonium chloride and any excess of hydrochloric acid, with warm alcohol. The residual deep brownish-red powder consists usually of nearly pure azolitmin, more rarely of *spaniolitmin*, a substance very similar to azolitmin, but which does not contain nitrogen.

Since spaniolitmin occurs so rarely in litmus, and erythroleïn is coloured reddish-purple and not blue by alkalis, Kane considers azolitmin and erythrolitmin to be the essential colouring matters of litmus, in which they are combined with ammonia, potash, and lime, and mixed with a considerable quantity of chalk, gypsum, &c.

Azolitmin is a deep brownish-red amorphous powder, insoluble in alcohol and sparingly soluble in water, but readily soluble in alkaline solutions with a pure blue colour. Its ammoniacal solution gives with metallic salt solutions blue or purple precipitates according as they are more or less basic in character. Kane's formula for it is $C_9H_{10}NO_5$, but Gerhardt considers it is best represented by $C_7H_7NO_4$. It differs from all the other colouring matters isolated from litmus by containing nitrogen. Gerhardt considered it to be derived from orcinol, possibly in accordance with the following equation :

$$C_7H_6O_2+NH_3+3O=C_7H_7NO_4+H_2O$$

or from orceïn thus $C_7H_7NO_3+O=C_7H_7NO_4$.

If the percentage composition assigned to this substance is correct, the explanation of the part played by the necessary alkaline carbonate in the manufacture of litmus may be that it facilitates and increases the oxidation of the orcinol, so that the orceïn at first formed is changed into azolitmin (Gerhardt, Ch. Org. 3, 816).

Scheitz (Zeitsch. anal. Chem. 1910, 49, 736) has isolated from litmus a blue colouring matter distinct from azolitmin in quantity equivalent to 1·5 p.c. of the weight of the purified material. It consists of a bright brown powder soluble in formic acid, pyridine, and ammonia, forming a bluish-violet solution with the last-named solvent. It absorbs ammonia gas with production of a dark blue ammonia compound, which dissolves in water to a reddish solution. This ammonia compound is a more delicate indicator than the corresponding derivative of azolitmin.

Erythrolitmin, which also constitutes one of the most important ingredients of litmus, is a bright-red powder, sparingly soluble in water and in ether. It is abundantly soluble in alcohol, from which it may be crystallised in the form of dark-red granular crystals. In strong caustic potash it dissolves with a blue colour. With ammonia it forms a blue compound which curiously enough is totally insoluble in water. With metallic salts it forms lakes of a fine purple colour. According to Kane its formula is $C_{13}H_{22}O_6$, and he considers it to be an oxidation product of his erythroleïc acid ($C_{13}H_{22}O_4$) obtained from orchil.

Erythroleïn forms a crimson semi-fluid mass, almost insoluble in water, soluble in ether and in alcohol with a red colour, and in ammonia with a purple colour. With metallic salts it gives purple lakes. Kane gives its formula as $C_{13}H_{22}O_2$. Its general properties are very similar to those of the above-mentioned erythroleïc acid.

Spaniolitmin occurs but rarely in litmus, hence its name. It is a bright-red substance, insoluble in alcohol and in ether, and very sparingly soluble in water. It dissolves in alkalis with a blue colour and gives lakes very similar to those of azolitmin. Kane's formula for it is $C_9H_7O_8$.

Under the influence of hydrogen sulphide, the colouring matters of litmus are decolourised, Kane's idea being, that a colourless hydrogen sulphide compound is thus formed. (*V.* also Malaguti, Ann. Chim. Phys. [iii.] 37, 206; Vogel, J. pr. Chem. [ii.] 16, 311.) Nascent hydrogen, and other reducing agents such as ferrous and stannous oxide, &c., decolourise them by reduction in the ordinary manner. Azolitmin thus yields colourless *leucazolitmin*, which, however, rapidly oxidises and becomes coloured on exposure to air. If stannous chloride is added to an ammoniacal solution of azolitmin, purple-coloured stannous-azolitmin is precipitated ; if this is boiled with slightly acidulated water there is formed the colourless compound of stannic oxide with leucazolitmin, which, if exposed to air, changes into the bright scarlet stannic-azolitmin.

Deoxidising agents such as sulphurous acid and sulphites do not decolourise the colouring-matters of litmus.

Azolitmin and erythrolitmin, suspended in water and submitted to the action of chlorine gas, are decolorised and give yellow chlorine derivatives, *chlorazolitmin* and *chlorerythrolitmin*, substances insoluble in water, but soluble in alcohol, ether, and in alkalis.

In his earliest memoir, Kane (Annalen, 36, 324) mentions that on heating the colouring matters of litmus mixed with chalk or gypsum, a red vapour is given off which condenses in the form of crystalline scales (atmérythrin) soluble in alcohol. When heated alone, this substance is not produced. Although Kane makes no subsequent mention of this body it is possible that it was indirubin or even indigotin, since at a later date, Wartha (Ber. 9, 217) states that he found some samples of litmus to contain indigotin, recognisable by the violet vapour given off on heating a few cubes of the commercial product in a test tube. Its presence may have been due to the use of urine containing indoxyl in the preparation of the litmus.

Wartha (*l.c.*) gives the following results of his examination of litmus. The commercial product is well shaken up with alcohol; the filtered purple solution thus obtained has a green fluorescence, and exhibits in the spectroscope a characteristic absorption band in the green with an almost total absorption of the violet end. The colouring matter (*a*) itself is obtained on evaporating the solution.

The litmus residue insoluble in alcohol is digested for 24 hours with distilled water, and the filtered deep-coloured solution is evaporated to dryness. The extract thus obtained is repeatedly treated with absolute alcohol containing a little glacial acetic acid and again evaporated, so that all traces of water may be removed, and there finally remains a brown powdery mass. On extracting this with absolute alcohol, a large quantity of a scarlet substance (*b*) is dissolved. It is similar to orceïn and dissolves in ammonia with a reddish-purple colour. That portion of the brown powder which is insoluble in the acidified alcohol is dissolved in water, the filtered solution is evaporated to dryness, and the residue is repeatedly washed with absolute alcohol and evaporated in order to expel all traces of acetic acid. The residual brown powder, which is very soluble in water, with a reddish-brown colour, but insoluble in alcohol and in ether, is the purified and extremely sensitive colouring matter of litmus (*c*). Its alkaline solution is blue, its aluminium and tin lakes are violet, and its calcium and barium lakes blue. It appears to be very similar to Kane's azolitmin, but it is said not to contain nitrogen. The yield of these various colouring matters is as follows: (*a*) 2·3 p.c., (*b*) 3·4 p.c., (*c*) 5·7 p.c. (Mitchell, Chem. News, 1876, 140).

An examination of the colouring matters of litmus was also made by Rochleder and Skraup (Wien. Anz. 1874, 118; Chem. Zentr. 1874, 424). Other references are Magner, J. Pharm. Chem. 12, 418; Desfosses, *ibid.* 14, 487; Peretti, *ibid.* 14, 539.

Of interest also in connection with this subject is the fact that when ethyl-amino-orsellinic acid is oxidised by air in alkaline solution it yields an orange coloured dye possessing basic properties (Heinrich and Dorschky, Ber. 1904, 37, 1416).

A peculiar blue colouring matter similar to litmus, and called *tournesol en drapeaux*, has long been manufactured at Grand-Gallargues, Département du Gard, France, from the *Croton tinctorium* belonging to the *Euphorbiaceæ*. Coarse linen cloth is steeped in the deep bluish-green sap expressed from the berries and the tops of the plant, then dried quickly in the open air, and exposed for 1–1½ hours between layers of straw to the ammoniacal vapours of lant or horse-dung (*aluminadon*), care being taken not to submit them to this influence too long. The cloth thus acquires a deep-blue colour. It is then steeped in the sap a second time and dried in air till it acquires a purple or dull green. These blue cloths are used by the Dutch farmers for making an infusion with which to impart a red colour to the outside of their cheese, the blue being changed to red by the lactic and butyric acids of the cheese.

According to Joly (Ann. Chim. Phys. [iii.] 6, 111) the colouring matter pervades the entire plant and is readily extracted therefrom by water heated to 50°–60°. On being evaporated, an azure-blue resinous mass remains. Acids change the blue colour of its aqueous solution red, and this blue is not restored by alkalis, the colour becoming thereby rather greenish. It is, therefore, probably quite distinct from the colouring matter of litmus. Possibly it is identical with the blue colouring matter which can be extracted from another plant belonging to the *Euphorbiaceæ*, viz. *Mercurialis perennis*. A. G. P.

LIVER OF SULPHUR. *Hepar sulphuri; potassa sulphurata.* This compound consists of a mixture of salts of potassium, chiefly the higher sulphide, and is prepared by fusing in a Hessian crucible a quantity of potassium carbonate with half its weight of flowers of sulphur. The fused mass is poured out on a greased flagstone and allowed to solidify, when it assumes a liver-brown colour; hence its name. It is alkaline, and acrid to the taste, and when quite dry is inodorous; but when moist it acquires the odour of sulphuretted hydrogen.

In medicine, it is given internally in cases of lepra and psoriasis; whilst externally it is used in the form of lotions, baths; as ointment in chronic skin-diseases, such as eczema, scabies, and pityriass. It is also largely used as a plant-spray.

LIXIVIATION. Lixiviation is the application of a liquid, generally water, to solid bodies for the purpose of extracting the soluble part. For instance, the preparation of pearl-ash by dissolving out the potassium carbonate from the wood ashes, and the preparation of sodium nitrate from the crude nitrate, of beet sugar by Schützenbach's process, are all applications of water to extract the soluble part. The extraction of gold from the tailings obtained from the stamp batteries, by means of dilute potassium cyanide solution in the presence of air, affords another example of the process of lixiviation.

In carrying out this process on a commercial scale, three things are sought to be attained: First, that the residue should be completely exhausted of soluble matter; second, that the solution obtained should be nearly saturated; and, thirdly, that the process should be continuous. A series of tanks is therefore provided, standing at the same level, and provided with false bottoms covered with a filtering bed, and with connecting tubes, pumps, and so on. Each of these tanks contains the substance to be lixiviated, and the water travels from tank to tank, increasing in saturation.

The process is so arranged that at any given moment a nearly saturated liquor is passing over a *fresh* supply of the substance, while clean water is running through the nearly exhausted residue. When the residue in any tank is completely exhausted it is removed, fresh stuff put in, and that tank made the last of the series. In some cases a pump is necessary between each tank to pump the liquid from beneath the false bottom into the next tank.

If the solution formed is of high sp.gr., so much pumping is not necessary. One detailed description will suffice. In the preparation of soda by the Leblanc process, the black ash (roughly speaking, soluble sodium carbonate and insoluble calcium sulphide) is lixiviated. For this purpose, four or more iron tanks are used, built side by side, each about 10 feet × 10 feet × 6 feet. Each tank has a false bottom of perforated iron plates, and a large cock in the bottom, by which all the liquor it contains can be run off. It has also an overflow pipe, rising from below the false bottom and communicating with the next tank, and a second overflow pipe which communicates with a trough outside. The first tank is connected with the last by a pipe. Any of these pipes can be closed by plugs or cocks. Suppose the process to be in full working order. Fresh black ash, broken in large lumps, has been placed in tank 4, on a bed of cinders laid over the false bottom. Tanks 3 and 2 contain partially exhausted black ash, and tank 1 completely exhausted black ash (tank waste). The overflow pipe between 3 and 4 is opened, and a pump connected with 1, which pumps the liquor over into 2. It flows from 2 to 3, from 3 to 4, until 4 is full. Tank 1 is now cut off, emptied, cleaned, and a fresh supply of black ash put in. While this is going on, fresh water is flowing into 2, and sufficiently saturated liquor flowing away from 4 by the outside overflow pipe. 4 is now connected with 1. The liquor is pumped out of 2 into 3, flows from 3 to 4, from 4 to 1. When 2 is empty of liquor it is in the same way cleaned out, and a fresh charge put in, and so the lixiviation is kept continuous, strong soda solution running off at one end, and exhausted tank waste being removed at the other.

LOADSTONE. A name applied to those specimens of the mineral magnetite (*q.v.*) which are magnetic with polarity, and are thus capable of orientating themselves when freely suspended. All specimens of magnetite are readily attracted by a magnet, but only few exhibit polarity in their natural state. Such specimens are found in exposed situations in mountainous districts, *e.g.* in the Ural and Harz Mountains, where they have no doubt been magnetised by the electric discharges of lightning. Such stones were at an early period mounted in iron frames and used as natural magnets. For historical details, *see* William Gilbert, De Magnete (1600; English edition with notes by S. P. Thompson, 1900). S. P. Thompson on Petrus Peregrinus's Epistola de Magnete (Proc. British Acad. 1907, vol. ii.).

LOBELACRIN *v.* LOBELIA.

LOBELIA. *Indian tobacco.* (*Lobélie enflée* Fr.; *Lobeliakraut*, Ger.) The official lobelia, *Lobelia inflata*, was described by Linnæus in 1741 (Acta Soc. Reg. Scient. Upsal. 1746) from specimens cultivated by himself, but he does not ascribe to it any medicinal properties. It is an annual herbaceous, somewhat pubescent plant, attaining a height of from 9 to 18 inches, with inconspicuous bluish racemose inflorescence. It is indigenous to the eastern portions of North America, and is cultivated in European gardens Flück. a. Hanb. 399; Bentl. a. Trim. 162). According to J. U. and C. G. Lloyd (Pharm. J. [iii.] 17, 566), the first to employ lobelia in medicine was Thomson, an American herbalist of some notoriety about the end of the 18th century. The Indians, although they made use of the great lobelia, *L. syphilitica* (Linn.), were not acquainted with the *L. inflata*, as has been commonly supposed and as one of its names would imply. Gradually the drug has come into favour as an article of *materia medica*, and it now finds a place in the pharmacopœias. The herb should be gathered when, after flowering, some of the capsules have become inflated. In physiological action, lobelia resembles tobacco. It is an acrid, narcotic poison, but in small doses is expectorant or emetic, and is largely employed in diseases of the respiratory organs. The seed is more active than the herb, but the latter is almost exclusively employed in medicine. It is generally administered in the form of tincture, made with proof spirit or a mixture of alcohol and ether.

Much uncertainty still exists as to the active constituents of lobelia. Colhoun investigated the plant in 1834 (J. Pharm. Chim. [ii.] 20, 545), but the first definite results were obtained by Procter a few years later (Amer. J. Pharm. 9, 98; 13, 1). The seed was exhausted with spirit containing a little acetic acid, the solution evaporated, and the residue mixed with magnesia and extracted with ether. On evaporating the ether an acrid alkaloidal liquid, *lobeline*, remained, which, by conversion into acetate and treatment with animal charcoal, was obtained in a purer form. Lobelia was further studied by Pereira (Mat. Med. 2nd ed. 2, 584), Reinsch (Pharm. J. [i.] 3, 128), Bastick (*ibid.* [i.] 10, 217), F. F. Mayer (Amer. J. Pharm. 37, 209), Richardson (*ibid.* [iv.] 2, 293), and, more recently, by Lewis (Pharm. J. [iii.] 8, 561), Dragendorff and Rosen (Chem. Zentr. 1886, 873), J. U. and C. G. Lloyd (Pharm. J. [iii.] 17, 566, 686, 1037; 18, 135), and Dresser (Arch. exp. Path. u. Pharm. 26, 237). To obtain lobeline, Bastick only slightly modifies the process of Procter; Richardson precipitates an infusion of the drug with potassium mercuric iodide; Lewis mixes the drug with animal charcoal, extracts with water containing acetic acid, and substitutes, at the end of the process, amyl alcohol for the ether used by Procter. The lobeline of Lewis is of the consistence of honey. Dragendorff and Rosen obtain two active compounds, lobeline and a crystalline substance soluble in chloroform, but difficultly soluble in water. J. U. and C. G. Lloyd also find associated with lobeline—which, however, they describe as an amorphous solid—a second compound *inflatin*, which is crystalline. Taking care to avoid heat, and the contact of free alkaloid with alkalis, these observers follow a process similar to that of

Procter. Ether and ammonia are used to separate the alkaloid from its combination, instead of ether and magnesia. The crude product is purified by successive conversion into a salt in aqueous solution, and treatment with ether and ammonia. Finally, the ether is acidified and evaporated, leaving a residue partly amorphous and partly crystalline. From this residue carbon disulphide separates the crystalline portion, inflatin, leaving amorphous lobeline acetate undissolved. The latter, on standing, loses a little adhering volatile oil, and is purified by the method already described (*cf.* Monatsh. 11, 131).

Lobeline, according to J. U. and C. G. Lloyd, is an amorphous powder or glassy residue, without colour or odour, and extremely active, a very small quantity of its solution applied to the tongue causing immediate vomiting. It is soluble in alcohol, chloroform, ether, benzene, carbon disulphide, and slightly soluble in water. In a pure state it is very stable. Oxidised by permanganate it yields benzoic acid (Paschkis and Smita, Monatsh. 11, 131). Salts of lobeline are soluble in water or alcohol, but, excepting the acetate, not in carbon disulphide. The aqueous solution is precipitated by alkalis and alkaloidal reagents. According to the experiments of Dresser, the only active constituent in lobelia is lobeline. Inflatin, which may also be prepared direct from the herb or seeds, is odourless and tasteless. It possesses neither acid nor basic properties. It melts at 107°, is insoluble in water, but soluble in carbon disulphide, benzene, chloroform, ether, or alcohol.

Lobeline occurs in the plant, according to most observers, in combination with *lobelic acid*, a compound first obtained by Procter. It is precipitated from an aqueous decoction of lobelia by copper sulphate, and separated from its copper compound by treatment with sulphuretted hydrogen and extraction with ether. When purified, it consists, according to Lewis, of small acicular crystals, non-volatile, and soluble in water, alcohol, or ether. The substance described by Enders (Flück. a. Hanb. 400), which appeared to be a glucoside, 'lobelacrin,' Lewis regards as lobeline lobelate. J. U. and C. G. Lloyd, however, consider it a mixture of several of the plant's constituents. The 'lobeliin' of Reinsch is also an indefinite compound.

Lobelia contains traces of a *concrete volatile oil*, the 'lobelianin' of Pereira. It is crystalline, and melts at 71° (Procter, Reinsch, Lewis, Lloyd). Procter found in the seed 30 p.c. of a drying *fixed oil*, and this has to be removed, usually by means of a solvent, before it can be used for the preparation of the alkaloid.

LOBELIANIN, LOBELIC ACID, LOBELIIN, LOBELINE *v.* Lobelia.

LOGANETIN, LOGANIN *v.* Nux vomica.

LOGWOOD. Logwood or Campeachy wood is one of the most important of all dyestuffs, and at the present time is very largely employed. Although for a long time it has successfully competed with the artificial colouring matters, its supremacy as a cotton dye has latterly been affected to a considerable extent by the introduction of the sulphide blacks.

Logwood appears to have been first imported into Europe by the Spaniards shortly after the discovery of America, and has been cultivated in Jamaica from the year 1715. In the time of Elizabeth, its employment as a dye was prohibited by Act of Parliament, and large quantities of the wood were burned, because it was said to produce fugitive colours.

It is derived from the *Hæmatoxylon campechianum* (Linn.), a tree which belongs to the family *Cæsalpiniacae*, and is a native of the warmer part of South America and some of the West Indian Islands. It also grows in the island of Mauritius, and trials indicate that this wood is of good quality (private communication).

Logwood usually comes into the market in large blocks weighing about 400 lbs.; these externally are of a deep brown colour, but internally have a much lighter tint. The best qualities come from Jamaica, Honduras, and St. Domingo, for the true Campeachy wood, at one time esteemed to be the best, is now practically exhausted.

The colouring principle of logwood, *hæmatoxylin*, was first isolated in a crystalline condition by Chevreul (Ann. Chim. Phys. [ii.] 82, 53, 126) who obtained it by extracting the wood with ether, evaporating the extract, and digesting the residue with alcohol. After distilling off the alcohol the residue was allowed to stand in contact with water, when the hæmatoxylin separated in crystals. It may also be prepared by similarly treating commercial logwood-extract which has been incorporated with a large quantity of sand (O. L. Erdmann, Annalen, 44, 292; J. pr. Chem. 26, 193; 36, 205; 75, 318). For this purpose ether containing water is preferable (Hesse, Annalen, 109, 332). It is, however, more easily obtained from the dark-coloured crusts which slowly separate when the concentrated logwood liquor stands for some time in a cool place. The crude mass is ground to a fine powder, extracted repeatedly with ether, the ethereal solution evaporated, and the residue left in contact with water, when dark-coloured crystals separate, which by recrystallisation from water containing a small quantity of sodium bisulphite, may be obtained colourless (W. H. Perkin and Yates, Chem. Soc. Trans. 1902, 81, 236).

Pure hæmatoxylin crystallises in prisms with $3H_2O$, and is sparingly soluble in cold, readily so in hot water. Its aqueous solution is coloured purple with alkalis, and this on exposure to air eventually assumes a brown tint. Hæmatoxylin is dextro-rotatory, a 1 p.c. aqueous solution having a rotation of 1·85 in a 200 mm. tube. It readily reduces salts of silver and gold, gives with alum a rose-red colouration, with iron alum a violet-black precipitate, and with neutral and basic lead acetates at first a colourless and then a blue deposit which darkens by air oxidation.

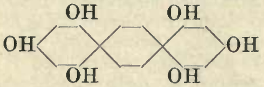
O. L. Erdmann (*l.c.*) was the first to submit hæmatoxylin to analysis, and proposed the formula $C_{40}H_{17}O_5$, which he subsequently altered to $C_{16}H_{14}O_6$. This latter formula was confirmed by Hesse (*l.c.*), and at the present day is accepted as correct.

By fusion with alkali, hæmatoxylin yields pyrogallol (Reim, Ber. 1871, 4, 331), and according to E. Erdmann and Schultz (Annalen, 216, 234) also formic acid. R. Meyer (Ber. 1879, 12, 1392) submitted hæmatoxylin to destructive distillation and considered that in this manner not only pyrogallol but also resorcinol is produced. According, however, to W. H. Perkin and Gilbody (Chem. Soc. Trans. 1902, 81, 245), no resorcinol is thus obtained.

Reim acetylated hæmatoxylin with acetyl chloride and prepared a substance which appeared to be the hexa-acetyl derivative

$$C_{16}H_8O_6(C_2H_3O)_6,$$

and as a result suggested the following constitution for this colouring principle:



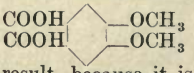
E. Erdmann and Schultz (Annalen, 1883, 216, 234) re-examined Reim's compound and showed that this was in reality a *pentaacetylhæmatoxylin* $C_{16}H_9O_6(C_2H_3O)_5$, m.p. 165°–166°, and that hæmatoxylin therefore contains five hydroxyl groups. This result was confirmed by the work of Herzig (Monatsh. 1894, 15, 143) who, by the action of sodium methoxide, and methyl iodide on hæmatoxylin, obtained the *tetramethyl derivative* $C_{16}H_{10}O_2(OMe)_4$, m.p. 139°–140°, a substance which still contains a hydroxyl group since on treatment with acetic anhydride it yields acetyltetramethylhæmatoxylin $C_{16}H_9O_2(OMe)_4(C_2H_3O)$, m.p. 178°–180°. It was thus shown that hæmatoxylin like brazilin, contains an alcoholic hydroxyl group which is not methylated by means of methyl iodide and sodium methoxide under the usual conditions, and indeed it has long been considered probable that these two colouring matters are closely allied in constitution (Liebermann, Ber. 1876, 9, 1883; compare also Hummel and A. G. Perkin, Chem. Soc. Trans. 1882, 41, 373).

The following derivatives of hæmatoxylin have also been prepared: *Pentamethylhæmatoxylin* $C_{16}H_9O(OCH_3)_5$ plates, m.p. 144°–147° (Herzig); *dibromhæmatoxylin* $C_{16}H_{12}Br_2O_6$ (Dralle, Ber. 1884, 17, 373); *penta-acetylbromhæmatoxylin* $C_{16}H_8BrO_6(C_2H_3O)_5$, needles, m.p. 110° (Buchka, *ibid.* 1884, 17, 685); *penta-acetyltetrabromhæmatoxylin* $C_{16}H_5Br_4O_6(C_2H_3O)_5$ (Dralle); and *hæmatoxylinphthalein* $C_{40}H_{30}O_{14}$ (Letts, Ber. 1879, 12, 1652).

Our main knowledge of the chemistry of hæmatoxylin and the fact that it is in reality hydroxybrazilin is due to the elaborate researches of W. H. Perkin and his pupils, and their results have arisen mainly from a study of the oxidation products of hæmatoxylin tetramethylether.

According to Perkin (Chem. Soc. Trans. 1902, 81, 1059), tetramethylhæmatoxylin is most readily prepared by treating the solution of hæmatoxylin in alcoholic potash with methyl sulphate, a method which had previously been found serviceable by Kostanecki and Lampe (Ber. 1902, 35, 1669) for the production of trimethylbrazilin from brazilin.

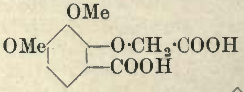
When tetramethylhæmatoxylin is oxidised with potassium permanganate (Perkin and Yates, *l.c.*), it yields *m-hemipinic acid*



an important result, because it is thus certain that hæmatoxylin like brazilin (Gilbody, Perkin, and Yates, Chem. Soc. Trans. 1901, 79, 1400) contains a catechol nucleus. Consequently, whereas in the molecule of brazilin a resorcinol and a catechol nucleus occur, in hæmatoxylin pyrogallol and catechol groups are present.

In addition to *m*-hemipinic acid, large quantities of a second acid $C_{11}H_{12}O_7$, m.p. 215°, are produced. This is *2-carboxy-5:6-dimethoxyphenoxyacetic acid* (I.)

I.



II.

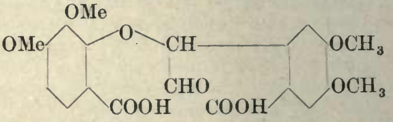
analogous to the *2-carboxy-5-methoxyphenoxyacetic acid* (II.), which was obtained in a similar manner from brazilin trimethyl ether (*see* Brazilin).

Finally, from the product of the oxidation a third compound *hæmatoxylinic acid* $C_{20}H_{20}O_{10}$, m.p. 180°, was isolated. This on reduction with sodium amalgam is converted quantitatively into an acid $C_{20}H_{20}O_9$, which is a monobasic lactonic acid, and it is therefore evident that the latter is produced in two stages, thus:

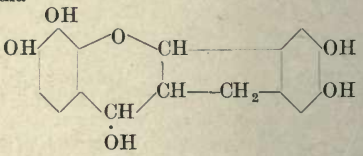
$$\underset{\text{Hæmatoxylinic acid.}}{C_{20}H_{20}O_{10}}+2H=\underset{\text{Dihydrohæmatoxylinic acid.}}{C_{20}H_{22}O_{10}}$$

$$C_{20}H_{22}O_{10}-H_2O=\underset{\text{Lactone of dihydro-hæmatoxylinic acid.}}{C_{20}H_{20}O_9}$$

The constitution at first assigned to hæmatoxylinic acid by these authors was as follows:

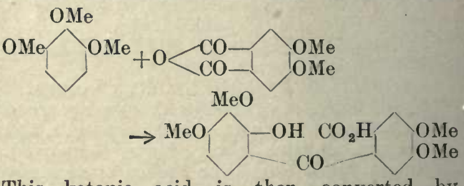


but this, and the corresponding hæmatoxylin formula



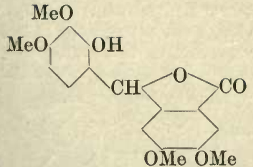
were subsequently modified, as the result of the synthesis of the lactone of the dihydro-hæmatoxylinic acid referred to above (Perkin and Robinson, Chem. Soc. Trans. 1908, 93, 492).

When aluminium chloride reacts with a mixture of pyrogallol trimethylether and *m*-hemipinic anhydride, *2′-hydroxy-3′:4′:4:5-tetramethoxybenzoylbenzoic acid* is produced:

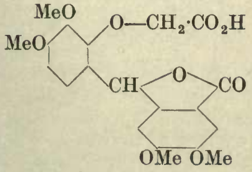


This ketonic acid is then converted by reduction with sodium amalgam into *2-m-meconyl-5:6-methoxyphenol* (1), which by treatment with chloracetic acid and sodium hydroxide gives the lactone of dihydrohæmatoxylinic acid (2).

1.

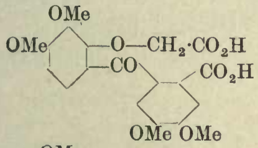


2.

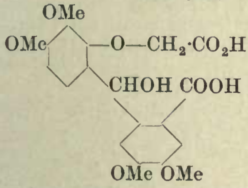


Consequently, the formulæ of *hæmatoxylinic acid* (3) and of *dihydrohæmatoxylinic acid* (4) are thus represented:

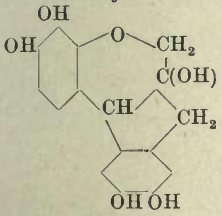
3.



4.

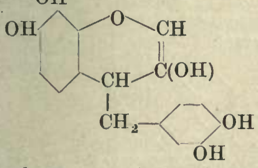


From these facts the constitution of hæmatoxylin itself naturally follows.

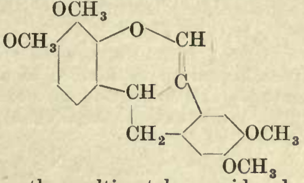


and this is identical with that which Pfeiffer (Chem. Zeit. 1904, 3, 380) from theoretical considerations suggested as possible.

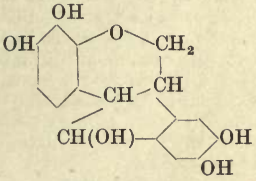
Other constitutional formulæ have been assigned to hæmatoxylin, of which that of Bollina, Kostanecki, and Tambor (Ber. 1902, 35, 1678), analogous to the brazilin formula of Feuerstein and Kostanecki (Ber. 1899, 32, 1024) is of interest:



It was, however, evident that such an expression does not account for the production of *m*-hemipinic acid or 2-carboxy-5:6-dimethoxyphenoxyacetic acid by the oxidation of hæmatoxylin tetramethyl ether. On the other hand, Kostanecki and Lampe (Ber. 1902, 35, 1667) at first suggested that previous to the degradation of the methyl ether by oxidation with permanganate an internal linkage is produced, with production of the following compound:



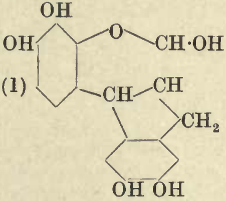
These authors ultimately considered, as W. H. Perkin contended, that a *m*-hemipinic residue is contained in hæmatoxylin tetramethyl ether, and as a result propose the following modification of their formula for this colouring matter:



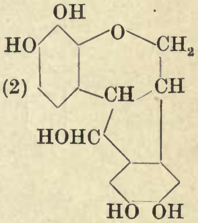
Hæmatoxylin.

Again, Herzig and Pollak (Monatsh. 1902, 23, 165), in a criticism of the earlier formula of Gilbody, Perkin, and Yates (*l.c.*), suggested two possible constitutions for brazilin, the second of which is identical with that of Kostanecki and Lampe (see above) and which applied to hæmatoxylin, are thus represented:

(1)



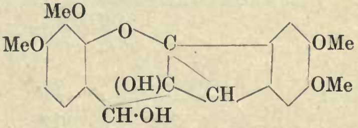
(2)



These formulæ of Kostanecki and Lampe and Herzig and Pollak cannot, however, be correct, as they do not account for the formation of hæmatoxylinic acid by the oxidation of tetramethylhæmatoxylin with permanganate (Gilbody, Perkin, and Yates, *l.c.*).

Herzig (Monatsh. 16, 906) submitted acetyl tetramethylhæmatoxylin to oxidation with chromic acid and obtained a new product, which on hydrolysis gave *tetramethyldehydrohæmatoxylin* $C_{16}H_5\cdot O(OMe)_4OH$. This latter, on acetylation, yielded *acetyltetramethyldehydrohæmatoxylin* $C_{16}H_5O(OMe)_4(OC_2H_3O)$ and by methylation *pentamethyldehydrohæmatoxylin.*

W. H. Perkin (Chem. Soc. Trans. 1902, 81, 1057) oxidised tetramethylhæmatoxylin with chromic acid, and obtained a substance *tetramethylhæmatoxylone* $C_{16}H_6O(OMe)_4(OH)_2$, corresponding in all its reactions with trimethylbrazilone. For this, at that time, the formula

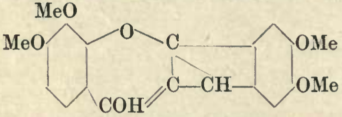


was proposed. In addition to this compound, 2-*carboxy*-5-6-*dimethoxyphenoxyacetic acid* and *m*-hemipinic acid were also produced during the oxidation. When digested with acetic anhydride, tetramethylhæmatoxylone gives *acetylanhydrotetramethylhæmatoxylone*

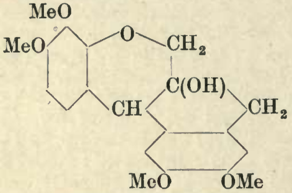
$C_{16}H_5O(OMe)_4OC_2H_3O$,

evidently identical with Herzig's acetyltetramethyldehydrohæmatoxylin referred to above.

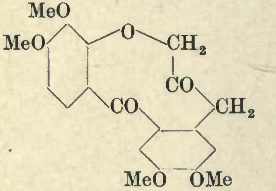
By hydrolysis, this compound gave anhydrotetramethylhæmatoxylone $C_{16}H_5O(OMe)_4OH$



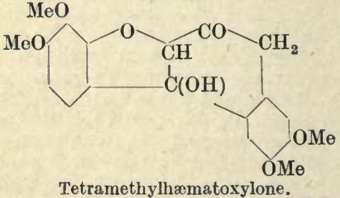
In a later paper, Perkin and Robinson (Chem. Soc. Trans. 1908, 498) discarded these expressions and assigned to tetramethylhæmatoxylone the constitution given below. These authors consider that during the oxidation of tetramethylhæmatoxylin with chromic acid, a destruction of the central linkage occurs, and the unstable diketone which is thus formed undergoes aldol condensation with the production of tetramethylhæmatoxylone.



Tetramethylhæmatoxylin.



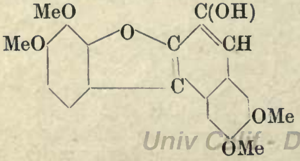
Diketone.



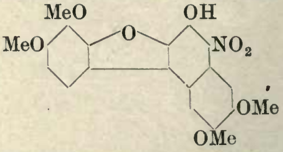
Tetramethylhæmatoxylone.

This formula indicates that tetramethylhæmatoxylone is a derivative both of coumaran and tetrahydronaphthalene.

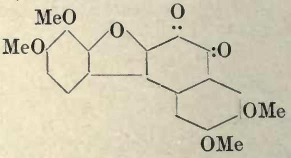
The formation of anhydrohæmatoxylone by means of acetic anhydride (*l.c.*) is due to the elimination of water from the aldol grouping in tetramethylhæmatoxylone, and the constitution thus given to this substance represents it as a derivative of β-naphthol, with which indeed it has many properties in common.



When acetylanhydrotetramethylhæmatoxylone is treated with nitric acid it readily reacts with the formation of the mononitro compound (Perkin and Robinson, *ibid.* 1909, 384).



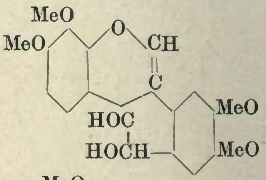
and from this substance by reduction with zinc dust and hydrochloric acid the corresponding amino derivative is produced. This, when oxidised by ferric chloride, yields *tetramethoxy-a-brazanquinone* (compare Kostanecki and Rost, *l.c.*):



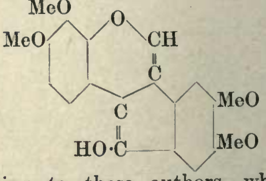
That this substance is an ortho-quinone is shown by its behaviour with *o*-tolylenediamine with which it condenses with formation of a characteristic quinoxaline. On reduction, the quinone is converted into the corresponding *dihydroxy* derivative.

Kostanecki and Rost (Ber. 1903, 36, 2202), on the other hand, proposed for the (1) tetramethylhæmatoxylone, and (2) anhydrotetramethylhæmatoxylone of Perkin the following expressions which harmonised with their suggested constitution for hæmatoxylin (*l.c.*):

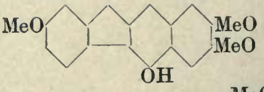
(1)



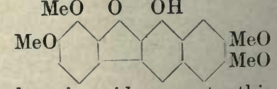
(2)



According to these authors, when tetramethylhæmatoxylone is treated with alcoholic sulphuric acid, a new compound (1′ or 4′) *hydroxy*-3 : 4 : 6′ : 7′-*tetramethoxybrazan* is formed, which is represented by one or other of the annexed formulæ:

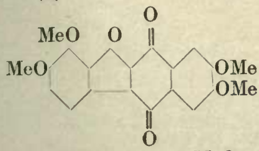


or

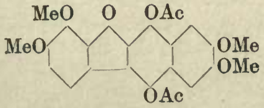


Oxidation with chromic acid converts this substance into 3 : 4 : 6′ : 7′-*tetramethoxybrazanquinone* (1), which by reduction and acetylation yields 3 : 4 : 6′ : 7′-*tetramethoxy* (1′ : 4′) *diacetoxybrazan* (2):

(1)

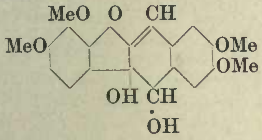


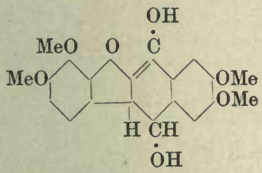
(2)



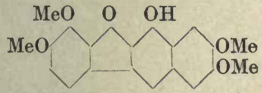
When distilled with zinc dust, both hydroxytetramethoxybrazan and tetramethoxybrazanquinone yield *naphthalene*.

Herzig and Pollak (Ber. 1904, 37, 631) also found that cold concentrated sulphuric acid converts tetramethylhæmatoxylone into an isomeric compound *ψ-tetramethylhæmatoxylone*, and suggested the following formulæ as applicable to this substance.

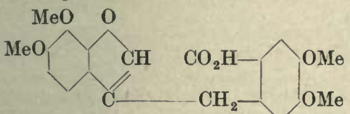




This, by loss of water, gives *β-anhydrotetramethylhæmatoxylone*, which is identical with Kostanecki and Rosts' hydroxytetramethoxybrazan:

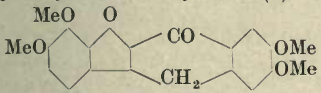


Perkin and Robinson (*l.c.*), as the result of a study of the work of Herzig and Pollak, have, however, shown that ψ-tetramethylhæmatoxyone is in reality a monobasic acid, and possesses the following constitution:

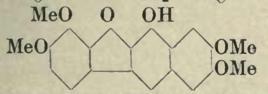


This, by elimination of water, passes into the compound (1) and by intramolecular change gives hydroxytetramethoxybrazan (2):

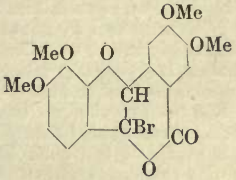
(1)



(2)



When ψ-tetramethylhæmatoxylone is treated with potassium hypobromite, a colourless precipitate soon separates. This crystallises in almost colourless prisms or needles, and possess the constitution of a *tetramethoxycumarono*-iso-*coumarinhydrobromide*:



For the theoretical considerations involved in the production of this interesting substance the original paper should be consulted.

Hæmatein. When oxidised under suitable conditions, hæmatoxylin readily passes into the colouring matter hæmatein, according to the equation $C_{16}H_{14}O_6 + O = C_{16}H_{12}O_6 + H_2O$.

Hæmatein was first produced by O. L. Erdmann (*l.c.*) by passing air through an ammoniacal solution of hæmatoxylin, and subsequently acidifying with acetic acid.

Erdmann and Schultz (*l.c.*), who adopted a somewhat similar procedure, succeeded in isolating hæmatein in leaflets which possessed a metallic lustre. Reim, on the other hand (Ber. 1871, 4, 331), treated an ethereal solution of hæmatoxylin with a little concentrated nitric acid.

By extracting 'aged' logwood with ether, Halberstadt and Reis (Ber. 1881, 14, 611) obtained 1 p.c. of a very pure crystalline hæmatein.

Hummel and Perkin (Chem. Soc. Trans. 1882, 41, 373) exposed an ammoniacal solution of logwood extract to the air for 2 or 3 days. The precipitated ammonia compound of hæmatein was collected, dissolved in water, dilute acetic acid added, and the mixture digested on the water-bath to dissolve as much as possible of the suspended amorphous hæmatein. The clear liquid after partial evaporation deposited crystals of the colouring matter, possessing a yellowish-green iridescence, and having the composition $C_{16}H_{12}O_6$.

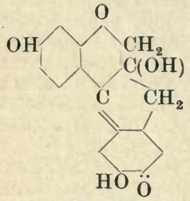
According to Mayer (Chem. Zentr. 1904, 1, 228), hæmatein may also be prepared by oxidising hæmatoxylin in aqueous solution with sodium iodate.

Engels, Perkin, and Robinson (Chem. Soc. Trans. 1908, 93, 1140) passed air for 6 hours through a solution of 15 grams of hæmatoxylin, dissolved in a solution of 15 c.c. of concentrated ammonia in 150 c.c. of water. The product of the oxidation was added in a thin stream to dilute acetic acid (250 c.c. of 10 p.c.) heated on the water-bath, when hæmatein separated in crystals.

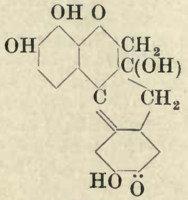
Hæmatein is very sparingly soluble in water and the usual solvents. Alkalis dissolve it readily; ammonia dissolves it with a rich brown-violet colour, whilst its strong alkaline solution has a rich purplish-blue colour. On exposure to air the colour of these alkaline solutions gradually becomes red and finally brown, the colouring matter being destroyed. By addition of potassium acetate to the boiling alcoholic solution of hæmatein, the monopotassium salt $C_{16}H_{11}O_6K$ is deposited (A. G. Perkin, Chem. Soc. Trans. 1899, 75, 443).

Sulphurous acid or sodium bisulphite solution converts hæmatein into a colourless addition product, readily soluble in water but no reduction hereby appears to occur, as on boiling the solution or by addition of acid, hæmatein is precipitated. With zinc and hydrochloric acid or with stannous chloride and caustic soda, a solution of hæmatein is decolourised, but on standing the liquid regains its former tint.

It has long been considered that hæmatein is hydroxybrazilein and this has now been clearly proved by a study of the behaviour of these compounds with reagents under similar circumstances. This relationship is at once evident from a comparison of the following formulæ (Engels, Perkin, and Robinson):



Brazilein.

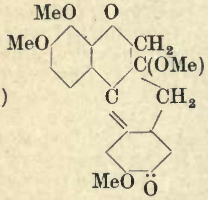


Hæmatein.

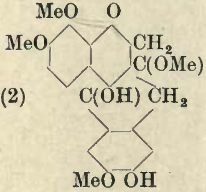
When hæmatein is methylated by means of alkali and methyl sulphate, the product consists essentially of tetramethylhæmatein and pentamethyldihydrohæmateinol.

Tetramethylhæmatein (1) crystallises in amber prisms, and when digested with dilute potassium hydroxide is converted by the addition of water into *tetramethyldihydrohæmateinol* (2) yellow prisms:

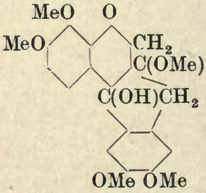
(1)



(2)



Pentamethyldihydrohæmateinol



the second product of the reaction crystallises in yellow plates, and is also produced when tetramethyldihydrohæmateinol is methylated with methyl sulphate and alkali.

In the year 1882, Hummel and A. G. Perkin (Chem. Soc. Trans. 41, 367) observed that hæmatein and also brazilein are converted by the action of mineral acids into orange or red salts, from which the original colouring matters could not be regenerated.

When hæmatein is dissolved in cold sulphuric acid, a reddish-brown solution is produced from which, by cautious addition of acetic acid, minute orange coloured prisms of *acid isohæmateinsulphate* $C_{16}H_{12}O_5SO_4$ are deposited. The reaction may be represented thus:

$$C_{16}H_{12}O_6+H_2SO_4=C_{16}H_{12}O_5SO_4+H_2O.$$

This substance, when left in contact with 80 p.c. alcohol, is gradually transformed, with loss of sulphuric acid, into a new compound crystallising in orange-red plates possessing a strong metallic lustre and to which the formula

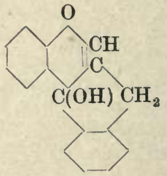
$$(C_{16}H_{12}O_6)_2C_{16}H_{12}O_5SO_4$$

was assigned. On the other hand, hydrochloric and hydrobromic acids in sealed tubes at 100° convert hæmatein respectively, into *isohæmatein chlorhydrin* $C_{16}H_{11}O_5{\cdot}Cl$ and *isohæmatein bromhydrin* $C_{16}H_{11}O_5Br$, which crystallise in orange red needles.

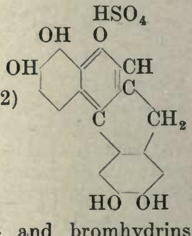
If to an aqueous solution of *iso*hæmatein chlorhydrin or bromhydrin silver hydroxide is added to remove the halogen, a solution of *isohæmatein* is obtained, which on evaporation leaves this substance as an amorphous mass possessing a green metallic lustre. *Iso*hæmatein and its salts dissolve in solutions of the alkaline hydroxides with a red-violet colour which is easily distinguished from the corresponding blue-violet solution of hæmatein; moreover the dyeing properties of these compounds and hæmatein differ considerably. Thus the *iso*hæmatein derivatives give, on cotton mordanted with alumina, a dull red inclining to chocolate, with strong iron a black, and with mixed alumina and iron a full chocolate. Again the tinctorial power of these compounds is much greater than that of the original hæmatein, and the colours are much faster.

As the result of the investigation of a large number of pyranol salts (Perkin, Robinson, and Turner, Chem. Soc. Trans. 1908, 93, 1085), it seems certain that these hæmatein salts are derivatives of 4 : 3-*indenobenzopyranol* (1), and that *iso*hæmatein sulphate possesses the constitution (2):

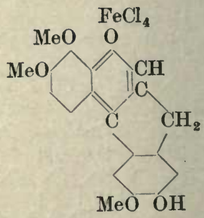
(1)



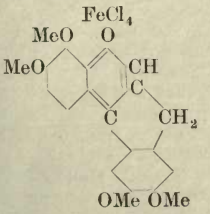
(2)



*Iso*hæmatein chlor- and bromhydrins are formulated similarly. Thus from tetramethylhæmatein, Engels, Perkin, and Robinson (*l.c.*) have prepared *5′-hydroxy*-7 : 8 : *4′-trimethoxy*-4 : 3-*indenobenzopyranol* (1 : 4) *anhydroferrichloride*:



which crystallises from acetic acid in well-defined elongated prisms. Pentamethyldihydrohæmateinol, on the other hand, gives 7 : 8 : 4′ : 5′-*tetramethoxy*-4 : 3-*indenobenzopyranol* (1 : 4) *anhydroferrichloride.*



Before being used by the dyer, logwood is reduced to chips or powder, and these products are known as ‘ chipped,’ ‘ rasped,’ or ‘ ground ’ wood. When first cut down the wood has a pale yellow colour and contains only hæmatoxylin, but during transport or storage this colour gradually deepens owing to a surface oxidation of the hæmatoxylin into hæmatein. Formerly, and even to some extent at the present time, it was the practice to submit the chipped or rasped logwood to what is known as the ‘ ageing ’ process, in order to facilitate the hæmatein formation. This consists in wetting the wood thoroughly with water, then forming it into heaps, 4 to 5 feet high, in large airy chambers. Very soon the mass begins to ferment, which is indicated by a rise of its internal temperature, the wood gradually darkens in colour, and during the operation the mixture is repeatedly turned over and remixed in order to avoid too vigorous a fermentation and to obtain an even result. Constant attention is necessary during this ‘ ageing ’ process, for if the reaction is allowed to proceed too far, a portion of the colouring matter is destroyed and ‘ burnt ’ or ‘ over-aged ’ wood is produced. In order to expedite this operation, the use of various oxidising agents has been suggested ; a sprinkling of the wood with ammonia has been said to exercise a beneficial result; but, on the other hand, such processes are best avoided, for it is difficult under these circumstances to control the reaction and prevent an over-oxidation.

Latterly this ageing operation has been less in vogue, not only on account of the increased employment of logwood extract, but because it is now recognised that where the mordant employed for dyeing purposes can exert an oxidising action, this preliminary treatment is unnecessary. Formerly, logwood blacks on wool were produced by means of an iron mordant, but this is now largely replaced by the use of potassium dichromate, which provides a mordant possessing the power of converting at least a portion of the hæmatoxylin into hæmatein.

Logwood extract is now prepared in enormous quantity not only in this country but also in Jamaica in the neighbourhood of the logwood plantations, and in the latter case an economy is naturally effected in the carriage of some varieties of the extract rather than that of the more bulky wood to this and other countries. Logwood extract is almost invariably prepared from the ‘ unaged ’ wood, because whereas hæmatoxylin is readily soluble in water, hæmatein is not. On this account, an aged wood is difficult to exhaust. For the manufacture on the large scale, two processes are in vogue known respectively as the ‘ American ’ and ‘ French ’ methods. These differ merely in the manner in which the wood is lixiviated, for this is carried out by the French process in open pans with warm or boiling water, whereas in the American process, closed vessels are used in which steam at from 15 to 30 lbs. pressure is employed. In both cases the liquid is afterwards concentrated, preferably in vacuum pans, and the product is sold at about 15°Tw. as *logwood liquor*, at 51°Tw. as *logwood extract*, or in the solid condition as *solid logwood extract.* As a rule, it is considered that the extract made at the lower temperature gives the brighter shade.

Certain processes are in use for the ‘ ageing ’ of ‘ logwood liquor,’ that is the conversion of the dissolved hæmatoxylin into hæmatein. For this purpose the following methods have been suggested : (*a*) treat the logwood liquor with bleaching powder solution ; (*b*) half neutralise with alkali or ammonia and blow air or oxygen through the liquid ; (*c*) employ air or oxygen for this purpose without the addition of alkali ; (*d*) boil with manganese dioxide (Weldon mud) and filter. Interesting also in this respect is the patented process of Haak (Chem. Zentr. 1905, ii. 867), who treats the extract with sodium nitrite.

A very important product somewhat recently introduced is the so-called crystalline hæmatein paste, which is a treacly extract containing in suspension minute crystals of hæmatein. The details of the preparation of this material, which appears to have been first introduced from Jamaica, although now also manufactured in this country, are kept secret. For experimental purposes, this paste may be employed as the source of a comparatively pure hæmatein, which can be isolated from it by dilution with glacial acetic acid and subsequent filtration (private communication).

Logwood and its extracts are enormously employed for the dyeing of blacks on silk, wool, and cotton, chiefly in conjunction with iron and chromium mordants. It also enters into the composition of numerous compound shades.

Bastard logwood. During the past few years, the growers of logwood in Jamaica have been greatly disturbed by the apparent increase on their properties of an unmerchantable variety of the tree known as ‘ bastard ’ logwood. Bastard logwood is practically devoid of hæmatoxylin, but contains instead a yellowish-green pigment which, when admixed with the commercial extract, reduces its characteristic tinctorial properties. Chips of the bastard logwood present a yellow, pale pink, white, or even chocolate coloured surface instead of the dark red or purple bronze tinted colour of the best Jamaican or Mexican logwoods of commerce.

So similar are the trees of the ‘ true ’ and the ‘ bastard ’ logwood, that it is frequently impossible to decide whether a tree is really a ‘ mulatto ’ or not. When first cut a bastard tree is frequently dark enough internally to indicate that it is a good red-wood tree, but instead of darkening with age, as all the best wood does, it remains the same colour or becomes lighter rather than darker.

Chemical tests readily distinguish between the red and bastard wood, for whereas alkaline solutions turn an extract of true logwood a purple colour, with a bastard extract the shade of yellow is merely deepened. Again mineral acids turn aqueous extracts of true logwood orange to bright red, whereas a bastard extract is not thereby affected.

Dyeing trials, employing stripe mordanted calico, are also serviceable because, in the case of the bastard variety, the aluminium mordant remains practically undyed. A. G. P.

LOKAO, a green dyestuff of Chinese origin, is, or rather was, since it has been supplanted by artificial colouring matters, met with in commerce in the form of thin laminæ of a dark bluish or bluish-green colour. Though formerly employed to some extent in Europe, it does not appear, owing to its extremely expensive nature, to have been extensively used. According to Crookes (Dyeing and Calico Printing, 429), lokao contains from 21·5 to 33 p.c. of ash, 9·3 p.c. of water, and 61·7 p.c. of colouring matter. It is insoluble in water, and the usual solvents, but dissolves in sulphuric acid with a red-brown colouration, and also in alkalis, but the solution thus obtained gradually acquires a brown tint.

According to Helot (Crookes, *l.c.*) and others, lokao requires for its preparation two distinct plants, the *Rhamnus dahurica* (Pall.) (hong. pi. lo. chou) and the *R. tinctoria* (Walldst. & Kit.) (pé. pi. lo. chou), the first of which is said to yield a deep and fast colour, whilst from the latter a weak but brilliant colour can be obtained. According to Rupe (Die Chemie der natürlichen Farbstoffe, 1900), the plant bark is extracted with hot water, the extract allowed to stand overnight, filtered, and then treated with potassium carbonate or milk of lime. Cotton yarn is immersed in this mixture, subsequently withdrawn and spread out in meadows overnight and a portion of the daytime, and the operation repeated ten or twenty times. The colouring matter is removed by rubbing the yarn with the hands in cold water, and the precipitate, which settles to the bottom of the receptacle, is washed by decantation, spread on paper and dried in the shade (*cp.* also Crookes, *l.c.*).

According to Cloez and Guignet (J. 1872, 1068) lokao or Chinese green is, in reality, a lake, and by treatment with ammonium carbonate is converted into the ammonium salt of the colouring matter *lokain* $NH_4{\cdot}C_{28}H_{33}O_{17}$. By the action of dilute sulphuric acid lokain is hydrolysed with formation of *lokaetin* $C_{18}H_{16}O_{10}$. glucose, and a soluble compound which is precipitated by basic lead acetate.

Kayser (Ber. 1885, 18, 3417) extracted finely powdered Chinese green with concentrated ammonium carbonate solution, added alcohol to the clear liquid, and thus obtained a precipitate of the crude ammonium salt of the colouring matter which he termed *lokaonic acid.* This was collected, extracted with ammonium carbonate, the solution precipitated by alcohol, and the operation repeated several times, the product being finally dissolved in water and the liquid evaporated to crystallisation with the addition of a little ammonia. Thus prepared the *diammonium* salt of lokaonic acid $C_{42}H_{46}O_{27}(NH_4)_2$ consists of small crystals possessing a bronzy lustre, which at 40°C. commences to lose ammonia, and at 100° gives the mono-ammonium salt $C_{42}H_{47}O_{27}(NH_4)$. The *potassium* salt

$$C_{42}H_{46}O_{27}K_2$$

separates in the form of a blue amorphous powder, when a concentrated aqueous solution of the diammonium salt is treated with alcoholic potash; whereas the *barium* salt $C_{42}H_{46}O_{27}Ba$, obtained by means of barium chloride, has a similar appearance, the lead salt $C_{42}H_{46}O_{27}Pb$ is a dark brown powder.

Lokaonic acid $C_{42}H_{48}O_{27}$, prepared by the decomposition of the diammonium salt with oxalic acid, consists of a bluish-black powder, which, when rubbed, develops a metallic lustre. It is insoluble in the usual solvents, but dissolves in solution of the alkaline hydroxides and ammonia with a pure blue tint. Treatment with sulphuretted hydrogen changes this to a blood-red colour, which passes to green on exposing the liquid to air. Digested with dilute sulphuric acid on the water-bath lokaonic acid is hydrolysed with formation of *lokanic acid* and a sugar *lokaose.*

Lokanic acid $C_{36}H_{36}O_{21}$ is a violet-black crystalline powder insoluble in water, alcohol, ether, and chloroform, but soluble in alkaline solutions with a violet-blue colouration.

The *ammonium* salt $C_{36}H_{35}O_{21}NH_4$, the *barium* salt $C_{36}H_{34}O_{21}Ba$, and the *lead* salt $C_{36}H_{34}O_{21}Pb$, are described by Kayser.

Hot 50 p.c. potassium hydroxide solution converts lokanic acid into *phloroglucinol* and *delokanic acid* $C_{15}H_9O_6$, which consists of a brown powder dissolved by dilute alkalis, whereas nitric acid gives with lokanic acid *nitrophloroglucinol.*

Lokaose $C_6H_{12}O_6$, obtained by the hydrolysis of lokaonic acid, crystallises in colourless needles, and is optically inactive.

According to Persoz, cotton can be dyed in a weak alkaline solution of lokao, and it behaves also as a vat dyestuff, for which purpose it may be reduced by faintly acid or alkaline stannous chloride. The colour thus obtained is blue, and can be converted into green by the subsequent employment of a yellow dyestuff.

In order to dye cotton a green with lokao, Persoz recommends a bath prepared by adding the pigment to a solution of soap, whereas for silk Michel obtained excellent results by employing lokao and alum solution in the presence of lime salts. For Chinese and other methods of employing this dyestuff, *see* Crookes (*l.c.*), and Rupe (*l.c.*). A. G. P.

LÖLLINGITE. A native ferric arsenide.

LONCHOCARPUS (*Lonchocarpus cyanescens*). The *Lonchocarpus cyanescens* (Benth.), a leguminous plant of the sub-order *Paplionaceæ*, is a woody climber from 10 to 14 feet long. The young leaves contain an indigo-yielding principle, and on this account the plant is employed by the tribes of Sierra Leone and the interior and those of Western Soudan as the source of a blue dye. In the former countries the young leaves are collected along with some more matured ones, roughly pounded and dried in the sun. In this state it is sent into the market as 'Gara,' and sold to the dyers. The natives of Western Soudan employ the young and tender buds, which are collected, pounded when quite raw, made into balls, and dried in the sun. For dyeing purposes the 'Gara' is covered with water, treated with potash and the bark of the *Morinda citrifolia* (Linn.), and left to ferment for some days. The cloth to be dyed is thrown into the vat, left there for some time, and dried in the sun. An examination of 'Gara' by Perkin indicated the presence of approximately 0·62 p.c. of indigotin (J. Soc. Chem. Ind. 1907, 389). Apparently also this plant is utilised in Northern Nigeria as a dyestuff in the form of a similar preparation to that described above, and for the manufacture of a crude indigo. A sample of this leaf product contained approximately 0·65 p.c. of indigotin, whereas in the indigo the presence of 21·47 p.c. of indigotin and 1·33 p.c. of indirubin was detected (Perkin, J. Soc. Chem. Ind. 1909, 353). The botanical examination of the former, and also of plant débris contained in the latter, by V. H. Blackman, indicated that they were derived from the *L. cyanescens*, or some closely related form. Rawson and Knecht (J. Soc. Dyers. 1888, 66) have described similar leaf and crude indigo products, which had been sent to this country by Sir. T. Goldie, Governor of the Royal Niger Co., and these respectively contained 0·51 p.c. of indigotin, and 39·12 p.c. of indigotin, together with 4·75 p.c. of indirubin. A more recent examination of the leaf fragments in Rawson and Knecht's samples has shown that these possessed the same structure as those of the *L. cyanescens* (Perkin, *l.c.*), and it thus appears evident that in Western Africa this plant is extensively employed for dyeing and the preparation of indigo. There is reason to presume that the indigo-yielding principle present in the young leaves of the *L. cyanescens* gradually disappears when these reach maturity, as samples of the latter examined in this country were devoid of indigo-producing property. The *L. cyanescens* is probably identical with the 'Taroom akkar' described by Bancroft (Philosophy of Permanent Colours 1813, i. 189 and 191). A. G. P.

LONDON WHITE. *Flakewhite* (*v.* PIGMENTS).

LORETIN. Trade name for *m*-iodohydroxyquinoline sulphonic acid $(C_9NH_4I(OH)HSO_3)$ used as a germicide in surgical dressings (*v.* SYNTHETIC DRUGS).

LOSOPHAN *v.* SYNTHETIC DRUGS.

LOTUS ARABICUS. The *Lotus arabicus* (Linn.) is a leguminous plant, indigenous to Egypt and Northern Africa, and in the young condition is extremely poisonous. The subject has been investigated by Dunstan and Henry (Phil. Trans. 1901, 194, 515).

Lotusin, the active principle, can be isolated by extracting the dried plant with methyl alcohol. The extract is evaporated, the residue treated with water to remove chlorophyll and resin, and from the aqueous solution tannin and other impurities are precipitated by means of lead acetate. The filtrate, on evaporation, leaves a syrupy residue, from which crystals of lotusin slowly separate. In the pure condition lotusin $C_{28}H_{31}O_{16}N$ forms yellow needles, and when hydrolysed by digestion with hydrochloric acid, or by means of an enzyme *lotase*, also found in the plant, yields dextrose, lotoflavin, and hydrocyanic acid, according to the following equation:

$$C_{28}H_{31}O_{16}N+2H_2O$$
$$=2C_6H_{12}O_6+C_{15}H_{10}O_6+HCN.$$

When warmed with alcoholic potash (20 per cent.) lotusin is gradually decomposed with production of ammonia and *lotusinic acid*:

$$C_{28}H_{31}O_{16}N+2H_2O=\underset{\text{Lotusinic acid.}}{C_{28}H_{32}O_{18}}+NH_3.$$

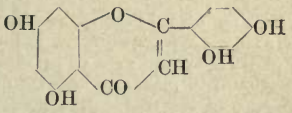
This compound is monobasic, gives yellow crystalline salts, and is hydrolysed by dilute hydrochloric acid with formation of *lotoflavin*, *dextrose* and *heptogluconic acid*:

$$C_{28}H_{32}O_{18}+2H_2O$$
$$=C_{15}H_{10}O_6+C_6H_{12}O_6+C_7H_{14}O_8.$$

Lotoflavin $C_{15}H_{10}O_6$ crystallises in yellow needles, soluble in alkaline solutions with a yellow colour. By fusion with alkali, *phloroglucinol* and *β-resorcylic acid* are produced.

With acetic anhydride lotoflavin gives a *tetraacetyl* compound $C_{15}H_6O_6(C_2H_3O)_4$, colourless needles, m.p. 176°–178°, and when methylated by means of methyl iodide the *trimethyl ether* $C_{15}H_7O_3(OCH_3)_3$ is obtained. This latter compound exists in two forms, viz. the α-form yellow rosettes, m.p. 125°, and the β-form glistening needles, m.p. 175°, which are mutually convertible. Both varieties give by means of acetic anhydride the same *monoacetyl lotoflavin trimethyl ether* $C_{15}H_6O_3(C_2H_3O)(OCH_3)_3$, yellow needles, m.p. 147°.

According to Dunstan and Henry, lotoflavin is probably a *tetrahydroxyflavone*, and possesses the formula:



The hydrolysis of the cyanogenetic glucoside lotusin, with formation of maltose, lotoflavin and hydrocyanic acid, may also be expressed as follows:

$$C_{28}H_{31}NO_{16}+H_2O$$
$$=C_{12}H_{22}O_{11}+C_{15}H_{10}O_6+HCN.$$

The following constitutions are respectively assigned to lotusin (1) and lotusinic acid (2):

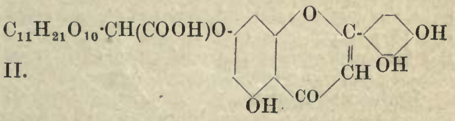
II.



A. G. P.

LOTUSIN *v.* GLUCOSIDES; LOTUS ARABICUS.

LUBAN MATI or **MEYETI** *v.* OLEO-RESINS.

LUBRICANTS. The purpose of lubricants is to reduce friction between surfaces which move one upon another.

As the value of a lubricant depends almost entirely upon the conditions of speed and pressure under which it is used, it is necessary to outline the theory of lubrication before describing the preparation and properties of lubricating oils and greases.

Static friction. If two clean surfaces of the same metal, say lead, are pressed together they will adhere firmly. In cases where metals work together without lubrication this '*seizing*' is only prevented by the existence of a '*contamination film*' on the surface of the metal. Thus the so-called 'solid friction' observed in such cases is really the friction of surfaces lubricated by an extremely thin film (*e.g.* of air).

Thurston, experimenting with sperm and lard oils, found that the friction rapidly increased with pressure up to about 70 lbs., and then increased less rapidly or remained constant.

With plastic substances, *e.g.* axle grease, under ordinary loads the frictional coefficient is least when at rest and gradually increases with increasing speed owing to the resistance of the grease to shear.

With liquids the reduction of static friction depends on the thickness of the film which remains on the bearing surfaces under the loads commonly used. Different liquids vary much in this respect, and the effect seems to depend less on the viscosity of the oil than on its 'oiliness' (*v. infra*).

Low-speed friction. In this case the film of oil is so thin that the irregularities of the surfaces engage one another, causing abrasion. This does not matter if the surfaces are of proper materials, but in some cases it may lead to seizing of considerable areas and so much distortion of the surface that at higher speeds the formation of the 'pressure film' may be prevented and serious over-heating of the bearing may result.

The friction of lubricated bearings at low speeds is really solid friction, *i.e.* it is (1) independent of velocity and area of bearing surface, (2) proportional to pressure, and (3) dependent on the nature of the surfaces, which should be made of dissimilar metals.

Where a complete oil film cannot form, the oiliness of the lubricant is very important, but as the speed increases the oil film thickens and the friction depends more on the viscosity of the oil and less on its oiliness.

Friction, especially at moderate speeds, depends very much on the manner in which the lubricant is applied to the bearing. The best results are obtained with bath lubrication, and the friction increases as the free supply of oil to the journal decreases.

The coefficient of friction at very low speeds —0·0005–0·01 feet per minute—is often greater than the static coefficient, but the change from one to the other is continuous. From about 6·0 feet per minute the coefficient of friction steadily decreases with increase of speed.

High-speed lubrication. At a speed depending on the nature of the lubricant and on the load the surfaces begin to separate, and a comparatively thick 'pressure film' forms between them, being carried into the bearing on the surface of the moving part.

The maintenance of a pressure film between two plane and parallel surfaces depends upon the *inertia* and the *viscosity* of the oil, but in the case of plane surfaces inclined to one another—and this is the case met with in practice—the liquid wedges itself between them and forces them apart.

To this action is due the great carrying power of cylindrical bearings, which in use always wear so that the radius of curvature of the brass is greater than that of the journal. The two surfaces are thus inclined to each other, and the journal, as it rotates, carries the lubricant into the space between the journal and the brass, where it is wedged under a pressure which increases to a maximum at the point where the two approach most nearly.

In the design of bearings great care has to be taken that oil-ways are not cut in this neighbourhood of maximum pressure, or the pressure of oil which should carry the load is released and serious friction results.

The theory of the pressure film has been worked out in great detail, mathematically, by Osborne Reynolds, but only his general results can be given here. At speeds sufficiently high to ensure the formation of the pressure film the following laws appear to be very nearly true:—

(1) The friction is independent of the load;

(2) The friction varies directly as the area of the contact surfaces; directly as the speed; and as the viscosity of the lubricant.

These are the laws of 'fluid friction.'

Above speeds of 100 feet per minute low speed effects are not observed and the friction is nearly proportional to the square root of the speed. This is probably due to lessened viscosity of the lubricant brought about by rise of temperature. From 490 to 790 feet per minute the friction is proportional to the fifth root of the speed, and above 1970 feet per minute it is practically independent of the speed.

With alternating pressures, especially when the alternations are rapid, *e.g.* in the big ends of connecting rods, a given bearing will sustain much greater loads without seizing than it would if the pressure were continually in the same direction, because the oil is trapped between the surfaces at each reversal of the stress.

Friction in ball and roller bearings is practically independent of the presence of any lubricant, the chief function of the oil used being to prevent rusting of the polished surfaces.

A mineral oil of moderate specific gravity is therefore a suitable lubricant for such bearings.

COMMON LUBRICANTS.

Lubricants are divisible into four classes:

(*a*) Fats and liquid waxes;

(*b*) Mineral oils;

(*c*) Blended oils;

(*d*) Greases and solid lubricants.

(*a*) **Fats and liquid waxes.** These are comprised under the name of fixed oils (*v.* OILS, FIXED, AND FATS). The fixed oils principally used as lubricants are: tallow oil, lard oil, neat's foot oil, olive oil, rape oil, and castor oil. For delicate machinery, such as clocks and watches, hazel-nut oil, ben oil, porpoise oil, and dolphin oil (blackfish oil) are used.

Sperm oil and Arctic sperm oil are liquid waxes, and are excellent lubricants because of their oiliness, and because their viscosity is less affected by temperature than is that of other oils.

Vegetable oils and all semi-drying oils, including fish oils and blubber oils (except porpoise and dolphin oils), are unsuitable for lubrication, and their addition to lubricating oils constitutes adulteration.

The fixed oils are seldom used alone as lubricants except for textile machinery, in which there is a risk of the oil being splashed on the fabric. Mineral oils are very liable to make stains which cannot be washed out subsequently without injury to the material.

(*b*) **Mineral oils** are derived from crude petroleum, shale and lignite, and consist of saturated, unsaturated, and closed-chain hydrocarbons of b.p. over 300°. Those of sp.gr. up to 0·900 are usually distillation products, while those of sp.gr. higher than 0·910 are either 'reduced oils' or oils that have been distilled with steam *in vacuô*. Heavy oils that have been distilled under atmospheric pressure are unsuitable for use as lubricants because of the presence in them of products of 'cracking' (*v.* PETROLEUM AND SHALE OIL).

(*c*) **Blended oils.** Mineral oils are miscible with all fatty oils except castor oil, and mixtures containing 20–30 p.c. of good fixed oil, *e.g.* sperm oil, are the best lubricants available for ordinary loads and speeds. Blown oils (partially oxidised oils) are soluble in mineral oils, and are sometimes used to give body to the lighter grades, but such blended oils have a great tendency to gum, and, though cheap, are not to be recommended.

(*d*) **Greases** and **solid lubricants.** The chief solid lubricants are graphite, soapstone (talc, steatite, French chalk), mica, and asbestos. These are seldom used alone, but are usually incorporated in a grease, the advantage being that under ordinary conditions the frictional resistance is merely that due to the resistance to shear of the grease, while under excessive pressure, though the grease may melt and run off the bearing, the solid lubricant remains and prevents damage. Filling materials, such as barytes and chalk, are sometimes added to greases, but they are not lubricants, and their addition is detrimental.

Anti-friction metals (*v.* ANTIMONY) may be regarded as solid lubricants, but their chief purpose is to afford a material into which the shaft can bed itself quickly.

Greases may be natural fats, *e.g.* tallow, but are more commonly prepared by adding to mineral or fixed oils alkali metal soaps or, more often, aluminium, lime or lead soaps of fatty acids or resin acids. Such greases frequently contain a considerable quantity of water, but if this is thoroughly incorporated in the grease it has no bad effect upon its properties as a lubricant.

Boiled greases are prepared by dissolving lime soap in mineral oil; they are very good for medium and heavy machinery.

'**Set**' or **axle greases** are made by adding to a mixture of mineral oil (100 gallons) and good slaked lime (500 lbs.), called the *lime part*, a certain proportion of resin oil (2–25 p.c.), called the *set*. The mixture is run at once into the packages in which it is to be sold, and in a short time sets to a solid or semi-solid mass, according to the proportion of resin oil added (*v.* also Archbutt, J. Soc. Chem. Ind. 1901, 1193).

Cup greases are prepared by saponifying fat, usually horse-fat, with freshly slaked lime in a large kettle heated by a steam jacket and provided with a mechanical stirrer. The usual proportions are 2000 lbs. fat, 200 lbs. lime, and 140 gallons of water. When saponification is complete and the excess of water has evaporated, a light-coloured mineral oil, sp.gr. 0·885–0·910 (about 100 gallons), is sprayed on the contents of the kettle until the right consistency is attained. The oil must previously be heated to 190°F.

Engine greases are made by incorporating cold mineral oil with hot soluble soda or potash soap. It is important that the soap should be neutral (Redwood).

Thickened mineral oils are often made by incorporating aluminium oleate with a light oil. The soap is made as follows: 112 lbs. oleic acid is mixed with 20 gallons hot water and a solution of 16¼ lbs. 77 p.c. caustic soda in 10 gallons water, and boiled until the formation of sodium oleate is complete. 70 lbs. alum, dissolved in 20 gallons water, are then added to the solution when aluminium oleate separates in greasy masses. It is freed from moisture by pressure (Hurst).

Railway waggon grease is usually composed of tallow, palm oil, soap, and water; and is prepared by heating the tallow and palm oil to 180°F., and running in a solution of sodium carbonate at 200°F. The whole is stirred well and run into tubs to set. It is usual to vary the composition of the grease according to the season of the year; the following are typical formulæ:

	Summer	Medium	Winter
Tallow . .	22	20	18
Palm oil . .	12	12	12
Sperm oil . .	1	1·5	2
Soda crystals .	5	5	5
Water . .	60	61·5	63
	100	100	100

The grease in use on the Midland Railway is prepared by dissolving 6 cwt. of palm oil in 12 cwt. of water and adding to the solution 6 cwt. of tallow and 2 cwt. of dark mineral oil.

Another English railway grease:—

	Summer	Winter
Tallow . .	504 parts	420 parts
Palm oil . .	280 „	280 „
Sperm oil .	22 „	35 „
Caustic soda .	120 „	126 „
Water . .	1370 „	1524 „

Other preparations are made of tallow with colza oil, soda, and water in various proportions; and, for fine machines, of tallow with castor oil, &c., &c.

Palm-oil lubricants. Although palm oil may be used alone, its melting-point is too low for most purposes; to correct this, tallow and other fats are added to the amount of one-third or one-half of the total weight of the lubricant. A small quantity of soda should form a part of these lubricants, as by its use the free fatty acids which are contained in palm-oil are saponified and their action on the metals with which they come in contact is destroyed. Soda also is the medium by which water is introduced into the mixture.

Lead-soap lubricants. Lead salts yield on saponification with fats solid combinations called lead-soaps; they are hard at low temperatures, viscous at ordinary temperatures, but sufficiently fluid on heating by friction. The melting-point of lubricants prepared from these substances is high, and they are therefore less suited for high speeds. So-called 'anti-friction lubricants' are composed of lead-soaps. A basic lead acetate (sugar of lead) is combined with the requisite quantity of fat in the following manner. The lead solution is thus prepared: Sugar of lead 10 parts, litharge 10 parts, and soft water 110 parts, are boiled with frequent stirring for an hour and a half or two hours. The mass is then allowed to rest, and the clear fluid drawn off and restored to 100 parts by the addition of water. It is then heated to from 145°F. to 165°F. and immediately mixed with ordinary fat (colza oil, lard, and sometimes neats-foot oil), as, *e.g.*, solution of sugar of lead 100 parts, colza oil 80 parts, lard 80 parts. The preparation should show a uniform grey colour, and, after melting, congeal at from 100°F. to 122°F. (Brannt).

Soap lubricants. Ordinary soft soap, or fat combined with potash, is serviceable for some purposes, but is liable to have a part of the potash lye not fixed, by which damage is done to metals.

The following are from Brannt (Practical Treatise on Animal and Vegetable Fats and Oils):—

Caoutchouc lubricants for belts. Caoutchouc 20 parts, linseed oil 1000 parts. Melt the caoutchouc together with the same quantity of linseed oil, and as soon as the mixture commences to evolve vapours, stir in 20 parts of linseed oil and afterwards add the remainder of the oil by instalments of 100 parts.

Asphaltum waggon grease. Asphaltum 32 parts, black pitch 8 parts, petroleum 8 parts, litharge 8 parts, water 80 parts.

Naphthalene grease. Naphthalene 100 parts, colza oil 50–100 parts. Crude naphthalene is used.

Resin lubricant. Common resin 100 parts, resin oil 50 parts, lard 300 parts.

Graphite waggon grease. Tallow 36 parts, lard 9 parts, palm oil 9 parts, graphite 2 parts.

Graphite lubricants for quick-moving axles, Tallow 100 parts, graphite 100 parts; especially adapted for shafts revolving with great velocity without great load, as circular saws, ventilators, &c.

Lubricant for cutting tools. This is usually a solution of soft soap and soda in water.

PHYSICAL PROPERTIES AND TESTING OF LUBRICANTS.

A. **Viscosity.** For methods of determining viscosity, *see* PETROLEUM. The methods there given are equally applicable to all lubricating oils.

The determination of the consistency of fats and greases is of importance, but the methods available are entirely empirical.

In *Kissling's apparatus* a pointed rod of glass or metal, weighted at the top, slides vertically through a hole in a fixed plate. The point of the rod presses on the surface of the grease contained in a small beaker, and the time taken for it to penetrate a definite distance into the fat is a measure of the stiffness of the latter.

Kunkler's apparatus consists of a metal cylinder having an orifice at the lower end through which the grease is squeezed by a weighted piston. The whole apparatus is surrounded by a water-jacket so that the temperature of the test can be regulated.

In any determination of the consistency of fats, great attention must be paid to the preliminary treatment they receive, as they are extremely sensitive to mechanical disturbance and to change of temperature. After the grease has been placed in position it is necessary to leave it for 24 hours before proceeding with the test.

B. **Specific gravity.** This property is used as an indication of the nature and purity of oils, and it forms the basis of the classification of the mineral oils. There is, however, no necessary connection between sp.gr. and lubricating power; *e.g.* it is well known that mineral oils commonly have less lubricating power than fatty oils of the same sp.gr. (*see* also PETROLEUM AND SHALE OIL).

The sp.gr. of oils may be determined by the sp.gr. bottle, by the Sprengel tube, or by the Westphal balance, but with viscous oils these methods are liable to be tedious, and hydrometers are commonly used for the purpose.

It is frequently necessary to know the density of an oil at a temperature at which it cannot conveniently be determined experimentally; it can then be calculated with sufficient accuracy (1 in 4000) from the following formula, if the density of the oil at 60°F. is known: $D = d - kt$, where d = the density of the oil at 60°F.,

$$k = \begin{cases} 0{\cdot}000368 \text{ for a fixed oil,} \\ 0{\cdot}000367 \text{ for a Scotch mineral oil,} \\ 0{\cdot}000345 \text{ for a Russian mineral oil,} \\ 0{\cdot}000350 \text{ for an American mineral oil,} \end{cases}$$

t = the number of degrees above 60°F., and D = the required density.

C. **Flash-point.** This is the temperature at which the oil gives off sufficient vapour to form an explosive mixture with air in the standard apparatus employed (for details *see* PETROLEUM). It is usually stated that only oils of flash-point over 350°–400°F. should be used as lubricants, but the loss on evaporation is at least as good a test.

D. **Volatility.** It is obviously desirable that lubricating oils should not evaporate to any considerable extent at the temperatures at which they are used. The fatty oils are satisfactory in this respect, but mineral oils frequently contain as much as 15 p.c. of hydrocarbons volatile at 100° C.

Archbutt's apparatus for the determination of this loss consists of a copper tube placed horizontally across an air-bath by which it can be kept at any desired temperature. The oil to be tested, usually 0·5 gram, is placed in a platinum tray within this tube and subjected to a current of air, previously heated to the temperature of the bath, passing at the rate of 2 litres per minute for exactly 1 hour.

In some cases the oil is tested in a current of steam, but the procedure is quite similar to that when air is used.

As an example of its use, an oil intended for cylinders working at 160 lbs. pressure is tested at 370°F. when it should not lose more than 0·5–1·0 p.c. of its weight. With machine oils and spindle oils, even at much lower temperatures, the permissible loss is much greater.

E. **Setting-point** (the *cold test*). With most oils this is taken as the temperature at which they cease to flow, but in the case of Scotch shale oils the setting-point is the temperature at which solid paraffin is first deposited.

The oil, contained in a corked tube, is cooled in water, or in ice and salt, until it ceases to flow on reversing the tube. It is necessary to maintain the temperature constant for about 20 minutes before observing the condition of the oil (*v.* Salkowsky, J. Soc. Chem. Ind. 1888, 37; and Holde, *ibid.* 1890, 112; 1896, 138, 160), and in Hofmeister's method this is attained by using solutions of various salts, of such concentrations that they are saturated at their freezing-points. The result is that freezing takes place with formation of a eutectic mixture, and the temperature remains constant till the whole is solidified.

Schultze's method, used in Germany, depends on finding the temperature at which the oil flows through a tube of 6 mm. diameter at a rate of 10 mm. per minute under a pressure equal to 50 mm. of water.

F. **Melting-point of fats** and **greases.** This is frequently of importance, as a grease loses its power of reducing friction under great pressure should it become liquefied. As in the case of determination of consistency, attention must be paid to the preliminary treatment of the grease, and it should, in most cases, be left undisturbed for 24 hours before the test is made.

Many methods are used, most of which depend on observing the temperature at which the grease begins to flow under its own weight (*v.* Bensemann, J. Soc. Chem. Ind. 1885, 535; Cook, Chem. Soc. Proc. 1897, 74).

G. **The colour of oils** is of some importance, and Redwood uses Lovibond's tintometer (*v.* art. COLORIMETERS) for making a numerical record of this characteristic. Most mineral oils exhibit a fluorescence, usually of a blue or green colour, but this is not of much importance as a test (*v.* PETROLEUM).

H. **Oiliness.** The most important property of oils and greases which are to be used under conditions of low speed and high pressure (under 100 feet per minute and over 70 lbs. per square inch), is that called '*oiliness*' (*unctuosity, lubricity*). It depends on (1) interfacial action, which causes oils to spread themselves over metallic surfaces, and (2) on the power of the film to resist disruption.

Oiliness may be defined as the power of a lubricant to maintain an unbroken film under a heavy load; it cannot be measured in any exact way, and information as to the extent to which any given oil possess this property may best be obtained by properly conducted tests on mechanisms resembling those on which it will be used. This property is not necessarily connected with viscosity, being possessed in much greater degree by fixed oils than by mineral oils of the same viscosity. This is the reason that mineral oils must be blended with fatty oils to get the best lubricants for ordinary machinery.

Oil-testing machines are made of many different designs, and may be used to investigate:

(1) Comparative oiliness or greasiness of lubricants;

(2) Frictional effects due to viscosity;

(3) Effects of temperature on friction;

(4) Effects of different loads;

(5) Effects due to varying speeds;

(6) Effects produced by different metals working in contact;

(7) Effects resulting from different methods of applying the lubricant.

Most of these effects, except (1), are amenable to calculation, or can be more easily determined in some other way; Nos. (6) and (7) are rather concerned with the design of bearings than with lubricants.

In most machines an experimental journal runs in brasses loaded in a manner which can be regulated by the operator, *e.g.* by a spring. The detailed description of such machines hardly falls within the scope of this article, and it is sufficient to say that Thurston's oil-testing machine is largely used (for a detailed description *see* Archbutt and Deeley, Lubricants and Lubrication, 332; Hurst, Lubricating Oils, Fats, and Greases, 254 *et seq*). Machines of similar type are those of R. H. Smith, A. Martins, Ingham and Stapfer, Stroudley, Goodman, and Lahmeyer (A. and D. chap. ix.).

These testing machines all suffer from the disadvantage that, at the speeds at which they are usually run, the frictional effects observed are due solely to the viscosity of the oil used, and therefore only give information as to that property; information which could better be obtained with a viscosimeter.

Machines of what is known as the *disc and collar* type are of much more use in investigating the 'oiliness' of lubricants. In them the oil is fed between a rotating disc and a stationary plate, a load is applied to force the two together, and low speeds are used. The best known machines of this class are MacNaught's, Woodbury's, Deprez and Napoli's, and Tower's.

Bailey's pendulum oil-tester is specially designed for use with oils intended for watches, clocks, and other small machines.

CHEMICAL PROPERTIES OF LUBRICANTS.

The chemical methods used for the examination of lubricants are those used for oils in general (*v.* PETROLEUM and OILS, FIXED, AND FATS).

The chemical properties of oils which are of special importance with reference to their use as lubricants are: (1) corrosive action on metals, which is closely connected with the acidity of the oil; (2) their tendency to gum or resinify; and (3) their liability to decomposition under the conditions of use.

(1) Most fatty oils, even when freshly prepared, contain some fatty acid, the amount of which increases with time of storage of the unrefined oil. This cannot be avoided, and is one of the chief reasons that such oils have been largely superseded by mineral or blended oils. The addition of resin or resin oil to a lubricant will often increase the acidity owing to the resin acids present.

Crude petroleum normally contains small amounts of organic acids, but refined mineral oils ought to be practically free from acidity. In many cases where they do not conform to this standard they are found to contain free sulphuric acid, which has been left in the oil owing to imperfect washing after refining with acid.

The extent of the corrosive action of an oil on metals is proportional to its acidity, but is conditioned by the access of air or water to the metal. In absence of air and water even a grease containing 70 p.c. of fatty acids has little or no action on metals (Burstyn, Dingl. poly. J. 217, 314; Redwood, J. Soc. Chem. Ind. 1886, 362; Fox, Analyst, 1883, 8, 116; Donath, J.

Soc. Chem. Ind. 1895, 283). The acidity is usually determined by titration, and is expressed in terms of alkali required to neutralise it, or as oleic acid.

(2) The *tendency to gum* in the case of fatty oils is closely associated with their drying properties. Such oils as linseed oil are impossible as lubricants. The semi-drying oils are not used as lubricants with the single exception of rape oil, the least oxidisable, which is largely used owing to its low cost.

A rough idea of the drying properties of oils can be obtained by coating them on pieces of clean glass and observing the length of time they take to set, or to arrive at the same consistency. Another way is to place drops of the oils at the upper end of an inclined steel plate, and observe the distances they travel before coming to rest. Care must be taken to distinguish those cases in which the thickening of an oil is due to its acidity, the corrosive action resulting in the formation of metallic soaps which dissolve in the oil.

Mineral lubricating oils can absorb small quantities of oxygen at a high temperature (Bach, J. Soc. Chem. Ind. 1889, 990; Ostrejko, J. Soc. Chem. Ind. 1896, 26, 345, and 645), but under ordinary conditions such oxidation is practically *nil*. Any tendency to gum in this case is due to evaporation of the lighter constituents with deposition of asphaltic and tarry matters (Holde, J. Soc. Chem. Ind. 1894, 668; 1895, 894). The amount of bituminous matter present can be determined by extraction with light petroleum (Bender, J. Soc. Chem. Ind. 1891, 354). Closely associated with the gumming tendencies of oils is their liability to cause spontaneous combustion of cotton waste, &c., with which they come in contact. For this reason mineral oils have entirely superseded fixed oils in many cotton mills.

(3) The danger of *decomposition* is present in those bearings which run at a high temperature, *e.g.* hot-neck rolls, but the commonest case where this has to be considered is that of cylinders of steam, gas, and oil engines. For these pure fixed oils should never be used, as in presence of steam they are hydrolysed to glycerol and fatty acids which rapidly corrode the cylinder and piston, forming large lumps of metallic soap. Steam cylinders are best lubricated with 'reduced' mineral oils of high viscosity, density, and flash-point, but very satisfactory results are obtained in practice by using lighter grades of mineral oils containing up to 30 p.c. of fixed oils or 'blown oils.'

For the lubrication of the cylinders of gas and oil engines a pure mineral oil should be used, preferably one which will evaporate without leaving any residue. The high temperature of the walls of such cylinders and the presence of flame cause such carbonisation of the oil and, unless care is used in its selection, this may cause serious trouble.

See OILS, FIXED, AND FATS; PETROLEUM; also Encyclop. Britt. 1910, arts. Lubricants and Lubrication; Archbutt and Deeley, Lubrication and Lubricants; Lewkowitsch, Chemical Technology of Oils, Fats, and Waxes; Redwood, Lubricants, Oils, and Greases; G. H. Hurst, Lubricating Oils, Fats, and Greases; Carpenter and Leask, Soap, Candles, Lubricants, and Glycerin, 258 *et seq.*

LUMINOUS PAINT *v.* BARIUM SULPHIDE.

LUNAR CAUSTIC. Silver nitrate fused and cast into rods or sticks.

LUPEOL. A substance of the formula $C_{30}H_{50}O$ found associated with cinnamic acid in *Palaquium* [*Dichopsis*] *Treubii* (Burck.). Crystallises in fine needles, dextrorotatory $\alpha_{D} = +27{\cdot}2^{\circ}$ in chloroform, m.p. 190°–192° (Jungfleisch and Leroux, Compt. rend. 1907, 144, 1435; *cf.* Van. Romburgh, *ibid.* 1907, 926).

LUPINES. *Lupinus luteus* (Linn.); *L. angustifolius* (Linn.); *L. albus* (Linn.). The above three varieties, whose flowers are yellow, blue, and white respectively, are the chief species grown. They are often grown for green manure on account of their nitrogen-collecting powers, and are employed to enrich poor sandy soils in nitrogenous organic matter. They are only occasionally used as food either for men or animals, because of their bitter taste, but in times of famine they are sometimes used as an addition to rye-bread.

The following gives the mean composition of several varieties of the seed (König):—

	Water	Protein	Fat	N-free extract	Crude fibre	Ash
White lupines	15·9	28·8	6·8	33·6	11·9	3·0
Black ,, .	14·3	38·8	4·6	23·9	14·5	3·9
Blue ,, .	14·3	29·7	5·3	35·6	12·2	2·9
Yellow ,, .	14·7	37·8	4·3	25·5	14·2	3·5

The "protein" of lupines contains a considerable proportion (10–20 p.c.) of non-albuminoids. A portion of the non-albuminoid nitrogen exists in the form of alkaloid-like substances. Blue and white lupines contain a substance *lupanin* $C_{15}H_{24}N_2O$, which can exist in two forms: a liquid which forms a hydrochloride $C_{15}H_{24}N_2O{\cdot}HCl,2H_2O$, crystallising in prisms melting at 132°–133°; and a solid, crystallising in monoclinic crystals, which melt at 99°, and which forms a hydrochloride of the same composition as the other, but melting at 105°–106°. *Lupinin* $C_{21}H_{38}N_2(OH)_2$ occurs in yellow lupines; it forms crystals melting at 67°–68°. *Lupinidin*, another liquid alkaloid-like substance, consists of a solution of a crystalline hydrate $C_8H_{15}N + H_2O$ in the oily base $C_8H_{15}N$. The latter is a thick, oily liquid easily soluble in alcohol and ether, smells like hemlock and has an intensely bitter taste. It oxidises rapidly by exposure to air and acts as a weak poison.

These alkaloid-like substances are present both in the seeds and in the leaves and stems, and thus render the plant unpalatable to animals. The poisonous properties of lupines, often fatal to sheep, were formerly ascribed to these alkaloids, but according to Kuhn and Liebscher, they are due to 'Ichtrogen,' a substance produced by the growth of a fungus which attacks lupines, and which can be extracted from diseased plants by treatment with water.

Lupines are sometimes deprived of their bitter taste before being given to animals. This can be done by an hour's steaming and washing with water; according to Kellner this treatment removes practically the whole of the alkaloids (95 p.c.), while it also removes about 3–4 p.c. of the nitrogenous substances, and 15–20 p.c. of the total dry matter. In spite of this loss the treated lupines are of greater feeding value than those untreated.

Of the proteids in lupines, conglutin is the largest constituent. The 'nitrogen-free extract' of lupines consists largely of gums and pectin bodies, together with starch and cane sugar. The blue lupine contains about 11 p.c. of *lupeose* (β-galactan); by heating with dilute sulphuric acid it splits up into *d*-fructose and galactose.

The following are analyses of the ash of lupines (König) :—

	K_2O	Na_2O	CaO	MgO	Fe_2O_3	P_2O_5	SO_3	SiO_2	Cl
Yellow lupines	30·5	0·7	7·1	12·8	0·7	38·6	8·7	0·2	0·8
Blue ,,	30·9	1·0	10·6	9·7	0·6	37·1	7·8	1·0	0·4
White ,,	33·7	17·9	7·8	6·2	—	25·7	6·8	0·9	2·1

H. I.

LUPININE *v.* VEGETO-ALKALOIDS.

LUPULIN *v.* OLEO-RESINS.

LUTECIENNE. A mixture of Fast Red A with Orange II. (β-naphthol orange), the sodium salt of *p*-sulphobenzene-azo-β-naphthol, comes into commerce under this name. Known also as French Red. The name is also given to the alkaline salts of dibromodinitro-fluoresceïn, prepared by simultaneous nitration and bromination of fluoresceïn in alcoholic solution or by nitration of dibromofluoresceïn in acetic acid or aqueous solution.

LUTECIUM. Sym. Lu. At.wt. 174. The identification of this rare earth metal has resulted from the systematic examination of Marignac's ytterbia (Compt. rend. 1878, 87, 578), which is isolated from the least basic portions of the yttria earths derived from xenotime or ytterbite (gadolinite) (*v.* CERITE METALS). Prolonged fractionation in nitric acid of the crude ytterbium nitrate removed yttrium, erbium, and finally thulium, a trace of thorium being separated with hydrogen peroxide. The atomic weight of the elements present in the final fractions rose from 169·9 to 173·8. The most soluble fractions, which give the highest atomic weights, showed 34 characteristic lines in the spark spectrum and the band γ (λ517·5–λ513) in the absorption spectrum which are characteristic of lutecium (Urbain, Compt. rend. 1907, 145, 759; *cf.* Auer von Welsbach, Sitzungsber. Wien. Akad. 1907, 468). The commercially separated yttrium earths from ytterbite have been further fractionated as chromates to remove yttrium, and crystallised as nitrates, and as double nitrates with bismuth and magnesium to precipitate cerium and lanthanum. After removing the excess of bismuth and magnesium, the lutecium fraction was precipitated as oxalate, converted into nitrate, and fractionated to eliminate successively erbium, yttrium and neoytterbium. The most soluble lutecium fraction, converted into chloride with sulphur chloride (*v.* CERIUM), was heated till scandium and thorium chlorides were volatilised. *Lutecium chloride* is more volatile than neoytterbium chloride (Urbain, Bourion, and Maillard, Compt. rend. 1909, 149, 127). The xenotime earths were freed from cerium, gadolinium, terbium and dysprosium by fractionating the ethyl sulphates; the most soluble ytterbium fraction (containing yttrium, erbium, and thulium) was converted into nitrate, and decomposed fractionally in nitric acid when neoytterbium and lutecium were obtained in the most easily decomposable portions.

Lutecia (*lutecium oxide*) Lu_2O_3 is less basic than neoytterbia, and can be separated from it by fractional precipitation with caustic alkali; it is less paramagnetic than the latter oxide, the magnetic susceptibilities being in the ratio $Yb_2O_3 : Lu_2O_3 = 53 : 13$ (Urbain, Compt. rend. 1908, 146, 406).

The final uncrystallisable mother liquors obtained in the separation of lutecium from ytterbite (but not from xenotime) probably contain a new element *Celtium* indicated by a characteristic arc spectrum. The magnetic susceptibility of celtium oxide is three or four times less than that of lutecia, and in basic strength the former oxide is intermediate between the latter and scandia (Urbain, Compt. rend. 1911, 152, 141).

G. T. M.

LUTEOLIN. The sodium salt of *m*-xylidinsulphonic-azo-diphenylamine. An orange-yellow dye discovered by Witt in 1883. No longer used. Also the colouring matter of weld (*q.v.*).

LUTES are used for packing joints, repairing fractures, and coating vessels externally to render them impervious to vapours, &c. For a lute to be effective it is important that the surfaces to which it is applied should be *clean*, and in the case of lutes that are applied in a molten or semi-fluid state it is preferable previously to heat the parts that are to be joined.

Of lutes for joints which are not to be subjected to high temperature may be mentioned: (1) Soaked bladder stretched and tied over a joint or employed to secure another lute on the joint. (2) India-rubber bands, or caoutchouc melted or dissolved in coal tar, naphtha, or other solvent. (3) A solution of 1 part caoutchouc in 2 parts hot linseed oil mixed with 3 parts pipeclay; this mixture remains soft and is very impervious. (4) Linseed or almond meal made into a paste with water, milk, glue, or lime-water. (5) A mixture of white lead and oil spread upon strips of linen or bundles of tow. (6) Quicklime reduced to a dry powder by addition of a small quantity of water, and mixed with white of egg diluted with its own volume of water, is spread on linen strips and rapidly applied to the joint. This lute dries quickly and adheres strongly to glass. (7) *Lute d'âne*, a very strong cement prepared by mixing strong glue with recently slaked lime, with subsequent addition of white of egg. (8) Chalk and linseed oil (glazier's putty). (9) Plaster of Paris made into a paste with water, gum water, or glue, and coated when dry, if the joint is to be gas-tight, with melted paraffin or oil. (10) *Fat lute*, consisting of a mixture of clay and boiled linseed oil, is applied and retained by bladder or other substance, to hot joints or to prevent escape of corrosive vapours. (11) A mixture of clay with a solution of gelatin in pyroligneous acid.

For joints which are to resist considerable internal pressure, especially the joints of steam pipes, a mixture is applied consisting of equal parts of red lead and white lead made into a paste with linseed oil and mixed with tow. Other lutes for this purpose are: (1) 12 of Paris white, 5 of red ochre, 2½ of Venetian red, and ½ of plumbago, ground and mixed to a stiff paste with boiled linseed oil (Thompson, Eng. Pat. 27975, 1895). (2) Metallic zinc powder mixed with tow or whiting and made into a paste with linseed oil or wood oil (Boneville & Co. Fr. Pat. 332788). (3) 6 parts graphite, 3 parts slaked lime, 8 parts powdered barytes, and 7 parts of boiled linseed oil.

For making permanent joints and closing joints between metal and glass, &c., various compositions containing beeswax are used. Beeswax when melted with one-eighth its weight of turpentine becomes less brittle and, when the materials are melted in equal proportions, the product becomes pliant when held in the hand, melts easily, and is known as *soft cement*. *Cap cement* or *hard cement*, for closing the covers, &c., of scientific apparatus, is prepared by mixing and melting 1 part beeswax, 5 parts resin, and 1 part dried red ochre or other colouring matter. The mixture is heated to 100°C. until all frothing has ceased, and is cooled with frequent stirring to prevent settlement of the pigment.

Bottle lutes are used to cover the stoppers or corks of bottles. That most commonly employed is sealing wax; paraffin wax is also good. Wholesale dealers usually lute the stoppers of acid bottles with a paste of linseed meal and water.

Plumber's lute is made by adding 2 parts of fine brickdust to 1 part of melted black resin and stirring in thoroughly.

A waterproof cement, introduced by Edmund Davy, is prepared by melting together 2 parts by weight of common *pitch* and 1 part of *gutta percha*, with constant stirring. The resultant homogeneous fluid adheres with great tenacity to metal, stone, wood, &c., if applied to warm surfaces of those substances, and, although hard, is not brittle. It softens when heated and passes through various stages of viscosity until above 100°F. it forms a thin fluid. It appears to be absolutely unaffected by contact with water.

Two good *acid-proof* lutes are: (1) Pipeclay made into a stiff paste with hot coal-tar; (2) equal parts of pitch and resin melted together and incorporated with 1 part of plaster of Paris.

A useful laboratory cement is obtained by mixing litharge to a stiff paste with glycerol. This quickly sets to a hard mass, impervious to water or gases.

Acetone collodion, a solution of collodion in acetone, is very useful as a lute in the laboratory. Painted on with a brush, it quickly dries to a hard film which is proof against water and dilute acids, and is perfectly impervious to gases. It may be used to lute cork or rubber stoppers, to cover rubber tubing, to waterproof labels, &c., but it should not be subjected to a temperature above 150°C.

A lute acquiring a hardness equal to that of marble, and known as *oxychloride of zinc cement* (Sorel's cement), is prepared by dissolving 3 p.c. of borax in a solution of zinc chloride of 1·49–1·65 sp.gr. with addition of sufficient recently ignited zinc oxide to produce the proper consistency.

Magnesia cement is prepared by makng a paste of powdered magnesite and 10–20 p.c. conc. hydrochloric acid, forming it into blocks, igniting, and finally grinding to powder. With water this yields a strong cement which quickly sets hard, but is not absolutely fireproof.

Bruyère's hydraulic cement is prepared by heating to bright redness for 3 hours a mixture of 3 parts clay and 1 part slaked lime, and powdering the product.

A cement employed for closing leaks in boilers, &c., is prepared by mixing 6 parts clay and 1 part iron filings to a paste with boiled linseed oil.

Iron cement, for permanently closing joints in iron, consists of a mixture of 100 parts iron filings, 3–20 parts flowers of sulphur, and 3–5 parts ammonium chloride, mixed with water to a paste and applied quickly. The larger proportion of sulphur is required when the iron filings are fine. The mixture soon becomes hot, with evolution of ammonia and sulphuretted hydrogen, and in a short time becomes almost as hard as iron. It is stated that the best iron lute consists of a mixture of 100 parts iron filings with only 1 or 2 parts of sal ammoniac and no sulphur. This lute, however, though stronger, requires a considerable time to set.

For coating earthenware, a paste is applied consisting of a mixture of equal parts of zinc white and fine sand, made into a paste with a concentrated solution of zinc chloride. *Willis' lute* for the same purpose consists of a paste made with slaked lime and a solution of 2 oz. borax in 1 pint water. It is applied with a brush, and when dry is covered with a plastic mixture of slaked lime and linseed oil and is ready for use after a few days.

Among lutes for resisting high temperatures may be mentioned Stourbridge clay made into a paste with water, which withstands a higher temperature than any other lute in general use, and *Windsor loam*, a natural mixture of clay and sand. Both are used for coating vessels and for packing hot joints of metal vessels. With the addition of about one-tenth part of borax these clays are useful for glazing earthenware vessels. Leaks and fractures in furnace linings, &c., may be stopped with *ganister*, a highly silicious fireclay.

Gas retorts and similar vessels closed temporarily to withstand high temperatures are usually merely luted with mortar.

For luting crucibles, a paste of fireclay and powdered firebrick is useful, preferably with addition of a small proportion of borax to render the lute coherent.

A most valuable mixture for repairing broken furnaces, &c., consists of a paste of firebrick and liquid sodium silicate. Even considerable openings, if roughly filled with broken firebricks, may be sealed with this lute (*v.* CEMENTS).

A fireproof cement for repairing retorts, &c., is made by taking 200 cwt. china clay, 100 cwt. barytes, 40 gall. sodium silicate (100°Tw.), 24 gall. water, and 28 lbs. borax, mixing well and adding magnesite to the extent of 25 p.c. of the mixture (Williams, Eng. Pat. 18064, 1903).

A lining for furnaces and crucibles may be made from 4 parts granular corundum, ground to a fine powder, mixed with 1 part powdered graphite and made into a paste with 10 p.c. of sodium silicate (Crowley and Payne, Eng. Pat. 8627, 1906; *v.* also Kilburn Scott, J. Soc. Chem. Ind. 1905, 501).

LUTIDINES, LUTIDINIC ACID, *v.* BONE-OIL.

LYCETOL. Trade name for dimethyl piperazine tartrate.

LYDIAN STONE or **LYDITE.** A black, jaspideous or cherty variety of quartz, which from its hardness and the closeness of its grain has been used as a touchstone for testing the quality of gold, whence its name *basanite*. The metal to be tested is rubbed on the polished surface of the stone, and the streak thus produced is compared with the streaks made by a series of alloys of known composition; the observer judging of the purity of the metal by the colour of the mark and by its behaviour when treated with a drop of acid. Lydite is also used as a hone-stone. Most Lydian stone has a schistose structure, and may be described as a hornstone-slate, or *Kieselschiefer*. The Lydian stone of Devon and east Cornwall is a fine-grained, indurated, carbonaceous shale, belonging to the Culm-measures. L. J. S.

LYDDITE *v.* EXPLOSIVES.

LYDIN. A synonym for mauve or aniline purple.

LYSINE $NH_2[CH_2]_4CH(NH_2)CO_2H$, *αε-diaminohexoic acid*, was discovered by Dreschel (J. pr. Chem. 1889, [ii.] 39, 425) among the products of hydrolysis of casein by hydrochloric acid and stannous chloride; it is produced by the hydrolysis of other proteins, conglutin, egg albumen, fibrin (Siegfried, Ber. 1891, 24, 418), and gelatin (Ernst Fischer, Arch. Anat. u. Physiol. 1891, 265); it occurs in antipeptone prepared from fibrin (Kutscher, Zeitsch. physiol. Chem. 1898, 25, 195); together with arginine it forms the chief product of hydrolysis of the protamines sturine, β-cyprinine, and crenilabrine (Kossel, Zeitsch. physiol. Chem. 1899, 26, 588; 1904, 40, 565; 1910, 69, 138); and it also occurs among the hydrolytic products of the proteins of the seeds of various conifers, and the seedlings of *Lupinus luteus* (Linn.) (Schulze and Winterstein, Zeitsch. physiol. Chem. 1899, 28, 459, 465; 1901, 33, 547).

Dreschel (Chem. Zentr. 1891, ii. 712) showed that lysine is a diaminocaproic acid, and Ellinger (Ber. 1899, 32, 3542) proved that the two amino groups are in the αε- positions, because on decomposition by putrefaction in an atmosphere of hydrogen, lysine is partially converted into cadaverine (pentamethylenediamine)

$$NH_2[CH_2]_4CH(NH_2)CO_2H = CO_2 + NH_2[CH_2]_5NH_2.$$

The synthesis of *i*-lysine has been effected by Fischer and Weigert (Sitzungsber. K. Akad. Wiss. Berlin, 1902, 270) from ethyl γ-cyanopropylmalonate; when this compound is treated with ethyl nitrite it gives ethyl α-oximino-δ-cyanovalerate $CN[CH_2]_3C(NOH)CO_2Et$, which on reduction with sodium in alcoholic solution, yields αε-diaminohexoic acid or *i*-lysine

$$NH_2[CH_2]_3CH(NH_2)CO_2H,$$

this is isolated by successive transformation into the phosphotungstate and picrate; the *picrate* forms thick needles that darken at 230°; the *hydrochloride* is crystalline and melts at 183°–186° (corr.); the *phenylcarbimide* forms colourless needles, m.p. 182°–185° (corr.); these derivatives differ from the corresponding derivatives of the naturally occurring *d*-lysine in being optically inactive and having slightly different melting-points. A further synthesis of *i*-lysine from ethyl cyanopropylphthaliminomalonate is described by Sörensen (Chem. Zentr. 1903, ii. 33); when this compound is reduced with sodium in alcoholic solution it yields the corresponding amino compound

$$C_6H_4:(CO)_2:N{\cdot}C(CO_2Et)_2[CH_2]_4NH_2,$$

which is transformed by the action of concentrated hydrochloric acid into *i*-αε-diaminohexoic acid (*i*-lysine).

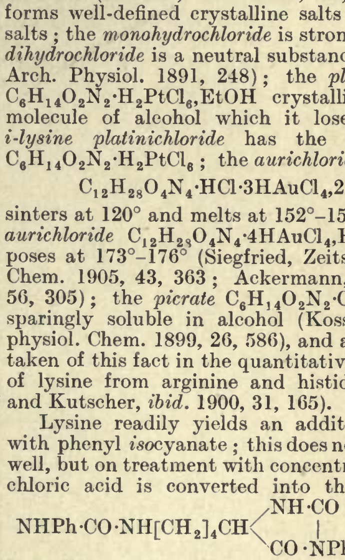
i-Lysine can also be obtained by a synthetic process from piperidine (Julius von Braun, Ber. 1909, 42, 839). The opening of the piperidine ring by phosphorus pentachloride affords among other products, benzoyl-ε-leucinenitrile $COPh{\cdot}NH[CH_2]_5CN$, which contains the skeleton of lysine, and yields on hydrolysis ε-benzoylaminohexoic acid $COPh{\cdot}NH[CH_2]_5CO_2H$; this on bromination forms the α-bromo derivative $COPh{\cdot}NH[CH_2]_4CHBr{\cdot}CO_2H$, which reacts with ammonia to give α-amino-ε-benzoylaminohexoic acid $COPh{\cdot}NH[CH_2]_4CH(NH_2)CO_2H$, from which *i*-lysine is obtained by hydrolysis.

Derivatives. *Salts.*—*d*-Lysine is a syrup (Winterstein, Zeitsch. physiol. Chem. 1905, 45, 77), it has $[\alpha]_D + 17{\cdot}5°$ in hydrochloric acid solution (Lawroff, *ibid.* 1899, 28, 388), and forms well-defined crystalline salts and double salts; the *monohydrochloride* is strongly acid, the *dihydrochloride* is a neutral substance (Dreschel, Arch. Physiol. 1891, 248); the *platinichloride* $C_6H_{14}O_2N_2{\cdot}H_2PtCl_6,EtOH$ crystallises with 1 molecule of alcohol which it loses at 120°; *i-lysine platinichloride* has the composition $C_6H_{14}O_2N_2{\cdot}H_2PtCl_6$; the *aurichloride*

$$C_{12}H_{28}O_4N_4{\cdot}HCl{\cdot}3HAuCl_4,2H_2O$$

sinters at 120° and melts at 152°–155°; *i-lysine aurichloride* $C_{12}H_{28}O_4N_4{\cdot}4HAuCl_4,H_2O$ decomposes at 173°–176° (Siegfried, Zeitsch. physiol. Chem. 1905, 43, 363; Ackermann, *ibid.* 1908, 56, 305); the *picrate* $C_6H_{14}O_2N_2{\cdot}C_6H_3N_3O_7$ is sparingly soluble in alcohol (Kossel, Zeitsch. physiol. Chem. 1899, 26, 586), and advantage is taken of this fact in the quantitative separation of lysine from arginine and histidine (Kossel and Kutscher, *ibid.* 1900, 31, 165).

Lysine readily yields an additive product with phenyl *iso*cyanate; this does not crystallise well, but on treatment with concentrated hydrochloric acid is converted into the *hydantoin*



$$NHPh{\cdot}CO{\cdot}NH[CH_2]_4CH\left\langle\begin{array}{l}NH{\cdot}CO\\ \quad\ \ |\\ CO{\cdot}NPh\end{array}\right.$$

, which is crystalline and melts at 183°–184° (Herzog, Zeitsch. physiol. Chem. 1902, 34, 525); the corresponding derivative of *i*-lysine has m.p. 156° (von Braun, Ber. 1909, 42, 839). *Lysuric acid*, the dibenzoyl derivative of lysine, has m.p. 144°–145°; the *acid barium salt*

$$2(C_6H_{12}Bz_2N_2O_2),(C_6H_{11}Bz_2N_2O_2)_2Ba,2H_2O$$

crystallises in beautiful needles, m.p. 144°–148°, at which temperature it becomes anhydrous; the *normal barium salt* $(C_{20}H_{21}N_2O_4)_2Ba,1\frac{1}{2}H_2O$ is a white crystalline powder, m.p. 168°; the *acid sodium salt* is white and crystalline, m.p. 108°–109°, and contains H_2O; the *acid strontium salt* contains $2H_2O$, crystallises in plates, and has m.p. 137°–138°; the *normal strontium salt* contains H_2O and is crystalline; the silver salt $C_{20}H_{21}N_2O_4Ag,1\frac{1}{2}H_2O$ is white and amorphous (Dreschel, Ber. 1895, 28, 3189; Willdenow, Zeitsch. physiol. Chem. 1898, 25, 523). *Methyl lysine hydrochloride* prepared by the action of methyl alcohol and hydrogen chloride on *i*-lysine hydrochloride, has m.p. 218° (decomp.); *lysine anhydride*, obtained by heating the methyl ester at 100°, forms the *picrate* $C_{12}H_{24}O_2N_4{\cdot}2C_6H_3O_7N_3$ yellow prisms or plates decomposing at 230°

(corr.), and the *hydrochloride*, microscopic colourless needles decomposing at 270° (corr.) (Fischer and Suzuki, Sitzungsber. K. Akad. Wiss. Berlin, 1904, 1333). *d-Lysyl-lysine dipicrate* $C_{12}H_{26}O_3N_4,(C_6H_3O_7N_3)_2$, m.p. 238°–242° was isolated from the products of hydrolysis of pepsin extract (Hugounenq and Morel, Compt. rend. 1909, 148, 236); *i-lysyl-lysine* $C_{12}H_{26}O_3N_4$ forms a yellow crystalline *picrate*, m.p. 185° (corr.), and a *hydrochloride* crystallising in short twin prisms, m.p. 205° (corr.) (Fischer and Suzuki, Ber. 1905, 38, 4173).

Lysine yields carbamide when decomposed by barium hydroxide (Dreschel, Ber. 1890, 23, 3096); it is oxidised by barium permanganate, yielding glutaric acid as the chief product (Zickgraf, Ber. 1902, 35, 3401); and when the sulphate or hydrochloride is treated with barium or silver nitrite, αε-dihydroxyhexoic acid, an aminohydroxyhexoic acid, m.p. 200°–201°, and a small amount of an alkaline yellow amorphous substance $C_6H_{13}O_3N$, m.p. 176°–178°, are produced (Szydlowski, Monatsh. 1906, 27, 821).

M. A. W.

M

MACE. *Description.*—Mace is the dried arillus or seed coat of the nutmeg, the latter being the fruit of *Myristica fragrans* (Houtt.) (or *Myristica argentea* (Warb.), *see* below).

The tree is a native of the Malay Archipelago, and is cultivated in both the East and West Indies.

The fruit (nutmeg) is surrounded by four coats: a thick pericarp on the outside, then the crimson arillus, then a thick tegument, and finally a thin membrane closely adherent to the kernel.

Many other species of *Myristica* are known in addition to *M. fragrans* (Banda or true mace), but only one yields aromatic seeds, viz. *M. argentea*, which furnishes the Papuan or Macassar mace.

The chief varieties of mace which appear on the British market are Penang, Singapore, Java, and West Indian, the first being the most highly esteemed. All these are derived from *Myristica fragrans*, but a small quantity of Macassar mace is also imported, and this variety has hitherto been sold as "mace" without any question being raised as to its genuineness. As it appears in commerce mace has a yellow-brown colour, the lighter the better. The arillus, when unbroken, is about 1½ inch long and ¾ inch wide at the base. It is usually flattened, the tapering segments or blades being from ⅛ to ¼ inch wide. Macassar mace is of a dull brown colour and has much wider blades. Both varieties have a similar aromatic flavour, but that of Macassar mace is distinctly acrid (*v.* Holmes, Pharm. J. 1908, 652). The sole use of mace is as a flavouring agent and condiment.

Composition.—The chief constituents of mace are a volatile oil to which the flavour is mainly due, a fixed oil and a carbohydrate, amylodextrin, the granules of which are easily visible under the microscope and turn red on treatment with iodine. The following table shows the composition of Banda and Macassar mace, and also of false or Bombay mace (*see* below).

(From Winton, Ogden and Mitchell, U.S. Dept. of Agric., Bul. 13 and 65, and other sources.)

			Ether extract				
	Water	Ash	Volatile oil	Fixed oil	Amylo-dex-trin	Crude fibre	Nitro-gen
Mace (*Myristica fragrans*)	5·67 to 12·04	1·62 to 4·10	4·04 to 10·80	21·20 to 29·08	22 60 to 31·60	2·90 to 8·90	0·73 to 1·12
Macassar mace .	4·18	2·01	5·89	53·50	10·40	4·57	1·11
Bombay mace .	0·32 to 7·04	1·36 to 1·98	0·00 to 0·67	56·70 to 59·80	16·20	3·21 to 8·17	0·81 to 0·79

Adulteration.—The only sophistication to which whole mace is liable is the addition of Bombay mace which is derived from *Myristica malabarica* (Lam.). The arillus of this species is about 2½ inches long by ¾ inch wide, and the numerous blades are narrow and their vermiform ends are coiled in a tangled mass at the apex. It is of a deep red-brown colour, and almost devoid of aroma. As it is quite useless as a flavouring agent, and its price is about one-fourth that of genuine mace, its presence in the latter can only serve the purposes of fraud.

Bombay mace is also the chief adulterant of ground mace, but potato, arrowroot, the cereal starches, and ground olive stones may possibly be found.

Detection of adulteration.—The presence of any of the above adulterants is best detected by means of the microscope. Banda and Macassar mace are practically indistinguishable from one another, but the presence of Bombay mace is at once revealed by the appearance of the dark orange-coloured oil cells, the contents of which when treated with alkali assume a blood-red tint. The oil cells in Banda and Papua mace are fewer in number, of a light yellow colour, and alter only slightly in appearance when treated with alkali. A further characteristic, which however can only be seen in transverse sections, is that the epidermal cells in Bombay mace are radially elongated whilst in the case of the other two varieties the elongation is tangential.

Chemical tests for the presence of Bombay mace are also available (Schneider, J. Pharmacol. 4, 57; Hefelmann, Pharm. Zeit. 1891, 122; Busse, Zeitsch. Nahr. u. Genussm. 1904, 590).

For the estimation of Bombay mace in the presence of Banda mace, provided that Macassar mace be absent, the determination of the fixed ether extract will afford a fair basis for calculation. Soltsien (Zeitsch. öffentl. Chem. 3, 253) recommends a preliminary extraction with light petroleum, the extract thus obtained being ten times greater from Bombay than from Banda mace.

The information thus obtained should be supplemented by comparison, under the microscope, of the sample with a mixture of Banda and Bombay maces in the proportions indicated. If there is a great discrepancy in the number of the characteristic orange-coloured oil cells the presence of Macassar mace may be suspected. The following test for this variety may also be applied (Griebel, Zeitsch. Nahr. Genussm. 1909, 202):—

Shake up 0·1 gram of the sample with 10 c.c. of light petroleum for 1 minute, filter and mix 2 c.c. of the filtrate with 2 c.c. of glacial acetic acid, and add concentrated sulphuric acid so as to form a layer under the acetic acid solution. In the presence of not less than about 20 p.c. of Macassar mace a red ring forms at the junction of the two layers, within two minutes. Banda mace similarly treated yields only a yellow ring within the same period, whilst Bombay mace produces no colour at all. Comparison experiments with samples of known authenticity should always be made.

Further confirmation of the presence of Bombay mace may be obtained by estimating the essential oil, preferably by Cripps's process (Analyst, 1909, 519), and the characters of the fixed oil may also be of use. These are shown in the following table (Spaeth, *ibid.* 1895, 200):—

RESULTS OF EXAMINATION OF THE FIXED OIL OF MACE.

	Melting point	Saponification number	Iodine number	Refraction index	Meissl number
True mace	25·0° to 26·0°	169·9–173·0	75·6–80·8	1·48–1·487	4·1–4·2
Macassar mace					—
Bombay mace	31·0° to 31·5°	189·4–191·4	50·4–53·5	1·463	1·0–1·1

Standards.—The standard fixed by the United States Department of Agriculture is as follows: Mace should contain not less than 20 nor more than 30 p.c. of fixed ether extract; not more than 3 p.c. of total ash; not more than 0·5 p.c. of ash insoluble in hydrochloric acid; and not more than 10 p.c. of fibre.

Soltsien (Zeitsch. öffentl. Chem. 3, 253) suggests that the ether extract after removal of the fat by light petroleum should never exceed 5·5 p.c. C. H. C.

MACE OIL *v.* OILS, ESSENTIAL.

MACLURIN *v.* OLD FUSTIC.

MADDER. Madder is the ground root of the *Rubia tinctorum* (Linn.), and has been cultivated for dyeing purposes from a remote antiquity, so remote indeed that one is unable to say with certainty from which countries it originated. It is known to have been employed by the ancient Egyptians, Persians, and Indians, probably by the latter in the first instance, and more recently by the ancient Greeks and Romans. About the time of the Crusades the cultivation of madder was introduced into Italy and probably also into France. The Moors cultivated it in Spain, and during the 16th century it was brought to Holland. Colbert introduced it into Avignon in 1666, Frantzen into Alsace in 1729, but only towards 1760–1790 did it become important. During the wars of the Republic, its cultivation was largely abandoned, and only after 1815 did this again become regular.

Owing to the beauty and fastness of the tints it yields, and the variation in colour that can be produced from it by a variation in the mordant, it was considered until recently as perhaps the most important dyestuff known. Although the commercial value of this product has been reduced to a minimum, through the introduction of artificial alizarin, it has still considerable scientific interest.

The plant is an herbaceous perennial belonging to the natural family of the *Rubiaceæ*, and its valuable portion is entirely the root, which is usually of considerable length but does not exceed an ordinary slate pencil in thickness. Old roots are richer in colour than young ones, and the plant is consequently left in the soil for at least 18 and sometimes for 28 months. It is subsequently removed from the soil, usually washed with water, allowed to dry in the sun or artificially by means of kilns, then finely ground and packed in casks. In certain districts, before grinding, it was stored in pits for several months, by which its tinctorial power was said to be greatly enhanced; but these and other refinements of its preparation are now of so little importance as to be hardly worthy of mention. The whole root bears in many countries the name 'alizari' or 'lizari,' whence we have the name 'alizarin.' Madder was principally cultivated in Holland, France, and Turkey, and to a less extent in Belgium, Italy, and Germany, and North and South America, but the small quantity which enters this country is principally obtained from Holland. Perhaps no substance was submitted to so much examination by the older chemists as madder, and in many of the earlier works on dyeing much space is occupied by a description of these researches.

The isolation of the most important colouring matters of madder, alizarin, and purpurin, occurred as far back as 1826 and 1828, and was due to the chemists, Robiquet and Colin; but it is a matter of doubt, whether they were successful in obtaining these substances in a state of chemical purity. By many of the earlier workers it was considered that these colouring matters did not exist as such in madder, but were present in combination with sugar or some other substance. About 1823, Kuhlmann extracted a bitter-sweet yellow amorphous compound from the root and named it xanthin, and a similar yellow substance was also isolated by Runge and Watt. In 1848, Higgin observed that if a cold aqueous solution of madder which has a deep yellow colour and an intensely bitter taste was allowed to stand for some time or was heated to 50°, it lost these characteristics, and a gelatinous flocculent precipitate was formed in which all the tinctorial power of the original infusion resided. Higgin considered, therefore, that the xanthin of madder must during this process have been converted into alizarin, and that the change was probably brought about by the action of some ferment contained in the madder, and extracted along with the xanthin by cold water. Somewhat later (1851), Schunck isolated from madder a substance which he called rubian, as a dark, brownish-yellow, transparent, amorphous hard mass, which by hydrolysis with acids or by the action of the special madder ferment, which he termed 'erythrozym' was converted into glucose, alizarin, and other substances.

The next important step was due to Rochleder, who prepared the alizarin glucoside in a crystalline condition and named it ruberythric acid. It appeared to possess the formula

$C_{20}H_{22}O_{11}$, and its hydrolysis could be represented according to the following equation:

$$C_{20}H_{22}O_{11} = H_2O + \underset{\text{Alizarin.}}{C_{14}H_8O_4} + \underset{\text{Sugar.}}{C_6H_{12}O_6}.$$

Subsequently, Schunck prepared a crystalline compound, rubianic acid, which he regarded as an oxidation product of rubian, and which proved to be identical with the ruberythric acid of Rochleder.

Finally, this portion of the subject was exhaustively examined by Liebermann and Bergami, who assigned the formula $C_{26}H_{28}O_{14}$ to ruberythric acid, and proved that its hydrolysis with acid proceeds as follows:

$$C_{26}H_{28}O_{14} + 2H_2O = C_{14}H_8O_4 + 2C_6H_{12}O_6.$$

For the preparation of the glucoside, madder (1 kilo.) is extracted with boiling absolute alcohol (8–9 litres) for 2 to 4 hours, and the mixture filtered hot. The alcoholic extract is evaporated to about one-quarter its bulk, and on cooling a yellowish-brown crystalline precipitate of the impure glucoside separates. After filtering and evaporating the filtrate still further, crystals of cane sugar separate, and by adding water to the remaining alcoholic solution impure alizarin is precipitated. In this way, according to Liebermann and Bergami, 1 kilo. of madder gave

Impure glucoside . .	50–60 grams	(5–6 p.c.)
„ sugar . .	15–30 „	(1·5–3 „)
„ colouring matter	30–40 „	(3–4 „)

The impure glucoside, which becomes resinous on drying, is dissolved in water, the solution is precipitated with lead acetate, filtered and the filtrate treated with basic lead acetate. The pink coloured precipitate is well washed, suspended in water, decomposed with sulphuretted hydrogen, and the lead sulphide which contains also the liberated ruberythric acid is collected and washed with cold water. The ruberythric acid is removed from the lead sulphide by means of boiling alcohol, the yellow extract is partially evaporated, water and some quantity of barium hydroxide solution are added, and after filtering off a white precipitate, an excess of barium hydroxide is added to the filtrate. The dark cherry-red precipitate of barium ruberythrate is dissolved in acetic acid, the solution is filtered, barely neutralised with ammonia, and then treated with tribasic lead acetate. The resulting red precipitate is washed with alcohol, suspended in alcohol and decomposed by hydrogen sulphide, and the liquid and precipitate together are heated to boiling and filtered hot. On cooling, the amber-coloured solution yields pale yellow needles of ruberythric acid which are recrystallised from hot water. The latter portion of this process, employed by Liebermann and Bergami, is due to Rochleder.

Ruberythric acid crystallises in silky needles of a pure yellow colour, melts at 258°–260°, and when strongly heated yields a sublimate of alizarin. It dissolves in caustic alkaline solutions with a cherry-red colour, which on boiling changes to violet, and on acidification a precipitate of alizarin separates. With potassium carbonate solutions, dark-red needles of potassium ruberythrate are produced. Ruberythric acid is not precipitated with lead acetate, but basic lead acetate gives a red flocculent precipitate. It possesses no dyeing power.

By the action of sodium acetate and acetic anhydride, Liebermann and Bergami obtained an octoacetyl derivative $C_{26}H_{20}O_6(C_2H_3O_2)_8$, which crystallises in yellow needles, melting at 230°.

Schunck and Marchlewski, by means of the method of Schotten and Baumann, obtained a hexabenzoyl, and a heptabenzoyl compound. The fact that ruberythric acid gives an octoacetyl derivative renders two constitutions possible for this substance, viz.:

I. 
$$C_{14}H_6O_2 \begin{cases} O{\cdot}C_6H_7O(OH)_4 \\ O{\cdot}C_6H_7O(OH)_4 \end{cases}$$

II. 
$$C_{14}H_6O_2 \begin{cases} O{\cdot}C_{12}H_{14}O_3(OH)_7 \\ OH \end{cases}$$

and of these the second is most probably correct, as an explanation is thus afforded of the well-characterised red-coloured salts which can be obtained from it.

Erythrozym, the madder enzyme, was prepared by Schunck by extracting madder with water at a low temperature (38°) and precipitating the solution with alcohol. When dried, it consisted of a brown amorphous mass. Under its influence, ruberythric acid is hydrolysed with formation of alizarin and glucose. This reaction no doubt takes place in the incompletely dried root on storing, and it is evidently due to this fact that madder was said to dye more readily after this treatment. In dyeing with madder, moreover, the presence of this enzyme will no doubt exercise a beneficial effect, because as it is frequently the practice to employ at first a cold dyebath and then to gradually raise the temperature, hydrolysis of the glucoside, which is itself devoid of tinctorial property, will thereby occur with formation of the colouring matter.

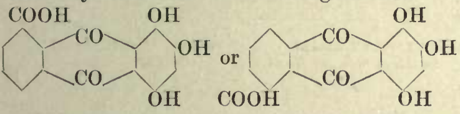
Though purpurin is considered to exist in madder in the form of glucoside, such a compound has not yet been isolated, and some uncertainty exists on this point. During some experiments carried out by the writer, it was found that an alcoholic extract of madder, on standing in cold weather, deposited a considerable quantity of cane sugar contaminated with a red precipitate. This latter was soluble in water, and on treating the solution with cold dilute acid, gave a precipitate of impure purpurin and appeared to consist of an acid calcium salt of this substance. On the other hand, it was not ascertained whether all varieties of madder behave similarly in this respect, and the matter requires further investigation. Presuming, however, that a purpurin glucoside is present in madder, it is evident that this compound is far less stable than ruberythric acid, and is hydrolysed by dilute acids at a temperature at which the latter is unaffected.

Kopp's process for the extraction of madder.—Based on this assumption, the commercial process of Kopp was devised, and this is specially interesting as it affords a fairly complete method for the isolation of the phenolic constituents of this dyestuff.

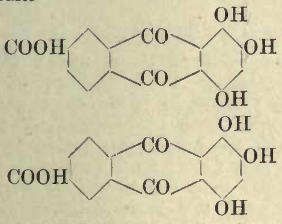
Ground madder is extracted with a cold aqueous solution of sulphurous acid, and the solution, after addition of 2 to 3 p.c. of hydrochloric acid (33 p.c.), is heated to 60°. A red flocculent precipitate of purpurin is thus thrown down which was collected, washed, dried, and sold under the name of 'commercial purpurine' or 'Kopp's purpurine.' This product is still prepared to a very small extent in France for the manufacture of a rose red lake, and for this purpose gives results differing in some respects from those produced by the artificial dyestuff.

Kopp's purpurine, in fact, is not pure purpurin, but consists mainly of a mixture of this colouring matter with three other substances: *pseudoPurpurin*, *Purpuroxanthin*, and *Purpuroxanthin carboxylic acid* or *Mungistin*.

pseudoPurpurin was first isolated from Kopp's commercial product by Schutzenberger and Schiffert, but the fact that it consists of a purpurin carboxylic acid is due to the investigation of Rosenstiehl. It consists of small red prismatic needles, and differs from purpurin in that it is more readily soluble in benzene. It melts at 218° to 220°, with evolution of carbon dioxide and formation of purpurin, and this decomposition is said to occur gradually at from 180° to 195°. Purpurin is also produced by boiling *pseudo*purpurin with dilute caustic alkali, and by long boiling with water or alcohol. The constitution of *pseudo*purpurin is represented by one of the two following formulæ:

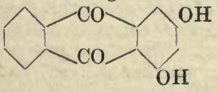


It has not been prepared synthetically, but it is interesting to observe that an isomeric compound which is obtained by the oxidation of alizarin carboxylic acid, and for which also the two formulæ



are possible, differs markedly from *pseudo*purpurin, and is an exceedingly stable compound (Perkin and Cope).

Purpuroxanthin or Xanthopurpurin, which forms glistening yellow needles, melting at 262°–263°, is a dihydroxyanthraquinone isomeric with alizarin, and was isolated from Kopp's purpurine by Schutzenberger and Schiffert. These authors also found that purpuroxanthin can be produced by digesting purpurin with phosphorus iodide and water, or by the action of a boiling alkaline stannous chloride solution on this colouring matter. The reverse action occurs, according to Rosenstiehl, when an alkaline solution of purpuroxanthin is boiled with excess of air, purpurin being thus produced. Purpuroxanthin was synthesised by Noah by heating 3:5-dihydroxybenzoic acid with benzoic acid in the presence of sulphuric acid, and possesses the following constitution:



According to Plath, the dimethyl ether melts at 178°–180°, and the diacetyl derivative (Liebermann) at 183°–184°.

Purpuroxanthin dyes aluminium mordanted fabrics a yellow colour (Schutzenberger and Schiffert).

Purpuroxanthin carboxylic acid (*Mungistin*) was discovered by Schunck and Römer in the crude purpurin. It crystallises from acetic acid in golden yellow leaflets, melts at 231°, and dissolves in alkaline solutions and ammonia with a red colouration. By heating above its melting-point or by boiling with alkalis, it is converted into purpuroxanthin. It has not been prepared synthetically, but probably contains its carboxyl group, in a similar position to that present in *pseudo*purpurin. It is said to dye aluminium mordanted fabrics an orange-red colour, which is, however, not fast to the action either of soap or light.

Green alizarin.—The sulphurous acid liquid from which the purpurin precipitate has been removed, is boiled for 2 hours, when the ruberythric acid and certain other glucosides present are hydrolysed and a deep green precipitate separates. This at one time was a commercial article, and was known under the name of 'green alizarin.'

Chlororubin.—The green tinge of this product arises from the presence in madder of a considerable quantity of a peculiar substance, possibly a glucoside, termed *chlorogenin* or *rubichloric acid*, but little or nothing is known of its chemical nature. It is also present in chay root, *Morinda* root, in certain species of *Galium* and in the *Gardenia grandiflora*. This compound, which has been obtained in the form of a colourless syrup and to which the formula $C_{14}H_8O_9$ has been assigned, on digestion with boiling dilute mineral acid, is converted into chlororubin and formic acid. Chlororubin consists of a dark green amorphous powder which is insoluble in all the usual solvents, but dissolves in alkaline solutions with a blood-red colour.

Yellow alizarin.—In order to obtain this product, the dried and finely powdered 'green alizarin' was extracted at 150° with petroleum oil (toluene or coal-tar solvent naphtha is more suitable for laboratory purposes), by which means the alizarin and other phenolic constituents pass into solution, whereas the chlororubin remains undissolved. The petroleum extract after cooling is agitated with 10 p.c. caustic soda solution, and the dark violet-coloured alkaline liquid thus produced is removed and neutralised with acid. The bright yellow precipitate was collected, washed, and dried and sold under the name of 'yellow alizarin.'

The alizarin prepared in this manner is not completely pure as it contains a small quantity of a mixture of non-tinctorial substances, which are derivatives of anthraquinone. To remove these, an alkaline solution of the 'yellow alizarin' is treated with milk of lime, which precipitates the alizarin in the form of its calcium compound. This, when collected, well washed, and decomposed with acid, gives a very pure alizarin which is best crystallised from solvent naphtha.

If the reddish-brown filtrate from the calcium alizarate is neutralised with acid, a small quantity of a dull yellow precipitate separates which is approximately equal to 0·02 p.c. of the madder employed. A preliminary examination of this product, carried out by the writer several years ago, indicated that it consisted of at least four yellow crystalline substances, with no special properties that would permit of their ready separation.

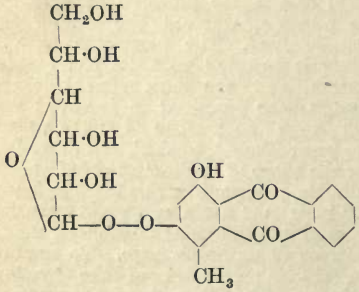
Schunck during his examination of madder obtained various yellow crystalline and amorphous products, by the action of acids and alkalis on his rubian. The individuality of most of these substances, to which the names rubiretin, verantin, rubiadin, rubianin, rubiafin, rubiagin, rubiadipin, rubidehydran, rubihydran, and rubiacic acid were assigned, has been doubted by later writers, and but one of these—namely, rubiadin—has been characterised. On the other hand, it is quite possible that certain of these may exist in the mixture of yellow non-tinctorial substances previously referred to. For a description of his compounds, the original papers of Schunck should be referred to.

Rubiadin glucoside (Schunck and Marchlewski). Madder is extracted with boiling water, the solution precipitated with lead acetate, and the filtrate treated with ammonia, by which means a second lead precipitate is formed. The latter is decomposed with sulphuric acid, the lead sulphate removed, and the clear liquid boiled with addition of hydrochloric acid. A dark green precipitate separates, only a portion of which dissolves in boiling alcohol. On treating the alcoholic extract with lead acetate, the alizarin present can be removed, and addition of baryta water now precipitates the barium salt of the rubiadin glucoside, which is decomposed by dilute hydrochloric acid. It crystallises from alcohol in citron yellow needles, melts at 270° with decomposition, and when hydrolysed by acid gives rubiadin and glucose

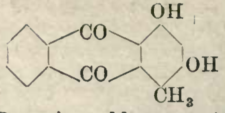
$$C_{21}H_{20}O_9+H_2O=C_{15}H_{10}O_4+C_6H_{12}O_6$$

Penta-acetylrubiadin glucoside, yellow needles, melts at 237°.

According to Marchlewski, the constitution of this glucoside is best expressed as follows:



Rubiadin, prepared by the hydrolysis of the glucoside, forms yellow needles, melting about 290°, soluble in alkalis with a red colouration. By oxidation with chromic acid it gives phthalic acid. Rubiadin, according to Schunck and Marchlewski, is a methyl purpuroxanthin and possesses the following constitution:



Rubiacin (Runge's madder orange) is a yellow crystalline substance obtained directly from the madder root, and is formed according to Schunck by the decomposition of a glucoside. It separates in small quantity from an infusion of madder made with only a little cold water, after it has become sour by 12 hours' standing. It crystallises in the form of plates and needles having a strong reddish-green lustre. Alkalis dissolve it with a purple colour.

The following table illustrates the analysis of madder by the sulphurous acid extraction method.

Madder is extracted with dilute sulphurous acid solution and the extract heated to 60°.

- Precipitate consists of Purpurin, Pseudo-purpurin, Purpuroxanthin carboxylic acid, Purpuroxanthin.
- Filtrate is digested with boiling dilute H_2SO_4, and the resulting precipitate of green alizarin extracted with boiling toluene or petroleum.
  - Chlororubin remains undissolved.
  - The toluene extract is agitated with caustic soda solution, and the alkaline liquid is treated with Baryta water.
    - Precipitate consists of calcium alizarate, which when decomposed with acid gives alizarin.
    - Filtrate on acidification gives a precipitate of yellow non-tinctorial derivatives of anthraquinone.

COMMERCIAL PREPARATIONS OF MADDER.

The principal of these were: Garancine, Garanceux, Flowers of Madder, Commercial Alizarin or Pincoffin, and Madder extract.

Garancine.—The preparation of this product results from the observation in 1827 of Robiquet and Colin, that by treating ground madder with an equal weight of concentrated sulphuric acid, the various principles of the madder were destroyed with the exception of the colouring matter alizarin. We now know further that the glucoside of the root is decomposed by the action of the acid. This first product was termed *charbon sulphurique*, but soon the method of its preparation was slightly altered, and it then received the name *garancine*.

Garancine was made by mixing, in a wooden tank with false bottom, 100 kilos. ground madder, 1000 litres water, and 2 kilos. sulphuric acid, 168°Tw. (sp.gr. 1·84), stirring up and allowing the whole to macerate for about 12 hours. The liquid is then drawn off, the residue is mixed with a little water and 30 kilos. strong sulphuric acid, and the whole is boiled for 2–3 hours. After running off the acid liquor, the garancine remaining is washed with water till free from acid, drained, pressed, dried and ground.

The colouring power of garancine is 3–4 times that of good madder, it dyes more readily, giving yellower toned reds and pinks, and greyer lilacs. They are not quite so fast to soap as the madder colours, but since, in the case of printed calicoes, the unmordanted white parts are not so much soiled in the dye-bath, the operation of soaping can be omitted.

Garanceux or *Spent Garancine* was introduced in 1843 by L. Schwarz of Mulhouse. It was simply a low quality of garancine prepared in the above manner from the spent madder of the dye-baths, and made by each calico-printer for himself, by way of economy. Its colouring power is about one-fourth that of good garancine.

Flowers of madder was first made in 1851 by Julian and Rogner of Sorgues. It can be prepared by macerating ground madder for several hours with cold water very slightly acidulated with sulphuric acid (1–2 p.c. on the weight of madder), then washing, draining, pressing, drying, and grinding. In this manner all soluble, mucilaginous, and sugary matter, &c., is removed, decomposition of the glucoside by fermentation occurs, and the residue has nearly double the colouring power of the original madder. The waste liquors were neutralised, allowed to ferment with the addition of yeast, and then distilled to gain the alcohol. 100 kilos. madder yielded 45–60 kilos. flowers of madder and 10 litres alcohol, suitable for making varnish, &c.

Commercial Alizarin or *Pincoffin* was introduced in 1852 by Schunck and Pincoff, who prepared it by submitting ordinary garancine to the action of high pressure and superheated (150°C.) steam. By this treatment the verantin and rubiretin present in the garancine were said to be destroyed, while the alizarin remained intact, and the product yielded in consequence more brilliant purples, and less soaping was required to clear the whites or unmordanted portions of printed calicoes.

Madder extracts.—Already in 1826, attempts were made by Gaudin to apply mordants along with the colouring matter of madder directly to calico, in the form of an extract, *i.e.* as a steam-colour, instead of by dyeing, and in 1837 Gastard succeeded in doing this successfully on a large scale by means of a product named *colorine.* The expense, however, of this and other early madder extracts retarded their application, but, their utility having been clearly demonstrated, the endeavours of numerous chemists were directed to their production in a reasonably cheap manner. Madder extracts consisted of variable mixtures of the two colouring matters of madder, alizarin and purpurin, or of each separately, in a more or less pure condition. Since the introduction of artificial alizarin, just when their manufacture had been perfected, they lost all their importance. The following were the chief methods of production employed.

Leitenberger's process consisted in first extracting all the purpurin from ground madder by water heated to 55°C., and afterwards dissolving out the less soluble alizarin from the dried residual madder by means of wood-spirit. The aqueous solution was precipitated by lime, the washed calcium-purpurin lake was then decomposed with hydrochloric acid, the liberated purpurin collected and washed, when it was ready for use. The alcoholic solution of alizarin was merely precipitated by water, collected and washed. Alizarin and purpurin extracts were thus obtained.

Paraf's method (1868) consisted in extracting madder with superheated water, with or without the addition of a small quantity of alum or sulphuric acid, then collecting and washing the flocculent alizarin precipitate which separated out on cooling.

The preparation of Kopp's 'purpurine,' 'green alizarine,' and 'yellow alizarine' are given earlier in this article.

Pernod's madder-extract, once largely used, was prepared by extracting garancine with boiling water very slightly acidified with sulphuric acid, collecting and washing the precipitate thrown down on cooling, and extracting the dried precipitate with boiling alcohol. After recovering the major portion of the alcohol by distillation, the remaining solution was mixed with water, and the precipitated alizarin was collected and washed.

USE OF MADDER IN DYEING.

Previous to 1870, madder and its derivative garancine were the dyestuffs *par excellence* of the calico-printer and Turkey-red dyer.

By the former, it was used because of its characteristic property of yielding a variety of colours with the aluminium, tin, and iron mordants, viz. red and pink, orange, lilac and black; also brown or chocolate, by employing a mixture of aluminium and iron mordants. Further, all these colours are fast to soap and light. To the calico-printer both the alizarin and the purpurin of the madder were of use, though undoubtedly the alizarin would, in most styles of work, be the essential colouring matter. The Turkey-red dyer employed madder, and afterwards garancine, because they yielded, by his peculiar process, the most brilliant and most permanent red on cotton which was known. In this case the alizarin was the all-important colouring matter, since the purpurin, although fixed on the fibre at first, was modified and more or less removed during the operations of clearing, no doubt chiefly by the action of the stannous salts employed. Alizarin, in conjunction with aluminium and iron mordants, gives a bluish-red and a comparatively bright lilac; purpurin, a yellowish-red and a greyish-lilac, respectively.

The method of applying madder in Turkey-red dyeing was similar to that now employed in the case of alizarin.

Another interesting feature in connection with the application of this dyestuff is that, if the madder was deficient in lime, it was necessary to add a certain proportion of chalk to the dye-bath; it now appears that calcium is a normal constituent of the madder colours, especially those obtained with aluminium and iron mordants.

Madder has also been used in the past, and is even now employed to a small extent, by the indigo dyer and the woollen dyer.

MADDER CAMPHOR *v.* CAMPHORS.

MADDER LAKE *v.* LAKES.

MAFOUREIRA NUT. A nut imported from Portuguese East Africa containing about 60 p.c. of fat, solid at ordinary temperatures and consisting mainly of palmitin and olein, together with some free fatty acids, chiefly oleic acid. Used in the manufacture of lubricants, soap, and candles. The supply is practically unlimited, the tree bearing the nut growing wild all over the country.

MAGDALA RED *v.* AZINES.

MAGENTA *v.* TRIPHENYLMETHANE COLOURING MATTERS

MAGISTERY. The term magistery was employed by the older chemists to denote the white precipitates which form on the addition of water to strongly acidified solutions of certain metals.

MAGISTRAL. An old medical term signifying a sovereign remedy, employed by the Spanish smelters of Mexico and South America to the roasted and powdered copper pyrites, which is added to the stamped silver ores in the *torta* or magma, obtained in the *patio* process of decomposing horn silver (*v.* SILVER).

MAGMA. A pasty or semifluid mixture. Applied in medicine to the residuum obtained after expressing certain substances to extract the fluid parts of them, or after treating a substance with some menstruum; a thick ointment or confection (Dunglison).

MAGNALIUM. An alloy of magnesium and aluminium (*v.* ALUMINIUM).

MAGNESIA ALBA. A hydrated basic magnesium carbonate (*v.* MAGNESIUM).

MAGNESIA NIGRA. An old name for native manganese dioxide (*v.* MANGANESE).

MAGNESITE, a mineral consisting of magnesium carbonate $MgCO_3$, and belonging to the calcite group of the rhombohedral carbonates. To French mineralogists it is known as giobertite or baudissérite, the name magnésite being applied by them to meerschaum. Crystals are of rare occurrence: they usually have the form of the primary rhombohedron, parallel to the faces of which are perfect cleavages. The angle between the faces of this rhombohedron is 72° 36′ (the corresponding angle in calcite being 74° 55′). Sp.gr. of crystals, 3·1; hardness. 4. More often the mineral occurs as dull white, compact or earthy masses, with the appearance of unglazed porcelain or chalk. Sometimes it is crystalline and granular, then resembling saccharoidal marble. Analyses of massive material show 85 to 96 p.c. $MgCO_3$, with calcium and iron carbonates and often a little silica. A ferriferous variety is known as breunnerite or brownspar.

The mineral occurs as an alteration product of olivine-rocks and serpentine; but in some instances (*e.g.* in the Alps) it has been produced by the action of solutions of magnesium hydrogen carbonate on limestone. Deposits have been worked commercially in Eubœa in the Grecian Archipelago, Veitsch in Styria, and several other places in the eastern Alps, the 'Chalk Hills' near Salem in Madras, in several counties of California, at Grenville in Quebec, and recently in the Transvaal.

Magnesite is used for the preparation of Epsom-salts and other salts of magnesium, and for the production of carbon dioxide. Calcined magnesite is made into refractory bricks for lining basic steel furnaces and electric furnaces. The strong cement made by mixing calcined magnesite with magnesium chloride is employed for the construction of fireproof partitions, flooring, artificial stone, tiles, emery-wheels, grindstones, &c. Other applications of magnesite are in the manufacture of paper and paint, and as a non-conducting covering on boilers and steam-pipes. L. J. S.

MAGNESIUM. Sym. Mg. At.wt. 24·32. The compounds of magnesium most widely occurring in nature are *magnesite* $MgCO_3$, *kieserite* $MgSO_4,H_2O$, *kainite* $MgSO_4{\cdot}KCl,6H_2O$, *carnallite* $MgCl_2{\cdot}KCl,6H_2O$, and the many silicates, as *enstatite, talc, meerschaum, augite, olivine,* and *serpentine.* Together with calcium it frequently occurs in huge mountain masses as *dolomite* $(MgCa)CO_3$. The sulphate $MgSO_4,7H_2O$ is one of the principal saline constituents of many springs, and the chloride occurs in sea water.

Preparation of the metal.—Magnesium, in an impure state, was first obtained by Davy in 1808 by electrolysis, and also by reducing the oxide in a current of the vapour of potassium. In 1830, Bussy obtained it in larger quantity and in a purer form by heating anhydrous magnesium chloride to redness with potassium. On dissolving out the residual chlorides the metal was obtained as a powder which could be readily fused into globules. Bunsen subsequently prepared it by electrolysis of the fused chloride, using a battery of ten zinc-carbon cells. The operation was conducted in a porcelain crucible, of which the upper part was divided by a vertical partition, ground to the right size out of an ordinary crucible lid. The crucible was fitted with a tile cover, through which the poles of gas carbon were inserted, one on each side of the partition. The negative carbon pole was cut like a saw, in such a manner as to form overhanging ledges, under which the light magnesium collected, and was thus prevented from floating to the surface and burning at the high temperature employed.

As the anhydrous chloride is difficult to prepare, Matthiessen improved the process by substituting a mixture of three equivalents of potassium chloride with four of magnesium chloride. A little ammonium chloride is added, the mixture fused and electrolysed in Bunsen's apparatus; it is, however, unnecessary to cut the negative pole, as the magnesium is heavier than the fused mixture. In small quantities, the metal may be readily obtained by electrolysing this mixture in a clay tobacco pipe heated over a lamp, the negative pole being formed by an iron wire inserted down the stem, and the positive by a piece of gas-carbon just touching the surface of the fused mass.

Manufacture.—The first steps towards the preparation of magnesium on an industrial scale were taken by Deville and Caron, whose process essentially consisted in heating a mixture of anhydrous magnesium chloride, fluorspar, and sodium. In the earlier experiments 600 grams of the fused chloride, 480 grams of finely-powdered fluorspar, and 230 grams of sodium in small pieces were employed. The fused magnesium chloride is obtained by evaporating to dryness a mixed solution of magnesium and ammonium chlorides, and fusion of the residue. Magnesium chloride alone cannot be fused without decomposition, hence the use of the ammonium chloride, which prevents this.

The dry mixture, in the proportions mentioned, is then introduced into a red-hot earthen crucible and the cover pressed down by a weight while the violent reaction occurs. When all action ceases, the contents are stirred with an iron rod, which causes the minute globules of metal to coalesce. After being left to cool, all the magnesium may be collected as a ball upon the rod before the melt becomes solid. The metal is then hammered to free it from slag, and should amount to about three-fourths of the theoretical equivalent of the sodium used.

Wöhler subsequently showed that the troublesome preparation of the anhydrous chloride may be avoided by using instead a mixture of magnesium chloride with one-sixth of its weight of sodium chloride, or of a mixture of sodium and potassium chlorides.

Deville and Caron also showed that the metal may be distilled at nearly the same temperature as zinc, in carbon-lined vessels, in an atmosphere of hydrogen, and were thus enabled to obtain it in a very pure form, free from carbon, silicon, and nitrogen.

Sonstadt, in 1863, introduced a few improvements in the process of Deville and Caron. An iron crucible was substituted for the earthen one, and the mixture used consisted of magnesium and sodium chlorides with one-fifth its weight of sodium. The heating is continued for about half an hour after the whole crucible has been raised to full redness.

In a later patent, Sonstadt extends the whole process to a manufacturing scale, and adopts an enlargement of Deville and Caron's method of purification by distillation. The 'magnesium still' consists of two wrought-iron vessels placed vertically over each other; the upper one serves as the crucible, and is connected with the lower one, which acts as receiver, by means of an iron condensing tube, which projects upwards into the crucible to within an inch of the lid. The whole apparatus can be rendered air-tight. The crucible filled with crude magnesium to the level of the top of the tube is fixed in a furnace and surrounded by fuel; the receiver is fitted into a recess of the fire grating, and projects below. Before commencing the distillation, the wrought-iron lid is screwed down, and the air displaced by a current of hydrogen or coal-gas. The receiver is cooled by external application of water. The crucible is maintained at an almost white heat until the operation is complete. The whole apparatus is then removed from the furnace and cooled; on taking to pieces, the magnesium is found as a solid mass in the receiver. This may then be remelted and cast into ingots.

Magnesium was formerly prepared on a large scale in this country by the Magnesium Metal Company, at Patricroft, near Manchester.

Von Püttner (Eng. Pat. 1031, Jan. 24, 1885) prepared the metal by a process very like the reduction of zinc, which metal magnesium very closely resembles. The magnesium mineral is first treated so that the metal is present entirely as oxide. This is then intimately mixed with carbonaceous matter, to which may advantageously be added oxide of iron, and heated to whiteness in retorts. The vapourised metal is condensed and collected in receivers similar to those used in the zinc manufacture.

Gerhard and Smith (Eng. Pat. 16651, Dec. 19, 1884) describe a process for the electrolytic deposition of magnesium as follows. Magnesium ammonium sulphate is prepared by crystallising together 228 parts of magnesium sulphate and 132 parts of ammonium sulphate. This is dissolved in 35,000 parts of water, and the electrodeposition is effected in this solution at a temperature from 150° to 212°F. If a white metal is desired, a nickel anode is employed; for magnesium bronze, a copper anode. In the latter case the most suitable bath is formed by dissolving 360 parts of magnesium ammonium sulphate, 550 parts of potassium cyanide, and 550 parts of ammonium carbonate in 35,000 parts of water.

According to J. W. Swan (J. Soc. Chem. Ind. 20, 666), the electrolytic method has superseded the chemical method. The electrolyte used is carnallite. The principal factory is at Hemelingen, Germany. Most of the recent patents deal with the form of the electrolytic cell. Briefly the details of the process, according to Borchers, are as follows. An anhydrous electrolyte consisting of chlorides having the composition corresponding to the formula $MgCl_2{\cdot}KCl{\cdot}NaCl$ is prepared by heating the crystallised salts in an iron pan. Magnesium chloride cannot be used alone, as it decomposes on heating with the liberation of hydrochloric acid and the formation of oxychloride. This reaction takes place to a certain extent in spite of the presence of the alkaline chlorides; and if the oxide is not removed as also any magnesium sulphate present, the globules of magnesium formed during electrolysis fail to unite to form a clean metal. The sulphate is therefore decomposed after fusion of the chlorides by stirring in some carbon or sawdust, when oxide is produced. The oxide is then converted to chloride by the addition of ammonium chloride, when a clear bath should result. The fused mass is then emptied into the electrolytic cells which are usually of iron and form the cathode. The anode is a carbon rod surrounded by a porcelain cylinder and cap from which a tube passes for leading off the chlorine. The apparatus is kept in a furnace and the temperature is maintained somewhat above the melting-point of magnesium. The current density is about 1000 amperes per square metre with a pressure of 7 to 8 volts. The resulting metal and salts are poured into a mould, and after cooling the buttons of magnesium are separated and remelted with pure carnallite in an iron crucible, the temperature being raised until the magnesium floats on the flux, and is so liquated from impurities. The magnesium is ladled off, remelted, and poured into ingots.

Properties.—Magnesium is a brilliant white metal resembling silver. When heated *in vacuô* to the temperature of the softening of porcelain it sublimes, and deposits itself upon the cooler parts of the vessel in beautiful silver-white crystals (Dumas, Compt. rend. 90, 1027). During the heating it gives off about one and a half times its volume of gas; 20 grams of the metal yielded 12·3 c.c. of hydrogen and 4·1 c.c. of carbon monoxide. The faces of the crystals are often curved and the edges rounded; the usual form is a regular hexagonal prism, the basal planes being less brilliant than the prism faces. The angle of the corresponding rhombohedron is 80° 3′, and is intermediate between those of zinc and arsenic (Des Cloizeaux, Compt. rend. 90, 1101). Its sp.gr. is 1·74–1·75. It melts just below 800° (V. Meyer, Ber. 20, 497), and the boiling-point is a little higher than that of zinc. It preserves its silvery lustre in dry air, but soon tarnishes in moist air owing to the formation of a film of hydrated oxide. It is readily malleable, but only ductile at high temperatures. On the large scale it is usually pressed into wire while in a state of semi-fluidity. This is then flattened into ribbon, in which form it is most employed. It burns when heated in a flame in air with an intense white light, very rich in the chemically active violet rays; hence its use in photography. According to Roscoe, a burning magnesium wire of 0·297 mm. thickness evolves as much light as 74 stearin candles of which five go to the pound. The light of burning magnesium is also employed in signalling and pyrotechny. For the production of the so-called 'Bengal lights,' the following mixtures are recommended. For white fire, 1 part shellac is fused with 6 parts barium nitrate, the fused mixture ground and mixed with 2·5 p.c. of powdered magnesium. For red fire, 1 part shellac is fused with 5 parts strontium nitrate, and the ground mass mixed with 2·5 p.c. of magnesium. These mixtures may either be made into ribbons about a finger's breadth or may be charged into thin zinc tubes so as to serve as torches. On burning the zinc case burns along with the mixture.

The strength of magnesium has been determined at the mechanical experimental station at Charlottenburg, and shown to be very considerable. Its breaking coefficient for tensile strain per square mm. is 23·2 kilos.; specific resistance to compression, 27·2 kilos. per square mm.; bending strength, 17·4 kilos. At a temperature of 450° it can be rolled, pressed, worked, and brought into complicated forms. Screws and threads of magnesium are considerably sharper and more exact than those of aluminium (J. Soc. Chem. Ind. 6, 730).

Magnesium has no action on pure water, but in presence of a trace of platinum chloride it decomposes water rather quickly, evolving hydrogen and forming magnesium hydroxide. Platinised magnesium constitutes a good deoxidising agent; it reduces nitrobenzene, for instance, completely to aniline (Ballo, Ber. 16, 694). Dilute acids rapidly dissolve it with violent evolution of hydrogen; with dilute hydrochloric acid it inflames when first thrown in. Strong sulphuric acid acts slowly, and a mixture of this acid with fuming nitric acid has no action upon it at ordinary temperatures. Solutions of caustic alkalis have no action upon it, but, heated with solutions of ammonium salts, it evolves hydrogen and dissolves, forming a double salt of ammonium and magnesium. Aqueous solutions, however, of acid sodium or potassium carbonates, as well as solutions of carbonic acid, dissolve the metal with evolution of hydrogen (Ballo, Ber. 15, 3003). Magnesium burns when heated in chlorine gas or bromine vapour, and especially brilliantly in the vapours of sulphur and iodine. It combines at determinate temperatures, when in a finely divided state, with sulphur, phosphorus, and arsenic, and at a red heat decomposes oxides of carbon, sulphur dioxide, and many hydrocarbons. Silica and boric acid are readily reduced by it. It combines directly with nitrogen, forming a crystalline nitride Mg_3N_2. It precipitates nearly all the metals from their neutral solutions in the metallic state; aluminium, uranium, and chromium as oxides.

Magnesium may be advantageously employed in place of zinc in toxicological investigations, owing to its freedom from arsenic. It may likewise be used instead of zinc in voltaic batteries, owing to its higher electromotive force (Roussin, J. Pharm. Chim. [iv.] 3, 413).

Alloys.—Magnesium forms malleable alloys with potassium and sodium, which decompose water at ordinary temperatures. 15 parts of magnesium form with 85 parts of tin a brittle lavender-coloured alloy, which also decomposes water. An alloy with 5 p.c. of thallium is stable and more malleable than pure magnesium. With mercury, it does not appear to form an amalgam at ordinary temperatures. Alloys with aluminium, zinc, cadmium, lead, bismuth, antimony, silver, gold, and platinum have also been prepared (Parkinson, Chem. Soc. Trans. 1867, 125) by fusing the metals together in a current of hydrogen, or by fusion in an earthen crucible under a flux of equal parts fluorspar and cryolite, or one part fluorspar with two parts of common salt. The magnesium was attached to the end of an iron rod and well stirred among the other metal, otherwise, being so light, it would float to the top. Triple alloys were also obtained with bismuth and copper, copper and gold, and with copper and nickel. All these alloys are brittle, showing a granular fracture, and are unfortunately too easily alterable for use in the arts.

Magnesium oxide. *Magnesia.* MgO. This is the product of the combustion of magnesium in air or oxygen. It is also formed when the carbonate or nitrate is heated in the air. As thus obtained, it is a white amorphous powder, but may be obtained crystallised in cubes and octahedra by heating the amorphous form in a current of hydrogen chloride. If ferric oxide be mixed with the magnesia, brilliant black octahedra of magnoferrite $MgO{\cdot}F_2O_3$ are formed, together with octahedra of MgO, slightly yellow in colour, due to oxide of iron, and identical with those of *periclase*, a mineral found at Monte Somma, near Vesuvius. Moissan obtained transparent crystals of magnesia, sp.gr. 3·654, by distillation of the oxide in the electric furnace. Ordinary magnesia is known in commerce as *magnesia usta* or calcined magnesia, and is much used for medicinal purposes. It is a fine bulky powder of sp.gr. 3·07 to 3·2. The sp.gr. is increased to 3·61 by heating in a pottery furnace.

It is only fusible at the temperature of the oxyhydrogen blowpipe flame, and on again solidifying forms a hard enamel, which scratches glass. It is alkaline to litmus, but is not caustic. It is almost insoluble in water; according to Fresenius, it requires 55,368 parts of either cold or boiling water to effect solution. This solution has an alkaline reaction. Magnesia containing 0·1 p.c. of chromic oxide becomes slightly fluorescent after ignition.

Manufacture.—Magnesia is generally obtained commercially by gentle but prolonged heating of the carbonate or by heating the hydoxide. Since the discovery, however, of the immense stores of carnallite, the double chloride of potassium and magnesium, in the saline deposits of Stassfurt, several processes have been patented for utilising the waste magnesium chloride liquor obtained as by-product in the manufacture of potassium chloride.

Schlœsing, in 1881 (Compt. rend. 93, 156, 215), describes the following process for obtaining cheap magnesia. A paste of slaked lime and water containing 34–36 p.c. of calcium oxide is allowed to run through perforations in a metallic plate into a solution of magnesium chloride containing 60–95 grams per litre. As soon as the lime paste reaches the solution it becomes coated with a layer of magnesium hydroxide, which acts like a shell, causing it to form long threads, which are entirely converted into magnesium hydroxide in about 6 days. The hydroxide thus obtained may be washed by diffusion, and, when triturated with water and dried, gives a compact, friable powder, which can of course be converted into calcined magnesia by heating in a suitable furnace. Presence of common salt has no effect on the value of the process, but if soluble sulphates are present, they must be removed by adding some of the calcium chloride solution from a previous operation, allowing to settle, and decanting from the more insoluble calcium sulphate.

Ramdohr, Blumenthal, & Co. in 1881 patented the following process (D. R. P. 19259, Sept. 1881). A solution of magnesium chloride is evaporated until it consists approximately of $MgCl_2,6H_2O$. About 4–10 p.c. of magnesite is added, and the mixture heated to redness in a current of air until the evolution of hydrogen chloride ceases. Magnesium oxychloride is left, which, on heating with water, splits up into magnesium hydroxide and chloride.

The United Chemical Works Joint Stock Co., Leopoldshall, in 1882, patented the following process (D. R. P. 20277, Feb. 1882). Burnt lime is treated with a solution of calcium chloride. After removal of the clear liquid, the paste is washed with a fresh solution of calcium chloride, whilst the clear solution in turn is repeatedly digested with fresh lime. A small portion of this solution is then mixed with the magnesium chloride solution in order to precipitate all the iron and sulphuric acid which it contains. The purified magnesium solution is then added to the bulk of the clear calcium solution, which contains calcium oxychloride $3CaO{\cdot}CaCl_2,16H_2O$, when pure hydrated magnesium oxide separates out.

On account of its infusibility, magnesia is now extensively used in the manufacture of firebricks, especially for use in the basic Bessemer steel process. The bricks are made of crushed dead-burnt magnesite mixed with sufficient gently calcined magnesite to give plasticity to the paste formed by mixing the materials with water to permit of moulding. The bricks are fired at a red heat before use.

Dolomite has also been extensively used for this purpose. Closson's plan was to mix calcined dolomite with a solution of magnesium chloride when calcium chloride and magnesia are formed; the calcium chloride can then be washed out. Many other wet methods for the recovery of magnesia have been employed, but, according to Wedding, magnesia prepared in the wet way, though obtained from cheap waste materials or by-products, is too expensive for the manufacture of bricks.

Magnesia, in combination with lime, also finds an extended use for mortar making in districts where only magnesium limestone is available. The dolomitic limestone is burnt at a lower temperature than ordinary limestone, otherwise its hydrating properties and consequently the quality of the mortar are impaired.

Magnesium suboxide. A substance of this nature appears to be formed when a solution of sodium or ammonium chlorides is electrolysed, using poles of magnesium wire, the positive pole becoming covered with a black deposit (Beetz, J. 1866, 172). The same substance is also obtained when magnesium is immersed in solutions of chlorides of the alkalis and alkaline earths, common salt giving the largest deposit. In a few days it disappears, being replaced by the ordinary white oxide. It turns white when heated just below redness. It dissolves in nitric acid with partial reduction of the acid. It readily dissolves in hydrochloric and sulphuric acids with effervescence, forming the ordinary chloride and sulphate (Gore, Chem. News, 50, 157).

Magnesium hydroxide $Mg(OH)_2$ occurs native as the mineral *brucite*, crystallising in the rhombohedral section of the hexagonal system. The hydroxide is precipitated as a white powder when the hydroxide of potassium or sodium is added to the solution of a magnesium salt. De Schulten (Compt. rend. 101, 72) obtained it in the form of flattened hexagonal prisms, of sp.gr. 2·36 at 15°, by heating a mixture of 12 grams crystallised magnesium chloride $MgCl_2,6H_2O$, 340 grams of potash, and 60 c.c. of water, at 210°–220°. The solid residue, after washing away the alkali, consisted of these small crystals of the hydroxide. They were readily soluble in acids and in a warm solution of ammonium chloride.

Magnesium hydroxide slowly absorbs carbon dioxide from the air. At a low red heat it loses its water, becoming converted into the oxide. This calcined magnesia is again capable of taking up water, with evolution of heat, to reform the hydroxide.

Magnesium hydroxide is much used upon the Continent for extracting sugar from molasses; it forms an insoluble granular crystalline magnesium saccharate, which when decomposed by carbon dioxide yields pure sugar.

In order to meet this demand, the Consolidated Alkali Company of Stassfurt manufacture large quantities of magnesium hydroxide by the following process. The 3 p.c. of sulphates contained in the last mother liquor from the extraction of potassium chloride from carnallite are first removed by means of a solution of calcium chloride. A quantity of milk of lime is then added rather less than sufficient to decompose the whole of the magnesium chloride; the precipitated magnesia is allowed to settle and then passed through filter presses, in which it is thoroughly washed. The magnesium hydroxide thus obtained contains only 0·1 p.c. of calcium sulphate, and is eminently suitable for the purpose of the sugar refiner (Hake, J. Soc. Chem. Ind. 2, 149).

Magnesia prepared by heating the nitrate is converted by prolonged immersion in water into a form of the hydroxide having the density of marble, but harder and more translucent. A similar form, but contaminated with oxide of iron and aluminium, magnesium carbonate and sand, is also obtained by action of water upon the product of the ignition of commercial magnesium chloride. This singular property of hardening is only possessed by magnesia prepared by ignition of the nitrate or chloride at a moderate red heat. After heating to whiteness it appears to lose it. Ignition of native magnesite at the lowest possible temperature also yields a product possessing the same hydraulic property, but the basic carbonates of commerce yield a perfectly soft hydroxide. The paste prepared from calcined magnesite and water hardens in about half a day, and afterwards not only withstands the action of water, but actually acquires in contact with it the hardness of the best Portland cement.

A mixture of magnesia with a concentrated solution of magnesium chloride of sp.gr. 1·16–1·26 hardens in a short time to a compact mass of basic chloride, which resists the action of water. The pasty mixture is very plastic, and is capable of binding more than twenty times its weight of sand.

Magnesium chloride $MgCl_2$ is one of the salts present in sea-water and the water of many springs. It also occurs combined with potassium chloride in large quantities as the mineral *carnallite* $MgCl_2{\cdot}KCl,6H_2O$ in the Stassfurt deposits. It is formed when magnesium burns in chlorine, or when a stream of chlorine is passed over a heated mixture of magnesia and carbon. It is also produced by dissolving the metal, oxide, or carbonate, in hydrochloric acid. On concentration of the solution monoclinic crystals of the composition $MgCl_2,6H_2O$ separate out. Crystals of this composition have also been discovered, associated with carnallite and rock salt, at Stassfurt, and named *bischofite*. On attempting to obtain the anhydrous chloride by ignition of these crystals, hydrochloric acid is evolved in addition to water, and a portion of the chloride becomes converted to oxide. If, however, the crystals be heated in a current of hydrogen chloride, the anhydrous chloride is obtained without the formation of any basic salt (Hempel, Ber. 21, 897). Another method of obtaining the anhydrous chloride is to add ammonium chloride to the solution, evaporate to dryness, and ignite in a platinum dish. The magnesium ammonium chloride thus formed loses its water without any decomposition of the magnesium chloride, and the ammonium chloride can then be sublimed out, leaving the anhydrous magnesium chloride as a clear fused mass, which on cooling solidifies to a crystalline solid. 100 parts of water at 0° dissolve 52·2 parts of the anhydrous chloride, with considerable evolution of heat, forming a solution of sp.gr. 1·3619 at 15° (Engel, Bull. Soc. chim. [ii.] 47, 318). At the ordinary temperature 100 parts of water dissolve about 130 parts, and at 100° about 366 parts. This solution on cooling again deposits the crystals. Magnesium chloride solution possesses a bitter taste. The solid, either anhydrous or crystals, is very deliquescent. It combines directly, with evolution of heat, with methyl and ethyl alcohols, the solutions yielding, on cooling with ice, crystals of $MgCl_2,6CH_3OH$ and $MgCl_2,6C_2H_5OH$, respectively.

Commercial preparation.—The last mother liquor obtained in the process of preparing potassium chloride from the carnallite at Stassfurt supplies as by-product large quantities of magnesium chloride. The liquor has a sp.gr. of 1·32, and contains no less than 35 p.c. of the chloride. It is first evaporated to sp.gr. 1·34, when potassium and sodium chlorides and magnesium sulphate separate out. The hot concentrated liquor is then run into casks, where on cooling it solidifies to a white translucent mass containing 50 p.c. of magnesium chloride. In this state it is largely exported to this country, being used by cotton-spinners as a thread lubricator (Hake, J. Soc. Chem. Ind. 2, 149).

Lanquetin, in 1881, patented (D. R. P. 20396) a process for preparing magnesium chloride by introducing burnt magnesite or dolomite into a solution of waste calcium chloride, and driving carbon dioxide through the mixture, when calcium carbonate separates out and magnesium chloride remains in solution.

Cochrane and Bramley, of Middlesbrough (Eng. Pat. 15498, Nov. 1886), charge hydrated magnesium carbonate into a series of closed vessels through which a solution of calcium chloride is circulated, carbon dioxide being at the same time injected. Magnesium chloride is in this case also gradually formed in solution and calcium carbonate precipitated.

Magnesium chloride may also be extracted from the mother liquor of the potassium chlorate manufacture (Muspratt and Eschellmann, Widnes, Eng. Pat. 1900, Feb. 1885).

Magnesium chloride unites with the alkaline chlorides to form crystalline double salts.

Magnesium potassium chloride $MgCl_2{\cdot}KCl,6H_2O$, the carnallite of Stassfurt, crystallises in colourless deliquescent rhombic prisms. On heating, the water is driven off without loss of chlorine, the anhydrous mixture fusing at a red heat. The native carnallite used at Stassfurt for the extraction of potassium and magnesium chlorides has the following average composition (Hake, J. Soc. Chem. Ind. 2, 149):

KCl	16·2	$CaCl_2$	0·2
$MgCl_2$	24·3	Clay and $CaCO_3$	2·1
$MgSO_4$	9·7	H_2O	28·8
NaCl	18·7		

Magnesium ammonium chloride

$$MgCl_2{\cdot}NH_4Cl,6H_2O$$

is deposited from mixed solutions of magnesium and ammonium chlorides in small rhombic crystals.

The corresponding sodium salt appears to contain only one molecule of water (Poggiale, Compt. rend. 20, 1130).

Magnesium calcium chloride, *Tachydrite*, $2MgCl_2{\cdot}CaCl_2,12H_2O$, is also found at Stassfurt in deliquescent yellowish masses.

Magnesium oxychlorides. When highly calcined magnesia is treated with a strong solution of magnesium chloride, it dries in a few hours to a hard mass of oxychloride, capable of receiving a polish. A sample prepared in this manner, and hardened by 6 months' exposure in the air, was found to consist of a mixture of $MgCO_3$ with a compound

$$MgCl_2{\cdot}5MgO,17H_2O.$$

On heating to 180° it was converted into $MgCl_2{\cdot}5MgO,6H_2O$. By prolonged treatment with water the whole of the magnesium chloride was extracted, and the compound $2MgO{\cdot}3H_2O$ left. This residual hydrate is a compact solid as hard as sandstone, possessing a brilliant surface, and taking a high polish; its cohesive power is not impaired by either cold or hot water (Bender, Annalen, 159, 341).

The crystalline deposit frequently found in bottles containing magnesia mixture (magnesium sulphate or chloride, ammonia and ammonium chloride) consists of a hydrated oxychloride $MgCl_2{\cdot}5MgO,13H_2O$. On washing the crystals with a large quantity of water the whole of the chloride may be removed, the residue consisting of hydrated oxide (Davis, Chem. News, 25, 258).

By mixing freshly calcined magnesia with a solution of magnesium chloride in a flask well corked and nearly filled with the liquid, and heating on a water-bath with frequent agitation, needle-shaped crystals of an oxychloride are formed. When washed and dried at 110° they consist of $MgCl_2{\cdot}10MgO,14H_2O$. The dry crystals are not attacked by carbon dioxide, but when moist are decomposed (Krause, Annalen, 165, 38).

When 20 grams of calcined magnesia are boiled with a solution of 400 grams magnesium chloride in 500 grams of water and the solution filtered, the filtrate deposits needles of $MgCl_2{\cdot}MgO,16H_2O$. When dried *in vacuô* they are converted into $MgCl_2{\cdot}MgO,6H_2O$. Both salts are decomposed by water and alcohol (André, Compt. rend. 94, 444).

When crystallised magnesium chloride is heated in air, an oxychloride of variable composition appears to be left, a portion of the chlorine passing away in the form of hydrochloric acid. If the chloride be heated to a sufficiently high temperature in a current of air a certain amount of free chlorine is evolved; and if a mixture of hydrogen chloride and air is passed over the heated chloride, especially in presence of a little free magnesia, a larger quantity of chlorine is obtained in the free state. This reaction forms the basis of the Weldon-Pechiney process of manufacturing chlorine, as worked at Salindres (Weldon, Eng. Pat. 9307, June, 1884; 11036, Aug. 1884). A solution of magnesium chloride is first evaporated down until it consists approximately of $MgCl_2,6H_2O$. This is then converted to oxychloride by addition of $1\frac{1}{3}$ equivalents of calcined magnesia. This oxychloride is crushed and sifted, solid pieces free from dust being eventually chosen not larger than the size of a walnut. It is next heated to remove a portion of its water, and finally decomposed by heating to a high temperature in a current of air. The furnace employed for the latter process is constructed upon the principle of a baker's oven. It consists of a series of vertical chambers, the thickness of the dividing walls of which is greater than the width of the spaces between them. Before charging these spaces with the small lumps of oxychloride, products of combustion are passed through them until the dividing walls are raised to a high temperature. After charging, the oxychloride becomes heated by contact with the walls, and a mixture of chlorine, nitrogen, excess of air, and hydrogen chloride is evolved. The hydrochloric acid is condensed in ordinary towers, and the remaining gases pass on to the bleaching powder chambers. The magnesium remains as oxide, the oxygen being furnished by a regulated supply of air, and is afterwards partly dissolved in the condensed hydrochloric acid for preparation of more oxychloride (Weldon, J. Soc. Chem. Ind. 4, 175). The reactions occurring in the process are probably as follows:

(1) $H_2O+MgCl_2=MgO+2HCl$.
(2) $2HCl+O=H_2O+Cl_2$.
(3) $MgCl_2+O=MgO+Cl_2$.

(Kingzett, J. Soc. Chem. Ind. 7, 286).

Nithack (D. R. P. May 29, 1884) decomposes magnesium chloride for the preparation of chlorine by injecting a fine spray of the solution into heated chambers, when the same reactions occur.

Mond (Brit. Assoc. 1896, 741) modified the process for recovering both ammonia and chlorine from the ammonium chloride produced in the ammonia soda process. Magnesia is mixed with a little china clay and potassium chloride to facilitate the production of a perfectly anhydrous chloride. The mixture is made into pills and placed in towers. These are heated from a previous operation to 300°; the ammonium chloride vapour is passed through, producing ammonia and magnesium chloride. Air at 600° is then circulated, when free chlorine is liberated and magnesia reformed. Hence the process becomes continuous.

Hermite (J. Soc. Chem. Ind. 7, 726, 737) prepares chlorine for bleaching purposes by the electrolysis of a solution of magnesium chloride.

Magnesium bromide $MgBr_2$ occurs in sea-water and many salt springs. It very much resembles the chloride, being deposited from a solution of magnesia in hydrobromic acid in needles of $MgBr_2,6H_2O$, which behave like the chloride on heating.

Magnesium iodide MgI_2 also occurs in sea-water and saline springs, and may be obtained by dissolving magnesia in hydriodic acid, when deliquescent crystals separate, which readily evolve iodine on warming.

Magnesium fluoride MgF_2 occurs native in the mineral *sellaïte* in colourless quadratic crystals, and may be prepared in an amorphous form by evaporating magnesia with excess of hydrofluoric acid. When the amorphous form is fused with sodium chloride and gradually cooled, it is obtained, after washing with water, in crystals resembling those of sellaïte.

Feldmann (Eng. Pat. 15295, Nov. 1887) patented a process for an industrial preparation of this salt. Magnesium chloride is treated with calcium fluoride in either the dry or the wet way. In the former the fluorspar is mixed with the anhydrous chloride in excess, and the mixture fused at a red heat, when $CaCl_2$ and MgF_2 are formed. After cooling, the mass is lixiviated, when the magnesium fluoride remains behind. In the wet method powdered fluorspar is suspended in a concentrated solution of magnesium chloride and heated till double decomposition occurs, water being added to make up the loss by evaporation. It is then allowed to cool, when the mass solidifies and is lixiviated as before. Any undecomposed calcium fluoride may be removed by elutriation from the specifically lighter magnesium fluoride.

A double fluoride of magnesium and sodium $MgF_2{\cdot}NaF$ is obtained in insoluble cubical crystals by fusing magnesium chloride with a large excess of sodium fluoride and chloride and allowing to cool slowly. Also in the amorphous state by boiling a solution of sodium fluoride with magnesia.

Magnesium carbide has not been isolated in the pure state. It is obtained mixed with carbon by heating magnesium powder to redness in the vapour of benzene (Parkinson) or acetylene (Berthelot). According to Moissan, it is completely decomposed in the electric furnace, which explains why magnesia can be fused in a carbon crucible without reaction (Ann. Chim. Phys. [vii.] 16, 151).

Magnesium carbonate $MgCO_3$ occurs native as *magnesite* in rhombohedral crystals isomorphous with those of calcite. It is also found in large compact or granular masses, and, combined with calcium carbonate, as *dolomite* $(MgCa)CO_3$, in immense quantities all over the world. The amorphous precipitate formed when an alkaline carbonate is added to a solution of a magnesium salt has the composition

$$MgCO_3,2H_2O,$$

but after standing an hour or two at a temperature below 16°, it becomes converted into tabular crystals of $MgCO_3,5H_2O$. If the temperature exceeds 22° it becomes converted into prismatic crystals of $MgCO_3,3H_2O$. Between 16° and 22° both these salts are formed. The amorphous precipitate is decomposed by water into a basic carbonate of the composition

$$5MgO{\cdot}4CO_2,11H_2O$$

or $5(MgCO_3,2H_2O)$, in which one molecule of $MgCO_3$ has been converted into $Mg(OH)_2$. This basic carbonate absorbs carbon dioxide from the air, and becomes $MgCO_3,2H_2O$ again (Engel, Compt. rend. 100, 911). According to Marignac, normal magnesium carbonate is also formed by the action of magnesium chloride on calcium carbonate.

When the precipitated carbonate is suspended in water and dissolved by the passage of a current of carbon dioxide, on evaporation of the solution the anhydrous carbonate is precipitated in minute crystals isomorphous with aragonite, the rhombic form of calcium carbonate. On the other hand, when mixed solutions of a soluble magnesium salt and an alkaline bicarbonate supersaturated with carbon dioxide are inclosed in a strong vessel closed by a cork, through which the carbon dioxide is slowly allowed to escape, microscopic rhombohedrons of the anhydrous carbonate resembling those of native magnesite and calcite are deposited.

Both the natural and artificial varieties of magnesium carbonate give an alkaline reaction with litmus solution. They dissolve slowly in acids with but little effervescence.

Magnesium carbonate dissolves in water saturated with carbon dioxide. According to Engel (Compt. rend. 100, 444, 1224) the solubility at constant temperature is proportional to the cube-root of the pressure of the carbon dioxide. The results of a large number of experiments agreed with those calculated from the general formula $x^{0{\cdot}333}=ky$ or $y=\frac{1}{k}\sqrt[3]{x}$, where x represents the pressure of carbon dioxide, y the quantity dissolved, and k a constant $=0{\cdot}03814$. At different temperatures under atmospheric pressure the amount of magnesium carbonate dissolved is proportional to the coefficient of solubility of carbon dioxide at the particular temperature. The following table is given by Engel and Ville (Compt. rend. 93, 340) showing the solubility first at constant temperature and second at constant pressure :

Atmospheres pressure	Temperature	$MgCO_3$ dissolved in a litre of water
1	19°5	25·79
2·1	19·5	33·11
3·2	19·7	37·30
4·7	19·0	43·50
5·6	19·2	46·20
6·2	19·2	48·51
7·5	19·5	51·20
9·0	18·7	56·59
mm. pressure		
751	13·4	28·45
763	19·5	25·79
762	29·3	21·94
764	46·0	15·70
764	62·0	10·35
765	70·0	8·10
765	82·0	4·90
765	90·0	2·40
765	100·0	0·00

When the solution in carbonic acid is left to evaporate spontaneously, or kept in a partially closed flask for some time at 50°, it deposits small hexagonal prisms of $MgCO_3,3H_2O$, which effloresce in air, becoming opaque. At a winter temperature the same solution deposits monoclinic prisms of $MgCO_3,5H_2O$. Warmed with water at 50°, they are converted into the trihydrate, whilst on boiling with water they lose carbonic acid and become converted eventually into the basic carbonate

$$2MgCO_3{\cdot}Mg(OH)_2,2H_2O.$$

Basic carbonates. A basic carbonate of the composition $3MgCO_3{\cdot}Mg(OH)_2,3H_2O$ occurs native as *hydromagnesite* in small white monoclinic crystals of sp.gr. 2·14–2·18. A salt of the same composition is also obtained by mixing magnesium sulphate with excess of a hot solution of potassium carbonate and boiling the precipitate with fresh quantities of water so long as acid carbonate dissolves out. Also by boiling a saturated solution of the acid carbonate, and twice boiling the precipitate produced with fresh quantities of water. When dried at 100° in the air it absorbs carbon dioxide, and is converted into $5MgO{\cdot}4CO_2,5H_2O$.

Another basic carbonate of the composition $2MgCO_3{\cdot}Mg(OH)_2,2H_2O$ is obtained as above from the solution of the normal carbonate in carbonic acid. Also, according to Fritzsche (Pogg. Ann. 37, 310), by precipitating magnesium sulphate with a very large excess of sodium carbonate and boiling till granular, then washing rapidly three times with fresh boiling water.

Commercial carbonates. The commercial preparation known as *magnesia alba* is a basic carbonate of slightly varying composition, according to the conditions of production. It is usually prepared by precipitation of either the commercial sulphate or chloride of magnesium with sodium carbonate. As thus obtained it is a very light bulky powder, and is distinguished as *magnesia alba levis.* If the precipitation is carried on at a higher temperature by the addition of one volume of a cold saturated solution of sodium carbonate to a boiling mixture of one volume of a saturated solution of magnesium sulphate with thirty volumes of water, the precipitate washed with hot water and dried at 100°, a denser form is obtained known as *magnesia alba ponderosa.* The composition of the light variety is generally given as the same as that of hydromagnesite $3MgCO_3{\cdot}Mg(OH)_2,3H_2O$. Beckurts (Arch. Pharm. [iii.] 18, 429; 19, 13), however, deduces the formula

$$5MgCO_3{\cdot}2Mg(OH)_2,7H_2O,$$

but also found several specimens of the hydromagnesite formula, but containing $4H_2O$. Kraut (Arch. Pharm. [iii.] 20, 180) gives $4MgCO_3{\cdot}Mg(OH)_2$ as the correct formula. Hence it appears likely that different samples vary somewhat in composition. As representing the composition of the heavy variety, Beckurts (*l.c.*) gives the formula $3MgCO_3{\cdot}Mg(OH)_2,4H_2O$, which only differs from that of hydromagnesite by one molecule of water.

Magnesia alba levis and *ponderosa* yield upon calcination corresponding light and heavy varieties of the oxide, known in commerce as *magnesia usta levis* and *magnesia usta ponderosa.*

Another method of preparing *magnesia alba* was patented by Pattinson. This consists in treating slightly ignited dolomite with water and carbon dioxide under a pressure of 5-6 atmospheres. So long as any magnesium carbonate remains undissolved, the calcium carbonate is unattacked, the acid magnesium carbonate being much more readily formed. This solution of hydrogen magnesium carbonate is decanted from the calcium carbonate and heated by injection of steam, when *magnesia alba* is precipitated as a white bulky powder of loose texture. Unignited dolomite does not yield any acid carbonate with carbonic acid.

Bramley and Cochrane, of Middlesbrough, patented a process (Eng. Pat. 13762, Oct. 1886) in which magnesia is added to the solution of an alkaline bicarbonate or sesquicarbonate and the mixture heated and agitated. The alkaline carbonate is converted to a normal carbonate, and hydrated magnesium carbonate formed. The operation is performed in closed vessels to prevent loss of carbon dioxide.

Magnesia alba can also be profitably prepared from sea-water (Gutzkow, Dingl. poly. J. 270, 30). The mother-liquor (bittern) obtained after extraction of common salt (bay-salt) is treated with milk of lime; the precipitated magnesium hydroxide is allowed to settle, the supernatant liquid removed by decantation, and the precipitate stirred up with water through which a stream of carbon dioxide is passed. The hydroxide is dissolved as acid carbonate. The clear solution is then heated rapidly to 70°, and afterwards more gradually to the boiling-point. The precipitated *magnesia alba* is filtered off and dried on plates heated by steam. If necessary, the original mother-liquor may first be freed from organic matter by treatment with alum.

Magnesia alba is almost insoluble in water, but dissolves readily in solutions of ammonium salts owing to the formation of soluble double salts of magnesium and ammonium and ammonium carbonate.

Magnesium ammonium carbonate

$$MgCO_3{\cdot}(NH_4)_2CO_3,4H_2O$$

separates in rhombohedral crystals from a mixture of cold aqueous solutions of magnesium sulphate or chloride and excess of ammonium carbonate and free ammonia.

Magnesium potassium carbonate

$$MgCO_3{\cdot}K_2CO_3,4H_2O$$

is obtained in small rhombic prisms when *magnesia alba* is digested with a solution of acid potassium carbonate for 15 hours at 60°–70°.

A salt of the composition

$$MgCO_3{\cdot}HKCO_3,4H_2O$$

is obtained in large crystals from a cold aqueous mixture of magnesium chloride or nitrate with excess of acid potassium carbonate. Engel (Compt. rend. 100, 1224) obtained the same salt by decomposing a solution of the acid magnesium carbonate with potassium bicarbonate, and also by direct action of the potassium bicarbonate upon normal magnesium carbonate.

Magnesium sodium carbonate $MgCO_3{\cdot}Na_2CO_3$ is similarly obtained in small anhydrous crystals by digesting *magnesia alba* with sodium bicarbonate.

Magnesium nitride Mg_3N_2. Magnesium combines directly with nitrogen when heated to redness. It is also one of the products of the incomplete combustion of magnesium in air. It is a greenish-yellow amorphous body which decomposes slowly in humid air, yielding ammonia and magnesia, rapidly in contact with water with elevation of temperature. Hydrochloric and nitric acids decompose it yielding ammonia and the magnesium salt. With sulphuric acid it yields sulphur dioxide and magnesium sulphate. Argon does not combine with magnesium.

Magnesium nitrate $Mg(NO_3)_2$ occurs in the mother-liquors of the saltpetre manufacture, and also frequently in well-water. It may readily be prepared by dissolving *magnesia alba* in nitric acid and evaporating to small bulk, when monoclinic prisms and needles of the hydrated salt $Mg(NO_3)_2,6H_2O$ separate out. These are soluble in half their weight of cold water, and also in nine times their weight of alcohol of sp.gr. 0·84, with which magnesium nitrate forms an alcoholate of the composition $Mg(NO_3)_2,6C_2H_6O$. When dried over sulphuric acid the hydrated salt loses four molecules of its water, and at the temperature of melting lead another molecule is evolved, leaving the salt $Mg(NO_3)_2,H_2O$. When this latter salt is heated to a still higher temperature the last molecule of water is given off, together with part of the nitric acid, and a trimagnesium nitrate $Mg_3(NO_4)_2$, analogous to the tri-orthophosphate, is left.

Magnesium borate. When magnesium oxide in slight excess is heated with a mixture of boric anhydride and potassium hydrogen fluoride in molecular proportions, the borate $3MgO,B_2O_3$ is obtained in transparent acicular crystals which are soluble in inorganic acids but not in acetic acid or water.

Magnesium phosphide Mg_3P_2 may be obtained by heating magnesium filings with red phosphorus (Parkinson) or by passing phosphorus vapour over magnesium filings, heated to redness, in a current of carbon dioxide. Gautier obtained it crystalline by heating red phosphorus and magnesium in a graphite boat, then driving off the excess of phosphorus in a current of hydrogen (Compt. rend. 128, 1167). It decomposes water, yielding phosphoretted hydrogen and magnesium hydroxide.

Trimagnesium orthophosphate $Mg_3(PO_4)_2$ is found in the ashes of plants and animals and occurs in nature as *wagnerite* $Mg(MgF)PO_4$ combined with fluorine. It may be prepared by adding magnesium sulphate in excess to a solution of trisodium phosphate and boiling. It is a white amorphous powder containing $5H_2O$, which on calcining loses water and becomes phosphorescent.

Di-magnesium orthophosphate $Mg_2H_2(PO_4)_2$ is formed by precipitating a solution of a magnesium salt with normal sodium phosphate. If the solution is dilute it separates in hexagonal needles containing seven molecules of water. It occurs in the fæces of man.

Ammonium magnesium phosphate

$$MgNH_4PO_4,6H_2O$$

is formed as a crystalline precipitate when sodium phosphate is added to an ammoniacal solution of a magnesium salt. The precipitate is almost insoluble in water and still less so in ammonia. It serves for the quantitative estimation of both magnesia and phosphoric acid. The compound occurs in nature in well-formed crystals known under the name of *struvite*.

Magnesium pyrophosphate $Mg_2P_2O_7$ is obtained by igniting either ammonium magnesium phosphate or the acid phosphate.

Magnesium sulphide MgS is formed by heating magnesium filings in the vapour of sulphur or sulphuretted hydrogen. So obtained it is a grey amorphous material which is difficultly fusible even in the electric furnace (Mourlot, Compt. rend. 127, 180). It is decomposed by cold water with the formation of magnesium hydrogen sulphide. In warm water it is said to form polysulphides, and on boiling, hydrogen sulphide is evolved leaving only hydrated magnesia.

Magnesium sulphite $MgSO_3$. When water containing magnesium hydroxide in suspension is saturated with sulphur dioxide, the solution concentrated *in vacuô* at a temperature below 100° and then allowed to cool, rhombohedral crystals of $MgSO_3,6H_2O$ are deposited (Hartog, Compt. rend. 104, 1793).

A basic magnesium sulphite of the composition $MgSO_3{\cdot}2Mg(OH)_2$, similarly prepared by passing sulphur dioxide into water holding magnesia in suspension, is used in sugar factories (Bergreen and Licht, Bied. Centr. 1884, 201).

Magnesium sulphate (*Epsom salts*) $MgSO_4$ occurs in the mineral *kieserite* $MgSO_4,H_2O$, in the Stassfurt salt beds; and as *epsomite*

$$MgSO_4,7H_2O$$

in the gypsum quarries of Montmartre, in Spain, Chile, and in the Mammoth Cave, Kentucky. Kieserite is occasionally found in rhombic prisms, but more generally occurs in granular masses. Epsomite is found both in the massive state and in silky fibrous crystals. Natural crystals of epsomite more than a centimetre long have also been found coating the walls of a gypsum quarry in the Department of Hérault, France. The sulphate was in a constant state of exudation, and as it solidified formed a lustrous coating of crystals upon the surface of the gypsum (De Rouville, Compt. rend. 87, 703).

Magnesium sulphate forms the purgative principle of bitter spring waters (hence its name of Bitter salt) such as those of Bath, and Seidlitz, Saidschütz, and Püllna in Bohemia. At the three latter places it is obtained by digging pits into which the bitter water runs, and allowing the solution thus collected to evaporate in shallow pans.

The magnesium sulphate of commerce is now chiefly obtained from the kieserite of Stassfurt.

The crude kieserite obtained from the upper layers (Abraumsalz) of the Stassfurt beds is first freed from magnesium and sodium chlorides by being placed in large sieves, standing in tanks of water. The two salts mentioned dissolve out, whilst the kieserite, which is very sparingly soluble in water, falls through the meshes of the sieves in a state of fine powder. Any gangue or other impurities such as anhydrite or larger lumps of rock salt remain behind in the sieves. The kieserite powder is then packed into conical wooden moulds, where it sets to a compact solid, owing to its combining with six more molecules of water to form epsomite. This solid 'stone' is then dried and afterwards powdered. In this condition it contains from 80 to 90 p.c. of $MgSO_4$ and about 1 to 2 p.c. of sodium chloride. A large quantity is brought into the market in this form. The rest is crystallised from water and brought into commerce as Epsom salts.

Another mode of manufacturing magnesium sulphate, which was almost universally employed before the working of the Stassfurt beds, consists in decomposing dolomite, magnesium limestone $(CaMg)CO_3$, with oil of vitriol. As calcium sulphate is only sparingly, while magnesium sulphate is readily soluble, the separation affords no difficulty.

The dolomite is first calcined, when on treatment of the hot mass with a small quantity of water it is readily broken up into powder. This powder is then suspended in water in large digesters constructed of wood lined inside with lead and Yorkshire flags. For a digester 6 feet square and 7 feet deep, about 3 tons of dolomite would form a convenient charge. Into this emulsion are then poured the contents of twelve carboys of sulphuric acid, and water added until the sp.gr. becomes 1·125 to 1·150. At the end of an hour, when the contents begin to cool down, steam is injected by a leaden pipe which completes the action. Excess of acid must be carefully avoided, as it causes loss in crystallising. The liquor is then run off into a settler made of lead or flags, but not of iron; after settling the clear solution is siphoned over into an iron evaporating pan, where it is evaporated down to 66° of Twaddell's hydrometer. The clear concentrated liquor stands for an hour or two to allow any suspended matter to settle, after which it is conveyed to the coolers, which are made of wood, flags, or, best of all, slate, where it is agitated so as to cause the salt to fall in small crystals. The crystals are then drained and finally dried on shelves in a stove room at a temperature not exceeding 80°F.

Magnesium sulphate is largely used in the Lancashire cotton trade in the process of warp-sizing; it is also employed for medicinal and agricultural purposes and for dyeing with the aniline colours.

The crystals have the composition of epsomite $MgSO_4,7H_2O$, and form right rhombic prisms, resembling those of the sulphates of zinc and nickel. They have a sp.gr. of 1·676 (Thorpe and Watts, Chem. Soc. Trans. 37, 106). On heating, they melt in their water of crystallisation, lose 6 molecules of water at 150° and the seventh at 200°.

A salt also having the composition $MgSO_4,7H_2O$ is occasionally deposited from cold supersaturated solutions in monoclinic prisms isomorphous with those of ferrous sulphate $FeSO_4,7H_2O$. By crystallisation of the ordinary salt above 40° monoclinic prisms of a hydrate $MgSO_4,6H_2O$, of sp.gr. 1·734, are obtained. By drying the heptahydrate over oil of vitriol to constant weight, $MgSO_4,5H_2O$, of sp.gr. 1·869 is obtained. A salt of the composition $MgSO_4,2H_2O$, sp.gr. 2·373, may also be prepared by boiling finely powdered Epsom salts with absolute alcohol. The sp.gr. of the monohydrate $MgSO_4,H_2O$ is 2·445 and that of the anhydrous salt 2·709 (Thorpe and Watts, *l.c.*).

Magnesium sulphate is readily soluble in water. According to Gay-Lussac 100 parts of water dissolve 25·76 parts of the anhydrous salt at 0° and 0·47816 parts for every degree beyond. One part of Epsom salts dissolves in 0·79 parts of water at 18·75°, forming a liquid of sp.gr. 1·2932.

The following table, due to Schiff (Annalen, 108, 336), shows the amounts of the sulphate in solutions of different specific gravities:—

Sp.gr. at 23°	Per cent of $MgSO_4,7H_2O$	Per cent. of $MgSO_4$
1·0048	1	0·488
1·0096	2	0·975
1·0193	4	1·951
1·0290	6	2·928
1·0387	8	3·904
1·0487	10	4·878
1·0587	12	5·854
1·0688	14	6·830
1·0790	16	7·806
1·0894	18	8·782
1·0997	20	9·756
1·1103	22	10·732
1·1209	24	11·708
1·1316	26	12·684
1·1426	28	13·660

1·1991	38	18·538
1·2108	40	19·512
1·2228	42	20·488
1·2349	44	21·464
1·2472	46	22·440
1·2596	48	23·416
1·2722	50	24·390
1·2850	52	25·366
1·2980	54	26·341

Magnesium sulphate also dissolves in dilute alcohol, but is insoluble in absolute alcohol.

Magnesium hydrogen sulphate $MgH_2(SO_4)_2$. If 2 parts of anhydrous magnesium sulphate are dissolved in 100 parts of boiling sulphuric acid of sp.gr. 1·7 and the solution evaporated at the boiling-point, $MgH_2(SO_4)_2$ is deposited in prisms. On cooling, an acid salt of the composition $MgSO_4{\cdot}3H_2SO_4$ crystallises out in small shining tables which fuse and decompose when heated.

Magnesium sulphate forms an isomorphous series of double salts with the sulphates of the alkali metals, of the general formula

$$MgSO_4{\cdot}M_2SO_4,6H_2O,$$

which crystallise in monoclinic prisms.

Magnesium potassium sulphate

$$MgK_2(SO_4)_2,6H_2O$$

is found in the Stassfurt salt deposits and is known as *schönite;* also as a volcanic product (*picromerite*). It is prepared by dissolving the salts in molecular proportions and crystallising. It forms monoclinic prisms.

Magnesium ammonium sulphate

$$Mg(NH_4)_2(SO_4)_2,6H_2O$$

is found in the fumeroles of Tuscany and is known as *cerbolite.* Prepared artificially it crystallises in monoclinic prisms and is isomorphous with the potassium double salt.

Magnesium silicates occur abundantly in nature and some of them have been prepared artificially. The more important silicates are the following :—

Forsterite Mg_2SiO_4 occurs in crystals in the volcanic ejections of Monte Somma. Ebelmen (Ann. Chim. Phys. [iii.] 33, 58) obtained the mineral artificially by fusing silica and magnesia in proper proportions with boric acid. The crystals obtained were similar to those from Vesuvius. Forsterite forms with the corresponding calcium orthosilicate (*monticellite*) an isodimorphous group of mixed crystals (V. Poschl, Tsch. Min. Mitt. 26, 413).

Olivine $nMg_2SiO_4+Fe_2SiO_4$ is a constituent of many basic rocks. It crystallises in the rhombic system. The olive green and bottle green crystals are used as gemstones under the name of peridote. Magnesium silicate forms isomorphous mixtures with iron orthosilicate, but there is a gap in the series (V. Poschl, *loc. cit.*).

Enstatite $MgSiO_3$ the metasilicate, occurs in nature crystallised in the rhombic system. Ebelmen (*loc. cit.*) obtained it by fusing magnesia and silica with boric acid in proportions corresponding to the metasilicate; Poschl (*loc. cit.*) has shown that it forms with diopside ($CaMgSi_2O_6$) an isodimorphous series similar to that given by magnesium sulphate and ferrous sulphate.

Sepiolite $2H_2O2MgO3SiO_2$ is a compact, earthy hydrated silicate, sometimes known as meerschaum.

Talc $H_2Mg_3(SiO_3)_4$ occurs as foliated masses, compact as steatite; the soft variety is known as soapstone or French chalk.

Serpentine $H_4Mg_3Si_2O_4$ forms large rock masses and usually contains ferrous oxide. The fibrous variety is known as *chrysotile* and comes into commerce under the general name of asbestos.

Magnesium titanate $MgTiO_3$ occurs in nature as *geikielite.*

Magnesium citrate $Mg_3(C_6H_5O_7)_2,14H_2O$ is obtained as a crystalline crust when magnesia is dissolved in slightly more than an equivalent quantity of a solution of citric acid, and the solution evaporated at about 50°. It is very soluble in water, and is often preferred to Epsom salts as a mild purgative on account of its pleasanter taste.

The citrate of magnesia of the shops, so popular as an effervescent salt, may be prepared by mixing 16 parts of sodium bicarbonate, 10½ of tartaric acid, 4 of citric acid, about 12 of sugar, ½ part of Epsom salts, and 2 parts of crystallised sodium bisulphate, and heating on an enamelled iron plate until it becomes spongy from the escape of carbon dioxide. The cooled mass is then put through sieves of four to six meshes per square inch. In this granular form it is again heated until quite dry. The solution of the granules in water, after the liberation of the carbon dioxide, contains principally citrate and tartrate of soda and sugar.

It may also be prepared by making a mixture of magnesium citrate, prepared by dissolving magnesia in citric acid solution and crystallising, with sodium bicarbonate, citric acid and sugar, and rendering granular by moistening with alcohol and drying.

The magnesia preparation called *sinodor*, used for removing unpleasant odours and for disinfecting and preserving purposes, is obtained by heating neutral magnesium acetate with magnesium oxide until the mass assumes a pasty consistency. It consists of basic magnesium acetate containing excess of magnesium hydroxide (Kubel, Pat. 18090, Nov. 1881).

Magnesium is usually estimated quantitatively by precipitating an ammoniacal solution with sodium or ammonium phosphate. The precipitate is washed with ammonia water, ignited and weighed as pyrophosphate.

G. S. B.

MAGNETIC IRON-ORE *v.* Magnetite; Iron.

MAGNETIC PYRITES *v.* Pyrrhotite.

MAGNETITE, or Magnetic iron-ore. A mineral of the spinel group, consisting of magnetic oxide of iron, Fe_3O_4 or $FeO{\cdot}Fe_2O_3$; an important ore of iron (Fe 72·4 p.c.). Sharply developed crystals with bright faces are not uncommon; these belong to the cubic system and usually have the form of the regular octahedron or the rhombic-dodecahedron. Granular to compact masses are, however, more abundant. The colour is iron-black with a dull, sub-metallic lustre and a black streak. Sp.gr. 5·18; hardness 6. The mineral may be always readily recognised by its strong magnetic character: small fragments are picked up by a magnetised knife-blade. Only occasionally are specimens magnetic with polarity (*v.* Loadstone).

As small grains and crystals, magnetite is of wide distribution in many kinds of igneous rocks, especially the darker coloured with a low silica percentage. In such rocks it sometimes forms rich segregations available for mining; as in the Ural Mountains, and at Kirunavara and Gellivara in Swedish Lapland. Other important deposits, *e.g.* some of those in southern Sweden and Norway, have been formed by the metamorphism of pre-existing iron-ores, where these have been subjected to the baking action of intrusive masses of igneous rock. Extensive deposits of magnetite are also mined in the crystalline Archæan rocks of the Adirondack region of New York and in Canada.

L. J. S.

MAGNOFERRITE *v.* Iron.

MAIZE. *Zea Mays* (Linn.). **'Indian corn'** or **'mealies.'** This plant was grown by the aborigines of America; it was introduced into Europe in the sixteenth century, and is now extensively grown in almost all countries possessing sufficiently warm climates. It grows to a height of from 5 to 12 or even 15 feet.

Many varieties of maize are known, differing greatly in size, shape, colour, and composition of the grain and in the arrangement of the grain around the cob.

The average composition of all varieties of maize has been given under Cereals.

South African, American, and Australian grown maizes contain distinctly less moisture than European samples. White and yellow are the commonest colours of the maize grain, but orange, red, blue, violet, and even black grains are known, as well as striped ones.

The separate parts of white American horsetooth maize have been analysed by Plagge and

Lebbin in 1897 (quoted by König). They obtained the following results :—

	P.c. of whole grain	In the dry matter, p.c.				
		Water	Protein	Fat	Carbohydrates	Ash
Germ . . .	11·78	6·70	13·75	29·36	46·99	7·23
Husks . . .	9·35	8·66	8·32	7·94	82·81	1·63
Horny part of starch	49·79	12·16	8·04	0·64	91·11	0·21
Mealy ,, ,,	29·08	9·68	6·46	0·93	92·97	0·34
Whole grain .		11·38	8·09	5·79	84·61	1·51

Hopkins, Smith and East (J. Amer. Chem. Soc. 1903, 25, 1166) determined the distribution of the proteids in maize grains of (*a*) low (9·89 p.c.), (*b*) medium (11·33 p.c.), and (*c*) high (12·64 p.c.) protein content. Their results were—

	(*a*)	(*b*)	(*c*)
Germ . .	19·31	20·14	18·45
Husks . .	2·75	2·07	1·85
Horny portion .	53·07	59·03	64·88
Mealy portion .	23·98	17·63	14·22
Tip caps . .	0·89	1·14	0·59

They found that the germ contained almost all the oil and about ten times the percentage of ash of the other parts of the grain. Hopkins, indeed (Bull. 55, Illinois Agric. Stat. 1899, 310), finds it possible to classify samples of maize according to their richness in protein or fat by mechanical examination only, the fat being mainly dependent upon the proportion of germ in the grain and the nitrogenous matter being largely determined by the proportion of horny or glutinous matter.

For proteids and oil of maize, *v.* Cereals.

The injurious effect of a diet consisting largely of maize upon animals has been ascribed to the absence of tryptophan among the products of hydrolysis of *zein*, the characteristic protein of maize (Willcock and Hopkins, J. Phys. Chem. 1906, 35, 88); also to the presence of much phenylalanine and tyrosine among such products, and the ease with which they split off phenolic compounds, thus producing phenolic poisoning (Baglioni, Atti. R. Accad. Lincei. 1908, 17, i. 109).

The 'non-nitrogenous extract' of maize consists mainly of starch and cellulose, but includes also cane sugar, dextrin, and gum.

As the average of several determinations of the soluble carbohydrates in various types of maize, König gives the following numbers:

Maize from		Number of determinations	In the original substance, p.c. Sugar	Dextrin and gum	Starch, etc.
South-eastern Europe		8	1·76	2·83	61·20
Italy . . .		22	2·22	1·09	64·41
America	Flint corn	23	2·29	2·30	64·04
	Dent corn	11	2·64	3·62	62·39
	Sweet corn	10	4·64	14·47	43·47

Stone (Bull. 34, O. Exp. St. 14) extracted 0·25 p.c. cane sugar from ordinary and 3·5 p.c. from sweet maize, but could not detect invert sugar in the former. Tollens and Washburn (J. Landw. 1889, 37, 503) found 9 p.c. of glucose and 7·8 p.c. of sucrose and dextrin in sweet maize, but only a trace of glucose and 1·78 p.c. of sucrose and dextrin in ordinary maize. Stone found about 5 p.c., Tollens 7·08 p.c. of pentosans in maize grain.

For ash of maize grain, *v.* Cereals.

An objection to the use of large quantities of maize as a cattle food is the effect which it has of lowering the melting-point of the fat produced by the animal (*e.g.* bacon in the case of the pig, butter in the case of dairy cows). Maize is too rich in fat and carbohydrates and too poor in ash constituents, especially lime, to form the sole diet of an animal.

Maize cob—the central portion of the ear—consists largely of cellulose and xylan (25 p.c. of the latter). American analyses show it to contain—

Water	Protein	Fat	N-free extract	Crude fibre	Ash
10·7	2·4	0·5	54·9	30·1	1·4

It is sometimes ground along with the grain, and the product, 'corn and cob meal,' is used as a cattle food.

Maize is also employed as a fodder plant, being cut green and either eaten fresh, or, in some cases, made into hay or ensilage. Though immature maize plants contain a cyanogenetic glucoside (Brünnich, Chem. Soc. Trans. 1903, 788), the quantity of hydrocyanic acid present —not exceeding 0·5 grain per 1 lb. of green material—is so small, that there is little or no danger of poisoning the animals fed upon them.

The following table gives the average composition of certain products from maize:

	Water	Protein	Fat	N-free extract	Crude fibre	Ash
Green fodder .	79·3	1·8	0·5	12·2	5·0	1·2
Silage . .	79·1	1·7	0·8	11·0	6·0	1·4
Straw . .	15·0	5·0	1·5	34·5	39·2	4·8
Bran . .	12·5	9·9	3·6	61·5	9·5	3·0
Maize germ cake	11·0	21·0	9·0	43·8	9·1	6·1
Corn & cob meal	15·1	8·5	3·5	64·8	6·6	1·5
Gluten meal .	9·6	29·4	6·8	52·4	1·6	0·7

H. I.

MAIZE OIL (Corn oil) is obtained from the germs of the maize plant, *Zea Mays*, L. The germs are recovered, in the process of manufacturing starch, by sifting and winnowing them from the starch granules in which they are imbedded. The oil is therefore a by-product of starch and glucose works using maize (corn) as their raw material.

Formerly maize oil was obtained as a by-product in alcohol distilleries. When the malted and crushed grain was allowed to ferment, the oil was laid bare and rose to the top in the fermentation vats. Before distilling off the alcohol, the oil was ladled off and purified in a crude fashion by washing, filtering, and 'settling.' Since, however, the presence of the germ imparts an unpleasant flavour to the spirit obtained by fermentation, and the oil so recovered was very impure, and had a different character from the oil expressed from the germs, the older process of fermenting the crushed grain has been abandoned. Nowadays, the corn is first malted, beaten up with water to a fine pulp, and the germs are separated from the starch by sieving. At present, maize oil is manufactured on a very large scale from the isolated germs by expression in hydraulic presses. In a dry condition, the germs contain 53 p.c. of oil, and yield in practice about 40 p.c. The whole grain contains 4·10 p.c. of oil.

Maize oil, if properly prepared, is clear in colour, and does not require refining for commercial purposes. If, however, the oil is badly prepared and allowed to stand in contact with albuminoid matter, so that it undergoes a process of fermentation, whereby considerable quantities of free fatty acids are produced, it acquires a dark colour and becomes unsuitable for light-coloured soaps. Such oil is therefore bleached in soap works in the same manner as linseed oil.

The freshly prepared maize oil is of a pale yellow or golden-yellow colour, and has a distinctive odour; its taste is pleasant at first, and is most characteristic in that it resembles that of newly ground corn-meal. It is therefore possible to identify the oil by its taste alone.

Maize oil is characterised by its high amount of unsaponifiable matter, amounting to as much as 1·55 and even 2·32 p.c. The unsaponifiable matter consists of lecithin, and of an alcohol which appears to be identical with sitosterol (phytosterol). The sp.gr. of maize oil is 0·925 to 0·927 at 15·5°. The saponification value is 190 to 192, and the iodine value varies between 120 and 130.

The saturated fatty acids in maize oil amount to about 5 p.c. and appear to consist of palmitic, stearic, and arachidic acids. As to liquid fatty acids, linolenic acid is absent, but the oil contains considerable amounts of linolic acid in addition to oleic acid. The oil has somewhat better drying powers than cotton-seed oil, but differs from the latter in that it is not oxidised with equal energy when finely subdivided on cotton waste.

Well-refined maize oil is used for edible purposes ('salad oil'). Since its 'grainy' taste is objectionable, the edible quality consists mostly of a mixture of maize oil with edible cotton oil and other edible oils. Maize oil is also used in the manufacture of margarine ('oleomargarine' of the United States), as also in the manufacture of compound lard (replacing cotton seed oil). Such maize oil as cannot be employed for edible purposes is used chiefly in the manufacture of soft soap, for which it is eminently suitable. A cotton 'softener' largely used in the United States contains maize oil soft soap. Maize oil is not suitable for hard soaps of acceptable quality. J. L.

MALACHITE. An ore of copper, crystallising in the monoclinic system, but usually occurring in mamillated and botryoidal forms, or in fibrous, compact, or earthy masses of a bright green colour. It is a basic copper carbonate $H_2Cu_2CO_5$ (or $CuCO_3+CuO_2H_2$), having a sp.gr. of 3·9 to 4·0, and hardness 3½ to 4. Heated in a tube, it evolves water and turns black, while on charcoal it yields metallic copper. Malachite is frequently found as an alteration-product of other copper-ores, and occurs as a pseudomorph after cuprite, &c. If derived from copper-pyrites it is generally accompanied by limonite. Malachite is not only important as an ore of copper (Cu, 57·4 p.c.), but is valued as an ornamental stone, since it takes a good polish and is prettily marked with light and dark green bands of colour. It is chiefly used for vases and small boxes, but its comparative softness stands in the way of its extensive use in jewellery. Large slabs are not generally attainable, but small pieces are skilfully joined together, the interstices being filled in with powdered malachite, and the whole polished; in this way it becomes easy to employ it for inlaid and encrusted furniture, especially for table-tops of considerable size. Malachite is also used to a limited extent as a green pigment, but the term 'malachite green' has been extended to certain organic dyestuffs. Malachite is widely distributed as a mineral, being found in greater or less quantity in most copper-deposits, but the finest examples occur near Nizhne-Tagilsk in the Ural Mountains, and in South Australia. L. J. S.

MALACHITE GREEN, VICTORIA GREEN, BENZAL GREEN *v.* TRIPHENYLMETHANE COLOURING MATTERS.

MALAKIN *v.* SYNTHETIC DRUGS.

MALARIN. Trade name for the citrate of acetophenone-phenetidide, prepared by heating equivalent proportions of acetophenone and *p*-phenetidine either alone or with addition of dehydrating agents. Crystallises in yellow needles, m.p. 88°, readily soluble in hot alcohol, ether, or glacial acetic acid.

MALAYAN CAMPHOR *v.* CAMPHORS.

MALE FERN *v.* FILIX-MAS.

MALEIC ACID *v.* FUMARIC ACID.

MALIC ACID, *Hydroxysuccinic acid* (*Acide malique*, Fr.; *Aepfel- säure*, Ger.)

$$\begin{array}{l}CH_2COOH\\ \,|\\ CH(OH)COOH.\end{array}$$

This acid contains an asymmetric carbon atom and hence can occur in three modifications, viz. a dextrorotatory form, a lævorotatory form, and an inactive variety. The lævo-rotatory variety occurs free or in the form of salts in many plant juices and hence is frequently termed *ordinary* malic acid. *l*-Malic acid was discovered by Scheele in 1785 in sour apples and Liebig in 1832 ascertained its composition. The inactive acid was first obtained by Pasteur in 1852 from inactive aspartic acid, and by Kekulé in 1861 from bromosuccinic acid. The *d*-acid was first obtained by Bremer in the reduction of *d*-tartaric acid.

Preparation.—*l-Malic acid* occurs free in unripe grapes, apples, gooseberries, &c., and in mountain ash berries (*Pyrus Aucuparia*) (Ehrh.), in the berries of *Hippophaë rhamnoides* (Linn.), and in *Berberis vulgaris* (Linn.) (Muttelet, Chem. Zentr. 1910, i. 376; Kunz and Adam, *ibid.* 1906, i. 1849; Farnsteiner, Zeitsch. Nahr. Genussm. 15, 598; Jörgensen, *ibid.* 17, 396; Adam. Chem. Zentr. 1905, ii. 1042; Erdmann, Ber. 1891, 3351; Pharm. Centralh. 41, 200; Hilger, Zeitsch. Nahr. Genussm. 8, 110; Kremla, Bied. Zentr. 1895, 24, 498). Suint contains potassium malate to the extent of 2½ p.c. of the solid residue and it is a product of excretion (A. and P. Buisine, Compt. rend. 106, 1426); *l*-malic acid is also found in the calcium precipitate formed in the treatment of beetroot (Lippmann, Ber. 1891, 3299). It can be prepared from the unripe berries of *Pyrus Aucuparia* (Ehrh.) (Hagen, Annalen, 38, 257), or of *Berberis vulgaris* (Linn.) (Lennsen, Ber. 1870, 966) in the following manner. The expressed juice is evaporated, filtered, heated to boiling, and saturated with milk of lime. The calcium malate which separates is dissolved in hot dilute nitric acid (1 : 10); on cooling, the solution deposits the acid malate, which is purified by recrystallisation from water. In order to obtain malic acid from it, its solution is precipitated with lead acetate and the lead salt is decomposed with sulphuretted hydrogen (Brœksmit, Pharm. Weekbad. 42, 637). It may be obtained from the juice of cherries or grapes by means of the cinchonine salt, which is very insoluble, the cinchonine salts of the other acids remaining in solution (Lindet, Bull. Soc. chim. 1896, 15, 1160). Castoro recommends separating malic acid from the expressed juice of the rhubarb, in which it occurs as the acid potassium salt, by means of its strontium salt (Chem. Soc. Abstr. 1902, i. 259).

l-Malic acid can be obtained from *l*-chloro- or *l*-bromosuccinic acid through the action of moist silver oxide, mercuric oxide, &c., or from *d*-chloro- or *d*-bromosuccinic acid by the action of potassium hydroxide, or hydroxides of the other alkali metals (Walden, Ber. 1896, 135; 1897, 2795, 3148; 1899, 1833, 1853). It can also be obtained by the action of nitrous acid on *l*-asparagine or *l*-aspartic acid (Walden, *l.c.*). By heating the ammonium salt of inactive malic acid to 80°, the active salt crystallises out from the solution of the inactive salt (Kenrick, Ber. 1897, 1749; Van't Hoff and Dawson, *ibid.* 1898, 528).

d-Malic acid occurs naturally in *Crassulaceæ* (Aberson, Ber. 1898, 1432; Walden, *ibid.* 1899, 2706). It can be obtained synthetically by methods similar to those for obtaining *l*-malic acid (Walden, *l.c.*; Piutti, Ber. 1886, 1693; Bremer, *l.c.*). Racemic acid can be reduced to inactive malic acid, which can be resolved into *d*- and *l*-malic acids by cinchonine (Bremer, Ber. 1880, 351; Rec. trav. chim. 4, 180).

Inactive malic acid can be prepared by methods similar to those above (Tanatar, J. Russ. Phys. Chem. Soc. 1891, i. 339; Annalen, 273, 37; Van't Hoff, Ber. 1885, 2170, 2173). It is also obtained by heating fumaric or maleic acids with caustic soda to 100° (Van't Hoff, *l.c.*; Lloyd, Annalen, 192, 80; Bremer, *l.c.*; Skraup, Monatsh. 12, 113); by heating chloral and malonic acid with acetic acid and treating the γ-trichloro-β-hydroxybutyric acid thus formed with potassium hydroxide (Garzarolli-Thurnbackh. Monatsh. 12, 556); and by reducing oxalacetic acid with sodium amalgam in acid solution (Wislicenus, Ber. 1891, 3416; 1892, 2448).

Properties.—Inactive malic acid. Melts at 130°–131°; sp.gr. 20°/4° 1·611. Affinity constant (Walden, Ber. 1896, 1698). The diethyl ester is obtained by reducing ethyloxalacetate with aluminium amalgam (Wislicenus, J. pr. Chem. 1896, [ii.] 59, 18). Dielectric constant *v.* Drude, Zeitsch. physikal. Chem. 23, 310).

d-Malic acid. Physical properties, *v. l-malic acid.*

l-Malic acid. Crystallises in colourless needles, m.p. 100°. Very soluble in water or alcohol. Rotation of acid (*v.* Nasini and Gemari, Gazz. chim. ital. 25, i. 422; Zeitsch. physikal. Chem. 1896, 19, 113; Winther, Chem. Zentr. 1896, ii. 22; Woringer, Zeitsch. physikal. Chem. 1901, 36, 336). Thermal constants, *v.* Massol. Compt. rend. 113, 800. The esters are prepared by adding dry silver malate in small quantities at a time to an excess of alkyl iodide and completing the reaction by heating on the water-bath; or by treating malic acid and an alcohol with hydrochloric acid or sulphuric acid. When the former method is used, a small quantity of a more active substance is always present, *e.g.* in the preparation of ethyl malate, ethyl ethoxysuccinate is also produced (Purdie and Lander, Chem. Soc. Trans. 1898, 293; Purdie and Pitkeathly, *ibid.* 1899, 154). The dimethyl ester boils at 129° (16 mm.) and has sp.gr. 1·2301 at 20°/4°; the diethyl ester boils at 138° (25 mm.) and has sp.gr. 1·1340 at 20/4° (Purdie, *l.c.*; Walden, Zeitsch. Physikal. Chem. 1895, 17, 245; Frankland and Wharton, Chem. Soc. Trans. 1899, 338). Rotation, *v.* also Anschutz and Reitter, Zeitsch. physikal. Chem. 1895, 16, 493. Dielectric constant, v. Walden, *ibid.* 46, 103. According to H. Traube (Zeitsch. Kryst. Min. 1899, 31, 160), the best method for the preparation of the salts of malic acid is by the interaction of strontium hydrogen malate with the sulphate of the metal. A detailed account of the composition and crystallographic properties of the salts is given.

On heating malic acid to 100° for 24 hours, there results malomalic acid $C_5H_7O_3(CO_2H)_3$, and on heating *in vacuô* at 180° there is formed an anhydride, *malide* $C_8H_8O_8$ and small quantities of fumaric acid and maleic anhydride (Walden, Ber. 1899, 2716). Prolonged heating at 140°–150° yields fumaric acid as the main product, and at 180°, fumaric acid, maleic anhydride, and water are formed. Oxidation with hydrogen peroxide in the presence of a ferrous salt yields oxalacetic acid (Fenton and Jones, Chem. Soc. Trans. 1900, 77); with hydrogen peroxide in a sealed tube at 120°, tartaric acid (Zinno, Mon. Scient. 16, ii. 493); with potassium permanganate, oxalacetic acid (Deniges, Compt. rend. 130, 32); with nitric acid, oxalic acid; with potassium dichromate, malonic acid. Reduction with hydriodic acid yields succinic acid. By heating malic acid with sulphuric acid, the half aldehydes of malonic acid and formic acid are produced, the former of which is changed into coumalic and trimesic acids (Von Pechmann, Annalen, 264, 261): heating with glycerol gives rise to carbon dioxide and acrolein (de Coninck and Raynaud, Compt. rend. 135, 1351). Carbon dioxide, acetaldehyde, and crotonic aldehyde are formed by the electrolysis of a concentrated aqueous solution of the sodium salt (Miller and Hafer, Ber. 1891, 470). The coumarins are produced when malic acid is heated with phenols and sulphuric acid (Pechmann, Ber. 1884, 929, 1646). Benzaldehyde and malic acid in piperidine at 150°–160° react to form β-benzoylpropionic acid (Mayrhofer and Nemeth, Monatsh. 1903, 24, 80). Heated with hydrobromic acid, malic acid yields bromosuccinic acid and with phosphorus pentachloride chlorosuccinic acid. A concentrated solution of an alkaline malate gives with calcium chloride on boiling a precipitate of calcium malate. Ammonium salts prevent the precipitation; addition of alcohol aids it. Piñuera (Compt. rend. 1897, 124, 291) uses as a reagent a solution containing 0·02 gram β-naphthol per c.c. strong sulphuric acid. If 0·05 gram of dry substance is added to 15 drops of the reagent in a porcelain dish and malic acid is present, a yellow green colouration is produced, changing to light yellow on heating and orange on dilution. Details as to estimation, *v.* Clowes, J. Amer. Chem. Soc. 1908, 30, 1285; Pozzio-Escot, Bull. Soc. chim. Belg. 1908, 22, 413.

Malic acid is present in wines. When fermentation is carried out with pure yeast on sterile musts, no decomposition of malic acid occurs until the wines become contaminated with micro-organisms in the ordinary cellar operations. Then gradual fermentation sets in and thus liberates the carbon dioxde necessary to prevent premature decay (Rosenstiehl, Compt. rend. 1908, 147, 150; *cf.* Mestregat, *ibid.* 1907, 145, 260; Emmerling, Ber. 1899, 1915). Seiffert (Chem. Zentr. 1903, ii. 257) has shown that malic acid is gradually converted into lactic acid by an anærobic micrococcus (*Micrococcus malolacticus*); this is also brought about by *Bacillus lactis aërogens* (Emmerling, *l.c.*).

Detection and estimation in wines and fruit juices, v. Schneider (J. Soc. Chem. Ind. 1890, 1068); Micko (Zeitsch. anal. Chem. 31, 465; 32, 481; Chem. News. 68, 286); Hilger (Chem. Zentr. 1900, ii. 597; Zeitsch. Nahr. Genussm. 1903, 6, 721); Kunz (Apoth. Zeit. 1905, 20, 677); Mestzerat (Compt. rend. 1906, 143, 185; Ann. Chim. anal. 1907, 173; 12, 194); Jörgensen (Zeitsch. Nahr. Genussm. 13, 241); Heide and Steiner, *ibid.* 1909, 17, 307). *In tobacco,* Kissling (Chem. Zeit. 1898, 22, 1; 1899, 23, 2). *In cider vinegar,* Leach and Lythgoe (J. Amer. Chem. Soc. 1904, 25, 375).

isoMalic acid. Methyltartronic acid, *v.* TARTRONIC ACID).

β-isoMalic acid. β-Hydroxyisosuccinic acid $CH_2(OH)CH(CO_2H)_2$. The ethyl ester is obtained by treating formaldehyde with hydrogen chloride and adding to the solution ethylsodiomalonate; the product is hydrolysed with potash and the acid so obtained is a syrup decomposing into acrylic acid on heating (Coops, Rec. trav. chim. 1901, 20, 430; Chem. Weekbad. 1, 535; *cf.* Tanatar, Annalen, 273, 44).

Citramalic acid. α-Methylmalic acid

$$CO_2H{\cdot}CH_2(CH_3)C(OH)CO_2H.$$

Prepared from acetoacetic ester by means of prussic acid and hydrochloric acid (Michael, J. pr. Chem. [ii.] 46, 287; Demarcy, Bull. Soc. chim. [ii.] 27, 120; Morris, Chem. Soc. Trans. 1880, 6); by the reduction of chlorocitramalic acid, which is formed from citraconic acid (Carius, Annalen, 129, 160; Morawski, J. 1878, 721); by the action of N_2O_3 on methylaspartic acid (Piutti, Ber. 1893, 2046); by the action of caustic soda on β-bromopyrotartaric acid (Ssemenoff, J. Russ. Phys. Chem. Soc. 31, 289). Melts at 115°–117° and on heating to 200° decomposes into water and citraconic anhydride (Wislicenus, Ber. 1892, 196).

β-Methylmalic acid

$$CO_2H{\cdot}CH(OH)CH(CH_3)CO_2H.$$

Prepared by heating the ester of methyloxalacetic acid with sodium amalgam in aqueous solution (Wislicenus, Ber. 1892, 199). Colourless syrup.

MALLEABLE CAST IRON *v.* IRON.

MALLET BARK. The bark of *Eucalyptus occidentalis* (Endl.), found in Queensland. Employed in tanning; contains from 30 to 50 p.c. of tanning substance. The commercial extract has a density of 22°–24°B. and contains 30–36 p.c. of tanning substance.

MALLOTOXIN *v.* RESINS.

MALONIC ACID $CH_2(COOH)_2$, the second member of the oxalic acid series, was first prepared by Dessaignes by oxidising malic acid with potassium dichromate (Annalen, 1858, 107, 251), and was found by Lippmann among the calcium salts formed in beet-sugar manufacture (Ber. 1881, 14, 1183). Malonic acid can be obtained by oxidising crude sarcolactic acid with potassium dichromate (Dossois, Zeitsch. Chem. 1866, 449); or allylene or propylene with potassium permanganate (Berthelot, Annalen (Supl.) 1867, 5, 97); by the action of fuming nitric acid on hexabromomethylethyl ketone (Demole, Ber. 1878, 11, 1714); or of boiling baryta water on ethyl chloracrylate (Pinner, *ibid.* 1875, 8, 963); or of silver oxide at 125° on ethyl dichloroacrylate (Wallach, Annalen, 1878, 193, 25); by boiling bromomucic acid with baryta water (Jackson and Hill, Ber. 1878, 11, 289); or by boiling barbituric acid with alkali (Baeyer, Annalen, 1864, 130, 143). Malonic acid is best prepared by the hydrolysis of cyanacetic acid (Conrad, Ber. 1879, 12, 749; Bourgoin, Compt. rend. 1880, 90, 1289). Endemann (D. R. P. 183328, 1907) has devised a method for preparing malonic acid from abietic acid and the accompanying resins, by hydrolysing the resin or abietic acid with sodium hydroxide, oxidising the product with permanganate at 0°, and separating the malonic acid from the mixture of acids by means of its sparingly soluble calcium salt. Malonic acid also occurs among the decomposition products obtained by hydrolysing cellulose nitrate with concentrated alkali solution (Berl and Fodor, Chem. Zentr. 1911, ii. 1039).

Properties and reactions. Malonic acid crystallises in large triclinic plates, m.p. 133°–134°, decomposing at a higher temperature into carbon dioxide and acetic acid; when heated under a pressure of 8–10 mm. it sublimes unchanged (Krafft and Noerdlinger, Ber. 1889, 22, 816). For its solubility in alcohol and in ether *v.* Lamouroux, Compt. rend. 1899, 128, 999; Klobbie, Zeitsch. physikal. Chem. 1897, 24, 615.

Malonic acid dissolves in hot acetic anhydride to give a yellowish-red solution with a strong yellowish-green fluorescence, intensified by the addition of glacial acetic acid: the reaction is sensitive, being produced by a milligram of the acid (Kleemann, Ber. 1886, 19, 2030).

When malonic acid or its sodium salt is administered internally it passes only in small quantity into the urine, and leads to an increase of urinary carbonates and to the formation of barbituric acid (Marjori, Chem. Zentr. 1896, ii. 106).

Estimation. Malonic acid or its salts may be estimated by oxidation with permanganate at 80°–90° first in acid and then in alkaline solution, and titrating the excess of permanganate (Durand, Ann. Chim. anal. 1903, 8, 330; Cameron and McEwan, Chem. Soc. Proc. 1910 26, 144).

The malonic acid contained in maple products is estimated by precipitation with normal lead acetate and converting the washed precipitate into lead sulphate by evaporation with nitric and sulphuric acids (Albert P. Sy, Chem. Zentr. 1906, ii. 714).

Salts. Malonic acid is a strong dibasic acid forming both acid and normal salts, and the following salts are described: ammonium, barium, cadmium, calcium, cerium, chromium, cobalt, copper, iron, lead, lithium, magnesium, manganese, nickel, potassium, silver, sodium, strontium, uranium, zinc, and brucine (Massol, Ann. Chim. Phys. 1894, [vii.], 1, 184; Finkelstein, Annalen 133, 338; Miczynski, Monatsh. 7, 260; Rimbach, Kilian, Annalen, 1909, 368, 110; Howe, J. Amer. Chem. Soc. 1903, 25, 444; Werner, Chem. Soc. Trans. 1904, 144; Lord, J. Phys. Chem. 1907, 11, 173; Motooki Malsui, J. Coll. Sci. Tōkyō, 1908, 25, ii. 1; Heintzel, Annalen, 139, 129; Mulder, Bull. Soc. chim. [ii.] 29, 532; Fay, Amer. Chem. J. 18, 281; Hilditch, Chem. Soc. Trans. 1909, 1580).

Esters. The *ethyl ester* $CH_2(CO_2Et)_2$, can be prepared from malonic acid by the ordinary processes of esterification (Finkelstein, Annalen, 1864, 133, 338; Conrad, Ber. 1879, 12, 749; Phelps and Tillotson, Amer. J. Sci. 1908, [iv.] 26, 243); but it is more usually prepared by heating cyanoacetic acid with absolute alcohol in the presence of sulphuric acid or in a current of hydrogen chloride (Venable and Claisen, Annalen, 1883, 218, 131; Noyes, J. Amer. Chem. Soc. 1896, 18, 1105; Phelps and Tillotson, *l.c.*), and commonly contains small quantities of ethyl cyanoacetate (Crossley and Gilling, Chem. Soc. Trans. 1909, 95, 27 *f.n.*). *Diethyl malonate* is a colourless liquid, b.p. 197·7°–198·2° (corr.), sp.gr. 1·06104 at 15°, 1·05284 at 25° (Perkin, *ibid.* 1884, 45, 508), 1·07607 at 0° (Wiens, Annalen, 1889, 253, 298); m.p. —49·8° (von Schneider, Zeitsch. physikal. Chem. 22, 233). *Ethyl hydrogen malonate* $HO_2C{\cdot}CH_2{\cdot}CO_2Et$ (Hoff, Ber. 1874, 7, 1572), has sp.gr. 1·201 at 0° n_D 1·337 at 22° (Massol, Ann. Chim. Phys. 1894, [vii.] 1, 184); b.p. 147°/21 mm., sp.gr. 1·1759 at 19°/19°, n_D 1·4275 at 19° (Marguery, Bull. Soc. chim. 1905, [iii.] 33, 541).—*Dimethyl malonate* $CH_2(CO_2Me)_2$, a colourless liquid, b.p. 181·5° (corr.), sp.gr. 1·16028 at 15°; 1·15110 at 25° (Perkin, Chem. Soc. Trans. 1884, 45, 509); b.p. 180·7 (corr.°), sp.gr. 1·1753 at 0° (Wiens, Annalen, 1889, 253, 297); solidifies to a vitreous mass at —80° (von Schneider, Zeitsch. physikal. Chem. 22, 233). Mercuri salts of possible therapeutic value are obtained by shaking mercuric oxide (1 mol.) and methyl malonate ($2\frac{1}{3}$ mols.) in water at 37°; when the *mono-mercuri-dimalonic ester* $Hg[CH(CO_2Me)_2]_2$ thus formed is hydrolysed the acid loses CO_2 and forms the *anhydride* of *oxymercuri-acetic acid* $\begin{array}{l}CH_2{\cdot}Hg\\ |\quad\ \ |\\ CO{-}O\end{array}$. The methyl esters of methyl, ethyl and propyl malonic acid, or the alkali salts of the acid yield similar compounds (Schoeller and Schrauth, D.R.P. 208634, 1909; 213371, 1909).—*Ethyl propyl malonate* $(CO_2Et)CH_2{\cdot}CO_2Pr$, b.p. 211° (corr.), sp.gr. 1·04977 at 0° (Wiens, *l.c.*).—*Dipropyl malonate* $CH_2(CO_2Pr)_2$, b.p. 228°–229° at 770·3 mm. or 228·3° (corr.); sp.gr. 1·02705 at 0° (Wiens, *l.c.*). *Dibutyl malonate* $CH_2(COOC_4H_9)_2$, b.p. 251·5° (corr.), sp.gr. 1·0049 at 0° (Wiens, *l.c.*). *Di*-l-*amyl malonate* $CH_2(COOC_5H_{11})$, has $[M]_D$ 8·09° (Walden, Chem. Zentr. 1899, i. 327). *Diphenyl malonate* $CH_2(CO_2Ph)_2$, has m.p. 50°, b.p. 210°/15 mm. *Dibenzyl malonate*

$$CH_2(CO{\cdot}OCH_2Ph)_2,$$

b.p. 234·5°/14 mm. (Bischoff and Hendenström, Ber. 1902, 35, 3452; Auger and Billy, Compt. rend. 1903, 136, 555). *Dimenthyl malonate* $CH_2(CO{\cdot}OC_{10}H_{19})_2$, m.p. 62°, $[\alpha]_D$ 79·24° (Hilditch, Chem. Soc. Trans. 1909, 95, 1579).

Amides and substituted amides. *Ethyl malonamate* $EtO{\cdot}OC{\cdot}CH_2{\cdot}CONH_2$, m.p. 50°, (Pinner, Ber. 1895, 28, 473); *malonamide* $CH_2(CONH_2)_2$, m.p. 170°, soluble in 12 parts of water at 8° (Henry, Compt. rend. 1885, 100, 943).

Malonylmalonamide

$$CH_2{<}\begin{array}{c}CO{\cdot}NH{\cdot}CO\\ CO{\cdot}NH{\cdot}CO\end{array}{>}CH_2$$

m.p. 252°–253°, prepared by condensing malonamide and ethyl malonate, and the alkyl substituted derivatives in which one or more of the methylene hydrogen atoms are replaced by alkyl groups, have no hypnotic properties (Remfry, Chem. Soc. Trans. 1911, 99, 610).

Malondimethylamide $CH_2(CONHMe)_2$, m.p. 135° (Whiteley, Chem. Soc. Trans. 1903, 83, 24). *Malondiisobutylamide* $CH_2(CONH{\cdot}C_4H_9)_2$, m.p. 126°–127° (Whiteley). *Malonanilic acid* $HOOC{\cdot}CH_2{\cdot}CONHPh$, m.p. 132° with decomposition (Rügheimer, Ber. 1884, 17, 235; Seifert, Ber. 1885, 18, 1358); *ethyl malonanilate*

$$EtO{\cdot}OC{\cdot}CH_2{\cdot}CONHPh,$$

m.p. 38°–39° (Rügheimer and Hoffmann, *ibid.* 1884, 17, 739); *malonmonophenylamide*

$$PhHN{\cdot}CO{\cdot}CH_2{\cdot}CONH_2,\tfrac{1}{2}H_2O,$$

m.p. 153°–154° (Whiteley, Chem. Soc. Proc. 1904, 93); *malonanilide* $CH_2(CONHPh)_2$, m.p, 225° (Whiteley, Chem. Soc. Trans. 1903, 83. 24); *dithiomalonanilide* $CH_2(CSNHPh)_2$, m.p. 149° (Reissert and Moré, Ber. 1906, 39, 3298). *o-*, *m-* and *p-Malonamidobenzoic acids*

$$CH_2(CONH{\cdot}C_6H_4{\cdot}CO_2H)_2,$$

melt and decompose at 242°, 258°–259° and 270° respectively (von Pollack, Monatsh. 1905, 26, 327); the *ethyl ester* of *p-malonamidobenzoic acid*, $CO_2Et{\cdot}CH_2{\cdot}CONH{\cdot}C_6H_4{\cdot}CO_2H$, has m.p. 172°–173° (Schiff, Annalen, 1886, 232, 129; Gazz. chim. ital. 1885, 15, 534); *malonyldiphenetidide*

$$CH_2(CONH{\cdot}C_6H_4{\cdot}OEt)_2,$$

has m.p. 226° (Bischoff, Ber. 1898, 31, 3248). The chloro and bromo substituted derivatives of malonanilide and malonanilic acid are described by Chattaway and Mason (Chem. Soc. Trans. 1910, 97, 340). Certain of the salts and ethyl esters of the three isomeric *malontoluidic acids* $CO_2H{\cdot}CH_2{\cdot}CONHC_7H_7$, were prepared by Rügheimer and Hoffmann (Ber. 1885, 18, 2971). The *o-*, *m-* and *p-* acids melt at 138°–143°, 99°–101°, and 156° respectively; compare also Chattaway and Olmsted (*l.c.* 938). *Malondi-*p*-tolylamide* $CH_2(CONH{\cdot}C_7H_7)_2$, has m.p. 250° *malonmono-*p*-tolylamide* has m.p. 144°; *malondi-*o*-tolylamide* has m.p. 193° (Whiteley, *l.c.*); *dithiomalondi-*o*-toluidide* $CH_2(CSNHC_7H_7)_2$, and the corresponding *p-* isomeride melt at 122°–123° and 145° respectively (Reissert and Moré, Ber. 1906, 39, 3298). *Malondi-α-naphthylamide* $CH_2(CONH{\cdot}C_{10}H_7)_2$, melts at 225°; the β-isomeride melts at 235° (Whiteley, *l.c.*). *α-Malonnaphthil* $C_{10}H_7N{<}\begin{array}{c}CO\\ CO\end{array}{>}CH_2$, has m.p. above 300°, (Meyer, Annalen, 1906, 347, 17). *Malondimethylanilide* $CH_2(CONMePh)_2$, m.p. 109° (Freund, Ber. 1884, 17, 133); *malontetraphenyl-*

amide $CH_2(CO{\cdot}NPh_2)_2$, m.p. 219°–220° with decomposition; *malonmonomethylanilide*

$NHPhCO{\cdot}CH_2{\cdot}CONMePh$,

m.p. 112° (Whiteley, Chem. Soc. Proc. 1904, 93). *Malondibenzylamide* $CH_2(CONH{\cdot}CH_2Ph)_2$, m.p. 142° (Whiteley).

Malonyldiurethane $CH_2(CONH{\cdot}CO_2Et)_2$, m.p. 124° (Conrad and Schulze, Ber. 1909, 42, 729). *Malonylpiperidide* $C_{13}H_{22}O_2N_2$, m.p. 57° (Franchimont, van Rijn and Friedmann, Rec. trav. chim. 1907, 26, 228). *Malonylazoimide* $CH_2(CO{\cdot}N_3)_2$, an explosive oil, is converted into methylenediurethane, $CH_2(NHCO_2Et)_2$, on treatment with alcohol (Curtius, J. pr. Chem. 1895, [ii.] 52, 210).

Ethylenemalonamide $CH_2{<}\begin{smallmatrix}CO{\cdot}NH\\CO{\cdot}NH\end{smallmatrix}{>}C_2H_4$, from ethylenediamine and malonamide at 170°–180° (Freund, *l.c.*); o-*phenylenemalonamide* and o-*tolylenemalonamide* melt above 300° (Meyer, Annalen, 1906, 347, 17).

Malonylcarbamide, barbituric acid (2 : 4 : 6-di-ketohexahydropyrimidine), *v. Pyrimidines.*

Hydrazides. *Malonhydrazide*

$CH_2(CONH{\cdot}NH_2)_2$

crystallises in needles, m.p. 154°; for condensation products with aldehydes and alkyl acetoacetates, see Curtius, Schöfer and Schwan (J. pr. Chem. 1895, [ii.] 51, 180); Ruhemann (Ber. 1894, 27, 1658); Bülow and Bozenhardt, (Ber. 1909, 42, 4784; 43, 234; 551). *Malonphenylhydrazide* $CH_2(CONH{\cdot}NHPh)_2$, m.p. 187° (Goldsmith, *ibid.* 1888, 21, 1240; Asher, *ibid.* 1897, 30, 1018). The phenylhydrazine salt of *phenylhydrazidemalonic acid*

$PhNH{\cdot}NH_2{\cdot}HO_2C{\cdot}CH_2{\cdot}CONH{\cdot}NHPh$

melts at 141°–143°, and yields the *acid*

$CO_2H{\cdot}CH_2{\cdot}CONH{\cdot}NHPh$,

m.p. 154° on treatment with acid, and *malonylphenylhydrazide*, $CH_2{<}\begin{smallmatrix}CO\\CO\end{smallmatrix}{>}N_2HPh$, m.p. 128°, when heated at 200° (Fischer and Passmore, Ber. 1889, 22, 2728).

Malondihydroxamic acid $CH_2(C(OH){:}NOH)_2$, m.p. 160°, *ammonium malonylhydroxamate*

$(NH_4)O_2C{\cdot}CH_2{\cdot}C(OH){:}NOH$,

m.p. 181° (Hantzsch, Schatzmann, and Urbahn, Ber. 1894, 27, 804; Pickard, Allen, Bowdler and Carter, Chem. Soc. Trans. 1902, 81, 1572).

Nitriles of malonic acid. The *seminitrile* or *cyanacetic acid* $CN{\cdot}CH_2{\cdot}CO_2H$, prepared by the action of potassium cyanide on chloroacetic acid (Fiquet, Ann. Chim. Phys. 1893, [vi.] 29, 438; Phelps and Tillotson, Amer. J. Sci. 1908, iv. 26, 267, 278), forms well-defined large prisms, m.p. 69°–70°. The salts of cyanacetic acid are either amorphous or crystallise with difficulty (Engel, Bull. Soc. chim. [ii.] 44, 425; Meves, Annalen, 1867 143, 201).

Ethyl cyanacetate $CN{\cdot}CH_2{\cdot}CO_2Et$, b.p. 207° (Phelps and Tillotson, *l.c.* 264, 257); condenses with carbamide to form the ester,

$CO{<}\begin{smallmatrix}NH\\NH\end{smallmatrix}{>}C{\cdot}CH_2{\cdot}CO_2Et$,

m.p. 162° (decomp.), soluble in 8333 parts of water at 24°. It gives *m*-toluidine, strychnine, bromine and metallic derivatives. The corresponding *methyl ester* crystallises with 1½ mols. H_2O, m.p. 116° (anhydrous has m.p. 128°) and gives similar derivatives to the ethyl ester (Frerichs and Hartwig, J. pr. Chem. 1905, [ii.] 72, 489; *ibid.* 1906, [ii.] 73, 21).

The *sodium* compound of ethyl cyanacetate, $CN{\cdot}CHNa{\cdot}CO_2Et$ or $CN{\cdot}CH{:}C{<}\begin{smallmatrix}ONa\\OEt\end{smallmatrix}$, forms a neutral solution in water which is not decomposed by hydrochloric acid in the cold. It absorbs iodine rapidly, forming the compound $C_5H_6O_2NI$, and also ethyl dicyanosuccinate, m.p. 120°, as the result of a secondary reaction.

Methyl cyanacetate $CN{\cdot}CH_2{\cdot}CO_2Me$ is a colourless liquid, b.p. 177° (Fenton, Chem. Soc. Trans. 1900, 1297). *Menthyl cyanacetate*

$CN{\cdot}CH_2{\cdot}CO_2{\cdot}C_{10}H_{19}$,

flattened needles, m.p. 83°–84°, $[\alpha]_D$—81·12° (2 p.c. solution in benzene); the monobromo-derivative has m.p. 134°–135° (Bowack and Tapworth, Chem. Soc. Proc. 1903, 22). o-*Tolylcyanacetate* $CN{\cdot}CH_2{\cdot}CO_2{\cdot}C_6H_4Me$, prisms, m.p. 70·4° (Haller, Compt. rend. 1889, 108, 1116).

Cyanacetamide $CN{\cdot}CH_2{\cdot}CONH_2$ forms hexagonal tablets, m.p. 120° (Hesse, Amer. Chem. J. 18, 724; Errera, Gazz. chim. ital. 27, ii. 412; Sachs, Ber. 1900, 33, 964; Fiquet, *l.c.*). *Cyanacetanilide*, $CN{\cdot}CH_2{\cdot}CONH{\cdot}C_6H_5$, m.p. 198·5°–200°. The fluorine derivative

$CN{\cdot}CH_2{\cdot}CONH{\cdot}C_6H_4F$

has m.p. 150°–151° (Wallach and Heusler, Annalen, 1888, 243, 223). *Cyanacetdiphenylamide* $CN{\cdot}CH_2{\cdot}CO{\cdot}N(C_6H_5)_2$, has m.p. 153°–154° (Guareschi). *Cyanacet*-p-*tolylamide*,

$CN{\cdot}CH_2{\cdot}CONH{\cdot}C_7H_7$,

m.p. 180° (Grothe, Arch. Pharm. 238, 608).

Cyanacetxylylamide

$CN{\cdot}CH_2{\cdot}CONH{\cdot}C_6H_3(CH_3)_2$,

has m.p. 167°.

Cyanacetpiperidide, $CN{\cdot}CH_2{\cdot}CONC_5H_{10}$, forms large prisms, m.p. 88°–89° (Guareschi).

Cyanacetphenocoll

$OEt{\cdot}C_6H_4{\cdot}NH{\cdot}CO{\cdot}CH_2{\cdot}NHCO{\cdot}CH_2{\cdot}CN$,

white crystals, m.p. 28°.

Cyanacetylanisidine

$OMe{\cdot}C_6H_4{\cdot}NH{\cdot}CO{\cdot}CH_2{\cdot}CN$,

m.p. 136°, and *Cyanacetyl*-p-*aminophenetole* $OEt{\cdot}C_6H_4{\cdot}NH{\cdot}CO{\cdot}CH_2{\cdot}CN$, m.p. 180°–181°, yield the corresponding oxamic acid on oxidation (Nicola, Ann. Chim. Farm. 18, 353).

Cyanoacetylhydrazine $CN{\cdot}CH_2{\cdot}CO{\cdot}NH{\cdot}NH_2$, m.p. 114·5°–115°. With aldehydes it yields the compounds $CN{\cdot}CH_2{\cdot}CONH{\cdot}N{:}CHR$, with ketones, the compounds $CN{\cdot}CH_2{\cdot}CONHN{:}CRR'$.

Cyanacetylacetylhydrazine,

$CN{\cdot}CH_2{\cdot}CONH{\cdot}NH{\cdot}CO{\cdot}CH_3$,

has m.p. 172°.

Cyanacetyl phenylsulphonylhydrazine

$CN{\cdot}CH_2{\cdot}CONH{\cdot}NH{\cdot}SO_2C_6H_5$,

is formed by the action of benzenesulphonic chloride on cyanacetylhydrazine (Rothenberg, Ber. 1894, 27, 1894).

Cyanacetylcyanamide $CN{\cdot}CH_2{\cdot}CO{\cdot}NH{\cdot}CN$, m.p. 93° (D. R. P. 167138, Chem. Zentr. 1906, i. 797).

Cyanacetylcarbamide $CN{\cdot}CH_2{\cdot}CONH{\cdot}CO{\cdot}NH_2$, m.p. 212° (decomp.). The *methyl carbamide*, m.p. 206°, the *phenyl*, m.p. 216°, and other alkyl derivatives are described (D. R. P. 175415; Chem. Zentr. 1906, ii. 1590; Baum, Ber. 1908, 41, 532; Conrad and Schulze, Ber.

1909, 42, 735.) They are employed technically in the production of the purine bases.

Cyanacetylurethane

$$CN{\cdot}CH_2{\cdot}CO{\cdot}NH{\cdot}CO_2Et,$$

m.p. 167°–168° (Conrad and Schulze, *l.c.*).

Malonodinitrile $CH_2(CN)_2$ (Henry, Compt. rend. 1886, 102, 1394; Hesse, Amer. Chem. J. 1896, 18, 726) is a colourless crystalline compound, m.p. 29°–30°, b.p. 218°–219°/760 mm. (Henry); b.p. 99°/11 mm. or 109°/20 mm., soluble in 7·5 parts water, 2·5 parts alcohol, 5 parts ether, 10 parts chloroform, or 15 parts benzene (Hesse); forms the mono- and di- silver salts $CHAg(CN)_2$ and $CAg_2(CN)_2$ (Hesse), and reacts with hydroxylamine (1 mol.) to form *cyanethenylamidoxime*

$$CN{\cdot}CH_2{\cdot}C(NH_2):NOH,$$

m.p. 124°–127° with decomposition, and yields an *acetyl* and *benzoyl* derivative, m.p. 142° and 184°–192° respectively; *malonodiamidoxime* $CH_2[C(NH_2):NOH]_2$ melts and decomposes at 163°–167°, and yields a *diacetyl* and *dibenzoyl* derivative, m.p. 153°–159° and 183°–185° respectively (Schidtmann, Ber. 1896, 29, 1168).

Aldehydes of malonic acid. The *semialdehyde*, $CHO{\cdot}CH_2{\cdot}CO_2H$, obtained by Wohl and Emmerlich (Ber. 1900, 33, 2760) from β-chloropropionacetal $CH_2Cl{\cdot}CH_2{\cdot}CH(CO_2Et)_2$ is not stable and its physical constants have not been determined. The *amide* $(CHO{\cdot}CH_2{\cdot}CONH_2)$ obtained by Langheld (Ber. 1909, 42, 2360) by the action of sodium hypochlorite on asparagine, is not a stable compound but yields a *phenylhydrazone* $C_9H_{11}ON_3$, m.p. 239°–240°. The *nitrile* or *cyanacetaldehyde* $CN{\cdot}CH_2{\cdot}CHO$ is a colourless, limpid, volatile inflammable liquid of b.p. 71·5° (Chautard, Ann. Chim. Phys. 1889, [vi.] 16, 176).

The dialdehyde and semialdehyde of malonic acid are stated to be among the products formed when the ozonide peroxides of α- or β-linolenic acids are decomposed by boiling with water (Erdmann, Bedford and Raspe, Ber. 1909, 42, 1334).

Malonic acid halides. *Malonic semichloride* $CO_2H{\cdot}CH_2{\cdot}COCl$, m.p. 65° with decomposition, obtained by the action of thionyl chloride on an ethereal solution of malonic acid, is unstable (Staudinger and Ott, Ber. 1908, 41, 2208); the *ethyl ester* $COCl{\cdot}CH_2{\cdot}CO_2Et$, has b.p. 170°–180°, (Van 't Hoff, Ber. 1874, 7, 1572), or 68°–70°/13 mm., loses HCl at 125°–130°, and yields the *compound* $C_{13}H_{12}O_8$, yellow prisms, m.p. 170°–180° (corr.) (Marguery, Bull. Soc. chim. 1900, [3] 33, 541: Leuchs, Ber. 1906, 39, 2641). The *nitrile* or *cyanacetylchloride* $CN{\cdot}CH_2{\cdot}COCl$, was prepared by Mulder (Bull. Soc. chim. [ii.] 29, 533). *Malonyl chloride* $CH_2(COCl)_2$, obtained when malonic acid is mixed with an excess of thionyl chloride and distilled under reduced pressure (Staudinger and Bereza, Ber. 1908, 41, 4461), and yields carbon suboxide (*q.v.*) when treated with silver or lead oxide (Staudinger and Bereza, *l.c.*), is a colourless liquid, b.p. 58°/27 mm. (Auger, Ann. Chim. Phys. 1891, [vi.] 22, 325).

The *seminitrile* of *malonyl bromide*, *cyanacetylbromide*, crystallises in the monoclinic system, and has m.p. 77°–79° (Hübner, Annalen, 1864, 131, 66).

Substituted Malonic Acids and Derivatives.

Alkyl malonic acids. The hydrogen atoms of the methylene group in ethyl malonate can be replaced by sodium (Conrad, Annalen, 1880, 204, 129; Ballo, Ber. 1881, 335); ethyl sodiomalonate, $CHNa(CO_2Et)_2$, is a colourless crystalline compound; it does not undergo dissociation in alcoholic solution (Vorländer and Schilling, *ibid.* 1899, 32, 1876); is not stable in the presence of water, and yields no colour with ferric chloride (Vorländer, *ibid.* 1903, 36, 268). It condenses with alkyl and aryl halides to form the alkyl or aryl substituted malonic ester, the sodio-derivative of which yields on similar treatment the di-substituted ester (Bischoff, *ibid.* 1895, 28, 2616). The corresponding substituted malonic acids can be obtained by hydrolysis of the esters, and these lose carbon dioxide when heated above their melting-point with the formation of the corresponding acid of the acetic series:

$$CH_2(CO_2Et)_2 \rightarrow CHR(CO_2Et)_2 \rightarrow CRR'(CO_2Et)_2$$
$$\rightarrow CRR(COOH)_2 \rightarrow CHRR'{\cdot}COOH.$$

With the exception of diethylmalonic acid, which is employed in the synthetic preparation of certain pyrimidines of therapeutic value, a description of the numerous alkyl malonic acids does not come within the scope of this article.

Diethylmalonic acid $CEt_2(CO_2H)_2$, m.p. 112°; the *anhydride*

$[CEt_2{<}^{CO}_{CO}{>}O]_n$, has m.p. 95°–97° (Staudinger and Ott, Ber. 1908, 41, 3829); the *quadrimolecular anhydride*

$$(CEt_2{<}^{CO}_{CO}{>}O)_4$$

has m.p. 220° (Einhorn and Diesbach, Ber. 1906, 39, 1222); the *ethyl ester* has b.p. 228·5°–229·5° (corr.) (Michael, J. pr. Chem. 1905, [ii.] 72, 537); *methyl ester* has b.p. 204°–205° (Meyer, Ber. 1906, 39, 198); *diethylmalonate* of *glycollamide*

$$CEt_2(CO{\cdot}O{\cdot}CH_2{\cdot}CO{\cdot}NH_2)_2,$$

has m.p. 126°; *diethylaminoethyl diethylmalonate* $CEt_2(CO{\cdot}OCH_2{\cdot}CH_2{\cdot}NEt_2)_2$ (Einhorn, Annalen, 1908, 359, 145); *ethyl diethylmalonamate*, has m.p. 79°, b.p. 263° (D. R. P. 182045); *diethylmalonamic acid*, m.p. 146°, *diethylmalondiethylamic acid* $NEt_2CO{\cdot}CEt_2{\cdot}CO_2H$, m.p. 88°–90° (Einhorn and Diesbach, Ber. 1906, 39, 1222); *diethylmalonamide*, m.p. 224° (corr.) (Fischer and Dilthey, *l.c.*), forms a crystalline compound, $CEt_2(CONH_2)_2{\cdot}CCl_3{\cdot}CHO$, m.p. 178° with chloral hydrate (Burrows and Keane, Chem. Soc. Trans. 1907, 91, 269). *Diethylmalonylmalonamide* has m.p. 175°–176°, *diethylmalonylmethylmalonamide* has m.p. 118°–119°; *diethylmalonylethylmalonamide*, m.p. 88°–89°; *diethylmalonylbenzidine*, m.p. 224° (Remfry, *l.c.*). *Diethylmalonylmonophenylamide* $NH_2{\cdot}CO{\cdot}CEt_2{\cdot}CO{\cdot}NHPh$, m.p. 132° the *sulphanilide* $NH_2{\cdot}CO{\cdot}CEt_2{\cdot}CO{\cdot}NH{\cdot}C_6H_4{\cdot}SO_3H$, has a strong acid reaction and decomposes carbonates, *diethylmalonanilic acid*

$$NHPh{\cdot}CO{\cdot}CEt_2{\cdot}CO_2H,$$

m.p. 105° (Conrad and Zart, Annalen, 1905, 340, 335). *Diethylmalonyl*-p-*phenetidine*

$$CEt_2(CO{\cdot}NH{\cdot}C_6H_4{\cdot}OEt)_2,$$

m.p. 143°, has antipyretic properties and exerts a soporific action (D. R. P. 165311). *Diethylmalonyldiurethane* $CEt_2(CO{\cdot}NH{\cdot}CO_2Et)_2$, a thick oil (Traube, D. R. P. 179946); *ureide of diethylmalonic acid* $CO_2H{\cdot}CEt_2{\cdot}CO{\cdot}NH{\cdot}CO{\cdot}NH_2$, m.p. 162° (corr.) (Fischer and Dilthey, Annalen, 335, 334); *ethyl diethylmalonylureide*

$$CO_2Et{\cdot}CEt_2{\cdot}CO{\cdot}NH{\cdot}CO{\cdot}NH_2,$$

m.p. 85°; *methyl diethylmalonylureide*, m.p. 115° (Boehringer and Söhne, D. R. P. 193447); *diethylmalonyluramide*

$$NH_2{\cdot}CO{\cdot}CEt_2{\cdot}CO{\cdot}NH{\cdot}CO{\cdot}NH_2,$$

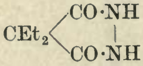
m.p. 199° (Conrad and Zart, *l.c.*); *diethylmalonyltetramethyldicarbamide*

$$CEt_2(CO{\cdot}NH{\cdot}CO{\cdot}NMe_2)_2,$$

m.p. 158°; *diethylmalonyltetraethyldicarbamide*, m.p. 123°–126° (Einhorn, D. R. P. 193446). *Diethylmalonylanthranilamide*

$$CEt_2(CO{\cdot}NH{\cdot}C_6H_4{\cdot}CONH_2)_2,$$

m.p. 215°. cyclo*Diethylmalonylhydrazide*



m.p. 256° (Einhorn, Annalen, 1908, 359, 145). *Diethylmalonodinitrile* $CEt_2(CN)_2$, m.p. 44°, b.p. 195°–195·5° (Hesse, Amer. Chem. J. 1896, 18, 723; Errera and Berté, Gazz. chim. ital. 1896, 26, ii. 220). The *seminitrile of diethylmalonic acid* (*diethylcyanacetic acid*)

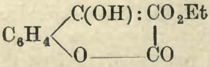
$$CN{\cdot}CEt_2{\cdot}CO_2H,$$

has m.p. 57°, b.p. 162°–164°/18 mm., the *ethyl ester*, b.p. 215°–216°, 100°–101°/14 mm. (Hesse, Amer. Chem. J. 1896, 18, 723; Hessler, *l.c.* 171). *Diethylcyanacetamide* $CN{\cdot}CEt_2{\cdot}CONH_2$, colourless plates, m.p. 120°, (Hesse). *Diethylmalonic semichloride* is an oil (Staudinger and Ott, Ber. 1908, 41, 2208); *diethylmalonyl chloride* $CEt_2(COCl)_2$, has b.p. 196·5°–197·5° (Fischer and Dilthey, Ber. 1902, 38, 844).

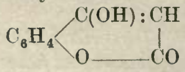
Acyl malonic esters. The acyl derivatives of malonic esters are prepared by the condensation of the sodiomalonic ester with the acyl chloride: the corresponding acids are not known.

The acetyl, diacetyl, phenacetyl, diphenacetyl, propionyl, butyryl, benzoyl, nitrobenzoyl, succinyl, adipyl, phthalyl, and camphoryl malonic esters and derivatives have been prepared, *see* Michael, Amer. Chem. J. 1892, 14, 481; Schott, Ber. 1896, 29, 1985; Guinchant, Bull. Soc. chim. 1895, [iii.] 13, 1029; Held, Compt. rend. 116, 720; Lang, Ber. 1887, 20, 1326; Knoevenagel and Faber, Ber. 1898, 31, 2771; Claisen, Annalen, 1896, 291, 72; Bischoff and Rach, Ber. 1884, 17, 2793; Haller, Bull. Soc. chim. [ii.] 45, 271; Barthe, *ibid.* [ii.] 21, 529; Scheiber, Ber. 1909, 42, 1318; Wislicenus, Annalen, 1887, 242, 23; Wislicenus and Winzer, Annalen, 1890, 257, 298; Baeyer, Ber. 1892, 25, 1039; Ingle, Ber. 1894, 27, 2526).

Ethyl sodiomalonate condenses with acetyl salicylyl chloride or ortho-substituted salicylylchlorides to form ethyl β-hydroxycoumarin-α-carboxylate



or the corresponding ortho-substituted derivatives; the acids obtained from these compounds by hydrolysis lose carbon dioxide and yield the β-hydroxycoumarin



or an ortho-substituted derivative, substances of potential therapeutic value.

Ethyl β-hydroxycoumarin-α-carboxylate has m.p. 93°; *β-hydroxycoumarin* has m.p. 206°; *ethyl 3:5-dichloro-β-hydroxycoumarin-α-carboxylate* has m.p. 135°, and *3:5-dichloro-β-hydroxycoumarin* has m.p. 275° (Aktien Gesellschaft für Anilinfabrikation, D. R. P. 102096, 1899; compare Anschütz, Ber. 1903, 36, 463).

Chloro, bromo, and iodo malonic acids. Malonic acid, its esters, amides and substituted amides react readily with chlorine or bromine, forming under suitable conditions the mono- and di-halogen derivatives. The halogen in certain of these compounds is highly reactive and liberates iodine from hydrogen iodide with the regeneration of the malonic compound according to the equation

$$(CONH_2)_2CBr_2+4HI\\=(CONH_2)_2CH_2+2HBr+2I_2.$$

The reaction is in most cases quantitative and affords a rapid means of estimating the halogen in the compound (Whiteley, Chem. Soc. Proc. 1908, 24, 278).

Chloromalonic acid $CHCl(CO_2H)_2$, m.p. 133°, (Conrad and Guthzeit, Ber. 1882, 15, 605), the *ethyl ester*, b.p. 137°–139°/50 mm., sp.gr. 1·1776 at 20°/4°, n_D 1·4327 at 20° (Brühl, J. pr. Chem. [ii.] 50, 140); b.p. 91°/2 mm. (Forster and Müller, Chem. Soc. Trans. 1910, 97, 126); the *seminitrile* or *ethyl chlorocyanacetate*

$$CN{\cdot}CHCl{\cdot}CO_2Et,$$

b.p. 190°, (Henry, Compt. rend. 1887, 104, 1618). *Chloromalonamide* $CHCl(CONH_2)_2$, m.p. 170° (Conrad and Bischoff, Annalen, 209, 231): *chloromalondimethylanilide* $CHCl(CONMePh)_2$, m.p. 184°, and *chloromalontetraphenylamide* $CHCl(CONPh_2)_2$, m.p. 213° (Whiteley). *Chlormalonaldehyde* $OH{\cdot}CH{:}CCl{\cdot}CHO$, m.p. 144°, gives with aniline, the *monoanilide*

$$NHPh{\cdot}CH{:}CCl{\cdot}CHO,$$

m.p. 193° (Dieckmann and Platz, Ber. 1904, 37, 4638).

Dichloromalonic acid $CCl_2(CO_2H)_2$ (Dootson, Chem. Soc. Trans. 1899, 169); the *aniline salt* has m.p. 105° (Conrad and Reinbach, Ber. 1902, 35, 1813); the *ethyl ester*, b.p. 231°–234°, sp.gr. 1·268 at 17°/15° (Conrad and Brückner, *ibid.* 24, 2993); the *methyl ester*, b.p. 110°–120°/20 mm., (Zincke, Kegel, *ibid.* 1890, 23, 244). *Dichloromalonamide*, m.p. 204° (Conrad and Brückner, *l.c.*; Zincke and Kegel, *l.c.*).

Bromomalonic acid $CHBr(CO_2H)_2$ (Petrieff; Ber. 1878, 11, 414; Conrad and Reinbach, Ber. 1902, 35, 1813; Lutz, Ber. 1902, 35, 2549) crystallises in plates, m.p. 113°; the *barium salt*, and the *silver salts* are crystalline. *Ethyl bromomalonate*, $CHBr(CO_2Et)_2$, b.p. 233°–235° with slight decomposition (Knoevenagel, Ber. 1888, 21, 1356), 118°–119°/11 mm. (private communication); 150°–152°/25 mm. (Bischoff, Ber. 1907, 40, 3134); sp.gr. 1·426 at 15° (Conrad and Brückner, Ber. 1891, 24, 2997); *methyl bromomalonate*

$CHBr(CO_2Me)_2$, b.p. 112·5°–113°/15 mm. (Bischoff, *l.c.*). *Bromomalondiurethane*

$CHBr(CO{\cdot}NH{\cdot}CO_2Et)$

m.p. 148° (Whiteley, private communication).

The *seminitrile* or *bromocyanacetic acid* $CN{\cdot}CHBr{\cdot}CO_2H$ (Petrieff, J. Russ. Phys. Chem. Soc. 10, 160). *Ethylbromcyanacetate*, b.p. 116°/25 mm. (Nef, Annalen, 1897, 298, 202).

Bromomalonitrile, $CHBr(CN)_2$, has m.p. 65°–66° (Hesse, Amer. Chem. J. 1896, 18, 723).

Bromomalonaldehyde $OH{\cdot}CH : CBr{\cdot}CHO$, m.p. 140°; the *anilide* $NHPh{\cdot}CH : CBr{\cdot}CHO$, has m.p. 184°; the *dianilide hydrobromide*

$NHPh{\cdot}CH : CBr{\cdot}CH : NHPh,HBr$,

crystallises with EtOH and has m.p. 217° (Lespieau, Compt. rend. 1901, 133, 538).

Dibromomalonic acid $CBr_2(CO_2H)_2$ (Petrieff, Ber. 1874, 7, 400; Willstätter, Ber. 1902, 35, 1374; Conrad and Reinbach, Ber. 1902, 35, 1813) has m.p. 130°–131° (Willstätter), or 147° (Conrad and Reinbach); the heat of solution is +2·02 cal. *Potassium hydrogen dibromomalonate* forms brilliant anhydrous crystals, heat of dissolution −5·60 cal.; the *potassium salt* becomes anhydrous at 100°, decomposes at 200°, and has heat of dissolution −9·94 cal. (Massol, Compt. rend. 1892, 114, 1200); the crystalline *aniline* salt melts at 113° (Conrad and Reinbach, *l.c.*). *Methyl dibromomalonate*, $CBr_2(CO_2Me)_2$, m.p. 63°–65°; *ethyl dibromomalonate* has b.p. 145°–155°/25 mm. (Conrad and Brückner, Ber. 1891, 24, 3001), b.p. 126°–131°/14 mm. (Reitter and Weindel, *ibid.* 1907, 40, 3358); 135°–137°/13 mm. (Ruhemann and Orton, Chem. Soc. Trans. 1895, 67, 1003); b.p. 134°/12 mm. (private communication). *Dibromomalonamide*

$CBr_2(CONH_2)_2$,

m.p. 206°, *dibromomalondimethylamide*

$CBr_2(CONHMe)_2$,

m.p. 162° (Freund, Ber. 1884, 17, 780); *dibromomalonanilide* $CBr_2(CONHPh)_2$, m.p. 143°–144° (Staudinger and Klaver, Ber. 1908, 41, 906). *Dibromomalonitrile* $CBr_2(CN)_2$, m.p. 123·5°–124° (Hesse, Amer. Chem. J. 1896, 18, 723). *Dibromomalonylchloride* $CBr_2(COCl)_2$, has b.p. 75°–77°/15 mm., and solidifies at the ordinary temperature (Staudinger and Bereza, Ber. 1908, 41, 4461); *dibromomalonyldibromide*

$CBr_2(COBr)_2$

has b.p. 91°–92°/13 mm. (Staudinger and Klever, *ibid.* 1908, 41, 906).

Iodomalondimethylanilide

$CHI(CONMePh)_2$,

has m.p. 164° (Vorländer and Herrmann, Ber. 1898, 31, 1826).

Di-iodomalonic acid $CI_2(CO_2H)_2$, is very unstable; it crystallises in pale yellow leaflets, m.p. 119°–120°. The *methyl ester* crystallises in pale yellow needles, m.p. 79°–80° (Willstätter, Ber. 1902, 35, 1374).

Ethyl chlorobromomalonate $CClBr(CO_2Et)$, has b.p. 136°–139°/35 mm., sp.gr. 1·467 at 16°/15° (Conrad and Brückner, Ber. 1891, 24, 2993); the *methyl ester* is crystalline, m.p. 40°–42° (Bischoff, Ber. 1907, 40, 3150).

Derivatives of cyanomalonic acid. *Ethyl cyanomalonate* $CN{\cdot}CH(CO_2Et)_2$, is a colourless oil, b.p. 120°–130°/25 mm., with a pungent smell and acid reaction, and forms crystalline soluble salts. *Methyl cyanomalonate* also yields crystalline metallic derivatives (Haller, Compt. rend. 1882, 95, 142; Ann. Chim. Phys. 1889, [vi.] 16, 403). The *ethyl ester* of the *seminitrile* (*ethyl dicyanacetate*) $(CN)_2CH{\cdot}CO_2Et$ is crystalline, and forms crystalline sodium, silver and copper salts. The methyl ester is also known (Haller, Compt. rend. 1890, 111, 53).

Ethyl dicyanomalonate or *ethyl cyanimino*iso*succinate* $NH{:}C(CN){\cdot}CH(CO_2Et)_2$, colourless needles, m.p. 93°.

Derivatives of triazomalonic acid. *Ethyl methyltriazomalonate* $CH_3{\cdot}CN_3(CO_2Et)_2$, is a colourless liquid, b.p. 69°/0·6 mm., sp.gr. 1·11695 at 16°/16°; *methyltriazomalonamide* $CH_3{\cdot}CN_3(CONH_2)_2$, m.p. 137·5°; *methyltriazomalonic acid* $CH_3{\cdot}CN_3(CO_2H)_2$, m.p. 87·5°; *ethyl triazomalonic acid* $C_2H_5{\cdot}CN_3(CO_2H)_2$, melts and decomposes at 105°–107°; the *ethyl ester* has b.p. 83·5°/0·7 mm., sp.gr. 1·1161 at 16°/10°; the *amide* has m.p. 167°.

Phenyltriazomalonic acid $C_6H_5{\cdot}CN_3(CO_2H)_2$, m.p. 99°; the *ethyl ester* decomposes on attempted distillation, the *amide* has m.p. 189°. *Ethyl bistriazomalonate* $C(N_3)_2(CO_2Et)_2$, has b.p. 115°–115·5°/0·81 mm., sp.gr. 1·2136 at 20°, and is violently decomposed by sulphuric acid; the *amide* melts at 162° with vigorous decomposition (Forster and Müller, Chem. Soc. Trans. 1910, 97, 126).

Aminomalonic acid and derivatives. *Aminomalonic acid* $H_2N{\cdot}CH(CO_2H)_2,H_2O$, m.p. 109° (Baeyer, Annalen, 131, 291; Ruhemann and Orton, Chem. Soc. Trans. 1895, 67, 1007; Lutz, Ber. 1902, 35, 2549); *ethyl aminomalonate hydrochloride*, $H_2N{\cdot}CH(CO_2Et)_2,HCl$, forms colourless needles, m.p. 162° (decomp.). The hydrochloride of the *methyl ester* melts and decomposes at 159°. *Aminomalonamide* $H_2N{\cdot}CH(CONH_2)_2$, m.p. 192° (Conrad and Guthzeit, Ber. 1882, 15 605; Piloty and Neresheimer, *ibid.* 1906, 39, 514). *Aminomalonanilide* $(CO{\cdot}NHPh)_2CH{\cdot}NH_2$, m.p. 141°–142°; *aminomalondimethylanilide* $(CONMePh)_2CH{\cdot}NH_2$, m.p. 108°; *aminomalontetraphenylamide* $(CONPh_2)_2CH{\cdot}NH_2$, m.p. 200°–201°, are obtained by reducing the corresponding *iso*nitroso derivatives (Whiteley, Chem. Soc. Proc. 1904, 92).

Methyl formylaminomalonate

$CHO{\cdot}NH{\cdot}CH(CO_2Me)_2$,

m.p. 85°, b.p. 250° (decomp.); the *ethyl ester* has m.p. 48°; the *amide* has m.p. 206° (decomp.) (Conrad and Schulze, Ber. 1909, 42, 729).

Diaminomalonamide $C(NH_2)_2(CO{\cdot}NH_2)_2$ (Conrad and Brückner, Ber. 1891, 24, 2993; Ruhemann and Orton, Chem. Soc. Trans. 1895, 67, 1002) loses ammonia and yields *iminomalonamide* $NH{:}C(CO{\cdot}NH_2)_2$ when carefully heated at 90°–100°. *Methyl tetramethyldiaminomalonate* $C(NMe_2)_2(CO_2Me)_2$, has m.p. 83°–85°, and yields on hydrolysis *tetramethyldiaminomalonic acid*, m.p. 133° (Willstätter, Ber. 1902, 35, 1378).

Iminodimalonamide

$(H_2N{\cdot}OC)_2CH{\cdot}NH{\cdot}CH(CONH_2)_2$,

decomposes without fusion (Conrad and Guthzeit, Ber. 1882, 15, 605).

Anilinomalonic acid $NHPh{\cdot}CH(CO_2H)_2$, m.p. 118°–119° (Reissert, Ber. 1898, 31, 382; Conrad and Reinbach, *ibid.* 1902, 35, 511). *Ethyl* *anilinomalonate* NHPh·CH(CO_2Et)$_2$, m.p. 44°–45° (Curtiss, Amer. Chem. J. 1897, 19, 691), yields indoxylic acid when heated (Blank, Ber. 1898, 31, 1812).

Methyl anilinomalonate, m.p. 68°; the *hydrochloride* has m.p. 133°–135°; the *amide*, m.p. 156°.

Ethyl p-*toluidinomalonate* and *ethyl β-naphthylaminomalonate* melt at 55° and 88° respectively and yield indoxylic acid derivatives when heated (Blank, Ber. 1898, 31, 1812).

Anilinomalonanilic acid

NHPh·CH(CO_2H)(CO·NHPh),

melts and decomposes at 157° (Reissert, *l.c.*). *Anilinomalonanilide*, m.p. 246°–247° (Wislicenus and Münzesheimer, Ber. 1898, 31, 551).

Ethyl dianilinomalonate (NHPh)$_2$C(CO_2Et)$_2$, m.p. 117°–118° (Curtiss, Amer. Chem. J. 1897, 19, 691); *methyl dianilinomalonate*, m.p. 124°–125° (Conrad and Reinbach, Ber. 1902, 35, 511).

Aniline dianilinomalonate melts and decomposes at 120° (Conrad and Reinbach, Ber. 1902, 35, 1813).

Methyl phenyliminomalonate

PhN:C(CO_2Me)$_2$,

is a thick yellow oil, reacting vigorously with water, alcohols, ammonia, amines and acids to form substituted anilinomalonates (Curtiss and Spencer, J. Amer. Chem. Soc. 1911, 33, 985).

Alkyl- and aryl-oxy-malonic acids. *Ethyl ethoxymalonate* CH(OEt)(CO_2Et)$_2$ has b.p. 228° and yields on hydrolysis *ethyl ethoxymalonic acid*, m.p. 123°–125°.

Ethyl diethoxymalonate C(OEt)$_2$(CO_2Et)$_2$, m.p. 43°–44°, b.p. 228° (Bischoff, Ber. 1897, 30, 487; Curtiss, Amer. Chem. J. 1897, 19, 691).

Ethyl diphenoxymalonate C(OPh)$_2$(CO_2Et)$_2$, b.p. 250°–260°/60 mm.; the *acid* has m.p. 173°.

Nitrophenoxymalonates. Sodium *o*-, *m*- and *p*-nitrophenoxides react with bromo-malonic esters in benzene or xylene solution according to the equation

$$NO_2{\cdot}C_6H_4{\cdot}ONa + CXBr(CO_2Y)_2 = NaBr + NO_2{\cdot}C_6H_4{\cdot}O{\cdot}CX(CO_2Y)_2$$

where X=H, Me, Et; Y=Me, Et: and sodium nitrophenoxides condense with methyl and ethyl dibromomalonates yielding bisnitrophenoxymalonic esters $(COOR)_2C(O{\cdot}C_6H_4{\cdot}NO_2)_2$ (Bischoff, Ber. 1907, 40, 3134, 3150).

Nitromalonic Esters and Derivatives. *Ethyl nitromalonate* $NO_2{\cdot}CH(CO_2Et)_2$ is a colourless liquid, b.p. 127°/10 mm., sp.gr. 1·1988 at 20°, 1·220 at 0°: the alkali salts are bright yellow and probably have the *iso*nitro structure $(CO_2Et)_2C{:}NO{\cdot}OR$ (Wahl, Compt. rend. 1901, 132, 1050; *cp.* Franchimont and Klobbie, Rec. trav. chim. 1889, 8, 283); *methyl nitromalonate* $NO_2{\cdot}CH(CO_2Me)_2$ forms a crystalline ammonium salt, m.p. 166° (Franchimont and Klobbie, *l.c.*). *Ethyl bromonitromalonate*

$NO_2{\cdot}CBr(CO_2Et)_2$

is a neutral oil, b.p. 136°–137°/11 mm.; the *methyl ester* has b.p. 133°/16 mm. (Willstätter and Hottenroth, Ber. 1904, 37, 1775).

Nitromalonamide $NO_2{\cdot}CH(CO{\cdot}NH_2)_2$, forms six-sided colourless prisms, m.p. 172° (with decomposition). The *potassium* salt is colourless, but yields yellow solutions (Ruhemann and Orton, Chem. Soc. Trans. 1895, 67, 1002). *Bromonitromalonamide* $NO_2{\cdot}CBr(CONH_2)_2$, has m.p. 131°–132° and decomposes on boiling with water yielding bromonitromethane (Ratz, Monatsh. 1904, 25, 687).

Nitromalonanilide $NO_2{\cdot}CH(CO{\cdot}NHPh)_2$ (Michael, Ber. 1905, 38, 22; Whiteley, Chem. Soc. Proc. 1904, 93) forms pale yellow leaflets, m.p. 141°–142°.

Nitromalonic aldehyde $CHO{\cdot}CH(NO_2){\cdot}CHO$ has m.p. 50°–51°. For its condensation products with amines, hydrazines, and hydroxylamine, *v.* Hill and Torrey, Amer. Chem. J. 1899, 22, 89; Hill and Hale, Amer. Chem. J. 1903, 29, 253.

Ethyl ester of the seminitrile of nitromalonic acid or *ethyl nitrocyanacetate*, $CN{\cdot}CH(NO_2)CO_2Et$, yields a potassium salt, m.p. 240° (Conrad and Schulze, Ber. 1909, 42, 735). *Nitrocyanacetamide* (fulminuric acid, *q.v.*) $(CN)CH(NO_2)CONH_2$ has m.p. 145° (decomp.) (*ibid.* 739).

Nitrocyanacetyl carbamide

$CN{\cdot}CH(NO_2)CO{\cdot}NH{\cdot}CONH_2$

is obtained as its potassium salt by the oxidation of the corresponding nitroso compound.

***iso*Nitrosomalonic acid and derivatives.** *iso*-*Nitrosomalonic acid* $(CO_2H)_2C{:}NOH$, m.p. 120°, first obtained by Baeyer by hydrolysis of violuric acid (Baeyer, Annalen, 1864, 131, 292; Conrad and Bischoff, Ber. 1880, 13, 595), is identical with the oxime of mesoxalic acid prepared from mesoxalic acid and hydroxylamine (Meyer and Müller, *ibid.* 1883, 16, 608). *Ethyl* iso*nitrosomalonate* $(CO_2Et)_2C{:}NOH$ (Conrad and Bischoff, Ber. 1880, 13, 595), is a colourless viscid liquid, b.p. 172°/12 mm., sp.gr. 1·206 at 4°/0° (Bouveault and Wahl, Compt. rend. 1903, 137, 196); or 1·149 at 15° (Conrad and Bischoff, *l.c.*). *Methyl* iso*nitrosomalonate*, b.p. 168°/13 mm., m.p. 67° (Bouveault and Wahl, *l.c.*).

The *iso*nitroso derivatives of malonamide and the substituted amides of malonic acid are obtained by the action of nitrosyl chloride at 0° on the amide dissolved or suspended in dry chloroform, and the yield is usually quantitative.

*iso*Nitrosomalonamide and the alkyl substituted derivatives are colourless, the aryl substituted derivatives are yellow, or exist in two forms one yellow and one colourless, exhibiting dynamic isomerism; all the *iso*nitroso derivatives form crystalline yellow alkali and silver salts, and deep violet or blue ferrous salts. It is probable that the yellow *iso*nitroso derivatives and the salts possess the true oximino structure

$$(CONHR)_2C{:}NOH;\ (CONHR)_2C{:}NOK,$$

whilst the colourless *iso*nitroso derivatives are

*iso*oximes 
$(CONHR)_2C\langle\begin{matrix}NH\\|\\O\end{matrix}$.

iso*Nitrosomalonamide* 
$(CONH_2)_2C\langle\begin{matrix}NH\\|\\O\end{matrix}$

colourless, m.p. 187° (decomp.); the *acetyl* derivative is colourless, m.p. 190°; *ethyl* derivative, pale yellow, m.p. 150°–151°; the silver salt $(CONH_2)_2C{:}N{\cdot}OAg,2NH_3$, deep yellow prismatic crystals; *potassium* salt

$(CO{\cdot}NH_2)_2C{:}N{\cdot}OK$

is yellow, and forms with ferrous sulphate the *ferrous potassium salt*

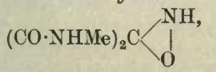
$$(CONH_2)_2{\cdot}C{:}N{\cdot}OK,[(CONH_2)_2C{:}N{\cdot}O]_2Fe$$

which crystallises in well-defined purple prisms with a bronze or green reflex. The *yellow* variety of *iso*nitrosomalonamide

$$(CONH_2)_2C{:}NOH$$

differs from the colourless form only in colour.

iso*Nitrosomalondimethylamide*



$$(CO{\cdot}NHMe)_2C\langle\begin{matrix}NH,\\ |\\ O\end{matrix}$$

m.p. 157°; the *potassium* salt

$$(CONHMe)_2C{:}N{\cdot}OK$$

is bright yellow; the *ferrous* salt

$$[(CONHMe)_2C{:}NO]_2Fe$$

is purple.

iso*Nitrosomalonanilide*. The *colourless* variety becomes yellow at 138°–140° and melts at 141°; the *yellow* variety becomes white at 120°–122° and melts at 141°; the equilibrium mixture of the two isomerides melts at 124°.

iso*Nitrosomalonmonophenylamide*

$$NHPh{\cdot}CO{\cdot}C(CO{\cdot}NH_2){:}NOH$$

has m.p. 180°–181° (decomp.).

iso*Nitrosomalondi*-p-*tolylamide*

$$(CONH{\cdot}C_7H_7)_2C{:}N{\cdot}OH$$

is pale yellow, m.p. 170°–171°; the *colourless* isomeride becomes yellow at 150° and melts at 170°–171°.

iso*Nitrosomalonmono*-p-*tolylamide*

$$C_7H_7{\cdot}HN{\cdot}CO{\cdot}C(CO{\cdot}NH_2){:}NOH$$

is lemon yellow, m.p. 183°.

iso*Nitrosomalondi*-o-*tolylamide*

$$(CONH{\cdot}C_7H_7)_2C{:}NOH$$

is yellow, m.p. 111°, the *colourless* isomeride changes to yellow at 75° and melts at 111°.

Ethyl iso*nitrosomalon*-o-*tolylamate*

$$C_7H_7{\cdot}HN{\cdot}CO{\cdot}C(CO_2Et){:}NOH$$

is pale yellow, m.p. 140°–141°.

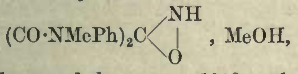
iso*Nitrosomalondi*-α-*naphthylamide*

$$(CONH{\cdot}C_{10}H_7)_2C{:}NOH$$

is orange coloured, m.p. 184°.

iso*Nitrosomalondi*-β-*naphthylamide* is pale yellow, m.p. 221°; the *acetyl* derivative is colourless, m.p. 179° (decomp.).

iso*Nitrosomalondimethylanilide* crystallises with 1 mol. methyl alcohol.



$$(CO{\cdot}NMePh)_2C\langle\begin{matrix}NH\\ |\\ O\end{matrix}\ ,\ MeOH,$$

is colourless and has m.p. 109°; the *acetyl* derivative has m.p. 130°, the *benzoyl* derivative m.p. 157°–158°, and the *ethyl ether* m.p. 138°.

iso*Nitrosomalontetraphenylamide*

$$(CONPh_2)_2C{:}NOH$$

forms pale yellow prisms, m.p. 237°–238° (decomp.); the *acetyl* derivative is pale yellow, m.p. 190°; the *benzoyl* derivative is colourless, m.p. 175°, the *ethyl ether* has m.p. 164°–165, (Whiteley, Chem. Soc. Trans. 1900, 77, 1040; 1903, 83, 18, 24; Chem. Soc. Proc. 1904, 93).

iso*Nitrosomalondiurethane*

$$(CONH{\cdot}CO_2Et)_2C{:}NOH,$$

m.p. 203°–204° (Conrad and Schulze, Ber. 1909, 42, 735). The *ammonium* salt forms bright orange prisms, m.p. 174°. The *potassium* salt $(CO{\cdot}NH{\cdot}CO_2Et)_2C{:}N{\cdot}OK$, is bright orange-red (Whiteley).

Derivatives of the seminitrile of isonitrosomalonic acid. *Ethyl isonitrosocyanacetate*

$$HON{:}C(CN)CO_2Et,$$

m.p. 133°, yields metallic derivatives (Conrad and Schulze, Ber. 1909, 42, 735).

The *methyl ester* has m.p. 123°. The *ethers*

$$EtON{:}C(CN)CO_2Et$$

b.p. 125°–127° 1/22–24 mm. and

$$EtON{:}C(CN)CO_2Me$$

b.p. 121°–124°/23–25 mm. and the corresponding benzoyl derivative, m.p. 131°–132° are described by Müller (Ann. Chim. Phys. [vii.] 1, 463).

Isonitrosocyanacetamide (Desoxyfulminuric acid) $CN{\cdot}C{:}NOH{\cdot}CONH_2$, m.p. 184°, (*ibid.* 738).

Isonitrosocyanacetyl carbamide

$$HON{:}C(CN)CO{\cdot}NH{\cdot}CONH_2$$

m.p. 220° (decomp.) (*ibid.* 741).

Isonitrosocyanacetyl urethane

$$HON{:}C(CN)CO{\cdot}NH{\cdot}CO_2Et$$

forms white crystals, m.p. 201° (decomp.) (*ibid.* 742).

Condensation of malonic acid with aldehydes. Malonic acid condenses with aldehydes according to the equation

$$(CO_2H)_2CH_2+OHC{\cdot}R=(CO_2H)_2C{:}CHR+H_2O.$$

The methylene malonic acids thus produced yield the corresponding alkyl or aryl malonic acids $CH_2R{\cdot}CH(CO_2H)_2$ on reduction; and lose carbon dioxide on heating to form the substituted acrylic acid $CHR{:}CH{\cdot}CO_2H$.

The *bis*malonic acid $CHR[CH{\cdot}CO_2H)_2]_2$ is sometimes obtained when the aldehyde and malonic acid are taken in the proportion of 1 mol. of the former to 2 mols. of the latter.

For the condensation products with formaldehyde, see Haworth and Perkin, Chem. Soc. Trans. 1898, 73, 339; Bottomley and Perkin, *ibid.* 1900, 77, 294. For the *ethylidene*, iso*butylidene*, iso*amylidene*, *œnanthylidene*, *valerylidene*, *citrylidene*, *furfurylidene*, *crotonylidene*, *benzylidene*, and *cinnamylidene*, *anisylidene*, *methylsalicylidene*, *piperonylidene* and *phenylpropionylidene* malonic acids and derivatives, see Kommenos, Annalen, 1883, 218, 145; Knoevenagel, Ber. 1898, 31, 2585; Braun, Monatsh, 1896, 17, 207; Riedel and Straube, Annalen. 1909, 367, 40; Knoevenagel, D.R.PP. 161171, 156560, 164296, 97735; Verley, Bull. Soc. chim. 1899, [iii.] 21, 414; Dakin, J. Biol. Chem. 1909, 7, 49; Röhmer, Ber. 1898, 31, 281; Riedel, Annalen, 1908, 361, 89; Stuart, Chem. Soc. Trans. 1883, 43, 403; 1885, 47, 155; 1886, 49, 360; Claisen and Crismer, Annalen, 218, 129; Einhorn and Gehrenbeck, Annalen, 1889, 253, 374; Claisen, Ber. 1903, 86, 3664). M. A. W.

MALONYLCARBAMIDE, *barbituric acid, v.* PYRIMIDINE.

MALT *v.* BREWING.

MALTASE is the enzyme which hydrolyses maltose to two molecules of dextrose. It is present in most, though not in all, species of yeasts: those yeasts (*e.g. Saccharomyces marxianus, S. exiguus* (Rees), *S. ludwigii, S. saturnus, S. anomalus*) which do not contain maltase are unable to ferment maltose. Maltase is found in *Aspergillus niger, Penicillium glaucum,* and other mould fungi; a maltose splitting enzyme is present in the intestine (Brown and Heron, Proc. Roy. Soc. 1880, 30, 393) and in numerous other animal tissues (Tebb, J. Physiol. 1894, 15, 421). Maltase is more difficult to extract than invertase; active extracts can only be obtained from yeast after the cells have been destroyed, or, better, after a preliminary drying in a thin layer at a low temperature. The enzyme is not liberated on shaking yeast with toluene water. Yeast juice made by Buchner's method of compression contains maltase. Brown and Heron found aqueous extract of pig's intestine to have no action on maltose, but after drying at 35° fine shreds of the intestine were active. Using similar methods Tebb found most maltase in the mucous membrane of the small intestine; it was also present in the spleen, lymphatic gland, liver, kidney, and in the pancreatic and salivary glands, and least of all in muscle. When the tissue is finely minced and sufficient time (several days) is allowed for adequate extraction, active maltase may be obtained from fresh tissues. Malt does not contain maltase.

Maltase is destroyed by precipitation of the aqueous extract with alcohol, so that it has not been possible to purify it.

Maltase also hydrolyses α-methylglucoside and other synthetical α-glucosides, although it is without action on the isomeric β-glucosides. Amygdalin is hydrolysed by an enzyme akin to maltase, present in some yeasts, to dextrose and amygdonitrileglucoside (Fischer, Ber. 1895, 28, 1508). This action is due, however, not to maltase, but to amygdalase (Caldwell and Courtauld, Proc. Roy. Soc. 1907, B, 79, 350). Maltase is able to cause synthetic as well as analytic changes (Croft Hill, Chem. Soc. Trans. 1898, 73, 634; 1903, 83, 578; *see* also Bayliss, The Nature of Enzyme Action, Longmans, 1911).

The optimum temperature of maltase is 35°–40° (*v.* Fermentation). E. F. A.

MALTHA. A variety of 'mineral tallow' or wax, sp.gr. 0·77, soluble in alcohol, naphtha, and oil of turpentine, said to be originally found on the coast of Finland. It is white, brittle, and stains paper like oil, melts at a moderate heat, and burns with a smoky flame. A similar hydrocarbon is met with in the oil-fields of California.

MALTODEXTRIN *v.* Dextrin.

MALTOSE *v.* Carbohydrates.

MAMMIN *v.* Synthetic drugs.

MANACCANITE. A variety of titaniferous magnetic oxide of iron found in grains and small angular fragments at Manaccan near Helstone, and other places in Cornwall, *v.* Ilmenite; Titanium.

MANCHESTER YELLOW. *Dinitronaphthol* *v.* Naphthalene. Dinitronaphthol-yellow has been used to artificially colour natural saffron. To detect the adulteration, an infusion of the matter is prepared, to which some tartaric acid is added. A hank of wool is then dipped in the boiling solution. The wool thus dyed is washed in very dilute sulphuric acid, and the acid afterwards neutralised with ammonia. If saffron contained any dinitronaphthol, the wool or the solution will be coloured yellow, whereas wool dyed with a decoction of genuine saffron and treated in the same manner becomes colourless (Cazeneuve and G. Ginnossier, J. Soc. Chem. Ind. 5, 437).

MANDELIC ACID (*Phenylglycollic acid; α-phenylhydroxyacetic acid*) $C_6H_5{\cdot}CH(OH)CO_2H$. Discovered by Winkler in 1852 in the emulsion of bitter almonds. It may be obtained by warming ω-dibromoacetophenone with dilute alkali (Engler and Wöhrle, Ber. 1887, 2202); by oxidising ω-hydroxyacetophenone with copper sulphate (Breuer and Zincke, *ibid.* 1880, 635); by boiling phenylchloracetic acid with alkali (Spiegel, *ibid.* 1881, 239); and by warming benzoylformaldehyde with alkali (Pechmann, *ibid.* 1887, 2905; Müller and Pechmann, *ibid.* 1889, 2558). It is best prepared by shaking commercial benzaldehyde with a concentrated solution of sodium disulphite, filtering off and drying the disulphite compound. This is then made into a paste with water, and the calculated quantity of potassium cyanide solution added with stirring. The oily mandelonitrile soon separates, and is hydrolysed by boiling with three times the theoretical quantity of hydrochloric acid (Pape, Chem. Zeit. 1896, 20, 90; Chem. Fab. vor. Hofmann and Schoetensack, Eng. Pat. 14886; J. Soc. Chem. Ind. 1896, 614; *cf.* Müller, Arch. Pharm. [iii.] 2, 385, 389; Ber. 1872, 980; Wallach, Annalen, 193, 38; Luginin, *ibid.*, 139, 299; Winckler, *ibid.* 18, 310).

Forms colourless rhombic prisms; m.p. 118° (Claisen, Ber. 1877, 847); sp.gr. 1·361 at 4°/4° (Schröder, *ibid.* 1889, 1612); readily soluble in alcohol and ether. On heating the acid at 200°, benzaldehyde and an amorphous mass is obtained; benzaldehyde, water and diphenylmaleic anhydride are formed when it is heated in a current of air under reduced pressure (Bischoff and Walden, Annalen, 279, 118; Liebig, *ibid.* 18, 312). Fuming nitric acid yields *o*- and *p*-nitrophenylglycollic acids (Pratesi, Gazz. chim. ital. 21, ii. 402). Electrolysis of an aqueous solution of the potassium salt results in the production of hydrobenzoin and a small quantity of *iso*hydrobenzoin (Walker, Chem. Soc. Trans. 1896, 1279); but according to Miller and Hofer (Ber. 1894, 469) benzaldehyde, carbon dioxide, and carbon monoxide are the products. By passing carbonyl chloride into an ice-cold solution of the acid in pyridine the bimolecular anhydride, m.p. 240°, is formed (Einhorn and Pfeiffer, Ber. 1901, 2951). Hydrogen iodide and phosphorus convert mandelic acid into phenylacetic acid, and fuming hydrochloric acid at 140° yields phenylchloracetic acid. Mandelic acid condenses with phenols in the presence of 73 p.c. sulphuric acid to *o*-hydroxydiarylacetic acid lactones and *p*-dihydroxydiarylacetic acids (Bistrzycki and Flatau, Ber. 1895, 989; 1897, 124); *v.* also Simonis (Ber. 1898, 2821) for condensation with β-naphthol, resorcinol, and orcinol. The nitrile prepared as above, is a yellow oil, solidifying at −10°. The amide has m.p. 190°, the anilide 151°–152°, and the phenylhydrazide 182° (Tiemann and Friedländer, Ber. 1881, 635; Reissert and Kayser, Ber. 1890, 3701; Biedermann, *ibid.* 1891, 4083; Bischoff and Walden, Annalen, 279, 118). The methyl ester has m.p. 52° (Zincke and Brewer, Ber. 1880, 636; Ruhe, *ibid.* 1895, 259), and the ethyl ester has m.p. 34°, b.p. 253°–255° (Michael and Jeanprêtre, Ber. 1892, 1684;

Beyer, J. pr. Chem. [ii.] 31, 389); m.p. 37° (McKenzie, Chem. Soc. Trans. 1899, 755).

Mandelic acid contains an asymmetric carbon atom, and hence can be split into two optically active isomerides. Lewkowitsch (Ber. 1882, 1505; 1883, 1565, 2722) obtained *l*-mandelic acid by treating the inactive acid with *Saccharomyces ellipsoideus* (Rees) and *d*-mandelic acid by using various microzoa, such as *Pencillium glaucum*, &c. Partial resolution of the inactive acid has also been effected by means of the fractional crystallisation of salts with alkaloids, such as quinine and morphine, and with active amines such as methylhydrindamine; and by esterification with active alcohols, such as menthol and borneol (McKenzie, Chem. Soc. Trans. 1899, 968; 1904, 378; McKenzie and Thompson, *ibid.* 1905, 1004; Marckwald and Paul, Ber. 1906, 3654; Kipping, Chem. Soc. Trans. 1909, 416; Findlay and Hickman, *ibid.* 1909, 1386). Racemisation is found to take place on boiling the active acid with alkali (Holleman, Rec. trav. chim. 1898, 17, 323; McKenzie and Müller, Chem. Soc. Trans. 1907, 1814). Asymmetric syntheses have been conducted by McKenzie and Humphries (*ibid.* 1909, 1106) from *l*-menthylbenzoylformate, and by Rosenthaler (Biochem. Zeitsch. 1908, 14, 238) from *d*-benzaldehydecyanhydrin. *d*- and *l*-Mandelic acids can also be prepared by the hydrolysis of amygdalinic acid (Dakin, Chem. Soc. Trans. 1904, 1512; *cf.* Wöhler, Annalen, 66, 238; Tutin, Chem. Soc. Trans. 1909, 663; Feist, Arch. Pharm. 248, 101; Rosenthaler, *ibid.* 105). Incomplete hydrolysis of the ethyl ester by *lipase* yields the *d*-acid, whilst the ester remaining is lævorotatory (Dakin, Chem. Soc. Proc. 1903, 161; J. Physiol. 1903, 30, 253).

l-Mandelic acid has m.p. 132·8°, and $[\alpha]_D$ −153·1° in water (Walden, Zeitsch. physikal. Chem. 1895, 17, 705; *cf.* Lewkowitsch, *l.c.*; Rimbach, Zeitsch. physikal. Chem. 1899, 28, 251; Ber. 1899, 2385). *d*-Mandelic acid has m.p. 132·8°, and $[\alpha]_D+156°$ (Kipping, Chem. Soc. Trans. 1909, 416). For experiments on the *Walden Inversion* with mandelic and phenylchloracetic acids, *v.* McKenzie and Clough, Chem. Soc. Trans. 1909, 777.

MANDRAGORA ROOT. In 1889 Ahrens (Annalen, 251, 312) extracted from *Mandragora* root an alkaloid possessing similar physiological properties to atropine, and which he named *mandragorin.* Thoms and Wentzel (Ber. 1898, 31, 2031) showed that the *mandragorin* of Ahrens was a mixture of bases, the chief of which was *hyoscyamine*, and subsequently isolated another base, which they named *scopolamine* (Ber. 1901, 31, 2031). Hesse (J. pr. Chem. 1901, 64, 274) further investigated the subject and found that *madragora* root contains 0·36 p.c. *hyoscyamine*, 0·04 p.c. *hyoscine* (*scopolamine* of Thoms and Wentzel), 0·01 p.c. *ψ-hyoscyamine*, and a still smaller quantity of a new base *mandragorine.* To obtain these alkaloids, the roots are powdered, moistened with a solution of caustic soda, and extracted with ether under a reflux apparatus. The ethereal solution is repeatedly extracted with dilute sulphuric acid, the acid solution being made alkaline with sodium bicarbonate and extracted with chloroform. This operation is then repeated, whereby the hyoscyamine remains in the aqueous solution. The bases from the chloroform extract are neutralised with hydrobromic acid, and the filtered solution allowed to crystallise. The hydrobromides of the bases are then extracted with acetone, which leaves the pure hydrobromide (m.p. 194°) of hyoscine, $C_{17}H_{21}NO_4$. The free base is decomposed by baryta into tropic acid and oscine, $C_8H_{13}NO_2$. The mother liquors of the hyoscinehydrobromide yield ψ-hyoscyamine on addition of sodium bicarbonate and extraction with chloroform. On adding sodium carbonate to the residual solution, a new alkaloid *mandragorine*, forming a gold double salt $C_{15}H_{19}NO_2HAuCl_4$ is obtained. The free base is decomposed by baryta into atropic acid, and a base resembling tropine.

MANGANATES *v.* MANGANESE.

MANGANESE. Sym. Mn. At.wt. 54·93. (Fr. *Manganèse*; Ger. *Mangan.*) Manganese is not found in the metallic state. In combination, especially as oxide, it is widely distributed. The most important ores are those corresponding with the dioxide MnO_2, *pyrolusite.* It is also found as the oxides *braunite* Mn_2O_3, *hausmannite* Mn_3O_4, as hydrated oxide Mn_2O_3,H_2O in *manganite*, and associated with barium oxide in *psilomelane.* As sulphide it occurs as *alabandite* MnS and *hauerite* MnS_2; as carbonate in *rhodocrosite* or *dialogite* $MnCO_3$; as silicate in *rhodonite* $MnSiO_3$. The latter is of a beautiful red colour, found largely in the Ural Mountains, and used as an ornamental stone. It is often present to a small extent in other silicates, and confers on them its colour. The chief sources of the manganese ores are Russia, the Caucasus, Brazil, and India. Manganese is present in soils, and frequently in mineral, particularly chalybeate, waters. It occurs in many plants, especially in tea and tobacco.

Preparation.—Metallic manganese is not used in the arts except when alloyed with other metals. It may be prepared by reduction of the oxide with carbon, but the temperature necessary for the reduction is so high (1105°C., Greenwood, Chem. Soc. Trans. 1908, 1491) that it is only obtained with difficulty in ordinary furnaces. The original method of preparation described by John (Gehlen's Jour. für. Chem. Phys. 3, 452) consisted in making an intimate mixture of finely divided manganous oxide and carbon by mixing with oil and heating, and exposing it to as high a temperature as possible in a crucible lined with charcoal. The impure manganese so obtained was purified by fusing under salt and nitre.

Brunner (Annalen, 102, 330) prepared the metal by heating a mixture of sodium and manganese chloride or fluoride in a blast furnace for 15 minutes. It may also be obtained by the reduction of the chloride by magnesium.

Deville obtained the metal by the reduction of the pure red oxide Mn_3O_4 by means of sugar charcoal present in insufficient quantity to reduce the whole (Ann. Chim. Phys. 1856, 46, 182).

Valenciennes (Compt. rend. 70, 907) produced it by reduction of the pure oxide with carbon in a magnesia-lined crucible as a hard and brittle mass, quickly oxidised by exposure to air.

Oxides of manganese are reduced to the protoxide but not to metal by ignition in hydrogen. Hugo Tamm (Chem. News. 26, 111) recommends the following process for the preparation on the large scale. Two fluxes are prepared. (1) A fusible 'white' flux of ground glass (free from lead) 63, quicklime 18½, and fluorspar 18½. (2) Flux No. 1 34 parts, lampblack 5½, native manganese dioxide of good quality 60½.

The crucibles used should be very refractory, lined with a mixture of 3 parts plumbago and 1 part fireclay, made into a paste with water. This casing resists the action of the flux for a considerable time. In such a crucible flux No. 2 is ignited at the highest temperature of a wind furnace with the production of 17½ parts of 'Cort manganese' and a green slag saturated with manganous oxide. Of this slag 635 parts are thoroughly mixed with 91 parts of lampblack (charcoal cannot be used), and then with 1000 parts of rich manganese ore. The whole is made into a paste with oil, pressed into the crucible, covered with a piece of wood to prevent oxidation, and luted down, leaving an aperture for the escape of gases.

The crucible is next heated in a blast furnace, at first gently, until fumes cease to escape, and finally to whiteness, for several hours. On cooling, the manganese is found as a coherent mass. The green slag may be used several times with the addition of a little white flux to increase the fluidity, provided too much gangue be not present in the ore.

Operating with an ore containing 79·5 p.c. manganese dioxide, 6·5 p.c. ferric oxide, and 10·5 p.c. gangue, the manganese obtained showed the following composition: Mn 96·9, Fe 1·05, Al 0·10, Ca 0·05, P 0·05, S 0·05, Si 0·85, C 0·95. This metal, when fused with one-eighth part of manganous carbonate, contained Mn 99·91, Fe 0·05, Si 0·015, C 0·025.

The metal is now almost entirely prepared either by reduction by aluminium by the Goldschmidt method or by means of the electric furnace. In the latter method pure manganous oxide is intimately mixed with carbon and heated in an electric furnace, a current of 300 amperes at 60 volts giving a yield of 100–120 grams of manganese in 5 or 6 minutes, or a current of 100 amperes at 60 volts giving the same amount in 10–15 minutes. Care has to be taken to avoid prolonged heating, as the metal readily volatilises in the electric furnace, and hence considerable loss may result. As carbon readily dissolves in manganese the metal so prepared usually contains from 5 to 14 p.c. carbon, which, if the manganese is volatilised, remains as graphite. By again fusing with oxide it may be obtained almost quite free from carbon and silicon (*v.* Moissan, The Electric Furnace).

Properties.—Pure manganese is soft and does not scratch glass; if it contains but little carbon it may be kept in open vessels. As the percentage of carbon increases it becomes more readily decomposed by the moisture in the air and small fragments exposed to the air become oxidised in 24 hours with the production of hydrogen and hydrocarbons. It appears to form a definite carbide Mn_3C, which is hard and brittle, and rapidly oxidises in air, and by moisture is decomposed according to the equation

$$Mn_3C+6H_2O=3Mn(OH)_2+CH_4+H_2$$

equal volumes of methane and hydrogen being evolved. This carbide is probably present in solid solution in the impure manganese, on which it confers its hardness.

The metal has been obtained crystalline by distillation in the electric furnace, and as a pyrophoric powder by gentle ignition of its amalgam in a current of hydrogen (Prelinger, Monatsh. 14, 353). If the temperature of ignition is too high it is no longer pyrophoric, and although paramagnetic at ordinary temperatures becomes ferromagnetic on heating.

The metal dissolves in dilute acids, and with hot sulphuric acid liberates sulphur dioxide; when used as an anode in electrolysis it behaves normally in acid and neutral electrolytes but becomes *passive* in alkaline sulphate or phosphate baths (Müller, Zeitsch. Elektrochem. 11, 755). Its sp.gr. is about 8.

The melting-point of a 99 p.c. manganese was found by Heraeus to be 1245° (Zeitsch. Elektrochem. 1902, 8, 185). When heated in nitrogen or ammonia a nitride is formed, possessing marked magnetic properties (Shukoff, J. Russ. Phys. Chem. Soc. 40, 457); the nitrides of composition Mn_3N_2, Mn_5N_2, and Mn_7N_2 are stated to exist (Wedekind and Weit, Ber. 41, 3769). From the lowering of the freezing-point by phosphorus the value 27·5 has been calculated for the latent heat of fusion (Schemtschuschny and Efremoff, J. Russ. Phys. Chem. Soc. 39, 777). At 1000° the metal is oxidised by carbon monoxide with formation of manganous oxide and carbon (Charpy, Compt. rend. 148, 560).

Detection.—All compounds of manganese, if strongly ignited, impart an amethyst-red colour to the borax bead in the oxidising flame; the bead can be rendered colourless by careful heating in the reducing flame. When heated with soda and a little nitre on platinum foil a very small quantity of manganese produces a green colour.

A very delicate test, in the absence of chlorides, consists in heating the substance or solution with dilute nitric acid and a little lead peroxide. The manganese is thus oxidised and imparts to the solution the pink colour of permanganic acid (Crum).

Minute quantities in soils, minerals, vegetables, &c., may be detected by incinerating, heating the ash with nitric acid, evaporating to dryness, taking up with water and adding to the filtrate some 40 p.c. ammonium persulphate and a drop of a 2 p.c. solution of cobalt nitrate when a pink colour is developed on boiling.

Tetraphenyldiaminodiphenyl methane is stated to be a very delicate test for manganese (in the absence of copper). The substance to be tested is warmed with sodium hydroxide, incinerated and the ashes moistened with acetic acid. On warming with the reagent a blue colour is developed. The same colour is also produced with lead.

Manganese may be detected in N/10000 solution of manganous salts by the red colour produced by the addition of a few drops of a N/10 solution of potassium periodate (Benedict, Amer. Chem. J. 34, 381).

It may also be detected and estimated by adding to 5 c.c. of the solution, 3 c.c. of glycerol, and 1 c.c. of a 50 p.c. solution of sodium hydroxide, and then drawing a current of air through the liquid. A fine ruby colour is developed, the intensity of which is proportional to the manganese present, so that the test may be used for colorimetric estimation (Tarugi, Gazz. chim. ital. 36, 332).

When manganese is present in its usual form, as a protosalt, sulphuretted hydrogen produces a flesh-coloured precipitate from alkaline, but not from acid or neutral solutions.

Potassium and sodium hydroxides precipitate white hydrated manganous oxide which rapidly becomes brown from absorption of oxygen. Ammonia produces the same precipitate, which is soluble in excess, especially in presence of ammonium chloride, but slowly forms a precipitate of the brown oxide.

Where the manganese exists as the acid oxide, as in manganates and permanganates, the reactions are different. Alkaline manganates produce green solutions which slowly become red on exposure to air, more rapidly on addition of an acid, from production of the permanganate. Both these compounds are rapidly reduced and rendered colourless by the addition of sulphurous acid, ferrous salts, or other reducing agent. The manganese then exists as a base and shows the usual reactions. All manganates and permanganates oxidise hydrochloric acid, especially when heated, with evolution of chlorine.

Estimation.—Manganese is usually precipitated as carbonate. To the nearly boiling solution, sodium carbonate is added drop by drop, until precipitation is complete, and the solution boiled for a few minutes and allowed to subside. The precipitate is washed by decantation three times and finally well washed on the filter. The dried precipitate is strongly ignited in a platinum crucible and weighed as Mn_3O_4, which contains 72·05 p.c. of manganese. The ignited mass should show no alkaline reaction with test paper. The precipitate of carbonate may also be converted into, and weighed as, sulphate.

A very delicate method of estimating small quantities of manganese, as in limestones, &c., has been devised by Chatard. The process, as modified by Thorpe and Hambly (Chem. Soc. Trans. 1888, 182), is as follows. The solution should be free from chlorides, should contain between 0·004 and 0·008 gram of manganese, and should occupy about 25 c.c. To it is added 5 c.c. concentrated nitric acid, 2 or 3 grams of lead peroxide, and 10–20 c.c. dilute sulphuric acid (1 acid to 2 water), and the solution gently boiled for 4 minutes. The sides of the flask are washed down to destroy any organic matter, and the liquid boiled for half a minute longer. The lead sulphate and excess of lead peroxide are allowed to subside and the solution is at once filtered (with the aid of a filter pump if possible) through a plug of asbestos recently ignited and washed with dilute sulphuric acid. The filtrate is heated to 60°C. and titrated with a weak solution of ammonium oxalate, freshly standardised by a standard solution of permanganate. It may also be titrated if desired with sodium arsenite, or hydrogen peroxide.

The separation from other metals is not difficult. From the alkaline earths it may be separated by addition of hydrated ammonium sulphide to the nearly neutral solution; the sulphide so precipitated is washed well, redissolved in hydrochloric acid, and precipitated as above with sodium carbonate.

From iron, chromium, uranium, and aluminium, it may be separated by digesting the dilute solution with freshly precipitated barium carbonate. These metals are thus deposited as hydroxides. The barium is removed from the solution by the addition of sulphuric acid, and the manganese precipitated as usual.

When manganese occurs together with a large proportion of iron, as in iron ores, iron, steel, &c., the following separation is useful. The nearly boiling solution of the substance in hydrochloric acid or *aqua regia,* which must be absolutely free from organic matter, is treated with ammonia, with constant stirring, until it becomes much darkened; weaker ammonia is then cautiously added until the liquid has become of a mahogany colour, but still without any permanent precipitate. A hot solution of ammonium acetate is then added. The precipitate of basic ferric acetate should be brick-red; if it be dark red, more ammonium acetate must be added. The solution is boiled for a few minutes only, and the granular precipitate filtered through a large filter paper. The filter with the precipitate is replaced in the beaker which still contains the remaining portions of the precipitate and is redissolved in hydrochloric acid, reprecipitated as before and filtered into the beaker containing the first filtrate. In this way the small portion of manganese contained in the first iron precipitate is separated. A portion of the second ferric acetate precipitate should, in important cases, be boiled with lead peroxide and nitric acid, when, if a trace of manganese be present, the liquid will acquire a pink colour.

The liquid containing the manganese may be concentrated by evaporation, filtered if necessary, and cooled. Sufficient bromine is added, with frequent shaking, to render it brown, and the whole rendered alkaline by ammonia. The manganese is thus precipitated as black hydrated peroxide.

The liquid is heated to boiling, filtered, and the precipitate washed and ignited as usual to Mn_3O_4. If a trace of organic matter be present in the solution, a portion of the iron will not be precipitated as acetate and will come down with the manganese. If this is the case the ignited oxide is redissolved and the iron precipitated as acetate, ignited, and weighed as Fe_2O_3 and its weight deducted from that of the manganese oxide obtained.

A convenient method for the volumetric determination of manganese in ores or alloys is due to Volhard, many modifications of which have been described. The method is based on the fact that manganese salts in the presence of zinc oxide are quantitatively oxidised to zinc manganite by means of potassium permanagnate ($3MnO+Mn_2O_7=5MnO_2$). The modification of Fischer (Zeitsch. anal. Chem. 1909, 48, 751; *cf.* Cahen & Little, Analyst, 1911, 36, 52) is as follows. One gram of the ore or alloy is dissolved in *aqua regia,* and the solution evaporated nearly to dryness with excess of hydrochloric acid. The residue is dissolved in 300 c.c. of water, mixed with a sufficiency of an emulsion of zinc oxide and made up to 1 litre. 100 c.c. of the clear solution are diluted to 500 c.c. and heated to boiling after adding 10 grms. of zinc sulphate. One gram of freshly ignited zinc oxide is added, and the liquid titrated with N/10 permanganate, boiling and shaking frequently until the supernatant liquid is red; 1 c.c. of pure glacial acetic acid is then added, when the red colour disappears, and the titration is slowly finished with permanganate in the hot but not boiling liquid.

Solutions of manganous sulphate are completely precipitated as manganese dioxide, which may be subsequently estimated, when boiled with excess of ammonium persulphate. Sodium bismuthate in cold nitric acid solution oxidises manganous salts to permanganate, which may then be titrated (*v.* ANALYSIS).

Iron alloys with manganese in all proportions (*see* IRON).

Copper and **manganese** yield a continuous freezing-point curve with a minimum of 866° at 65 p.c. copper. The form of the curve and the microscopic examination of the alloys indicate that a continuous series of mixed crystals exist, and that no compounds are formed. The alloys are only homogeneous if heated for some time below the melting-point. In appearance the alloys resemble bronzes, and are generally hard and malleable. A bronze—known as 'manganese bronze'—is made by adding a copper manganese alloy to the molten bronze and usually contains from 1 to 4 p.c. manganese, and from 80 to 90 p.c. copper. It forms a useful, workable alloy, possessing very great tenacity, and is used for stay bolts on some of the Continental railways. Alloys resembling German silver are also obtained from copper, zinc, and manganese.

Brunck describes an alloy with **aluminium** of composition Mn_2Al_7, which forms in white crystals soluble in hydrochloric acid (Ber. 25, 777). According to Hindricks (Zeitsch. anorg. Chem. 59, 414) two compounds exist, Mn_3Al and $MnAl_3$, both of which form mixed crystals. Alloys containing between 57 and 86 p.c. aluminium separate into two liquid layers.

Alloys with **Boron** may be produced in the electric furnace and exhibit magnetic properties due to the compound MnB. A second compound MnB_2 probably also exists, but is not magnetic (Jassoneix, Compt. rend. 142, 1336).

Antimonides may be produced by the 'thermit' method. By removal of excess of manganese by means of dilute acid and of antimony by chlorine, alloys regarded as MnSb and $MnSb_2$ have been obtained. Both are magnetic (Wedekind, Zeitsch. physikal. Chem. 66, 614).

With **Tungsten** alloys containing from 12 to 60 p.c. tungsten have been obtained by the 'thermit' method as hard, brittle, steel-grey ingots, from which dilute acids dissolve the manganese.

By the same method hard brittle homogeneous alloys containing from 12 to 29·6 p.c. **molybdenum** are obtained (Arrivant, Compt. rend. 143, 464, 94).

Nickel and manganese give a continuous freezing-point curve with a minimum of 1030° at 56 p.c. manganese.

With **silver** between 30 and 90 p.c. manganese, two liquids are formed, and no solid solutions (Hindricks).

With **tin** compounds $SnMn_3$ and SnMn are indicated by potential measurements. Alloys with below 40 atomic p.c. Mn are white and soft, above they become hard and brittle (Puschin, J. Russ. Phys. Chem. Soc. 38, 869).

Silicides are obtainable in the electric furnace, compounds Mn_2Si, MnSi, and $MnSi_2$ having been described. Of these the first forms lustrous prisms, which scratch glass, and the second can scratch topaz; the sp.grs. are 6·4, 5·9, and 5·2. The existence of these compounds is also indicated by the MnSi freezing-point curve (Doernickel, Zeitsch. anorg. Chem. 50, 117). Gin describes also a compound Mn_3Si_2 (Compt. rend. 143, 1229).

Phosphides are obtained by heating manganous chloride and phosphorus in a current of hydrogen. Compounds Mn_5P_2 and Mn_3P_2 are described, both of them magnetic. The latter is probably, however, an eutectic mixture (Schemschuschzy and Efremoff, *l.c.*, *supra*).

Manganese oxides. The compounds of manganese with oxygen are numerous. The lower or manganous oxide MnO is powerfully basic; the sequioxide Mn_2O_3 is less basic, the tetroxide Mn_3O_4 and the dioxide MnO_2 are practically neutral; the dioxide occasionally reacts as a basic oxide, but at other times as an acidic oxide forming *manganites* of the type M_2MnO_3, *i.e.* it belongs to the class of amphoteric oxides. The higher oxides, however, MnO_3 and Mn_2O_7, have decided acid-forming properties and produce well-marked series of salts.

Manganous oxide MnO is prepared by ignition of any other oxide, or of the carbonate, in a current of hydrogen. It is of an olive-green colour and absorbs oxygen from the air with formation of a brown oxide. In solution in acids it forms manganous salts.

Manganese sesquioxide Mn_2O_3 occurs in nature as *braunite* in brownish-black, anhydrous, acute octahedra frequently containing silica. In the hydrated form it occurs as *manganite* in brilliant, black or steel-grey, rhombic prisms.

It may be prepared hydrated, by passing chlorine, not to saturation, through water in which manganous carbonate is suspended, and removing the excess of carbonate by dilute nitric acid. It is slowly acted on by dilute acids yielding either manganic salts of tervalent manganese, isomorphous with the salts of aluminium and ferric iron, or a mixture of manganous salts and manganese dioxide. The colour of the amethyst is attributed to the presence of this oxide.

Manganese tetroxide. Red oxide of manganese M_3O_4 occurs as *hausmannite* in brownish-black octahedra, and in massive forms. It is produced by heating any oxide of manganese in the air. By the action of acids it yields a mixture of manganous and manganic salts or a manganous salt and manganese dioxide. It was formerly used as a pigment under the name of *manganese brown*.

Manganese dioxide. Peroxide or black oxide of manganese, frequently known as 'manganese,' MnO_2.

This important oxide occurs as *pyrolusite* in very pure iron-black or steel-grey, rectangular rhombic prisms of sp.gr. 4·8–5, and frequently massive or reniform, in radiating fibrous masses, usually brittle. Its hardness varies within wide limits, and it seldom occurs pure, but usually associated with other manganese ores.

A hydrated variety occurs largely as *psilomelane* in amorphous, massive, stalactitic, and frequently in botryoidal masses, but never in crystals. Its composition is very variable. It is usually found in the same localities as pyrolusite, frequently in alternate layers with that mineral. *Varvicite* and *newkirkite* are also hydrated varieties of pyrolusite.

Wad is an important earthy variety produced by the decomposition of other manganese minerals. It occurs, generally, in low-lying districts, in amorphous, earthy, dull black or brownish pieces of very variable composition and hardness. It frequently contains oxide of cobalt; one variety known as *asbolane* or *earthy cobalt* sometimes contains as much as 32 p.c. of cobalt. Another variety, *lampadite*, contains 18 p.c. of copper oxide. In addition to its employment as a chlorine producer, wad is used as an 'umber' paint.

Of these oxides pyrolusite is the purest and contains the highest percentage of oxygen; it has therefore the greatest commercial value. At a red heat it evolves one-third of its oxygen, leaving the red tetroxide.

When heated with concentrated sulphuric acid, it dissolves with formation of manganous sulphate and evolution of half its oxygen. If organic matter be present the oxygen decomposes it with evolution of carbon dioxide.

Its action on hydrochloric acid is of great importance. The hydrogen of this acid is oxidised, a portion of the chlorine thus liberated combines with the manganese, while the remainder is set free;

$$MnO_2+4HCl=MnCl_2+2H_2O+Cl_2.$$

On this account it is very largely used for the production of chlorine and of bleaching powder (*q.v.*).

Nitric acid has but slight action upon it. Pyrolusite is a good conductor of electricity and is strongly electronegative: it is used as the depolarisor in the Leclanché battery. In the electric furnace it melts and evolves oxygen forming the monoxide. It is used to destroy the injurious tint produced in glass by the presence of ferrous compounds. The oxygen converts the greenish salt into the nearly colourless ferric salt, whilst the slight pink tint imparted by the manganese still further counteracts the bluish colour. It seems probable that the effect is due principally to the latter cause, as red lead and other oxidising agents have not this decolorising power.

Pyrolusite is also used in the preparation of black enamel for pottery, and has been used as a pigment under the name of *manganese black*. It is used as a *drier* for oils, *i.e.* a substance added to confer drying properties to the oils. In this respect it is one of the most powerful driers known, and is added in the boiling in the proportion of about ½ lb. to 1 cwt. of oil.

(For further information regarding these oxides *v.* CHLORINE.) Manganese dioxide may be prepared artificially by moderately igniting the nitrate, boiling the residue with nitric acid, washing and gently heating (Berthier). The hydrated oxide has been used for the removal of iron from aluminium sulphate.

According to Fremy (Compt. rend. 82, 1231) it forms a definite sulphate on solution in sulphuric acid, and a solution containing this under the name of manganese peroxide sulphate, produced by the electrolysis of a sulphuric acid solution of manganous sulphate is used as a mild oxidiser in aniline dye manufacture. Double salts containing $MnCl_4$ also exist.

Manganese trioxide. Franke (J. pr. Chem. 1887, 14) has described a trioxide MnO_3; its existence has been confirmed by Thorpe and Hambly (Chem. Soc. Trans. 1888, 177). This oxide appears to form a sulphate $(MnO_3)_2SO_4$.

Manganese heptoxide Mn_2O_7 is a highly hygroscopic, non-volatile, reddish-brown liquid, which gradually decomposes on exposure to the air. Its composition was determined by Aschoff (Pogg. Ann. 3, 217). These two oxides are of interest, as they form the acid radicles of manganates and permanganates; thus, $MnO_3{\cdot}K_2O$, $Mn_2O_7{\cdot}K_2O$.

SALTS OF MANGANESE.

Of the salts corresponding to these various oxides, only two series are of practical importance, manganous salts, corresponding to the monoxide, and manganates and permanganates, in which manganese acts as an acid corresponding to the tri- and hept-oxides.

Manganous chloride $MnCl_2$ is produced by the action of chlorine gas on metallic manganese, or of hydrochloric acid gas on the heated carbonate. In solution, it is obtained by dissolving the oxide or carbonate in hydrochloric acid.

On the large scale it is usually produced from the residual solutions from the chlorine manufactures. This is first evaporated to remove excess of hydrochloric acid, and one-fourth of the solution is removed and precipitated by sodium carbonate. The precipitate, which contains manganous carbonate and ferric hydrate, is washed and boiled with the remainder of the solution. The iron in solution is thus precipitated as hydrate, being replaced by an equivalent quantity of manganese from the carbonate. Copper, if present, is precipitated by the addition of sulphuretted hydrogen, leaving in solution manganese, and usually calcium and other alkaline earthy metals. Cobalt and nickel may be removed by the addition of freshly precipitated manganous sulphide, as long as it becomes darkened; those metals are then precipitated as sulphides.

The manganese is precipitated by means of ammonium sulphide, washed, dissolved in hydrochloric acid, evaporated, and crystallised.

It may be obtained pure by evaporating the crude solution of the ore in acid to dryness, igniting gently in a crucible, exhausting the residue with water, concentrating and crystallising. It forms pink deliquescent crystals, containing 4 molecules of water, soluble in two-thirds their weight of water at 60°, soluble in alcohol.

In commerce it usually occurs as a rose-red, very deliquescent mass, obtained by evaporating the solution to dryness. It is used for dyeing cotton manganese-brown or -bronze. The fabric is soaked in a solution of the salt and then passed through a caustic alkali, whereby manganous hydroxide is precipitated in the fibre and by subsequent atmospheric oxidation becomes brown. The material thus treated may also be used for the subsequent dyeing by aniline black. The presence of over 1 p.c. calcium chloride in the salt renders it practically useless for calico-printing and dyeing.

Manganous sulphate $MnSO_4$ may be prepared by dissolving the carbonate or oxide in sulphuric acid. On the large scale it is usually obtained from the black oxide. This is ignited with about one-tenth part of powdered coal, and thus reduced to the monoxide. The mass is dissolved in sulphuric acid, evaporated, gently ignited to decompose the ferrous sulphate, and the manganous sulphate dissolved out by water. By another process the peroxide is first digested with dilute sulphuric acid to remove carbonates, and made into a paste with strong sulphuric acid, heated until the evolution of oxygen has ceased, and then to strong redness, cooled, digested in water, and the solution evaporated and crystallised. If iron be still present, it may be removed as in the case of the chloride by boiling with manganous carbonate. Manganous sulphate forms pink crystals very soluble in water, insoluble in absolute alcohol. It is used in calico-printing. It is also used as a drier for pale oils or for conversion into the oxalate or borate which are also used for the same purpose.

Manganese borate, used as a drier, is a salt of a faint pink colour, prepared by adding a solution of borax to one of a manganous salt, washing and drying the powder so obtained.

Manganese oxalate, also used as a drier, is prepared by precipitation of a manganese salt by a soluble oxalate, or by the action of oxalic acid on manganese hydroxide or carbonate. *Manganese linoleate* is also used for the same purpose, and prepared by addition of linseed oil-soap to manganous chloride.

Potassium manganate K_2MnO_4. This compound is produced when equal weights of finely powdered manganese dioxide and caustic potash are fused together, a sesquioxide of manganese being produced at the same time. By the addition of potassium nitrate or by performing the ignition in a flat vessel, a portion of this oxide is reoxidised, and increases the yield of manganate.

It dissolves in water, forming a fine green solution, which, on evaporation *in vacuô*, produces green crystals isomorphous with potassium sulphate and chromate. The solution, especially if dilute, when exposed to the air becomes converted into the permanganate with precipitation of hydrated manganese dioxide; the liquid passes through various shades from green to pink, whence its name of 'mineral chameleon.' In presence of excess of alkali this change does not take place. On the addition of free acid, especially sulphuric acid, the change is immediate, the alkali and manganese, instead of being liberated as hydrates, being at once converted into sulphates, and thus losing their tendency to reproduce the manganate. Potassium manganate is a powerful oxidising agent. Its general action in this respect resembles that of the permanganate.

Sodium manganate Na_2MnO_4 is largely manufactured for disinfecting purposes on account of its greater cheapness.

Condy's fluid consists chiefly of a mixture of sodium manganate and permanganate (*v. infra*). For its preparation 30 cwt. of soda ash are converted into caustic soda by lime; they are then mixed with 7 cwt. manganese dioxide, and ignited in a shallow vessel at a dull red heat for about 48 hours. The mass is treated with water, decanted, and the solution evaporated to the required concentration. When the product is required to consist only of permanganate the solution is treated with sulphuric acid, and evaporated until crystals of sodium sulphate separate. Sodium permanganate is, however, much more difficult to purify by crystallisation than the potassium salt (*v.* Hofmann, Reports on Chem. Processes at the Exhibition of 1862, 109).

According to Desclabissac (Dingl. poly. J. 201, 58), the following methods are used for the preparation of sodium manganate and permanganate on the large scale. (1) 500 parts of soda lye (45°B.) are evaporated with 100 parts potassium chlorate mixed with 180 parts of the finely powdered oxide, and ignited in iron pots until quietly fused, cooled, with constant stirring, again heated to redness, cooled, and extracted with water. (2) 12 parts of caustic soda, dissolved in 58 parts of water are heated with 12 parts potassium chlorate and 18 parts manganese dioxide, until it begins to crumble; the heat is then increased to redness, and the mass, after cooling, is extracted with 200–220 parts of water. (3) To a fused mixture of 10 parts caustic soda and 1 part nitre are added 6 parts strongly heated manganese dioxide; the cooled mass is ladled out and extracted as before.

Potassium permanganate $KMnO_4$ or $K_2Mn_2O_8$. This salt may be prepared directly by the addition of 10 parts of potash dissolved in the minimum of water to a mixture of 8 parts manganese dioxide and 7 parts potassium chlorate. The solution is evaporated to dryness, finely powdered, and ignited at a dull red heat for about 1 hour, until the chlorate has become decomposed. The mass is boiled with water, decanted, evaporated rapidly to a small bulk until crystals form on its surface, decanted from the precipitate which has fallen, and allowed to crystallise; 1 part of permanganate is produced from 3 parts of the oxide (Gregory, J. Pharm. Chim. 21, 312).

It is, however, usually prepared by the action of an acid on the manganate.

According to Städeler (J. pr. Chem. [i] 103, 107), 90 p.c. of the oxide may be converted into permanganate by first preparing the manganate and converting it into permanganate by the addition of chlorine instead of acid

$$2K_2MnO_4+Cl_2=2KCl+K_2Mn_2O_8.$$

The solution is evaporated and the permanganate crystallised, leaving the potassium chloride in solution.

Tessié du Mothay and Maréchal prepare it by addition of magnesium sulphate to the manganate, according to the equation

$$3K_2MnO_4+2MgSO_4+2H_2O$$
$$=K_2Mn_2O_8+2K_2SO_4+2Mg(HO)_2+MnO_2$$

It may also be prepared electrolytically by passing a current through a solution of the hydroxide using a ferromanganese anode (White, J. Physical. Chem. 10, 502).

Potassium permanganate forms fine dark

purple prismatic crystals of greenish metallic lustre, soluble in 16 parts of water at 15°C. When heated they decompose, evolving oxygen, and leaving a mixture of manganate and manganese dioxide. Heated in hydrogen they ignite and leave a green mass containing manganese monoxide and potash.

It is an extremely powerful oxidising agent; each molecule contains five atoms of 'available' oxygen, *i.e.* more than any other salt. It is largely used as a local disinfectant.

When triturated with sulphur or phosphorus it detonates; when mixed with carbonaceous matters and many other reducing agents, and heated, it burns. Mixtures containing permanganates and organic substances are very liable to spontaneous decomposition.

The crystals oxidise strong hydrochloric acid in the cold, with evolution of chlorine; in solution the same effect is produced on heating.

A solution of the salt is rapidly reduced by the addition of sulphurous acid, ferrous salts, and most other reducing agents; less rapidly by organic matter. The solution is therefore used as a test for such substances, and to estimate their amount.

Solutions of the salt can only be filtered through asbestos or glass wool, as they quickly destroy filter-paper.

Zinc, iron, lead, mercury, and many other metals are oxidised more or less rapidly by the solution. Pure potash has no action on permanganate, even when heated, but in presence of organic matter the permanganate is rapidly reduced to the green manganate.

On mixing concentrated solutions of this salt and of silver nitrate, a red crystalline precipitate of *silver permanganate* $Ag_2Mn_2O_8$ is produced. It may be used for the preparation of other permanganates. On mixing with a solution of barium chloride, silver chloride is precipitated, and *barium permanganate* remains in solution, from which *permanganic acid* may be produced by the addition of dilute sulphuric as long as a precipitate falls. On evaporation of the solution the acid is obtained as a brown, crystalline, very soluble mass, easily decomposed by heat.

Sodium permanganate $Na_2Mn_2O_8$ resembles in its properties the potassium salt (*v. Sodium Manganate*).

Aluminium permanganate. Condy (Eng. Pat. 1884, 10015) patented a method of preparing this salt for disinfecting purposes. It is said to give up five-sevenths of its total oxygen to reducing agents. The alumina present would also assist in the precipitation of impurities in water, &c. To 1000 parts of a solution of aluminium sulphate, containing one-third its weight of the sulphate, is added 53 parts of potassium permanganate, which is dissolved by the aid of heat. On cooling, potassium alum crystallises out, and the decanted solution, which contains the whole of the permanganate and a considerable amount of aluminium sulphate, is ready for use.

MANGANESE BRONZE *v.* Manganese; Tin.

MANGANESE-SPAR *v.* Rhodonite; Rhodochrosite; and Manganese.

MANGANITE. A manganese-ore consisting of hydrated sesquioxide $Mn_2O_3{\cdot}H_2O$ or $MnO(OH)$. It occurs as well-developed orthorhombic crystals of prismatic habit and as columnar masses. These possess three perfect cleavages in the direction of the length of the prism, namely, one parallel to the brachypinacoid and two parallel to the unit rhombic prism. The colour is dark steel-grey, with a sub-metallic lustre, and the streak is brownish; sp.gr. 4·3, hardness 4. Good crystals are found, often in association with barytes, at Ilmenau in Thuringia, Ilfeld in the Harz, Granam in Aberdeenshire, Pictou in Nova Scotia, &c. Manganite occurs together with the other black oxides of manganese (pyrolusite, psilomelane, &c.), but as an ore of manganese it is less abundant than these.

L. J. S.

MANGEL-WURZEL or **MANGOLDS.** *Beta vulgaris* (Linn.). A plant largely grown as a farm crop, the root being used as a winter food for cattle and sheep. It is a variety of the garden beet-root or of the sugar-beet. Many varieties are known, differing in size, shape, and colour. Average composition—

	Water	Protein	Fat	N-free extract	Crude fibre	Ash
Large roots .	89·5	1·3	0·1	6·7	1·0	1·4
Medium ,, .	88·0	1·2	0·1	8·7	0·9	1·1
Small ,, .	86·5	1·1	0·1	10·6	0·8	0·9

Large roots of any variety are more watery, richer in nitrogenous substances and crude fibre than small ones; they are not so valuable for feeding purposes nor do they keep so well. When first harvested, mangolds are not suitable for food, especially for sheep, but after keeping a few weeks they form a valuable addition to the dry, winter food of all farm animals. The beneficial effect of storage appears to be the conversion of nitric nitrogen into amides (Wood, J. R. Agric. Soc. 1898).

The nitrogenous constituents of mangolds include much non-proteid material, in which betaine, asparagine, glutamine, nitric acid, and ammonia are the most important. Of the total nitrogen in the root, about 48 p.c. exists as true proteid, from 1 to 6 p.c. as betaine, about 4 p.c. as ammonia, and from 10 to 15 p.c. as nitric acid; the proportions, however, are subject to great variations.

The nitrogen-free extract consists largely of sugar, but there are also present oxalic acid, citric acid, pectins, and pentosans.

As an example of a more detailed analysis of mangolds the results obtained by Pitsch (Landw. Versuchs-Stat. 1892, 21, 471) in an analysis of the dry matter of 'Golden Tankard' mangolds (the roots contained 86·82 p.c. water) may be quoted—

Protein	Pure proteid	Nitric acid	Fat	Sugar	Other N-free substances	Crude fibre	Ash
8·75	4·06	0·31	0·58	60·17	16·98	6·33	7·36

The ash of mangolds, according to König, contains—

Per cent. of ash in dry matter	K_2O	Na_2O	CaO	MgO	Fe_2O_3	P_2O_5	SO_3	SiO_2	Cl
6·44	53·0	15·4	4·1	4·5	0·8	8·4	3·1	2·3	8·4

The leaves are sometimes used as food for cattle, but are very watery and contain oxalic acid (3 or 4 p.c. of the dry matter). They sometimes produce poisonous symptoms if used in large quantities. The addition of about 1 part of finely divided calcium carbonate to 1000 parts of leaves is found to prevent the poisonous action of the oxalic acid. Kellner gives as the average composition of the leaves—

Water	Protein	Fat	N-free extract	Crude fibre	Ash
89·0	2·4	0·4	4·6	1·6	2·0

Mangold seeds have been examined by Devarda (Landw. Versuchs-Stat. 1897, 49, 239). They consisted of 11·55 p.c. of water and 88·45 p.c. of dry matter. The dry matter contained—

Protein	Fat	N-free extract	Crude fibre	Ash
12·84	6·08	38·41	34·01	8·38

The ash consisted of—

K_2O	Na_2O	CaO	MgO	Fe_2O_3	P_2O_5	SO_3	SiO_2	Cl
22·0	8·0	16·1	11·0	1·0	10·0	5·0	24·6	2·3

Mangolds require a deep, somewhat loamy soil, and, with abundant nitrogenous manuring, yield very heavy crops. They have a longer period of growth than turnips, and are less dependent upon phosphatic manuring. They are one of the few crops which are benefited by applications of common salt to the soil and, perhaps for this reason, grow well on land near the coasts. H. I.

MANGO. The fruit of *Mangifera indica* (Linn.), a tree of the East Indies, now grown in other tropical countries. It is eaten raw or used for the preparation of pickles and chutneys.

Prinsen-Geerligs (Chem. Zeit. 1897, 21, 719) gives the following data:—

	Mean weight in grammes	Flesh p.c.	Rind p.c.	Stone p.c.	The flesh contains Glu-cose	Lævu-lose	Suc-rose
Sweet variety	200	67	3	30	0·6	2·0	9·5
Sour variety	300	75	3	22	0·0	1·9	3·6

The gum of this tree was examined by Lemeland (J. Pharm. Chim. 1904, 19, 584), who found it to consist largely of galactose and pentoses. H. I.

MANGROVE BARK. The bark of the mangrove is exported from Mozambique, Parapat, Ibo, Pemba Bay, and other parts of East Africa, mainly to Germany, Russia, and the United States, and for use as a tanning material. It contains from 35 to 40 p.c. of tannin.

MANILA ELEMI *v.* Oleo-resins.

MANIOT or **MANIHOT** is the farina of *Manihot utilissima* (Pohl.), formerly known as *Jatropha Manihot* (Linn.), the plant which furnishes tapioca. Indigenous to America, but also cultivated in Africa and tropical climates generally. Maniot is occasionally imported under the name of 'Brazilian arrowroot.'

MANJAK. A form of asphaltum found in Barbadoes.

MANNA. The concrete juice of the manna-ash, *Fraxinus Ornus* (Linn.), although the name is also applied to the sweet exudations from other plants. Ordinary manna is procured by making incisions in the bark of the trees during the summer and allowing the sap to evaporate. Most of the manna of commerce comes from Sicily or Southern Italy. When freshly prepared, it is pleasant to the taste and is used, to some extent, as a food; but on keeping, it acquires mild laxative properties and is used medicinally.

Manna consists largely of mannitol (*q.v.*), of which it is usually stated to contain from 50 to 80 p.c., together with some invert sugar, gum, and ash. According to Tanret (Bull. Soc. chim. 1902, 27, 947), however, it contains notable quantities of two complex sugars, which he names *manneotetrose* and *manninotriose.* His analyses show ordinary manna to contain mannitol 40–55, lævulose 2·5–3·4, dextrose 2·2–3·0, manneotetrose 12–16, manninotriose, 6–16 p.c., together with small quantities of resin and ash.

Manneotetrose $C_{24}H_{42}O_{21}4H_2O$ forms monoclinic crystals, melts at 100°, and has $[\alpha]_D+150°$; it is very soluble in water, does not reduce Fehling's solution, and is hydrolysed by acetic acid or enzymes, yielding lævulose and manninotriose; by dilute mineral acids into 1 mol. dextrose, 1 mol. lævulose, and 2 mols. galactose.

Manninotriose $C_{18}H_{32}O_{16}$ separates from hot alcohol in spherical masses, melts at 150°, and has $[\alpha]_D+167°$. It reduces Fehling's solution, slowly ferments with yeast, and is hydrolysed by mineral acids, but not by enzymes.

Among many other vegetable exudations which go by the name of 'manna' the following may be mentioned:—

Australian manna: (*a*) from *Myoporum platycarpum* (R. Br.) contains mannitol 89·6, sugar 3·4, water 3·5, ash 1·1 p.c. (Malden, Chem. Zentr. 1894, ii. 341).

(*b*) From the leaves of *Eucalyptus dumosa* (A. Cunn.) containing sugar, inulin, starch, and gum (Anderson, quoted by König).

(*c*) From *Eucalyptus Gunnii*, var. *rubida*, contains water 9·7, ash 6·8, melitose 68·5, dextrose 20·9, sucrose 2·1, gum 3·2, insoluble 4·3 p.c. (Ebert, Chem. Zentr. 1908, ii. 1874).

Persian manna, from the leaves and thorns of the camel's thorn, *Alhagi maurorum* (Medic.) containing moisture 5·2, ash 9·4, chlorophyll and some gum 0·5, sucrose 42·0, gum 20·3, residue 32·0 p.c. (E.).

Sinai or *Tarfa manna*, exuding from punctures caused by an insect, *Coccus manniparus* (Ehrbg.), in the stems of *Tamarix gallica*, var. *mannifera*, containing chiefly sugar and dextrin. *Cedar* or *Lebanon manna*, from the branches of *Cedrus Libani* (Barrel. Ic.).

Trehala manna from the larval cocoons of a beetle, *Larinus maculatus*, living on the stems of *Echinops persicus* (Stev.), containing water 11·1, ash 2·6, trehalose 17·5, gum 27·1, tannin, starch, and residue 44·5 p.c. (Ebert, *loc. cit.*).

Manna of *olives*, a morbid secretion of bacterial origin initiated by the attacks of insects upon olive trees, contains 52 p.c. mannitol, 7·8 p.c. reducing sugars, and 21·5 p.c. of other organic matter (Trabut, Compt. rend. 132, 225).

The term 'manna' is also loosely used for the seeds of certain cereals, *e.g.* 'Boer manna,' and 'Kaffir manna' are often employed as names for certain millets. H. I.

MANNHEIM GOLD *v.* Gold, Mannheim.

MANNITOL, MANNOSE, MANNOTRIOSE *v.* Carbohydrates.

MANQUETA or **MAQUATA.** The African names of a fossil gum resin, resembling copal gum, found in Angola, below the surface of a ferruginous hard clay or soil, at a depth of a few inches to a couple of feet, often in pieces weighing several pounds.

MANTLES, GAS *v.* Gas mantles.

MANURE, ARTIFICIAL *v.* Fertilisers.

MAPÉ. A coarse starch obtained from

Tahiti, derived from the fruit of *Inocarpus edulis* (Forst.).

MAPLE. The name of trees of the genus *Acer*. Some species are valued as shade and timber trees, whilst one, *A. saccharinum* (Wangenh.), affords an important source of sugar in America and Canada. This tree, which attains a height of 100 feet with a trunk of 3 or 4 feet in diameter, affords a considerable quantity of saccharine sap if tapped in the early spring. The sap varies in composition, but, on the average, contains from 2 to 3 p.c. of sucrose, small quantities of proteids, ash constituents, and vegetable acids, mainly malic acid. The flow of sap is most rapid when frosty nights are followed by warm days. The sap is received in buckets and rapidly boiled down in an open pan, the proteid matter which coagulates being removed by skimming. A deposit, often containing calcium malate and silica, forms on the pan bottom. When the syrup has attained a sufficient density it is run off and either preserved as syrup, after filtration or sedimentation, or is boiled down still further, until it solidifies to a white or brown mass of sugar on cooling.

Maple sugar and syrup are highly prized for table use in America and Canada, and are chiefly used in the locality where they are produced. They vary considerably in composition according to the method adopted in their preparation, but generally retain a characteristic 'maple' flavour.

Genuine maple sugar is distinguishable from imitations made of cane sugar by the large precipitate it yields with basic lead acetate, mainly due to the malic acid present (*see* Winton and Kreider, J. Amer. Chem. Soc. 1906, 28, 1204). For the results of an investigation into the conditions affecting the flow of sap of the sugar maple, *see* Jones, Edson and Morse (Bull. 103, Vermont, Expt. Stat. 1903).

H. I.

MAQUI. The maqui is a small evergreen tiliaceous shrub (*Aristotelia Macqui*, L'Hérit.), common in Chile along the course of torrents, and in shady mountainous woods. It is not cultivated, but grows wild, and the berries, which in Chile are eaten either fresh or preserved, contain a red pigment, and are exported largely to Europe for the purpose of colouring wines.

MARBLE. Although this term should strictly be limited to those varieties of limestone which are sufficiently compact to receive a polish, it is loosely applied in trade to a great range of ornamental stones, including many which, like serpentine and alabaster, are not true limestones. Typical marble, such as that used for statuary, has a crystallo-granular texture, resembling that of loaf-sugar, whence it is termed 'saccharoidal.' Under the microscope it commonly shows an aggregation of grains of calcite, exhibiting twin-lamellæ. The development of such a structure appears to be due to that kind of metamorphic action which Sir A. Geikie has termed *marmorosis*. That an ordinary limestone may be converted by the operation of heat and pressure into a crystalline marble is known to every field geologist, while the fact has been confirmed experimentally by Sir J. Hall (in 1805) and others. Metamorphic limestones, such as statuary marbles, are often rich in various crystallised silicates, such as garnet, idocrase, tremolite, and mica, which are supposed to have resulted from the alteration of the foreign materials originally associated with the limestone.

Of ancient marbles, the most renowned for the purposes of sculpture was the *Parian*, obtained from the isle of Paros, one of the Cyclades, in the Ægean sea. The finest kind, known as *Lychnitis*, had a peculiar sparkling grain and a warm surface, which enabled the sculptor to render the texture of skin with great effect. The old quarries have been described by R. Swan (Brit. Ass. Rep. Newcastle, 1889). The famous *Pentelic* marble, largely used in Athenian architecture in the age of Pericles, was a coarser material, adapted for bold sculpture rather than for delicate statuary. *Carrara* marble, extensively employed in Rome under the name of *Luna* marble, and used by Michael Angelo and Raphael, is a very fine-grained saccharoidal limestone, still worked with other varieties at Carrara, Massa, and Serravezza, in the province of Emilia. According to the geological survey of Italy it is of Triassic age.

The ancient marbles used in Italy have been studied by Corsi and other antiquaries. *Giallo antico* was a fine yellow marble from Numidia, while *rosso antico* was a homogeneous red marble, probably from Greece, sometimes confounded with *porfido rosso antico*, a hard red porphyry with white felspar crystals, from Jebel Dokhan in Egypt, the quarries of which have been described by W. Brindley. *Verde antico*, or *verde antique*, is a mixture of serpentine and limestone from near Atrax, on the Peneus, in Sicily, quite distinct from the *porfido verde antico*, or Lacedæmonian stone, a felspathic porphyry from Mount Taygetus. Many marbles are known by fanciful names derived from colour, locality, or a superficial resemblance to natural objects: thus, *bardiglio* is a grey or bluish marble with white veins, whilst *cipollino* is a white marble with green veins of mica or talc. (For Italian marbles *v.* W. P. Jervis, I Tesori Sotterranei dell' Italia, vol. 4, 1889. For ancient marbles *v.* M. W. Porter, What Rome was Built with, 1907.)

The marbles of the British Isles are derived mainly from the Devonian and Carboniferous formations. *Plymouth* marble occurs in the Upper Devonian, while the Great Devon limestone, of Middle Devonian age, has been worked as a marble at Babbacombe and St. Mary Church. The *madrepore marbles* of Torquay are largely used for trivial ornaments. The Carboniferous limestone of Derbyshire has long been famous for the beauty and variety of its marbles, the best known being the *encrinital* marbles, which owe their characteristics to the embedded remains of crinoids or 'stone lilies.' Similar encrinitic marble occurs at Dent in Yorkshire and in King's Co., Ireland. *Rosewood* marble is a beautiful brown variety from Ashford in Derbyshire. *Black* marble, such as is worked in Derbyshire, Galway, and Kilkenny, usually emits a fetid odour when struck, and loses its colour on calcination. W. N. Hartley found 1·48 p.c. of carbon and 0·01 of sulphur in the black marble of Kilkenny (Proc. R. Dub. Soc. 5, 486). The black Carboniferous limestone of Belgium and France, with small white sections of encrinites, is termed locally *petit granit*.

Lumachella is an Italian name for any shelly marble, but is specially applied by mineralogists to a Liassic limestone from Bleiberg, in Carinthia, containing the remains of ammonites, which by their brilliant play of colour resemble precious opal. An argillaceous limestone, remarkably rich in dendritic markings, occurs in irregular masses in the Rhætic series, near Bristol, and has been polished under the name of *landscape marble.* The *ruin marble* of Tuscany is a soft argillaceous material, found near Pisa, and sometimes described as a kind of lithomarge. The *ammonite* marble, found near Yeovil, is a brown Liassic limestone, rich in the remains of ammonites. The oolitic formation known as *Forest marble* takes its name from Wychwood Forest in Oxfordshire, which yields a coarse shelly limestone, occasionally polished as an ornamental stone. The famous *Purbeck* marble, extensively used in Gothic architecture, especially for slender clustered shafts, is a grey fresh-water limestone of Upper Oolitic age, crowded with *paludinæ*; whilst the *Sussex* marble is a similar shelly limestone, of fresh-water origin, occurring in bands in the Weald clay. (For English marbles *v.* H. B. Woodward, Geology of England and Wales, 2nd ed. 1887. J. A. Howe, Geology of Building Stones, 1910.)

Among foreign marbles those of the Pyrenees and of Numidia deserve special mention. The so-called *Algerian onyx* is a beautiful stalagmitic form of calcium carbonate, formerly called alabaster, and now known as 'Oriental alabaster,' the adjective being used to distinguish it from true alabaster, which is a native form of calcium sulphate. The *Mexican onyx-marble* is a similar stalagmitic material, used as an ornamental stone. (For American marbles *v.* S. M. Burnham, Limestones and Marbles, Boston, 1883. G. P. Merrill, Stones for Building and Decoration, 3rd ed., New York, 1903.)

Ophicalcite is a name applied to serpentinous limestones, which generally display clouded patterns, due to the interblending of a white limestone or dolomite with a green serpentinous mineral. The 'Irish green' of architects is a rock of this character from Connemara in western Galway. Of a similar nature are the serpentinous marbles of Anglesey, the eozoonal marble of Canada, and the verde antique previously mentioned. As the two constituents of an ophicalcite are unequally attacked by atmospheric agents, such a rock is unsuited for use in exposed situations, since it soon weathers to a rough surface.

In fact, marble generally is hardly suitable for outdoor work in large towns. The atmosphere of a city becomes charged with the products of the combustion of coal, including acid compounds of sulphur, and must sooner or later attack all marble monuments. It has been shown by Sir A. Geikie that marble slabs exposed in the churchyards of Edinburgh suffer total destruction in less than a century (Proc. Roy. Soc. Edinb. 1880, 10, 518).

A minor use of marble is for the production of carbon dioxide in soda-water manufacture. In the United States about 25,000 tons of scrap marble are annually ground into dust for this purpose.

MARCASITE. An orthorhombic form of iron disulphide FeS_2, dimorphous with the cubic iron-pyrites (*v.* PYRITES) and isomorphous with mispickel (FeAsS). Crystals are not infrequent, but their form is usually much obscured by twinning, producing more or less characteristic forms, which have given rise to the names 'spear-pyrites' and 'cockscomb-pyrites.' Stalactitic and nodular forms with an internal radiated structure are also common. The sp.gr., 4·8, is rather lower than that of iron-pyrites, but the hardness (H.=6) is about the same. The colour is pale brass-yellow, rather lighter than that of iron-pyrites (hence an old name 'white pyrites'), but the material frequently shows a surface tarnish. Marcasite is less stable than iron-pyrites, and in a moist atmosphere it decomposes more readily with the production of iron-vitriol. When the material shows no crystal-forms it is not always distinguishable from iron-pyrites.

Marcasite occurs in mineral-veins, as crystals and nodules in the chalk-marl of Kent, in lignite and clay at Littmitz in Bohemia, &c. It is much less abundant than iron-pyrites. When found in large amount it is used, like iron-pyrites, for the manufacture of sulphuric acid and iron-vitriol. L. J. S.

MARCASOL *v.* SYNTHETIC DRUGS.

MARCTINE. Trade name for an antithermic $CH_3{\cdot}C_6H_4{\cdot}NH{\cdot}NH{\cdot}CO{\cdot}NH_2(1:3)$, *i.e.* methyl-acetanilide, in which the acetyl radical is replaced by the group $NH{\cdot}CO{\cdot}NH_2$. For reactions and tests, *v.* Lemaire, Rep. Pharm. 1907, 19, 49; J. Soc. Chem. Ind. 1907, 342.

MARC BRANDY OIL *v.* FUSEL OIL.

MARETIN *v.* SYNTHETIC DRUGS.

MARGARIC ACID $C_{16}H_{33}COOH$ occurs in the wax of lichens, and is obtained by boiling margaronitrile with alcoholic potash (Becker, Annalen, 102, 209; Heintz, J. 1857, 355).

MARGARINE (American, *Oleomargarine*) is the generic term for butter substitutes, consisting either of a mixture of animal fats alone, or of animal and vegetable oils and fats churned with milk to a butter-like emulsion, and coloured yellow (unless forbidden by law) with annatto, methylorange, &c. During latter years, with the expansion of the margarine industry, two further kinds of 'margarine' have been brought into commerce, namely (1) margarine made exclusively of vegetable fats and oils churned to an emulsion with cow's milk, and (2) margarine made from vegetable oils and fats, wherein for cow's milk is substituted an emulsion made from kernels of almonds. Thus the last-named article consists exclusively of *vegetable* products. A variety of the last class of butter substitutes, no doubt suggested by the fact that their consistence was too soft, is made from a mixture of oleomargarine and milk of almonds (with an addition of sesamé oil, where prescribed by law).

The industry of butter substitutes owes its origin to experiments (induced by a prize offered by the French Government in 1869) made by Mège-Mouriès, which were worked out to a manufacturing process in Paris in the year 1870.

In the manufacture of the original margarine, as made by Mège-Mouriès's process, the animal fats used were oleomargarine—'oleo oil,'—and (or) neutral lard (the latter is almost exclusively used in the United States). Both ingredients must be prepared from the freshest beef fat and (or) hog-fat respectively.

For the production of oleomargarine, the rough fat is removed from the slaughtered animal as quickly as possible and brought into the works, where it is sorted. The kidney and bowel fats are selected, then carefully washed with warm water and thoroughly cleansed. The cleansed fat is brought immediaately into large, well-aired, artificially cooled rooms to dry and harden (being allowed to hang there suspended from tin hooks for several hours), or is immersed in iced water in order to secure more rapid hardening. The hardened fat is then cut up and shredded in a shredding machine, and finally ground between rollers. The disintegrated mass is introduced into tin-lined jacketed vessels ('melting kettles') and brought to a temperature not exceeding 42°C., this temperature being maintained by steam or hot water passing through the jacket.

At this temperature a portion only of the tallow contained in the tissue separates on the top of the comminuted rough fat. The settling and clearing is assisted by sprinkling salt over the surface of the melted fat. This melted portion, termed 'premier jus,' is run off into shallow tin-lined trays arranged in tiers in a cooled room, when the bulk of the 'stearine' separates in a crystalline condition. The crystallised mass in the tins is cut up into square pieces of about 3 lbs. weight each, wrapped in canvas cloths, and placed in hydraulic or mechanical presses.

For the best qualities of margarine, the 'premier jus' is remelted at a temperature not exceeding 45°C. and allowed once more to settle out, after salt has been added, whereby the last remnants of membrane and tissue are precipitated. In large works the clear fat is allowed to run into wooden vats, in which it stands for from 3 to 5 days at a temperature suitable for the crystallisation of the 'stearine.' The whole is then stirred up into a homogeneous pulpy mass; this is wheeled in wooden waggons to the presses and treated as described already.

The oleomargarine, 'oleo oil,' which runs out from the presses formerly constituted the exclusive raw material for the manufacture of margarine.

In some works the rough fat from which the 'premier jus' has been taken off (in the manner described above) is heated once more to about 50°C., when a second portion of fat is recovered. This is sold as 'secunda jus,' and is used in the manufacture of inferior kinds of margarine ('secunda' margarine).

Amongst the vegetable oils, cotton-seed oil and cotton-seed stearine, sesamé oil, arachis oil, and recently even soya-bean oil, are preferred. According to the intended quality of the margarine, the quality of the cotton oil varies. In any case the cotton-seed oil must be practically devoid of free fatty acids, and rendered as free as possible from the peculiar flavour characteristic of this oil. The best brand of cotton-seed oil used for margarine making is known under the name 'butter oil.' Arachis oil (also olive oil) and sesamé oil are used to a greater extent in Europe than in the United States. Refined cocoa-nut oil and palm-kernel oil are now incorporated to a very considerable extent with the fat stock of margarine.

The oleomargarine, 'oleo oil' (and neutral lard) is mixed in *churning machines* at as low a temperature as is consistent with a semi-fluid condition with the vegetable oils and fats, and with milk.

The quality of the resulting product depends, to a great extent, on the quality of the milk and on its treatment previous to its admixture with the fats. The milk may be either sweet milk or sour. Sweet milk is more difficult to amalgamate with the oils and fats, and is retained with greater difficulty than soured milk, but the advantage the employment of sweet milk offers is that the resulting product has a finer taste and keeps better. The soured milk is, however, more easily incorporated with the fats and gives a higher yield. The proper treatment of the milk in the margarine works constitutes one of the most important features, just as the corresponding part of the butter-making process does in large dairies. The milk should be worked up as soon as possible after arrival. In any case it should be pasteurised immediately after it is received, and no preservatives—not even salt—should be used to prevent the fermentation of the milk. If the cream has not been taken off before the milk reaches the margarine works, it is removed (for butter-making) by means of a centrifugal machine, &c. The regular determination of the fat in the milk is necessary, not only for the proper control of the works, but also for the further reason that it has not infrequently occurred (on the Continent) that too much cream is taken off by the seller and replaced by sesamé oil, cotton-seed oil, or even by margarine.

In place of cow's milk, kephir milk, or even kephir fungus, have been recommended (and patented). It is claimed that the margarine so obtained has a full butter flavour and 'browns' on being heated.

The churning machines consist of oval, jacketed vessels provided with one or two sets of stirring and mixing gear. During the process of churning a constant temperature must be maintained by means of steam sent through the jacket of the churn. The object of churning, besides thoroughly mixing the ingredients, is to destroy the tendency of the oleomargarine to crystallise, and to pulverise ('atomise') the mixture, as it were, into single globules, such as butter-fat forms in milk. The art of the margarine maker at this stage of the process consists, therefore, in carefully regulating the inflow of milk and fat stock, so that a thorough emulsion is finally obtained.

First, the milk is put lukewarm into the churn and is mixed up with a little cream, followed by the addition of butter (if any be added). When the mass is thoroughly emulsified, part of the oleomargarine is added carefully, and when this has been properly incorporated with the emulsion, the oils required for the margarine stock are entered gradually and only then the remaining oleomargarine is mixed in. At this stage some manufacturers add colouring matters. The steam is then turned off, and the warm material cooled to a definite temperature by cold water being sent through the jacket.

From the churn the cooled margarine is run into cooling tanks, which are built up of marble or white tiles or simply consist of large wooden tanks. While running out, the margarine is met by a current of ice-cold water, delivered under high pressure, in order to pulverise the mass thoroughly. The disintegrated globules, after solidifying, somewhat resemble butter granules.

The cooling of the still liquid margarine by running it off to a cooled table, has the serious drawback that the cooled mass is of uneven thickness, and hence an unevenly cooled product is obtained. This drawback is avoided by E. and H. H. Schou, who cool the margarine in a thin layer, of a thickness of about 1–1·5 mm., between two hollow cylinders which revolve in opposite directions and are cooled by a cold brine solution.

A large number of patents have been taken out for 'homogenising' or 'atomising' in special machines the mixture of milk and oils and fats. The merit claimed for these machines is that the product is more solid and has no 'oily' but 'rather a nut-like' taste. The important demerit of all these apparatus is, however, that the margarine retains more water, and hence the proportion of fat falls below 80 p.c. Therefore in those countries where the maximum percentage of 16 p.c. of water is prescribed by law, the sale of such margarine would meet with difficulties.

In order to obviate this drawback, and at the same time to dispense with the kneading machines, in which the excess of the milk is removed, Schroeder (D. R. PP. 204061; 204062) carries out the blending and emulsifying process in three churning machines arranged one above the other and working in conjunction with an 'atomiser.' The temperature in the three churns through which the mixture of fats and milk passes is regulated carefully so that the completely emulsified contents of the lowest churn can be discharged on to a cooled table, where the mass solidifies to a thin layer, which is scraped off by a tangentially acting 'doctor,' so that the thin solidified film is curled up and discharged into a waggon. The ingredients forming the margarine are mixed (*v. infra*) in the proportion of 80 parts of fats and oils, 16 parts of milk, and 4 parts of cream, consisting approximately of one-third of butter-fat.

The solidified margarine is taken out of the cooling tanks by means of long wooden spoons, placed in wooden waggons (where adhering water drains off), and is then carted to large kneading machines. These consist of huge circular wooden tables, which rotate slowly, while at the same time a set of conical, fluted, or specially shaped rollers move along the top of the revolving tables. The margarine is thus thoroughly worked through, and the excess of water squeezed out, so that a homogeneous mass results. This is then salted to taste, mixed with a little colouring matter (if permitted by law), and again submitted to thorough kneading in a second set of kneading machines of the same or of different type, in order to produce the required texture throughout the whole mass. At this stage also other additions (such as sugar, perfumes, &c.) are made. The margarine is finally moulded into lumps, pats, rolls, or any other desired shape.

A general working recipe for the manufacture of margarine is to mix 65 parts of oleomargarine, 20 parts of vegetable oils, and 30 parts of milk. The yield is 100 parts of finished product, 15 parts of water being eliminated in the course of manufacture. The more milk used, the better will be the margarine.

The object of the margarine maker being to render his product as closely similar to butter as possible, and to take away the 'tallowy' or too strongly 'oily' taste of the material, some manufacturers (provided the law permits) add cow's butter. Others add small quantities of volatile acids, volatile aldehydes, mixed glycerides containing butyric acid, such as dibutyromonostearin and dicaprylomonostearin, or 'butter perfumes,' which consist chiefly of volatile acids, such as propionic, butyric, caproic, and their ethyl esters. Also coumarin (sold as an emulsion with sesamé oil) would fall under the head of 'perfumes.'

It should, however, be stated that margarines prepared from the best material and in an unobjectionable manner do not require any of these additions. The latter are chiefly used in order to mask low-grade materials, or to afford analytical data which may create a fictitious impression as to the real nature of the product.

An important point in the manufacture is to produce margarine which will froth and 'brown' on heating, so that even in cooking the margarine may resemble butter. Since the property of butter to brown and froth is due to casein and milk sugar, it is evident that the more milk is used in the manufacture of margarine, the nearer will the product approximate to butter.

Milk is liberally used in this country and in America; but in some continental countries where the law forbids the addition of more than a strictly limited quantity of milk, a number of patents have been taken out for substances which are credited with imparting to margarine the desired properties. Prominent amongst these patented products are casein and other albuminoids. Some patentees claim cholesterol and cholesteryl esters, or lecithin. Lecithin is now incorporated with margarine in the form of egg yolk, which is, of course, cheaper than lecithin.

Vegetable waxes have also been proposed as admixtures, and the use of beeswax for this purpose has even been patented, although the addition of such substances must seriously interfere with the digestibility of the margarine.

Besides the taste, the consistence also plays an important part in the valuation of margarine. If the finished margarine has not been worked sufficiently on the tables, its consistence may be either too 'greasy' or too 'sandy,' *i.e.* the semi-crystalline mass has not been properly 'broken,' and its grain differs from that of a properly prepared dairy butter. Some margarines are also finally mixed with a little glycerin, or glucose, or sugar, in order to improve the texture or to give them a glossy appearance and also a sweeter taste. The addition of glucose or cane-sugar must, however, be considered a mistake, as this only leads to premature development of fungus on the margarine.

The manufacture of butter substitutes is differently affected by legislation in different countries. In this country the adding of butter to margarine in any proportion was at first allowed, for, according to the Margarine Act of 1887, any ‘ butter ’ containing even the smallest quantity of foreign fat was looked upon as margarine. By the Margarine Clause of the Food and Drugs Act, 1899, however, the maximum proportion of butter-fat in margarine has been restricted to 10 p.c.

This restriction has been confirmed by the Butter and Margarine Act of 1907, and it has been further enacted that margarine must not contain more than 16 p.c. of water. Margarine factories must be registered, and are open to Government inspection. Prohibited preservatives must not be used, nor is an excess of boric acid allowed. According to the same act ‘ margarine ’ means ‘ any article of food, whether mixed with butter or not, which resembles butter, and is not milk-blended butter.’ For the latest enactments in other countries the reader is referred to Lewkowitsch, Chemical Technology, vol. iii. 26–27.

In the *examination* of margarine the determination of the Reichert-Meissl value constituted the most important characteristic, as it indicated in the briefest and surest manner the amount of butter-fat contained in the margarine, either added as butter or originating from the milk which had been incorporated with the oils and fats in the process of manufacture. Since, however, considerable quantities of cocoa-nut oil and palm-kernel oil form ingredients of margarines, and since even margarines are made at present which consist exclusively of the last-named two oils, without even an addition of cow’s milk, the indications of the Reichert-Meissl value no longer have that importance which they formerly possessed. Accurate methods for the detection of butter-fat and cocoa-nut oil or palm-nut oil in the presence of other vegetable oils and fats have not yet been elaborated in such a satisfactory manner that complete confidence can be given to them. An important test is the detection and determination of unsaponifiable matter, as latterly unscrupulous manufacturers have again commenced to admix paraffin wax with margarine. J. L.

MARINE ACID. *Syn.* for hydrochloric acid (*q.v.*).

MARINE ANIMAL OILS *v.* OILS.

MARIPA FAT. The fat of the fruit of *Maximiliana* [*Attalea*] *Maripa* (Drude), used in the West Indies as a butter. It is employed in French Guiana as a medicinal liniment, and is practically identical with coco-nut fat in characters.

MARJORAM, *Origanum Majorana* (Linn.), a herb employed in flavouring. It is generally used in the air-dried state, when it has the following composition :—

Water	Protein	Fat	Ethereal oil	N-free extract	Crude fibre	Ash	Sand
7·6	14·3	5·6	1·7	35·6	22·1	9·7	3·4

Commercial dried marjoram often contains much sand; a good sample should not contain more than 14 p.c. of ash, of which not more than 3·5 or 4·0 p.c. should be insoluble in hydrochloric acid. The following analyses of the ash of marjoram were made by Rupp (Zeitsch. angew. Chem. 1892, 681) :—

	K_2O	Na_2O	MgO	CaO	Fe_2O_3	Mn_3O_4	P_2O_5	SO_3	Cl	CO_2	Sand
German	20·2	0·7	4·8	17·6	7·3	1·0	8·9	4·9	2·1	6·1	26·5
French .	18·3	0·7	6·7	24·8	6·1	trace	9·1	4·8	1·5	8·6	19·4

(*v.* OILS, ESSENTIAL). H. I.

MARKASOL. *Bismuth borophenate* (*v.* BISMUTH, ORGANIC COMPOUNDS OF).

MARKING-INK is used for stamping or marking fabrics, and should be permanent, and indestructible to the material. The basis of many marking-inks is a silver salt dissolved in aqueous ammonia containing a little gum. This is only coloured on decomposition, so a little dye is needful : dark-brown inks contain archil and chlorophyll, crimson contain carmine, whilst copper sulphate is an ingredient of blue ink.

Redmond’s ink is made thus : dissolve 3 oz. 2 drms. silver nitrate and 3 oz. sodium carbonate each in 2 pints boiling water, mix, and collect the precipitate so formed on a filter, wash with water, transfer to a mortar, add 10½ drms. tartaric acid, triturate the whole, and when effervescence has ceased, add 3½ oz. of ammonia (0·880), stir until dissolved, and add 1½ oz. powdered white sugar. Mix 1 oz. chlorophyll and 1 oz. archil with 4 oz. water, add 2½ oz. of acacia gum to this when dissolved, strain, add to the ammoniacal solution and make up to 20 oz. with water. This ink, if carefully prepared, contains only the tartrate of silver ; on heating metallic silver is left on the fabric.

An indelible ink is made by dissolving 1 oz. silver nitrate and 1½ oz. of sodium carbonate separately in 3 oz. distilled water; mix the solution, collect and wash the precipitate with distilled water. Add 160 grs. tartaric acid, dissolved in 1 oz. water, to the precipitate in a mortar, stir until effervescence ceases, and then add 2 oz. liquid ammonia to dissolve the precipitate. Mix in 80 grs. aniline black, dissolved in 1 oz. boiling water, and add 5 drms. glycerol and water to make up to 8 fl. oz. (Spon’s Workshop Receipts, 1909, 510).

Aniline marking-ink is prepared thus : in two bottles (1) add 1 fl. drm. aniline and 10 grs. toluidine to 2 fl. drms. mucilage of acacia and dilute hydrochloric acid, and mix ; (2) powder 40 grs. cupric sulphate, 20 grs. ammonium chloride, 20 grs. potassium chlorate, and dissolve in 6 fl. drms. water ; lastly, add 2 fl. drms. of thick mucilage and mix. Leave for 2 or 3 days before using. Equal parts of each solution are mixed immediately before using and applied with a quill pen (Scient. Amer. Ency. 1903, 276).

An ink suitable for rubber stamps, as it dries rapidly, is made by adding 15 oz. glycerol to a solution of ½ oz. aniline black and 15 oz. pure alcohol.

To use silver marking-ink for stamping, add to 1 oz. ink, 1 drm. glycerol and 1 drm. treacle.

To make an indelible red ink, dissolve 2 oz. shavings of dry white curd soap in 1 part balsam of copaiba by heating, add sufficient vermilion and stir occasionally until cold.

Indian-inks are used for marking.

An ink suitable for labels which cannot be bleached is made by mixing equal parts of pyrogallol and iron sulphate. The label is varnished when dry (Hiscox, Receipts, 1907, 407).

The juice of the banana and of the marking-nut have to some extent the properties of marking-ink, but no practical method of preparing them for sale has been developed.

MARL (Ger. *Mergel*), a name properly restricted to calcareous clays, but frequently extended so as to include any clay which, when dry, is readily friable. Thus the Keuper or New Red Marls, of Triassic age, often contain little or no calcareous matter. An analysis of a red Keuper marl, from Worcester, by Voelcker, yielded 4·85 p.c. of lime. Marls have been used for ages by agriculturists for the purpose of improving certain lands, the material for 'marling' being systematically dug from 'marl pits.' Since a marl is a calcareous clay, it may obviously pass into an argillaceous limestone; the *chalk marl* is a rock of this kind. When a marl becomes indurated it is often known as *marlstone* or *marl-rock*, and the hard beds of the Middle Lias, which in Yorkshire yield the Cleveland iron-ore, are recognised by geologists as the 'marlstone.' A laminated variety of hardened marl is termed *marl-slate*, which readily passes into a calcareous shale. The marl-slate occurring in the Permian series in the north of England is equivalent to the German *Kupferschiefer*, a bituminous marly shale, containing copper-ore. The *shell-marl* found at the bottom of certain lakes, especially in Scotland, is a calcareous ooze, consisting largely of organic remains. L. J. S.

MARRUBIIN *v.* Marrubium.

MARRUBIUM, *Horehound, Hoarhound.* (*Marrube blanc*, Fr.; *Andornkraut*, Ger.) Horehound has been employed for its mild tonic, stimulant, and laxative properties, especially in domestic medicine, for a long period. It consists of the leaves and tops of the *Marrubium vulgare* (Linn.), a perennial herb growing throughout most parts of Europe, Asia, and America (Bentl. a. Trim. 210). The only constituent which has been examined, except a trace of *volatile oil*, is the bitter neutral *marrubiin.*

Marrubiin was discovered by Mein (Gm. 18, 234), and further studied by Harms (Arch. Pharm. [ii.] 83, 144; 116, 141) and Kromayer (*ibid.* [ii.] 108, 257), and recently by Gordin (Amer. Chem. J. 30, 265). The dried plant is exhausted with hot water, the solution evaporated to a syrup, the syrup extracted with alcohol, and the extractive obtained, after distilling off the alcohol, is mixed with sodium chloride and treated with ether. On spontaneous evaporation of the ether the marrubiin remains (Harms). Kromayer takes advantage of the power of animal charcoal to absorb marrubiin from the juice of the plant or an infusion, and to yield it again on treatment with alcohol. An alcoholic extractive is thus obtained from which ether removes the marrubiin.

Marrubiin crystallises from ether in plates and from alcohol in needles. It has a bitter and somewhat acrid taste. It melts at 154·5°–155·5° (Gordin). It is insoluble in cold, very slightly soluble in hot water; but dissolves in alcohol or ether.

Marrubiin has the composition $C_{21}H_{28}O_4$; it does not contain any methoxyl groups, and does not decolourise bromine solution. When boiled with alcoholic potassium hydroxide it is converted into *potassium marrubate.*

Marrubic acid $C_{20}H_{29}O_3{\cdot}CO_2H$, m.p. 173°–174°, forms long white silky needles, and when heated at 190°–200° under 15 mm. pressure is reconverted into marrubiin. The acid reduces ammoniacal silver nitrate and Fehling's solution. It appears that marrubiin is a lactone, and can take up a molecule of water to form the hydroxy acid, marrubic acid. A. S.

MARSH GAS. *Methane* or *methyl hydride* (*v.* Methyl).

MARSH-MALLOW GUM *v.* Gums.

MARSH ROSEMARY. *Andromeda Polifolia* (Linn.); also an American name for *Statice caroliniana* (Walt.) [*S. Limonium* (Linn.)]. *Andromeda Polifolia*, belonging to the *Ericaceæ*, is the only British species of the genus; it is found also in peat-bogs throughout the north of Europe, Asia, and America. It is an acrid narcotic and is fatal to sheep pasturing off it.

Statice caroliniana is found in marshy situations from Maine to Florida. According to Parrish, it contains 12 p.c. of tannin and has been used in the manufacture of leather.

MARTENSITE. The principal constituent of all hardened steels containing over 0·16 p.c. of carbon. It is a solid solution of carbon in iron; when saturated, as in high-carbon steels, it is known as '*hardenite*' (Howe).

On a polished surface, etched with picric acid, it shows under the microscope three systems of cleavage planes inclined to each other at 60°. It is very hard and cannot be scratched by a needle.

Martensite is magnetic and forms one of the principal constituents of permanent magnets.

MARTIUS'S YELLOW. A synonym for Naphthalene yellow; known also as *Jaune d'or, naphthol yellow, Manchester yellow.* The sodium or lime salt of dinitro-α-naphthol (*v.* Naphthalene).

MASOPIN RESIN *v.* Resins.

MASS ACTION *v.* Chemical affinity.

MASSECUITE *v.* Sugar.

MASSICOT *v.* Lead.

MASTIC CEMENT *v.* Cements.

MASTIC RESIN *v.* Resins.

MASTIC VARNISH *v.* Varnish.

MATAZIETTE. A name given to an explosive made in Switzerland, formed of nitroglycerin, sand, and chalk, coloured with ochre.

MATCHES. (Ger. *Zündhölzer, Zündhölzchen*; Fr. *Allumette*; Sw. *Tändsticka*, pl. *Tändstickor*; Du. *Zwavelstokje, Fosforus-stokje*; It. *Zolfanello, Fiammifero*; Da. *Svovlstik*; Hung. *Gyufa.*)

Derivation and variants of the word 'match.'—Older Eng. forms, *mec(c)he, metch, matche, mache, macche*; O. Fr. *mesche, meiche*; Mod. Fr. *mèche*; Pr. *mecca, mecha*; Catal. *metxa*; Sp. and Port. *mecha*; It. *miccia*; perhaps from Gr. *μύξα*, L. *myxa, mixa, myxus*, lamp-nozzle, lamp-wick, mucus of the nose; connected with L. *muccus*, nasal mucus, whence It. *moccolo*, L. *mucculus*, snuff of a candle.

Definitions. I. (*Ordinary language*).—An instantaneous fire-producer, consisting of a short stem, rod, or tube, tipped at one or both ends with a composition or paste, inflammable by friction; or (as in the earlier forms) when brought into contact with a chemical reagent.

2. (*Military and mining*).—A cord or thread impregnated with combustible material, capable of burning along its entire length, so that fire can be conveyed from one point to another. This kind of match, which is better termed a fuse, is not ignitable by friction, and may be 'slow' or 'quick,' according to requirements.

I. Friction Matches.

History and development. Friction matches are among the most useful products of the period immediately preceding the Victorian age, and afford a signal instance of the ministration of science to human needs. Developed in less than three-quarters of a century from fire-producing appliances of the most primitive types, they have been so perfected that it is difficult to foresee in what direction further progress is possible.

Since the discovery of phosphorus in 1673 by Brand, of Hamburg, many attempts had been made to obtain light and heat expeditiously by its aid; one of the earliest consisting in rubbing a particle of phosphorus between folds of coarse brown paper, the flame produced igniting a sulphur-tipped splinter of wood. This plan was found to be inconvenient and dangerous, and phosphorus gradually fell into disuse. After the element had been, in a technological sense, left severely alone for more than a century, renewed attempts were made to utilise it. One contrivance was the somewhat impracticable '*phosphoric taper*' (1781). This was of wax, enclosed in a sealed glass tube, at one end of which was a fragment of phosphorus. After the tube had been dipped in warm water, the end remote from the phosphorus was cut off with a file, the taper was withdrawn, with some phosphorus adhering to it, and spontaneously inflamed. Another appliance was the '*phosphorus bottle*' of Cagniard de Latour (1810), containing partially oxidised phosphorus, some of which was withdrawn by a brimstone match, dipped into the phial, and then ignited by friction. A '*briquet phosphorique*,' brought out in Paris in 1786, consisted of a small tin box containing sulphur-tipped matches, together with a bottle coated internally with phosphorus. '*Pocket luminaries*,' soon afterwards sold in London, and '*portable fire boxes*' were similar. Various early devices for quickly producing fire were Homberg's '*pyrophorus*' (an oxidisable powder, free from phosphorus, prepared by roasting alum with flour, honey, or sugar, and inflamed by exposure to air), and Döbereiner's pyrophorus, of similar character; '*pneumatic tinder-boxes*,' containing amadou or ordinary tinder, ignited by the heat generated when air was compressed by a piston, such as Mollet's Pump, and Lorentz's '*light syringe*' (1807); '*electropneumatic fire-producers*' (invented by Brander, 1778, and by Fürstenberger, 1780), in which hydrogen was kindled by an electric spark—to which category belonged Mayer's apparatus (1811); Volta's '*inflammable air lamp*'; Fyfe's '*hydropneumatic lamp*'; and, lastly, Döbereiner's '*platinum lamp*' (in which contact with spongy platinum, or iridium, ignited hydrogen gas)—with Eisenlohr's, v. Babo's, v. Römer's, Palkl's, Hare's, Schiele's, and Böttger's modifications of the same.

The principal stages in the evolution of matches will now be referred to in chronological sequence. During the year 1804, phials, charged with a mixture of phosphorus, wax, and oil were sold in cases containing also some brimstone-tipped matches and a piece of cork. The matches were dipped into the mixture, withdrawn, and ignited by friction on the cork. In 1805, Chancel, of Paris, applying the principle discovered by Berthollet, of oxidation by chlorates in the presence of strong acid, invented '*oxymuriate matches*,' strips of wood tipped with a mixture of potassium chlorate, sugar, and gum, ignited by contact with sulphuric acid. In the same year, according to Niklès, *friction matches* containing the element phosphorus were made and used in Paris. In 1806 various improvements in the tinder-box were suggested by Phillips, who was followed by Lorentz (1807), with an apparatus for igniting hydrogen gas by the aid of an electrophorus, and with the 'light syringe' already mentioned (same patent). In 1809, to Derepas, of Paris, was granted a French patent 'for a peculiar composition of phosphorus match lights.' This was an attempt to render phosphorus more manageable and less inflammable, by intimately mixing 8 parts, 'half melted,' with 4 parts of magnesia. When cold, the substance was described as forming 'an opaque body fit for inflaming a common match' (Description des Brevets). During the year 1812, '*chemical matches*,' manufactured according to Chancel's invention, began to be sold extensively, a hundred for a florin, in Vienna. The sticks were tipped with potassium chlorate, sugar, and gum, or with the same ingredients and lycopodium: colophony, gum benzoin, &c., were also used. These matches, packed in suitable cases, together with bottles containing asbestos soaked in sulphuric acid (in accordance with a proposal made in 1812 by v. Römer, of Vienna), were sold more widely on the Continent than any others, up to the year 1844. Among the makers were v. Römer, Peters, Wagner, Siegel, Ehrlich, and Merckel. The cases were known as '*tunkfeuerzeugen*,' '*briquets phosphoriques*,' '*inflammable match-boxes*,' '*instantaneous light boxes*,' '*phosphorus boxes*,' &c.; and one form was prominently sold in this country as Heurtner's '*Eupyrion*.' Violence of combustion, and liability of the acid to be spirted about, were characteristics of these matches. In 1816, friction matches tipped with a composition containing phosphorus are stated to have been manufactured in Paris by François Dérosne, who by Gintl and others is regarded as the first maker of the phosphorus friction-match. The year 1823 is marked by the invention of the Döbereiner lamp, already referred to. About this time, too, were used, at Erfurt, in Prussia, small glass tubes containing equal quantities of phosphorus and sulphur carefully fused together, into which thin sticks or splints of wood were introduced, easily inflamed afterwards by friction. The early attempts to make friction matches in Paris and elsewhere appear to have failed completely; and the honour of having invented, in 1827 or earlier, the first practical and useful matches ignitable by friction, indisputably rests with an Englishman, John Walker, of Stockton-on-Tees, Durham (*d.* 1859). Walker was an apothecary, who had been apprenticed to a local surgeon before starting in business as a druggist. He was much interested in experimental chemistry, and for some years prior to 1827 had been preparing and selling, under the name of 'percussion powder,' dried mixtures of potassium chlorate and antimony sulphide, made up with gum-water. Eventually it occurred to him to dip splinters of wood into such a composition, and to supply these matches in tin boxes, together with a piece of folded glass-paper, under the name of 'friction-lights.' Samuel Jones, of 201, Strand, London, who from 1829–1830 onwards sold imitations of Walker's matches under the designation of '*lucifers*' (a name always repudiated by Walker), publicly announced in 1831 that about a year previously they had been 'lectured on at the London and Royal Institutions.' Matches resembling Walker's, but mostly sulphur-dipped, were made also by Jones's competitor, G. F. Watts, in 1831 ('*Watts's chlorate* or *lucifer matches*'), and by Richard Bell & Company in 1832 ('*improved lucifers*'). Watts and Bell both 'borrowed' the name 'lucifer' from Jones. '*Allumettes infernales*' were brimstone-dipped matches of the same type; and German matches of a similar kind, but not sulphured, were also manufactured. H. Link's '*allumettes chémiques*,' produced in Germany for the French market, and L. Achleitner's (Salzburg) '*snellzünder*,' were of like character. Among French makers of matches of an allied type were J. Joseph et Cie (1833), and A. Perpigna (1834).

Though non-phosphoric, Walker's matches inflamed when pressed between the folds of the glass paper and sharply withdrawn. Thus ignitable by friction, they were the lineal ancestors of twentieth-century matches.

Walker at first used strips of cardboard for the stems of his matches, but later he substituted splinters of wood, which he employed the poor people of the district to cut.

In the year 1828, Samuel Jones patented the '*prometheans*,' a return to the principle of the oxymuriate match. These consisted of slightly tapering, spirally-rolled paper tubes, containing in the broader or ignition end a minute fusiform glass tube (not a bulb, as usually stated), 10·5 mm. long by 1·0 mm. wide which enclosed a dark-blue liquid, shown by the writer's analysis to be composed of sulphuric acid coloured by indigo. The glass vessel was imbedded in a composition, variously stated to contain potassium chlorate and sugar, 'fulminate,' &c., but found by the writer to be composed of potassium chlorate, lycopodium, and sulphur. Neither sugar nor fulminate was present in the prometheans examined.

'*Lucifer matches*' or '*lucifers*,' *i.e.* non-phosphoric matches, of Walker's type, which inflamed when rapidly *drawn through* folded sand- or glass-paper, were followed in the early thirties by non-phosphoric friction matches, which could be ignited, though with difficulty, by being *struck upon rubbers affixed to the boxes*. Such were the friction matches made by Savaresse and Merckel (Paris), the igniting composition of which was a mixture of potassium chlorate, antimony sulphide, sulphur, and gum. The rubbing surface was composed of potassium chlorate, minium, pumice, and gum. Similar non-phosphoric friction matches were patented in 1832 by Siegel, an Austrian manufacturer; and Link's 'Chemische Streichfeuerzeuge' were of a like description. Matches, capable of being *struck upon the box*, soon became known as '*Congreves*,' both in this country and abroad; and the name was applied to the phosphoric friction matches which next came on to the market. 'Congreves' succeeded to 'lucifers'; 'lucifers' followed 'friction-lights;' 'friction lights' superseded 'chemical matches.'

It may be mentioned here that Samuel Jones seems to have been the first user of the word *fuzee*, or fusee, as applied to a match for lighting pipes or cigars. But Newton, a few months earlier, applied the term to a match for use by 'smelters.'

Hare's pyrophorus, described in 1831, was made by heating Prussian blue to redness in a glass tube, which immediately afterwards was hermetically sealed. On breaking the tube and throwing out the contents they took fire.

Efforts meanwhile were being made to produce *a practicable and satisfactory friction match*, in which *phosphorus* should take the place of antimony sulphide; and this important result appears to have been achieved simultaneously in several different places during the period 1831–1833. At all events, in 1833–1834, v. Römer, Preschel, and Siegel, in Vienna, and Moldenhauer, at Darmstadt, were manufacturing wooden friction matches, the igniting compositions of which contained phosphorus. The date of v. Römer's patent was January 4, 1834. Other pioneer makers, associates or otherwise of the above, were Pollak and Kreutz (Vienna); Anthon (Darmstadt); and Amüller (Waiblingen). Many of these early continental makers called their matches 'congreves.' In France, the invention of the phosphorus friction match is now generally attributed to Dr. Charles Sauria, of St. Lothair (*d.* 1895), who, in January, 1831, while a student at the College d'Arc, Dole (Jura), made very good friction matches containing phosphorus, but neglected to protect his invention. Sauria's claims have been well attested; and it is possible that a rumour of his experiments somehow was conveyed to other countries during the few months following the discovery. The French Government in 1884 recognised 'L'Invention des Allumettes Chimiques' by a grant to Sauria of a '*bureau de tabac*,' the Academic Nationale Agricole bestowed upon him a medal, and during the year 1896 there was a movement to set up a monument to him in Paris. The design was not carried into execution, however. J. F. Kammerer (*d.* 1857), of Ludwigsburg, Würtemburg, is in Germany usually credited with having invented phosphorus friction matches in 1833; and he is said to have worked out the idea during the previous year; but the invention was not protected, and was pirated in every direction. Claims have been advanced also for a young Hungarian student at the Vienna

Polytechnic School, named János Irinyi (who in 1895 was still living in south Hungary). He is alleged to have made the discovery in 1835, and to have sold his process to v. Römer. Possibly Irinyi's invention marked an advance upon the type of phosphoric friction match which had already begun to be manufactured. Lastly, a professor at the Technical High School in Stockholm, Dr. J. S. Bagge, between 1830–1840, worked out a method for procuring light by means of phosphorus friction matches, and drafted directions for their manufacture.

The oxidising agent used in the earliest matches was potassium chlorate only, but in 1835 Trévany partly replaced it, as being too violent in its action, by a mixture of minium and manganese dioxide.

In the United States of America the first patent for the invention of phosphorus friction matches was granted in 1836 to A. D. Phillips, whose igniting composition was a mixture of phosphorus, sulphur, chalk, and glue. In 1837, v. Römer substituted lead peroxide for potassium chlorate; in 1838, Preschel and Kreutz patented a composition consisting of phosphorus, manganese dioxide, nitre, and gum arabic; Beyer (Vienna, 1838) and Riess (Vienna, 1843) used as the oxidising agent a mixture of minium and nitric acid; and in 1842–3, Böttger, of Frankfort, recommended the substitution, for potassium chlorate, of mixtures of minium and saltpetre, or of lead peroxide and lead nitrate. Moldenhauer, about the year 1838, introduced the use of calcined magnesia in order to counteract the effects of the formation of hygroscopic oxidation-products of the phosphorus; and chalk also (introduced in 1836 by Ehrlich, of Prague) was used for the purpose. Preschel and Klug (1837) endeavoured to accomplish the same end by coating the match-heads with resinous spirit-varnishes. Between 1820 and 1840 various machines for cutting the wooden stems or 'splints' rapidly and in large quantities, were introduced; and the match industry has since developed in country after country until it is now of very great magnitude and world-wide importance. Although in the conditions and processes of manufacture, as well as in the character of the materials used (especially during the past 20 years), there have been improvements and modifications, so far-reaching and gigantic that the industry may be said to have been revolutionised, nevertheless the ordinary friction match of to-day is not *essentially* different from the 'lucifers' and 'congreves' made during the first third of the 19th century. But the use of machinery has been greatly extended. Continuous and automatic machines are at the present time widely and increasingly employed; and, following upon a gradual diminution in the proportion added, in only a very few countries now is white or yellow phosphorus used at all in the manufacture (*see post*, pp. 408 and 412). In 1855 J. R. Wagner recommended that less phosphorus should be used, and experimented with barium nitrate and potassium dichromate, as oxidising agents. The latter salt he considered too costly, and he remarked that lead dioxide, though more expensive and no better, had then largely replaced the mixture of minium and manganese dioxide. In view of the subsequent introduction and present widespread use of tetraphosphorus trisulphide, or phosphorus 'sesquisulphide,' P_4S_3, it is interesting to record that in 1860, Puscher, of Nuremberg, introduced the use of phosphorus sulphide instead of phosphorus, but found few followers. Bals (D. R. P. 89700, 1896) also tried a fused mixture of sulphur and red phosphorus. For making matches *waterproof*, Zimmermann (1864) used collodion, as an improvement on the resinous varnishes of Preschel, Klug, Winterfeld (1842), and Krutzler. Barker (1845), and, after him, Gaillard, applied a coating of sulphur over the friction composition, such matches being found by Abel (1863) to be waterproof, but somewhat difficult to ignite. Hannan and Mills (1882), for the same purpose, mixed paraffin, fatty bodies, or resins, with the compositions. The inventions of Thomas (1895), Fowler and Bower (1895), and Ramsden and Hirst (1900), had a similar end in view. *Scenting ingredients*, such as gum benzoin, frankincense, &c., were often added to the varnishes; and in 1854 Krakowitzer, of Pottenstein, Austria, introduced a process by which a metallic lustre was imparted to the heads of matches '*de luxe*,' or 'parlour' matches (containing lead compounds), by exposing them to sulphuretted hydrogen gas. This process was modified by J. Ginzky in 1860, and again by Schindler, in 1867. A later improvement (A. Kielmeyer, 1879) was to varnish over the silvered heads with an alcoholic solution of colophony, shellac, &c., to which an aniline or other dye was added. Thus, to obtain a greenish bronze, Kielmeyer used fuchsine or methyl violet; other colours employed were methyl green, aniline orange and the like.

Great as was the improvement effected by the substitution of phosphorus for the less easily oxidisable antimony sulphide, there were serious disadvantages attending its use. The poisonous nature of phosphorus, the somewhat too ready inflammability of the igniting compositions made with it, and especially the 'phosphorus disease' (a carious affection of the lower jawbone, leading to necrosis, from which a small proportion of the workers—especially the dippers—were liable to suffer), were much the most important of these. The phosphorus disease, first described in 1845 by Lorinser, of Vienna, has intermittently called for the anxious attention of match manufacturers and statesmen in most countries where white phosphorus has continued to be used in match-making, from 1870 to the present time. In Great Britain, and in other countries where the use of ordinary phosphorus in this industry is forbidden, phosphorus necrosis may be regarded as a thing of the past. But in countries such as America, where there is not yet prohibition, the prevention of the 'phosphorus disease' is still a 'burning question.' Good ventilation, impregnation of the air of the factories with the vapour of oil of turpentine, and scrupulous personal cleanliness on the part of the operatives, combined with particular attention to the condition of their teeth, have been found greatly to diminish the number of cases of necrosis. It was shown by Thorpe and Tutton that the disease is caused by the direct action of the vapour of phosphorous oxide P_4O_6 on the bone, and that the characteristic smell, noticeable in the dipping-room of a match-factory where white phosphorus is used is due, not to the vapour of the element phosphorus, but to the fumes of phosphorous oxide. Only those workers with carious teeth are liable to suffer from necrosis of the jaw. Recognising the bad state of the teeth of many of their workers, Messrs. Bryant and May, in London and Liverpool, some 16 years ago, before white phosphorus had ceased to be used, were the first match manufacturers to take the important preventive step of establishing dental departments, where all the workers could be treated free of charge. This great benefit to the workers is still available at the factories, although the use of white phosphorus in Great Britain has for a long period been discontinued. In the annual report of the German inspectors of factories for 1879 it was stated that, in that year, among 5724 workmen coming in contact with phosphorus vapours, only nine cases of necrosis were observed, six of illness, and three of death (Jettel, Chem. Zeit. 1883, 7, 89). In 1884, however, stringent regulations were put into force in Germany with regard to the arrangements in match-factories, especial stress being laid upon the efficient ventilation of the separate rooms in which the operations of mixing the igniting compositions, dipping, drying, and removal of the splints from the dipping frames, were to be conducted. Finally, in 1906, Germany adopted absolute prohibition of the use of white phosphorus (*see post*, p. 412).

In Denmark and Switzerland, the use of matches containing ordinary phosphorus was forbidden in 1875 and 1879 respectively; and only the so-called Swedish safety matches have been permitted to be used in Denmark since 1875.

Between 1879 and 1882 the use of matches free from phosphorus and inflammable on any surface was allowed in Switzerland; but a commitee appointed by the Department of Commerce found that these matches were unreliable and often dangerous: in 1882 the Swiss Government passed an Act, prohibiting the use of any but safety matches; and in 1906 Switzerland was one of the high contracting parties to the international treaty for enforcement of the total prohibition of poisonous phosphorus.

Efforts were early made to use red phosphorus, discovered by v. Schrötter in 1845; and G. E. Pasch, in 1844, took out a patent for a red phosphorus-product, which he believed to be an oxide of the element; and he is by some authorities regarded as the pioneer in the utilisation of red phosphorus. It is claimed for him that he discovered that a striking surface containing this substance could be used for matches free from phosphorus. Matches tipped with compositions prepared with red phosphorus were manufactured in Germany in 1850, in England (by Dixon & Co., and Bell & Black), Austria (Fürth, of Schüttenhofen, and Foster & Wawra, Vienna), and France (Coignet & Co., Paris), in 1851: but they were not successful; and, although improved matches of this description were patented by Albright, of Birmingham, in 1856, and were again to be seen at Paris in 1867, and Vienna in 1873, they did not come into general use. The higher cost of red phosphorus had much to do with this; but, in addition, the mixtures used were unstable and dangerous. Some of the earlier igniting compositions made with red phosphorus undoubtedly contained excessive proportions of the element. Of late years, matches of very fair quality have been produced, with far lower percentages; and there are upon the market at the present time various red phosphorus matches, some of which have been analysed by the writer. Many inventors of late years have proposed methods of diminishing the violence of the reaction between this variety of phosphorus and potassium chlorate, of lowering the ignition temperature of mixtures containing red phosphorus, or of rendering matches made with it less absorbent of moisture; such as previously mixing it with zinc (Simonet, 1893) or with sulphur (Bals and Gurowitz, 1896); substituting calcium plumbate for the potassium chlorate in red phosphorus compositions (Schwiening, 1896); adding chalk, &c. (Cordes, 1898); coating the red phosphorus with paraffin wax or some other suitable hydrocarbon (Akester, 1899, and Thompson, 1899); associating it with a borate or a phosphate (Säfström, 1901); boiling in aqueous solutions of various metallic salts (Purgotti, 1902); admixture with cork and flour (Bokmayer and Swoboda, 1905); or with zinc oxide and chalk (Chem. Fab. Griesheim Elektron, 1909). Schwiening's composition was adopted by the German Government, in consequence of the weighty objections to the use of ordinary phosphorus. The calcium plumbate apparently retards the explosion of the red phosphorus and chlorate mixture, thus moderating the violence of the combustion; but the matches have been subjected to somewhat severe and general criticism, on various grounds.

The Société Caussemille Jeune & Cie and Roche & Cie in 1909 proposed the treatment of red phosphorus by distillation and filtration, for the purpose of purifying it from acidity and alkalinity. The product they termed 'neutral amorphous phosphorus.'

In 1855 Lundström, of Jönköping, Sweden, acting on Böttger's suggestion, that friction matches might be so made as to be capable of igniting only on an especially prepared surface, manufactured the first true '*safety matches*,' by putting the oxidising mixture on the matchsticks and red phosphorus on the *box*. Such matches ignited only when rubbed on the specially prepared surface, or 'rubber,' on the side of the box. Lundström's process was patented in England in 1855 by F. May, of Bryant and May, and since that date 'patent safety matches' have been largely and increasingly manufactured in Great Britain (*cf.* p. 421). Matches on the same principle were made, soon after Lundström's invention, by Coignet & Co., by Fürth, of Schüttenhofen, and other continental manufacturers. In the 'allumettes androgynes' of Bombes Devilliers and Dalemagne (1859), the red phosphorus composition was at one end of the splint and the potassium chlorate at the other. The splints were broken, and the ends rubbed together. Field (1882) adopted a similar plan. The Swedish safety matches, so largely imported into this country, are on Lundström's principle. There have been comparatively few attempts to improve upon the safety match. Herz (1894) and Thimann (1894) worked in this direction. Viebig (1895) proposed to coat the heads of safety matches with a layer of the rubbing composition, or with a 'strike-anywhere' paste; and Craveri (1897), also Engl (1903), described safety compositions and rubbing surfaces therefor. It is common knowledge that some safety matches can be ignited, without the aid of an especial rubber, by friction—with a swift, sweeping movement—against a smooth, even surface, such as glass, polished oak or ebony, slate, &c.

A further step was taken in 1857 by Canouil, and by Hochstätter, of Darmstadt, in the production of '*non-poisonous safety matches*,' neither the igniting nor the friction compositions of which contained any variety of phosphorus. In Hochstätter's matches the oxygen compounds used were potassium chlorate, potassium dichromate, lead dioxide, &c., and the phosphorus was replaced by a mixture of antimony oxysulphide and flowers of sulphur. The oxidisable ingredients of Canouil's compositions, where stated, consisted of sulphur, iron pyrites, and various cyanogen compounds of lead. It is probable that some of the earlier so-called non-phosphoric matches were not altogether free from phosphorus. Vaudaux and Paignon improved upon Canouil's formulæ; and other compositions for non-phosphoric matches were those of Lutz (1858) and Kummer and Günther (Königswalde, Saxony, 1861). Schnell (London, 1861), Palmer (London, 1868), and others used lead thiosulphate, recommended by Wiederhold in 1861. Mayer (1865), C. Liebig, and Palmer (1869), also produced friction matches, containing, respectively, antimony sulphide and lead cyanide (Mayer), antimony sulphide and nitromannite (Liebig), and iron thiosulphate (Palmer), in place of lead thiosulphate. Jettel, in 1869, suggested the use of basic lead picrate. (Wiederhold had already tried potassium picrate.) Later, in 1879, L. Wagner, of Mühlheim, patented a match containing lead thiosulphate, antimony sulphide, sulphur, and finely powdered charcoal. Again, in 1881 and 1884, Schwarz, of Gratz, patented compositions containing lead thiocyanate, and lead sulphide in place—partly or entirely—of antimony sulphide. Among other substances proposed as ingredients of non-phosphoric safety match compositions are the thiosulphates of copper and sodium (R. Peltzer); copper thiocyanate, lead chlorate, finely divided metallic sodium (Fleck, 1868); and barium chromate (Garber, 1888).

Most of the compositions for non-phosphoric matches have been described by their inventors as 'ignitable by friction on *ordinary* surfaces'; in some instances, however, a special rubber was necessary. Many of the earlier non-phosphoric friction matches inflamed on ordinary surfaces with great difficulty; others ignited with almost explosive violence, and most were very hygroscopic. The vapours of lead, cyanogen, and thiocyanogen compounds, evolved during the manufacture and ignition of such matches, were probably in some cases injurious.

The more notable compositions for non-phosphoric 'strike-anywhere' matches, as now made, will next be described.

Among the various substitutes for white phosphorus, used of late years in strike-anywhere matches, phosphorus sesquisulphide undoubtedly holds the first place. Discovered by G. Lemoine in 1864, this compound was introduced in 1898 for match manufacturing purposes by H. Sévène and E. D. Cahen, of Paris. Having regard to present conditions, it is, in the opinion of practical match-makers whom the writer has questioned on the subject, unquestionably the best substitute for ordinary phosphorus so far discovered. It is non-poisonous, yields no injurious vapours during the operations in the factory, is reasonable in price, and the matches made with it are as sensitive as can be desired. Phosphorus sesquisulphide is a yellow powder, soluble in carbon disulphide, and inflames in air at 98°–99°C. This compound was at first adopted in 1898 by the French Government; it is used for 95 p.c. of the strike-anywhere matches manufactured in this country, and is becoming largely employed in the United States (*cf.* p. 412). On the Continent, also, phosphorus sesquisulphide is by most manufacturers preferred to other phosphorus substitutes.

Another ingredient, used in this country to a limited extent, is 'scarlet phosphorus,' or 'bright-red phosphorus,' patented in 1902 by W. Muir and C. R. E. Bell. This 'bright-red allotropic form of phosphorus,' which Schenk first prepared by boiling a solution of ordinary phosphorus in phosphorus tribromide, is chemically more active than dark-red amorphous phosphorus, inflames at *circa* 170°C., and, like phosphorus sesquisulphide, is claimed to be non-poisonous. About 5 p.c. of the strike-anywhere matches manufactured in the United Kingdom are made with scarlet phosphorus.

Several varieties of light-red amorphous phosphorus are in use abroad; and different compounds or derivatives of phosphorus have been patented or suggested—such as metallic hypophosphites (Bohy, Gallay & Co., 1898); hypophosphites in conjunction with chromium trioxide (Clayton, 1899); hydrides of phosphorus (Wheelwright, 1906 and 1909; Castiglioni, 1907); combinations of phosphorus with proportions of sulphur differing from that present in sesquisulphide (Wheelwright, 1902; Chem. Fab. Griesheim-Elektron, 1902; Huch, 1903; Gartenmeister, 1908); and the supposed suboxide P_4O (Chem. Fab. Greisheim-Elektron, 1903). The last-named company has introduced (D. R. P. 153188, 1902), under the designation 'sulfophosphit,' a product consisting of phosphorus, sulphur, and zinc, very intimately associated together, the basis of the invention being the production of metallic hypothiophosphites and thiophosphites by the union of red phosphorus, sulphur, and metallic sulphides, in theoretical proportions.

Besides the foregoing, inventors have proposed the use of lead thiosulphate, associated with calcium sulphide (Braly, 1897), and with potassium dichromate (Gurowitz and Bals, 1898; Trachsel, 1899); copper thiosulphate (Gans, 1898); tin thiosulphate (Jones and Bates, 1898); antimony thiosulphate (Truillet, 1899); copper thiosulphate and 'thiocyanite' (Rosenthal, 1899); cuprous thiocyanate (Purgotti, 1899); and the like. Craveri (1897) suggested the employment of persulphocyanic acid; and a later dipping-composition prepared by Gans

(1903) contained 'sulfocuprobariumpolythionate.'

Various materials for the stems have been suggested at different times, such as earthenware, pipeclay, bass, cotton or linen stiffened with chalk and gum (Bell, 1859); bone (Letchford, 1867); cardboard and stiffened calico (Cribb and Rackham, 1874); asbestos (Hynam, 1874); jute and glue in a double wire spiral (Byrt, 1882); wood pulp and paraffin (Molyneux, 1889); compressed peat, turf, or moss (Rosenkütter, 1891; Stiemer and Ziegler, 1892); paper (Farrel, 1890; Bowman, 1893); straw (Castner and Swoboda, 1897); straw, rushes, grasses of various kinds, and the like, dipped in solutions of inflammable substances (Carré, 1908); stems of dried leaves of alfa or esparto (Schaefer, 1906), &c., &c. Fredrikson in 1897 and Lärn (1907) used wooden cores for the stems of wax matches. Craveri (1899) proposed as a composition for the tapers a mixture of ceresin, resin, calcium sulphate, zinc oxide, and potassium nitrate. Steedman (1906) patented waxed stems made from single strips of veneer, with one or more threads applied longitudinally, the whole coated by wax; and the present writer has come across Finnish 'superior patent vestas' (of very poor quality), with stems made in a similar way: obviously the same patented method.

The treatment of the wooden stems has also varied greatly. In the early days of match-making the splints were usually dipped in melted sulphur (v. Römer and others), to ensure ready inflammability of the stems; and hot tallow, resin, and wax were sometimes used for the same purpose. Sulphur-dipping is in this country only of historic interest, but sulphur-coated splints are still to be seen occasionally in matches of the cheapest and worst qualities, mostly of continental manufacture. Of the above-named substitutes for sulphur, Böttger (1843) preferred wax, which was also used by Mennons (1857) and others. Later (1861), Letchford introduced the use of melted paraffin or petroleum, also a mixture of paraffin with stearin and Japan wax. Bruce (1863) saturated the stems with potassium nitrate by immersing them in a boiling solution of that salt. In 1891, Bell proposed the use of coloured paraffin. Match-stems have occasionally been impregnated with camphor. In 1867 resin was again applied by Letchford, and Grawitz (1873) used naphthalene instead of sulphur. Mapple (1881) preferred oil or tallow. Paraffin is now almost everywhere used.

Another method of treating the stems is widely adopted at the present time in Great Britain and abroad, especially for safety matches. It consists in impregnating the stems with solutions which have the effect of preventing the wood from burning or remaining red-hot. Stems so prepared become cool almost instantaneously, and do not readily break; there is thus less chance of the heads and fragments of the splints falling and giving rise to fires—a risk commonly present with the thin badly-cut splints (not so treated) of the cheaper sorts of foreign matches. To render the stems uninflammable, solutions of sodium phosphate, sodium tungstate, zinc sulphate, alum, ammonium sulphate, and magnesium sulphate have been used. Field (1879) employed solutions of phosphoric acid, ammonium phosphate, borax and ammonium phosphate together, or boracic acid and ammonium phosphate; Percival (1887) proposed the use of 'cyanite' for the end held in the hand, the body of the match being impregnated with a 'weak gummy varnish' to prevent the embers from falling about; and Louisa A. Thomas (1896) suggested the employment of sodium silicate.

F. Gerken and G. Goliasch (1883) affixed small friction-tablets to the stems, so that when a match was withdrawn from the case its head came in contact with the roughened surface on the stem of an adjacent match, and in this manner was inflamed. The proposals of Galy (1908) and Walsh (1908) were not altogether dissimilar. The last-named inserted the striking composition in a notch in the stem of the match.

Tubes, to hold a single match, have been so constructed that the match on withdrawal is inflamed by friction of the head against striking composition lining one end of the tube. The other end is closed. An allied device is a tube open at both ends, and on finger-pressure being applied to the match-stem projecting at one end, the head of the match is pushed past the striking composition lining the other end; on coming into the air directly afterwards it is inflamed.

To render match-stems waterproof, collodion, resinous varnishes, and caoutchouc solutions have been employed.

Headless matches have been suggested by Simonet (1893), Neuberg (1897), Fog and Kirschner (1898–9), Budde (1900), and Haffner (1907). Matches tipped at both ends were proposed by Scarlett (1891), Aldridge (1899), Potts (1901), and Nicolay (1904). 'Double-tip' matches, an important modern invention, are described further on.

The development of the machinery used in match-making has more than kept pace with the improvements in the compositions and in the treatment of the stems. Continuous and automatic machines will be described in the portion of this article devoted to details of the manufacturing operations.

Some remarks may now be made about vestas and fusees.

Vestas.—The earliest account of the *wax-taper* as a match stem is in the specification of an English patent taken out by W. Newton in 1832; and, according to Payen, matches of this description were first made in France in 1836 by Savaresse and Merckel, of Paris. Wax, however, in conjunction with colophony, was used in 1832 by Siegel, of Vienna, as an easily inflammable coating (in place of sulphur) for the previously carbonised splints of his oxymuriate matches. In 1862 J. Childs recommended a mixture, of high melting-point, of one part of Carnaüba wax with 9 parts of paraffin; in 1866 Letchford substituted jute for cotton in the tapers; and J. G. Gomez and P. Franco (1889) used strips of Bristol board, immersed in a mixture of resin, stearin, zinc-white, &c. Baron (1896) recommended wood-fibre. Hathaway (1897), Scott (1899), Glenister (1907), and others have employed paper in strips or coils. The use in the waxed stems of a wooden core has already been mentioned; and pine-wood sticks are very largely taking the place of wax tapers for this class of match. Wax vestas have been sold in metal cases containing sand-paper so folded that, on the withdrawal of a vesta, its head is inflamed by friction against the sand-paper, the act of withdrawal thus igniting the match.

Fusees, &c.—Cigar lighters—of brown paper, cardboard, German tinder and the like—impregnated with a solution of nitre, often scented, and tipped with various igniting compositions, mostly phosphoric, were made by Siegel (1832, 1835), v. Römer, and others. Of the newer kinds of cigar-lighters, variously known as 'flaming vesuvians,' 'etnas,' 'fixed stars,' 'braided lights,' &c., consisting generally of three parts—a stem of wood or glass, a head or ball of 'pastille' composition, and a tip of igniting composition—one of the first was described in 1849 by J. Palmer. Grimes (1859) introduced wires into the composition-ends of his splints, to prevent the heads from falling off when pressed against the cigar or pipe. Bell & Black (1859) made the stems of wire, coated with a non-conducting composition, such as gum and whiting, or glue and whiting or flour. Simlick (1862) put the composition on a tube fitted on to the end of the splint, and preferred glass. He also (1863) tried stems of slag and powdered oyster-shell, mixed into a paste and calcined; and wire covered with thread or cotton, dipped in coloured liquid gum. Battcock (1863) made stems of stone and slate; and Barker, in the same year, used pipeclay stems, tipped at each end. Ford (1878) softened the splints by treatment with caustic potash or soda, and then subjected them to the action of a solution containing 10 parts of nitre, 1 part of potassium chlorate, and 1 part of sugar in 12 parts of water: this process of course rendered the wood highly combustible. Methods of treating the wooden stems with alkaline and other solutions were patented by the Aktieselskabet 'Progress' (1902), and in the previous year by A. G. Haehre. Evans (1882) rendered the stems of his vesuvians incombustible, by the use either of asbestos paint or of sodium tungstate solution. The invention of A. Hill (1904) was similar. G. A. Sweetser (1884) formed his stems of plastic material moulded into the required shape and size round a core. In the 'braided' lights, still manufactured to a small extent by Bryant & May, and J. Palmer & Son, the composition is retained in position by pieces of thin wire, over which strands of cotton are twisted by the braiding machine. T. J. Clanchy, in 1868, obtained provisional protection for a combined match and fusee, consisting of a shaft or stem with a fusee-head at one end and a match-head at the other. In 1885 R. Bell, proceeding on closely similar lines, introduced the 'fusee vestas,' or wax-stemmed vesuvians, in which the essential parts of a vesuvian are present, but the stem was of jute, hemp, flax, cotton, or a mixture of some of these fibres, coated with paraffin, wax, or stearin. According to another patent of the same year, this inventor introduced a wire core into the stems; and in 1886, C. R. E. Bell devised a hollow cylinder or bead of combustible material, to be sold separately, for application to a match or vesta, for use in a light wind. J. J. Williams (1895) had a somewhat similar idea. Salts of strontium and barium have sometimes been introduced into the compositions of vesuvians, to cause them to burn with coloured flames.

Vesuvians have been almost entirely superseded in this country by vestas with pine-wood stems (such as the 'Swan' vestas, introduced by Bryant & May), and in America by the 'double-tip' match, invented in 1905 by the Saginaw Match Company. There is also a considerable production of matches with cardboard stems, somewhat upon the lines of the earlier 'fusees.' The 'book-matches,' made by Bryant & May, are of this type; two layers, stitched together, of flat, cardboard-stemmed matches, united by the base, are contained in a thin pasteboard case, with a red phosphorus striking surface on the exterior. These matches are of the safety class.

Repeating or continuous matches have been invented, but have never had much sale. The earliest English patent of this kind was that of Dove (1862), in which the igniting composition was attached at intervals to a continuous band or strip of material, inclosed in a box. Later devices of similar nature were those of Tylor (1865); Rogers (1869); Perkins (1869), who mixed the igniting composition with collodion, a strip so composed fitting into a case like a pencil case, from which it could be withdrawn at will; Samuel (1871); Jonas (agent, Pollet, 1878); and Klein, same year.

Cigar-lighting appliances of a special kind. Many instantaneous igniters, not matches, have been invented for the convenience of smokers. These contrivances, though numerous, have not interfered with the steady development and increase of the match industry; and a few types only of such inventions will be mentioned. Among the earliest were the 'D'Bleaml'n Cigarrenzünder,' cigar-lighters, made by Pollak, of Vienna. This appliance consisted of a small, nitre-steeped, variously coloured, artificial flower, the stalk of which was inserted in a cigar. A little boss of igniting composition in the centre of the flower was inflamed by friction. An alloy of the metals sodium and potassium has been used. A small quantity of the alloy is withdrawn from a case or tube by a wire, which is then rubbed across and ignites a charred wick (1887 and 1888). Another appliance is simply a pocket edition of the old flint, steel, and tinder-box. A fourth device (W. D. Borland, 1889) is an attachment to cigars or cigarettes, by which they are easily lighted, even in a high wind. A minute portion of nitrocellulose fabric, forming a ring round the cigarette, is inserted under the paper, and on applying a spark the material takes fire and slowly smoulders until the whole end is glowing.

Automatic igniters in which is used an alloy of cerium are now extensively sold in France, and to a smaller extent in this country.

Statistics and Legislation. According to the Census of Production, 1907, the total value of the output of matches of all kinds, including wax tapers, vesuvians, braided lights, &c., of British manufacture, was in 1907, £775,000. The value of the exports of matches of United Kingdom manufacture amounted in 1907 to £76,000, or about one-tenth of the output. The annual output of one British company alone, Bryant & May, is at present not less than about eight million gross of boxes.

The consumption in Great Britain and Ireland of *all* matches amounted in 1910 to about 17¼ million gross of boxes. In 1910 the matches consumed would appear to have been practically half British and half foreign. Safety matches have greatly increased in popularity. Whereas in 1899 about 18 p.c. of the matches consumed were safety, and 82 p.c. strike-anywhere, in 1910 the proportions were nearer 37 p.c. safety and 63 p.c. strike-anywhere. Vesuvians are almost obsolete, but *small* quantities of braided lights and flaming vesuvians are still made. Swan vestas, with pine-wood stems, introduced by Bryant & May, have virtually supplanted vesuvians, and have considerably reduced the consumption of wax vestas.

The value of *all* matches (British and foreign together) consumed in Great Britain and Ireland in 1910 may be computed at about £1,293,750. Assuming that 17¼ million gross of boxes, each containing, say, sixty matches, were so consumed, and taking the population of the United Kingdom at 45·2 millions (Census of 1911), this consumption would be equal to about nine matches per day per head of the population.

In the United States of America, there are said to be manufactured 250,000 million matches per annum. Assuming a census of 76·3 millions this is equivalent to nearly nine matches a day *per caput*.

At the present date (June, 1911) there are in Great Britain and Ireland eleven match factories. By far the largest and the most modern are those of Bryant & May, Limited, at Liverpool and Bow, London, E.

In Russia there are stated to be 49 factories, in Sweden 10, in Norway 2, in Belgium 14, in Germany 75, in Austria-Hungary (originally the chief centre of the European match industry) 10, and in France 7. The most important Swedish factories are those of the Jönköpings och Vulcans Tändsticksfabriks Aktiebolag, at Jönköping and Tidaholm, Uddevalla, Wenersborg and Anneberg, and these may be regarded as among the best-equipped of European match works. The total value of Swedish matches exported from that country was in 1902, £432,000, and in 1903 £466,000. Among the principal German factories are those of Stahl & Nölke, at Cassel and Kostheim a./M., the Deutsche Zundholzfabriks Aktien-Gesellschaft, at Lattenburg, Rheinaubaden and Vordamm, of the 'Union' Aktiengesellschaft, at Augsburg and Habelschwerdt, Ulm, Göppingen, and elsewhere, and of C. Grübel, at Habelschwerdt. The French factories, which are under the direct control and supervision of the Government, the manufacture of matches having been a State monopoly since 1890, are at Pantin and Aubervilliers (both near Paris), Marseilles, Bégles (Bordeaux), Aix-en-Provence, Saintines (Oise), and Trélazé (Angers). The total receipts of the monopoly in 1904 were £1,423,000, the profits being £1,048,000. Official estimates gave the receipts in 1905 as £1,427,000, with profits slightly exceeding those of 1904. In the United States there are 19 companies and firms and 16 factories, including the Diamond Match Company's five works in New York, Michigan, Ohio, California, and Wisconsin. The Diamond Match Company is by far the largest and most influential American company, and its output is probably about 75 p.c. of the entire production.

By the international treaty of Berne, 1906, most of the countries of Europe have bound themselves to enforce within their territories the prohibition of the use of white or yellow phosphorus. The importation and sale of matches containing ordinary phosphorus are entirely prohibited in Great Britain and her Crown colonies (since 1908); in Germany, France and her colonies, Austria, the Netherlands and the Dutch Indies, Luxemburg, Finland, Italy, Spain, and Switzerland (since 1906); and in Denmark (since 1875). In Australia the importation is forbidden. Similar prohibition may eventually be enforced in Canada, where a White Phosphorus Prohibition Bill has recently been introduced. In Norway and Sweden, the use of white or yellow phosphorus is forbidden in the manufacture of matches for home consumption, but not in making matches for export trade. As the outcome of the Conferences at Berne, in 1905 and 1906, of representatives of most European Governments, the British Legislature on Dec. 21, 1908, passed the 'White Phosphorus Matches Prohibition Act' (8 Edward VII., 1908, ch. 42), which has been in operation since January 1, 1910. With one exception, the countries which have not yet forbidden the use of white or yellow phosphorus in the manufacture of matches, namely Russia, Japan, Belgium, Hungary, and the United States of America, have passed very stringent laws regulating the operations and arrangements in the factories. Only in the United States is there no legislation relating to the manufacture or use of matches made with white or yellow phosphorus. The extremely sensitive and readily ignitable double-tip match of recent introduction, which in America is superseding the 'parlour' match (the ordinary paraffin-dipped strike-anywhere match), is stated to contain as much as 20 p.c. of white or yellow phosphorus, and in the course of manufacture this match is alleged to generate 40–50 p.c. more phosphorus oxide vapour than the ordinary match. The stringent regulations in European countries, previously to the entire prohibition of white phosphorus, kept down the quantity used to 6 or 7 p.c. (Denmark 10 p.c.); but American match manufacturers are now said to be using for their compositions from 14 to 20 p.c. The humidity and warmth of the American climate, increase the danger to the workers.

The President of the United States recommended the imposition of a heavy Federal tax in order to discourage the use of white phosphorus, and the Diamond Match Company have voluntarily surrendered their patent rights for the use of tetraphosphorus trisulphide, so that any match manufacturer in the United States is free to use this compound.

Great Britain's exports of matches to foreign countries are smaller than formerly, and even her Colonial trade has diminished. Notwithstanding excessive competition, the home trade is, nevertheless, very large.

As regards the quantities of phosphorus used in the match industry, there are not at the present time any figures available. Probably about 40–50 tons per annum were used in the British Isles over the 15 years prior to 1890. The relative quantities consumed of the two substances now used in this country in the manufacture of strike-anywhere matches, namely, phosphorus sesquisulphide and scarlet phosphorus, are about 95 and 5 p.c. respectively.

MANUFACTURE.

Probably the best way of conveying an idea of twentieth-century methods of manufacturing matches will be to begin by describing the operations as they are conducted in the most extensive and modern match works in this country—the factories in London and Liverpool of Bryant & May, Limited, who are, as already stated, the largest British makers, and among the largest in the world. The operations so described may be regarded as typical of the work as now carried on under the latest and most advantageous conditions. Some account will then be given of the manufacture as conducted upon a smaller scale, and of the more noteworthy differences and modifications in the machinery used, or processes followed, in other British, and—so far as space permits—in the more important foreign, match works.

The manufacture may be considered under the following heads: (1) *Ordinary matches*:—the nature of the wood used; making the match-sticks, or splints, and boxes; making and packing the matches; (2) *Wax matches*:—making the tapers; making and packing the matches; (3) *Safety matches*; (4) *Vesuvians*, (5) '*book-matches*,' and (6) '*double-tip*' matches.

1. Ordinary matches. *Nature of the wood used.*—There is considerable variety in this. Pine, aspen, spruce, fir, poplar, lime, willow, and beech-wood are used. Alder- and cedar-wood have also been employed. Aspen, and poplar-woods are imported into this country mostly from Russia (Riga, Libau, Windau, and St. Petersburg); pine, spruce, and fir from Canada and the United States of America. There is an increasing scarcity of timber, especially of pine-wood. For British matches, the splints formerly were chiefly, and still are largely, manufactured from pine-wood: aspen, poplar, and other woods have long been used for this purpose by continental makers. Aspen-wood for match manufacturers' requirements must be free from pith and knots; and stems from 10 to 20 inches in diameter are the most serviceable. Rafted aspen is less satisfactory than unrafted. Eventually in this country, aspen-wood, which is already used for match-boxes, may in a great degree supplant pine-wood. Already, aspen-wood sticks, imported in wooden cases holding about 1,000,000 ready-cut splints, are in use by some manufacturers. Spruce-wood is employed for the packing cases, planed and dovetailed boards for which are shipped to this country from Quebec. Canadian pine-wood splints for the larger square matches are now cut in the Dominion, and imported to this country; later on, they will be cut here.

Making the boxes and splints.—Although some of the smaller match-makers, here and in parts of the Continent, still use boxes made, or put together, by workpeople in their homes, a highly important and prominent department in the leading manufactories of Great Britain, America, and continental Europe, is that devoted to match-box making by machinery. The operations, both for box-making and splint-cutting, begin with 'cross-cutting,' by a circular saw, of the 7-feet long aspen-logs into 26-inch lengths. These are barked by hand, taken to the 'log-peeling-' or 'skillet-' (squelette) room, and placed in a species of lathe, the '*peeling-*' or *veneer-cutting* machine, made by A. Roller of Berlin (Fig. 1), in which they revolve against a horizontal planing knife acting upon the entire length of the log. A veneer is thus cut from the log, as wide as the rotating wood is long, and of a thickness which depends upon circumstances.

FIG. 1.

Log-peeling or veneer-cutting machine.

(*a*) *Splints.*—If the veneers be required for the production of splints, the machine is adjusted so that they are 2·3 mm. thick: if the thinner veneers, used for wooden match-boxes, are desired, the thickness is about $\frac{18}{1000}$ of an inch. Cutters, placed slightly above the planing knife, divide the veneers into narrow bands (=the length of a match), or wider bands (for box-work), as required. In the former case, the narrow bands, divided into convenient lengths and superimposed into piles of 70 or 80 veneers together, are passed under an alternately rising and falling knife, in a guillotine machine constructed by Roller, which cuts them into square or rectangular splints. These fall into a hopper, from which by a cyclone fan they are blown along a pipe into another building, where they are 'impregnated' with an acid ammonium phosphate solution and then dried in a revolving cylinder heated by a coke furnace, capable of drying 40,000,000 splints per day of 10 hours. Next, they are cycloned back to the peeling-room, where they are 'cleaned' in a Roller's '*splint-cleaning*' machine, 'straightened' in a '*straightening*' machine, and packed in trays ready to be fed to the *match-machine*. During both the cleaning and straightening operations, the splints are subjected to a 'jogging' or oscillating motion. This description of splint-making applies only to the smaller rectangular splints, of aspen-wood. The stouter and longer square match-sticks, used for the large ordinary and safety matches, are at present cut from Canadian pine-wood. The blocks are sawn from a deal, and fed into the hopper of a machine of the company's own construction, which cuts by means of lancets set horizontally, instead of vertically. These splints, after impregnation, are dried, not by the cylinder method, but by drying-chamber process. Eventually the larger match-sticks will be made at Bow, as already stated. There are two other kinds of wooden match-splints: round-sticks and grooved-sticks. But as these are cut actually in the match machines, an account of the process will be given when those machines are described.

(*b*) *Boxes.*—The thin veneers, intended for the boxes, are wider than those for splints, but they are produced by the peeling-machines in the manner already detailed, the wood being simultaneously scored in readiness to be folded by the box-making machine. They are then guillotined into sizes suitable for the insides and covers of boxes, and the edges of these 'skillets,' where the wood is not covered by the labels, are hand-dipped in pink dye by boys. The skillets for the 'cases,' 'covers,' 'outers,' or (as they are sometimes uneuphoniously called in America) '*shucks*,' are next folded up, pasted and labelled by '*outer*' box-machines, of which there is a row on each side of an endless band or conveyer, carrying the box-covers onwards to a drying chamber. The 'inners,' or drawers of the boxes, are made by Arehn's drawer-making or '*inner*' machines (Lundgren's patent), which fold up the skillets, paste, and paper-coat the drawers, and similarly feed them on to a carrier, by which they are transported to a drying chamber. Fig. 2 shows some of the box-making machines. The next step is the application of sand to the 'outers' by the 'sanding-machine' or '*sander*.' The 'inners' are put into the 'outers' by a machine called in the works a '*nester*.' In one room of one of the factories there are about 120 wooden-box machines. Thicker skillets are by some manufacturers used for penny vesta boxes, and these are cut from spruce-wood by an ordinary 'flaking' machine (Day's): but spruce is becoming scarce, and will probably be discarded for the purpose.

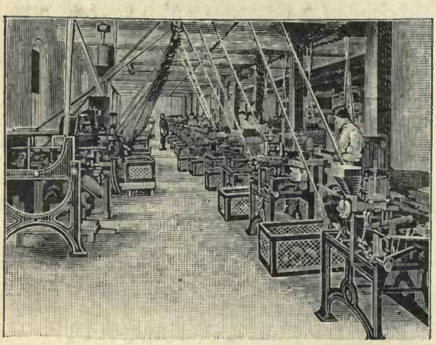

FIG. 2.
Wooden box-making machines.

Cardboard box-making.—The 'outers' of some strawboard boxes, are made by a machine which cuts and scores the cardboard for folding, pastes, and folds it into the form of a flattened tube, prints it above and beneath, glues and sands one side, cuts off the proper lengths, and ejects the finished cases at the rate of 1000 per minute. The insides are made by an equally ingenious machine which cuts out the pieces of cardboard, scores, folds up, glues the ends, and conveys the completed 'inners' in links of a travelling chain until they are dry and ready for filling. A cardboard box-room is shown in Fig. 3. In one room at Liverpool there are 150 cardboard box-machines. The cardboard 'outers' of some boxes for vestas (pine-wood and other) are made by hand, but the flaps and tabs are affixed by machinery of Bryant & May's construction. The 'inners,' of chip-wood, are machine-made, as above described.

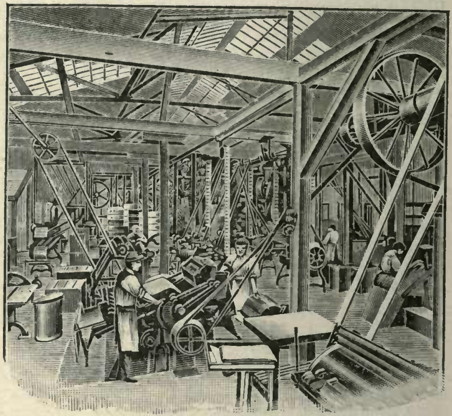

FIG. 3.
Cardboard box-room.

Metal box making.—The metal match-boxes used for 'knapsack' matches are made at Liverpool by a machine invented by Carbone.

THE MANUFACTURE OF WOODEN MATCHES.

A. By continuous and automatic machinery. In one form of match machine, used by Messrs. Bryant & May, the ready-cut square splints are fed into a hopper near the front of the machine, 'jogged,' and pushed by plungers into apertures in the iron match-plates, or carrier-plates, composing an endless chain about 700 feet long. The chain conveys the splints in enormous numbers, tips downwards, over a hot plate, then through a steam-heated bath of melted paraffin wax (m.p. 102°–105°F.), temperature *c.* 220°F., next over the dipping-roller, which revolves in a trough or vat charged with the match composition, and finally over a great series of drums or carrier-wheels. The period occupied by this is about an hour, and during the passage over the carrier-wheels the matches are dried by the currents of air to which they are freely exposed. There are 100 matches in each row on a match-plate. Having traversed the carrier-wheels, the dry and finished matches arrive near the starting-point, are ejected by plungers from the holes in the match-plates, and are filled into boxes by a '*box-filling* machine,' manufactured by the Diamond Match Company. This machine neatly and regularly deposits the matches in the drawers or insides of the boxes (to which a shaking motion is given, so that the drawers become filled, and there are no spaces left); sheaths the drawers in the covers; and passes the completed boxes along an endless band to an Arehn's *packing* or *wrapping* machine (Lundgren's patent), by which they are put up in the familiar 'dozen-packets.' Eight girls attend to a match machine; and the daily output of one machine is 1000 gross of boxes, averaging about 60 matches to a box=8,640,000 matches *per diem.* The machinery is continuous in its production, and automatic, from the feeding in of the match-sticks to the wrapping of the dozen-packets, which girls put up into gross parcels by hand. The gross parcels are packed in the Canadian spruce-wood cases, which are nailed together at the factories by an automatic nailing machine (W. S. Doig's patent).

The machines so far described yield square matches. But Messrs. Bryant & May use other match machines, also continuous and automatic, called *grooved-stick* machines. These yield matches with pine-wood stems, nearly circular, but scored longitudinally by two grooves, so that the stems are of the section shown in the figure (Fig. 4). A machine of this kind cuts its own match-sticks from pine blocks, $1\frac{7}{8}$ inches deep, fed in horizontally, but at an angle of 17° with the front of the machine. The match sticks are cut from the blocks by dies which act on the downward stroke, leaving the splints sticking up, to be grasped by their upper ends in the apertures of carrier-plates composing a conveyer-chain, just as in the machines last described. The match sticks, bristling from the under surface of the endless chain, pass successively over a hot plate, paraffin-bath, dipping-roller, and series of carrier-wheels, returning to the forepart of the machine, where the finished matches are discharged, and filled into the drawers or 'inners' of cardboard boxes fed to the filling apparatus by hand. Thence the filled drawers are passed along in a continuous stream to a revolving circular table, where sit six or eight girls to receive and sheath them in the cases, also to add a few matches to boxes not completely filled. Fifteen workers attend to a machine, and each machine produces 800 gross of boxes of matches (averaging 55 matches to a box) in a day of ten hours. The yield of matches per minute may be estimated at 12,000. One girl can feed the machine with 106 boxes a minute, or nearly two boxes a second. From the splint-cutting station of this match machine an exhaust fan draws out wood-dust and imperfect sticks, and conveys them by a pipe to the boiler-house.

FIG. 4.

Section of a 'grooved stick.'

The *round-stick* machines, which produce the circular-stemmed, pine-wood 'Swan' vestas, punch out round splints, but are constructed similarly to, and upon just the same principles as, the grooved-stick machines. Blocks of pine-wood are fed in; finished matches come out, and are automatically filled into the 'inners,' the final operations of 'boxing' being performed by eight girls stationed at a revolving circular table. Dust and imperfect splints are removed in the manner already described. One of these round-stick machines can turn out about 3,000,000 vestas *per diem.*

Larger-sized matches.—For the production of the larger-sized strike-anywhere matches and safety matches, with square sticks $2\frac{1}{4}$ inches long, the continuous and automatic machinery is of exactly the same kind as that used for the matches of 'minik' size, with sticks $1\frac{7}{8}$ inch long. The single-length splints (there is now no 'halving') are fed into the receptacle or hopper of the machine, and the finished matches are deposited in the drawers of the boxes by the filling apparatus previously mentioned. The drawers pass along a channel on to a circular table, where the cases or covers are put on by hand. The productive capacity of one of these machines may be estimated at 6,960,000 matches per day of ten hours. [*v.* Amer. Pat. 389435, 1888 (E. B. Beecher); and Eng. Pats. 20786, 1894 (E. B. Beecher and J. P. Wright); 17022, 1896 (J. P. Wright).]

Fig. 5 gives an idea of the general appearance of a match machine; Fig. 6 shows one of the machines at first installed, in greater detail and on a larger scale; and Fig. 7 shows a machine-room with its range of automatic machines.

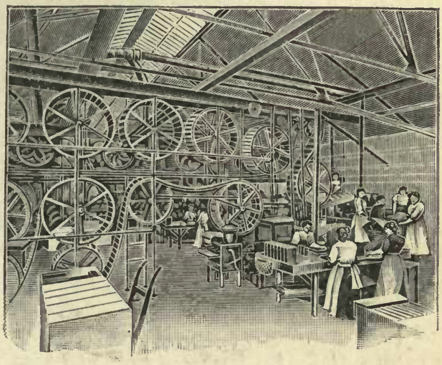

FIG. 5.

A match machine.

The adoption of automatic machinery has wrought so great a change in most of the operations of match making, in the conditions under which they are performed, and in the rate and amount of the output, that to describe the present mode of manufacture is virtually to relate the particulars of a new industry. The advantages of the automatic machinery, with the continuous system of manufacture, are enormous. Production is greater, with less labour, than in former days; and the operations are immeasurably more healthy for those engaged. It is scarcely an exaggeration to state that hand labour has been almost entirely eliminated from the actual manufacturing processes. Three or four workers now produce as much as 15 or 20 under the old conditions.

Examples of other forms of automatic match machines are Lagerman's machine, used at Jönköping (described on page 417, and Figs. 9 and 10), and Roller's. The last-named is constructed upon the same general principles as the match machines already described, but it is of smaller dimensions and capacity. This type of machine is used at Messrs. J. Palmer & Son's, Maguire Miller & Co's, W. J. Morgan & Co.'s, R. Bell & Co.'s, and Paterson & Co.'s, factories, for

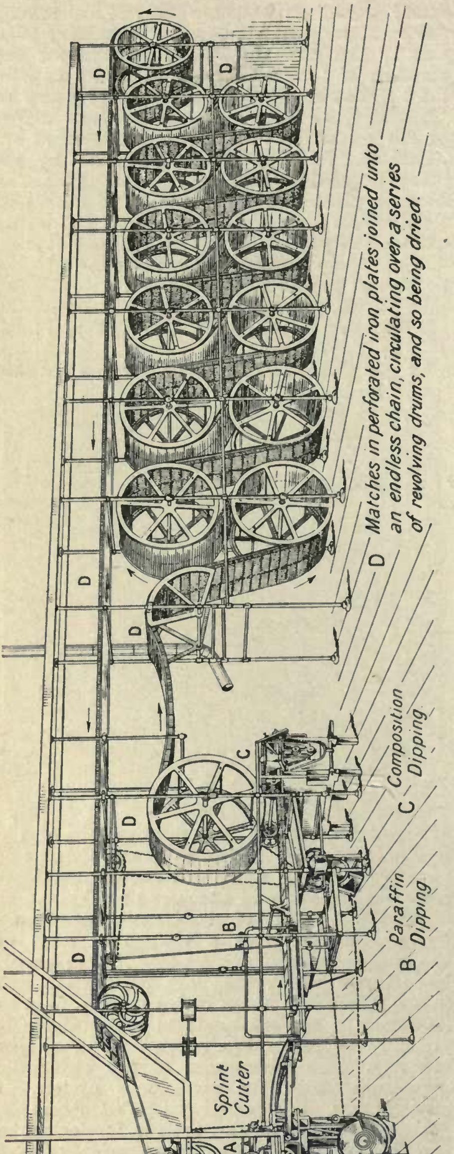

FIG. 6.
A match machine.

the manufacture of products such as the minik-sized 'Our Flag' matches, and the like. Ready-cut, single-length splints of aspen-wood are fed into the hopper of the machine; pushed into apertures—150 in a row—in an endless chain; paraffined; dipped; dried by passing over a series of drums; discharged or 'racked out,' and filled into the box 'inners.' These are sheathed in the covers by four workers. There are seven girls to a machine. Roller's and Arehn's wood box-making appliances are employed at Messrs. Palmer's factory for the ordinary boxes, one girl working each machine. Aspen-wood is planed into the thin box-veneers by a Roller's log-peeling machine, already described and figured; but the thicker veneers, used for penny vesta boxes, are at present cut from spruce-wood by a flaking machine (Day's).

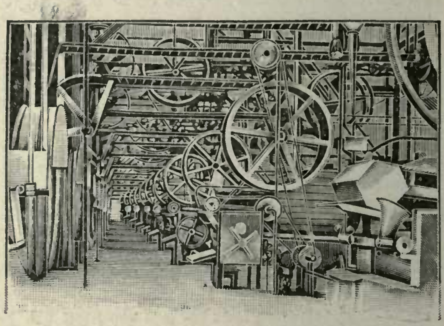

FIG. 7.
A match machine-room.

Besides the match machines described, there are other continuous and automatic machines, of which the 'Ideal,' made and supplied by Messrs. Sebold, of Durlach, Germany, is an example. An extensive trial, and with more or less success, has been made of this machine, recently, by S. J. Morland & Sons, of Gloucester.

Preparation of the Dipping Composition.

Almost every maker has his own especial composition and way of preparing it. But the mixtures in use for ordinary matches invariably contain—(1) an *oxidisable body* in a fine state of division, and intimately mixed with (2) *oxidising agents*; (3) *cementing* or *binding materials*; (4) certain chemically *inert bodies* added to increase friction; and (5) *colouring matters*. In strike-anywhere matches, the oxidisable or combustible body in general use is tetraphosphorus trisulphide. Other combustible ingredients are employed, mostly abroad. The more important have been mentioned (pp. 409–410). The oxidising agents principally employed are potassium chlorate, potassium nitrate, lead nitrate, minium, manganese dioxide, and lead peroxide: potassium dichromate, 'oxidised minium' (made by heating minium with nitric acid), ferric oxide, and litharge must also be mentioned. In English matches, potassium chlorate is the customary oxidising agent, used alone or with manganese dioxide, &c. Potassium nitrate is frequently present in continental matches. Glue, gum, gelatin, and dextrin are the binding media mostly used: in Great Britain, glue is almost exclusively employed. Very much depends on the quality of the glue, and its drying properties. Powdered glass, chalk, gypsum, and fine sand are among the indifferent bodies added. Prussian blue, ultramarine, smalt, vermilion, chrome yellow, and coal-tar dyes are used to colour the mixtures.

Excepting that phosphorus sesquisulphide is now in general use, and that coarsely crushed glue is preferred to glue in large pieces or cakes, there is not much that is new to relate about the operations in the composition mixing-room. There are, of course, numerous minor differences in the methods of mixing the ingredients of an igniting paste; but the guiding principles usually are that the oxidisable body is first mixed with a portion of the inert substances, and with part of the glue or other binding medium, previously dissolved in water, and that the oxidising substance or substances must be mixed separately in another vessel, with the remainder of the glue, &c. Each mixture is passed through a mill, after which the two sections are combined and the whole mass is milled. All quantities are weighed and checked, and proper precautions are taken to avoid 'firing.' Fig. 8 shows a composition mixing-room of the latest type. Some additional particulars, especially with regard to older methods of working, will be found on pp. 422–424. The other operations, paraffining, dipping, drying, discharging, box-filling, and packing, by automatic machinery, have already been described.

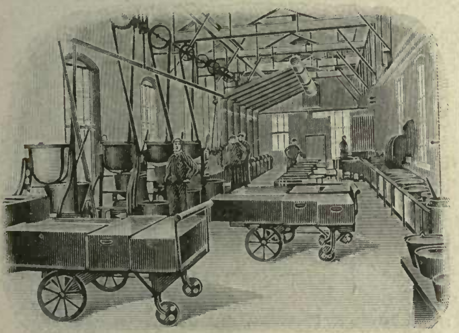

Fig. 8.

Composition mixing-room Liverpool.

The Manufacture of Matches abroad.

Sweden.—The most important Swedish match manufactories are those belonging to the Jönköpings och Vulcans Tändsticksfabriks Aktiebolag. The Jönköping works of this company are particularly well provided with labour-saving machinery, much of it the invention of the former chief engineer, the late Mr. Alexander Lagerman. These mechanical appliances for saving manual work have been in use for a considerable number of years, and include continuous machinery for paraffining, dipping, drying, and discharging the matches, machines for box-filling, 'sanding' or 'coating' machines, and wrapping machines. The writer is indebted to Chamberlain Berndt Hay, the general manager of the company, for the following particulars of the continuous machines at present in use at Jönköping.

The match sticks, cut and dried, are placed in magazines on the front top of the machine, whence the splints are pushed out into 'perforated wooden frames, moving upwards on endless chains.' The frames, holding the sticks at one-third of their length by means of springs, are brought along, one by one dipped in melted paraffin wax, and then in the strike-anywhere or safety-composition, as the case may be. After passing a 10-metre track, to dry the match heads, the frames return to the front bottom part of the machine, where the matches are discharged, apportioned off, and filled into the empty boxes brought to this part of the machine on a transporting chain, consisting of small iron plates. In Fig. 9 is shown some of the Jönköping machinery. A number of these machines are installed at the older of the two Jönköping factories. Fig. 10 shows one of the box-filling machines used at Jönköping. The striking-surfaces, whether of sand, emery, glass, or of a red phosphorus composition, are applied to the sides of the boxes by machinery ('sanding' or 'coating' machines); and the finished boxes are mechanically wrapped in parcels of ten or a dozen ('wrapping' machines). One of these machines will pack in a single day, under the management of two girls, a quarter of a million boxes of matches into finished, labelled 'dozen-packages,' thus doing the work of 16 or 17 hand-packers.

The Vulcan Factory, at Tidaholm, is a large, well-equipped match-works, where safety matches (chiefly) are now manufactured on a great scale. Continuous match machines are not in use at the Vulcan works, where no essential change has been made in the character of the plant during the past 12 or 13 years.

Holland. The industry in Holland is of comparatively small dimensions. At Loyens' factory at Breda, a box-filling machine, invented by Paulson, is in use, and is said to be very satisfactory.

Belgium. The principal Belgian factory is that of La Société Caussemille Jne & Cie. et Roche & Cie. (Ghent). Although there have been great improvements in the conditions of the industry during the past few years, Belgium must still be regarded as behind some other countries, in regard to her match-factory legislation, and in the quality of the matches produced.

Germany. The match manufacture is of considerable proportions in Germany, where, besides a great output of safety matches, there is a rapidly increasing use of the strike-anywhere match. The largest German company is the Deutsche Zundholzfabriks Aktien-Gesellschaft, previously mentioned (p. 412). The Aktien-Gesellschaft für Zündwarenfabrikation Stahl & Nölke, also mentioned above (*loc. cit.*), uses aspen-wood for the production of both splints and boxes, the veneers for which are cut in a 'peeling' machine of the usual type. 'Inner' and 'outer' machines, like those already described, are employed to make the boxes, into which the dipped matches are filled by a machine, similar in principle to those in use at Jönköping. The productive capacity of the box-filling or 'boxing' machine is such that, under the superintendence of one girl, it will yield 25,000 filled boxes in 10 hours. After filling, the boxes are coated on the two narrow sides with a striking composition, by conveyance on an endless band between two revolving brushes, supplied with the composition by rotating discs. The boxes are next carried through a drying channel 6 metres long; and, finally, a 'packing' or 'wrapping' machine automatically assembles the boxes in series of ten or twelve, wraps these in paper (cut by the machine from a roll, and properly folded), pastes the folded flaps, and labels the package. The writer is indebted to the Stahl and Nölke Company for some of the foregoing particulars, and for further information relating to the industry in Germany. Other German manufactories have been referred to on p. 412. One of the principal manufacturers of modern types of match-making machinery is A. Roller, of Berlin. A

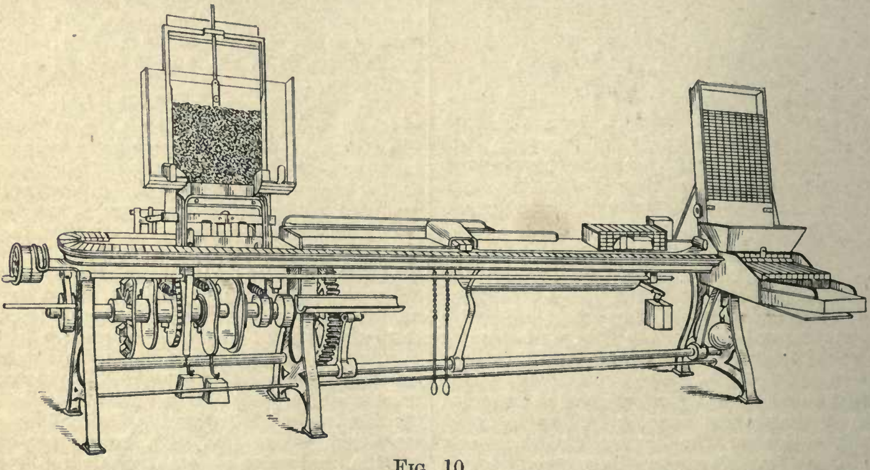

FIG. 10.

Box-filling machine used at Jönköping. (Lagerman's invention.)

large part of the aspen-wood used in Germany is imported from Russia; some, however, comes from native forests. But there is a growing scarcity.

Austria-Hungary. In Austria-Hungary, proably the most important firm, and certainly one of the oldest, is that of Bernard Fürth, at Schüttenhofen, in Bohemia, established in 1838. The founder is stated to have been the first to use red phosphorus as a substitute for white or yellow phosphorus, and in 1854–55 he sent into the market matches with red phosphorus in the rubbing surface on the box—thus adopting a suggestion made by Böttger. These first matches of the safety type were not commercially successful, however, and it was not until in 1855 Lundström improved the invention, that the 'safety match' of the present day became a practical match.

France. The processes and machinery in use at the two chief State factories in France are here briefly described. In the match factory at Aubervilliers, twenty automatic machines, invented by H. Sévène and E. D. Cahen, are employed. One of these machines, worked by only three operatives, can produce in 10 hours 50,000 boxes of 50 finished matches, or about 15 million boxes per annum. For the same output in the old days twenty workers would have been required. The French machinery is constructed upon the same general principles as that already described. Splints, fed into a receptacle by hand, fall from a vibrating hopper into 110 grooves of a horizontal iron plate, to be expelled by a plunger at every stroke of the machine into corresponding grooves of a charger, bridge, or transporting table, having a backward-and-forward motion between the horizontal plate and a vertical part of a long, endless band of carrier plates—the carrier or 'presse.' Each carrier plate is 2½ inches long (in the direction of its journey), 48 inches wide, and is perforated by five rows of equidistant circular holes, 110 in each row. The diameter of an aperture is equal to the side of the square section of a match-stick. When the charger approaches the 'presse,' a plate or 'follower' rises behind the grooves and prevents the sticks from receding. The splints, being longer than the width of the charger, project beyond its edge, and are pushed into the 110 holes of a row in the carrier plate. To prevent bending and breakages of the splints, a horizontal plate presses upon the grooves of the charger, which retreats empty to receive its fresh load. The endless band moves along, bristling with splints, which are carried, over a hot plate, and through a paraffining-bath, secondly, through a sulphur-bath, and thirdly over a rotating grooved cylinder partially immersed in the igniting composition or 'paste.' Thence the conveyer chain travels many yards, for the drying of the matches to be effected; and, finally, at the end of the cycle of operations, plungers expel from the holes the finished matches. These fall, in regulated series, into receptacles, whence pistons fill them into boxes, fed into the machine by an operative, but mechanically opened and shut.

In France, the splints are made of Russian aspen and French willow, the former being preferred. Birch and poplar are used as well. The timber is sawn and cut into splints at Saintines. 'Parlour' and safety matches are largely manufactured at Pantin; wax stems or tapers only at Marseilles.

Norway. The chief match works in Norway is the factory of the Nitedals Tandsticksfabriks, near Christiania. Fig. 11 shows Arehn's box-filling machine (Lundgren's patent) in use at most of the European factories and in many parts of the world.

America. An account has already been given of the present conditions of the industry in the United States of America, and of the Diamond Match Company's machinery, used in the States by that company, as well as in Great Britain by Bryant & May.

Japan. In Japan, a country enjoying at one period a virtual monopoly of the markets in the Far East, there are about 150 factories. Three-fourths of the workers, 25,000 in number, are women. Osaka and Kobé are the centres of the industry. As long ago as 1892 matches ranked fourth among the articles exported from Kobé, and in the following year many new factories were established in Japan, with the result that the output and export of matches enormously increased, and continued to expand until about six years ago. Depression of trade set in, and in 1910 seventeen factories in Kobé and thirteen at Osaka for a while suspended operations, with the result that the output fell off considerably. The most formidable competitors of the Japanese are the Chinese, Swedish, and German manufacturers, who have encroached upon the markets in the Far East. Phosphorus and sulphur matches are manufactured at Osaka; safeties at Kobé. The production of wax matches is almost entirely a household industry. In the year 1909, the total export of matches from Japan amounted to 41,407,083 gross, valued at £1,186,738. During the first half of 1910 there was a decrease of 40 per cent. in the export as compared with the corresponding period in 1909. The leading manufacturers in 1910 had in contemplation the incorporation of the industry into one company, and a monopoly of the export trade of matches from Japan.

China. In 1907 there were three factories in the Canton district: now there are works in Pekin, Hankow, Tientsin, Shanghai, and other towns. The largest works are at Hankow with 3600 operatives.

India. Hitherto the match industry has not prospered in the Indian Empire, but it has been pointed out that the natural advantages of the country, such as plentiful timber, cheap labour, and inexpensive water transport, justify a belief that the prospects of success are good, provided that the industry is developed on proper lines. India might ultimately secure some of the considerable trade of the Persian Gulf, at present enjoyed by Sweden.

2. **Wax matches.** The tapers for these are made as follows: from 60 to 100 strands of cotton, of about 20 threads each, are led from a bale, through a measuring machine and guides arranged at a convenient height, into a steam-jacketed tank, containing a mixture of stearin and gum copal or gum dammar, thence through perforations in a draw-plate, and afterwards over a '*drawing drum*' (Fig. 12), 6–10 feet in

diameter, revolving on an axis, by hand or steam power (Fig. 13).

From this drum the tapers are led back again through the bath to a similar drum on the opposite side of the tank, and by winding alternately from one drum to the other, they are made to pass 6–7 times through the bath, until the cotton has a coating of fat just sufficient to allow it to pass through holes in a suitable gauge plate. The tapers lastly pass through a perforated hot plate, which imparts a polish to the surface, and are again wound on to a drum, from which they are fed to a 'wax-match machine' of the above-described continuous type. In this machine, patented by the Diamond Match Company, the tapers are cut into stems of the usual length, and inserted in spaces (in which they are held in position by brass springs or clips) in the sections of an endless carrier chain. By this they are conveyed over the dipping roller. Of course, neither the steam-heated plate nor the paraffin-bath is in this case empoyled. The heads of the wax matches are dried by the journey over the carrier wheels, and the finished matches are automatically filled into the drawers of the boxes. These pass on to a circular table, where girls put them into the covers or outers—just as in the wood-match machines. Some wax matches, however, are filled into the boxes by hand. Each wax-match machine yields about 3 million matches *per diem.* Some manufacturers, Messrs. Palmer & Son, for instance, still use the frame-dipping method for wax matches. The taper is then either cut into lengths, which are bundled together and cut into vesta stems by a pivoted knife, the stems being afterwards filled into dipping frames by a small filling machine (Day's) worked by hand or steam, or 60–100 strands of it are wound upon a small drum, and passed from it through guides to a 'cutting and filling' machine of the kind indicated in Fig. 14. In this class of machine the tapers are caused to advance between two feed rollers covered with caoutchouc or other elastic material, and having an intermittent motion, their rotation at each revolution of the driving shaft, or movement of the treadles, being through such an angle as to

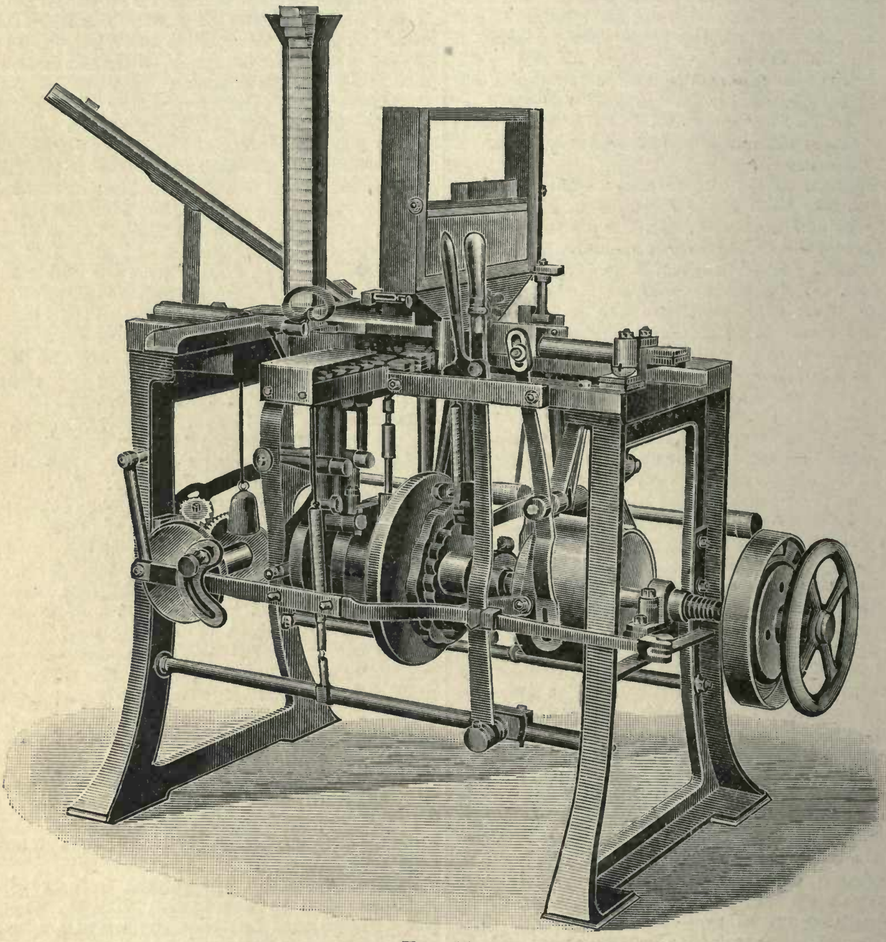

FIG. 11.

Arelın's (Lundgren's patent), box-filling machine, used at Grönvold, Norway.

advance the tapers the required distance under a cutter or cutters working in a vertical plane in front of the feed rollers. The dipping frame (which will fold 6400 stems (80×80) is held immediately in front of a perforated plate through which (when the machine is worked) the cut stems are pushed, so as to rest on a lath of the frame; the frame is now lowered, and the next lath is dropped into position, to receive a row of cut stems, immediately the treadles have been pressed down. When the frame is filled, the stems are dipped, on one side only, in the striking composition. At Messrs. Palmer's factory, the dipped frames of wax matches are dried on shelves in a square chamber, heated by steam pipes, and with a paddle fan in the centre. The 'racking out' is effected by hand, and the vestas are packed in the large penny boxes, or in the small 'Plaid' boxes for exportation, &c.

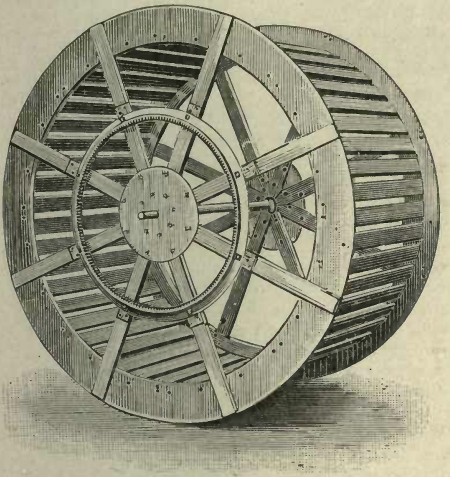

FIG. 12.

Taper-making room.

(For wax match machinery, *v.* patents of Beecher and Wright (1895), Hargreaves & Clegg (1896), Pickles (1899), Wiessner (1900), and Harvey (1901).)

3. **Safety matches.** All that has been stated, with regard to the processes of manufacture of ordinary matches, applies to safety matches, excepting the section on dipping compositions. Many more ingredients have been and are used for safety match compositions than are added to ordinary match pastes. So far, safety matches for the most part have been made with red phosphorus in the rubbers only: but attempts, mostly unsuccessful, have been made to manufacture matches, more or less of the safety type, but without phosphorus, either in the heads or rubbers. The best-known English, Swedish, and other safety matches belong to the first class. The igniting compositions of ordinary safety matches usually contain, as an oxidisable ingredient—apart, of course, from the red phosphorus in the rubbers—grey antimony sulphide, with or without sulphur; charcoal, too, is occasionally added.

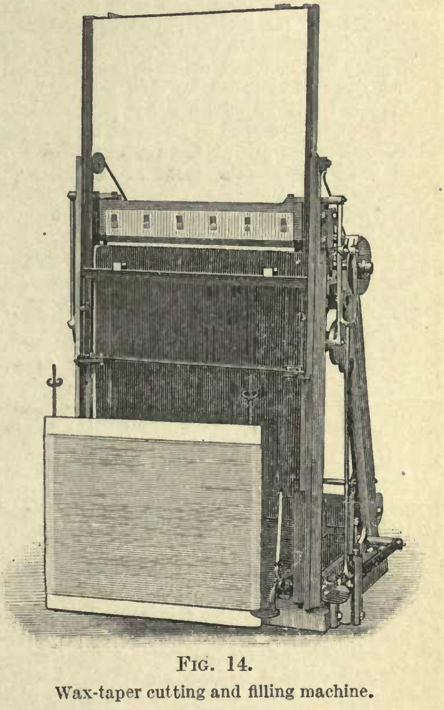

FIG. 14.
Wax-taper cutting and filling machine.

Potassium chlorate, potassium dichromate, and minium are the ordinary sources of oxygen, but manganese dioxide and nitre are also used: glue is the usual binding medium. Colouring matters are seldom added to safety match pastes, which are usually black.

Certain safety matches, made abroad and imported into this country, bearing on their boxes the legend 'Utan swafel och phosphor,' some years since were analysed in the writer's laboratory and found to contain much sulphur.

4. **Vesuvians.** The manufacturing processes for cigar lights, fixed stars, braided lights, and the like, differ little from the methods in use for ordinary matches. The stems, however, are generally of alder or other hard wood (when not of glass, &c.), circular in section, sometimes

braided and wired, and shorter than ordinary match sticks. Comparatively few braided lights are now made. Single workers are now employed occasionally in this branch of the industry, which used to engage the services of scores of hands. The dipping frames are smaller, usually filled by hand, and contain from 1600 (40×40) to 2000 short splints, which are dipped at one or both ends. Two distinct compositions are used: the pastille or burning composition, used for the head or ball; and the igniting or striking paste, with which the head is tipped. The pastille composition is a mixture of nitre with charcoal (or coal- or coke-dust), glass-powder, gum or glue, and some scenting ingredient, such as cascarilla bark, satinwood, gum benzoin, lignum vitæ, &c. The stems are dipped more than once in this composition, until the heads are of the required size, and a final dip in any ordinary striking composition is given to the heads after they have been dried. The early 'fusees' (of brown paper or cardboard, impregnated with nitre, tipped with sulphur, &c.) gave place to vesuvians, which in their turn have been largely superseded by wax matches, and these are being supplanted by pine-stemmed vestas. It will be seen in the next section that cardboard stems are at the present time once more used for certain sorts of matches (*cf.* 'book-matches').

5. '**Book**' **matches.** These, in one respect, are an interesting reversion to some of the very earliest types of matches, and to the original 'fusee'; the stems are of cardboard. Two layers of such matches connected together at the base are fastened in a little flat book, the pasteboard covers of which carry a special striking surface. These matches are of the safety type, striking only upon the prepared surface; they are manufactured by machines which automatically print the cardboard, cut it into combs, dip the teeth in the igniting composition, fold up, stitch into books, and affix to the outsides the special striking composition. [*v.* English Patent of Diamond Match Co. (C. H. Palmer, and J. W. Denmead), 21788, 1899.]

6. '**Double-tip**' **matches.** The genesis of the double-headed match is perhaps to be found in a proposal of R. and D. Maguire (1898), according to which a large flame-producing head, consisting of a composition containing no phosphorus, highly inflammable, but not ignitable by friction, is tipped with a cap composed of a white phosphorus bearing composition, readily ignited on any striking surface. The cap, which is applied by a second dipping, may contain 6 p.c. of white phosphorus (but this, of course, could not now be used in any country a party to the Berne treaty); and the inventors remark that they prefer red phosphorus, which answers satisfactorily. Somewhat similar suggestions are those of Lindner (1899) and the Saginaw Match Company (1905). The last-named company, which in America is credited with having originated the double-tip match, uses for the bulky part of the head a 'detonable composition,' consisting of an ordinary strike-anywhere 'parlour' match compound, containing about 6½ p.c. of white phosphorus, and for the cap or tip a noiseless and non-detonable composition, containing no less than 22 parts of white phosphorus. Matches of this character strike with delightful ease on any surface, and virtually without noise. But the large quantity of white phosphorus present is an obvious objection. It is said that double-tip matches in the States are very formidable rivals to the ordinary strike-anywhere, or 'parlour' matches. But if eventually the use of white phosphorus ceases in America, as appears probable, this competition must become less severe. At all events, the composition of the double-tip match will in such a case obviously have to be modified. In 1909, J. E. State patented a process for producing matches of an allied type, by dipping them successively in a material ignitable by friction, and in a material not so ignitable. The latter is then pushed back by mechanical means, such as a series of rollers, so as to leave exposed a portion of the striking composition at the extreme tip.

The striking surfaces or rubbers. For ordinary matches, mixtures of sand, glass, emery, and the like, with glue or gum, spread on the paper with which the sides of the match-boxes are coated, form convenient friction surfaces; metal gratings, tablets of unglazed porcelain, and porcelain or metal plates with parallel ridges very close together, are frequently employed; and practically any rough or uneven surface—even cloth—can be made to answer. The compositions used in the special rubbing surfaces for safety matches are very various; but the ingredients chiefly present are red phosphorus, antimony sulphide, and powdered glass, made into a paste with glue. The antimony sulphide is sometimes omitted, and manganese dioxide is not infrequently added to safety rubbers.

Among the patents for match striking or rubbing surfaces may be mentioned those of Neuberg (19418, 1897); Craveri (27520, 1897); and Prestwich (23048, 1904).

OLDER METHODS OF MANUFACTURE.

The complete process of manufacturing wooden matches formerly comprised the following separate and distinct operations, carried on for the most part, or at all events very largely, by hand labour: 1. 'Scurfing'; 2. Cross-cutting; 3. Steaming; 4. Splint Cutting; 5. Drying the Splints; 6. Filling the Dipping Frames or Coils; 7. Paraffining (originally Sulphuring); 8. Dipping; 9. Drying the dipped splints; 10. 'Laying out,' 'Racking out,' or 'Racking off'; 11. Halving (sometimes also called 'cross-cutting'); 12. 'Boxing'; 13. Packing. It has been shown that nearly all the work can be, and in the more extensive factories is, carried on automatically by continuous machinery; but in some smaller establishmntes the operations, or most of them, are still performed by the old ways. The three main operations are splint-cutting, dipping, and drying, but a summary of the entire older process will be given. [The smaller manufacturers buy their splints already cut and made up into bundles, or packed in cases.]

Splint-cutting. The planks of wood, usually 12–13 feet long, and 3 inches thick by 11 inches wide, are first of all freed from irregularities and roughnesses by the operation called *scurfing*, knives or cutters, rotatory or otherwise, cleaning and smoothing the surface. The planks are then *cross-cut* into blocks or lengths 4⅝ inches long × 3 inches thick × 11 inches wide. An ordinary English match-splint, to yield two match-stems, 2⅜ inches long, is 4⅝ inches long, so that the pieces cut off from the plank, measured in the direction of the grain of the wood, have just the length of a splint. Unless the wood is newly felled, and therefore sappy, these blocks must next be *steamed* (third operation) for about 20 minutes. They are then taken to the *splint-cutting* machine (fourth operation). Very many forms of such machines have been invented, but only three kinds have been at all generally used in the United Kingdom. The two earlier types of splint-cutting machines were the *toothing* machine and the *flaking* machine. The toothing machine answered well for 'clean' wood, such as pine-wood, but was not adapted for poplar, aspen, &c. The 'vertical flaking' machine is suitable for coarse-grained and even knotty wood, requires little skill in working, and is capable of cutting 650 bundles of splints in a day. The earliest machine belonging to the third class, or combined '*toothing and flaking*' machines, was invented by Tillett (1859). A machine, which for London work to a great extent superseded the foregoing kinds, was Pace and Howard's, and was an improvement upon Tillett's. Some years since, all English and nearly all foreign match-splints were square or rhombic in section. Round splints, such as were yielded by the early machines, were comparatively rarely seen, excepting in Vienna. But at the present time, as has been shown, round-stick matches, such as the pine vestas, and grooved-stick matches, are extensively used. Vesuvians, also, usually are round-stemmed.

Splints made from previously separated veneers are now very largely employed, and many of the later machines for splint-cutting have been upon this principle. Some account has been given (*cf*. p. 413) of Roller's log-peeling and splint-cutting machines; and this must serve; merely a reference can be made to the numerous patents for splint-cutting appliances taken out during the past 14 years. Some of these inventions relate not only to splint-cutting from veneers or otherwise, but to means of assembling the splints in coils, plates or other holders; also, in certain cases, the splint-cutting is described as the initial stage of a process of continuous manufacture.

The next operation is the *drying of the cut splints*. The splints were formerly always made into *bundles* and then dried. Now they are sometimes thrown loosely into large trays and dried by exposure to warm dry air. (Swedish splints are dried in wire-gauze cylinders revolving within a brick stove.) The dried splints are ready for the operation of *filling the dipping clamps or frames* (sixth operation). Prior to the use of dipping frames, there were the so-called 'bundle-dipped' and 'block-dipped' matches. In the earlier days of match-making, 'dipping-boards' were sometimes employed. 'Frame-' or 'clamp-dipping' was introduced in 1849, and its adoption, which by degrees became general, effected a great saving of time and labour. The dipping clamps are square frames with sides consisting of iron rods, on to which slip laths, each having grooves on its upper surface, and being lined with felt below. The match-splints are firmly held in the grooves by the pressure of the felt. Each frame holds 3900 splints, which, dipped at each end and halved, will yield 7800 matches. The dipping frames were at first filled by hand, but Hynam (1850) and Bell and Grimes (1854) invented machines for the purpose. Improvements followed, and in 1865 Simlick introduced self-acting machinery, driven by steam power, to produce the various movements of these frame-filling machines with greater rapidity and economy of labour.

In 1876, E. B. Beecher, of New Haven, Connecticut, invented machinery to replace frame-dipping, by 'coil'-dipping. This system of working having been introduced into the largest English match-works, effected great and, in many respects, beneficial changes in the method of manufacture; and coil-dipping, where it was adopted, for wooden matches entirely superseded frame-dipping. It is not adapted for the manufacture of vesuvians.

In Beecher's original machine (Eng. Pat. 4293, 1876) the splints were so delivered from a hopper as to be set at regular intervals between the coils of a long, flexible tape, band, or belt of cotton webbing, about the thickness of a splint, but considerably narrower than its length; this belt was continuously wound upon a short cylinder or drum adapted to a rotating mandril or axis, until a coil, or bundle, or frame, of the desired size was completed. The end of the binding tape was then secured to the preceding coil by a pin or otherwise, the drum and coil of match-splints thus bound upon it being now ready for removal from the mandril for dipping. Being separated from each other by the thickness of the webbing, and by an interval the width of a splint between every two splints, the splints individually received the proper proportion of composition when dipped, and could be conveniently dried in the coil. In an improved form of the machine (1887), Beecher employed an auxiliary or secondary band in connection with the first, for the purpose of holding the match-splints more securely.

The match-splints, having been arranged for dipping in one or other of the ways described, according to the older method now being described, are ready for *paraffining*, or 'the first dipping,' as it is sometimes called (seventh operation). The frames are put on a table, and the splint-ends are levelled, if necessary, by taps with a piece of wood: they are afterwards heated (to facilitate absorption of the paraffin) by application to a hot iron plate, and then immersed in melted paraffin contained in a shallow steam-heated iron tank. Both ends of the splints are thus treated. Sometimes the operation is effected in a brick stove, on the top of which are three shallow, flat-bottomed, square pans, one serving for the preliminary heating of the splint-ends, the second for the paraffining, and the third for the subsequent dipping in the igniting composition.

In all but the most inferior matches, paraffining has entirely superseded treatment with sulphur.

8. **Dipping.** The usual constituents of a match-igniting composition have already been enumerated (pp. 416, 417), and are mixed in the following manner. The glue and potassium chlorate or nitrate are dissolved in warm water, and the phosphorus (assuming that the worker is in a country where it is still legal to use it) is then added to and stirred in the liquid (which should be of a syrupy consistence and at a temperature of about 38°C.), until a perfect emulsion is obtained. The rest of the constituents, powdered glass or sand, colouring matters, and metallic oxides, if present, having been previously 'milled,' are now added, and thoroughly mixed with the emulsion. When, as is now generally the case, a substitute for white phosphorus is used, it is at first intimately mixed with part of the glue solution and inert materials only; the potassium chlorate, with the rest of the ingredients, being added later. The whole is finally put through a mill.

For the operation of dipping, which—in manufacturing upon the older lines—is performed by workmen in a separate apartment called the dipping-room, the emulsion is ladled from a steam-jacketed iron pan on to the dipping plate or table—generally a shallow, flat-topped, iron box, kept hot by steam admitted to its interior. The composition is spread over the plate, and levelled to the required depth by a gauge or 'strickle.' The ends of the splints in the filled frames (or coils) are then dipped in the thin layer of igniting composition. After the splint-ends on one side have been dipped, the frames or coils are placed in racks, the tipped ends downwards, for a few minutes. The opposite ends are then dipped.

Dipping by hand, as already described, is most usual in working upon a comparatively small scale; but the igniting composition is sometimes applied by the aid of cylinders or rollers, partly rotating in hot-water jacketed cases, receptacles, or boxes containing the mixture, endless chains conveying the frames or coils over the rollers. And it will have been seen (*ante*, pp. 414, 415) that this system is generally employed in the newer, automatic, and continuous methods of manufacture. Bevelled wheels and other devices (L. Urion, 1856) have also been used for the purpose.

9. **Drying.** The frames or coils of double-tipped splints are placed on supports or racks, either in the open air or in the drying-room—an apartment maintained during the summer at a suitable temperature by fans or otherwise, and in damp weather and winter kept warm and dry by pipes conveying steam or hot air.

10. **Laying out**; 11. **Halving**; and 12. **Boxing.** The 'headed' and dried splints are next taken out of the frames or coils, as the case may be. The operation is usually termed 'laying out,' 'racking out,' or 'racking off,' and in England is sometimes effected by hand, if the establishment be not very extensive. The nuts and crosspiece at the top of a clamp are removed, and then lath after lath is lifted and the row of double-tipped splints beneath deftly withdrawn. Laying out is also performed mechanically, the machines of Sebold, Schnetzer, and others being used, especially abroad. In the case of coil-dipped splints the process is called 'unwinding,' and differs, of course, materially from the methods applicable to frames. Beecher (1877) invented a machine which simultaneously performs this operation and the next, 'halving,' 'cutting-down,' or 'cross-cutting.'

According to the older method, for frame-dipped matches, handfuls of the laid-out, double-headed splints were divided, 'halved,' or 'cross-cut,' generally by a pivoted or 'lever' cutting knife, and the resulting matches were at once *boxed* (*i.e.* put into boxes) by women, who became exceedingly dexterous in taking up handfuls of splints of just the required size to fill two boxes. The operations of halving and boxing, where white phosphorus was used, caused more loss by 'firing' than any other part of the proceedings in a match factory. It has been mentioned that the loss during boxing or filling is quite trivial under modern working conditions. And, with the continuous manufacture, there is now no halving.

The writer is under obligations to Messrs. Bryant & May, and to Messrs. Bridwell, Hammond, Parrott, Marchant, and Crowther-Beynon for help in the preparation of this article.

E. G. C.

MATECERIC ACID. An acid obtained from the wax of the yerba maté (*Elaeodendron quadrangulatum* (Reiss.)). When the solution obtained by exhausting the leaves of this plant with ether, or better with ether-alcohol, is treated with lime, then filtered and evaporated, a waxy residue is left, which may be freed from chlorophyll by treating its ethereal solution with animal charcoal. This solution, agitated with water to remove caffeïne and other substances, and evaporated, leaves the pure waxy matter, which, when boiled with aqueous potash, partly dissolves, leaving a residue soluble in ether, much more butyraceous than the original substance and separable by treatment with alcohol into an insoluble yellow transparent substance, and a soluble portion which is white and melts at 55°. On neutralising with hydrochloric acid, the alkaline solution obtained by saponification of the wax, mateceric acid, is obtained as a white precipitate which has acid properties, and is soluble in ether and in boiling alcohol. It melts at 105°–110°, and has a density of 0·8151 at 26°. From the results of its analysis, it does not appear to belong to the acetic series, but its molecular weight is very high (Arata, Gazz. chim. ital. 1877, 366).

MATEZITE. A saccharine substance obtained by Girard from Madagascar caoutchouc; when treated with hydriodic acid, yields methyl iodide and *matezo-dambose*, an isomeride of glucose. Crystallises in radiating nodules. Rotatory power $[\alpha]_D + 65$; m.p. 187° (Girard, Compt. rend. 77, 995, and 100, 84; Combes, *ibid.* 110, 46).

MATICO CAMPHOR *v.* CAMPHOR.

MATLOCKITE. A lead oxychloride

$$PbCl_2 \cdot PbO$$

of a yellowish colour, found at Cromford, near Matlock, Derbyshire; sp.gr. 7·21.

MATRASS. An egg-shaped glass vessel with a narrow neck, used by the older chemists, mainly for sublimations.

MAURITIUS ELEMI *v.* OLEO-RESINS.

MAUVANILINE $C_{19}H_{17}N_3$. A base isolated by Girard, De Laire, and Chappolot, from the insoluble residues obtained in the manufacture of rosaniline (Zeitsch. Chem. 1867, 236).

MAUVE or **MAUVEÏNE** *v.* Azines.

MAYNAS RESIN or **CALABA** *v.* Resins.

MEAD or **HYDROMEL.** An alcoholic drink prepared by the fermentation of honey. Well-made hydromel has a colour between that of champagne and Madeira, is fine in flavour, and contains about 13 p.c. of alcohol.

MEADOW ORE *v.* Limonite; also Iron.

MEADOW SAFFRON *v.* Colchicum.

MEAT EXTRACTS. *Historical.* It is well known that extract of meat consists of beef tea evaporated to the consistency of a thick syrup. It therefore contains the whole of those constituents of meat which are soluble in hot water.

It was first correctly prepared in 1821 by Proust, by whom, in conjunction with Parmentier, it was very highly recommended as a stimulant quite as valuable for the strong and healthy as for invalids. In 1847 Liebig, in his celebrated treatise on 'Researches on the Chemistry of Food,' most warmly approved of Proust and Parmentier's extract, and subsequently made every effort to popularise the use of the preparation. The attention of many men of science, but more particularly of the medical profession in Germany, was attracted to Liebig's abstract scientific researches into the nature of meat, and it was ascertained that extract of meat was of great usefulness in medical cases.

In consequence, the *Extractum Carnis* was, without Liebig's assistance, introduced into the Bavarian Pharmacopœia of 1856, and from that time all Bavarian apothecaries were legally bound to keep the extract in stock, or to make it when required, just as any other drug. From Bavaria the knowledge and medical use of the extract spread over the whole of Germany, but its manufacture remained confined to pharmaceutical chemists, and its use to the sick chamber. Liebig, on the other hand, while fully appreciating the clinical importance of the extract, and further endeavouring to improve the alimentation of sick persons by various modifications of this invention, proposed to bring meat extract into commerce as an article of food, and to make its manufacture the object of industrial enterprise on a large scale. His endeavours were, however, without success until, early in 1862, George Christian Giebert, an engineer, well acquainted with the meat-producing districts of South America, went to Munich to receive instruction in the method of preparing the extract by Liebig himself, aided by von Pettenkofer, and then returned to Uruguay and established a manufactory on a considerable scale. In November, 1864, the first samples of Giebert's manufacture arrived at Munich and their quality far exceeded the expectation of Liebig. He consented to Giebert's proposition that the extract should bear the name of the inventor, on condition that it should always be free from fat and gelatin, and that each consignment should be subjected to a gratuitous analysis by him or his delegate. The establishment of Liebig's Extract of Meat Co., Ltd., was thus founded.

The industry has flourished and immense areas of land are farmed to produce cattle required for the manufacture of meat extracts. Take, for example, some facts connected with the enterprising company to which Liebig gave permission to bear his name. The Liebig's Extract of Meat Company farmed, in 1868, some 28,494 acres of land, and the total herd of horned cattle reared on this area was 12,000. In 1908, the acreage was 1,302,386 and the number of cattle 224,406, and in 1910 the acreage was 5,000,000, and the number of cattle 350,000. Striking as the figures may be as illustrating the enormous expansion of the cattle-rearing industry, they become still more impressive when regard is paid to the fact that the cattle are no longer, as in Liebig's day, and according to his own words, 'half-wild animals,' but are bred from the choicest pedigree stock taken from the farms of our best English breeders.

Each animal is allotted about 5 acres of pasturage. The average daily amount of grass consumed by one animal is 88 pounds; a herd of 250,000 would therefore consume *per diem* 22,000,000 pounds of grass, or approximately 10,000 tons. Thus the yearly consumption of grass would mean not far short of 4,000,000 tons. The composition of pasture grass, according to the average of a large number of analyses, is as follows:—

	Per cent.
Water	80·00
Proteins with a small quantity of nitrogenous extractives[1]	3·50
Fat	0·80
Carbohydrates	9·70
Fibre	4·00
Mineral salts	2·00
	100·00

This means for a herd of 250,000 head of cattle per year a food yield in the form of grass of the following quantities of its individual solid constituents:—

	Tons
Protein or flesh-forming substances	140,000
Fat	32,000
Carbohydrates	388,000
Fibre	160,000
Mineral salts	80,000
	800,000
Balance due to 80 p.c. of water in grass	3,200,000
Total	4,000,000

Similarly, the annual amount of water consumed, based on the fact of one animal requiring 30 litres per day, would amount to 700,000,000 gallons per annum for the herd. These figures refer only to the stock of one company. The Argentine, Uruguay, and Paraguay republics are immense fodder-yielding tracts, and the metamorphosis of grass proceeds steadily and uninterruptedly day by day on a colossal scale. There are occasions when the ordinary grass is supplemented by 'Alfalfa,' a rich clover corresponding to our lucerne and containing a good proportion of nitrogenous food.

Method of manufacture. In principle the lines laid down by Leibig, which he considered essential to success, are still followed by the Liebig Company. In the first place, the meat is hung in the cooling halls for 12 or more hours,

---

[1] $N \times 6{\cdot}25$.

then the fat and sinews are carefully removed, and the meat is fed to chopping machines with revolving knives. From the chopping machines the meat emerges in chunks, which drop into mincing machines especially constructed for the purpose. The meat emerges from these machines as mincemeat, and is then transferred to the extracting pans, each capable of holding about 4 tons, in which it is left with its own weight of pure filtered water. After the addition of more water the mixture is heated to a temperature not exceeding 95° by means of steam jackets. During this time fat continuously rises and is skimmed off. The more or less clear liquor is then run off and the work of concentration is commenced. Fat is again skimmed off until at length the extract or soup is practically free. Concentration proceeds again *in vacuô*, and during evaporation is twice filtered before passing into the final concentrator, which is fitted with a revolving worm through which low pressure steam is passing. Constant stirring during the final stages of evaporation is essential to secure uniformity in regard to consistency and composition of the finished extract. The treacly mass is then run off while hot into 100 lb. tins, cooled, hermetically sealed and dispatched to the European blending factories.

The extract is finished within 3 days of the death of the animal.

One thousand pounds of lean meat, treated upon a manufacturing scale, furnishes 31 lbs. of extract. Commercial extract manufactured as described contains an average of 18·25 p.c. moisture, 61·5 p.c. of organic matter, 20·25 p.c. of mineral substances, and yields an alcoholic extract of 57 p.c.

It should be as free as possible from gelatin, fat, and coagulable or insoluble albumen. By far the greater proportion of the meat constituents, namely, the fibrin, gelatin-yielding tissue, and fat is therefore rejected in the preparation of extract.

Lemco, which is the standard extract manufactured by the Liebig's Extract of Meat Company, has the following composition :—

		Per cent.
Water		20·05
Organic matter		58·52
Mineral matter		21·43
		100·00
The mineral matter contains:		
Combined chlorine		1·88
Phosphates as P_2O_5		6·00
The organic matter contains:		
Total nitrogen		9·45
Distribution of the total nitrogen:		
Nitrogen in fibrin and albumen	0·14	
,, meat bases soluble in alcohol	5·64	
,, meat bases rendered soluble in alcohol	0·70	
,, gelatin	0·02	
,, albumoses	1·73	
,, peptones	1·17	
Ammoniacal nitrogen	0·05	
	9·45	
Creatine		1·85
Creatinine		4·95
Total		6·80
Fat (ether extract)		0·12

The meat bases constituting the essential part of the extract contain creatine, creatinine, xanthine bases, carnine, carnic acid, and other complex organic bodies.

Whilst all commercial extracts are essentially of the same character, the proportions of the various constituents differ. From Table I. it is observed that Nursing Oxo contains a proportion of proteins derived from the peptonisation of meat. Oxo and Bovril contain a higher proportion of water, and about 5 p.c. of meat fibrin derived from partially extracted lean meat.

TABLE I.

	Composition of Nursing Oxo p.c.	Oxo p.c.	Bovril p.c.
Water	23·53	41·00	41·90
Organic matter	59·26	39·74	40·58

,, albumoses	1·53	0·17	0·78
,, peptones	1·67	0·59	0·26
Ammoniacal nitrogen	0·14	—	—
	9·68	5·94	6·10
Creatine	3·64	1·58	1·99
Creatinine	0·83	1·97	1·56
Total	4·47	3·55	3·55

A practice has arisen of mixing meat extracts with extracts of yeast. The extract of yeast has valuable dietetic properties and contains the active principles of fermentation. It also resembles, in many respects, physically and chemically, the extract of meat, and can, therefore, be mixed with meat extract, and, being a cheaper article, forms a mixture which can be sold at a greater profit, and ought not to be classed as a meat extract.

According to Wiley the presence of yeast extract in meat extract can be determined by treating the mixture with a strong solution of zinc sulphate and filtering. In meat extract the filtrate obtained is always quite clear, but when a yeast extract is present the filtrate is turbid. Hehner applied the Folin reaction for the estimation of creatine and creatinine in meat extracts, and as yeast extract contains neither creatine or creatinine the test is of importance in determining the source and value of a meat extract.

The Folin method for the estimation of creatinine is a colorimetric one, based on the fact that creatinine gives with picric acid, in presence of alkalis, an orange to deep red solution, the intensity of the colouration depending upon the amount of creatinine present (Zeitsch. physiol. Chem. 1904, 41, 223). Folin recommends the use of Dubosq's colorimeter for making the colour comparisons.

The test is carried out as follows: With good quality extracts 5 grams are dissolved in water and the solution made up to 500 c.c.

Creatinine. 20 c.c. of this solution are taken for the determination of creatinine, viz. 0·200 gram of extract. To 20 c.c. of the solution in a 500 c.c. flask are added 20 c.c. of picric acid solution (saturated) and 5 c.c. of a 10 p.c. caustic soda solution.

The mixture is shaken and allowed to stand exactly 5 minutes, and is then made up to 500 c.c. with pure water at 18°, and its colour compared with that obtained from a standard solution of potassium dichromate (24·565 grams per litre).

All colorimetric readings are made with a Dubosq colorimeter, having the left-hand cylinder fixed at exactly 8 mm. depth of bichrome solution.

The following readings were obtained :—

x=4·99 p.c. creatinine.

Total creatinine and creatine. 15 c.c. of the extract solution (5 grams in 500 c.c. water) =0·15 gram extract, are placed in a porcelain basin 8 cm. diameter, and 10 c.c. of normal HCl (1 c.c.=0·0365 gram HCl) added, and slowly evaporated to dryness on a water-bath taking at least 2 hours for the evaporation. The residue is dissolved in 15 c.c. of water, then to the contents in the basin 20 c.c. picric acid are added, and 5 c.c. of the caustic soda solution. The mixture is stirred with a glass rod, and exactly after 5 minutes' standing transferred to a 500 c.c. flask, the basin being washed out several times into the flask, and the liquid made up to 500 c.c. at 18°. The following readings were obtained :—

8·4 mm.	8·5 mm.	
8·4 ,,	8·6 ,,	Jaffe's formula

1·37×1·16=1·5892 creatine.

Corrected results :

Creatinine	4·99 p.c.
Creatine	1·59 ,,
	——
	6·58 ,,

In carrying out this test care must be taken to observe all the details as regards :

(*a*) Strength of solutions employed ;
(*b*) Time of contact ;
(*c*) Dilution of original liquid ;
(*d*) Depth in mm. of the unknown solution should not vary more than between 7 mm. and 9 mm. ;
(*e*) Temperature to be as near 18°C. as possible.

With extracts that yield low creatine and creatinine figures it is necessary to treat the extract before applying the test. 10–50 grams of the substance are dissolved in the smallest bulk of water possible. Then 250 c.c. methylated spirits are added and allowed to stand for 12–16 hours, filtered, the alcohol distilled off, the residue dissolved in water, and made up to 100 c.c., an aliquot part not exceeding 20 c.c. being taken for the estimation.

It has been pointed out by Jaffé (Zeitsch. physiol. Chem. 1886, 10, 391), and more recently by A. C. Chapman (The Analyst, Nov. 1909), that other substances, such as acetone, dextrose, and lævulose reduce picric acid and produce the same colouration. When the presence of any reducing substance other than creatinine is suspected, preliminary treatment with methylated spirits is desirable.

Methods of analysis. For the sale of commercial high-grade extracts the following method is applied.

In some meat extracts during the cooling in pots, crystals and other solids settle to the bottom before the mass becomes semi-solid, consequently the material must be well mixed without warming before analysis.

Water. 2 grams are evenly spread by means of a glass rod round the inside of a porcelain crucible 37 mm. high and 55 mm. wide on top to within 10 mm. of top edge; dried for 36 hours in a water-oven at a temperature of 97°, cooled for 20 minutes in a desiccator over vitriol and quickly weighed. A Moslinger's cellular water-oven is best for this class of work.

Ash. 2 grams are weighed in a platinum basin and slowly burned without the basin becoming visibly red. The burner employed has a round cover 7 cm. in diameter with 28 holes, each 1 mm. in diameter. After carbonising, the mass is crushed twice and the ash obtained should be a greyish-white without showing fusion—too strong or too quick ignition will cause loss.

For absolutely correct ash estimation the basin is put on an asbestos sheet to protect the contents from sulphurous acid of the gas, or better still, burned in an electric furnace at 6–8 ampères until the ash is clear grey. This is weighed when cold and washed into a small beaker, acidified with nitric acid, and warmed until the light brown coloured matter coagulates. Filter and use the filtrate for the chlorine estimation, wash the carbonaceous matter from the filter into a small crucible, dry at 105° and weigh. Deduct this carbon from the former weight to get the true pure ash.

The chlorine is estimated in the acidified filtrate from the ash gravimetrically, as phosphates interfere with the volumetric estimation.

Alcoholic extract. By this is meant that portion of the extract soluble in ethyl alcohol, 80 p.c. by volume. 2 grams are weighed out into a small Soxhlet flask, 9 c.c. water added, and the extract dissolved without warming, 50 c.c. alcohol (93 p.c. by volume, sp.gr.=0·8234) slowly added with gentle shaking, allowed to stand over night at 17°–18°, and then carefully poured from the fast sticking mass into a weighed porcelain basin 76 mm. diameter and 34 mm. deep; the alcohol is evaporated slowly on a water-bath at 70°–75°. In order to prevent creeping the basin is placed on a layer of flannel over the hole in the bath, or in a copper basin soldered into the opening in the bath and having a layer of sand between the copper and porcelain basins. Meanwhile to the insoluble mass in the flask 50 c.c. alcohol of sp.gr. 0·8639 (80 p.c. by volume) are added with gentle shaking and allowed to stand at 17° until the first alcoholic solution is evaporated when the second portion is decanted into the basin, and this again evaporated until the contents have the consistency of honey. The basin is then dried at 98° in the water-oven for exactly 6 hours, cooled 20 minutes in the desiccator, and quickly weighed. The extraction temperature must be within 17°–18°, or variable results will be obtained.

General Analysis of Meat Extracts.

Modified Stutzer method. 30 grams are weighed, dissolved in water and made up to 250 c.c. A fair average sample is thus obtained, and all estimations necessary can be begun the same day.

Moisture. Cleaned ignited Calais sand is put into a flat nickel basin 9 cm. in diameter along with a small glass stirring rod until the whole weighs exactly 100 grams. Dried in steam oven until weight is constant, then 25 c.c. extract solution added (= 3 grams extract), stirred amongst the sand, evaporated until granular on a water-bath, transferred to a steam oven for 36 hours, cooled and weighed.

Ash. 25 c.c. (= 3 grams) evaporated and carbonised. Owing to the quantity of carbonaceous matter the estimation of ash cannot well be made direct, hence the charred mass has to be extracted three times with boiling water, and filtered through an ashless filter paper into a porcelain basin, the char and filter paper burned off in the platinum basin, and the filtrate put back in the platinum basin, evaporated, dried, ignited gently, and weighed. The ash is dissolved in cold water, acidified with nitric acid, made up to 250 c.c., and used for estimation of chlorides and phosphates.

Chlorides are estimated gravimetrically in 50 c.c.

Phosphates are estimated by the molybdate and magnesia mixture method in 50 c.c.

Fibrin and **already coagulated albumen.** 25 c.c.(=3 grams) are diluted and settled in a 100 c.c. cylinder over night. The top liquid decanted and the residue either transferred to a counterpoised filter, washed, dried at 100°, and weighed, or the residue transferred to a centrifuge tube, washed, and the nitrogen estimated by Kjeldahl's method.

Soluble albumen. The decantations from the above are acidified with acetic acid, boiled for 5 minutes, settled, filtered, and weighed or treated by Kjeldahl's process. If the total fibrin and albumen together be required, then it is only necessary to acidify 25 c.c. of extract solution diluted to 100 c.c., with acetic acid, boil for 5 minutes, settle, filter, and either weigh at 100° or treated by Kjeldahl's method.

Gelatin. 25 c.c. of extract solution (= 3 grams) are poured on to asbestos fibre in a small porcelain basin, evaporated to dryness, extracted with 93 p.c. alcohol three times, then with ice-cold water containing 10 p.c. alcohol, until the decantations are free from colour (the temperature must never rise above 5°). The gelatin is either dissolved and washed from the asbestos and treated by Kjeldahl's process, or the asbestos and gelatin may be put direct into the Kjeldahl flask. With some extracts it is better to take 25 c.c. extract solution, and, without evaporating, add 250 c.c. methylated spirit, stand 8 hours, decant off alcohol from the sticky mass and wash with 10 p.c. ice-cold alcohol until free from colour, then treat by the Kjeldahl method.

Total nitrogen. 10 c.c.(=1·2 gram extract) are treated by Kjeldahl's method direct.

Meat bases soluble in alcohol. 25 c.c. (=3 grams extract) taken in beaker, 250 c.c. absolute alcohol added with constant stirring and settled for 12–16 hours. The alcohol passed through filter into a 500 c.c. round-bottomed flask, the residue washed twice with 25 c.c. absolute alcohol, and the alcohol distilled off, standing the flask inside a water-bath. The meat bases are then treated by the Kjeldahl process in the flask without transference so as to avoid loss.

Residue insoluble in alcohol. The insoluble residue from the absolute alcohol is dissolved in water on the water-bath. A few drops of acetic acid added to coagulate the soluble albumenoids, then boiled and filtered into a 250 c.c. flask for the estimation of gelatin albumoses and peptones. The residue on the filter, consisting of fibrin, albumenoids, may be treated by Kjeldahl's method as a check on former estimation.

Total nitrogen in gelatin albumoses and peptone fraction. 50 c.c. of the 250 c.c. taken for the Kjeldahl process.

Albumoses and gelatin. 50 c.c. of the 250 c.c. are taken in a porcelain basin, and powdered zinc sulphate crystals added with frequent stirring until saturated. The precipitate is filtered, washed with saturated zinc sulphate solution, and subjected to Kjeldahl's process. The filtration of the precipitate is slow, but proceeds steadily, and works better if the liquid is rendered slightly acid with sulphuric acid (1 : 4).

Peptones, albumoses, and gelatin. 50 c.c. of the 250 c.c. are put into a beaker 50 c.c. sulphuric acid (1 : 3) added, and an excess of phosphotungstic acid, prepared by making a strong solution of sodium tungstate in boiling water, and adding phosphoric acid with continued boiling until the mixture gives a constant acid reaction.

An alumina-like precipitate is formed which, if left for a few hours, filters fairly well. The precipitate is washed several times with dilute sulphuric acid, and then treated by Kjeldahl's method. This operation has to be carefully conducted as the precipitate causes bumping.

The nitrogen from this estimation comes almost up to the total nitrogen of the section insoluble in alcohol, but a little of the meat bases are sometimes rendered insoluble by the alcohol, and the traces obtained by difference are to be added to the meat bases. Having obtained the gelatin figure by a separate estimation, then (gelatin and albumoses) − gelatin = albumoses, and (gelatin + albumoses + peptones) − (gelatin + albumoses) = peptones.

Ammoniacal nitrogen. Traces only of this are present, 50 c.c. of the standard extract solution (= 6 grams extract) are distilled with barium carbonate into standard acid.

All nitrogen determinations are made by the Kjeldahl-Gunning method, using about 15 c.c. nitrogen-free vitriol to start with. After frothing, and the thick carbonaceous mass has settled, 10 grams of potassium sulphate and a small crystal of copper sulphate are added. Heating must be continued until the yellow colour has changed to a clear blue, indicating complete oxidation. In distilling off the ammonia it is preferable to use steam with a small flame under the alkaline liquid to prevent dilution by condensation, instead of a naked flame under the distillation flask, when zinc-dust has to be added to prevent bumping.

In calculating the percentage of the various nitrogenous compounds in extracts it is usual to use the factor N × 6·25. This is not, however, strictly accurate, but is generally accepted as the best approximation to the truth. Analyses, therefore, should disclose the actual nitrogen figures obtained.

An auxiliary method for the estimation of gelatin is that of Beckmann (Forschungs Berichte, 1896, 3, 324) based upon the fact that gelatin and albumenoids are rendered insoluble by formaldehyde. 3 grams extract dissolved in 20 c.c. cold water are treated with 3 or 4 drops of formaldehyde solution (40 p.c. strength) and evaporated to dryness on a water-bath and for 2 hours in an air oven, then moistened with a 5 p.c. formaldehyde solution, and after standing 5 minutes, warm water, 60°–70°, is added and allowed to digest 15 minutes, the water is then decanted, and the washing repeated until free from colour. The insoluble mass is subjected to the Kjeldahl process. Care must be observed to use a formaldehyde solution which is neutral, since free acid affects the reaction.

A convenient method for the determination of the total soluble proteids in extract is based on the fact that halogens precipitate those bodies. Bromine water is for convenience employed. Allen and Searle take 1 gram of the substance dissolved in 100 c.c. water in a flask and acidify with dilute hydrochloric acid. A considerable excess of bromine water is added and the liquid shaken for some time. The precipitate is allowed to settle for several hours, the supernatant liquid decanted through an asbestos filter, the precipitate washed with cold water and treated by Kjeldahl's method. F. S.

MECCA BALSAM. *Opobalsam*; *Balm of Gilead* (*v.* OLEO-RESINS).

MECONIC ACID, MECONIDINE *v.* OPIUM.

MECONINE *v.* LACTONES.

MEDLAR. The fruit of *Mespilus germanica* (Linn.). When fresh, the fruit has a yellowish-white flesh, which is hard and of an unpleasant astringent taste; on keeping for some weeks, the flesh becomes brown, soft, and doughy, and possesses an agreeable flavour. In the latter condition, Bersch (Landw. Versuchs. Stat. 1896, 46, 471) examined the various parts of the fruit and obtained the following results:—

	Whole fruit	Rind	Flesh	Pips
Percentage of dry matter	30·9	36·9	24·8	61·6

The dry matter contained—

	Protein	Fat	Invert sugar	Other N-free extract	Crude fibre	Ash
Whole fruit	2·79	1·04	36·08	40·98	16·29	2·82
Rind .	4·12	2·66	—	72·62	17·51	3·09
Flesh .	2·62	0·57	48·56	37·63	7·35	3·27
Pips .	2·55	0·62	—	46·66	48·52	1·65

Malic acid, acetic acid (0·03 p.c.) and alcohol were present.

The ash of the medlar has been found to contain about 0·3 p.c. boron trioxide. In the N-free extract there is a considerable portion of pectin matter. H. I.

MEDULLADEN *v.* SYNTHETIC DRUGS.

MEDULLIC ACID $C_{20}H_{41}{\cdot}CO_2H$, m.p. 72·5°, an acid found as a glyceride in beef suet and in beef marrow, associated with oleic and palmitic acids.

MEERSCHAUM. A hydrated magnesium silicate $H_4Mg_2Si_3O_{10}$, occurring as nodules and compact masses, of white, grey, or creamy colour. From its appearance and its extreme lightness (sp.gr. 0·988–1·279) it has acquired the name of *meerschaum* or 'sea-froth' (*écume de mer*), although it is sometimes described by mineralogists under the name of *sepiolite*, a word introduced by Glocker to indicate its resemblance to the light white porous material known as the bone of the cuttle-fish or sepia. Meerschaum is a soft mineral (hardness 2–2·5), easily carved; has a greasy feel, and readily adheres to the tongue. In consequence of this porosity, a meerschaum pipe absorbs the oily matter of the tobacco; and, for a like reason it is difficult to determine the proportion of water in the mineral. The following analyses illustrate the composition of meerschaum:—

	I	II	III
Silica . .	60·87	61·30	53·8
Magnesia . .	27·80	28·39	23·8
Alumina . .	—	—	1·2
Water . .	11·29	9·74	20·0
	99·96	99·43	98·8

I. From Asia Minor, by Lychnell. II. From Greece, by Scheerer. III. From near Madrid, by Berthier.

Meerschaum is found as nodular masses in alluvial deposits in the plains of Eski-Shehr, in Asia Minor, where it is associated with magnesite ($MgCO_3$). It is here dug from a number (now some 1270) of shallow pits, from the bottom of which short galleries are occasionally run. The nodules are scraped free from earthy matter with a special knife, air dried, polished with wax, and sorted into a number of grades and sizes (J. Soc. Arts., 1909, 57, 411). It also occurs at Kiltschik, near Konieh, in Natolia; in Greece, Negroponte, and Samos; in Moravia; and in New Mexico. In New Mexico it occurs as nodules and seams in limestone, and has been exploited at two localities, namely Gila valley and Bear Creek (D. B. Sterrett, Bull. U.S. Geol. Survey, 1908, No. 340, 166). At Vallecas, near Madrid, it is said to be used as a light material for constructive purposes. Meerschaum has been employed as an ingredient in porcelain, while in Turkey it is used, when fresh, in the place of soap, and as a kind of fuller's earth. From the East large quantities are sent to Vienna to be carved as tobacco pipes. The pipes are prepared for use by being soaked in melted tallow and wax, and are polished with shave grass. Imitations are fabricated in plaster of Paris hardened with paraffin, and in a preparation of potatos treated with dilute sulphuric acid. L. J. S.

MEGASSE. Spent or crushed sugar-cane.

MEILER. The German name for the stack of timber piled up for burning into charcoal (*v.* Carbon).

MELACONITE. Native copper oxide CuO (*v.* Copper).

MELANTERITE. Native ferrous sulphate (*v.* Iron).

MELDOLA'S BLUE *v.* Oxazine colouring matters.

MELDOMETER. An instrument designed for the purpose of ascertaining the melting and boiling-points of small quantities of substances. It consists essentially of two pairs of forceps mounted on a stage and carrying between them a thin platinum ribbon. Through this ribbon an electric current may be passed, the strength of the current being regulated by a carbon-mercury rheostat. The apparatus is mounted on the stage of a compound microscope, provided with a 1-inch objective. The substance to be examined is placed in focus on the platinum ribbon, and then the current is gradually increased until the substance is melted or volatilised. Experiments made in this way show interesting phenomena, sufficiently characteristic in many cases to identify a substance at once. By arranging side by side different fragments it is easy to find their order of melting-points with greater exactness than can be the case when the blow-pipe is employed.

The meldometer is also of value in studying sublimates. A piece of glass is held over the heated strip and upon this the sublimate deposits. A long series of trials have led to the conclusion that the appearances so obtained are excellent as tests to the mineralogist and chemist (J. Joly, Industries, 1889, 20, and J. Soc. Chem. Ind. 8, 306).

MELEZITOSE *v.* Carbohydrates.

MELIBIOSE *v.* Carbohydrates.

MELICITOSE *v.* Carbohydrates.

MELINITE *v.* Explosives.

MELISSA. The leaves and tops of *Melissa officinalis* (Linn.) contain a small quantity of a volatile oil. They are used occasionally in the form of a warm infusion as a diaphoretic in slight febrile conditions.

MELISSIC ACID $C_{29}H_{59}COOH$ is obtained by heating myricyl alcohol with soda-lime at 220° until hydrogen ceases to be evolved (Stürcke, Annalen, 223, 295); m.p. 91° (Marie, Ann. Chim. Phys. [vii.] 7, 145). It is probably identical with an acid found in beeswax (Nafzger, Annalen, 224, 225; Marie, *l.c.*).

MELISSYL ALCOHOL, MYRICYL ALCOHOL *v.* Waxes.

MELITOSE, *Raffinose* (*v.* Carbohydrates).

MELLITIC ACID. *Benzenehexacarboxylic acid* (Ger. *Mellithsaüre*) $C_6(CO_2H)_6$. Obtained by oxidising charcoal with fuming nitric acid, fuming nitric acid and potassium perchlorate, or with sulphuric acid (Dickson and Easterfield, Chem. Soc. Proc. 1898, 163; Staudenheimer, Ber. 1899, 2824; Hübner, Chem. Zeit. 1890, 440; Verneuil, Compt. rend. 1907, 132, 1340; Bartoli and Papasogli, Gazz. chim. ital. 15, 546; Schulze, Ber. 1871, 802, 806; also *v. infra*). By the electrolysis of alkaline solutions, using graphite electrodes, mellitic acid $C_6(CO_2H)_6$, hydromellitic acid $C_6H_6(CO_2H)_6$, and pyromellitic acid

$$C_6H_2(CO_2H)_4$$

are formed (Bartoli and Papasogli, Gazz. chim. ital. 1882, 113; 1883, 37). Also formed together with pyromellitic acid as a decomposition product of sugar (Lippmann, Ber. 1894, 3408). Has been synthesised by passing a current of methyl chloride through a warm solution of toluene containing aluminium chloride and oxidising the hexamethylbenzene thus formed with potassium permanganate (Friedel and Crafts, Compt. rend. 91, 257; Ann. Chim. Phys. [vi.] 1, 470). Mellitic acid is best prepared in the following way: Carbon, fine enough to pass through an 80 or 90 sieve is boiled vigorously with nitric acid (sp.gr. 1·5) until the liquid becomes faintly amber in colour; this usually takes 3 days. The excess of nitric acid is distilled off at 130°–140° and the residue, containing 80–90 p.c. mellitic acid extracted with water (Holliday & Sons and Silberrad, J. Soc. Chem. Ind. 1908, 522; Eng. Pat. 24662; D. R. P. 214252). According to Michael (Ber. 1895, 1631), the raw material may be purified by boiling with acetic acid, filtering and concentrating the filtrate.

Mellitic acid decomposes when heated in an open tube at about 260° and has no definite melting-point under these conditions, but when heated in a closed tube melts at 286°–288° (Michael, Ber. 1895, 1631); crystallises in long needles, soluble in alcohol and ether: heat of formation, 546·8 cal.; heat of combustion, 788·2 cal. (Stohmann, Kleber, and Langbein, J. pr. Chem. [ii.] 40, 128); heat of solution +3·672 cal. at 20·4° (Berthelot, Compt. rend. 101, 685): dissociation of acid (Quartaroli, Gazz. chim. ital. 1905, 35, i. 470). It dissolves unchanged in boiling sulphuric acid, and is not acted on by chlorine, bromine, concentrated nitric or hydriodic acids. Dry distillation yields carbon dioxide and pyromellitic acid, and by strong heating with glycerol trimesic acid and carbon dioxide are produced. By fusion with caustic soda, benzene and carbon dioxide are formed (Baeyer, Annalen, Suppl. 7, 5); reduction with sodium amalgam yields hydromellitic acid. By the electrolysis of the aqueous solution, the chief gaseous products are oxygen, hydrogen, and carbon dioxide, very little carbon monoxide being produced (Boungué, Bull. Soc. chim. [ii.]

35, 561). Acetonitrile and mellitic acid give rise to the triimide, *paramid* $C_6(C_2O_2NH)_3$ and the diimide, *euchrons* $C_6(C_2O_2NH)_2(CO_2H)_2$, when heated at 265°–275° (Mathews, J. Amer. Chem. Soc. 20, 648). A warm aqueous solution of the acid acts on anhydrous or hydrated bismuth oxide producing bismuth mellitate $Bi_2C_{12}O_{12}$, which when heated under reduced pressure in closed tubes at 350° yields pyrophoric bismuth (Thibault, Bull. Soc. chim. 1904, [iii.] 31, 135). Mellitic acid condenses with resorcinol to form phthaleins (Silberrad, Chem. Soc. Trans. 1906, 1787; Green, Chem. Soc. Proc. 1907, 12) and with amino-phenols to form rhodamines (Silberrad and Roy, *ibid.* 1908, 204; J. Amer. Chem. Soc. 32, 189); these compounds are dyestuffs (Eng. Pat. 28638; J. Soc. Chem. Ind. 1903, 414). According to Van Loon (Ber. 1895, 1271), mellitic acid is not esterified by alcohol and acids; but Meyer (Monatsh. 1904, 25, 1201) states that by heating mellitic acid with methyl alcohol and sulphuric acid in a benzene bath, the *pentamethyl ester*, m.p. 141°–144°, is formed; at 100° a mixture of the pentamethyl and hexamethyl esters is produced and at higher temperatures the hexamethyl ester predominates. The *hexamethyl ester* melts at 187° and may be formed by the action of methyl iodide on the silver salt (Kraut, J. 1862, 281; Kraut and Busse, Annalen, 177, 273) or by the action of diazomethane on the acid (Pechmann, Ber. 1898, 501). The *hexaethyl ester* melts at 73°.

MELON. The fruit of various plants of the *Cucurbitaceæ* of tropical or sub-tropical countries. There are many varieties, among which may be mentioned musk-melon, *Cucumis melo* (Linn.), and water melon, *Citrullus vulgaris* (Schrad.). The characteristic of melons is the large quantity of water which they contain, while the solid matter consists mainly of dextrose.

Bersch (Landw. Versuchs. Stat. 1896, 46, 473) found the following:—

	Sugar melon		Persican melon		Water melon	
	Whole fruit	Flesh	Whole fruit	Flesh	Whole fruit	Flesh
Water .	92·85	95·15	93·87	95·90	93·44	93·69
Dry matter	7·15	4·85	6·13	4·10	6·56	6·31

The dry matter contained—

		Protein	Fat	Dextrose	Other N-free extract	Crude fibre	Ash
Sugar melon	Whole	22·25	6·73	36·32	12·97	14·90	6·84
	Flesh	13·39	1·69	70·63	0·29	6·90	7·09
Persican melon	Whole	20·71	13·14	30·18	4·49	21·50	9·94
	Flesh	11·80	1·85	65·85	3·44	8·44	8·62
Water melon	Whole	13·74	6·89	37·36	21·74	15·41	4·86
	Flesh	9·73	1·06	66·73	16·95	1·95	3·58

The seeds of melons contain much oil (30–40 p.c.).

For analyses of the pulp of several varieties of melon, *v.* Saco (Compt. rend. 94, 1126); also Jaffa (Rep. Agric. Expt. Stat. California, 1894–95, 155).

The ash of water melon is rich in potash and iron (Payne, J. Amer. Chem. Soc. 1896, 18, 1061). H. I.

MELTING-POINT. A knowledge of the melting-point of a substance, *i.e.* the temperature of its transition from the solid to the liquid state, is of importance for many reasons. Thus the melting-point of an *organic compound* affords a criterion of purity and constitutes a means of identification, and is of service in elucidating relations in chemical constitution.

Melting-points of *alloys* yield evidence of the existence of eutectics and compounds formed from the constituent metals.

Melting-points of *hydrates* may be used to determine their degree of hydration (Roozeboom, Zeitsch. physikal. Chem. 1893, 10, 477; Lidbury, *ibid.* 1902, 39, 453).

Melting-points of *silicates* serve to indicate the formation of double and complex silicates, and the dissociation of complex silicates into simpler molecules.

Melting-points of *pure substances* provide standards in calibrating thermometric apparatus.

Occasionally, on heating under ordinary conditions, sublimation occurs without melting, as in the cases of iodine and fumaric acid, when the usual methods are not applicable. But, generally speaking, every pure substance exhibits a definite melting-point, sharp and well-defined, and identical with its solidifying point. The slightest impurities, however, such as traces of moisture, frequently lower the melting-point considerably, although it may be still apparently sharp; whilst if foreign substances are present in larger quantity, it is no longer well-defined, nor coincident with the solidifying point. It has been observed (Rohland, Chem. Zentr. 1906, i. 1401) that in some instances addition of impurities may raise instead of lower the melting-point. Pure aluminium melts at a lower temperature than the impure metal, and alumina raises the melting-point of pure kaolin.

Within the ordinary limits, change of atmospheric pressure has no sensible effect upon the melting-point, but at high pressures the effects may be very considerable, *cf.* Demerliac (Compt. rend. 1897, 124, 75); Hulett (Zeitsch. physikal. Chem. 1899, 28, 629); Tammann (Ann. Chim. Phys. 1899, [ii.] 68, 553, 629). The melting-point of benzene, for example, varies from 5·4° to 36·5° with pressures ranging from 1 to 1200 kilos. per sq. cm.

For theoretical relationships, *see* Thomson (Phil. Mag. [iii.] 37, 123), Negreanu (Chem. Zentr. 1906, i. 116).

Pawloff (Zeitsch. physikal. Chem. 1908, 65, 1; 1909, 65, 545) finds that even with a pure substance, the melting-point is affected by the state of subdivision, that is, it is dependent on the surface energy, and he deduces an equation expressing the relation between the melting-point of a substance and the radius of its granules. Experiments with salol showed that particles of less than 2μ diameter melt 1·1° lower than those of 40μ.

He considers that the lowest attainable temperature in the region of fusion is determined by the melting-point of the crystalline germ of maximum surface, and that larger solid particles above this temperature are super-heated. Similarly the super-cooling of liquids is a general phenomenon, a liquid super-cooled to a definite extent being in equilibrium with solid particles of a definite size, larger particles causing crystallisation and smaller particles dissolving, and the limit of super-cooling is that temperature below which the crystalline germ can arise of itself in the interior of the liquid.

Apart from the foregoing considerations, the manipulative details concerned in the actual determination of a melting-point, particularly by the capillary tube method, *v. infra*, affect the result. This is due partly to unequal heating of the thermometer stem, which may be corrected by adding the value $n(\mathrm{T}-t)\times 0{\cdot}000143$ to the observed point of fusion (n=length of mercury column in degrees outside the bath, T=observed temperature, and t=temperature registered in the middle of the projecting portion of the column), or avoided by using a short-stemmed thermometer (see Fig. 1). Irregular and too rapid heating is also found to affect the value. Schuyten (Chem. Zentr. 1901, ii. 1326) adduces instances of the variations which may be obtained under different conditions of experiment.

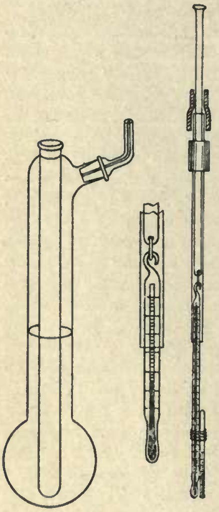

FIG. 1.

The fusion of a solid substance is accompanied by an absorption of heat ('latent heat of fusion'), the temperature remaining constant till all the solid has melted. This provides the most accurate means of determination (Landolt, Zeitsch. physikal. Chem. 1889, 4, 349), the thermometer, or thermo-element with galvanometer attachment, being immersed in the molten substance, and the temperature of the slowly cooling liquid noted at short intervals, the resulting curve indicating the stationary temperature. This method is suitable for all ranges of temperature and for all substances giving a definite melting-point, but requires the use of large quantities of material. In the case of organic compounds, a small quantity of the finely pulverised substance is introduced into a capillary tube closed at one end, and attached to a thermometer, close to the bulb, usually by a thin platinum wire or indiarubber ring, or by adhesion through a drop of sulphuric acid. Weyl (Chem. Zeit. 1910, 34, 488) uses a thermometer slightly expanded just above the bulb, supporting a glass ring carrying glass hooks upon which the tubes are hung in position close to the bulb. Other methods of attachment are described by Lenz (Chem. Zentr. 1906, i. 169); Landsiedl (Chem. Zeit. 1905, 29, 765).

The heating bath may be of glycerol, paraffin, or sulphuric acid, the last-named substance being most generally used. It is contained in a small beaker or long-necked flask, the thermometer and tube being either immersed in the liquid or enclosed in a tube dipping into the liquid.

A form of laboratory apparatus is shown in Fig. 2, unequal heating being avoided, as far as possible, by stirring with a glass stirrer passing through the cork holding the thermometer, or by heating very slowly with a small flame. For temperatures at which the escape of sulphuric acid fumes becomes unpleasant, the flask is provided with a side tubulure (Roth, Ber. 19, 1970), as shown in Fig. 1. Alternative apparatus for condensing the fumes are described by Houben (Chem. Zeit. 1900, 24, 538) and Matton (Zeitsch. angew. Chem. 1910, 23, 557).

A mixture of three parts potassium sulphate with seven of sulphuric acid, sp.gr. 1·84, boiled together for five minutes, may be used for temperatures up to 325°. From 360° to 600°, fused zinc chloride gives satisfactory results (Scudder, J. Amer. Chem. Soc. 1903, 25, 161).

Thiele (Ber. 1907, 40, 996) has devised a simple and effective apparatus, consisting of a glass tube 2 cm. diameter and 12 cm. long, with a bent tube of 1 cm. diameter sealed in as shown in Fig. 3. Sufficient sulphuric acid is poured in to cover the upper opening of the bend, and the lower bend is heated by a small flame which causes an even circulation of the acid.

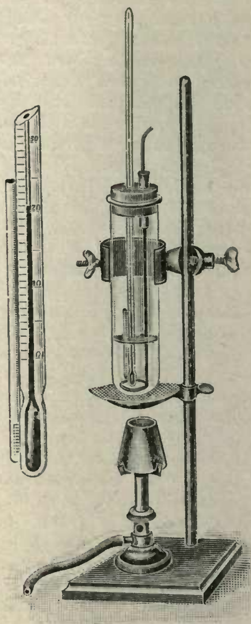

FIG. 2.

If the material is transparent, or becomes so before the melting-point is reached, observation of the exact point at which it liquefies is difficult, and Piccard (Ber. 8, 687) has proposed the apparatus shown in Fig. 4, in which the wide tube (*b*) is sealed after a small quantity of the substance has been melted and allowed to solidify in the capillary bend. On fusion the air pressure in *b* forces the liquid forward. The melting-points of coloured substances are conveniently obtained in this way (Baither, Ber. 1887, 20, 3290). The values are, however, slightly too high.

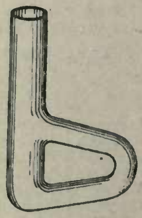

FIG. 3.

As modified by Potilitzin (Chem. Zentr. 1893, i. 379) for the melting-points of salts, the apparatus consists of a glass tube, 5 mm. wide and 50 cm. long, drawn out to a capillary at one end, the other being bent first at right angles, and then in the shape of a U to form an open manometer. The capillary is sealed with the molten salt and immersed in the bath. When the salt melts, the mercury sinks in the open end of the manometer. The method is employed to advantage where a non-transparent heating bath is used.

For organic compounds which decompose at or near the melting-point, Maquenne (Bull. Soc. chim. 1904, 31, 471) advocates the use of a metal block, rapidly heated, upon which the substance is thrown in small portions (0·1 m.g.)

at a time, till the point is reached at which the substance melts instantaneously. *See* also Michael (Ber. 1895, 28, 1629).

Fatty acids, waxes, and similar bodies are not easily introduced into capillary tubes, and in such cases Kuhara and Chikashigé (Chem. News, 1899, 80, 270) place a thin layer of the substance between microscope cover glasses suspended in a platinum foil support in a test-tube placed in the sulphuric acid bath. A modified method is described by Bunker (Pharm. J. 1909, [iv.] 28).

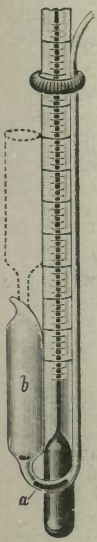

Fig. 4.

Air baths, which may be used at high temperatures instead of liquid baths, are described by Anschütz and Schultz (Ber. 1877, 10, 1800) and Kutscher and Otori (Zeitsch. physiol. Chem. 1904, 42, 193).

For a comparison of the different methods of procedure in the case of minute quantities of material, see Reinhardt (Zeitsch. anal. Chem. 25, 11).

The air thermometer has been adapted for use at extreme temperatures (Haase, Ber. 1893, 26, 1052; Meyer, Riddle, and Lamb, *ibid.* 1894, 27, 3129) but is less convenient than the thermo-element, for the application of which consult McCrae (Ann. Phys. Chem. 1895, [2] 55, 95); Carrara and Coppadoro (Gazz. chim. ital. 1903, 33, 1, 329); Guttmann (Chem. Soc. Trans. 1905, 87, 1037).

Stolzenberg (Ber. 1909, 42, 4322) has described two ingenious forms of apparatus for temperatures up to 350° and down to −60° respectively, which are similar in principle to that of Thiele, but the circulation is brought about not only by heating or cooling a spiral side tube, but also by bubbling dry carbon dioxide through it. For high temperatures, paraffin is used, and for low temperatures alcohol, the spiral being cooled in a Dewar flask with ether and solid carbon dioxide.

Slightly modified, it provides an accurate means of determining solubilities and (Chem. Zeit. 1910, 34, 66; Zeitsch. physikal. Chem. 1910, 71, 649) of measuring temperatures down to −140°, and is recommended as a low-temperature bath in physico-chemical laboratories. For further particulars and diagrams of apparatus, the original papers should be consulted.

A number of electrical methods have been devised, depending upon the completion of a circuit when the insulating coating of a substance on a platinum wire dipped in mercury melts (Löwe, Zeitsch. anal. Chem. 11, 211; Thierry, Arch. Sci. Phys. Nat. 1905, [iv.] 20, 59; or the breaking of a circuit when a wire connection in the case of metals (Loebe, Zeitsch. Elektrochem. 1907, 13, 592; Shukoff and Kurbatoff, J. Russ. Phys. Chem. Soc. 1907, 39, 1546; Jacquerod and Perrot, Arch. Sci. Phys. Nat. 1905, [iv.] 20, 28), or a bead connection in the case of borax and other glasses (Burgess and Holt, Proc. Roy. Soc. 1904, 74, 285) is broken on fusion, the temperature being ascertained by a thermo-element.

Burgess (Bureau Stand. Washington, 1907, 3, 345) describes an adaptation of the optical pyrometer to the determination of the melting-points of metals.

The melting-points of silicates are determined by Doelter by placing the finely powdered substance upon a small quartz plate heated in an electric resistance furnace, and observing with a microscope as the temperature is slowly raised (Zeitsch. Elektrochem. 1906, 12, 617).

A general account of melting-point methods at high temperatures is given by White (Amer. J. Sci. 1909, [iv.] 28, 453).

MENDIPITE. A lead oxychloride $PbCl_2{\cdot}2PbO$ found near Churchill on the Mendip Hills in Somersetshire. Crystallises in yellowish white rhombic prisms; perfect prismatic cleavage; adamantine lustre, sp.gr. 7·1.

MENHADEN OIL is obtained from the body oil of the 'Menhaden fish' *Alosa menhaden*, Cuv. (*Brevoortia tyrannus*), a fish somewhat larger than a herring. From about May until November this fish appears in enormous quantities off the Atlantic coast of America (especially of New Jersey), so that as much as 400,000 tons of fish are caught in one season.

The fish are delivered from the steamers by means of elevators, on to automatic conveyors, from which they are passed over automatic scales into large boiling pans. These are provided with false bottoms, below which open steam coils are fixed. On boiling the contents of the pan, the fish are disintegrated and the oil separates easily from the flesh. After turning off the steam and allowing the mass to rest, the oil rises to the top and can be easily skimmed off by means of swivel skimmers.

During the last few years, 'boiling' vessels have been introduced which permit of continuous working, the fish being passed on conveyors through the boilers continuously, whilst open steam acts on the fish. The time required for the fish to pass lasts from 15 to 20 minutes. The whole mass is then transported by screw conveyors into settling tanks, where the oil separates by gravitation. In either process, the 'fish scrap' falls to the bottom of the vessels, and is then pressed in hydraulic presses, similar to those used in the working up of 'tankage,' when a further quantity of oil, inferior in colour, is obtained. In some works, such pressed cake —termed 'chum'—is boiled out with hot water and pressed once more; but this process being unremunerative, except when the oil is very high in price, is not carried out in large works. The scrap is finally dried in continuous dryers, of which various types are in use (Anderson dryer, Cummer dryer, vacuum dryers), and is sold as a valuable manure. In fact, the 'scrap' was formerly considered as the main product, and it is owing to the demand for scrap that the fish oil industry has assumed such large dimensions. As the fish contain only from 1 to 16 p.c. of oil —rarely more—processes for its recovery from the scrap by means of solvents are most unlikely to prove remunerative, considering the enormous quantities of fish that must be dealt with.

With the extension of the industry, new uses have been found for the oil, which now not only ranks equal in value to the scrap, but has acquired a much higher price, especially at times when the price of linseed oil is very high.

The colour of menhaden oil varies in the first instance with the state of freshness in which the fish arrives, and in the second instance with the duration of the boiling process. The longer the oil has been allowed to remain in contact with the putrescible mass and the longer the fish has been boiled and hence the longer the oil has been in contact with the gluey water, the darker is its colour. Therefore, the separation of the oil from the gluey water is carried out as rapidly as possible. Fresh fish yield a light-coloured oil; the oil running from the 'scrap' in the presses is the darkest in colour.

In commerce the following three qualities are known: 'Prime crude,' 'Brown strained,' and 'Light strained oil.' Frequently the oils are differentiated into four grades—A, B, C, and D; A being extra pale, B pale, C brown, and D dark brown oil. Since the menhaden oil industry has extended along the Atlantic coast even down to Texas, the trade differentiates also between *northern menhaden oil* and *southern menhaden oil.* The process of refining consists mainly in brightening the oil by filtering, &c.

The light-coloured oils are allowed to rest some time in the cold, whereby 'stearine' separates; thus the 'winter oils' are obtained. They are then bleached by filtering over fuller's earth, &c.; in this manner two grades are obtained, viz. 'bleached winter white' and 'bleached winter' oils.

The sp.gr. of menhaden oil is 0·930 to 0·935. Freshly prepared menhaden oil has an iodine value reaching as high as 200 (Lewkowitsch). Most of the analytical data contained in textbooks must be corrected, especially as regards the iodine value, as those samples, the iodine values of which had been recorded, refer to oils which have undergone considerable oxidation on standing. Menhaden oil contains considerable amounts of clupanodonic acid. Thus the author obtained from specimens of pure menhaden oil as high a yield as 40 p.c. of clupanodonic octobromide.

The unsaponifiable matter consists chiefly of cholesterol, to the presence of which the slight optical activity of menhaden oil is due.

The principal use of menhaden oil is in the currying trade, and in the manufacture of sod oil. The oil is also employed in soap-making and for the tempering of steel. When linseed oil is high in price, menhaden oil is used to a considerable extent to adulterate linseed oil (to the detriment of the quality of the product) and further as a substitute thereof in the manufacture of varnishes, paint oils, and even linoleum. Menhaden oil is also used for adulterating Newfoundland cod-liver oil.

MENTHANTHONES *v.* KETONES.

MENTHENE *v.* CAMPHORS, TERPENES.

MENTHOL *v.* CAMPHORS.

MENTHONE *v.* CAMPHORS.

MERCAPTANS (*sulphhydrates, thioalcohols*) are a group of substances derived from sulphuretted hydrogen in the same way as alcohol from water by the replacement of one hydrogen atom by an alkyl group. The mercaptans differ from alcohol in the same way that sulphuretted hydrogen differs from water; thus they have considerably lower boiling-points than the corresponding alcohols. They also possess one hydrogen atom replaceable by metal, but they are more acidic than the alcohols and form mercaptides of the heavy metals. The mercaptans were discovered by Zeise in 1833 (Annalen, 11, 2), and the name is derived from 'mercurio aptum,' owing to the formation of a characteristic mercury salt by the action of ethyl mercaptan on mercury oxide.

Formation.—General methods:

(1) By warming alkyl halides with potassium hydrogen sulphides in concentrated alcoholic solution.

$$R\boxed{X+K}SH=R{\cdot}SH+KX$$

(where R=alkyl, X=halogen).

(2) By heating alcohols or phenols with phosphorus pentasulphide

$$5ROH+P_2S_5=5R.SH+P_2O_5.$$

(3) By distilling a solution of potassium alkyl sulphate with potassium hydrogen sulphide.

$$R\boxed{OSO_3K+K}SH=R{\cdot}SH+K_2SO_4.$$

They are also formed in the reduction of thiocyanic esters, $CNS{\cdot}R+2H=HCN+HSR$.

Aromatic mercaptans can be obtained by acting on the diazo-aromatic compounds with potassium ethyl xanthate and decomposing the compound thus formed with caustic alkali (Lenhart, J. pr. Chem. [ii.] 41, 179; Bourgeois, Rec. trav. chim. 1899, 18, 426); by the reduction of the chloride of the sulphonic acid derivative, and by the electrolytic reduction of the thiochlorides or their nitro derivatives in sulphuric acid solution using lead electrodes and keeping the anode liquid at 20° (Fichter and Bernouilli, Ber. 1909, 42, 4308).

Mercaptans of the anthracene series are obtained by heating together the halogenated anthraquinones and the alkali sulphides or hydrosulphides (D. R. P. 204772, 208640; Frdl. 1908–10, 20).

Mercaptans of the anthraquinone series are obtained in the following manner: 10 kilos. of anthraquinone-α-thiocyanate are made into a paste with 20 litres of alcohol and boiled under a reflux condenser with 60 litres of a 10 p.c. sodium hydroxide solution until the product forms a clear cherry red solution in water. Hot water is now added until the whole product is dissolved and after filtration, the mercaptan is precipitated by addition of hydrochloric acid containing a little sulphurous acid (D. R. P. 208640, 1907; 212857, 1909; J. Soc. Chem. Ind. 1909, 469).

Mercaptans yielding dyes with diazo compounds can be obtained by heating sodium naphthalene-β-sulphonate and a 50 p.c. solution of potassium hydrosulphide for 3 hours at 200°–220° under a pressure of 10–12 atmospheres in an iron vessel. The product is then treated with dilute hydrochloric acid and extracted with ether. The disulphide which remains undissolved can also be converted into the mercaptan by heating with potassium hydrosulphide and alcohol. When benzene sulphonic acid and *m*-disulphonic acid are similarly treated, coloured products having the odour of mercaptans are formed (Schwalbe, Ber. 1906, 39, 3102).

Properties.—The mercaptans are mostly liquids insoluble in water, soluble in alkalis and, particularly the lower, more volatile ones, have a very characteristic disagreeable odour, their smell being indeed a far more delicate test than any of their chemical reactions. Like hydrogen sulphide they are readily oxidised by oxidising agents and even by air, forming disulphides $2R{\cdot}SH+O=RS{\cdot}SR+H_2O$. When oxidised with nitric acid they form sulphonic acids

$$R{\cdot}SH+O_3=RSO_3H.$$

Mercaptans condense with nitriles thus:

$$RSH+R'CN=NH:CR'{\cdot}SR$$

Thus by the action of ethylene cyanide on ethylene sulphhydrate, *succiniminodithioethylene ether* $(CH_2C(NH){\cdot}S{\cdot}CH_2)_2$ is formed, the hydrochloride of which is an amorphous dark green powder soluble in water; the solution dyes wool and silk a bright green, fast to light but turning yellow (owing to the liberation of the free base) when treated with alkalis (Autenrieth and Brüning, Ber. 1903, 36, 3464).

The alkyl mercaptans and their derivatives react in general with acid chlorides to form esters of the corresponding thio acids thus:

$$3RSH+PCl_3=P(SR)_3+3HCl$$

or $(COCl)_2+Pb(SC_6H_5)_2=(CO{\cdot}S{\cdot}C_6H_5)_2+PbCl_2$. The final products of the reaction, however, depend on the stability of the ester formed, or, if it is unstable, on the manner of its decomposition. When treated with hot potassium hydroxide solution, the stable esters are converted into the mercaptide, whilst with alcoholic potassium hydrosulphide they yield potassium thio salts (Jones and Tasker, Chem. Soc. Trans. 1909, 1904).

With sulphuryl chlorides, the mercaptans react thus:

$$8RSH+4SOCl_2=8HCl+2SO_2+3(R{\cdot}S)_2+R_2S_4$$

and $4RSH+SOCl_2=(R{\cdot}S)_2+R_2S_3+H_2O+2HCl$ which reaction preponderates depending on the conditions of the experiment (Jones and Tasker, *l.c.* 1910). The reaction of mercaptans with nitrosyl chloride and with thionylaniline is similar to that with sulphuryl chloride. When nitrosyl chloride is added to a mercaptan, the latter absorbs it, forming a rich cherry-red coloured solution which rapidly evolves nitric oxide and finally loses its colour. In a freezing mixture of solid carbon dioxide in ether, however, hydroxylamine hydrochloride is formed (Jones and Tasker, *l.c.*; Holmberg, Ber. 1910, 43, 226).

Mercaptans combine with aldehydes in the presence of hydrogen chloride, forming *mercaptals*, $R{\cdot}CH\boxed{O+2H}SR'=R{\cdot}CH(SR')_2$ (Baumann, Ber. 1885, 18, 883; Blanksma, Rec. trav. chim. 1901, 20, 399). They are insoluble in water, stable in the cold but readily decomposed on warming.

Mercaptans combine with certain sugars in cooled hydrochloric acid solution, forming mercaptals (Fischer, Ber. 1894, 27, 673).

Glucose ethyl mercaptal $C_6H_{12}O_5(SEt)_2$ forms slender colourless needles or thin plates, m.p. 127°–128°, α_D $-29{\cdot}8°$ at 50°. It has a bitter taste and decomposes on distillation, yielding a product with an odour of roasted onions. A number of other similar mercaptals are described by Fischer.

Similarly, the mercaptans condense with ketones, forming *mercaptoles*

$$R_2C\boxed{O+2H}SR'=R_2C{\cdot}(SR')_2+H_2O$$

(Baumann, *l.c.*; Posner and Fahrenhorst, Ber. 1899, 32, 2749; Blanksma, *l.c.*), and the latter, on oxidation, yield disulphones.

The nature and stability of the mercaptoles and disulphones formed by the interaction of ketonic esters and the mercaptans depend both on the nature of the ester and of the mercaptan (Posner, Ber. 1901, 34, 2643).

α-, β-, or γ-Diketones containing both carbonyl groups attached to methyl radicles, readily react with four molecules of a mercaptan yielding dimercaptoles which on oxidation yield tetrasulphones. If, however, one of the carbonyl groups of the diketones is attached to a substituted methyl group, the ketone reacts with only two molecules of a mercaptan forming a ketomercaptol which on oxidation gives a keto-disulphone. A number of these products are described by Posner (Ber. 1900, 33, 2983).

In the presence of hydrochloric acid, the mercaptans react with unsaturated ketones, forming both addition and condensation products (Posner, Ber. 1902, 35, 799; 1904, 37, 502; *see* also Fasbender, Ber. 20, 460); but if piperidine or sodium ethoxide is employed as catalytic agent instead of hydrogen chloride, only additive products are obtained (Ruhemann, Chem. Soc. Trans. 1905, 17, 461; Proc. Roy. Soc. 1904, 251). The number of mercaptan groups uniting with a diolefinic ketone also depends on the nature of the catalytic agent. The mercaptans also combine with many unsaturated hydrocarbons and acids (Posner, Ber. 1905, 38, 646; *ibid.* 1907, 40, 4788).

According to Stadler (Ber. 1884, 17, 2075), the mercaptans of the aliphatic series react with diazo compounds yielding explosive substances.

Ethyl mercaptan (mercaptan), produced technically by the interaction of ethyl chloride and potassium hydrogen sulphide, is a sparingly soluble liquid with a very disagreeable smell, b.p. 36·2°, sp.gr. 0·83907 at 20°/4° (*v. Ethyl sulphydrate*, art. ETHYL). It combines with acetone, forming dimethyl diethyl mercaptole, which when oxidised with potassium permanganate yields diethyl sulphomethyl methane (acetonediethyl sulphone) $Me_2C(SO_2Et)_2$. The latter crystallises in colourless prisms, m.p. 126°, is sparingly soluble in water and is employed in medicine, under the name 'sulphonal,' as a soporific. Trional $MeEtC(SO_2Et)_2$, m.p. 75°, and tetronal $Et_2C(SO_2Et)_2$, m.p. 85°, are prepared similarly and are also used in medicine (*v.* TETRONAL AND TRIONAL).

Ethyl mercaptan has no action on anthraquinone or phenanthraquinone, but it reacts with quinone forming quinol, quinhydrone, and thioaldehyde and under certain conditions it forms a red crystalline compound in which two hydrogens in the quinone nucleus are substituted by SEt groups (Tarbouriech, Bull. Soc. chim. 1901, [iii.] 25, 313; Sammis, J. Amer. Chem. Soc. 1905, 27, 1120).

Ethyl mercaptophthalimide

$$C_6H_4\left\langle\begin{matrix}CO\\CO\end{matrix}\right\rangle N(CH_2)_2SH$$

becomes plastic at 76° and melts at 79°–80°. When boiled with 20 p.c. hydrochloric acid it yields phthalic acid and aminomercaptan hydrochloride $NH_2C_2H_4SH,HCl$ (Gabriel, Ber. 1891, 24, 1110, 3098).

Phenyl mercaptan has b.p. 169·5°; *p-tolyl* *mercaptan*, b.p. 195°; *m-tolyl mercaptan*, b.p. 195·5°; and *β-naphthyl mercaptan*, b.p. 288° (Bourgeois, *l.c.*; Autenrieth and Geyer, Ber. 1908, 41, 4256).

p-Tolylaminoanthraquinone mercaptan

$$C_7H_7NHC_{14}H_6O_2SH$$

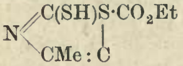
forms dark blue needles and yields on sulphonation a violet wool dye (D. R. P. 206536, 1909).

Anhydroformaldehyde dimethyl-p-phenylenediamine mercaptan (*5-dimethylamino-2-methyleneaminophenyl mercaptan*) $SHC_6H_3(NMe_2)N:CH_2$ is formed by treating *as*-dimethyl-*p*-phenylenediamine thiosulphonic acid dissolved in aqueous ammonia, with formaldehyde and hydrochloric acid. It rapidly polymerises and is isolated as the ferrocyanide $3C_9H_{12}N_2S,2H_4Fe(CN)_6,5H_2O$. When the freshly prepared mercaptan is treated with sodium nitrite and hydrochloric acid it yields 5-dimethylaminobenzthiazole

m.p. 73°-74° (Schmidt, Ber. 1906, 39, 2406).

Mercaptothiazoles are prepared by the condensation of α-halogenated ketones with ammonium dithiocarbamate (Miolati, Gazz. chim. ital. 23, i. 575).

Ethyl methyl mercaptothiazolecarboxylate

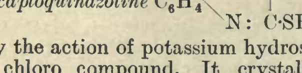


melts at 141°, and is soluble in alcohol and ether but not in water; the free acid has m.p. 211°-212°.

Methylmercaptothiazole melts at 89°-90° and is soluble in organic solvents. *Phenyl mercaptothiazole* melts at 168°.

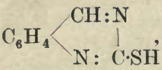
For a number of mercaptothiazoline derivatives, see Hirsch (Ber. 23, 964); Kahan (*ibid.* 1897, 30, 1318); Gabriel and Leupold (*ibid.* 1898, 31, 2837); Jänecke (*ibid.* 1899, 32, 1103); Straus (*ibid.* 1900, 33, 2830).

Mercaptogalactoxazoline



m.p. 185°-186°, is formed by heating galactamine with carbon disulphide. Like the corresponding dextrose derivative it gives a crystalline compound with silver nitrate (Roux, Compt. rend. 1902, 135, 691).

2-*Mecaptoquinazoline*



, is prepared by the action of potassium hydrosulphide on the chloro compound. It crystallises in hexagonal plates, sinters at 225° and melts at 229°-231° (Gabriel, Ber. 1903, 36, 800). Mercapto oxazoline derivatives are described by Maquenne and Roux (Compt. rend. 1902, 134, 1589).

Many other mercaptan derivatives have been prepared (Baumann, Ber. 1885, 18, 891; Jacobson, *ibid.* 1887, 20, 1895; *ibid.* 1888, 21 2624; Klason, *ibid.* 20, 3409; *ibid.* 28, ref. 942; Freund, *ibid.* 1896, 29, 2483; Brjuchonenko, J. pr. Chem. [ii.] 59, 46, 596; Eibner, Ber. 1901, 34, 657; Freund and Bamberg, *ibid.* 1902, 35, 1753; Posner, *ibid.* 799; de Jong, Rec. trav. chim. 1902, 21, 295; Autenrieth and Geyer, Ber. 1908, 41, 4249, 4256).

Mercaptides are formed by the action of the metal on the mercaptan (as in the case of the alkali salts) or by the interaction of an alcoholic solution of the mercaptan with the oxide or acetate of the metal.

Many such crystalline compounds are known. They are mostly decomposed by mineral acids, with liberation of the mercaptan, and react with alkyl halides forming thio ethers, thus:

$$RS|Na+I|R'=R\cdot S\cdot R'$$

(Otto, J. pr. Chem. 1895, [ii.] 51 285). With ethyl α-chloroacetoacetate they yield alkyl sulphide and ethyl diacetyl succinate:

$$2RSNa+2CMeO\cdot CHCl\cdot CO_2Et$$
$$=2NaCl+R_2S_2+(CHAc\cdot CO_2Et)_2$$

(Finger and Hemmeter, J. pr. Chem. 1909, 79, 449). The mercaptides react with mustard oils, forming dithiourethanes:

$$RNCS+R'SNa$$
$$=R\cdot N:CSNa\cdot SR' \xrightarrow{HCl} NaCl+RNH\cdot CS\cdot SR',$$

and this is suggested by Roschdestvensky as a good method of identifying the mercaptans (J. Russ. Phys. Chem. Soc. 1909, 41, 1438).

Mercury mercaptide $(EtS)_2Hg$ crystallises in white leaflets. With mercuric chloride, however, ethyl mercaptan forms a sparingly soluble double salt, EtS·HgCl. Similar iodide and bromide compounds are also known.

Mercapturic acids are hydroxycarboxylic acids in which the hydroxyl group is replaced by an SH group (Carius, Annalen 124, 43; Claesson, Ber. 1877, 1346; Friedmann, Beitr. Chem. Physiol. Path. 1903, 4, 486).

Mercaptal acids are obtained by the condensation of aldehydes with thiol acids (Holmberg and Mattisson, Annalen, 1907, 353, 123).

Selenium and tellurium form compounds corresponding with the mercaptans and having a similar offensive smell.

MERCERISING. Mercerising or 'lustreing' consists in impregnating cotton fibres with concentrated caustic soda lye, either with or without the application of tension, and in stretching the material before and during the removal of the soda by means of washing.

John Mercer noticed in 1844 that cotton fabrics, when immersed in concentrated soda lye, became transparent and that a considerable swelling and shrinkage of the fibres occurred. He also found that the soda could be readily removed by washing with water and that the fibres afterwards again became opaque and exhibited increased affinity for a number of dyestuffs. The fact that concentrated caustic soda lye causes the cotton fibre to contract seems, however, to have been known in France at the time when Mercer made his discovery (J. Hübner, J. Soc. Dyers and Col. 1911, 27). The treatment briefly described above was patented by Mercer in 1850. About the same time, he applied his discovery to the 'crimping' of cotton fabrics, by printing stripes upon the fabric with thickened concentrated caustic soda lye, with the result that the portions printed upon became contracted, whilst the parts which had not been acted upon by the soda became drawn together or 'crimped.'

It has been suggested that 'hydrated cellulose' is the result of mercerisation, but although mercerised cellulose contains more water in the air-dry condition than ordinary cellulose, C. G.

Schwalbe (Zeitsch. angew. Chem. 20, 2172, 1907) and H. Ost and F. Westhoff (Chem. Zeit. 33, 197, 1907) state that they have not been able to prove that mercerised cellulose contains chemically combined water. It should also be pointed out that the excess of water contained in mercerised cotton can be readily removed by drying (J. F. Copley, J. Soc. Dyers and Col. 24 72); by the application of heavy pressure after mercerising, whilst the material is still in the wet state (J. Hübner, Eng. Pat. 12455); by extraction with absolute alcohol (J. Hübner and F. Teltscher, J. Soc. Chem. Ind. 1909, 28, 641) and by drying at ordinary temperature over calcium chloride or phosphorus pentoxide.

In 1889, H. A. Lowe observed that if a cotton fabric is prevented from contracting during treatment with concentrated caustic soda lye and subsequent washing it acquires a silk-like lustre (Eng. Pat. 20314). Lowe allowed his patent rights to lapse and in 1895 Thomas and Prevost patented the same process in Germany (Ger. Pat. 85564). This patent was, however, ultimately annulled. Mercer had already noticed that effects, similar to those obtained by caustic soda, could be produced by the application of sulphuric acid, phosphoric acid, and zinc chloride.

Soon after the publication of Thomas and Prevost's patent, a large number of patents of doubtful value were taken out in order to protect the application of various mercerising agents. The fact that a superior lustre could be obtained on the long-stapled Sea Island and Egyptian cottons was also made the subject of a patent (*see* Gardner, Die Mercerisation der Baumwolle).

Knecht (J. Soc. Dyers and Col. 1896, 12, 89) found that cotton could be mercerised by treating it with nitric acid of 83° to 84°Tw., and J. Hübner and W. J. Pope (J. Soc. Chem. Ind. 1903, 22, 70) discovered that saturated solutions of iodides produce a similar effect. A saturated solution of barium-mercuric iodide produces practically the same degree of shrinkage and increased affinity for dyestuffs as concentrated caustic soda lye.

Mercer pointed out that soda lye of as low a strength as 20°Tw., produces a distinct effect on the cotton fibre, and it had been commonly accepted that lyes below this strength exerted practically no action on the fibres. Hübner and Pope (J. Soc. Chem. Ind. 1904, 23, 404), however, found that a lye of only 1°Tw. concentration appreciably increases the affinity of the cotton fibre for the substantive dyestuffs and produces a certain degree of shrinkage. They also showed that the degree of shrinkage is not directly proportionate to the concentration of the lye used, and that maximum shrinkage is produced by a soda lye of about 45°Tw., whilst the shrinkage again decreases if the strength of the lye is increased above 45°Tw.

This supplied an explanation of the fact that cotton yarn and cloth, after treatment under tension with soda lye of 60° to 70°Tw., are frequently torn on the mercerising machine during the first stages of washing.

It had been generally assumed that a mercerising agent, in order to produce lustre on the fibre, must exert a shrinkage and swelling action. Hübner and Pope (*l.c.*) observed that the agent must also be capable of untwisting the naturally twisted cotton fibre.

This, coupled with the fact that single cotton fibres (Fig. 1) are twisted in parts to the right and in parts to the left, several changes in the direction of the twist being noticeable in a single fibre, affords a rational explanation of the production of lustre in mercerising. As a result of the untwisting of these different twists during mercerisation under tension, during which operation the fibres are firmly held by the twist of the yarn, the original ribbon-like twisted fibre becomes converted into a straight rod, of nearly circular cross-section, which carries on its surface smooth elevations in the shape of rounded ridges, which reflect the light falling on them from any direction (Fig. 2). Maximum lustre can, therefore, only be obtained if the mercerising agent is capable of producing shrinking, swelling, and untwisting of the fibres in a high degree. Waterglass, glycerol, common salt, if added to the caustic soda lye used in mercerising, diminish the extent of the swelling and the shrinking of the fibres, the lustre obtained is, therefore, inferior to that produced by caustic soda alone. Sodium sulphide, nitric acid, and hydrochloric acid, which cause untwisting of the fibre, accompanied, however, with but little shrinking and swelling, give still less lustre, whilst barium-mercuric iodide, which produces maximum swelling and shrinking but no untwisting, produces practically no lustre.

Fig. 1.

Gladstone (Quart. J. Chem. Soc. 1853, 5, 17) suggested that in mercerising a definite chemical compound, ‘soda cellulose’ $(C_6H_{10}O_5)_2NaOH$, is formed, which decomposes readily on treatment with water. J. Hübner and F. Teltscher (J. Soc. Chem. Ind. 1909, 28, 614) have shown that the existence of such a definite compound is very doubtful and that the amount of soda retained by the cellulose after extraction with absolute alcohol is much smaller than that given by Gladstone.

The dyeing properties of mercerised cellulose have been studied by a number of investigators. R. Haller (Zeitsch. Farb. und Textilchemie, 1907, 8, 125) assumes that the soda lye removes the cutinised layer from the fibres, thus exposing pure cellulose, which is capable of absorbing dyestuffs more readily.

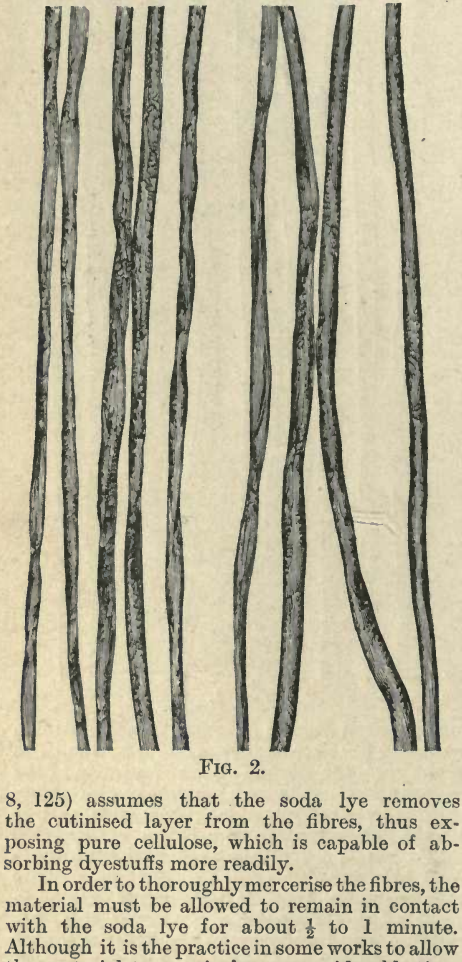


Fig. 2.

In order to thoroughly mercerise the fibres, the material must be allowed to remain in contact with the soda lye for about ½ to 1 minute. Although it is the practice in some works to allow the material to remain for a considerable time after impregnation in contact with the soda lye, and before stretching and washing, the results obtained are in no way superior to those obtained when working continuously.

Uniform results in mercerising can only be obtained if the soda lye used is kept at uniform strength and temperature. Special refrigerating machines are frequently employed for cooling the soda lye.

Doubled yarns, made of long-stapled Sea Island or Egyptian cotton, give the most brilliant results in mercerising, but good results can also be obtained on yarns spun from combed American cottons. Single yarns cannot be successfully mercerised on account of the twist being too weak to resist the shrinking of the fibres. The best results in mercerising cotton fabrics are obtained on face cloths, such as sateens, Italian linings, &c. A considerable change in the structure of the fabric takes place during mercerisation (J. Hübner, J. Soc. Dyers and Col. 1911, 27, 128).

The removal of all loose fibres from the surface of the material by careful singeing leads to an increase of the lustre of the mercerised fabric.

Cotton yarn is usually mercerised after it has been boiled in the kier whilst cotton fabrics are sometimes only scoured before mercerising. More frequently the fabrics are mercerised after the first ‘boil’ in the kier, or in some cases after they have been bleached (‘chemicked’). Cotton in the loose state, as it comes from the bale, cannot be successfully mercerised.

A number of methods have been suggested for mercerising cotton in the state of ‘sliver,’ but none of these methods has, so far, found any extensive practical application.

No satisfactory lustre can be produced by treating cops or ‘cheeses’ (cross-wound spools) with caustic soda lye; but cotton yarn in the hank is very largely and successfully mercerised. Automatically working machines are used for this purpose, in which the yarn is stretched, by subjection to tension, over heavy iron rollers, both during impregnation with the lye and during washing.

Cotton warps can be mercerised in a machine resembling the ordinary warp-dyeing machine. The warp is usually impregnated with the soda lye in the first two compartments, while it is washed free from soda in the other compartments. Provision should be made in order to allow each successive set of squeezing rollers to be run at a slightly higher speed. In some cases, warps are mercerised in a machine resembling the ‘warp slasher.’

Although a great variety of machines have been invented and used for mercerising cotton piece goods, machines in which the fabric after impregnation is stretched on a ‘clip stenter,’ are now chiefly employed. A complete mercerising range consists of a padding mangle, the stenter with washing arrangement and the necessary washing, souring, and washing cisterns. In the padding mangle, the cloth is usually twice impregnated with the caustic soda lye and squeezed after each impregnation between cast iron and indiarubber bowls. The trough containing the lye is often provided with an outer cavity to which ice may be supplied or through which refrigerated brine may be circulated in order to keep the lye at a low and uniform temperature. After impregnation, the cloth passes usually directly on to the stenter in which the edges are seized and held by two endless chains of clips, which travel along each side of the stenter. The end of the stenter at which the cloth enters is tapered and thus the fabric is gradually stretched out to its ‘grey width,’ after which the chains run parallel to the delivery end. While on the stenter the caustic soda is removed by showering hot water on the cloth. The economy of recovery of the caustic being of importance, it is customary, in order to obtain a wash-water containing a high percentage of caustic soda, to conduct the washing on the counter-current principle.

For this purpose three or more sets of spirt pipes are provided, clean hot water being introduced into the first set of pipes, which are placed nearest the delivery end of the machine, whilst the same water is then used successively in the other sets. The cloth is ultimately released from the clips and passed through a number of tanks containing hot water and weak acid and passes finally through a washing machine.

With a view to ensure complete penetration of cotton fabrics when mercerising at a high speed, Mather and Platt have introduced a mercerising plant in which the fabric, after having been impregnated in the mangle, is conducted over a number of iron drums, from which it passes into a second impregnating mangle, before being conducted on to the stentering frame.

Krais has patented an arrangement by means of which the soda lye is forced out of the cloth by blowing steam against it.

In order to enable the soda lye to be used over again, the washwaters are concentrated in multiple-effect evaporators and ultimately treated with caustic lime.

Reactions for the characterisation of mercerised cotton.—Although thoroughly mercerised cotton fibres exhibit very specific microscopic characteristics (see Fig. 2), it is exceedingly difficult in many instances to decide with certainty whether goods have been mercerised or not, because the fibres have frequently only been incompletely penetrated by the soda lye. The following chemical reactions (J. Hübner, J. Soc. Chem. Ind. 1908, 27, 105) may be used in order to ascertain whether cotton has been treated with caustic soda lye.

1. If dark coloured samples have to be tested, it will be necessary to first discharge the colour and to completely remove any starch which may be present. The sample should then be squeezed between filter-paper and immersed for a few seconds in the following solution: 20 grams iodine dissolved in 100 c.c. of a saturated solution of potassium iodide. If a non-mercerised sample is immersed along with a mercerised one and if, after removal from the iodine solution, both samples are washed repeatedly in water, it will be noticed that the non-mercerised cotton becomes white, whilst the mercerised sample remains of a bluish-black colour, which only fades very slowly on prolonged washing.

2. Two solutions are prepared, (*a*) containing 280 grams of zinc chloride in 300 c.c. of water and (*b*) 1 gram of iodine, 20 grams of potassium iodide, 100 c.c. of water. The reagent is prepared by adding about 10 drops of (*b*) to 100 c.c. of (*a*). A mercerised pattern, immersed in this solution for about 20 minutes, turns a dark reddish-blue, whilst non-mercerised cotton remains practically white.

By immersing samples which have been mercerised with known strengths of caustic soda along with the one under examination, it is possible, by comparing the depth of colouration of the samples, to ascertain, with a certain degree of accuracy, the strength of caustic soda which has been employed in the mercerisation.

MERCUROL, MERCURIOL, MERCOCHINOL, MERGOL, MERIODIN *v.* Synthetic drugs.

MERCURY. Quicksilver. (*Mercure*, Fr.; *Quecksilber*, Ger.) Sym. Hg. At.w. 200.

Ores. *Native mercury* occurs as a decomposition product of cinnabar in the upper portions of the deposits of that mineral. The mercury is usually disseminated through the ore in the form of minute globules which sometimes collect in cavities in the rock. In California, native mercury disseminated through serpentine or in detritus has been found near the outcrops at the Sonoma mine, Rattlesnake mine, &c., associated with mere traces of cinnabar. At greater depths the ore is always cinnabar alone (Egleston's Metallurgy of Silver, Gold, and Mercury in the United States, ii. 801).

Native amalgam containing about 70 p.c. of silver is found in crystals belonging to the cubic system at Arqueros, near Coquimbo, at Moschellandsberg in the Rhine provinces and elsewhere. Native calomel (*horn mercury*) HgCl occurs at Idria and Almaden, and selenide, sulphoselenide (*onofrite*), and other compounds of mercury have also been found in small quantities in various localities.

Cinnabar HgS is the only ore which is regularly worked for mercury. It occurs in rhombohedral crystals, but is usually found massive or earthy, intermixed with quartz, sandstone, schists, bituminous substances, iron pyrites, &c. It is distinguished by its red colour and scarlet streak. When intermixed with bituminous substances which give it a dark colour, it is known as hepatic cinnabar. Cinnabar occurs in eruptive rocks and in sedimentary rocks of all ages.

The chief deposits are at Almaden in Spain, at Idria in Carniola, at Monte Amiata in Tuscany, at Nikitowka in South Russia, and at New Almaden, New Idria, and other localities in California. There are also deposits in Mexico, Hungary, and many other countries.

The famous Almaden mines in Spain were known to Theophrastus, 315 B.C., as furnishing cinnabar to the Greeks, and they were afterwards worked by the Romans. The cinnabar permeates or occurs as pockets in thick veins of quartz inclined at a high angle and contained in Silurian slates (Phillips' Ore Deposits, 374). The ore contains bituminous matter and iron pyrites. Native mercury accumulates in the numerous clefts and cavities in the deposit. The richest ore contains about 25 p.c. of mercury, and the mean yield of the ores, worked in 1908, is stated to be 2·5 p.c. (Mineral Industry for 1909, 18, 843).

At Idria the sulphide occurs as a dark-red slaty deposit contained in veins or disseminated in triassic shales and limestones. Some hepatic cinnabar occurs and also *korallenerz* or coral ore, which contains calcium phosphate (Phillips, *l.c.* 329; Lipold, Oesterr. Zeitsch. 1882, 30, 84). The mines were discovered in 1490 and have been in the hands of the Government since 1580. The ore varies in grade from *stahlerz*, containing 75 p.c. mercury, down to ores containing 0·2 p.c., the average being 0·6 p.c. in 1908.

At Monte Amiata, cinnabar occurs as

segregations in Eocene formations. These deposits were exploited by the ancient Etruscans and again in the Middle Ages. The present operations were begun at Siele in 1846. The average amount of quicksilver contained in the ores was 0·8 p.c. in 1908. The output has risen from 173 tons in 1898 to 684 tons in 1908 (Spirek, Zeitsch. prakt. Geol. 1897, 369; Schnabel and Louis' Metallurgy, 2nd ed. ii. 335).

At Nikitowka, the ore consists of sandstone of carboniferous age impregnated with cinnabar. In 1906, the yield of mercury was only 0·28 p.c. and the production fell from 616 tons of mercury in 1897 to 47 tons in 1908. The deposits were worked by the ancient Greeks, and after a lapse of 2000 years operations were begun again in 1886 (Schnabel and Louis, *l.c.*).

In California cinnabar occurs disseminated through a zone of slates, serpentine, sandstones, and limestones of Cretaceous and Tertiary age. Some rich ore occurs, especially where serpentine and sandstone are in contact, but the average yield is now under 0·75 p.c., although it was 36 p.c. in 1850 with a similar output. The deposits were known to the Indians, who used the cinnabar as paint, but the mines were first worked systematically in 1845. The most important mine, that at New Almaden, is now almost exhausted.

Mercury also occurs as a sulphide in ores of other metals. The *mercurial fahlore* (*see* FAHLORE) of Hungary contains up to 17 p.c. of mercury. At Kotterbach this fahlore occurs in spathic iron ores (Schnabel and Louis, *l.c.* ii. 438). According to Bellingrodt (Chem. Zeit. 1886, 10, 1039), zinc blende roasted at Oberhausen contains 0·2 p.c. of mercury which is extracted as a by-product. Zinc ore is also treated for mercury at the Taghit mine, Algeria (Min. Ind. for 1902, 11, 548).

Extraction from ores. There are two methods of extracting mercury from cinnabar suitable for use on a large scale:—

1. By heating cinnabar in air, the action being represented by the equation

$$HgS+O_2=Hg+SO_2.$$

2. By heating cinnabar with lime or iron, air being excluded. The chemical action may be represented by the equations

$$4HgS+4CaO=4Hg+3CaS+CaSO_4$$
$$HgS+Fe=Hg+FeS.$$

In each of these cases, the temperature necessary for the reaction is higher than the boiling-point of mercury, so that the latter is volatilised and has to be condensed. In the air roasting process, the mercurial vapours are mixed with a large volume of sulphur dioxide, nitrogen, carbon dioxide, and other gases, and condensation is difficult. Nevertheless, the roasting process is now generally used, partly owing to the high cost of retorting with lime or iron, which prohibits the use of that method for poor ores, but mainly on account of the injury to the health of the workmen by the concentrated mercury vapour which they inhale when the retorts are emptied.

Some of the difficulties of treating cinnabar by the roasting process are as follows:—

1. The amount of mercury in the ores is small, sometimes only 0·2 or 0·3 p.c., and part of this is obstinately retained by the residues, necessitating long-continued treatment at a red heat.

2. The mercurial vapours readily penetrate the brickwork of the furnace and condensers. This is checked by keeping the pressure of the gases inside the furnace and condensers slightly below the outside atmospheric pressure by means of a fan placed at the outlet. By this device also the workmen are protected from the mercury vapours. The exhaust must not be excessive or the retention of the mercury in the condensers would not be complete. The furnaces are now always covered with iron plates, so that penetration of the masonry by mercury occasions only a temporary loss.

3. Liquid mercury penetrates the furnace bottoms. According to Spirek, over 1000 centners of mercury have been recovered from the foundations of furnaces at Idria. To prevent ultimate loss, furnaces stand on iron plates with upturned edges, draining to a little sump where the mercury may collect.

4. The gases from the furnace are acid, owing to the presence in them of SO_2 and SO_3. The condensed water accordingly attacks iron condensers, whilst most other metals, such as copper, would form amalgams with the condensed mercury. Stoneware, glass, and wood, as well as iron are used in the construction of condensers.

5. *Stupp* or mercurial soot is formed, consisting of finely divided mercury together with mercury sulphate, and chloride, and sooty products of the fuel and the bituminous and other constituents of the ore. The soot accumulates in the condensers and is treated subsequently by special processes. At Monte Amiata, it contains 70 or 80 p.c. of all the mercury recovered. Although inconvenient if formed in very large quantities, however, soot is useful when amounting to about 1 p.c. of the ore treated, as it assists the condensed mercury (*quicksilver-mist* or *quicksilver-foam*) to settle in the condensers and dust chambers and reduces the vapour loss by forming a dry crust over the liquid quicksilver.

According to Christy (Trans. Amer. Inst. Ming. Eng. 1884, 13, 547; 1885, 14, 206), the issuing gases are saturated with mercury vapour at New Almaden, and the loss as vapour can be calculated from the vapour pressure of mercury at the temperature of the gases. According to Spirek, however (Min. Ind. for 1897, 6, 571), the gases at Monte Amiata had a saturation of only 30 to 45 p.c., owing to the action of the stupp. In any case, it is clear that the temperature and volume of the issuing gases should be kept as low as possible.

The mist loss, due to fine particles of mercury being carried away mechanically in the effluent gases, depends on the method of condensation and the velocity of the gaseous current. It is usually from 2 to 2½ times the vapour loss.

The total losses of mercury, which, according to Schnabel, formerly amounted to 50 p.c. or more, have now been reduced to 5 p.c. or even less of the mercury present in the ores, in spite of the great fall in the richness of the ores treated. This reduction of loss is largely due to the labours of the metallurgists at Idria since 1870, the names of Exeli, Langer, Czermak, Spirek, Novak, and others being associated with improvements in the methods of treatment.

Ores are not usually finely crushed for the roasting process, and they are not now prepared for reduction by means of concentration in water at any works, as the additional cost and the heavy losses in the tailing outweigh any advantage to be gained. For ten years the ore at the Cornacchino mine, Monte Amiata, was dressed. with the production of a concentrate containing 25 or 30 p.c. of mercury, and tailing assaying from 0·6 to 1 p.c. of mercury which was thrown on the dump. The tailing was subsequently treated at a profit in the continuous fine ore roasters and concentration has been discarded (Mineral Industry for 1897, 6, 569).

Types of furnaces. A number of different furnaces have been used for the treatment of mercury ore in the course of the last 100 years. In the discontinuous shaft furnace (Aludel and Idria furnaces) the ore in the form of lumps, or fines made into balls, was piled in a shaft on a perforated arch or grate and heated by the products of combustion of a fire placed below. Shaft furnaces working continuously (Exeli, Langer, and Knox furnaces) succeeded, in which there was no grate to support the ore. The heating gases entered the shaft at the side some distance from the bottom. In a more recent type of continuous shaft furnace for treating coarse ore (Hähner, Valalta, Novak, and Spirek furnaces), there is no external fire, the ore being charged in mixed with charcoal.

In fine-ore shelf furnaces (Hüttner and Scott, Livermore, Czermak, and Czermak-Spirek furnaces) the ore passes down over a series of sloping shelves and is heated by the gases from an external fire. These furnaces are more economical than the coarse-ore furnaces and are in wide use. Reverberatory furnaces (Alberti, Exeli ironclad reverberatory, Czermak-Spirek reverberatory) are used in certain cases. Lastly there are the retort furnaces.

A more detailed description of some of these furnaces is appended.

Aludel or Bustamente furnace.—This old-fashioned form of furnace was still in use at Almaden in 1907 and is probably not yet entirely discarded. It is an intermittent shaft furnace, designed by Barba in Peru and introduced into Almaden by Bustamente in 1646. One form of Aludel furnace using wood as fuel is shown in elevation and plan in Figs. 1 and 2, and another and later form with a grate for coal is Figs. 3 and 4. In Fig. 1, *a* is the fire-door, *b* the fireplace, *c* a perforated brick arch above which is the circular distillation chamber, 4 feet 3 inches in diameter in the smaller furnaces, and 6 feet 6 inches in the larger. The ores are first charged in through the opening *d*, which is afterwards bricked up and charging is completed through the door in the top arch. The total height of the cylindrical shaft is from 20 to 26 feet. On the arch *c* is placed 2000 kilos. of quartz or of poor ore in large pieces so that the flames rise through them readily. This is covered with 10–14 tons of ore, beginning with ore of medium quality (*requiebro*, containing from 7 to 15 p.c. of mercury). Upon this is charged the poorer ores (*china*, containing about 1 p.c. of mercury), then the rich ore (*metal* containing over 15 p.c. of mercury), and lastly small ore of mixed quality (*vasisco*) made into balls.

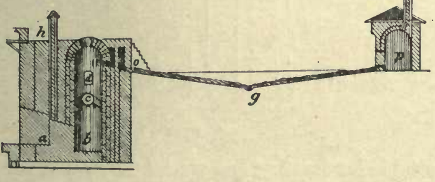

FIG. 1.

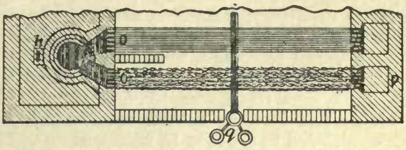

FIG. 2.

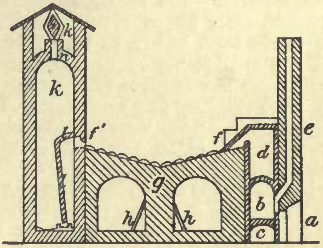

FIG. 3.

The furnace is then closed and the charging doors luted up, and the aludels are luted together in position. These are pear-shaped clay condensers, 18 inches long, glazed on the outside, and so shaped that the narrow end of each fits into the wider end of the next following one. They are arranged in 12 parallel rows each containing 40 to 45 aludels, lying in grooves on a sloping roof, *ff'*, Figs. 3 and 4. The aludels communicate with condensing chambers *k*, Figs. 3 and 4, *p*, Fig. 1. The products of combustion from the fire pass in part through the flue *h*, Fig. 1, *e*, Fig. 3, but mainly through the bed of ore. The mercurial vapours, sulphur dioxide, and the products of combustion of the fuel pass through the aludels where partial condensation takes place and into the chamber *k*, Figs. 3 and 4, passing below the partition *l*. The condensed mercury in part drains out of the aludels into cast-iron pans situated below (*q*, Fig. 2). In the coal furnace shown in Fig. 3, the mercury drains from the aludels at *g*, through the wooden pipes, *h*, to cisterns filled with water.

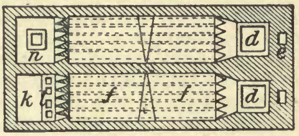

FIG. 4.

The fire is maintained for 10 or 12 hours, thus heating the column of ore sufficiently to enable the cinnabar, pyrites, and bituminous matter to burn in the current of air, which is raised to a temperature of 200°–300° by passing through the layer of quartz before it reaches the ore. The ores burn for 44 hours, a period during which the first aludel reaches a temperature of 245°–260°, and the last aludel one of 29° somewhat later (Kuss, Ann. des Mines, 1877, 13, 39; 1878, 15, 524). The furnace is then opened and the residues allowed to cool for 18 hours, after which they are withdrawn and the furnace recharged.

The aludels are cleaned out once in one or two months, according to position, and the soot collected and prepared for re-treatment. The losses of mercury, according to Langer (Berg. u. Hüttnm. Jahrb. Berg-Akad. 1879) amounted in 1879 to an average of 20 p.c. (*See* also Moreau, Le Génie Civil, 1884, 380; Eng. and Mng. Jour. 1881, 32, 335.)

Idrian furnace.—The aludel furnaces were introduced at Idria about 1750, but were soon altered into the form known as Idrian furnaces, in which the condensing apparatus consists of large brick chambers in place of aludels. These furnaces gave higher percentage losses than aludel furnaces but were worked more cheaply. They were discarded at Idria in 1870. (*See* Schnabel and Louis, *l.c.* ii. 352.) For description of older methods of ore treatment at Idria, *see* Mitter (Vortrag auf dem Bergmannstag zu Klagenfurt, 1893); also Agricola (De re Metallica, Lib. ix. 1556).

Exeli furnace.—The introduction of shaft furnaces fired continuously marked a great advance on the older forms. One of the earliest of these was the Exeli furnace, built at Idria in 1872 (Das K. K. Quecksilber bergwerk Idria in Krain, Vienna, 1881; Schnabel and Louis, *l.c.* 358), and introduced by Randol at New Almaden in 1874 (Egleston, *l.c.* ii. 857). It was surrounded by three external fireplaces and cased in wrought iron to prevent loss of mercury. It was afterwards altered by bricking up the fireplaces and charging charcoal with the ore at the top of the furnace. For the *Langer furnace*, see Schnabel and Louis, *l.c.* ii. 365, and for the *Knox furnace*, see Egleston, *l.c.* ii. 841.

Novak furnace.—This is a good example of a continuously working shaft furnace in which the ore and fuel come into direct contact. It is suitable for coarse ore in cases where charcoal can be obtained cheaply. The earliest shaft furnace of the kind was the Hähner furnace, used at Idria from 1849 to 1852 (Schnabel and Louis, *l.c.* ii. 407). It was replaced by the Valalta furnace (Berg. u. Hüttmn., Ztg. 1864, 284; 1868, 32; Eng. & Mng. Jour. 1872, 14, Nos. 11, and 12). The Novak furnace was introduced at Idria in 1892. One of these furnaces is shown in elevation and plan in Figs. 5 and 6, but three furnaces are united in a single block. The outer walls are cased in iron plates. The shaft *a* is rectangular, 7 metres in height and 2 metres by 2·4 metres in cross section at its widest part. There are four openings, *b*, *b*, for the removal of the residues. The brick shaft stands on a cast-iron plate, *c*, supported by legs and standing on a brick foundation, accessible also from below at *d*. Any loss of mercury in the foundations is thus prevented. The roof-shaped ridge *e*, in the bottom of the furnace, is pierced with many small holes for the supply of air. The charging hopper *f* is fitted with a water-joint and the pipe *g* leads to the condensers. Poor ore in lumps not smaller than 0·67 inch mesh and pressed soot are treated, one ton of ore together with 16 p.c. of its weight of charcoal being charged into the furnace every 2 hours. The condensers are of the usual Czermak type, see Fig. 11. The production of soot amounts to 0·5 p.c. and the loss of mercury to 7 or 8 p.c. With furnaces of this type the formation of soot is much less than in the fine ore furnaces about to be described.

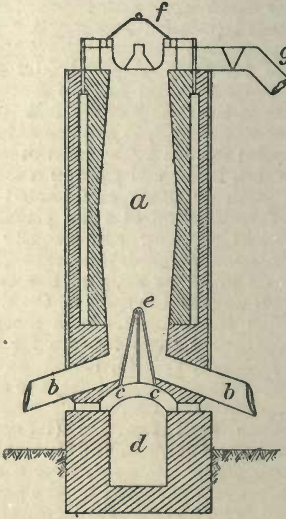

FIG. 5.

The modern Czermak-Spirek shaft furnaces used at Siele, Monte Amiata, in which the loss is only 2 or 3 p.c. of mercury, are described in the Mineral Industry for 1901, 10, 559. (*See* also Spirek, Sixth Internat. Cong. of Appl. Chem. Rome, 1906.)

Hüttner and Scott furnace (Schnabel and Loius, *l.c.* ii. 372; Egleston, *l.c.* ii. 864). This furnace was introduced at the New Almaden mines, California, in 1875, and was the earliest of the shelf furnaces, which are especially suitable for treating fine ore. At New Almaden the small ore of less than 1·2 inch cube was called *tierras*, and the larger ore of between 1·2 inch and 2·3 inch cube, was known as *granzitas*. These materials were treated in separate furnaces built on the same principle, with a large number of inclined shelves sloping at an angle of 45° in alternately opposite directions, upon which the fine ore slides down, filling up the spaces between

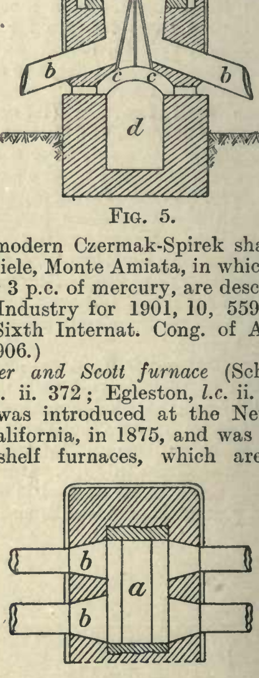

FIG. 6.

the shelves. The products of combustion of the fire pass horizontally between the under side of the shelves of each tier and the surface of the ore resting on the shelves of the next tier below. The ore is thus heated and roasted, and is finally discharged at the bottom of the furnace.

One of the newer forms of this furnace was built by Newcomb at Oat Hill, California, in 1898 (Mineral Industry, 7, 583). Fig. 7 is a vertical section through the furnace and the first section of the condensers; and Fig. 8 is a front view, with the furnace in section and the condensers partly in elevation. Fig. 9 is a horizontal section of the furnace on A, B, Fig. 8.

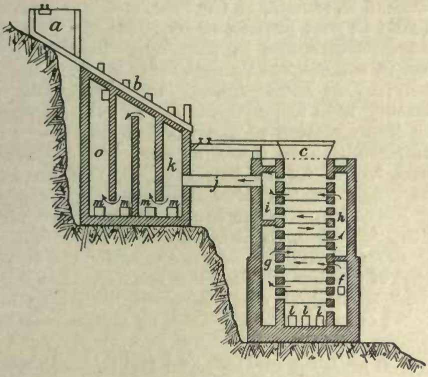

FIG. 7.

The ore is passed through 1·5 inch gratings before entering the ore-bin *a*, Figs. 7 and 8, whence it passes over a drying platform *b*, placed above the condenser, and is discharged into a hopper, *c*. The hopper is kept full of ore which acts as a seal when a slot is opened and some ore let fall into the furnace. Two tons of ore are thus charged in at intervals of one hour.

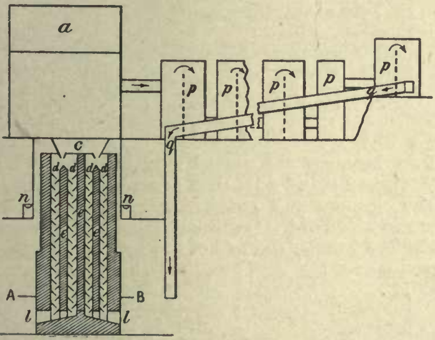

FIG. 8.

The furnace is of brick, 22 feet by 16 feet, and 37 feet high, outside measurements. The roasting chamber is divided into four compartments, *d*, Figs. 8 and 9, by three vertical partitions, *e*, and in each compartment is a series of 24 sloping shelves (*see* Fig. 8) consisting of fire-clay tiles which allow the ore to slide down in a zig-zag path. The ore piles up on the shelves bridging over the 6-inch spaces between them, so that the products of combustion from the fire-box *f*, Figs. 7 and 9, cannot rise vertically in the shaft but pass horizontally under the shelves from *f* to *g*, thence from *g* to *h*, following the course indicated by the arrows, and finally from *h* to *i*, whence they escape by two cast-iron exit pipes *j*, to the condenser *k*.

The spent ore is discharged by being raked, at intervals of 15 minutes, through the openings *l*, *l*, which are placed 5 feet below the level of the fire-grate, so as to enable the ore to be cooled before it is withdrawn. The furnace holds 40 tons of ore, so that the ore remains under treatment about 20 hours. The fuel used is 2½ cords of wood in 24 hours. The temperature is kept as low as possible, a cherry-red heat being aimed at, and hardly a trace of cinnabar is found in the material discharged.

FIG. 9.

The condensers are of brick with cemented floors sloping down to the discharge apertures *m*, *m*, Fig. 7, whence the metal runs to the quicksilver troughs *n*, *n*, Fig. 8. Very little mercury is condensed in the first compartment *k*, but the amount increases up to the last compartment *o* of the first condenser. After this, in passing through the remaining six brick condensers *p*, *p*, Fig. 8, the amount of mercury recovered decreases. The fumes next pass into the wooden flue condenser *q*, Fig. 8, eventually being discharged into the open air through a vertical flue in which an exhaust fan is placed. The length of travel in the condensers is 400 feet. About 30 p.c. of the total yield of mercury is obtained from the soot. The loss of mercury is estimated at about 5 p.c., and the labour required is 4 men per shift with a fifth during the day to attend to the soot-pan.

In California, the Hüttner-Scott furnaces are in general use, very coarse ore being crushed to enable it to be treated in these fine-ore furnaces. Shaft furnaces appear to have been discarded in California, as less advantageous than the shelf furnaces.

Czermak-Spirek continuous roasting furnace (Mineral Industry for 1897, 6, 572). This furnace is a modification of the Czermak furnace introduced at Idria in 1886 (*see* Schnabel and Louis, *l.c.* ii. 388). It is on the same principle as the Hüttner-Scott furnace, and is similar in being suitable for the treatment of fine ore.

It consists of a rectangular chamber of iron, with two fireplaces, one at each end. The fires are lighted alternately, only one being at work at any given time. The products of combustion pass into a wide flue or combustion chamber extending longitudinally in the middle line of the furnace near its base. Hot air from iron pipes used to cool the ore just before it is discharged is used for combustion, and an excess of air is supplied.

The ore is fed from above upon V-shaped tiles, with the apex upward, ranged in parallel lines, in such a way that the apex of each tile is opposite the space between two tiles in the layer next above (*see* Fig 10). The ore slips down the tiles and completely fills the space *a* between two successive layers of tiles. When part of the residues are withdrawn from the bottom of the furnace, there is a general subsidence of ore extending to the top. There is a regular system of oval openings in the sides of the furnace provided with movable covers, through which iron bars may be introduced to dislodge the sintered ore in case of necessity. The V-shaped tiles are supported on longitudinal walls made of perforated bricks.

The products of combustion and hot air from the combustion chamber circulate through the furnace by the passages *b*, between the tiles and the ore and pass out at the top of the furnace through cast-iron pipes into the condensers. The temperatures in the furnace are as follows: ore on discharge, 100°; air supplied for combustion, after being used to cool the roasted ore before it is discharged, 300°–360°; combustion chamber, 800°–900°; in the first tier of tiles of the roasting zone, 700°–800°; in the fourth and highest tier, 360°–400°; in the passage to the condenser, 260°–360°.

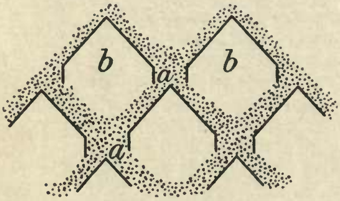

Fig. 10.

The condensers are of the usual Czermak pattern, consisting of cast-iron pipes of elliptical section (*a*, Fig. 11). In positions where the temperature is below 100° so that the acid vapours are condensed, the iron is lined with cement to avoid corrosion of the iron. Glazed stoneware is also used instead of cast iron. These condensers are cooled with water. The lower part *b* of the condensers is sometimes constructed of wood, and dips for about two inches into water contained in lined cast-iron or wooden boxes, *c*. The flue leading from the furnace is shown at *d*. The vapours escape into the wooden flue *e*. The large furnaces have two sets of condensers which can be cleaned alternately without stopping the work of the furnace. From the condensers, the vapours pass into flat wooden flues, or dust chambers, in which a poor soot is collected.

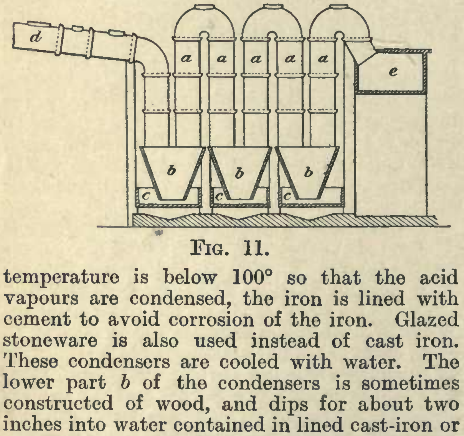

Fig. 11.

The pressure of the vapours within the furnace and condensers is kept below atmospheric pressure by means of a fan which provides an exhaust equivalent, according to Spirek, to a water column of about 4 mm. at the outlet or 1 mm. at the junction between the furnace and the condensers.

The capacity of the furnace depends on the nature of the ore, and in the case of the largest sized furnace at Siele varies from 16 to 26 tons per day. The ore remains in the furnace from 41 to 68 hours and is shifted by the withdrawal of a portion every 2 or 3 hours. The ore is roasted at a bright red heat until the last trace of mercury has been driven off. The condensation is also very good, about 90 p.c. of the mercury and soot collecting in the first 3 U-tubes, within a length of 4 metres. The greater part of the metal, and in the case of low-grade ores the whole of it, remains in the soot, and is recovered in part in soot presses, or by rubbing on an inclined surface and in part by redistilling the soot in a small continuous roaster of the same pattern. At Monte Amiata, the average loss of mercury with these roasters is 4 or 5 p.c., after the impregnation of the wooden condensers is completed. Two workmen per shift are sufficient to attend to this furnace, one on the charging floor, the other as fireman.

These furnaces are in use at Monte Amiata, Idria, Almaden, Nikitowka, and elsewhere.

Reverberatory furnaces are used for the treatment of fine ore which yields too much flue dust when treated in shelf furnaces, and also for coarse ore which decrepitates or sinters readily.

The first reverberatory was employed by Alberti at Idria in 1842, and the latest form is the Czermak-Spirek long-bedded calciner introduced in 1888 and shown in Figs. 12 and 13.

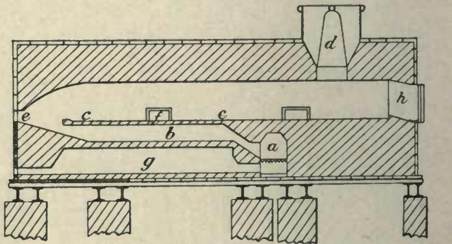

Fig. 12.

Two furnaces are placed side by side in one block and stand on a dish of riveted sheet-iron. The fire-grate *a* extends across almost the whole width of the furnace. The flame traverses the flue *b* under the bed of the hearth and then passes over the tiled hearth *c*, which is 5½ metres long and 2·4 metres wide. The charging hopper is at *d*, and there are five working doors at *e* and *f*. The residues are withdrawn every 2½ hours through the door *f* into the receptacle *g*. The gases and vapours pass through the

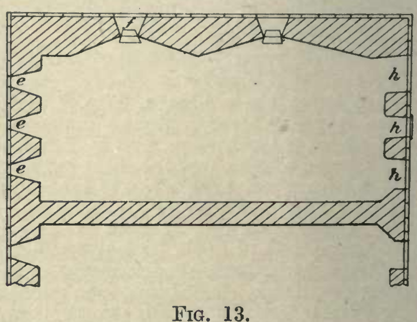

Fig. 13.

openings *h* into Czermak condensers of the usual pattern.

These furnaces treat 6·6 tons of poor ore and soot in 24 hours with a consumption of 148 cubic feet of wood per 10 tons of ore. The production of soot amounts to 1·9 p.c. and the loss of mercury to 8 or 9 p.c. (Schnabel and Louis, *l.c.* ii. 402).

For the description of a similar reverberatory furnace designed by Spirek for the treatment of mercury-lead ores, see Mineral Industry for 1902, 11, 548.

Retort furnaces were used for a time at Idria, Monte Amiata, and California, but are probably no longer in use in any part of the world except, according to Schnabel, at Littai, in Carniola. The ore is mixed with lime or iron and heated in cast-iron or clay retorts, which are pear-shaped or cylindrical in shape, and usually contain from 1 to 5 cwt. of ore. The method is suitable only for rich ore or soot, but even for such material the process gives no better results than the air-roasting process, and apart from cost, it has the disadvantage of producing concentrated vapours of mercury which have injurious effects on the workmen.

At Littai (Schnabel and Louis, *l.c.* ii. 421), cast-iron retorts are used, taking a charge of 2 cwt. of ore. The ore contains 2 or 3 p.c. of mercury, and 5 or 6 p.c. of lime is added. The retorting lasts 6 hours and the loss of mercury is stated to amount to from 5 to 6 p.c.

Soot or *Stupp*, the deposit on the walls of the condensers, consists of finely divided mercury and compounds of mercury, together with carbon, tarry matters, and ash from the fuel and dust from the ore, amounting in all, according to Spirek, to about 1 p.c. of the ore at Monte Amiata. The composition of soot varies largely. One sample from the condenser of a Czermak furnace was found to contain :

Metallic mercury	22·01 p.c.
Mercury as cinnabar . . .	6·75 ,,
Mercury as sulphates, chlorides, &c.	3·04 ,,
Total mercury . . .	31·80 ,,

(*See* Schnabel and Louis, *l.c.* ii. 425, where many analyses are given.)

The soot is usually treated mechanically to separate part of the mercury contained in it. It may be worked with hoes on an inclined surface until no more mercury flows off, as at Almaden (Berg u. Hüttnm. Jahrb. der K. K. Montanlehranstalten, 27, 46). When rubbed with lime, more mercury is separated.

At Idria and Monte Amiata, Exeli stupp presses are used. These are iron pans fitted with vertical knives fastened to the bottom. Revolving arms carrying similar knives stir the soot and press it against the stationary knives. Lime is added little by little to the extent of from 17 to 30 p.c. of the soot during the course of the operation, which occupies one or two hours in the case of rich material. When the soot is stirred and pressed, mercury separates from it and flows away through small openings in the bottom of the pan.

The soot residues after treatment still contain 10 p.c. or more of mercury and are treated mixed with ore in the same furnace as before, or mixed with other rich materials in similar furnaces of small size, or more rarely in retorts. Formerly where coarse ore furnaces were in use, the soot residues were moulded into bricks and treated with the ores.

Purification. Impure mercury is recognised by the fact that globules are pear-shaped with tails, instead of spherical, when made to run down a sloping surface, and may even leave a trail behind them on paper. Mechanical impurities are removed by squeezing through chamois leather or by filtering through punctured blotting paper.

Retorting at a low temperature with a cover of charcoal and lime will remove most of the impurities. Oxidisable impurities are best removed by the passage of a stream of air through the mercury which is covered with dilute nitric or sulphuric acid. The base metals are rapidly oxidised by the air and dissolved by the acid. Small quantities of impurities may be removed merely by digesting or shaking mercury with dilute nitric acid.

Mercury is kept in a glass or stoneware vessel under a layer of dilute nitric acid of sp.gr. 1·1 and drawn off as required by a stop cock at the bottom and washed with water before use.

Properties. Mercury is a silver-white liquid metal with a slight bluish tinge. In thin films it transmits violet light (Melsens). Its sp.gr. at 0° is 13·59545 when compared with water at 4° (Volkmann, Thiesen and Scheel). At −38·85° it solidifies (Balfour Stewart), contracting considerably and forming a tin-white, soft, malleable and ductile metal of sp.gr. 14·193 at its melting-point (Mallet, Phil. Mag. 1877, [v.] 4, 145). Its electric conductivity is 1·63, if silver =100 (Matthiessen), and its thermal conductivity is 1·83, if silver =100 (Angström, Gray). For thermal expansion *v.* Callendar and Moss, Phil. Trans. 1911, 211 A, 1.

It is volatile at ordinary temperatures and even at −44° (Merget); its b.p. is 357·25° at 760 mm. pressure (Regnault), forming a colourless vapour. (For its vapour pressures from 40° to 512°, *see* Ramsay and Young, Chem. Soc. Trans. 1886, 49, 37.)

It is unaltered in air, oxygen, nitrous and nitric oxides, carbon dioxide, &c., at ordinary temperatures. When heated to about 350°, it becomes gradually converted into the red oxide, HgO, which is decomposed below a red heat.

Mercury is not acted on by HCl, and is almost unaffected by dilute H_2SO_4, although dissolved by hot strong H_2SO_4. It is dissolved even by cold dilute HNO_3, and is rapidly attacked by hot or concentrated nitric acid. It is also dissolved by aqua regia.

When agitated with oils, turpentine, &c., or triturated with grease, fats, sulphur, certain sulphides, arsenides, &c., mercury is subdivided into minute globules, not easily reunited. This is known as the flouring, sickening, or deadening of mercury and is the cause of losses in the extraction of silver and gold from their ores by amalgamation. The coalescence of floured mercury can be effected with some loss by the action of nitric acid.

Vapours of mercury have a poisonous effect ('salivation') on the animal system. Among the remedies are cleanliness, fresh air, acid foods, and moderation in the use of alcohol. The use of potassium iodide is also recommended.

Uses. Mercury is used in the extraction of gold and silver from their ores, for the manufacture of vermilion (*v. infra*), of mirrors and of fulminates, in medicine, and in dentistry. The metal and its amalgams are used in small quantities for a variety of other purposes.

The consumption of mercury in silver milling was formerly very large when the pan amalgamation process was in wide use. In treating the ores of the Comstock lode, for example, 7 lbs. of mercury was formerly lost in the treatment of a ton of ore. In modern stamp-battery practice on gold ores, the loss is only 0·2 or 0·3 oz. of mercury per ton of ore. The progress of the cyanide process and the abandonment of the patio and pan amalgamation processes have caused a reduction in the amount of mercury required in the extraction of silver ores.

The *production* of mercury during the years 1907–1909 in metric tons was as follows (Mineral Industry for 1910, 19, 594):—

—	1907	1908	1909
Austria . .	527	572	637
Hungary . .	40	78	80
Italy . .	434	684	771
Mexico . .	200	200	200
Russia . .	130	47	(?)
Spain . .	1212	1068	1393
United States .	712	685	713
Total .	3255	3334	3794

Mercury is transported in wrought-iron flasks or bottles closed by screw stoppers. The weight of mercury in a full flask was formerly 76·5 lbs. but was reduced to 75 lbs. in Europe in 1903, and in California in 1904. The old sheepskin bag used to contain 55 lbs.

The price of mercury is usually between £8 and £10 per flask. T. K. R.

COMPOUNDS OF MERCURY.

Mercury forms two series of salts: the *mercuric* compounds, in which the metal is divalent, and the *mercurous* compounds, in which it is apparently monovalent.

The *mercuric salts* are often obtained when excess of acid acts on metallic mercury. Reducing agents convert them into mercurous salts, which may be further reduced to metallic mercury. The soluble salts are extremely poisonous and are acid to litmus.

The *mercurous salts* are produced when an acid acts on excess of mercury, or by the reduction of mercuric compounds. In solution they readily dissociate into metallic mercury and a mercuric salt (Hada, Chem. Soc. Trans. 1896, 1667). This reaction is reversible and ends with the establishment of equilibrium between the mercurous and mercuric ions present (Abel, Zeitsch. anorg. Chem. 1891, 26, 361).

Mercury forms three oxides, *mercurous oxide*, *mercuric oxide*, and *mercuric peroxide*.

Mercurous oxide Hg_2O is obtained as a blackish-brown powder by the addition of alkalis to a solution of mercurous salt, or by triturating a solution of alkali with calomel. It is washed, dried spontaneously, and kept in the dark. By the action of light or of a gentle heat it is decomposed into the red oxide and mercury, and it combines with oxygen at 100° (Colson, Compt. rend. 1899, 128, 1104). It may be obtained in colloidal solution by treating the aqueous solution of a mercurous salt with alkali salts of the albinic acids in presence of alkali hydroxide or carbonate (Hofmann, D. R. P. 185599, 1905; J. Soc. Chem. Ind. 1907, 1254).

Mercurous hydroxide does not exist at the ordinary temperature but is obtained as a bright-yellow precipitate by the action of alcoholic potash on alcoholic mercurous nitrate at −42° (Bird, Amer. Chem. J. 8, 826).

Mercuric oxide, *Red oxide of mercury, Red precipitate*, HgO. This oxide is slowly produced when the metal is heated in air to near the boiling-point. It may be obtained pure by pouring a boiling solution of mercuric chloride into an excess of boiling potassium carbonate solution and boiling till the precipitate is of the right colour (Dufau, J. Pharm. Chim. 1902, 16, 439). It is usually prepared by heating the nitrate until nitrous fumes cease to be evolved, but not sufficiently to decompose the oxide itself. When prepared slowly on the large scale the oxide is obtained in fine brick-red crystalline plates of sp.gr. 11·163 (Playfair and Joule).

By precipitating a mercuric salt with cold potash, the oxide is obtained as an orange-yellow powder of the same composition, but more easily acted on by reagents. With oxalic acid it produces the oxalate, whilst the crystalline oxide is not so affected. When heated with mercuric chloride solution it rapidly forms an oxychloride; the crystalline form is only slowly so converted. The amorphous oxide is also more easily decomposed by heat. It was formerly considered by many chemists that the red and yellow oxides differed only in the size of the particles (see *e.g.* Ostwald, Zeitsch. physikal. Chem. 1900, 34, 495; Schick, *ibid.* 1902, 42, 155). Schoch, however, has shown (Amer. Chem. J. 29, 319) that the crystalline form of the red is different from that of the yellow oxide, that the dissociation pressure of the yellow oxide at 300° is considerably greater than that of the red oxide, and that when heated at 250° it is converted into the red oxide with partial decomposition.

Mercuric oxide is a powerful poison. It dissolves in about 20,000 parts of water at 25° or about 2200 parts at 100° (Schick, *l.c.*). When heated it becomes of a bright red, and finally nearly black, but regains its colour on cooling. A superficial change of colour from bright red to brownish red is produced when the red oxide is exposed to light. When strongly heated, it is decomposed into mercury and oxygen. By this reaction, oxygen was first prepared by Priestley.

When heated with zinc, tin, or antimony filings, the oxide is reduced to metal with incandescence. When added to fused sodium the action is still more intense. The mixture with sulphur explodes violently when heated. Mixed with phosphorus it detonates when struck. At a red heat it is converted by chlorine into mercuric chloride, with liberation of oxygen. It dissolves in fused potash with formation of a double oxide, without evolution of gas.

Mercuric oxide is frequently used as an oxidising agent in chemical operations.

A colloidal solution of mercuric oxide is obtained when mercuric chloride solution is treated with the sodium salts of protalbinic or lysalbinic acids and caustic soda. A yellow solution is obtained which can be purified by dialysis and then gives on evaporation *in vacuô* at 40° red-brown plates of the stable hydrosol (Paal, Ber. 1902, 35, 2219).

Mercury peroxide HgO_2 is formed in small quantities during the catalytic decomposition of hydrogen peroxide by metallic mercury (Antropoff, Zeitsch. Elektrochem. 1906, 12, 585), and is prepared by the interaction of alcoholic mercuric chloride, hydrogen peroxide, and alcoholic potash (Pellini, Atti. R. Accad. Lincei, 1907, [v.] 16, ii. 408). Either method yields the anhydrous peroxide as an amorphous, brick-red powder, which is fairly stable in dry air. It is slowly decomposed by water, and with acids yields a mercuric salt and hydrogen peroxide: with hydrochloric acid chlorine is liberated.

Mercuric sulphide HgS occurs native as *cinnabar*, which is the principal source of the mercury of commerce. Cinnabar is found, granular or massive, in sub-transparent rhombohedral crystals which cause circular polarisation of transmitted light. It has a cochineal-red colour and gives a scarlet streak.

Mercuric sulphide exists in two forms (*a*) a red, crystalline variety, of which cinnabar is an example, and (*b*) a black, amorphous substance.

The black sulphide is produced by the action of hydrogen sulphide on solutions of mercuric salts, or by triturating or heating mercury with sulphur. Thus prepared it was formerly used in medicine under the name of *Æthiops mineral*. It occurs native in California (Moore, J. pr. Chem. 1870, [ii.] 2, 319).

Under the name of *vermilion*, the red variety is prepared on the large scale and used as a pigment. Native cinnabar cannot be so used because of impurities which affect the colour. Vermilion is prepared both by *dry* and *wet* processes.

Dry processes.—These all depend on the preparation of the black sulphide, usually by the combination of mercury and sulphur, and its subsequent conversion into the red variety by a process of sublimation. The following method was formerly largely used in secret in Holland. 1080 lbs. of mercury and 150 lbs. of powdered sifted sulphur are moderately heated in an iron pan with constant stirring, and the black *œthiops* obtained is cooled and powdered. This is introduced in charges of about 25 lbs. four times an hour into long subliming pots of refractory clay, each holding about 410 lbs., heated from below to about two-thirds of their height. As each charge is added it ignites, and a long flame escapes from the pot; when this has subsided, the pot is covered with an iron plate. The operation occupies about 36 hours. The pots are cooled and broken, and the vermilion, which is principally in the upper portions, is ground with water between stones, sifted, elutriated, and dried.

It is said that if 1 part of antimonious sulphide be added to the mixture of sulphur and mercury before sublimation, and the vermilion be digested with potassium sulphide, an improved pigment is obtained which contains no antimony.

At Idria, a mixture of 8 lbs. sulphur and 42 lbs. mercury is placed in a well-bound cask, which is rotated for some hours until the contents consist of a uniform brownish powder.

A number of vertical, cast-iron cylindrical retorts heated to dull redness are charged with the mixture, and immediately covered. When crackling has ceased the covers are replaced by stoneware necks, each connected with a tube and receiver. The fire is then increased to drive the whole of the sulphide from the retort.

When cooled the necks are taken off, and the cake of vermilion removed. That nearest the retort is best, whilst that in the receiver contains free sulphur, and is resublimed with a fresh charge. The cakes are broken, ground with water, boiled with sodium hydroxide solution, washed and dried.

The Chinese vermilion is celebrated for its fine colour, which inclines to carmine. It is said to be prepared as follows:—

About half a bottle (38 lbs.) of mercury and 17½ lbs. of sulphur are mixed in an iron pan, about 25 inches wide and 7 or 8 inches deep, and heated by charcoal. When melted, it is stirred with an iron spatula, and the remainder of the mercury is gradually added. When the metal has disappeared the mass is removed from the fire, cooled by the addition of a little water, rapidly stirred, and coarsely powdered. The reddish or black semicrystalline powder, which contains free mercury and sulphur, is placed in a fixed iron pan, and covered with porcelain tiles 8 inches diameter (many of which are broken), arranged in the shape of a dome. The whole is covered by a pan 4 inches less in diameter than the fixed one, to which it is luted by clay, leaving four holes in the luting for the escape of gases. The charcoal fire is then lighted and kept fiercely burning for 18 hours; blue flames are seen burning round the holes, showing loss of sulphur and of mercury. The fires are then allowed to die out and the pans to cool. Most of the vermilion is found adherent to the porcelain, and is removed. That attached to the iron is inferior, and is made with the other waste into cakes with alum and glue water, dried, and resublimed. The sulphide on the porcelain is blood-red and crystalline. It is powdered and ground with water in a hand-mill between stones, and washed into a vessel. At the close of a day's work a solution of alum and glue (1 ounce of each to 1 gallon of solution) is well stirred with the powder, and the whole is allowed to stand until morning. The glue tends to lengthen the period of deposition, and to render the stratification into the various qualities more perfect. The alum is said to improve the colour. The liquid is decanted, and the upper portions of the deposit are set aside. The lower parts are reground and treated as before, the grinding being sometimes repeated several times. The fine vermilion is stirred in water and settled, and the water is decanted. The residue is dried in the open air, powdered, sifted through muslin, and packed in papers holding about 1⅓ ounce each (*v.* Chem. News, 1884, 50, 77; J. Soc. Chem. Ind. 1882, 1, 195). It is used for making Chinese red-ink; for painting on porcelain and wood and colouring candles and paper. Most of the numerous temples throughout China are painted red, and everything lucky and pleasant among the Chinese is of vermilion colour (J. Soc. Chem. Ind. 1890, 9, 1047).

It is said that China imported in 1880 mercury to the value of 170,032 dollars, the whole of which was converted into vermilion.

Wet processes.—The processes most used depend on the action of alkaline sulphides on the amorphous mercury sulphide. The temperature adopted largely influences the colour.

The action of these sulphides is attributed by Ditte (Compt. rend. 98, 1380) to the alternate production and decomposition of a double sulphide of mercury and alkali. In the case of potassium sulphide the compound $K_2S{\cdot}5HgS$ is first produced, and is decomposed at about 45° (the temperature generally employed), with deposition of the *red crystalline* mercuric sulphide, whilst the liberated alkaline sulphide dissolves a further amount of the more readily attacked amorphous sulphide, and again forms the double sulphide, which is again decomposed as before.

In order to prepare a polysulphide free from hyposulphite (which is said to have an injurious effect on the colour), potassium sulphate is converted into sulphide by ignition with carbon. The mass is extracted with water, and boiled with sulphur out of contact with air.

Of this strong solution 2¼ kilos. is digested and agitated with 1 kilo. sulphur and 5 kilos. mercury at a gentle heat. The mixture gradually becomes heated, and in about 2 hours acquires a greenish-brown colour. After a further period of 2 hours it becomes of a rich brown, and is allowed to cool to 50°, and is maintained at that temperature for 3 or 4 days with frequent agitation. A fine-coloured vermilion gradually settles down; it is washed with potash, then with dilute nitric acid, and finally with water (Firmenich, Dingl. poly. J. 1864, 172, 370).

According to Liebig, a fine vermilion is produced by immersing recently precipitated *white precipitate* in a solution of ammonium polysulphide. The mixture at first produced is black, but when heated to about 45° gradually acquires a fine colour resembling that of Chinese vermilion. It may be digested with potash, and washed to improve the colour.

Hausmann (Ber. 1874, 7, 1746) adds excess of dilute ammonia to a solution of mercuric chloride, and dissolves the precipitated *mercuric ammonium chloride* in a slight excess of sodium hyposulphite. On warming to 70° or 80° the vermilion begins to precipitate. The heat is continued until the mass has become pasty, the sulphide is then separated as usual. The above temperature and the presence of the ammonia and ammonium chloride are said to be essential.

One of the best processes is that of Brunner (Pogg. Ann. 1828, 15, 593). A mixture of 100 parts mercury with 38 parts sulphur (flowers) is triturated for some hours, mixed with a solution of 25 parts potash in 150 parts water, and digested at a temperature below 45°, keeping the liquid at constant volume by adding water.

After 2 or 3 hours it becomes brownish, and then gradually brightens. The temperature must be carefully regulated and the volume kept constant, or the precipitate loses its pulverulent character and becomes inferior in colour. At the proper point, usually after about 8 hours, the heating is stopped and the contents are washed as quickly as possible, as the further action of the potash would produce a brown colour. It is lixiviated to separate any black sulphide, and dried.

The method of Gauthier Bouchard is strongly recommended. Concentrated ammonia solution is saturated with sulphuretted hydrogen, and 400 c.c. of the solution is digested in a stone bottle with flowers of sulphur, with production of a solution of ammonium sulphide of sp.gr. 1·034. This is mixed with 200 grams of sulphur and 1000 grams of mercury (as pure as possible) agitated well in a closed vessel for about 7 hours, and finally heated for 3 or 4 hours to 50°. The liquid is decanted and the residue is washed with water, followed by dilute nitric acid and finally by water.

The chief difficulty in all these methods is to free the vermilion from alkaline sulphides and sulphur, the presence of which is detrimental to the colour of the product. Picton and Linder therefore recommend (Eng. Pat. 5120, 1892) that the black sulphide, produced by one of the usual methods, be suspended in water and treated with a stream of hydrogen sulphide gas until it dissolves. This solution is then heated in a closed vessel to 160°–170° for several hours, when a very pure vermilion is deposited.

Vermilion is adulterated with red lead, red ochre, chrome red, red oxide of iron, and frequently with gypsum. These all remain on volatilisation of the vermilion in a glass tube. Dragon's blood, if present, gives a characteristic odour on heating; it also dissolves in alcohol with a red colour. Chinese vermilion usually contains a little glue, which is not, however, an adulteration. Mercuric sulphide is occasionally present in vulcanised caoutchouc (Frank and Jacobsohn, Gummi. Zeit. 1909, 23, 1046).

The sp.gr. of red mercuric sulphide is 8·12; that of the black sulphide is 7·5.

Mercuric sulphide when heated in the air is decomposed with production of the metal and sulphur, which is at once oxidised to sulphur dioxide. With lime, alkaline carbonates, or metals such as iron, copper, and tin, it is reduced with formation of alkaline or metallic sulphide. When heated with litharge both lead and mercury are reduced, the oxygen and sulphur combining, and passing off as sulphur dioxide.

If boiled in water with powdered zinc, metallic mercury is liberated. A similar but slower action occurs with copper.

Concentrated nitric acid has no action except after prolonged heating. It is then converted—especially if freshly precipitated—into a white insoluble compound containing both sulphide and nitrate of mercury. It dissolves easily in *aqua regia* and in cold concentrated hydriodic acid. Barium sulphide readily dissolves it.

The solubility of mercuric sulphide in solutions of alkali sulphides has been investigated by Knox (*v.* Abegg's Handbuch der anorg. Chem. Bd. 2, Abt. 2, s. 633; and Trans. Faraday Soc. 1908, 4, 29). The black sulphide is more soluble than the red sulphide and the amount of either dissolved per mol. of sodium sulphide increases with dilution. The compound Na_2HgS_2 exists in the solution but when evaporated over sulphuric acid it deposits yellow crystals of the composition

$$2Na_2S,5HgS,3H_2O.$$

The solubility of the sulphides in water is very small, $K_{25}=0{\cdot}01-0{\cdot}02\times10^{-6}$ (Name, Zeitsch. anorg. Chem. 1904, 39, 108).

Mercuric sulphide can be obtained in colloidal solution by washing the precipitated sulphide with a solution of hydrogen sulphide (Winssinger, Bull. Soc. chim. [ii.] 49, 452; Linder and Picton, Chem. Soc. Trans. 1892, 61, 123; see also Picton, *ibid.* 139). By saturating with hydrogen sulphide a solution of 12 grams mercuric cyanide in 100 of water, a deep brown solution is obtained which when dialysed gives an unstable hydrosol. If, however, the hydrocyanic acid is distilled off *in vacuô* an oily stable hydrosol is obtained (Lottermoser, J. pr. Chem. 1907, [ii.] 75, 293).

Mercurous sulphide Hg_2S is not known.

Mercurous chloride, *Calomel* Hg_2Cl_2, occurs native in small quantities as *horn-quicksilver*, crystallising in rhombic prisms. Artificially prepared calomel has been known from early times, and was used in the 16th century as a medicine under the names *Aquila alba*, or *Draco mitigatus.*

Mercurous chloride is formed by the union of its elements.

It may be prepared by addition of an alkaline chloride to a solution of mercurous nitrate or other mercurous salt. The precipitate is washed well to remove the alkaline chloride, which if allowed to remain would render the calomel slightly soluble. It may be prepared on the large scale by mixing 17 parts of corrosive sublimate with a little alcohol or water to prevent the escape of irritating fumes, and rubbing in 13 parts of mercury until *deadened.* The mixture is then sublimed in glass flasks, in the upper portion of which the calomel condenses as a solid, translucent, fibrous cake. The flasks are broken and the cake is removed, ground to a powder, washed repeatedly with boiling water to remove mercuric chloride, and dried. The powder has usually a slight yellowish tinge.

It is also prepared from the sulphate; 1 kilo. of mercury is mixed with 1·5 kilos. of concentrated sulphuric acid in an iron boiler, gently heated until the fumes of sulphur dioxide cease to escape, and evaporated to dryness. It is then mixed with 1 kilo. of mercury and 1½ kilos. of common salt until *deadened*, and is sublimed as usual.

Instead of condensing the calomel in a cake, the vapours may be led into chambers containing air or steam, in which it falls as a very fine powder, which requires no grinding. Sometimes the distillation is conducted in an iron tube connected with the condenser.

At Apothecaries' Hall, the proportions used are 62 parts of mercury sulphate, 40½ parts of mercury, and 34 parts of common salt.

The Japanese have long manufactured a very pure calomel, absolutely free from mercuric chloride, called '*keifun*' (light powder). Balls of porous earth and salt, soaked in 'bittern' (mother liquor of concentrated sea-water), are heated in iron pots lined with earth, each containing a little metallic mercury. Hydrochloric acid is formed from the magnesium chloride in the bittern and the mercury distils into the closely fitting, but unattached clay covers of the pots. Air enters by diffusion and the following reaction takes place:

$$4Hg+4HCl+O_2=2Hg_2Cl_2+2H_2O,$$

by which calomel is formed at a temperature below its subliming point and fills the cover with a network of micaceous particles (Divers, J. Soc. Chem. Ind. 1894, 13, 108).

In preparing calomel by the wet way, 9 parts of mercury are digested in 8 parts of nitric acid (sp.gr. 1·2) with the aid of heat towards the end, until no more dissolves. The decanted solution is mixed with a boiling solution containing 8 parts of common salt in 64 parts of water and a few drops of hydrochloric acid. The precipitate is *well* washed with water. This form is said to be more effective for medicinal purposes than that prepared in the dry way.

Calomel is also produced by the action of reducing agents upon solutions of mercuric chloride.

Calomel is a white, tasteless powder, of sp.gr. 6·56–7·41, crystallising in four-sided prisms terminating in pyramids. When heated it volatilises without previous fusion, giving a colourless vapour of sp.gr. 8·21 (air=1). This appears to indicate a molecular constitution HgCl, but Smith and Menzies (J. Amer. Chem. Soc. 1910, 32, 1541) have shown by quantitative measurements of vapour pressures that calomel vapour, even when saturated, is completely dissociated into mercury and mercuric chloride, and contains no molecules of the type HgCl or Hg_2Cl_2. The results also show that calomel is soluble in mercury and its molecular weight in that solution at 360°–400° corresponds to the monomolecular formula, HgCl. The boiling-point of calomel is 382·5°. (For methods used *v.* S. and M. *ibid.* 32, 1419; *cp.* also Harris and v. Meyer, Ber. 1894, 27, 1482.) Baker states (Chem. Soc. Trans. 1900, 646) that perfectly dry mercurous chloride can be vapourised without dissociation and then has a v.d. corresponding to the formula Hg_2Cl_2. Further, by cryoscopic measurements, Beckmann has shown that mercurous chloride dissolved in fused mercuric chloride has the formula Hg_2Cl_2 (Zeitsch. anorg. Chem. 1907, 55, 175).

By conductivity measurements, the solubility of calomel in water has been found to be about 0·4 mgm. per litre at 20° (Ley and Heimbucher, Zeitsch. Elektrochem. 1904, 10, 301).

By treatment with alkalis and alkaline carbonates it is converted into mercurous oxide, ammonia converts it into black mercurous ammonium chloride. By digestion with ammonium chloride it is partially decomposed, mercuric chloride passing into solution and metallic mercury remaining undissolved (Richards and Archibald, Zeitsch. physikal. Chem. 1902, 40, 385). Hydrochloric acid or sodium chloride acts less rapidly. The prolonged action of steam, hot water, or hot air has a similar effect.

Calomel is largely used in medicine. The usual adulterations or impurities are corrosive sublimate, ammonium and sodium chlorides, lead and calcium carbonates and barium sulphate. The last three may be distinguished by their non-volatility, the others by their solubility in water or alcohol. According to Bonnewyn, if the calomel be shaken with a little alcohol the presence of even $\frac{1}{50000}$ part of corrosive sublimate can be detected by the black deposit produced on a knife-blade inserted into the solution.

Mercuric chloride, *Corrosive sublimate* $HgCl_2$. Mercury is converted into this salt when acted on by chlorine or *aqua regia.*

On the large scale it is prepared by distilling mercuric sulphate with common salt. Mercury is gently heated with concentrated sulphuric acid in an iron boiler until sulphur dioxide ceases to be evolved. The whole of the metal having dissolved, a slight excess of sulphuric acid is added to ensure the absence of mercurous sulphate, and a portion is tested by the addition of sodium chloride. If a precipitate of calomel falls, more acid is added. The mixture is evaporated and thoroughly dried. 20 parts of the sulphate is mixed intimately with 8 parts of sodium chloride and 1 part of manganese dioxide (to minimise the production of calomel) and introduced into glass subliming pots which are placed on iron plates, surrounded by sand to the necks and gently heated to remove moisture, which passes, through hoods placed over the necks, into a flue.

The moisture being removed, the hoods are replaced by small inverted conical condensers. Sufficient sand is then removed to uncover the upper half of the flasks, and the heat is increased until the whole has sublimed. The heat is finally raised sufficiently to render the sublimate coherent, but not to melt it. When cooled, the upper half of the flask is cracked away and the cake of sublimate is removed. On the lower part of the cake is frequently found a small quantity of the less volatile *calomel*; this is removed and added to a subsequent sublimation.

Wagner (Dingl. poly. J. 186, 135) recommends for the preparation on the large scale the decomposition of *turpeth mineral* (*v. Mercuric sulphate*) with hydrochloric acid. Mercuric chloride is thus obtained in a solution of sulphuric acid containing excess of mercuric oxide and is removed by crystallisation:

$$HgSO_4{\cdot}2HgO+2HCl=HgCl_2+H_2SO_4+2HgO.$$

For the crude salt, he precipitates mercuric oxide by the addition of sodium hydroxide to mercuric nitrate and digests the precipitate with crude magnesium chloride (the mother-liquor from *carnallite*). Where the presence of potassium chloride is not injurious the carnallite itself may be used, in which case the crystals obtained on evaporation contain $KCl,HgCl_2,H_2O$.

Mercuric chloride occurs as a white, satiny, translucent mass, sp.gr. 5·403; or, when crystallised from solutions, as needles or four-sided prisms, belonging to the rhombic system (Mitscherlich, Pogg. Ann. 1833, 28, 118; Luczizky, Zeitsch. Kryst. Min. 1909, 46, 297). It fuses at 288° (Carnelley) and boils at 303° (Carnelley and Williams), giving a vapour of sp.gr. 9·8, corresponding to the normal molecular weight. The vapour condenses in triclinic crystals (Von Lang, Wien. Akad. Ber. 1862, 45, 119). The relations between the vapour pressures and the molecular volumes of the mercuric halides have been examined by Prideaux (Chem. Soc. Trans. 1910, 97, 2032).

100 parts of water dissolve at 10° 6·57 parts, and at 100° 53·96 parts of the salt. The solution is acid to test paper and gradually deposits calomel on exposure to light. Mercuric chloride is soluble in 3 parts of cold alcohol and in about 1·2 parts of boiling alcohol. It is soluble in 4 parts of cold ether and can be extracted from aqueous solution by this solvent. In aqueous solution, mercuric chloride undergoes electrolytic dissociation only to a very slight degree (Grotrian, Wied. Annalen, 1883, 18, 177; Luther, Zeitsch. physikal. Chem. 1904, 47, 107), but it is partially hydrolysed (Ley, Ber. 1897, 30, 2192). Sulphuric acid precipitates it from aqueous solution (Viard, Compt. rend. 1902, 135, 242), but it dissolves in the strong acid and in nitric acid without decomposition. Aqueous solutions of mercuric chloride decompose in the dark to form mercuric oxide, chlorine, and hydrochloric acid, or in the light to form only mercurous chloride and the acid (Verda, Chem. Zentr. 1907, i. 1392). Mercuric chloride is volatile with steam and the salt can be recognised in the vapour from its solutions by chemical tests, or by its action on a photographic plate (Kof and Haehn, Arch. Pharm. 1907, 245, 529; Zeitsch. physikal. Chem. 1907, 60, 367). The dry salt or its solution is easily reduced, first to calomel, and finally to metallic mercury, by arsenic, zinc, tin, &c.; or by stannous chloride, oxalic acid or other reducing agents (*v. e.g.* de Coninck and Dautry, Bull. Acad. roy. Belg. 1908, 55).

Corrosive sublimate has a sharp, metallic taste and is extremely poisonous. The best antidotes are egg-white, with which it forms an insoluble compound, or, in order of efficacy, sodium thiosulphate ('hypo'), hydrogen sulphide, sodium iodide, sodium bromide, and sodium chloride (Raimondi, Chem. Zentr. 1907, ii. 1807). It is used in medicine both internally and externally, especially in cases of syphilis, and in surgery as an antiseptic in the form of dilute solutions (usually 1 : 1000) and in gauzes and lint. (For the estimation of mercuric chloride in surgical dressing-materials, see Utz, Pharm. Post. 39, 785.) It is also used in preserving anatomical specimens and samples of milk, syrups, &c., for analysis.

Mercuric chloride forms numerous double salts and additive compounds. With the alkali chlorides it forms the compounds $KCl{\cdot}HgCl_2,H_2O$;

$$2KCl{\cdot}HgCl_2,H_2O\ ;\ KCl{\cdot}2HgCl_2,2H_2O\ ;$$

$2NaCl{\cdot}HgCl_2$; $NaCl{\cdot}HgCl_2,2H_2O$, and many others. Of the double salts with ammonium chloride only $HgCl_2{\cdot}2NH_4Cl,H_2O$ can be crystallised from water, but others are formed (Meerburgh, Zeitsch. anorg. Chem. 1908, 59, 136). To the formation of such compounds is due the increased solubility of mercuric chloride in solutions of alkali chlorides and in hydrochloric acid. In many cases, these solutions contain complex anions in which mercury is present (*v.* Shenill, Zeitsch. physikal. Chem. 1903, 43, 705). It forms additive compounds with alcohols and ketones, aromatic nitro derivatives (Mascarelli, Atti. R. Accad. Lincei, 1908, [v.] 17, i. 29), and with alkaloids. The latter compounds are frequently used in the purification of the alkaloids.

A series of *mercury oxychlorides* can be obtained from mercuric chloride by boiling its solution with mercuric oxide or by the action of potassium hydrogen carbonate or calcium carbonate upon it (Tarugi, Gazz. chim. ital. 1901, 31, ii. 313; Arctowski, Zeitsch. anorg. Chem.

1896, 12, 353). $2HgCl_2{\cdot}HgO$ crystallises in red monoclinic needles; $HgCl_2{\cdot}2HgO$ is a black crystalline precipitate and $HgCl_2{\cdot}3HgO$ occurs in glistening yellow scales as the mineral *kleinite* (Sachs, Sitzungsber. K. Akad. Wiss. Berlin, 1905, 1091). Hewitt states that when caustic soda solution diffuses into a solution of mercuric chloride and sodium chloride, very dark red crystals of the formula $Hg_6O_5Cl_2$ are produced (Chem. Soc. Proc. 1907, 23, 10; *v.* also Buttle and Hewitt, Chem. Soc. Trans. 1908, 93, 1405).

Mercurous bromide Hg_2Br_2 is obtained as a white precipitate by adding a soluble bromide to a solution of a mercurous salt, or by the prolonged action of bromine water on the metals. It crystallises from mercurous nitrate solution in white, pearly, tetragonal leaflets, sp.gr. 7·037, but is nearly insoluble in water. At 340°–350° it sublimes without decomposition.

Mercuric bromide $HgBr_2$ is formed from its elements with evolution of heat (Nernst, Zeitsch. physikal. Chem. 1888, 2, 20; Varet, Compt. rend. 120, 620), and is produced by dissolving mercuric oxide in hydrobromic acid. Cold water dissolves 0·4 p.c. and boiling water 2·5 p.c. of the salt, and on cooling it crystallises out in anhydrous glistening scales. From alcohol it crystallises in white rhombic prisms. Mercuric bromide melts at 244° (Carnelly and Williams, Chem. Soc. Trans. 1880, 127) (235° given for m.p. by Guinchant, Compt. rend. 1909, 149, 479). Like the chloride it is decomposed by boiling with water, *oxybromides* being formed (Fischer and Wartenburgh, Chem. Zeit. 1902, 26, 966).

It is occasionally administered in medicine instead of mercuric chloride, usually by hypodermic injection of a solution of the soluble compounds with sodium chloride $HgBr_2{\cdot}2NaCl$ or bromide, $HgBr_2{\cdot}2NaBr$ (Vicario, J. Pharm. Chim. 1907, [vi.] 26).

A double bromide of mercury and potassium has been used as a disinfectant (Cooke, Eng. Pat. 1530, 1905).

Mercurous iodide Hg_2I_2 is a green insoluble powder employed medicinally. It is prepared by triturating a mixture of 5 parts iodine and 8 parts mercury, moistened with alcohol; or by precipitation of a mercurous salt with potassium iodide. A purer product, obtained by boiling excess of iodine with a solution of mercurous nitrate containing nitric acid, crystallises in transparent, yellow, tetragonal plates, blackened by light. When heated it becomes first yellow, then red and finally garnet-red, and on cooling passes through the same colour changes in reverse order. It begins to sublime at about 190° and at 290° melts with decomposition (Stroman, Ber. 1887, 20, 2818; François, J. Pharm. Chim. 1899, [vi.] 10, 16; Compt. rend. 1895, 121, 888; 1896, 122, 190). It dissolves slightly in various oils. The best solvent is castor oil, of which 100 parts dissolves 2 parts of the iodide.

Mercuric iodide HgI_2. A mixture of 5 parts iodine and 4 parts mercury is moistened with a little alcohol, triturated, and sublimed. Dublanc pours 1 kilo. of alcohol upon 100 grams of mercury and adds 124 grams of iodine in 10 successive portions, triturating each time until the alcohol becomes colourless. The last 4 grams usually produce a permanent colour. The precipitate is then washed with alcohol and dried.

In the wet way, which is the best, a solution of 10 parts potassium iodide is added to a solution of 8 parts mercuric chloride, and the precipitate, which is salmon-coloured at first but soon becomes red and crystalline, is washed. A slight excess of either the chloride or iodide will redissolve a portion of the precipitate.

Mercuric iodide may be obtained in comparatively large crystals by the action of a mercuric salt on ethyl or methyl iodides (Bodroux, Compt. rend. 130, 1622); by the action of these iodides on the metal a very pure product may be obtained (Neogi, Chem. Soc. Abstr. 1907, ii. 772).

Mercuric iodide is dimorphous, existing in a red and a yellow form. The *red* variety is produced by the above methods of preparation. It crystallises from hot potassium iodide, alcohol, or nitric acid in tetragonal prisms and pyramids (Luczizky, Zeitsch. Kryst. Min. 1909, 46, 297), and is soluble in many organic solvents (Beckmann and Stock, Zeitsch. physikal. Chem. 1895, 17, 130). Its sp.gr. is 6·26. When heated to 126° it changes into the *yellow* modification with absorption of heat (Guinchant, Compt. rend. 1907, 145, 68). The yellow form melts at 253°–254° and volatilises without decomposition, the vapour density corresponding to the formula HgI_2. By cooling, the liquid or condensing the vapour (Gernez, Compt. rend. 1899, 128, 1516), the yellow modification is obtained in rhombic prisms of sp.gr. 6·06 which retain their form and colour when cooled to the ordinary temperature, but slowly (or immediately on rubbing) pass into the red variety. Nevertheless the yellow form may be kept at the ordinary temperature for many years (Gernez, Compt. rend. 1909, 148, 1015), and it separates from nearly all organic solvents in this form, though it is only stable above 126° (Kastle and Clark, Amer. Chem. J. 1899, 22, 473; Kastle and Reed, *ibid.* 1902, 27, 209; Gernez, Compt. rend. 1903, 136, 889); 129·5° (Reinders, Zeitsch. physikal. Chem. 1900, 32, 507). 1 litre of absolute alcohol at 18° dissolves 11·18 grams of the salt; 80 p.c. alcohol dissolves only 2·86 grams. It is almost insoluble in water; 1 litre at 17·5° dissolves 0·0403 grams (Bourgoin, Bull. Soc. chim. [ii.] 42, 620).

In potassium or other alkaline iodide, it dissolves freely with formation of a double iodide.

The solution in potassium iodide is a more powerful antiseptic than mercuric chloride. It has been employed in the preparation of an antiseptic soap (Thomson, J. Soc. Chem. Ind. 1888, 192). An alkaline solution of mercuric iodide in potassium iodide is employed as a delicate test for ammonia and its compounds, being known as *Nessler's solution.*

In mercuric chloride it dissolves readily, forming a double chloride and iodide.

Mercuric iodide forms a very large number of double salts (*v.* Duboin, Ann. Chim. Phys. 1909, [viii.] 16, 258). With alkali iodides and ether it forms both crystalline and liquid compounds, *e.g.* $KHgI_3{\cdot}3Et_2O$, and $KHgI_3{\cdot}4Et_2O$ (Marsh. Chem. Soc. Trans. 1910, 2297).

Mercuric iodide is much used in photography as an intensifier, a solution in sodium sulphite containing the proportions, $HgI_2 : Na_2SO_3$: water : : 1 : 10 : 100, being the best. For details see Lumière Bros. and Seyewetz (Monit. Scient. 1899, 13, 782; J. Soc. Chem. Ind. 1899, 1155).

Mercurous fluoride Hg_2F_2, produced by the action of hydrofluoric acid on the carbonate or of silver fluoride on calomel (Finkener, Pogg. Ann. 110, 142), is a yellow crystalline powder, hydrolysed by hot water and blackened by light.

Mercuric fluoride $HgF_2,2H_2O$, prepared by dissolving mercuric oxide in aqueous hydrofluoric acid (Finkener, Pogg. Ann. 110, 628) is a white crystalline salt. It is decomposed in air at 50° forming an *oxyfluoride* $HgF(OH)$; and in dilute aqueous solution is completely hydrolysed, but without formation of oxyfluorides (Jaeger, Zeitsch. anorg. Chem. 1901, 27, 22; Cox, *ibid.* 1904, 40, 146).

Mercurous sulphate $Hg_2(SO_4)_2$ is prepared by dissolving 2 parts mercury in 3 parts sulphuric acid with the aid of a gentle heat; or by the addition of sulphuric acid to a solution of mercurous nitrate; or by the electrolysis of sulphuric acid with a mercury anode (Hulett, Zeitsch. physikal. Chem. 1904, 49, 494). It is a white crystalline salt which with water yields first the basic salt $Hg_2SO_4 \cdot Hg_2O,H_2O$, and finally the oxide.

Mercurous sulphate is used in the standard cells of Clark and Weston.

Mercuric sulphate $HgSO_4$ is prepared by dissolving mercury in strong sulphuric acid with the aid of heat, or mercuric oxide in dilute sulphuric acid. Its preparation has been described under *Mercuric chloride.*

From its solution in sulphuric acid it crystallises in small, silvery, stellate plates. When strongly heated, it becomes reduced to mercurous sulphate with evolution of oxygen, mercury, and sulphur dioxide.

It is soluble in sodium chloride solution. When heated with water it produces a yellow basic sulphate $HgSO_4 \cdot 2HgO$, which turns red when heated, known as *turpeth* or *turbith mineral*, which is soluble in 2000 parts of cold and 600 parts of hot water. Turpeth appears to be the only basic sulphate which can exist in equilibrium with water at 25° (Cox, Zeitsch. anorg. Chem. 1904, 40, 165; Hoitsema, Zeitsch. physikal. Chem. 1895, 17, 651; Guinchant, Bull. Soc. chim. 1896, [iii.] 15, 555). A thiobasic mercuric sulphate, $4HgO \cdot 2HgS \cdot 3SO_3,4H_2O$, has been described by Estrup (Zeitsch. anorg. Chem. 1909, 62, 168).

Nitrates. Several nitrates of mercury are known. When excess of mercury is dissolved in a cold mixture of 1 part nitric acid and 4 parts water, the *mercurous* salt is formed. If the acid be sufficiently strong to effervesce, or be used in excess, or if the mixture be heated, *mercuric* nitrate is produced.

Mercurous nitrate $Hg_2(NO_3)_2$ forms monoclinic tables containing 2 molecules of water. They effloresce and become anhydrous in dry air and when heated to 70° melt to a clear liquid of sp.gr. 4·3 (Retgers, Jahrb. Min. 1896, ii. 183). The pure salt is immediately decomposed by water with formation of a basic nitrate, and when it is boiled with water mercury is volatilised and may be condensed in globules (Hada, Chem. Soc. Trans. 1896, 1667). Several basic nitrates are known (*v.* Cox, Zeitsch. anorg. Chem. 1904, 40, 174).

Mercuric nitrate $Hg(NO_3)_2$ is produced by boiling mercury with nitric acid until the solution no longer gives a precipitate with sodium chloride. Large crystals containing

$$2Hg(NO_3)_2,H_2O$$

separate on concentration.

The action of water at 25° on mercuric nitrate produces a basic salt, $Hg(NO_3)_2 \cdot 2HgO$, as a heavy white powder, which is decomposed on further treatment with water yielding the oxide (Cox, Zeitsch. anorg. Chem. 1904, 40, 159).

Mercurous nitrite $Hg_2(NO_2)_2$ is produced by the action of dilute nitric acid upon mercury and forms yellow needles which are partially decomposed by water. Dilute nitric acid slowly converts it into mercurous nitrate, and when heated it decomposes yielding nitric oxide, mercurous nitrate, mercury, and mercuric oxide (Rây, Zeitsch. anorg. Chem. 1896, 12, 365, Chem. Soc. Trans. 1897, 337; Rây and Sen, *ibid.* 1903, 491). The pure salt has sp.gr. 5·925 (Rây, Chem. Soc. Trans. 1908, 999).

Mercuric nitrite $Hg(NO_2)_2$ is obtained by the action of mercuric chloride on silver nitrite or by the decomposition of mercurous nitrate by water (Rây, Chem. Soc. Proc. 20, 57; Chem. Soc. Trans. 1897, 71, 337).

Mercuric hyponitrite HgN_2O_2, formed by the action of sodium hyponitrite on mercuric nitrite, is a buff-coloured powder which decomposes spontaneously into nitric oxide and mercurous hyponitrite (Divers, Chem. Soc. Trans. 1899, 119; see also Rây, *ibid.* 1907, 1404, 2031; Rây and Gañguli, *ibid.* 1399).

Mercury nitride N_2Hg_3 is produced as a brown powder by the action of potassamide on mercuric bromide in liquid ammonia solution. When dry it is very explosive (*v.* Franklin, Zeitsch. anorg. Chem. 1905, 46, 1).

Mercury acetylide (*mercury carbide*)

$$3C_2Hg,H_2O,$$

prepared by passing acetylene into a solution of mercuric oxide in ammonium hydrate and carbonate, is a heavy white powder, which is explosive (*v.* Plimpton and Travers, Chem. Soc. Trans. 1894, 264). For the action of acetylene on solutions of mercuric chloride and acetate, see Burkard and Travers (Chem. Soc. Trans. 1902, 81, 1271); Biltz and Mumm (Ber. 1904, 37, 4417), and Brame (Chem. Soc. Trans. 1905, 427).

Mercuric cyanide $Hg(CN)_2$ is prepared by boiling a solution of 1 part potassium ferrocyanide and 2 parts mercuric sulphate in 7 parts water:

$$2K_4Fe(CN)_6+7HgSO_4$$
$$=6Hg(CN)_2+4K_2SO_4+Fe_2(SO_4)_3+Hg.$$

It may also be prepared by adding 31 grams sodium cyanide dissolved in 50 c.c. water to 90 grams mercuric sulphate. Heat is evolved and the whole solidifies to a mass of granular mercuric cyanide which is extracted with boiling alcohol and finally recrystallised from water (Rupp and Goy, Apoth. Zeit. 1908, 23, 374).

It crystallises in white needles or tetragonal prisms soluble in 8 parts of cold water, insoluble in absolute alcohol. When ignited, it decomposes with evolution of cyanogen.

In aqueous solution mercuric cyanide only undergoes ionic dissociation to a very small extent, and therefore does not exhibit all the usual reactions of mercuric salts. For example, with potassium iodide it yields, not mercuric iodide, but a complex salt $Hg(CN)_2{\cdot}HgI_2{\cdot}2KCN$ (Rupp and Goy, Arch. Pharm. 1909, 247, 100). It is decomposed with formation of hydrocyanic acid by hydrochloric, hydrobromic, and hydriodic acids, or by sulphuretted hydrogen, but not by dilute sulphuric or nitric acids.

The aqueous solution readily dissolves mercuric oxide forming the basic salt $Hg(CN)_2{\cdot}HgO$, which is used as an antiseptic under the name of *mercuric oxycyanide* (Holdermann, Arch. Pharm. 1905, 243, 600; 1906, 244, 133; Rupp, *ibid.* 1906, 244, 1).

Mercuric thiocyanate $Hg(CNS)_2$ is prepared by the addition of an excess of mercuric chloride to a solution of ammonium thiocyanate. It forms a white crystalline precipitate which burns freely when ignited with evolution of mercurial vapours, and forms a most voluminous ash.

It is occasionally made into a thick paste with gum and worked into pilules which when dried are sold as *Pharaoh's serpents' eggs.*

It is soluble in a solution of ammonium thiocyanate and this solution, under the trade-name 'Agfa,' is used as an intensifier for photographic negatives (Eberhard, Photo. Mittheil, 1901, 38, 15; J. Soc. Chem. Ind. 1901, 387).

AMMONIACAL COMPOUNDS OF MERCURY.

Very many of these compounds have been described, but little is known as to their constitution because the ordinary methods for the determination of molecular weight are not applicable to them.

It is probable that there exist substitution products of ammonia of the type $(OHg_2)NH_2{\cdot}X'$ (*amino-mercuric compounds*); substitution products of ammonium compounds of the type

$$NHg_2X'{\cdot}H_2O$$

(*mercuri-ammonium compounds*); and additive compounds of ammonia and mercuric salts. (*See* Rammelsberg, J. pr. Chem. 1888 [ii.] 38, 558; Barfoed, *ibid.* 1889, [ii.] 39, 201; Pesci, Gazz. chim. ital. 1891, 21, 569; Zeitsch. anorg. Chem. 1899, 21, 301; *see also* Hofmann and Marburg, Annalen, 1899, 305, 198; Zeitsch. anorg. Chem. 1900, 23, 126; Franklin, J. Amer. Chem. Soc. 1907, 29, 35.)

Millon's base has the empirical formula $H_5O_3NHg_2$, and is regarded as *dihydroxydimercuriammonium hydroxide* $(HO{\cdot}Hg)_2:NH_2{\cdot}OH$, or as dimercuriammonium hydroxide

$$NHg_2{\cdot}OH{\cdot}2H_2O.$$

It is formed as a pale yellow powder when mercuric oxide is gently warmed with dilute ammonia. It deflagrates when heated.

Salts of Millon's base are formed by digesting the base with dilute acids, or by adding ammonia to solutions of mercuric salts of oxyacids. Anhydrous salts of the formula NHg_2X' have been obtained but are probably not true derivatives of Millon's base, but amino compounds of the type $Hg:N{\cdot}HgX'$ (Franklin, Zeitsch. anorg. Chem. 1905, 46, 1; *see also* François, Compt. rend. 1900, 130, 332, and 1022).

The iodide of Millon's base $(OHg)_2NH_2{\cdot}I$ (*oxydimercuriammonium iodide*) is formed by adding ammonia to a solution of mercuric potassium iodide (Nessler's solution, *v.* ANALYSIS), or by the action of excess of ammonia on mercuric iodide. It is a brown powder, fusible without decomposition.

Amino-mercuric chloride, *Infusible white precipitate* $NH_2{\cdot}HgCl$ (Hofmann and Marburg; Franklin), is prepared by the addition of ammonia to a solution of mercuric chloride. For medicinal purposes 1 ounce of mercuric chloride is dissolved in 3 quarts of water, and to the cool solution 8 fluid ounces of concentrated ammonia is added with frequent agitation, and the precipitate is washed and dried.

It is a white, inodorous, highly poisonous powder, totally volatile on heating to 360°, slightly soluble in boiling water, easily soluble in nitric, hydrochloric and sulphuric acids, insoluble in alcohol.

An analogous compound derived from ethylamine, $NH(C_2H_5)HgCl$, is known.

Fusible white precipitate $Hg(NH_3)_2Cl_2$ is produced by boiling the above compound with ammonium chloride solution, and form crusts of small regular dodecahedra.

MERCURY SALTS OF ORGANIC ACIDS.

Mercurous formate $Hg_2(HCO_2)_2$, obtained by adding sodium formate to mercurous nitrate solution forms white leaflets soluble in 250 parts of water at 17°. When boiled with water it is reduced to metallic mercury (Liebig, Annalen, 3, 207).

Mercuric formate $Hg(HCO_2)_2$, obtained by solution of yellow mercuric oxide in dilute formic acid, slowly changes to mercurous formate with liberation of formic acid and carbon dioxide (Varet, Compt. rend. 1905, 140, 1641).

Mercurous acetate $Hg_2(CH_3{\cdot}CO_2)_2$ forms white leaflets, more stable than the formate, soluble in 133 parts of water at 12°–15° (Lefort, Annalen, 56, 247).

Mercuric acetate $Hg(CH_3{\cdot}CO_2)_2$ also forms white leaflets soluble in 2·75 parts of water at 19° and in 1 part at 100°. The aqueous solution is acid, and on warming the salt is largely hydrolysed. Both these salts are used in medicine for the treatment of skin diseases.

Mercuric oleate and **stearate,** prepared by double decomposition, are used in pharmacy (Dott, Chemist and Druggist, 1909, 74, 785).

Mercurous oxalate $Hg_2C_2O_4$ is a white salt, very slightly soluble in water, insoluble in excess of oxalate (Schäfer and Abegg, Zeitsch. anorg. Chem. 1905, 45, 299). It has been used in gelatin emulsions for phototype printing (Castellani, Phot. Korr. 1906, 43, 281; J. Soc. Chem. Ind. 1906, 827).

Mercuric oxalate HgC_2O_4 is also sparingly soluble in water, but forms soluble double salts with many oxalates. In solution it is quantitatively reduced to mercurous oxalate by the action of light (Roloff, Zeitsch. physikal. Chem. 1894, 13, 324). This reaction is made use of in *Eder's mercury oxalate photometer* (*v.* Abegg, Zeitsch. Elektrochem. 1903, 9, 569). The sensitiveness of the solution to light is increased by the fluoresceins and their sodium salts (Jodlbauer and Tappeiner, Ber. 1905, 38, 2602).

Mercury fulminate $(C:N{\cdot}O)_2Hg,\frac{1}{2}H_2O$ is prepared by adding 17 parts of alcohol (90 p.c.) to a cold solution of 3 parts of mercury in 36 parts of nitric acid (sp.gr. 1·34), contained in a large flask. The mixture froths and turns black, and a very violent reaction takes place which is moderated by the addition of another 17 parts of alcohol. On the large scale the reaction is carried out by mixing in large glass balloons 1 part of mercury, 10 parts of nitric acid (sp.gr. 1·33), and alcohol (sp.gr. 0·833) in the proportion of 1 litre to each kilo. of acid. The reaction generally begins spontaneously and is allowed to proceed by itself (Beckmann, Ber. 1886, 19, 993; Lobry de Bruyn, *ibid.* 1370) (*v.* FULMINIC ACID).

On cooling the solution produced by either method, mercuric fulminate crystallises in shining white or grey coloured prisms, sp.gr. 4·42. It is insoluble in cold water, but fairly soluble in hot water and in aqueous ammonia (*v.* Steiner, Ber. 1876, 9, 779).

Mercuric fulminate explodes violently on percussion or when treated with sulphuric acid, and is much used as a detonator (*v.* EXPLOSIVES); but when ignited with a flame it burns with a reddish flame yielding carbon monoxide, nitrogen, and mercury.

Mercury gallate, prepared by triturating 37·6 grams gallic acid and 21·6 grams yellow mercuric oxide in 25 c.c. of water, is used therapeutically as an antisyphilitic (Brousse and Gay, Compt. rend. 1893, 117, 284).

Mercury tannate is prepared by triturating mercurous nitrate (20 grams) with tannin (12 grams), and is also used in medicine (Zdarck, J. Pharm. d'Anvers, 58, 98).

Mercuric *p*-phenolsulphonate is used medicinally under the name '*hydrargyrol*,' and its compound with ammonium tartrate is similarly used and known as '*asterol*.'

ORGANIC MERCURY DERIVATIVES.

Mercury can replace hydrogen in most organic compounds, and the substances so formed fall into two broad classes: (*a*) those in which mercury is attached to carbon, and (*b*) those in which it is attached directly to nitrogen. Generally, compounds of class (*a*) are non-electrolytes and in general chemical properties resemble the parent compounds. Compounds of class (*b*) are usually less stable and in solution show the reactions of the mercuric ion.

Mercury Derivatives of Aliphatic Compounds.

Mercury alkyl derivatives are of two classes:

(1) Monalkyl derivatives

$X{\cdot}Hg{\cdot}C_nH_{2n+1}(X{=}Cl,Br,I,\ etc.)$

(2) Dialkyl derivatives $Hg(C_nH_{2n+1})_2$.

(1) *Monalkyl mercury compounds* are prepared:

(*a*) By the action of mercury on alkyl iodides in sunlight.

(*b*) By the action of halogens, haloid acids, or mercury halides on the dialkyl derivatives.

The halogen compounds are usually colourless crystalline solids, which have a definite melting-point and can be sublimed and distilled in steam. Treated with moist silver oxide they yield hydroxy compounds which are thick liquids, soluble in water and alcohol, strongly basic in character and forming series of salts.

Methyl mercuric iodide $CH_3{\cdot}HgI$, forms colourless crystals, m.p. 143°, which sublime when heated (Frankland, Annalen, 85, 361).

Ethyl mercuric chloride $C_2H_5{\cdot}HgCl$. forms pearly leaflets, sp.gr. 3·48, subliming at 40° (Dünhaupt, Annalen, 92, 379; *see* also Buckton, *ibid.* 112, 221).

Ethyl mercuric hydroxide $C_2H_5{\cdot}HgOH$, produced by the action of moist silver oxide on the preceding compound, is a viscous caustic liquid which gives rise to a number of salts.

(2) *Mercury dialkyls* are prepared:

(*a*) By the action of sodium amalgam on alkyl iodides in presence of ethyl acetate (Frankland, Annalen, 130, 105).

(*b*) By the action of potassium cyanide on mercury alkyl iodides.

(*c*) By treating zinc alkyls with mercuric chloride or an alkyl mercuric chloride (*v.* also Buckton, *ibid.* 108, 103).

They are colourless heavy liquids, unchanged by air or water at the ordinary temperature. They have a peculiar faint odour, and are extremely poisonous (*v.* Hepp, Ber. 1887, Ref. 798). When heated in air they burn.

Mercury dimethyl $Hg(CH_3)_2$ has b.p. 93°–96° and sp.gr. 3·07. Hydrochloric acid converts it into mercuric chloride (Seidel, J. pr. Chem. [ii.] 29, 134).

Mercury diethyl $Hg(C_2H_5)_2$ has b.p. 159°, sp.gr. 2·44. Mixed mercury alkyls of the type $CH_3{\cdot}Hg{\cdot}C_2H_5$, have not been obtained (Frankland, Annalen, 111, 57; Buckton, *ibid.* 109, 222).

(For an account of the many known aliphatic compounds containing mercury, *see* Beilstein's Handbuch der Org. Chem. Bd. i. 1524–1526; suppl. i. 854.)

Mercuriethylene-diamine sulphate

$Hg(CH_2{\cdot}NH_2)_2{\cdot}H_2SO_4$

mixed with a molecular proportion of ethylene diamine is used as an antiseptic under the trade name '*sublamin*.' It does not precipitate soap, or coagulate albumen, and has a greater germicidal and a less toxic action, weight for weight, than mercuric chloride (Scordo, Chem. Soc. Abstr. 1907, ii. 713; Pesci, Gazz. chim. ital. 1909, 39, i. 143).

Mercury Derivatives of Aromatic Compounds.

Aryl mercuric compounds are formed with an ease comparable with that of sulphonation or nitration and the metal enters the usual position in the molecule (except in the case of benzoic acid, *v.i.*). They are usually prepared by boiling the aryl compounds with mercuric chloride solution. When acted on by stannous chloride in alkaline solution they yield mercury and mercury aryls of the type HgR_2 (Dimroth, Chem. Zentr. 1901, i. 449).

Mercury diphenyl $Hg(C_6H_5)_2$ is prepared by heating bromobenzene, mercuric chloride, and metallic sodium in benzene (Michaelis and Reese, Ber. 1882, 2876); or by heating bromobenzene with an equal volume of xylene, a little ethyl acetate and excess of sodium amalgam (Aronheim, Annalen, 194, 145). It is also obtained by the action of mercuric chloride on an ethereal solution of magnesium phenylbromide (Pfeiffer and Truskier, Ber. 1904, 37, 1125). It crystallises from benzene in white needles or rhombic prisms, m.p. 125°–126°, is easily volatile and gives a vapour irritating to the eyes. Mercury diphenyl has a therapeutic action equal to that of the fatty compounds, but it is less poisonous (Louise and Moutier, Compt. rend. 1905, 140, 1703).

Phenyl-mercuric chloride $C_6H_5{\cdot}HgCl$, made by the action of chlorine on mercury diphenyl, forms small white rhombic prisms, m.p. 250° (Dreher and Otto, Annalen, 154, 93).

Phenyl-mercuric hydroxide $C_6H_5{\cdot}HgOH$ is a strongly-caustic liquid and forms numerous salts (Otto, Ber. 1885, 246).

Mercury di-tolyls, di-xylyls, di-napthyls, &c., are known, and each forms similar series of compounds.

o- and *p-Hydroxyphenyl mercurioxides* and *hydroxy-phenylene-dimercuryoxides* are present in the so-called 'mercury phenate,' the *hydrargyrum carbolicum,* of the pharmacopœias (Dimroth, Ber. 1902, 35, 2853). This is obtained by precipitating a solution of mercuric chloride with sodium phenate (Merck, Apoth. Zeit. 1889, 4, 651; Andres, Pharm. Zeitsch. Russe, 27, 625), and is used medicinally in the treatment of syphilis.

o-Hydroxymercuribenzoic anhydride

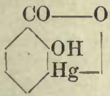
$$C_6H_4\left<\begin{matrix}Hg\\CO\end{matrix}\right>O$$

is the chief constituent of the 'mercury benzoate' used medicinally. It is prepared by digesting freshly precipitated mercuric oxide with benzoic acid and water and is formed by the action of dilute acids on the salts of *o-hydroxymercuribenzoic acid*

$$C_6H_4\left<\begin{matrix}Hg{\cdot}OH\\CO{\cdot}OH\end{matrix}\right.$$

o-Mercuridibenzoic acid $Hg:(C_6H_4{\cdot}COOH)_2$ is also known (Pesci, Atti. R. Accad. Lincei, [v.] 10, i. 413).

Anhydro-o-hydroxymercurisalicylic acid



is produced by boiling mercury salicylate with water for 15 minutes, and is therefore the main constituent of '*hydrargyrum salicylicum,*' which is prepared by digesting yellow mercuric oxide with aqueous salicylic acid. It is much used in the treatment of syphilis (Buroni, Gazz. chim. ital. 32, ii. 307; Dimroth, Ber. 35, 2872; *see* also Larin, Chem. Zeit. Rep. 1901, 25, 193).

(For further details of mercury aromatic compounds and a complete bibliography, *v.* Beilstein, Handbuch der Org. Chem. Bd. iv. 1703–1713; suppl. iv. 1208–1218.

For further information as to mercury compounds used in medicine, *v.* Hare, Caspari, and Rusby, National Standard Dispensatory (1905), 784.)

MESITOL *v.* PHENOL AND ITS HOMOLOGUES.

MESITYLENE *v.* CUMENES.

MESORCINOL *v.* PHENOL AND ITS HOMOLOGUES.

MESOTAN. Trade name for a yellowish oily liquid, $OH{\cdot}C_6H_4{\cdot}CO{\cdot}OCH_2{\cdot}OCH_3$, obtained by treating sodium salicylate with monochlordimethyl ether (*v.* SYNTHETIC DRUGS).

MESO-THORIUM *v.* RADIOACTIVITY and THORIUM.

MESOXALIC ACID *v.* KETONES.

META-ARABIC ACID *v.* GUMS.

METACETONE. By heating sugar with lime Fremy obtained a substance, b.p. 84°, to which he gave the name *metacetone* and the formula $C_6H_{10}O$. Fischer and Laycock find that this body is in reality a mixture of *propylaldehyde, dimethylfurfuran,* a third substance with the properties of a hydrocarbon, and a number of other lower and higher boiling homologues. Fischer and Laycock distilled 100 kilos. of sugar and 300 kilos. of burnt lime, and collected the distillate in fractions. Fraction *a*, distilling below 65°, combined partly with phenylhydrazine, yielding the phenylhydrazone of propylaldehyde. The distillate boiling at 25°–45°, consisted of furfuran, and that boiling at 45°–65° is probably methylfurfuran. Fraction *b*, distilling at 65°–115°, was treated like fraction *a*, phenylhydrazine being added, and the product distilled. The distillate consisted of a hydrocarbon and a substance which dissolved on heating with dilute hydrochloric acid to 170°, forming acetonylacetone, and which is probably dimethylfurfuran. The residue, which combined with phenylhydrazine is the phenylhydrazone of propylaldehyde. The fraction boiling above 115° is a complex mixture, consisting of higher homologues of furfuran and aldehydes, which could be removed with sodium bisulphite.

Fischer and Laycock have investigated wood tar, and found that this likewise contains propylaldehyde and dimethylfurfuran (Ber. 1889, 22, 101).

METACETONIC ACID *v.* PROPIONIC ACID.

METALDEHYDE *v.* ALDEHYDE.

METALLIC SOAPS *v.* SOAPS.

METALLOGRAPHY deals with the internal structure and constitution of metals and their alloys. The science is a comparatively young one, dating back only to 1864, when Sorby (Proc. Sheffield Lit. Phil. Soc. 1864) first applied the microscope to the study of metals and established the close analogy which exists between the internal structure of metals and of rocks. Sorby's pioneer work, however, remained neglected for a long time, and the microscopic study of metals and alloys was revived independently in Germany by Martens (A. Martens, Zeitsch. Ver. deut. Ing. 1878, 22, 11) and in France by Osmond (F. Osmond and J. Werth, Compt. rend. 1885, 100, 450). Since then the subject has developed rapidly, and now numbers many enthusiastic workers, among whom may be mentioned in England the late Roberts-Austen, Arnold and Stead; in France Osmond, Le Chatelier, Charpy, and Guillet; and in Germany Heyn, Wüst, Friedrich, and Tammann.

The metallographic study of metals and alloys is carried out by both microscopical and physical means, the most important of the latter being the thermal or pyrometric study of the behaviour of these bodies on heating and cooling. Other physical methods, such as measurements of thermal expansion, electrical resistance, solution potential, and many other quantities have also been employed. The pyrometric method is, however, at present far the most fruitful and important, and in the present article attention will be almost entirely confined to this one among the physical methods just referred to. In the majority of metallographic researches the pyrometer and the microscope are practically the only instruments used.

The pyrometric study of metals and alloys consists in observing the phenomena which occur in the heating or cooling of the substance between the ordinary or even an artificially lowered temperature, and a high temperature at which the metal or alloy is completely molten. The phenomena in question arise from the fact that when the substance undergoes either a change of state, an allotropic or polymorphic transformation, or a chemical reaction, these changes are almost universally accompanied by an absorption or an evolution of heat. A familiar example is found in the freezing of water to form ice, a process which is accompanied by the evolution of a very large amount of heat, viz. the latent heat of fusion of the water. If the cooling process of a body liable to such changes is followed with a suitable instrument for measuring temperatures, and the rate of cooling be observed it is found that the occurrence of a heat-evolution at any stage of the cooling process results in a retardation, and sometimes even in an entire cessation of the cooling process—the heat evolved by the transformation of the substance for a time balances the loss of heat due to radiation, conduction, &c., and keeps the temperature stationary. For this reason the temperature at which such changes occur are frequently referred to as 'arrest-points' in the cooling (or heating) 'curves' of the body in question. In the case of metals, these curves are obtained by means of a pyrometer, and generally some form of time-observation which enables the observer to record the rate of cooling over the whole range of temperatures involved. Such observations are most simply represented by plotting them in a curve having the temperature of the metal as ordinate and the time as abscissa, such a curve being known as a 'time-temperature' cooling (or heating) curve; on such a curve the arrest-points are shown as more or less marked flattenings of the curve (Fig. 1). If it is desired to plot such a curve on a large scale—and in practice the temperature range involved may be as much as 1000°—this mode of plotting is found cumbersome, and it is preferable to plot the observations in the form of an 'inverse rate' curve. The ordinates of this curve are again the temperatures of the metal, but the abscissæ are the time-intervals occupied by each successive decrement (or increment) of the temperature of the metal. Thus, during the steady cooling preceding the commencement of solidification, each fall in temperature of 3° might occupy, for example, 12 seconds; then the 3° interval including the commencement of freezing might occupy a time of 120 seconds, the next following fall of 3° might occupy 40 seconds, and the following one as little as 10 seconds; in the inverse-rate curve these observed intervals would be plotted against the mean temperature of each 3° interval. In these curves, uniform rates of cooling are represented by vertical lines, while arrest-points appear in the form of more or less sharp peaks, whose areas approximately represent the quantity of heat evolved by the transformation in question (W. Rosenhain, Observations on Recalescence Curves, Proc. Phys. Soc. London, 1908, 21, 180; *see* Fig. 2). Both types of curves represent observations of time and temperature; in another method of working, the temperature of a uniformly cooling body, such as a piece of pure platinum or porcelain, is used as one of the elements of the curve. Against the actual temperature of the cooling piece of metal is plotted the difference between its temperature and that of the neutral comparison body just mentioned; this method—known as the 'differential' or difference method of Roberts-Austen—has the advantage of extreme delicacy, but it is somewhat more laborious and requires more skill on the part of the observer in manipulating the apparatus, while it is also limited to the observation of heat-evolutions occurring at temperatures at which the metal in question remains solid. For all these methods of taking cooling or heating curves, the temperature observations are usually made by means of a thermo-couple whose E.M.F. is measured in some convenient way. The most widespread method of making this measurement is by reading the deflection of a galvanometer, usually of the moving-coil type, but this method has serious disadvantages, and for cases where any considerable accuracy is required the electro-motive force of the couple should be measured accurately by means of some suitable form of potentiometer (W. Rosenhain, The Metallographic Investigation of Alloys, Journ. Inst. Metals, 1909, i. 200; Observations on Recalescence Curves, Proc. Phys. Soc. London, 1908, 21, 180). The neglect of this condition has rendered a large amount of metallographic investigation unreliable.

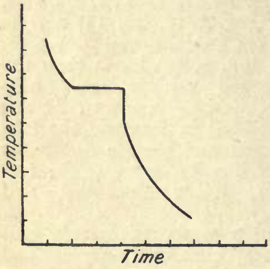


FIG. 1.

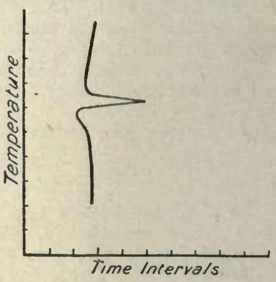

FIG. 2.

The cooling-curves of metals and alloys, taken from a temperature at which the metal is liquid downwards, always show as the highest arrest-point the initial 'freezing-point' of the metal; below this temperature, at which the liquid metal first begins to deposit solid crystals, the cooling-curves may show from one up to four or five further arrest-points, even in simple alloys containing two metals only. In studying such a 'binary' system of alloys, the arrest-points on the cooling-curve of each alloy are generally plotted as points on a diagram in which the concentration of the alloy is used as abscissa and the temperatures as ordinates, the result being a temperature-concentration diagram. If properly completed in such a manner as to indicate all the conditions in which alloys of the two metals can exist in equilibrium at all possible temperatures and concentrations, this diagram is termed the 'equilibrium diagram' of the binary system in question. As a rule, however, the mere plotting of observed arrest-points in the cooling-curves of a series of alloys is not enough to allow such a diagram to be drawn, the evidence of the microscope and of other physical methods being often required to allow of the correct interpretation of the arrest-points observed. The first and simplest line of such an equilibrium diagram is that known as the 'liquidus'; this is the boundary of the region in which the alloys are completely liquid; immediately below the 'liquidus' the alloys in general consist of a mixture of liquid with solid crystals, although in some cases the range of temperature over which such a mixture occurs is very short—in pure bodies, consisting entirely of one chemical entity (pure element or pure compound) the whole process of solidification occurs at a single definite temperature and no region of mixed solid and liquid exists. The liquidus line of the equilibrium diagram can, as a rule, be drawn definitely from pyrometric observations alone, although exceptions occur in the case of pairs of metals possessing either limited miscibility in the liquid state or where the formation of a definite compound takes place slowly in the liquid metal. In other cases, small breaks of continuity in the liquidus curve cannot be definitely located by pyrometric observations alone.

The process of solidification which follows, in any given alloy, upon the commencement of freezing at the temperature of the 'liquidus' curve depends, in the first place, upon the position of the alloy in the binary system to which it belongs and also upon the type which that system follows. This type depends again upon the manner in which the two component metals undergo mutual mixture, solution, combination, or separation during freezing and melting. A large number of these types can be distinguished, but only the most important can be mentioned here. The first and simplest type are those alloys in which the two metals, when they have reached their final equilibrium in the solid state, retain the condition of intimate mixture in which they existed in the liquid state at a higher temperature. In the language of metallography, two such metals form an unbroken series of solid solutions. In their final condition such alloys resemble pure metals in being built up of an aggregate of crystals which are all alike in composition and properties. In the cooling and freezing process, however, the alloys of such a series differ markedly from pure metals in showing at times a very wide range of temperature over which the freezing process is distributed. The equilibrium diagram of such a system of alloys is shown in Fig. 3. the line ACB representing the liquidus or line of commencing freezing, and ASB representing the line of complete solidification or 'solidus.' At temperatures lying between these two lines the alloys consist of a definite proportion of solid crystals in equilibrium with liquid alloy, but it is important to notice that the compositions of the crystals and of the liquid in equilibrium with them are not identical.

The opposite extreme to the type of alloys just described is found in those groups where the component metals are completely, or almost completely, immiscible in the solid state. A typical equilibrium diagram of this type is shown in Fig. 4, where the liquidus curve is represented by the lines ACB, forming a more or less deep V; the addition of the metal A to the metal B lowers the temperature of initial freezing, and this lowering is continued with increasing additions of B. Similarly successive additions of A lower the initial freezing temperature of B until a concentration is attained where the two branches of the liquidus curve meet at the point C, which represents the freezing-point of the most fusible alloy of the series. This alloy, both in the free state and when it occurs as a constituent of alloys of different composition, is known as the 'eutectic' alloy of the series, or more briefly as 'the eutectic' (Guthrie, Phil. Mag. 1884, [v.] 17, 462). This eutectic alloy shares with the pure metals and with pure inter-metallic compounds the property of undergoing complete solidification at one temperature instead of showing a 'freezing range.' The solidification of any alloy of intermediate composition, such as that represented by the line PQ, may be described as follows: when the cooling alloy reaches the temperature at which the lines PQ and AC intersect, solid crystals begin to separate, but these are crystals of the metal A. As a result of this separation, the residual liquid metal or 'mother liquor' becomes enriched in B; the residual liquid is now, in fact, an alloy lying further to the right than the line PQ. As the temperature falls, the temperature of initial freezing of this richer alloy is reached and a further quantity of solid A is separated, again increasing the concentration of B in the liquid. This process is continued until the concentration of the point C, and its temperature, are simultaneously reached. At that point the residual liquid has the composition of the eutectic alloy and solidifies as such. The alloy thus becomes completely solid on reaching the temperature of the line DE, which is usually called the eutectic line—this line (CE) is, therefore, in this case, the 'solidus' of the system, since it forms the boundary of the region of completely solid alloys. An alloy such as PQ, at all temperatures below that of DE consists of an agglomerate of crystals of the metal A embedded in a matrix of the eutectic alloy; if the composition of the alloy is such that the line PQ lies close to A, then the crystals of A in the solid alloy will be large and numerous, and little eutectic will be present, while, as the point C is approached, the proportion of eutectic

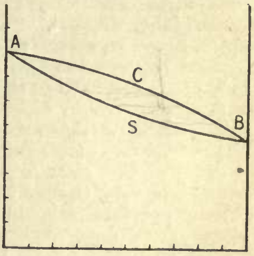

FIG. 3.

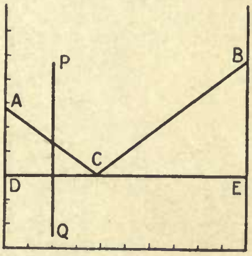

FIG. 4.

increases. On the other side of C, the alloys consist of crystals of B embedded in the eutectic, and these crystals increase in amount as we move from C to B. Actual examples of binary alloys strictly following this simple type are rare, if indeed they exist at all; so far as at present known the alloys of lead and antimony approximate closely to this type (Antimony-Lead, Gautier, Recherches sur la fusibilité des alliages metalliques, Bulletin de la Soc. d'Encouragement, 1896; Gold-Thallium, Levin, Zeitsch. anorg. Chem. 1905, 45, 31). The great majority of alloys, however, belong to a type which is intermediate between the two extremes which have just been described; this intermediate type consists of alloys in which the two component metals are mutually soluble in the solid state to a limited extent. The typical equilibrium diagram of this class is given in Fig. 5. The liquidus is very similar to that of type II., a eutectic point being again evident at C, but the eutectic line DE no longer crosses the whole width of the diagram. Alloys from O to F and from H to G behave as regards solidification exactly like alloys of type I., forming homogeneous crystalline aggregates which consist of only a single constituent. Alloys from F to G, however, behave like members of type II., but with the difference that the substance which commences to crystallise when these alloys reach the temperature of the line AC is not pure A, but a solid solution of B in A, or, if the alloy lies to the right of C, the crystals consist of a solid solution of A in B.

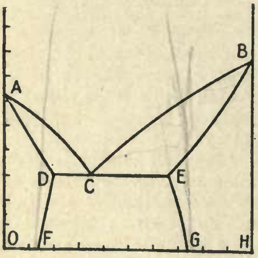

FIG. 5.

A considerable number of further types of binary series of alloys can be distinguished, but it is not possible to deal with these fully here. The only other class which need be mentioned are those in which a definite inter-metallic compound is formed. A typical equilibrium diagram of such a series is shown in Fig. 6, where the liquidus curve ACPDB shows a maximum (P) and two minima or eutectic points, C and D. The occurrence of a maximum in the curve of initial freezing, such as that shown at P, is a definite indication of the existence of an intermetallic compound, although the presence of such compounds is not always indicated in this way. The simplest way of regarding an equilibrium diagram of the type shown in Fig. 6, is to suppose it divided into two separate diagrams by the vertical line through P, the one half being thus a diagram of the alloys of A with the compound metal P, and the other half representing the alloys of B with P. In the diagram as drawn, the left-hand half then becomes a diagram of type II., while the right-hand half falls under type III. It should be mentioned, however, that in actual alloys the formation of the compound P may not take place quite completely, and the alloys may in reality contain some free B as well as A and P—the system thus becomes practically one of three components, to which reference is made below.

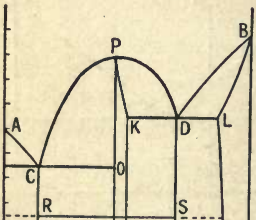

FIG. 6.

Equilibrium diagrams frequently contain lines other than those forming parts of the 'liquidus' and 'solidus' curves; these lines represent the occurrence of transformations or chemical reactions within the metal, frequently at temperatures well below those at which the alloys are completely solid. These changes are represented on the cooling curves by heat evolutions or absorptions, which are sometimes so faint as to escape detection by any but the most sensitive instruments, while in other cases they rival the freezing-point in intensity. These heat evolutions may represent either:

(1) An allotropic change in a pure metal or in the pure metal forming the basis of a solid solution or existing in the form of crystals in a eutectiferous alloy.

(2) A polymorphic change in an inter-metallic compound.

(3) A chemical reaction resulting in the formation or the decomposition of a compound or of a solid solution.

Two or more of these changes may occur together. An example of such a change is indicated in an imaginary case by the line RS in Fig. 6, which is supposed to represent the decomposition of the compound P. It will be seen that the line extends over the whole range of composition in which the compound P can exist, either as free crystals or as a constituent of the eutectics in which it occurs. As a rule, however, it is difficult, and sometimes impossible, to find any evidence—either pyrometric or otherwise—for the occurrence of such changes in alloys where the compound in question exists only as a constituent of a eutectic; the line of transformation is therefore shown as a full line only between the points R and S, where the compound exists in the form of primary crystals, and as a dotted line over the rest of the range of its existence. The interpretation of such a line of arrest-points in an equilibrium diagram will, as a rule, be based principally upon microscopic evidence, and this also applies to several of the other facts tacitly implied in such a diagram as that of Fig. 6; but before passing on to consider the microscopic study of alloys, certain other lines of pyrometric evidence must be mentioned.

The most important of these is the determination of the end-points of a series of arrest-points, and of the point of maximum intensity of such a series. The first of these is important for fixing the position of such points as D and E in Fig. 5, and O, K, and L in Fig. 6. Points D, E, K, and L serve to fix the limits of solid solubility of the metals and compounds in one another, while the point O assists in determining the exact composition of the compound P, since the maximum in the liquidus curve is not always very sharply marked. Probably the best method of determining the end-point of such a series of arrests consists in observing, by means of the most delicate pyrometric apparatus available, large samples of the alloys cooling at a slow rate, but it is also necessary in such cases to secure the complete equilibrium of the alloy at a temperature just above that of the arrest to be observed. For this purpose it is necessary, in some cases, to maintain the specimens of alloy at a definite, more or less high, temperature for prolonged periods—sometimes up to several weeks—and then to take the observations of cooling without having allowed the specimens to cool down intermediately (Rosenhain and Archbutt, Aluminium-Zinc Alloys, Phil. Trans. 1911, A, 211). The exact end-point found, however, will always lie a little short of the true end-point. For this reason a method of extrapolation is often employed. If the quantities of heat evolved at such a series of arrest-points were measured, the measurements being reduced to quantities of heat per gramme of alloy, then a curve could be plotted with concentration as abscissæ and quantities of heat evolved as ordinates. Provided that the measurements were strictly accurate, such a curve would simply be a straight line running from the concentration at which the heat-evolution was largest down to the two end-points of the series; even if not observed very close to these end-points, the line could be continued until it cut the axis, and this intersection would indicate the true end-point of the heat-evolutions. In practice this method is frequently applied, especially by Tammann and his school (Tammann, Zeitsch. anorg. Chem. 1903, 37, 303), both for the determination of end-points and of maxima of heat-evolutions; but unfortunately it is not possible to make the measurements of the quantities of heat evolved with any great degree of accuracy. The determination of the duration of the arrest itself or of the area of the peak of the inverse-rate cooling curves is usually employed, and it has been shown that this is only a rough approximation; the variation of specific heat with concentration of the alloys also affects the shape of these intensity curves, so that very great care is required in employing this method, which has more than once led to erroneous results (W. Rosenhain, The Metallographic Investigation of Alloys, Journ. Inst. Metals, 1909, i. 200; Observations on Recalescence Curves, Proc. Phys. Soc. London, 1908, 21, 180; Rosenhain and Tucker, Lead-Tin Alloys, Phil. Trans. 1908, A, 89; Rosenhain and Archbutt, Aluminium-Zinc Alloys, Phil. Trans. 1911, A, 211).

The above account of the pyrometric study of alloys and its diagrammatic representation has so far dealt only with alloys consisting of two component metals; in practice, however, alloys frequently contain three or more metals. Unfortunately the difficulty of making a complete metallographic study of a system of alloys increases very rapidly with the number of component metals; for fifty determinations required for the elucidation of a binary system of alloys, 1250 would be required for a system of three metals, while no attempt at the complete systematic study of a quaternary system (of four metals) has yet been made, but for corresponding completeness over 30,000 determinations would be needed. In the case of a ternary system (of three metals) it is still possible to employ graphic representation; the concentrations of a system of ternary alloys may be plotted in the form of an equilateral triangle, each corner representing one of the pure component metals, each side of the triangle then represents one of the three limiting binary systems, while the position of any point within the triangle represents the composition of an alloy of a ternary system, on the principle of trilinear co-ordinates. Upon this equilateral triangle as a base, the 'equilibrium diagram' can be erected as a three-dimensional model, ordinates representing temperature being erected upon each point of the area of the triangle. A few such equilibrium models of ternary systems have been more or less completely determined (Lead-Tin-Bismuth, G. Charpy, Compt. rend. 1898, 126, 1569; E. S. Shepherd, J. Phys. Chem. 1902, 6, 519; Lead - Cadmium - Mercury, E. Jänecke, Zeitsch. physikal Chem. 1901, 60, 399; Magnesium - Lead - Tin, A. von Vegesack, Zeitsch. anorg. Chem. 1901, 54, 367; Aluminium-Copper-Manganese, Rosenhain and Lantsberry, Ninth Report to the Alloys Research Committee, Proc. Inst. Mech. Eng. 1910), but the field is still largely unexplored. It is interesting to note, however, that no tri-metallic compound has yet been discovered.

The microscopic study of metals is always carried out by looking at suitably prepared surfaces illuminated by reflected light; the thin sections employed in petrography cannot be used in the case of metals as these are too opaque for such a purpose. The preparation of a suitable surface for examination by reflected light consists in three distinct processes, viz. the cutting and grinding of a small flat area, the fine-polishing of this surface in order to remove physical irregularities, and the treatment of this polished surface in such a manner as to indicate the nature of the structure of the metal beneath. The cutting and grinding process, in the first place, consists in preparing an area, as nearly flat as possible, which may range in size from a few square millimetres to several square centimetres—but the difficulty of the subsequent operations increases rapidly with the area to be treated, so that it is preferable to examine several small specimens rather than one very large one. The initial rough cutting and grinding is followed by some process of fine grinding, generally by the use of carefully graded abrasives, each stage reducing the depth of the scratches left on the surface.

The grinding operation is followed by that of fine-polishing. The purpose of this process differs essentially from that of the ordinary polishing process, the object of which is solely the production of the most brilliant surface; in most ordinary polishing processes this is largely accomplished by a species of 'burnishing' action, in which there is much surface flow of the metal, the previously existing scratches being largely 'smeared over' and filled up. For metallographic purposes this action should be avoided as far as possible, since scratches or holes thus hidden immediately become conspicuous under subsequent treatment (etching). It follows that for this work the entire processes of cutting, grinding, and polishing, should be conducted as gently as possible, particularly in the case of the softer metals. For polishing purposes a material which acts as an exceedingly fine abrasive is indeed much preferable to one which, though more rapid in action, tends to cause flow. The polishing materials most widely used consist of the oxides of such metals as aluminium, magnesium, and iron, alumina being probably the best.

A perfectly polished metallic specimen shows, under the microscope, a featureless surface, which will appear either uniformly bright or uniformly dark, according as the light falling upon it is or is not reflected into the objective of the microscope. In order to obtain a sectional view of the structure of the metal it is necessary to employ some method of 'etching.' As a rule, this consists in exposing the specimen to the action of some reagent, such as a weak acid, which gradually dissolves the metal. It is found that this solution does not take place uniformly over the surface of the metal, and that, in fact, it differentiates clearly and consistently the various constituents of metals and alloys. In the case of pure metals and of certain alloys which consist of a single constituent or phase, the etching agent cannot, of course, act by differentiating two or more distinct constituents; but in that case a differentiation occurs between the different crystals of the same constituent, the rate of attack being apparently dependent upon the orientation of the particular section of the crystal exposed to the solvent. Such a 'homogeneous' metal consists, in fact, of an aggregate of minute crystals which have grown together in such a manner that the boundary of each crystal is determined not by the natural symmetrical surfaces commonly associated with the term 'crystal,' but by the surfaces of mutual interference of adjacent crystals—each crystal has grown until checked by meeting its neighbour. In section such a structure exhibits a network of roughly polygonal areas, and the etching reagents employed in metallography attack these various areas at different rates, thus producing both differences of level and varieties of surface texture which readily reveal the arrangement of the constituent crystals. In the case of alloys possessing a duplex or more complex structure, although each of the constituents is still built up of such aggregated crystals, the differences of solubility between the various constituents are very much greater than those between adjacent crystals of the same constituent. Consequently the resulting surface pattern generally shows all those areas which represent sections of crystals of one of the constituents as comparatively deeply etched or eroded, while those corresponding to the other constituent remain practically untouched. In duplex alloys, therefore, etching reveals the distribution of the constituents rather than the crystal structure of any of them.

The specimens of metal thus prepared can be examined by means of almost any good ordinary microscope if it is provided with certain special accessories, but for the greatest convenience and for more refined purposes it is desirable to employ one or other of the specially designed 'metallurgical' microscopes. Two general types of such instruments have been evolved for this special purpose. In the one type, which is generally used by British workers, the ordinary arrangement of the microscope is adhered to, but the stage is provided with a focussing movement, while the body-tube is provided with one of the devices known as 'vertical illuminators.' In the most highly specialised instrument of this kind (Rosenhain, On an Improved Form of Metallurgical Microscope, Journ. R. Microscopical Soc. 1906) the body-tube is entirely fixed to the limb and all the focussing, both coarse and fine, is done by movements of the stage; further, the illuminating arrangements are made integral with the main tube of the instrument, while in other microscopes they are removable and are only screwed on at the lower end of the tube. The function of the 'vertical illuminator' is simply that of sending a beam of light down the tube of the microscope in such a way as to fall upon the back lens of the objective, and then, after being concentrated by the objective, to fall upon the specimen and to illuminate the portion of the surface which is under examination. Such a vertical illuminator consists essentially of a reflector, which may be a thin disc of glass or an opaque reflector or a totally reflecting prism so placed as to cover one-half or less than one-half of the aperture of the objective. The path of the light-rays in both cases is shown diagrammatically in Fig. 7. It will be seen that under this mode of illumination the light falls upon the surface of the specimen in a direction more or less parallel to the optical axis of the microscope, and as this is sometimes placed vertically, this mode of illumination has received the name of 'vertical illumination,' although 'normal illumination' is a more rational term, since the light remains normal to the surface of the specimen whatever the position of the microscope. Under this mode of illumination it is evident that flat, bright surfaces will appear light, while sloping surfaces, or areas rendered rough so as to scatter the light which falls upon them, will appear dark—since the light reflected from such regions will be more or less completely thrown outside the aperture of the obective of the microscope. With lenses of moderate power, which leave a certain amount of space between the lens and the specimen, the surface under examination may be illuminated directly by a beam of light falling obliquely upon the surface of the specimen, in the manner indicated in Fig. 8. With such lighting, plane polished surfaces will appear dark, while those with a suitable slope and those roughened so as to

scatter the incident light, will appear more or less bright; the consequence is that in many respects the image as seen by ‘oblique illumination’ bears to that seen by ‘normal illumination’ a relationship like that of a photographic negative to its positive. Oblique illumination, however, is much more searching, particularly as regards minute holes and scratches, while it also tends to reveal the natural colours of the various constituents much more definitely than normal light. On the other hand, its application is generally limited to magnifications not much greater than 200 diameters, while normal illumination is readily employed with the highest powers of the microscope.

The use of the vertical illuminator, whether as a permanent or a more or less temporary attachment to the microscope, entails a special arrangement of the source of light. Whether this be an ordinary lamp or some more or less elaborate optical system, it must be so placed that the light coming from it enters the aperture of the illuminator at the desired angle. This requires a definite relative position of the source of light and the illuminator itself. In any ordinary microscope where focussing is done by moving the tube of the instrument, the position of the illuminator will vary with every adjustment of the focus, and this would entail corresponding re-adjustment of the source of light. By using a focussing stage and leaving the body-tube with the illuminator attached to it in a fixed position, this difficulty is overcome, and this arrangement is the essential feature of the majority of metallurgical microscopes. For certain purposes, of course, special provision for taking large and heavy specimens, for complete rotation of the specimens, and for other special requirements is desirable and can be obtained.

The second type of metallurgical microscope originated with H. le Chatelier (Le Chatelier, Étude des Alliages, 1901, 421), and its use is widely extended in France and Germany. The observation tube of this instrument is horizontal, and directly in line with a tube carrying condensing lenses through which light from a suitable source is concentrated upon the specimen. The stage of this instrument is a table provided with a small hole, and the specimen is placed over this hole, polished face downwards. The objective of the microscope faces upwards towards the specimen, and the incoming light as well as the rays forming the image are turned off at right-angles by means of two totally reflecting prisms. In its most recent forms this instrument presents many points of great convenience, but it also possesses certain very marked limitations and disadvantages from which the more ordinary type of microscope is free.

The observations of the structures of metals and alloys made by such microscopes are readily recorded by means of photography. If the beam of light employed for illuminating the specimens is made sufficiently powerful, and particularly if the ordinary eyepiece of the microscope is replaced by one of the well-known ‘projection eye-pieces’ now available, the image of the surface under examination can be projected upon a screen, and this image can be made large enough and bright enough to be visible even to an audience of moderate size. Instead of projecting the image upon a large screen it can equally well be focussed upon the ground glass of a suitably placed camera, and there photographed in the ordinary manner. The manipulation requires some experience and skill, particularly when very high magnifications are attempted, but in principle it does not differ materially from ordinary photography, except that the microscope with its system of lenses is used in place of the ordinary camera lens.

The typical micro-structures met with in metals and alloys may now be briefly considered. We have already indicated that a pure metal is an aggregate of minute crystals whose sections, in the form of irregular, more or less polygonal areas, are revealed by etching a polished surface. In such metals as cast lead or tin the crystals are often very large, and can be seen without the aid of the microscope, but in iron and copper they are usually very small and require magnifications ranging from 100 to 400 diameters to be readily observed. Seen under normal illumination, the crystals of iron appear as illustrated in Fig. 9, Plate I.; the same field of view seen under oblique light is shown in Fig. 10, Plate I. The appearance there seen arises from the fact that the etched surface of each crystal is covered with a number of minute facets all similarly oriented over the whole area of the same crystal, but differing in orientation from one crystal to the next. Oblique light falling on a surface thus constituted picks out those areas where the facets are so placed as to reflect the light into the microscope, and these areas accordingly appear bright, while others, situated unfavourably, appear more or less dark. A rotation of the specimen on the stage of the microscope alters these relative positions, and different crystals appear bright in turn.

The description of the typical structure of a pure metal which has just been given applies equally to the structure of those alloys which consist either entirely of a definite intermetallic compound in a state of purity, or of a homogeneous ‘solid solution.’ The term ‘solid solution’—sometimes called ‘mixed crystals’—implies a state of mutual admixture or solution existing in the solid state which is as intimate as the condition of liquid solutions; probably the best interpretation of the conception is to regard the crystals of a solid solution as being built up of molecules of both the solvent and the solute indiscriminately. Where the two metals are completely isomorphous, these composite crystals may be built up of two kinds of molecules indiscriminately in any proportion, and we then have a series of alloys consisting of solid solutions only; in other cases the number of molecules of the solute which can be incorporated in the crystals of the solvent is limited, and in that case there is a limit to the ‘solid solubility’ of the two metals. While the final condition of a solid solution is thus simply that of an aggregate of homogeneous crystals resembling in appearance and character the structure of a pure metal, this final condition is not at once arrived at during the solidification of such an alloy. The central part of each individual crystal of such a solid solution when first formed contains considerably less of the solute than the liquid alloy from which it is being deposited, and as solidification proceeds this core of relatively dilute solution is surrounded by successive layers of more and more concentrated solution. Ideally the concentrations of these layers should be continually equalised by diffusion of the solute from the more concentrated to the less concentrated regions, but this is a slow process, and generally remains incomplete during the ordinary cooling of an alloy from fusion. Samples of alloys consisting of a single solid solution when taken from castings which have not been subjected to prolonged annealing, therefore always show traces of the original 'cores' within the polyhedral crystals. An example of this kind in the case of cast brass is shown in Fig. 11, Plate I. When this alloy has been reheated and subjected to such a process as rolling into bars or rods, these 'cores' are obliterated, and a homogeneous polyhedral structure is then found, such as that illustrated in Fig. 12, Plate I.

We may now consider the micro-structure of such an alloy as that represented by the line PQ in Fig. 4. In accordance with the nature of the freezing process of such an alloy, which has already been described, the microscope shows that it consists of two very distinct constituents; as a rule one of these, which represents the crystals of the pure metal A, remains practically unaffected by the etching reagent, while the other, which represents the eutectic, is more or less eroded and darkened. The relation between the two constituents is readily followed if a series of alloys are considered, commencing with one very rich in A and gradually increasing the concentration of B. At first the micro-structure closely resembles that of a pure metal, but the boundaries between adjacent crystals are seen to be thicker than the fine lines observed in pure metals. With a very slightly higher concentration of B the presence of a dark-etching constituent between the crystals of A becomes evident, and as the concentration of B increases the proportion of this dark-etching constituent (the eutectic) increases, while the crystals of A become mere islands. Ultimately, as the concentration of the point C is reached these islands of A disappear entirely, and the whole field is occupied by the eutectic. An example of such a eutectiferous alloy lying midway between the pure metal and the pure eutectic is shown in Fig. 13, Plate I., while the typical structure of a pure eutectic is shown, under much higher magnification, in Fig. 14, Plate I. It will be seen that the 'dark etching' eutectic is not uniformly etched, but itself exhibits a duplex structure, which is very characteristic of these bodies, although it is not one of their essential characters. The eutectic, as it crystallises from the residual mother-liquor along the eutectic lines, such as DE, Fig. 4, is really the product of the simultaneous crystallisation of both the constituents, and we thus generally find it with a laminated structure consisting of alternating layers of the two constituents. It was formerly thought that these were simply minute independent crystals deposited side by side, but later research has shown that most eutectics crystallise in the form of the predominating constituent, the crystals of the other metal being forced into the interstices of the other, the whole arrangement frequently adopting the spherulitic form (Rosenhain and Tucker, Lead-Tin Alloys, Phil. Trans. 1908, A, 89).

The great majority of alloys exhibit in their micro-structures varieties of the three types illustrated and described above, but in a certain number of cases special structures are met with.

In the course of metallographic investigations it is frequently necessary to adopt special methods for determining the exact temperature at which the solidification of a given alloy is completed. For various reasons it has been found that the best available method of making this determination is by a process of quenching small pieces of the alloy from a series of suitably chosen temperatures. By the micro-structure of the quenched specimen it is then possible to determine whether the alloy contained any liquid at the moment of quenching. The rationale of this process lies in the fact that while that part of the alloy which was solid at the instant of quenching had solidified slowly, and had, therefore, been allowed to form relatively large crystals, any liquid metal present when the specimen was suddenly cooled would be forced to solidify very rapidly and would, therefore, form extremely minute crystals. Thus in a series of specimens quenched from successively higher temperatures, it is found that the resulting specimens show the ordinary typical and comparatively large-scale structure of the alloy until the quenching temperature exceeds a certain limit, but that beyond that point small areas of very minute crystals are found. It may then be concluded that the limiting temperature in question is that of the final solidification of the alloy. The first traces of 'liquid' in such specimens appear as minute dots or 'fusion spots,' but with slightly higher temperatures the original solid crystals of the alloy are seen to be embedded in a matrix which had obviously been fluid at the moment of quenching.

When such a quenching process is employed for locating one of the lines of an equilibrium diagram, it is of great importance that the exact temperature of the specimen at the moment of quenching should be accurately known, and that the small specimens should be protected from oxidation as far as possible during the progress of the experiment in order to avoid changes of composition and structure. In all earlier investigations quenching was carried out by heating the specimens in a small furnace, and when the desired temperature had been attained, withdrawing them by means of a rod or wire and quickly throwing them into water or other quenching fluid. More recently an apparatus has been devised (Rosenhain, The Metallurgical and Chemical Laboratories in the National Physical Laboratory, Journ. Iron and Steel Inst. 1908, I.) in which the specimen is heated electrically while contained in an exhausted tube made of fused silica; when the desired temperature has been reached, water is admitted into this exhausted tube through a wide-bore tap, and the powerful stream of water, driven by the pressure of the atmosphere, quenches the specimen, and carries it out of the furnace with it; the quenching is thus carried out very rapidly at an accurately known temperature, and without any exposure to the atmosphere.

Apart from the processes of solidification, a great many metals and alloys undergo transformations which are frequently accompanied by thermal phenomena shown on the cooling-curves, and, as a rule, these transformations are accompanied by more or less striking changes in micro-structures. In the case of pure metals these changes occurring at temperatures below that of solidification are generally regarded as being 'allotropic'; in the case of alloys, however, these transformations or 'inversions' may arise from a variety of causes, such as the formation or decomposition of a compound, an allotropic change in one of the components resulting in the rejection of the other component from solid solution, or the rejection from solid solution of a phase the limit of solubility of which has been reached owing to a variation of solid solubility with temperature. Typical examples of these and similar changes are met with in such systems of alloys as iron-carbon, copper-tin, copper-zinc, copper-aluminium, aluminium-zinc, and others, and some of these will be referred to in connection with the equilibrium diagrams of these systems.

The equilibrium diagrams and general metallography of some of the more important alloys will now be briefly described. Among alloys forming uninterrupted series of solid solutions (type I. above) perhaps the most important are the iron-manganese and the copper-nickel series, whilst iron-nickel and copper-manganese probably also belong to this type. The equilibrium diagram of the copper-nickel series is given in Fig. 15, these alloys being important on account of their electrical uses (resistance alloys) and also as forming the basis of such industrially important metals as German silver and Monel metal. The diagram is of the simplest type, and the micro-structures met with in the alloys are correspondingly simple—in the cast alloys some core-formation is visible, but in the worked materials, such as sheet or wire, complete homogeneity is attained, the resulting structure being very similar to that of brass (*see* Fig. 12, Plate I.), but usually on a more minute scale.

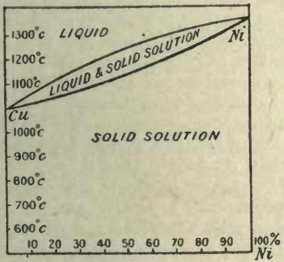

Fig. 15.

A typical example of another type of equilibrium diagram is that of the alloys of lead and tin, which are important on account of their use as solder, pewter, &c., and also because they form the basis of important ternary and quaternary alloys such as certain anti-friction alloys and type-metal. The diagram given in Fig. 16 (Rosenhain and Tucker, Lead-Tin Alloys, Phil. Trans. 1908, A, 89) shows the typical V-shaped liquidus with a long eutectic line running up to, or very nearly up to, the tin end of the series, but stopping some little distance (at about 18 p.c. of tin) from the lead end. Formerly the line was supposed to run up to the lead end also, but this was an error arising from the fact that these alloys take up their equilibrium condition very slowly, so that alloys cooled from fusion in the ordinary way show eutectic practically up to the lead end; this, however, disappears on prolonged heating of the alloys at a temperature near 170°. Below the solidus this diagram shows a line indicating an inversion occurring in the alloys from 18 to 63 p.c. of tin at a temperature of 150°, but with lower tin-contents the temperature at which this change occurs falls rapidly, and the inversion cannot be traced at all at concentrations of less than 8 p.c. of tin. This inversion is accompanied by a partial rejection of the tin from solid solution, and involves a change of density.

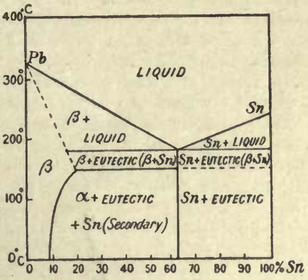

Fig. 16.

As typical of a comparatively simple system exhibiting a maximum in the liquidus corresponding to a definite compound, the alloys of aluminium and magnesium may be taken (G. Grube, Alloys of Aluminium and Magnesium, Zeitsch. anorg. Chem. 1905, 45, 225). Of this series those near the aluminium end are employed under the name 'Magnalium,' while they also enter into the composition of special light alloys used for constructional purposes, notably 'Duralumin,' which contains over 90 p.c. of aluminium and 0·5 p.c. of magnesium, the rest being copper, manganese, and iron. The aluminium-magnesium diagram, as far as at present known, is given in Fig. 17. The liquidus has four branches: Al–I. corresponding to the commencement of the deposition of aluminium containing only little magnesium in solid solution, with a corresponding eutectic line AI.; I.–II. corresponding to the formation of a series of solid solution of very narrow freezing range and ending at the freezing-point of the

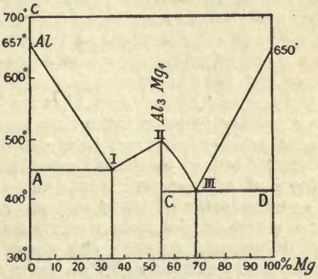

Fig. 17.

definite compound Al_3Mg_4; II.-III. corresponding to the deposition of crystals of Al_3Mg_4, with a eutectic line CD, and the branch III.-Mg, corresponding to the deposition of crystals of nearly pure magnesium. The micro-structures of the alloys from A to I. show crystals of aluminium, often developed as beautiful dendrites, embedded in eutectic; those from I. to II. are homogeneous crystalline aggregates, while those from II. to III. and from III. to D show crystals of the compound or of magnesium, as the case may be, embedded in eutectic. In connection with this diagram it is interesting to note that inter-metallic compounds, such as the body Al_3Mg_4, are almost always exceedingly brittle bodies, even when their constituent metals are so soft and ductile as aluminium and magnesium—compounds of copper with such metals as tin and aluminium furnish equally striking examples of this fact. It follows that in those binary alloys where a definite inter-metallic compound is formed, over a considerable range of composition on either side of this compound the alloys are usually so brittle that they cannot be used for any technical purpose; this removes the greater part of the ranges of most binary systems from all practical usefulness, and in fact it is found in the great majority of cases that industrially useful alloys rarely contain much more than 15 p.c. of substances other than the predominating metal. The only real exceptions to this rule are to be found in the alloys of zinc with such metals as copper and aluminium; apparently the addition of zinc can be pushed much further without producing serious brittleness than is the case with any other metal, and industrially useful alloys containing over 40 p.c. of zinc are well known. The alloys of lead and tin furnish another example, but in their case practical utility does not depend upon mechanical strength; similarly in certain anti-friction or bearing metals large proportions of added elements are sometimes employed, but these alloys are intended to meet special requirements and a considerable degree of brittleness is permissible.

Probably the most widely used of all non-ferrous alloys are those of copper and zinc, which include the whole series of 'brasses,' although in many industrial varieties of brass other metals besides copper and zinc are met with in varying proportions. It should perhaps be mentioned here that a considerable degree of confusion at present exists in the nomenclature of such alloys, the terms 'brass' and 'bronze' being used very loosely or even indiscriminately; in the present article, however, it is proposed to use the term 'brass' to denote approximately pure alloys of copper and zinc, while alloys consisting principally of these two metals, but with one or more added elements, will be described as 'special brasses,' or with the name of the most important third element, as, for instance, 'manganese brasses,' 'aluminium brasses,' or 'tin brasses.' The term 'bronze,' on the other hand, is to be confined to copper-tin alloys.

The equilibrium diagram of the copper-zinc alloys, as worked out by Shepherd (Copper-Zinc Alloys, E. S. Shepherd, J. Phys. Chem. 1904, 8, 421), and modified in accordance with the work of Carpenter and Edwards (Copper-Zinc Alloys, H. C. H. Carpenter and C. A. Edwards, Journ, Inst. Metals, v. 1911), is given in Fig. 18. In this diagram each of the six Greek letters indicates a definite phase; according to Shepherd these are all solid solutions, but it appears probable that each of these solid solutions owes its separate existence to some definite compound associated with it—there is some evidence for the existence of the two compounds Cu_2Zn and Cu_2Zn_3. It will not be necessary to discuss the whole of this diagram in detail, since the industrially important alloys consist either of pure α, or a mixture of α and β, and in special cases of either pure β or of β with a little γ; in accordance with what has been stated above in general terms, the β phase is decidedly harder and stronger, but also much more brittle than the α phase, while the γ phase is very brittle, and at the same time weaker than the β body. As indicated by the diagram, alloys containing up to 37 p.c. of zinc, when solidified and in equilibrium, consist of the pure α phase; this is a ductile body whose characteristics closely resemble those of copper itself, but with increasing zinc-content the strength increases while the ductility diminishes slightly. The micro-structure of these alloys closely resembles that of copper; in the cast state they consist of the usual aggregate of roughly polygonal crystals, similar to those illustrated in Fig. 11, Plate I.; as these alloys, however, consist of solid solutions of considerable concentration, they show a strong tendency towards the formation of dendritic 'cores,' as described above. In alloys as ordinarily cast this structure is very prominent, and tends to obliterate the ordinary polygonal structure so far as to suggest to the observer, at first sight, that he is dealing with a truly duplex alloy. Annealing, however, entirely removes this appearance from the micro-structure, and leaves the alloys perfectly homogeneous; if the annealing has been accompanied by or associated with mechanical work, the disappearance of the 'cores' is accompanied by the formation of numberless 'twinned' crystals which indicate their presence on the micro-sections by the appearance of crystals with rectilinear edges and crossed by one or more parallel bands showing a distinct orientation, as shown in Fig. 12, Plate I. These structures, it may be added, are also characteristic of the α body met with in other alloys of copper, such as those with tin, aluminium, manganese, &c., although in each class of alloys the range of existence of the α phase may be widely different—thus in the copper-aluminium series the range of the pure α phase is only slightly over 7 p.c.

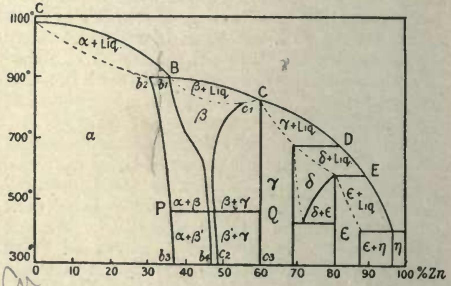

FIG. 18.

It will be seen that in the equilibrium diagram of the copper-zinc series the region of the pure α phase is bounded on the right by the curved line b_2b_3; immediately to the right of this line lies the region in which the alloys consist of a mixture of the α and β phases. If we consider the cooling from fusion of an alloy containing, for instance, 34 p.c. of zinc, we see that it will begin to solidify at a temperature of about 915°, depositing α crystals until the temperature of the line b_2b_1 is reached at about 880°. At that temperature the remaining liquid solidifies in the form of β crystals, which fill up the interstices between the previously deposited α crystals; if quenched from a temperature just below this line, such an alloy is found to exhibit the duplex structure of α and β thus indicated. On further cooling, however, the alloy crosses the line b_2b_3 and passes from the region of mixed α and β into that of pure α. If time enough is allowed to permit of the establishment of full equilibrium, the whole of the β present in the alloy will be transformed into α and the alloy will become homogeneous in accordance with the indications of the diagram; with most ordinary rates of cooling, however, this transformation is not completed, and the alloy retains some of its original β in that condition, remaining in what is known as 'meta-stable equilibrium.' In such a case the tendency for the β phase to undergo transformation is always present, but it is held permanently in check by the internal resistance of the metal to such rearrangements—this resistance being very considerable at low temperatures, but diminishing rapidly when the temperature is raised. All metals and alloys in which a transformation or 'inversion' of any kind has been prevented by rapid (or insufficiently slow) cooling, are thus in a meta-stable state, and the attainment of stable equilibrium only requires a raising of the temperature. Alloys which have been quenched are usually intentionally thrown into a meta-stable condition. In the present case it follows that the rate of cooling, in the first instance, or the subsequent application of heat, as in annealing, will make a very great difference to the character of the alloy and to all its physical and mechanical properties, since in the meta-stable state the relatively hard, strong, but brittle β body is present, while in the annealed state this body is absent.

To the right of the line b_2b_3 we have first the region of α and β, and then, to the right of the line b_1b_4, the region of pure β, while beyond that again is the region of $\beta+\gamma$. The industrially important Muntz metal, containing about 60 p.c. copper and 40 p.c. zinc, lies in the region of $\alpha+\beta$, and accordingly always exhibits a very definite duplex structure which is not removed by annealing, in this respect differing from a typical brass such as that used for condenser tubes, which contains 70 p.c. copper and 30 p.c. zinc, and therefore lies in the region of pure α. Study of the curves of the diagram will at once show that the alloys containing the β body during cooling undergo a decomposition on passing through the temperature of the line b_1b_4 or c_1c_2 respectively, breaking up from pure β into α plus β or β plus γ respectively. These decompositions are also readily prevented by somewhat rapid cooling, so that the final state of the alloys depends a good deal upon the rate at which they have been allowed to cool from fusion or from subsequent heating.

Some reference is required to the horizontal line in this diagram, running from P to Q through the entire region of the alloys in which the β phase occurs. This line represents a series of heat-evolutions, which, originally observed by Roberts-Austen (Roberts-Austen, Fourth Report to the Alloys Research Committee of the Inst. Mech. Eng. 1897, 31–100), have been redetermined by Carpenter and Edwards (H. C. H. Carpenter and C. A. Edwards, Journ. Inst. Metals, v. 1911). The nature of the change indicated by these arrest-points is not quite clearly established; the authors just named suggest the interpretation that at this temperature the β phase undergoes decomposition into α and γ, and they quote some microscopical and mechanical evidence in support of this view. There are, however, serious difficulties in the way of this explanation, and the writer prefers to regard the change, for the present, as a transformation in the β phase; the critical points in question, however, appear to be of some importance in the thermal treatment of brass.

Before leaving the metallography of the copper-zinc alloys the effect of heat-treatment on the micro-structure of these metals must be mentioned. It has been shown that even at the ordinary temperature the crystals of brass which have previously undergone severe mechanical distortion undergo a gradual rearrangement, resulting in the formation of larger crystals of normal shape (E. Cohen, Revue général des Sciences, Paris, 1910); at higher temperatures this recrystallisation is decidedly rapid, the size of the resulting crystals depending upon both the highest temperature reached and on the duration of heating, although at each temperature there appears to be a limiting size of crystal structure, which is gradually attained, but is not exceeded on prolonged heating at that temperature. For practical purposes the scale of crystal structure is important, because it is a universal law in metals and alloys that increasing size of crystals brings with it decrease in strength and increase in brittleness or fragility. It follows that in brass, as in most other metals, prolonged heating, or heating to an excessive temperature, tends to injure the metal, which becomes 'overheated,' and if the heating is very excessive, may become 'burnt,' a stage where the injury to the internal structure has become so severe that it cannot be eradicated by any treatment short of re-melting.

The influence of the most frequent impurities on brass has received much attention, both from the mechanical point of view and from that of the effect on the micro-structure. A very frequent, and in many respects very injurious, impurity is lead. This metal apparently does not remain in solid solution in the α body of the copper-zinc series, and in all ordinary brasses, therefore, appears as a distinct micro-constituent whose presence can be recognised, in the form of minute dark globules, which are readily seen before the specimen is etched, when present to the extent of not less than 0·2 p.c. When the specimens are etched in the more usual manner by means of ferric chloride solution, these minute dark specks are no longer very conspicuous; on the other hand, their presence can be made very obvious by etching the specimens with concentrated nitric acid, applied in the form of a single drop, and immediately washed off in a rapid current of water. This reagent develops a more or less deep and irregular pit in the surface at the spots previously occupied by lead globules, and the etched specimen accordingly appears to be deeply pitted. It may be mentioned that the presence of lead—at all events when present in quantities exceeding 0·40 p.c.—tends to produce 'pitting' by corrosion of the brass around the lead globules, a process which frequently leads to the rapid failure of such objects as condenser tubes, &c. The method of etching a polished specimen with strong nitric acid mentioned above thus furnishes an approximate guide to the probable behaviour of such metal—a brass which pits deeply under such etching is likely to pit rapidly in service. It should, however, be mentioned that these minute lead globules are not the only impurities which cause pitting under the action of strong nitric acid, minute globules of oxide behave in the same manner, although their appearance before etching is different from that of the lead particles.

With regard to other impurities, it may be stated generally that the less injurious or non-injurious ones are rarely if ever visible as distinct constituents under the microscope; in fact, the question whether a given impurity is injurious or not is very largely a question of whether it does or does not form a distinct micro-constituent. Thus arsenic (in small amounts), nickel, silver, &c., all remain in solid solution in the α body—some of these, indeed, as well as manganese and tin and iron are deliberately added to certain 'special' brasses in order to obtain valuable ternary alloys. The constitution of these ternary alloys has not yet been studied sufficiently to make it possible to discuss their metallography in detail, although much work has been done on them (*see* L. Guillet, Alliages Métalliques, ch. x.).

The alloys of copper and tin constitute one of the most complex of the binary series, but their constitution has been exhaustively studied and the results are embodied in the diagram reproduced in Fig. 19. Space does not permit of a full description and discussion of this diagram (Heycock and Neville, Phil. Trans. 1903, 202, A, 1; Giolitti and Tavanti, Gazz. chim. ital. 1908, 38, ii. 209; Shepherd and Blough, J. Phys. Chem. 1906, 10, 630), and attention must again be confined to that end of the series which embraces the industrially useful alloys, which, with the exception of 'speculum metal,' contain less than 14 p.c. of tin.

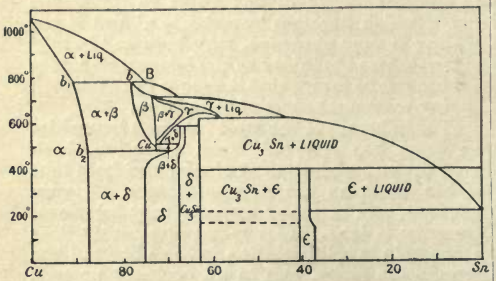

FIG. 19.

The industrially important alloys are entirely included among those which begin to solidify along the branch AB of the liquidus; these alloys begin to solidify by the deposition of crystals of the α body, which is a simple solid solution of tin in copper. Those alloys which contain more copper than the concentration indicated by the abscissa of the point b_1 (about 92 p.c. of copper) completely solidify in the α form and undergo no further changes on cooling to the ordinary temperature. This α body of the copper-tin series is, it may be remarked, somewhat similar in character to the corresponding body of the copper-zinc and copper-aluminium series, *i.e.* a tough ductile body of gradually increasing strength and hardness as the proportion of the added element is increased; there is, however, a marked difference between the three series as regards the relative influence of various proportions of the added element—the concentration of the point corresponding to b_1 in Fig. 19 being in the copper-zinc series approximately 70 p.c. of copper. This may be expressed by saying that the effect of 7 or 8 p.c. of tin is equivalent to that of 30 p.c. of zinc. It is interesting to note that this relatively feeble action of zinc is met with in other alloys of this metal.

Alloys still belonging to the group represented by the line AB, but containing more than about 8 p.c. of tin, do not solidify completely until they reach the temperature of the line b_1bB (just below 800°), and at that temperature the remaining liquid solidifies in the form of the β constituent. In the field $bb_1b_2c_4$ the alloys thus consist of a mixture of the two phases α and β, but if they are cooled sufficiently slowly, the β body disappears entirely. In the case of alloys lying between 92 and 87 p.c. of copper, the cooling alloy crosses the line b_1b_2, which is exactly analogous to the line of the copper-zinc diagram; on crossing this line the β body disappears and the alloys again consist entirely of α. Since in these as in all similar alloys, the β body is much more brittle than the α, this transformation has a powerful effect on the mechanical properties of the alloys. A still more important change takes place in the alloys containing rather less than 87 p.c. of copper; in these, along the line b_2c_4 the β body is transformed into the δ phase, and this phase is considerably harder and very much more brittle than the β phase. When these alloys are slowly cooled in the ordinary course, these transformations occur only to a limited extent, and the resulting structure shows a mixture of transformed and unchanged constituents, while the mechanical properties are also intermediate. By quenching the alloys containing less than 87 p.c. of copper from a temperature just above the line b_2c_4, however, the $\beta = \delta$ change can be entirely prevented, very much to the advantage of the strength and ductility of the alloys.

Copper-tin alloys to which other metals or metalloids have been added include a number of important 'special bronzes,' many of which are known under trade names. Among the special bronzes, the class of alloys known as 'phosphor bronze' are perhaps the most important. The

[*To face* p. 467.

addition of phosphorus to copper-tin alloys is usually made in the form of either phosphor-copper or phosphor-tin alloys previously prepared. The quantity of phosphorus introduced varies according to the purpose for which the alloy is intended. In a great many cases the object of adding the phosphorus is simply to free the metal from oxide of tin, which is apt to occur in ordinary bronze in the form of small angular crystals the presence of which reduces the strength and ductility of the alloy. Phosphorus thus added merely as a de-oxidising agent passes almost completely into the slag, and mere traces are found in the resulting 'phosphor bronze.' In other cases it is desired to retain a certain amount of phosphorus, probably in the form of the hard and brittle compound Cu_3P in the resulting alloy, in order to increase its hardness and to give it the special properties desired in a bearing metal—properties which are obtained by alloys consisting of crystals of a hard brittle constituent embedded in a soft and comparatively plastic matrix. The constitution of the copper-tin-phosphorus alloys has been studied to some extent, but the reader must refer to the original paper of Hudson and Law (Hudson and Law, A Contribution to the Study of Phosphor-Bronze, Journ. Inst. Metals, iii. 1910, 1, 161) for further details.

The alloys of copper with aluminium (aluminium bronzes) can only be very briefly considered here. The equilibrium diagram, as given by Carpenter and Edwards (Carpenter and Edwards, Eighth Report to the Alloys Research Committee of the Inst. Mech. Eng. 1906), is reproduced in Fig. 20. Again, industrially useful alloys are only found near the extreme ends of the series, but in this case the light alloys of aluminium containing up to 4 p.c. of copper are of importance, as well as the heavy alloys rich in copper (89 p.c. copper and over). The remarkable properties of these alloys and of others directly derived from them have been closely studied (Carpenter and Edwards, Eighth Report to the Alloys Research Committee of the Inst. Mech. Eng. 1906; Rosenhain and Lantsberry, Ninth Report to the Alloys Research Committee of the Inst. Mech. Eng. 1910). From the point of view of constitution and micro-structure, the copper-aluminium series is closely related to the copper-zinc and copper-tin series. Near the copper end of the series we have again an α body consisting of a solid solution of aluminium in copper and gradually increasing in strength and hardness with increasing content of aluminium, but with the important difference that the degree of combined strength and ductility obtainable by the aid of aluminium is much greater than that found in either of the two other series named. An additional property of very great value is the high resistance of these alloys to corrosion. In the copper-aluminium series we again have a β body, which is hard and comparatively brittle, while great brittleness, rendering the alloys industrially useless, appears with the occurrence of the third phase of the series.

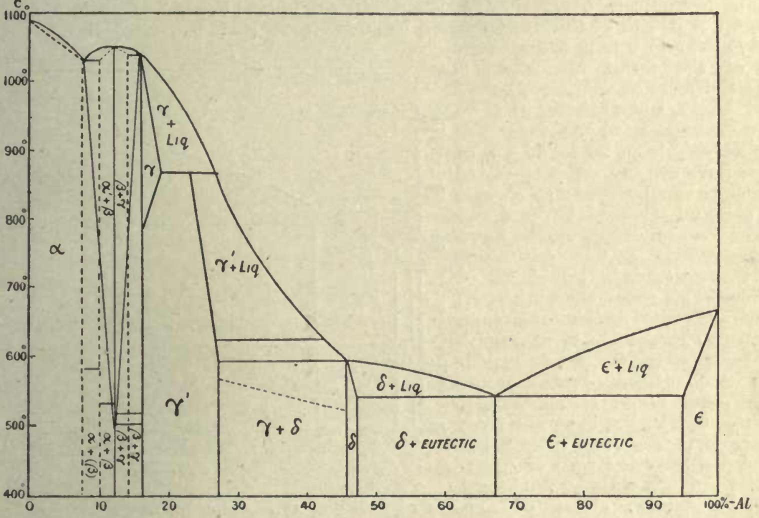

FIG. 20.

The micro-structures of all the copper alloys which have been described above are very similar. Those alloys which consist of the α constituent alone show a structure closely resembling that of pure copper, and already illustrated in the case of brass in Figs. 11 and 12, Plate I. Where the β phase is present, etching usually does not reveal the crystal boundaries of the α phase at all, the β constituent being merely darkened and eroded. A typical example from the copper-aluminium series is given in Fig. 21, Plate II. It should be remembered that the scale of this micro-structure will depend, in any given alloy, upon the heat treatment which the metal has received; prolonged heating, especially at high temperatures, produces a coarse structure, and this coarsening of the micro-structure is accompanied by a degradation of the mechanical properties.

The alloys of aluminium have acquired a considerable degree of importance which later developments tend to increase. Only a few of the most important ones can be discussed here. The alloys of aluminium with copper have already been mentioned; their constitution is represented by the right-hand side of the diagram of Fig. 20. It has been found that aluminium possesses a small, but not definitely ascertained power of dissolving copper in the solid state; at concentrations above 5 p.c., however, the copper forms a eutectic alloy with aluminium, the copper being present in this eutectic in the form of the definite compound $CuAl_2$, which—like almost all inter-metallic compounds—is an exceedingly brittle body. Alloys of aluminium containing as much as 3 and 4 p.c. of copper contain small quantities of this eutectic, and as a consequence they are harder and stronger, but also far less ductile than pure aluminium. When the copper content exceeds 4 p.c. the degree of brittleness becomes too great for most purposes, and the alloys can no longer be rolled into bars or sheets, even when hot.

The alloys of aluminium with manganese have not been studied sufficiently for the construction of a complete equilibrium diagram, but sufficient is known of their constitution to state that in the alloys near the aluminium end of the series, manganese is present in the form of the hard, brittle compound Al_3Mn, and additions of more than 2 p.c. appear to be injurious. Alloys containing from 30 to 60 p.c. of manganese have the curious property of disintegrating spontaneously; a cast ingot of such an alloy, whilst hard and sound when first solidified, breaks down spontaneously into a fine crystalline powder, in some cases in the course of a few hours. This process is not accompanied by any considerable oxidation, and appears to be the result of a polymorphic change of the compound Al_3Mn. Similar spontaneous disintegration occurs in certain other alloys of aluminium, notably those of iron, but in certain cases this change is permanently inhibited if an ingot of the alloy is forged or otherwise worked soon after casting. Certain other, more complex, alloys of aluminium exhibit a process of spontaneous change leading to gradual weakening in the course of several years, so that aluminium alloys should only be employed after a careful study of the properties of the particular combination in question. As regards many of the better-known alloys of aluminium, such as those with copper, copper-manganese, and zinc, this study has already been carried out, so that reliance can be placed on these materials.

The structure and constitution of ternary alloys of aluminium with both copper and manganese has been studied (Rosenhain and Lantsberry, Ninth Report to the Alloys Research Committee of the Inst. Mech. Eng. 1910), but the matter cannot be dealt with here. An interesting development from the alloys of this group is represented by the material known as 'Duralumin,' a patented alloy of aluminium with copper, manganese, and a small amount (about ½ p.c.) of magnesium. Treated in the ordinary manner this alloy is very similar in properties to the simple aluminium-copper alloys, but after heating to a definite temperature lying in the neighbourhood of 400° the alloy undergoes an ageing process occupying 8–10 hours, in the course of which it increases nearly 100 p.c. in strength and hardness without a corresponding loss of ductility. The metallographic explanation of this phenomenon has not, as yet, been arrived at.

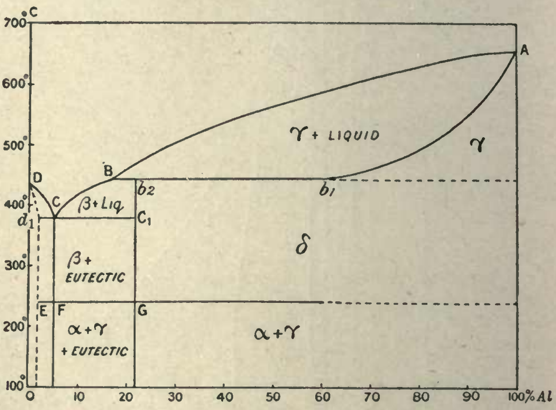

Fig. 22.

The alloys of aluminium with zinc, and derivatives of these alloys, have received much attention (Rosenhain and Archbutt, Aluminium-Zinc Alloys, *v. supra*). The equilibrium diagram of the aluminium-zinc series is given in Fig. 22. Owing to the fact that zinc is soluble in solid aluminium up to a considerable concentration (exceeding 40 p.c.) a considerable range of these alloys is industrially useful, and even the more brittle members of this series may be of practical utility as casting alloys on account of their comparative lightness and cheapness. The liquidus curve of the aluminium-zinc series is given by the line ABCD (Fig. 22). Along AB a solid solution of zinc in aluminium begins to crystallise; up to about 40 p.c. of zinc the solidification is completed in this form (the γ phase) along the curved solidus Ab_1. The break in the liquidus at B, however, indicates that beyond this point the liquid alloys deposit a new phase (β), which is probably the definite compound Al_2Zn_3; along the line Bb_2b_1 this compound is formed by a reaction between the solid γ phase already present and the residual liquid; since the solid crystals become encased in sheaths of the compound, the completion of this reaction is very slow, and in fact only takes place when the alloys are annealed for several hours at a temperature just below that of the line Bb_1. At the point b_2 the alloy possesses the composition of the compound, and the whole of the solid solution reacts with the whole of the residual liquid to form the compound; to the right of b_2 there is an excess of the original solid solution, and this forms an unbroken series of solid solutions with the compound—*i.e.* the compound and aluminium are mutually soluble in all proportions. To the left of the point b_2 there is an excess of liquid, and this solidifies as the eutectic of zinc and the compound along the line d_1c_1. The compound (β) is, however, again decomposed—throughout the entire range of its existence, even in the state of solid solution—on reaching the temperature of the line EFG (256°), when it breaks up into its constituents, viz. the α and γ phases, which are simply saturated solid solutions of aluminium in zinc and *vice-versâ*. An interesting feature of this decomposition, however, is that the two products arrange themselves in the form of fine laminæ closely resembling the typical structure of a eutectic alloy, but on a much smaller scale. This phenomenon presents a striking analogy to the formation of 'pearlite' in steel (*v. infra*), and is of importance because of its rarity. How far this decomposition occurs in those alloys of most industrial importance (viz. those containing less than 30 p.c. of zinc) is not yet definitely known, but it is probable that the phenomena in question affect the behaviour of these alloys on heating and cooling.

Iron and Steel. The iron-carbon system is, from the metallographic point of view, one of the most complex groups of alloys; although a range of only 5 or 6 p.c. of carbon-content is to be studied, since alloys richer in carbon cannot at present be prepared, and although probably a larger amount of investigation has been expended on these alloys than on any other system, it cannot be said that their metallography is as well understood as that of such alloys as copper-zinc or copper-tin. The reason probably lies in the difficulty of studying the constitution of these alloys at high temperatures —difficulties which are due to the rapidity with which they undergo oxidation at high temperatures, and the rapidity with which many of them undergo transformations on cooling through certain temperatures. Quenching such alloys fails to maintain them entirely in the condition which it is desired to study, and a series of complex transition products are accordingly met with, which vary in character according to the exact circumstances, and have consequently given rise to much controversy The metallography of the iron-carbon series will be described from the standpoint of the so-called 'allotropic theory,' which is now almost universally accepted, but it is desirable to mention the fact that somewhat divergent views are held in some quarters; these divergences, however, affect only the interpretation and not the actual facts of iron and steel metallography.

The equilibrium diagram of the iron-carbon series, somewhat modified from that originally drawn up by Roozeboom (Roberts-Austen, Fifth Report to the Alloys Research Committee of the Inst. Mech. Eng. 1890; Roozeboom, Zeitsch. physikal. Chem. 1900, 34, 437; Goerens, Erstarrungs und Erkättungsvorgäuge bei Eisenkohlenstofflegierungen Halle, 1907; Carpenter and Keeling, Journ. Iron and Steel Inst. 1904, I) is shown in Fig. 23. It should be remarked at once, however, that this diagram represents what is not in reality a diagram of completely stable conditions; the stable equilibria are indicated by the dotted lines in the diagram, and will be dealt with later, but the meta-stable equilibria represented by the full lines occur with such persistence, especially in the alloys containing less than 2 p.c. of carbon, that they are of greater interest and importance than the conditions of true stability, which are met with in practice only in the case of cast iron and pig irons generally.

The liquidus curve of the iron-carbon alloys, within the limits open to investigation, consists of two branches, AB and BC, the former representing the commencement of solidification of a solid solution of carbon or of iron carbide in iron; the branch BC as drawn in Fig. 23 represents the solidification of carbide of iron (or ('cementite'). This branch of the curve probably tends to a definite maximum at a concentration corresponding to the formula Fe_3C, but this portion of the curve cannot be pursued up to that point, principally because with these high concentrations of carbon the stable system, in which iron carbide or cementite has no place, tends to predominate, and the liquidus curve becomes that representing the separation of graphite according to the dotted line B′C′. Along the line b_1BC$_1$ the eutectic of the solid solution (AB) and of cementite (C) separates, while the curved solidus line Ab_1 represents the completion of solidification of the alloys containing up to 2·2 p.c. of carbon. The exact position of this line has only recently been determined (Gutowsky, Metallurgie, 1909, 6, 512), and it is of considerable practical importance since it indicates a superior limit above which steel may not be heated without permanent injury due to 'burning'—steel which has been heated to the point of incipient fusion (*i.e.* above the line Ab_1) appears to be permanently spoilt in such a way as to be unfit for any use except re-melting. It may be added that even at considerably lower temperatures steel may be rendered weak and brittle, but if the injury has not gone too far the quality of the metal can be restored by suitable treatment.

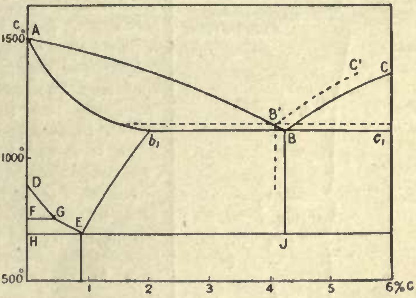

FIG. 23.

To understand the lower portion of the diagram of Fig. 23, *i.e.* the portion comprising the lines DE, Eb_1, FG, and HEJ, we must first consider the transformations undergone by pure iron in cooling from a temperature above 900° down to the ordinary temperature. The cooling-curve of electrolytic iron nearly free from impurities is shown in Fig. 24. At or near the temperature of 900° there is the first arrest-point in the cooling-curve; then the cooling proceeds regularly down to a temperature of 750° (point F in Fig. 23), where there is a second arrest-point which sometimes exhibits a double peak; if even a trace of carbon is present there is a third very slight arrest-point at or about 700°, and after that the iron cools normally. The interpretation to be placed on these arrest-points is that at the temperatures in question the iron undergoes a transformation or rearrangement of the constituent atoms of its molecule, which liberates a considerable quantity of latent heat, thus producing the arrest of cooling. These transformations or molecular rearrangements are analogous to similar phenomena observed in such elements as sulphur, selenium, &c., and are described as 'allotropic' transformations. In the case of iron, the form which is stable—in pure iron—at temperatures above 900° is called γ iron, and the arrest-point which indicates the transformation of γ iron is called Ar_3 (Osmond, Journ. Iron and Steel Inst. 1890, 1). The form of iron which exists between this arrest-point and the next (Ar_2) is called β iron, while the form which exists below Ar_2, down to the ordinary temperature, is called α iron. No marked difference in crystalline form has as yet been demonstrated between the three allotropic modifications of iron, but the point Ar_2 coincides with the disappearance of magnetic permeability, so that β and γ iron are generally regarded as being non-magnetic. It has been shown, however, that the transition of nearly pure iron from the α into the β form is accompanied by a marked and sudden increase in hardness and tensile strength (Rosenhain and Humfrey, The Crystalline Structure of Iron at High Temperatures, Proc. Roy. Soc. 1910), and it is also known that the allotropic transformations are accompanied by sudden changes in volume. It further follows from the equilibrium diagram of Fig. 23 that while γ iron can hold carbon or carbide of iron in solid solution to a considerable extent, both β and α iron have little or no power of dissolving carbon or carbide of iron.

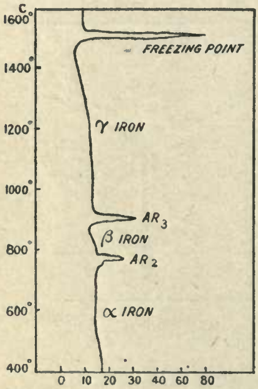

Fig. 24.

The area $ADEb_1$ of the diagram of Fig. 23 thus represents a region in which the alloys consist of a solid solution of carbon or more probably carbide of iron in γ iron. On cooling, this solid solution behaves very much like a liquid solution of two metals; along the line DG crystals of β iron are deposited, leaving the solid solution richer in carbon; along the line GE this process is continued except that the crystals which separate are now α iron; along the line Eb_1, on the other hand, crystals of cementite (carbide of iron) are deposited, leaving the residual solid solution poorer in carbon than it previously had been. If we follow the cooling of a steel containing from 0 to about 0·45 p.c. carbon, we find it passing first through the line DG, and then commencing to deposit crystals of β iron; these crystals increase in quantity until the line FG is crossed, when the whole of the β iron is transformed into α iron, and the quantity of this α iron now continues to increase, the carbon becoming increasingly concentrated in the residual solid solution. This concentration continues in such a way that at any instant if a horizontal line be drawn representing the temperature of the alloy, then the abscissa of the point where this line crosses the line DGE indicates the concentration of the residual solid solution. Accordingly, when the steel has reached the temperature of the line HEJ, the residual solid solution has at the same time reached both the concentration and the temperature of the point E. This point, and, indeed, the whole line HEJ, corresponds closely to the eutectic line of a simple system of eutectiferous alloy, such as the line DE of Fig. 4. At the temperature of the line HEJ the remaining γ iron of the residual solid solution undergoes transformation into α iron, and rejects the carbide which it held in solution up to that temperature; the result is that the residual solid solution breaks up into two phases, viz. α iron and cementite, giving rise to a regular laminated eutectic-like structure, which is called a 'eutectoid.' The micro-constituent corresponding to this decomposition is called 'pearlite,' from the pearly appearance which its laminated character gives it under certain conditions of illumination. The α iron, on the other hand, which has previously separated, is known micrographically as 'ferrite,' since it is practically pure iron. The microscopical appearance of pure ferrite has already been illustrated in Figs. 9 and 10, Plate I.; Fig. 25, Plate II. shows the structure of a very mild steel, containing about 0·15 p.c. carbon and consisting of ferrite (light) and pearlite (dark). Fig. 26, Plate II. shows the 'eutectoid' structure of pearlite more highly magnified.

Alloys lying between the concentrations of points E (0·9 p.c. C), and b_1 (2 p.c. C) undergo a somewhat similar series of changes, but here it is cementite which is separating out at all temperatures below the line Eb_1, while the residual solid solution is lowered in carbon content until the temperature of the line EJ, and the concentration of the point E are again simultaneously reached. The alloys of this group accordingly consist, when slowly cooled, of crystals of cementite embedded in the eutectoid pearlite.

Alloys lying to the right of the point b_1, so far as they follow the equilibria of the cementite system at all, consist, immediately below the line Bb_1, of crystals of the solid solution of cementite in γ iron embedded in a true eutectic of cementite and solid solution. The subsequent behaviour of these alloys is similar to that of the group just previously described, the solid solution behaves exactly like that of an alloy having the concentration b_1, the additional cementite remaining unchanged throughout. After slow cooling through the line EJ these alloys consist of two kinds of cementite, viz. that derived from the original eutectic solidification and that deposited by the solid solution during cooling, the latter being embedded in pearlite.

The constitution of the iron-carbon alloys at high temperatures, as indicated by the equilibrium diagram, is of special importance, owing to the wide use in the arts and industries of the process of hardening steel by quenching. It has already been explained that the effect of quenching is to inhibit the occurrence of those changes which take place in the metal in the course of normally slow cooling; this inhibition may be more or less complete according to the vigour of the quenching process employed. A very rapid cooling, as by quenching in water or even in iced brine, prevents the transformations more completely than more moderate rates of cooling caused by plunging the hot steel into oil or mercury (Benedicks, Journ. Iron and Steel Inst. 1908, ii. 152).

The iron-carbon alloys in the region ADGEb_1 of the diagram consist, as has already been stated, of a homogeneous solid solution of carbide of iron in γ iron. This solid solution, so far as it is known in micro-sections, has received the name of 'austenite.' In the case of certain alloy steels containing considerable proportions of such elements as nickel or manganese, this austenite solid solution remains stable down to the ordinary temperature, or may be retained by moderate quenching. In pure carbon steels it is never preserved unchanged by quenching, but it has been observed by etching steel surfaces at a temperature of over 1100° by means of hydrogen chloride acting in an atmosphere of hydrogen (Baykoff, Révue de Métallurgie, 1910). In quenched carbon steels, austenite is only met with if the carbon content is over 1 p.c., the quenching temperature over 1000°, and the quenching a vigorous one. Even then the austenite is always accompanied by some of the transition products which are intermediate between the unaltered solid solution (austenite) and the normal final decomposition product, pearlite. Among these transition products, three definite stages are observed. The first of these is the constituent known as 'martensite.' This always accompanies austenite in severely quenched carbon steels, and appears in the form of jagged areas showing a minute structure of fine interlacing needles or laminæ, generally crossing at angles approaching 60°. An example of the austenite-martensite structure of severely quenched carbon steels is shown in Fig. 27, Plate II. In the case of steels of lower carbon content, this constituent, martensite, may appear entirely without austenite, and it may occupy the entire area of the specimen. A photograph of a typical martensite structure is shown in Fig. 28, Plate II. This constituent is the hardest body met with in carbon steels; it is distinctly harder than austenite, but while austenite appears to be non-magnetic, martensite is distinctly magnetic, and it is, in fact, this constituent to which the large coercive force of hardened steel is due. The nature of martensite has been much discussed, but a rational view appears to be that the acicular structure arises from a partial decomposition of the austenite along the cleavage planes of its crystals, the whole process, however, being complicated by the changes in volume which accompany the allotropic transformations of iron. Austenite being principally γ iron, is capable of transformation into both β and α iron, the condition of the dissolved carbide being correspondingly altered. Although β iron cannot exist as a stable constituent of steel containing more than about 0·45 p.c. of carbon, yet it is very probable that γ iron in breaking down passes through the β condition before reaching the α stage, although the β condition is itself meta-stable. Martensite being the first stage in the breaking down of austenite, it is reasonable to suppose that the former constituent consists of or contains β iron. This view is supported by the fact that it has been shown (Rosenhain and Humfrey, The Crystalline Structure of Iron at High Temperatures, Proc. Roy. Soc. 1910) that β iron is decidedly harder and stronger than α iron. As regards the magnetic properties, it is admitted that β iron at high temperatures has only a small magnetic permeability, but it is quite possible that this property in this material has a high temperature-coefficient, so that if β iron could be obtained in the cold it might possess sufficient magnetic permeability to account for the magnetic properties of hard steel. Martensite may thus be regarded, provisionally at all events, as containing a considerable proportion of β iron, and as owing a considerable share of its great hardness to the presence of that form of iron. The hardness of martensite, however, is also due in part to two other causes; one of these is connected with the change of volume which is associated with the allotropic transformation; this change is to some extent inhibited by quenching, and severe internal stress is set up, and such a stress contributes materially to the hardness of the metal. The presence of carbon also plays an important part; in the first place the presence of carbon is essential in order that any process of quenching shall retain the iron in the γ or β state. This action of carbon is evident when an attempt is made to harden iron free, or nearly free, from carbon; no hardness comparable with that of steel can be obtained in that case. Carbon is said to act as a species of 'brake' on the allotropic transformations, and the nature of its action may be understood when it is considered that the transformation of pure iron from one allotropic form to another merely involves a rearrangement of the atoms within the molecule, or at most the interchange of atoms between closely adjacent molecules. When the γ iron contains dissolved carbide of iron, however, the allotropic change of the iron involves the expulsion of the carbide from solution, and, for completion, its rejection from the crystals of iron. This rejection involves a transfer of the carbide molecules across distances which are very large compared with molecular dimensions, and it is not difficult to understand that such a transfer occupies time, and that it is, therefore, more or less readily inhibited by the action of quenching.

In the case of martensite the rejection of the carbide from its state of solution in the γ iron of the austenite has only just begun, and the carbide probably exists in a separated form only on the cleavage planes of the original γ iron crystals. When the rate of cooling has been somewhat slower, however, the rejection of the carbide, as well as the allotropic transformation of the iron itself, are allowed to go somewhat further, and as a result a further transition product is found in the micro-sections. This is the dark-etching body known as 'troostite,' found in oil-hardened and in many tempered steels. In this constituent the rejection of the carbide is practically complete, but the carbide is in a state of extremely fine division, according to some views, indeed, in a state of ‘colloidal solution’ or suspension in the iron (Benedicks, Journ. Iron and Steel Inst. 1905, ii. 352, and 1908, ii. 217). In troostite it appears probable that while some of the iron still retains the original γ condition, and a large proportion is in the hard β condition, some has already passed into the soft α stage, with the result that steel containing troostite is distinctly softer than that consisting entirely of martensite. When the quenching or tempering is so adjusted that the whole of the γ iron has just disappeared, the proportion of troostite would attain its maximum, this being the state of tempered steel called ‘osmondite,’ by Heyn (Heyn and Bauer, Journ. Iron and Steel Inst. 1909, i. 109). Further tempering, or still slower cooling, leads to the appearance of a further transition product, which is not very sharply differentiated from troostite on the one hand, and from pearlite on the other. This is known as ‘sorbite.’ Here the iron has reached the α stage, and the carbide has begun to segregate into masses which are at first too minute to be seen under the microscope; but with further tempering, or less vigorous cooling, the segregation of the carbide reaches the point where it can be resolved under the microscope into granular or laminated pearlite. Steel containing sorbite is not really hard in the ordinary sense, although it possesses distinctly greater hardness and tensile strength than the same steel in the pearlitic state. Rail and other comparatively low-carbon steel is sometimes so treated as to render the carbonaceous constituent sorbitic, and in this condition the steel exhibits specially valuable physical properties.

The hardening of steel may be summarised metallographically as follows :—

Fully hardened steel = Martensite or austenite-martensite.
Moderately hardened or slightly tempered = Martensite-troostite.
Tempered steel = Troostite with either martensite or sorbite.
Slightly hardened or much tempered = Sorbite.

The causes which produce hardness in quenched steel may be summarised as :

(1) The retention of iron in the γ and β state.

(2) Internal stress set up by the partial retention of carbide in solution under conditions where stable equilibrium would require the separation of the carbide.

(3) Internal stresses and strains caused by the partially suppressed volume changes which accompany the allotropic transformations of iron.

It is desirable to mention at this point that, according to a rival theory, the hardness of quenched carbon steels is due to the existence of a definite iron-carbon compound (containing about 0·9 p.c. of carbon); on slow cooling this compound is said to decompose into pearlite, while quenching retains it in existence as ‘hardenite.’ This theory has, however, met with so little general acceptance and presents so many inherent difficulties that it could not be dealt with in the limits of this article.

A large and increasingly important class of alloys are those produced by the addition of various metals, such as nickel, chromium, manganese, and the rare metals such as vanadium, tungsten, molybdenum, and others, to iron and to certain grades of steel. The metallography of these steels is, however, so complex that it cannot be described here. Broadly speaking, these ‘special’ steels may be divided into four large classes, the class to which any particular steel belongs being dependent upon the total proportion of alloyed elements present. The first class of the special steels are those containing relatively small proportions of the added elements; these possess a simple structure of ferrite and pearlite, very similar to that of pure carbon steels, although differing in minor details; their mechanical properties are frequently markedly superior, and notably those containing nickel, chromium, and vanadium are finding much technical application. The second class of the alloy steels show a structure resembling that of martensite; they are hard and practically unworkable, but their existence is utilised in certain special cases, as in the production of case-hardened objects without quenching in the cementation of certain grades of nickel steel. The third class of alloy steels are those containing still larger proportions of alloyed elements, as, for example, a nickel steel containing about 25 p.c. of nickel. They exhibit a simple polyhedral structure, which is that of austenite, but in this case the solid solution contains the alloyed elements as well as the γ iron and carbon. These steels are non-magnetic, and possess remarkable mechanical properties, notably a high degree of ductility combined with great tensile strength. In some cases, however, they possess the peculiar property of being converted into steels of the previous class (martensitic) by mechanical work; such a steel, when first cut by a saw, for instance, is quite soft, but it rapidly hardens under the tool, until it can no longer be cut at all. This property is, however, confined to steels lying near the border-line of the two classes. A further increase in the proportion of the alloyed elements brings the steel into the fourth class, in which the presence of a carbide of the alloyed element can be detected in the micro-structure. For most general purposes such steels are useless, but certain of them appear to be capable of use as high-speed cutting tools. This highly important type of alloy steels cannot, however, be discussed in detail here. It can only be mentioned that while in ordinary carbon steels the temperature required for tempering, and therefore softening the steel is as low as 400°, these special steels can be made to withstand temperatures as high as a dull red heat without losing their hardness; they are thereby enabled to maintain their cutting edge at speeds which render the tools almost red hot. The manner in which the presence of the alloyed elements effects this behaviour can be approximately understood when it is mentioned that the critical points of an ordinary carbon steel are to some extent displaced, according to the temperature to which the steel has last been heated. The presence of an alloyed element not only itself displaces the normal position of the critical points—in the case of nickel steels, for example, extending the range of stable existence of γ iron down to the ordinary temperature—but the alloyed element also increases the extent to which the critical points can be displaced by heat treatment. In the case of high-speed tool steels it is found that by heating the steel to a temperature of 1200° or higher (a white heat), and allowing it to cool in a current of air, the critical point on next heating is raised to so high a temperature that a dull red-heat does not affect the 'temper' of the steel.

The micro-structure of steel has so far been described as the result of either 'normally slow cooling' or of quenching. For the steels containing higher proportions of carbon this classification is practically sufficient, but for the class of 'mild' steels containing up to 0·70 p.c. of carbon the effects of quenching need scarcely be considered, except in the case of the 'sorbitic' steel mentioned above. On the other hand, for these steels the temperature and duration of annealing, and the application of work by rolling, pressing, or forging is of vital importance, both to the micro-structure and to the mechanical behaviour of the material. Metallographic methods have cleared up the greater part of this field, but only general results can be mentioned. Thus it may be taken as a fundamental fact that coarse and well-defined micro-structures imply undesirable mechanical properties, especially as regards behaviour to shock, while a fine, close structure offers the best prospect of good quality in the metal. It is, however, a universal tendency of crystals forming an aggregate such as iron or steel, to grow; *i.e.* certain of the constituent crystals of the aggregate tend to increase in size at the expense of their neighbours. In the case of such comparatively 'refractory' metals as iron or steel, this growth of crystals is *nil*, or exceedingly slow at ordinary temperatures, although in the case of lead (Ewing and Rosenhain, The Crystalline Structure of Metals, second paper, Phil. Trans. A, 1900) and brass (*see* L. Guillet, Alliages Métalliques, ch. x.),such growth takes place measurably even without the application of heat. When iron or steel is heated, however, the tendency for crystal growth rapidly asserts itself, and, indeed, it is to this process of growth, or of 're-crystallisation,' that we owe the power of annealing or softening metal which has been rendered hard and brittle by the application of cold work. In the case of steel, when the temperature of a critical point is passed (on heating) the transformation occurs at a number of centres which behave as centres of crystallisation, and a new system of crystals begins to grow from each of these centres, although to some extent the new set of crystals tends to follow the outlines of those previously in existence. With rising temperature the rate of crystal growth increases, and the ultimate size of structure attained is thus a function of both the time of heating and of the temperature attained. When steel which has been thus heated is allowed to cool slowly, although there is a distinct tendency for rearrangement to occur on passing through the critical points, yet the coarse structure is very apt to persist, and if the heating has been carried too far we have a coarse, weak structure typical of 'overheated' steel. To some extent this coarse structure may be removed by heating the steel for some time to a temperature just above the critical point, and then cooling it somewhat rapidly through the critical point down to the ordinary temperature. A more effective method, however, consists in exposing the steel to hot working (rolling, forging, &c.). This process deforms the existing crystals in a manner described below, and these deformed crystals are unstable, *i.e.* crystal growth starts afresh in them, and can no longer follow the previous outlines; the result is an entirely new and much more minute system of crystals. The exact analogue of this process has been watched, in the case of lead, taking place at the ordinary temperature.

Cast iron, Pig iron. The equilibrium diagram and constitution of iron-carbon alloys has so far been discussed only in reference to alloys containing less than 2 p.c. of carbon, and usually known under the name of 'steel.' The alloys richer in carbon must now be dealt with; these are met with industrially in the shape of a large variety of cast and pig irons, but it must be remembered that while the better kinds of steel consist essentially of almost pure iron-carbon alloys, the cast and pig irons generally contain very considerable proportions of impurities, such as silicon, sulphur, phosphorus, &c. In addition, a large number of these higher-carbon alloys differ essentially from steel by containing carbon in the form of graphite. The equilibrium diagram of the iron-carbon system given in Fig. 23 represents, as has already been mentioned, what is in reality a meta-stable condition of the iron-carbon system; if sufficient time at a suitable temperature be allowed it is probable that carbide of iron would decompose completely into iron and graphite. Apparently it is also possible for free carbon (graphite) to separate as primary crystals from the molten iron-carbon alloys containing over 4·3 p.c. of carbon. If it is true—as seems probable—that in the liquid alloys the carbon is dissolved in the form of only slightly dissociated carbide, then in these high-carbon alloys the carbide (cementite) in certain conditions, and notably in the presence of silicon and in the absence of manganese, is liable to undergo decomposition at a temperature near that of incipient solidification, one of the products of decomposition being graphite, which thus appears as a solid phase in the shape of crystals separating from the liquid. The equilibrium diagram of this ultimately stable system (Fig. 23, dotted lines) thus contains the liquidus branch corresponding to the separation of the γ iron solid solution, but this is carried to a eutectic point differing slightly from the γ iron-cementite eutectic, and corresponding to a γ iron-graphite eutectic; below the temperature of this eutectic the alloys are completely solid, and consist, to the left of the eutectic-point (B) of γ iron embedded in the graphite eutectic, while to the right of the point B they should consist of primary graphite crystals embedded in the eutectic; owing to the low density of the graphite, however, this substance does not remain embedded in the liquid metal from which it is separated, but floats to the surface in the form of 'kish.' On further cooling the behaviour of these alloys should theoretically lead to the complete decomposition of all the cementite, including that contained in the γ iron solid solution, but the exact circumstances in which such decomposition occurs are not fully ascertained. The lower part of the dotted-line diagram of Fig. 23 has not, therefore, been filled in.

In practice certain varieties of cast and pig iron tend to follow the system of solidification just indicated, but they rarely, if ever, do so completely; whilst, if the rate of cooling is rapid, and especially if the iron contains little silicon and much manganese, the decomposition of the cementite is more or less completely prevented, and the iron cools with the formation of little or no graphite, forming what is known as 'white iron'; iron which contains much graphite and little cementite is known as 'grey,' whilst intermediate varieties are known as 'mottled.'

Microscopically, all varieties of iron may, in accordance with the above, be regarded as mixtures of steel with a certain amount of graphite. The 'steel' portion will have the characteristic structure of an iron-carbon alloy whose carbon content corresponds to the amount of 'combined' carbon, *i.e.* of undecomposed cementite, present in the iron. Thus an iron containing, for instance, 0·5 p.c. of combined carbon, together with 3 p.c. of graphite (total carbon 3·5 p.c.), will show a structure of ferrite and pearlite corresponding to that of a 0·5 p.c. carbon steel, together with a considerable amount of graphite. A typical example of the micro-structure of a 'grey' iron of this type is shown in Fig. 29, Plate II., but the presence of impurities, particularly of phosphorus, very materially affects the appearance of such micro-structures, since the phosphorus forms, with the iron, a definite compound Fe_3P, and this compound forms with the iron a well-defined and characteristic eutectic, which may be mistaken for pearlite under the microscope. This phosphide eutectic can, however, be readily distinguished from pearlite by exposing the specimen to a moderate degree of heat which causes a slight surface oxidation, and in consequence a differential tinting of the various constituents.

Increasing total carbon-content, with constant amount of combined carbon, merely causes an increase in the amount of graphite found in the micro-sections; an increase in the proportion of combined carbon, however, causes the 'steel' portion of the iron to move up the carbon-scale, first producing an increase of the amount of pearlite, and finally the appearance of cementite in place of ferrite. In the case of 'white' irons produced by chilling high-carbon cast iron, the graphite disappears entirely, and the resulting micro-structure consists entirely of cementite and pearlite, together with the constituents due to impurities. As regards mechanical properties, it is obvious that the presence of plates of graphite, destroying the continuity of the 'steel' matrix, largely reduces the strength of the material as compared with a steel of equal combined carbon; on the other hand, the iron will be 'soft' or 'hard,' according to the micro-structure of the 'steel' matrix, an iron containing ferrite and pearlite will be much softer and less brittle than an iron containing cementite and pearlite. These latter constituents are responsible for the great hardness of 'chill' iron castings.

For certain purposes castings are treated in such a manner as to be deprived of their graphite content more or less completely by a process known as the production of 'malleable' castings. This process consists in heating or annealing the castings for a considerable time, generally while packed in an oxidising material, such as iron oxide. To a considerable extent decarburisation occurs, while much of the combined carbon is deposited in the form of a very finely divided graphite known as 'temper carbon.' The softening effect of the process depends partly upon the actual removal of carbon by oxidation and partly upon the effect produced by prolonged heating upon the arrangement of the graphite which remains in the metal. While in ordinary castings it is present in the form of plates and veins, in 'malleable' castings it is found in small nodules and patches which do not affect the strength and ductility of the material to anything like so great an extent.

A converse process, for producing surface hardness in articles made of iron or mild steel is that known as 'case hardening.' In this process the iron or steel is heated for a considerable time in contact with carbonaceous matter, preferably also containing nitrogenous matter. The iron takes up carbon and forms a hard external layer rich in cementite, which, therefore, has the power of being hardened by quenching. Micro-sections of case-hardened articles readily show the depth and nature of the hard 'case,' and the structure of the underlying softer and tougher material.

Deformation, fracture, and fatigue in metals. Microscopic metallography has made it possible to determine the mechanism by which metals undergo plastic deformation, and incidentally to explain the mode of fracture under tension, shock, and 'fatigue.' It has already been indicated that when a piece of metal is forced to change its shape, as by hammering, rolling, pressing, &c., the component crystals of the metal also undergo a corresponding change of shape, although subsequently if the temperature is high enough to permit of sufficient molecular mobility in the particular metal in question, the crystals tend to rearrange themselves into more normally shaped forms. If a bar of metal be forcibly stretched, the constituent crystals will be found to be stretched also. Thus cold-rolled iron shows the structure illustrated in Fig. 30, Plate II., where the ferrite crystals are seen to be lenticular in section in place of the normal polyhedral shape. The manner in which metallic crystals undergo such changes of shape becomes evident if a surface of a specimen of metal is prepared for microscopic examination (*i.e.* polished) before the piece of metal is subjected to the change of shape. The crystals which, before deformation, appeared as practically featureless polygonal areas, after the application of the strain, are seen to be cross-hatched by systems of fine lines. In the case of highly plastic metals, such as lead or copper, the lines are seen to be characteristically straight and regular, while in the harder metals, such as iron, the lines appear more or less branched and curved. It has been possible, however, to observe the formation of these lines in iron at high temperatures (up to 1100°) (Rosenhain and Humfrey, The Crystalline Structure of Iron at High Temperatures, Proc. Roy. Soc. 1910), and in those circumstances they are as straight and regular as those of copper. The typical appearance of these lines is shown in Fig. 31, Plate II. Their nature has been elucidated by a long series of experiments, including the preparation of transverse sections of specimens of metal upon which the lines had previously been developed, and the conclusion arrived at is that they are in reality minute steps in the surface arising from the fact that the adjacent portions of the crystal have slipped over one another along the cleavage or gliding planes of the crystal. It may be accepted as abundantly proved that the polygonal grains seen in the micro-sections of metals are true crystals, possessing all the essential features of crystals as regards the regular and symmetrical arrangement of the constituent molecules, although these crystals have grown together into an aggregate without allowing the individual members to develop their characteristic external shape. Such crystals, then, may be regarded as built up of minute elements or groups, much as a stack of bricks is built up of individual bricks. It has been shown (Ewing and Rosenhain, The Crystalline Structure of Metals, Bakerian Lecture, Phil. Trans. A, 1899; Rosenhain, Deformation and Fracture in Iron and Steel, Journ, Iron and Steel Inst. 1906, I.; Rosenhain and Humfrey, The Crystalline Structure of Iron at High Temperatures, Proc. Roy. Soc. 1910) that these crystal 'bricks' or units are themselves never deformed or changed in shape (excepting the temporary 'elastic' deformations which are left out of consideration here), and that the crystals which are built up of these units accommodate themselves to changes of shape imposed upon them by allowing the 'bricks' to slide over one another along at least three sets of gliding planes. Where these planes of slip reach the surface of a crystal forming part of the previously polished face of the specimen, the result is the formation of a minute step in the surface, and the short sloping surface of such a step, when viewed by 'normal' light, appears as a fine dark line. Illumination by oblique light, on the other hand, shows the lines shining brightly against the dark background whenever the short sloping surfaces are turned so as to face the incident light. On account of their mode of formation these lines have been called 'slip bands.'

In certain metals, notably in copper and its α alloys, and also in lead and many other plastic metals and alloys, the process of deformation by slip as just described is also accompanied by what is known as 'mechanical twinning.' In this process a certain portion of the crystal, in order to accommodate itself to the circumstances created by the application of plastic strain, swings over into an entirely new orientation, which is, however, definitely related by crystallographic laws to the orientation of the parent crystal; this process usually occurs in a series of parallel bands. The presence of crystals showing regular alternating bands of similar orientation is always an evidence of 'twinning,' and since twinned crystals rarely occur in cast metals, this feature is generally evidence of the application of work to the specimen in which it appears. Where deformation by slip and by mechanical twinning occur together, the slip-bands change their direction on passing the edge of the twinned area, and a stair-like shape of the bands results.

The process of deformation by slip obviously implies that the metal retains its truly crystalline character after it has undergone a permanent change of shape, and it is found that, unless the amount of deformation has been very large, this is actually the case.

A further series of phenomena must, however, be considered; these relate to the changes which occur in the structure of the crystal at and in the immediate neighbourhood of the surfaces upon which slip has taken place. It has been shown that when the surface of a piece of metal is rubbed or polished (G. T. Beilby, The Hard and Soft State in Metals, Phil. Mag. 1904; G. T. Beilby, Hurter Memorial Lecture, J. Soc. Chem. Ind. 15, 1903), some of the molecules in the surface layer of the metal are torn away from their crystalline arrangement, and are left upon the surface in a state of relative freedom, which allows them to behave in a manner resembling a thin film of viscous liquid. It is by the spreading out of such a film under the action of pressure and of polishing media, that polished surfaces are formed. The material of this thin surface film, however, is no longer in the crystalline condition; its condition resembles that of an exceedingly viscous liquid, and is therefore to be regarded as being truly 'amorphous,' and it has been shown that in this amorphous condition, although temporarily mobile, the material is much harder and also much more brittle than the same substance in the crystalline state. Now in the interior of the crystals of a metal which undergoes deformation by slip, metal surfaces move over one another under very considerable pressures, and it follows that an action very similar to that which occurs upon a surface which is being polished will take place on every gliding plane; *i.e.* a thin layer of molecules will be disturbed from their normal position in the crystalline arrangement, and a layer of temporarily mobile, amorphous material will be formed. Now it has been shown that if this layer is thin, the directive forces of the adjacent crystalline systems are sufficient to cause the disturbed molecules to reassume the orientation of the system, and in that case the surface on which slip has taken place may be said to have 'healed up.' On the other hand, two different cases may occur. In the first case the process of slip may be carried so far that the disturbed layer becomes too thick to allow of complete and almost immediate recrystallisation, and then each surface of slip remains as a species of 'scar' within the metal, taking the form of a thin layer of hard, amorphous material. The presence of these hard layers tends to render the metal both harder and stronger, but also more brittle, and it is well known that this is the universal result of the application of cold work or plastic deformation to ductile metals. If the process of plastic deformation is carried to an extreme, as in the hammering of thin metal foil, a large proportion of the metal may ultimately be present in the amorphous condition; but this condition is unstable, and a very moderate amount of heating is sufficient to induce recrystallisation. This stage, however, is only reached in special circumstances; more usually the application of stress results first in a certain amount of plastic deformation (by slip), followed by a local and rapid deformation—also by slip—which results in fracture at some point where the amount of slip has carried the adjacent parts of a crystal out of contact. The fracture resulting from such a mode of breaking has a fine silky fibrous appearance, owing to the fact that all the minute surfaces of slip along which fracture has occurred are inclined at small angles to the direction of stress, but the metal has remained essentially crystalline; indeed, apart from non-metallic inclusions, such as the 'cinder' in wrought iron, there is no true 'fibrous' structure or condition in metals.

The second class of circumstances which do not permit of the immediate re-crystallisation of the layer of disturbed molecules, which are formed on surfaces of slip arise when the stress which has produced a small amount of slip is reversed; such a reversal of the stress will, if it comes soon after the first occurrence of the slip, cause the reversal of the slip itself, and the layer of disturbed molecules will still be in the mobile condition, and will serve as a species of lubricant to facilitate the return slip. At the same time, the reverse motion will produce an increase in the number of disturbed molecules, and the disturbed layer will grow in thickness with each reversal. After a large number of such reversals of stress some of this disturbed material will be forced—in its temporarily mobile state—out of the space between the adjacent sections of the crystal, and what was before a surface of slip will thus become an actual fissure, which spreads rapidly through the whole mass. The resulting fracture will show comparatively large bright facets representing the planes on which slip has occurred, so that the fracture will have a 'crystalline' appearance, although the metal itself is neither more nor less crystalline than it was at the beginning. The view that metals 'become crystalline' under alternating stresses or under vibration is thus entirely without foundation. It should be said that the explanation of the manner in which metals fracture under 'fatigue,' *i.e.* under the repeated alternation of stresses which would fail to fracture the material at a single prolonged application, which has been given here is no longer to be regarded as of a speculative character, since every point in the explanation has been definitely observed and verified by several independent observers (Ewing and Humfrey, The Fracture of Metals under Repeated Alternations of Stress, Phil. Trans. A, 1903, 200; Stanton and Bairstow, The Resistance of Iron and Steel to Reversals of Direct Stress, Proc. Inst. C.E. 1907).

The methods of metallography, although they have so far been described largely from the point of view of affording a clearer insight into the nature and constitution of metals and alloys, are also capable of direct practical applications. These applications include, in the first place, the control of metallurgical operations, particularly of the temperatures employed in thermal and mechanical treatment of all kinds and the investigation of new alloys. There is also an important field of usefulness for these methods, and more especially for the microscopic examination of metals in conjunction with exhaustive mechanical tests, in the investigation of cases of failure or breakage either under test or in service, including such questions as apparently mysterious fractures, unduly rapid wear or corrosion and similar problems. Although it would be too much to claim that metallographic methods are always capable of finding the correct solution of problems of this class, a great deal of light can often be thrown upon the causes which have led to the failure, and, in many instances, the true cause of failure can be discovered. A considerable number of such investigations have been described (W. Rosenhain, The Study of Breakages, Engineering, Sept. 1908), but the greater number are—for obvious reasons—never allowed to reach the public. It is, however, to be borne in mind that it is largely by the investigation of cases of unexpected breakage or other failure that fresh knowledge on the properties of our engineering materials can be obtained. In a number of actual cases it has been found that the metal had been damaged by modes of treatment which had been regarded as harmless. Metallography is therefore a science which has not only placed in the hands of metallurgists a mass of valuable and detailed knowledge of the internal structure and constitution of metals and alloys, but it has also furnished them with methods of investigation which are probably destined to elucidate many of the still 'mysterious' features in the behaviour of the materials of engineering. W. R.

METANIL YELLOW *v.* AZO- COLOURING MATTERS.

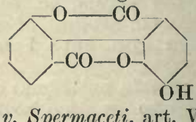
METARABIN *v.* GUMS.

METAXYLORCINOL *v.* PHENOL AND ITS HOMOLOGUES.

METELLAGIC ACID. Metellagic acid $C_{14}H_6O_5$ is prepared by the oxidation of *m*-hydroxybenzoic acid with potassium persulphate and sulphuric acid. It crystallises from pyridine in colourless prismatic needles, and when distilled with zinc dust gives fluorene. The acetyl derivative

$$C_{14}H_5O_5(C_2H_3O)$$

colourless needles, melts at 269°–271°. According to Perkin and Nierenstein (Chem. Soc. Trans. 87, 1425), metellagic is related to ellagic acid, and possesses the following constitution:



METHAL *v. Spermaceti,* art. WAXES.

METHANE. *Methyl hydride* (*v.* METHYL COMPOUNDS).

***p*-METHOXYBENZENEDIAZO CYANIDES** *v.* DIAZO- COMPOUNDS.

METHYL CH_3 is a univalent, compound radicle, not known in the free state. The compound C_2H_6 discovered by Frankland and Kolbe (Chem. Soc. Trans. 1, 60) was called methyl, and believed to be the free base, and even when its molecule was recognised as dimethyl $(CH_3)_2$, it was at first thought to be distinct from ethane, the gas obtained by Frankland from ethyl iodide by heating with zinc and water. It was, however, proved to be identical with that body by Schorlemmer (Chem. Soc. Trans. 17, 262).

METHYL COMPOUNDS.

Methyl acetate *v. Alkyl acetates,* art. ACETIC ACID.

Methyl alcohol CH_3OH. *Methyl hydrate, hydroxymethane, wood spirit, pyroxylic spirit, wood naphtha*, 'Columbian spirit,' 'Colonial spirit,' 'kakol' (proprietary names in U.S.A.), (Ger. *Holzgeist*). B.p. 64·56°/760 mm. (J. Gyr, Ber. 1908, 4322); sp.gr. 0·796472 at 15°/15° (Klason and Norlin, Chem. Soc. Abstr. 1906, i. 821; Gyr, Ber. 1908, 4322; Doroschewsky and Roschdestvensky, Chem. Soc. Abstr. 1909, i. 868); 0·81000 at 0°/4° (Young and Fortey, Chem. Soc. Trans. 1902, 735); H.C. = 170·6 (Stohmann, Kleber, and Langbein, J. pr. Chem. [ii.] 40, 341); H.F. = 61·4 (S., K., and L.).

Boyle found that the liquid obtained by distilling wood contained two constituents, an acid portion and a neutral spirit.

Various conjectures were made as to the nature of this 'spirit,' the first investigation of which was made by Dumas and Peligot in 1834 (Ann. Chim. Phys. 58, 5; 61, 193). They gave it the name 'methyl alcohol' (μέθυ, wine; ὕλη, wood).

Formation.—By the dry distillation of wood, of beet-sugar molasses (Vincent, Bull. Soc. chim. [ii.] 27, 148), or of calcium formate (Paternò and Lieben, Annalen, 167, 293; Friedel and Silva, J. 1873, 526). Methyl alcohol occurs in the free state in plants (Gutzeit, Maquenne, Geuther). It is also recovered from the waste water of the steamed wood pulp in paper manufacture, by allowing the liquors to concentrate through repeated use and subsequently distilling (Alkier, Eng. Pat. 1514, 1890).

Preparation.—Methyl alcohol is prepared on the large scale from the distillate from wood, which contains various tarry matters, acetic acid, and the methyl alcohol. The distillates from the wood are allowed to stand for some time, when the tarry, resinous, and oily matters precipitate; the supernatant liquid is then filtered through gravel into another vessel, from which it is either distilled at once or after previous neutralisation with lime. The distillation is effected in the first case in copper stills, and heat is applied by coils of copper pipes conveying steam; in the second case boilers of sheet iron are employed, and the heat applied by the direct fire.

The distillate is then purified by repeated redistillations from caustic lime, and lastly, from a little sulphuric acid (in order to remove NH_3 and amines). In some cases chalk is used instead of lime, and sometimes chalk and sodium bicarbonate.

The distillation is carried on in copper stills heated by steam coils, or the retorts are guarded by iron jackets, and heated over the fire. The crude spirit thus obtained is colourless, and its sp.gr. varies from 0·87 to 0·82.

The disagreeable-smelling constituents are sometimes got rid of by Wildsmith's process, which consists in the application of oxidising agents, *e.g.* potassium dichromate, aided by the action of light, to the crude spirit, by which means the hydrocarbons, &c., are destroyed, and a colourless, almost odourless, liquid obtained.

The usual yield of pyroxylic spirit is from 1 to 3 gallons from each ton of wood distilled, but the quantity depends upon the kind of wood employed, and also upon the proper regulation of the temperature during distillation. The best yields are obtained by using a mixture of oak, beech, and hornbeam (Barillot, Compt. rend. 122, 469).

Large quantities of methyl alcohol are now made by the distillation of kinasse (residues obtained by the evaporation of the spent wash in the preparation of ordinary alcohol from beet-sugar molasses). The distillate contains ammoniacal compounds, methylamine, methyl cyanide, and methyl alcohol. After neutralising with sulphuric acid the mixture is evaporated, the vapours being condensed; these contain methyl cyanide and methyl alcohol; the former is decomposed by rectification over lime, and the distillate, which contains dilute methyl alcohol, is dehydrated by means of lime.

Commercial wood spirit contains very variable proportions of the pure alcohol, from as low as 35 p.c. to as high as 95 p.c. It contains acetone, methyl acetate, and often, various empyreumatic bodies; these have considerable influence, not only upon its density, but also upon its solvent powers for shellac and other resins. The purest spirit is always preferred for use in lamps as a fuel, but for the use of the varnish-makers and polishers some of the impurer varieties, containing essential oils, &c., are sometimes chosen.

The following process for the production of methyl alcohol from wood is patented by F. J. Root (U.S. Pat. 713552, 1902). In the destructive distillation, a pressure is maintained in the apparatus slightly lower than that of the atmosphere. The readily condensable gases are condensed in primary condensers, whilst the gases which are not readily condensable are mixed with a definite proportion of steam and the acids thus set free are recovered in a secondary condenser. The degree of vacuum and the supply of steam required for mixing with the less condensable gases are obtained by means of a steam exhauster situated beyond the primary condensers. This exhauster is regulated automatically by the volume and tension of the gases generated so that both functions are kept constant. The introduction of superheated air, containing only a little oxygen and a good deal of steam, which increases the yield of volatile products in the ordinary destructive distillation, is patented by Zwillinger (Eng. Pat. 18823, 1889).

A variant of the ordinary method of destructive distillation of wood consists in first adding strong sulphuric acid. 100 kilos. of wood, containing 35 p.c. of moisture, with 20 kilos. of strong sulphuric acid on distillation up to 160° and rectifying the distillate, yield wood alcohol 3 kilos., acetic acid 7 kilos., oil of turpentine 2 kilos., and 40 kilos. of wood charcoal of good quality (Orljavacer, Chem. Fabrik, Fr. Pat. 357432, 1905).

Hofer and Moest find that a good yield of methyl alcohol is obtained by the electrolysis of sodium acetate solution containing sodium chlorate (Annalen, 323, 284; D. R. P. 138442, 1901).

The conversion of methane, which often occurs in large quantities near oil fields, into methyl alcohol or other commercially useful articles, is a problem which is still undergoing examination. Lance and Elworthy (Eng. Pat. 7297, 1906) claim the use of hydrogen peroxide (with or without ferrous sulphate or monopersulphuric acid) and monopersulphuric acid alone. Von Unruh has utilised atmospheric air as an oxidising agent with bark as a catalyst, but in this case methyl alcohol is the subsidiary product, the oxidation proceeding farther and producing formaldehyde chiefly. 24 litres of methane by this process, when mixed with 180 litres of air at 45°, yield in the apparatus described, 1565 grams of formaldehyde in 12 hours (U.S. Pat. 891753, 1907; *see also* Hausmann & Co., D. R. P. 214155, 1906).

Purification.—According to a method patented by Piper and Rotten of Berlin (D. R. P. 36827, 1886), the wood spirit is first distilled with lime and then by fractional distillation the acetone is reduced to 1 or 2 p.c. To remove the remaining acetone the spirit is heated to boiling (with reflux condenser), and dry chlorine is passed into it; portions are tested from time to time by distilling, and testing the distillate for acetone by the iodoform reaction (*see also* Rotten, J. Soc. Chem. Ind. 1901, 604). Treatment with bleaching powder is also sometimes adopted. When this reaction is no longer given the passage of the chlorine is stopped, and the methyl alcohol separated by fractional distillation from the high boiling chlorinated acetone, and purified by distillation over lime from traces of chlorine. The methyl alcohol thus obtained is perfectly free from acetone; the chloracetone can be reconverted into acetone by reducing agents. Methyl alcohol purified in this way invariably contains some chlorinated impurities, which may be removed by heating under a reflux condenser with lime.

In order to obtain pure methyl alcohol, the oxalic or formic ester is prepared, and then decomposed by heating with water (Wöhler, Annalen, 81, 376), or ammonia (Grodzki and Krämer, Ber. 7, 1494). Methyl benzoate when heated with a solution of 1 part sodium hydroxide in 5 parts of water yields methyl alcohol (Carius, Annalen, 110, 210). Pure methyl alcohol may be prepared by treating 10 parts of commercial wood spirit with 1 part of iodine, and then adding caustic soda until the colour of the iodine disappears, and distilling (Regnault and Villejean, Bull. Soc. chim. [ii.] 42, 255). 100 c.c. of the crude spirit are digested with 150 grams of solid caustic soda, and afterwards distilled, 500 grams of oxalic acid are mixed with 200 c.c. of sulphuric acid, and then 400 c.c. of the purified alcohol are added, and the mixture is heated on the water-bath; the crystals of methyl oxalate are dried by pressure and saponified by heating with water at 70°. The distillate is then dehydrated by means of baryta, lime, and anhydrous copper sulphate (Dittmar and Fawsitt, Trans. Roy. Soc. Edin. 33, 509). Apparatus for the purification of wood spirit is best constructed of aluminium or an aluminium alloy free from copper. Copper heavily coated with tin, or iron or copper lined with earthenware may also be used with connecting pipes of earthenware. Air should be excluded as completely as possible as this oxidises the methyl alcohol to formaldehyde, acetaldehyde, and methylal, the reaction being readily catalysed by copper vessels. Aldehyde resin is likely to form in the still if the alkaline reagent has been added to the crude wood spirit (P. Pikos, J. Soc. Chem. Ind. 1909, 1118).

The following is a continuous method of preparing pure concentrated wood spirit. The crude spirit is distilled and the vapours passed first through lime water, then warm concentrated alkali solution (15°–20° Beaumé), afterwards washed with stearic or other fatty acid, and finally with alkali again. This treatment removes all aldehydic resins, higher alcohols, ketones, &c. (J. Farkas, D. R. P. 166360, 1904).

The purest anhydrous methyl alcohol is prepared from the best acetone free commercial article by first heating for some time with freshly burnt lime, then leaving in contact with ignited potassium carbonate for some weeks, and finally distilling several times from metallic calcium. The most accurate criterion of dryness is the esterification constant which, for the anhydrous alcohol and phenyl acetic acid, is 3·556. One-twentieth of a p.c. of water by volume lowers this to about 0·532 and ordinary pure dry methyl alcohol from methyl oxalate is often as low as 0·465 (J. Gyr, Ber. 1908, 4322).

Other processes are patented by Rosencrans (U.S. Pat. 793542, 1905); Chute (U.S. Pat. 824906, 1906); and Schmidt (U.S. Pat. 885183, 1908).

Detection and estimation.—The recognition of methyl alcohol itself is a somewhat difficult matter but its oxidation products, formaldehyde and formic acid, are more readily characterised. Of its compounds, the most characteristic is the *oxalate*, which is a crystalline solid melting at 54°. Mulliken and Scudder (Amer. Chem. J. 1899, 21, 266; 1900, 24, 444; J. Amer. Chem. Soc. 1905, 892), Barbet and Jandrier (Chem. Soc. Abstr. 1898, ii. 265), Jandrier (Chem. Zentr. 1899, i. 1296), Leach and Lythgoe (J. Amer. Chem. Soc. 1905, 964), Scudder and Riggs (*ibid.* 1906, 1202), Franz Utz (Chem. Zentr. 1905, ii. 1467), Hinkel (Analyst, 1908, 417), Voisenet (Bull. Soc. chim. 1906, [iii.] 35, 748), Trillat (Compt. rend. 1899, 127, 232), Vorisek (J. Soc. Chem. Ind. 1909, 823), and others have all made contributions to the vexed question of the most reliable test for methyl in the presence of ethyl alcohol. As an outcome, the following official test of the U.S. Pharmacopœia has been adopted for quantities of 2 p.c. and upwards: the liquid is diluted so as to contain about 10 p.c. total alcohols. About 3 c.c. is oxidised by plunging a red hot copper spiral five or six times into it while it is kept from boiling away by being surrounded by a beaker of cold water. It is then filtered and boiled till free from the smell of acetaldehyde, After cooling, 1 drop of 0·5 p.c. resorcinol is added and sulphuric acid poured into the test tube so as to form a layer. It is allowed to stand for 3 minutes and gently rotated. If no rose-red ring appears, methyl alcohol is below 2 p.c. Quantities from 2 p.c. down to 0·1 p.c. may be detected by fractionating 50 c.c. three times through a good fractionating head. The first two distillations should proceed till about 35 and 20 c.c. respectively in the case of a strong spirit, or 20 c.c. and 10 c.c. with a weak one, have passed over. The first 3 c.c. of the third distillation is tested as above.

The detection of methyl alcohol in the presence of formaldehyde necessitates first the removal of the formaldehyde. This may be done in several ways. Gnehm and Kaufler (Chem. Soc. Abstr. 1904, ii. 520; 1905, ii. 209) recommend combining it with sodium sulphanilate. Stritar (*ibid.* 1904, ii. 686) uses ammonia. Bamberger (*ibid.* 786) prefers sodium hydrogen sulphite. The best reagent for this purpose is probably potassium cyanide, as proposed by Leffmann (Chem. Zentr. 1905, ii. 1467). The methyl alcohol is subsequently distilled off and estimated by the sp.gr. of the distillate. *See* also Duyk (Chem. Soc. Abstr. 1902, ii. 110) and Blank and Finkenbeiner (Ber. 1906, 1326).

For the estimation of methyl alcohol, in the absence of other materials than water, a reference to the table of sp.gr. is the most rapid method, but Zeisel's well-known methyl iodide method is very reliable. The latter is only interfered with by acetal or ethyl alcohol. In the presence of ethyl alcohol the most accurate method is that due to Thorpe and Holmes (Chem. Soc. Trans. 1904, 1), depending on the fact that when oxidised with dichromate and sulphuric acid, ethyl alcohol gives rise to acetic acid and a minute quantity (about 0·5 p.c.) of carbon dioxide, whilst methyl alcohol is completely oxidised, under the stipulated conditions, to carbon dioxide and water. The process is as follows: the sample is mixed with water in such proportion that 50 c.c. of the mixture shall contain not more than 1 gram of methyl alcohol, and in the presence of ethyl alcohol not more than 4 grams of the mixed alcohols. Fifty c.c. of this mixture are then introduced into the oxidation flask, 20 grams of potassium dichromate, and 80 c.c. of dilute sulphuric acid (1 : 4) added, and the mixture allowed to remain for 18 hours. A further quantity of 10 grams of potassium dichromate and 50 c.c. of sulphuric acid mixed with an equal volume of water are now added and the contents of the flask heated to boiling for about 10 minutes. The carbon dioxide is swept out by a current of air and collected in weighed soda-lime tubes. When ethyl alcohol is present, a subtractive correction of 0·1 gram of carbon dioxide for each gram of ethyl alcohol must be made. This method is of great convenience in determining the adulteration of tinctures and other medicinal preparations by methylated spirits.

Other substances yielding carbon dioxide in these circumstances are allyl alcohol, methyl acetate, and acetone. Ether and pyridine do not affect the estimation.

Properties.—A colourless liquid with an odour like that of ethyl alcohol; miscible with water in all proportions, and with contraction and evolution of heat (*v.* table). It burns with a blue flame. It possesses, like ethyl alcohol, remarkable solvent powers, dissolving most substances which are soluble in ethyl alcohol; consequently it may be used in many cases instead of that liquid.

Its vapour pressure at various temperatures is given in the following table (Dittmar and Fawsitt):—

Temperature	Vapour pressure	Temperature	Vapour pressure
°C	mm.	°C.	mm.
0°	29·7	40°	259·4
5°	40·2	45°	327·3
10°	53·8	50°	409·4
15°	71·4	55°	507·7
20°	94·0	60°	624·3
25°	122·7	65°	761·1
30°	158·9	64·96°	760·0
35°	203·9		

Anhydrous copper sulphate is slightly soluble in absolute methyl alcohol, yielding a bluish-green solution, hence it cannot be used as a test of the freedom of methyl alcohol from water (Kelpl, J. pr. Chem. [ii.] 25, 526). This blue solution deposits crystals of $CuSO_4,2CH_3OH$ (Forcrand, Compt. rend. 102, 551). Hydrated copper sulphate dissolves to the extent of 11·5 p.c. at 0° and the solution on standing deposits green rosettes of crystals having the composition $3CuSO_4{\cdot}CuO,4CH_3OH$ (Auger, *ibid.* 142, 1272). Methyl alcohol combines with many salts in a manner similar to water of crystallisation, *e.g.* $LiCl,3CH_3OH$; $MgCl_2,6CH_3OH$; $CaCl_2,4CH_3OH$, six-sided tables, decomposed by water, may be heated to 100° without decomposition (Kane, Phil. Mag. [iii.] 10, 45). A compound with barium oxide, $BaO,2CH_3OH,2H_2O$, is obtained in brilliant prisms, when BaO is dissolved in aqueous methyl alcohol, and the liquid evaporated at the ordinary temperature (Forcrand, Compt. rend. 102, 1557).

When passed over heated zinc, methyl alcohol yields carbon monoxide, hydrogen, and a small quantity of methane (Jahn, Ber. 13, 983). By the action of zinc chloride, hydrocarbons C_nH_{2n+2} are the chief products, also some hexamethyl benzene (Le Bel and Greene, J. 1878, 388). By electrolysis in presence of sulphuric acid, *methylal* $CH_2(OCH_3)_2$ is produced (Renard, Ann. Chim. Phys. [v.] 17, 290).

Methyl alcohol is not decomposed by *bacterium aceti.* Potassium or sodium liberates hydrogen and forms a methoxide; sodium methoxide $NaCH_3O$ combines at 160° with carbon monoxide to form sodium acetate.

Magnesium dissolves in methyl alcohol on gently heating, forming magnesium methoxide, which separates in pointed prisms from solutions containing about 6 grams in 40 of alcohol, or as an amorphous powder from more concentrated solutions. The crystals contain 3 molecules of methyl alcohol and effloresce rapidly. Bromine converts it into bromoform and magnesium bromide. Magnesium nitride reacts energetically with methyl alcohol forming trimethylamine, according to the equation:

$$Mg_3N_2+6CH_3OH =3Mg(OH)OCH_3+NH_3+N(CH_3)_3$$

(Szarvasy, Ber. 1897, 305, 806).

Chlorine acts on methyl alcohol readily if moist. In diffused daylight at 99·5° the chief product is formaldehyde, which probably results through the intermediate formation of chloromethyl alcohol CH_2ClOH, and dichloromethyl ether $(CH_2Cl)_2O$. The latter may actually be isolated. Carbon dioxide and carbon monoxide and also methyl chloride are continuously evolved during the reaction. If the alcohol is diluted with water the reaction proceeds with explosive violence. Bromine has but little action, but in sunlight at 130°–150° methyl bromide is formed, mixed with carbon monoxide and dioxide and formic acid if the bromine is not in excess.

Iodine is even more inert, but at 180°–200° hydrogen iodide, carbon dioxide, and methyl iodide are formed. The chief bulk of the alcohol is converted into methyl ether, which is also readily produced by heating the alcohol in sealed tubes with 5 p.c. of iodine (André Brochet, Compt. rend. 121, 130).

Cold methyl alcohol absorbs one molecular proportion of boron trifluoride forming *boron methoxy difluoride* $BF_2{\cdot}OCH_3$, crystallising in prisms melting at 41·5° and boiling at 87°. Sodium methoxide (1 mol.) readily converts this compound into *boron dimethoxy fluoride*

$$BF(OCH_3)_2$$

which is a colourless mobile liquid fuming in air, burning with a green flame, and boiling at 53°. It has a sp.gr. of 1·053 at 0°. Sodium methoxide changes this into *methyl borate* $B(OCH_3)_3$. Methyl borate boils at 55°–56° and has sp.gr. 0·919 at 0°. It burns with a green flame and is readily decomposed by moist air or water.

There is also formed by the action of boron trifluoride on methyl alcohol a molecular compound with methyl ether, $BF_3,O(CH_3)_2$. It boils at 126°–127° and dissociates at a slightly higher temperature. Sp.gr. at 0°=0·140. In addition an acid product of still higher boiling-point is produced to a small extent (V. Gasselin, Ann. Chim. Phys. [vii.] 3, 5).

The catalytic oxidation of methyl alcohol to formaldehyde is the subject of several papers by E. Orloff (J. Soc. Chem. Ind. 1908, 139, 419, 1176). Ozone oxidises methyl alcohol to formaldehyde very readily in 50 p.c. aqueous solution (Harries, Ber. 1903, 1933).

White phosphorus, when heated with methyl alcohol (1 mol.) for some hours at at least 250°, produces tetramethyl phosphonium hydroxide and, in addition, phosphines and phosphoric acid (J. Berthaud, Compt. rend. 143, 1166).

Methyl alcohol decomposes diazonium salts, forming, with benzene diazonium nitrate, anisole, *o*-nitrophenol, and 2 : 4-dinitrophenol. If water is present, *p*-nitrophenol is also formed. The alkoxy derivative only is produced from diazobenzenesulphate. Sodium methoxide in solution in methyl alcohol produces benzene and diphenyl (Beeson, Amer. Chem. J. 16, 235).

Impurities.—The impurities of commercial wood spirit are small quantities of aldehyde, dimethylacetal, allyl alcohol, acetone, methylethyl ketone, higher ketones, and chloroform.

Acetone is the most objectionable, especially when the alcohol is to be used in the preparation of aniline colours. In order to estimate the amount of acetone 1 c.c. of the wood spirit is mixed with 10 c.c. of a double normal solution of soda, and 10 c.c. of a double normal solution of iodine are added with constant shaking, and then 10 c.c. of absolute ether. The ethereal layer is then measured, an aliquot portion taken and evaporated on a watch-glass and the residual iodoform weighed. The weight of the iodoform (calculated to the total volume of ethereal solution) multiplied by 0·28 gives the amount of acetone in 1 c.c. of wood spirit (Kramer, Ber. 1880, 1002).

According to Messenger (Ber. 21, 3366), this method gives too high results if the quantity of acetone be small. The following method and details are due to Milan and Stritar (Zeitsch. anal. Chem. 1904, 387). *Crude wood spirit*: 5 c.c. are diluted to 500 c.c. and 5 c.c. of this mixture are submitted to Zeisel's process. The weight of silver iodide multiplied by 272·9 gives grams of methyl alcohol per 100 c.c. *Aqueous wood spirit* containing under 10 p.c. methyl alcohol: 10 c.c. are diluted to 50 c.c. and shaken for ¼ hour with 0·5 gram of charcoal, filtered, washed, and diluted to 100 c.c. and estimated as above. *Crude pyroligneous acid*: 50 c.c. are neutralised with sodium carbonate made up to 250 c.c. and filtered. 100 c.c. are then made strongly alkaline and distilled till 50 c.c. have collected. The distillate is treated with charcoal, &c., as above. The shaking with charcoal removes guaiacol and other phenol ethers, but the estimation is invalidated by the presence of acetal, methyl acetate, and allyl alcohol. A correction for these may be made by determining the iodine number and esterification number of the sample.

Methyl boride $B(CH_3)_3$, *bormethyl, trimethylborine*, V.D. 1·9108 (calc.=1·9314), a gas obtained from methyl borate by the action of zinc methyl (Frankland and Duppa, Annalen, 124, 129); has an intensely disagreeable smell, ignites spontaneously in the air; can be liquefied by a pressure of three atmospheres at 10°. Caustic potash absorbs the gas and yields, on evaporation, a viscid residue of $B(CH_3)_3{\cdot}KOH$. Ammonia forms a compound, $B(CH_3)_3{\cdot}NH_3$, which can be crystallised from ether in large crystals; m.p. 56°; b.p. 110°.

Methyl bromide CH_3Br, *bromomethane*; b.p. 4·5° (corr.) (Perkin, Chem. Soc. Trans. 1884, 454); sp.gr. 1·73306 at 0·8°/0·8°.

Preparation.—By heating the cacodyl compound, $As(CH_3)_2(OH)_2Br$ (Bunsen, Annalen, 46, 44); from methyl alcohol, bromine, and phosphorus (Pierre, Ann. Chim. Phys. [iii.] 15, 373). 133 grams red phosphorus, 800 grams methyl alcohol, are mixed in a retort, and 800 grams of bromine are gradually added; after some hours the mixture is distilled (Merrill, J. pr. Chem. [ii.] 18, 293).

Methyl bromide is a colourless mobile liquid with a smell resembling that of chloroform, unites with water to form a crystalline hydrate $CH_3Br,20H_2O$ (?) which is decomposed at 4° (Merrill).

For brominated compounds of methyl bromide, *v. Methylene bromide*, art. BROMOFORM; and *Carbon tetrabromide*, art. CARBON.

Methyl chloride CH_3Cl, *chloromethane*; b.p. −23·73° (Regnault); −21° (Berthelot); −23° (Vincent and Delachanal); sp.gr. 0·99145 at −23°; 0·95231 at 0° (Vincent and Delachanal, Bull. Soc. chim. [ii.] 31, 11). Vap. press. at 0°= 2·48 atmospheres, at 15°=4·11, at 30°=6·50 (Vincent and Delachanal).

Preparation.—From methyl alcohol, common salt and sulphuric acid (Dumas and Peligot, Annalen, 15, 17); from methane and chlorine (Berthelot, Ann. Chim. Phys. [iii.] 52, 97); by heating the cacodyl compounds

$$As(CH_3)_2(OH)_2Cl$$

or $As(CH_3)_2Cl$ (Bunsen, Annalen, 46, 44).

On the large scale by the dry distillation of 'vinasses' from beetroot. The methylamine is saturated with hydrochloric acid and concentrated, then heated to 260°–300°, when methyl chloride together with mono- and trimethylamine is evolved; the bases are removed by means of hydrochloric acid and the methyl chloride dried over calcium chloride and condensed by pressure in wrought-iron cylinders (Vincent and Delachanal, Bull. Soc. chim. [ii.] 31, 11; J. 1878, 1135). One part of melted zinc chloride is dissolved in two parts methyl alcohol and hydrogen chloride led into the mixture (Groves, Chem. Soc. Trans. 1874, 641).

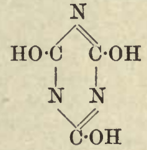
Properties.—Methyl chloride is a colourless gas with ethereal odour, and burns, when ignited in air, with a greenish flame. One part of water dissolves 4 volumes of methyl chloride; 1 of absolute alcohol, 35 volumes; and 1 of acetic acid, 40 volumes (Berthelot). The neutral solution is not precipitated by silver nitrate. With water at temperatures below 7·3° at 760 mm. it forms a solid hydrate $CH_3Cl,6H_2O$ (de Forcrand and Villard, Compt. rend. 106, 1402; Villard, Ann. Chim. Phys. [vii.] 11, 377). With chlorine in sunlight it yields methylene chloride (CH_2Cl_2), chloroform ($CHCl_3$), and finally carbon tetrachloride CCl_4 (*q.v.* art. CARBON); the chlorination can also be effected by leading a mixture of chlorine and methyl chloride over animal charcoal at 250°–350°.

Methylchloride forms with bromine methylene bromide, bromoform and carbon tetrabromide (Damoiseau, J. 1881, 376).

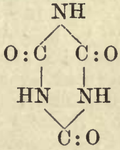
Methyl chloride is extensively used in the preparation of various coal-tar colours and also as a means of producing cold. By its evaporation a temperature of −23° is produced, or if the evaporation be accelerated by blowing in air −55° is easily reached, and since its vapour is non-poisonous, its superiority to liquid sulphur dioxide for this purpose is evident.

Methyl ***iso*****cyanate** $CH_3{\cdot}N:CO$, *methyl carbimide*; b.p. 43°–45° (Gautier, Annalen, 149, 313). Formed by the distillation of a mixture of 1 part of potassium cyanate with 2 parts of potassium methyl sulphate (Wurtz, Ann. Chim. Phys. [iii.] 42, 43); also by the action of diazomethane on nitro-urea (Degner and von Pechmann, Ber. 1897, 649). A liquid with intensely suffocating smell, converted by dry ammonia into methyl-urea $NH(CH_3)CO{\cdot}NH_2$ which forms prisms soluble in water. Water converts it into dimethyl-urea $NH(CH_3)CO{\cdot}NHCH_3$ with evolution of carbon dioxide.

Methyl cyanurates. Monomethyl, dimethyl, and trimethyl derivatives of both normal (I.) and *iso*cyanuric (II.) acids are known.



I.



II.

Normal trimethyl cyanurate $(NCOCH_3)_3$ is prepared from sodium methoxide and cyanogen chloride (Hofmann and Olshausen, Ber. 1870, 271). From dry sodium methoxide and cyanogen bromide (Ponomarew, *ibid.* 1885, 3264; Klason, J. pr. Chem. [ii.] 33, 131). Soluble in ether and water and crystallises in trimetric prisms melting at 135° and boiling at 265°. On long boiling it changes into the isomeride, melting at 175° (trimethyl *iso*cyanurate).

Normal dimethyl cyanurate $C_3N_3(OH)(OC_3H)_2$ results by heating 2 grams sodium in 15 grams absolute methyl alcohol and 15 grams normal trimethyl cyanurate to 100° for 1½ hours and decomposing the sodium salt with acetic acid (Hofmann, Ber. 1886, 2067). It forms small six-sided leaves soluble in alcohol and water but not ether. It softens at 165°–170° and decomposes on further heating into dimethyl *iso*cyanurate, m.p. 222° and also trimethyl *iso*cyanurate, m.p. 175°.

Trimethyl isocyanurate $C_3O_3N_3(CH)_3$ is produced together with the normal trimethyl ester from silver cyanurate and methyl iodide (Ponomarew, Ber. 1885, 3271); also from the silver salt of the dimethyl derivative and methyl iodide (Hofmann, *ibid.* 1886, 2096); also by the interaction of cyanuric acid and diazomethane (Palazzo and Scelsi, Gazz. chim, ital. 1908, 38, i. 659). Monoclinic prisms melting at 175°–176° and boiling at 274°. Soluble in alcohol but not in water.

Dimethyl isocyanurate $(CH_3)_2H(CNO)_3$ is obtained by the dry distillation of methyl acetyl urea (Hofmann, Ber. 1881, 2069); also from the normal dimethyl derivative (*v. supra*). Monoclinic, thin leaves from water melting at 222°.

Monomethyl isocyanurate

$(CH_3)H_2N_3C_3O_3,H_2O$

is prepared by heating nitrosocarbonyldimethylurea with water (Fischer and Frank, Ber. 1897, 2615). It forms thin leaves, readily dehydrated at 100°, melting at 296°–297°, and has an unpleasant odour. On methylation the trimethyl derivative is produced.

Mixed derivatives have been prepared by Hantzsch and Bauer (Ber. 1905, 38, 1005). The di-O-mono-N-derivative, m.p. 105°, is prepared by the interaction of silver cyanate and methyl iodide below 0°. The mono-O-di-N-derivative, m.p. 118°, is prepared from silver cyanurate and methyl iodide at low temperatures.

Methyl cyanide $CH_3{\cdot}CN$, *acetonitrile*; b.p. 81·6°; sp.gr. 0·8052 at 0°, 0·7891 at 15° (Vincent and Delachanal, Bull. Soc. chim. [ii.] 33, 405). H.C. at 18°=312·14 (Thomsen, Th. 4, 128) =291·6 (Berthelot and Petit, Compt. rend. 108, 1217).

From ammonium acetate and phosphorus pentoxide (Dumas, Compt. rend. 25, 383); from acetamide and phosphorus pentoxide; by distillation of potassium methyl sulphate with potassium cyanide (Dumas, Malaguti, and Leblanc, Annalen, 64, 333); in heating cyanacetic acid at 165° (Van 't Hoff, Ber. 1874, 1382); also by heating dimethyl sulphate with potassium cyanide (Walden, Ber. 40, 3214). It is also formed by the action of prussic acid on diazomethane (von Pechmann, *ibid.* 1895, 857); and by pouring acetic acid over magnesium nitride (Emmerling, *ibid.* 1896, 1635).

Preparation.—A mixture of 5 molecules of acetamide and 1 molecule of phosphorus pentasulphide is distilled, the product washed with caustic soda and digested with lead oxide (Henry, Annalen, 152, 149). By long heating of a mixture of acetamide and glacial acetic acid under a reflux condenser (Demarçay, Bull. Soc. chim. [ii.] 33, 456).

Acetonitrile is a colourless liquid with a pleasant ethereal smell, miscible with water, from which it separates on the addition of common salt. It burns in air with a peach-blossom flame; with acetic acid at 200° it produces diacetamide. It is miscible with methyl alcohol or with ethyl alcohol, and its b.p. is lowered by such admixture—a liquid containing 80 p.c. wood spirit and 20 p.c. acetonitrile has the lowest b.p. (63·7°), whilst, in the case of ethyl alcohol, a mixture of 56 p.c. spirits of wine and 44 p.c. acetonitrile boils at 72·6° (Vincent and Delachanal, Bull. Soc. chim. [ii.] 33, 405). It combines easily with dry hydrobromic or hydriodic acids, more difficultly with hydrochloric acid (Gautier, Annalen, 142, 291); by passing hydrogen chloride into a cooled mixture of acetonitrile and acetic acid, acetyl chloride and acetamide result (Colson, Bull. Soc. chim. [iii.] 17, 57). $CH_3CN{\cdot}2HBr$ forms crystals melting at 47°–50° (Engler, Annalen, 149, 306). Bromine combines with acetonitrile at 100° to form a compound—$CH_2Br{\cdot}CN{\cdot}HBr$—crystallising in prisms which melt at 65°, and are decomposed by moist air, forming ammonium bromide, acetic acid, and dibromodiacetamide (Engler, Annalen, 133, 137; 142, 69). Sulphur trioxide produces the compound $(CH_3CN)_2 2SO_3$, which crystallises and dissolves in water, but not in organic solvents. By precipitating its aqueous solution with alcohol and ether crystals of the composition $(CH_3CN)_3(SO_3)_2,H_2O$ are obtained (Eitner, Ber. 1893, 2834).

By the action of sodium upon methyl cyanide, methane and an oily substance $C_4H_6N_2$ soluble in ether (Holtzwart, J. pr. Chem. [ii.] 38, 343), sodium cyanide, and *cyanmethine* $C_6H_9N_3$ are obtained (Baeyer, Ber. 1869, 319). This is best obtained by heating 6 parts methyl cyanide with 1 part of sodium under a pressure of 100 mm., distilling off the excess of methyl cyanide and crystallising the residue from alcohol (Meyer, J. pr. Chem. [ii.] 27, 153). It forms monoclinic crystals (m.p. 180°–181°, which dissolve in 0·64 parts of water or 5·25 parts of alcohol at 18°. Cyanmethine unites with many acids, *e.g.* $C_6H_9N_3{\cdot}HCl$, needles soluble in water; b.p. 200°–250° $(C_6H_9N_3)_2H_2SO_4$, crystallises with difficulty. It also forms chlorine and bromine derivatives (Baeyer, Ber. 4, 176).

Substitution products of acetonitrile.

Chloracetonitrile $CH_2Cl{\cdot}CN$, from chloracetamide and phosphorus pentoxide (Bisschopinck, Ber. 6, 732); the reaction is better carried out in a vacuum (Scholl, *ibid.* 1896, 2417). A liquid; b.p. 123°–124°, sp.gr. 1·204 at 11·2°, 1·193 at 20° (Engler, *ibid.* 1873, 1003).

Dichloracetonitrile $CHCl_2{\cdot}CN$; b.p. 112°–113°; sp.gr. 1·374 at 11·4 (Bisschopinck, Ber. 6, 732).

Trichloracetonitrile $CCl_3{\cdot}CN$; b.p. 83°–84°, sp.gr. 1·439 at 12·2°. From trichloracetamide and phosphorus pentoxide (Bisschopinck, Ber. 6, 732). By action of chlorine upon acetonitrile in presence of iodine (Beckurts, *ibid.* 1876, 1594).

Bromacetonitrile $CH_2Br{\cdot}CN$, and *dibromacetonitrile* $CHBr_2{\cdot}CN$, m.p. 142°, are also known (*v.* Engler, Annalen, 142, 69, and Van 't Hoff, Ber. 1874, 1571; also Henry, Compt. rend. 103, 413).

Iodacetonitrile $CH_2I{\cdot}CN$; b.p. 186°–187°; sp.gr. 2·3065 at 12°; from chloracetonitrile and sodium iodide in alcoholic solution (Henry, Compt. rend. 103, 413).

Nitroacetonitrile $CH_2(NO_2)CN$ *v.* FULMINIC ACID.

Dinitroacetonitrile $CH(NO_2)_2CN$, a syrupy liquid obtained by the action of sulphuric acid upon the ammonia compound $CH(NO_2)_2CN{\cdot}NH_3$. This compound is obtained by the reduction of an ethereal solution of trinitroacetonitrile by means of dry sulphuretted hydrogen:

$$C(NO_2)_3CN+4H_2S$$
$$=CH(NO_2)_2CN{\cdot}NH_3+2H_2O+4S$$

(Schischkoff, Annalen, 101, 215; 119, 249; 104, 250).

Trinitroacetonitrile $C(NO_2)_3CN$, a solid, m.p. 41·5°; explodes when heated to 220°. Formed by the action of a mixture of fuming nitric and sulphuric acids upon sodium fulminate (Schischkoff, Ann. Chim. Phys. [iii.] 49, 310). Soluble in ether, but decomposed by alcohol, water, or alkalis.

Methyl *iso*cyanide $CH_3{\cdot}NC$, *iso-acetonitrile, methyl carbylamine*; b.p. 59·6°; sp.gr. 0·7557 at 14° (Gautier, Annalen, 152, 222). From methyl iodide and 2 molecules of silver cyanide at 130° (Gautier, Compt. rend. 65, 468); also from chloroform, methylamine, and alcoholic potash (Hofmann). It is also formed in small quantity when potassium methyl sulphate is distilled with potassium cyanide.

Methyl *iso*cyanide is a liquid with a very unpleasant smell; soluble in 10 parts of water at 15°; forms crystalline salts with acids.

Methyl fluoride CH_3F. A gas, sp.gr. $(H=1)$ 17·38, calc. = 17·05 (Collie, Chem. Soc. Trans. 1889, 110). Obtained from potassium methyl sulphate and potassium fluoride (Dumas and Péligot, Annalen, 15, 59); by the action of heat upon tetramethyl ammonium fluoride (Collie); from a mixture of methyl iodide and silver fluoride (Moissan and Meslans, Compt. rend. 107, 1153; Chem. Soc. Trans. 1889, 364). Liquefied by a pressure of 30 atmospheres at ordinary temperatures; slightly soluble in water, more so in methyl alcohol. It is very stable; critical temp. 44·9°; pressure 47123 mm. (Collie). Chlorine in sunlight displaces hydrogen and forms CH_2ClF, a gas soluble in water and of sp.gr. 34·18 (calc. = 34·25).

Methyl formamide $H{\cdot}CO{\cdot}NH(CH_3)$; b.p. 180°–185° (Gautier, J. 1869, 618); 190° (Linnemann, J. 1869, 601); sp.gr. 1·011 at 19°. A thick oily liquid soluble in water and alcohol, insoluble in ether, formed by the distillation of methylamine formate.

Methyl formate $H{\cdot}CO{\cdot}OCH_3$; b.p. 32°–32·5° (corr.) (Perkin, Chem. Soc. Trans. 1884, 491); Volhard, Annalen, 176, 133). Sp.gr. 0·98239 at 15°/15°

Preparation.—130 parts of methyl alcohol saturated with hydrogen chloride are gradually poured upon 100 parts of calcium formate; the mixture is then digested for some time, and finally distilled (Volhard, Annalen, 176, 133). A mixture of equivalent proportions of sodium formate, hydrochloric acid, and wood spirit may be used (Bardy and Bordet, Ann. Chim. Phys. [v.] 16, 561). Wood spirit is digested with formic acid, sp.gr. 1·22, and distilled; the distillate is then dehydrated by means of phosphorus pentoxide.

Methyl formate is a colourless liquid with a characteristic smell; its vapour is decomposed at a red heat, forming carbon monoxide and methyl alcohol. Chlorine in presence of sunlight yields *trichloro-methyl chloroformate* $Cl{\cdot}CO{\cdot}OCCl_3$, b.p. 127·5°–128°, sp.gr. 1·6525 at 14°, which, when heated at 340°–350°, yields the isomeric carbonyl chloride $COCl_2$ (Hentschel, J. pr. Chem. [ii.] 36, 99). If the action be stopped at an earlier stage, a compound $C_4H_3Cl_5O_4$, b.p. 108°–109°, sp.gr. 1·4741 at 27°/27°, is formed. In the absence of sunlight, chloroformic ester $Cl{\cdot}COOCH_3$ is produced immediately (Hentschel, J. pr. Chem. [ii.] 36, 213).

Methyl hydrate *v. Methyl alcohol.*

Methyl hydride, Methane, *marsh gas*, CH_4; sp.gr. 0·559 (air = 1); b.p. = −164·0° at 736·6 mm. (Olszewski, Ann. Chim. Phys. [ii.] 31, 58); sp.gr. of liquid = 0·415 (O.). H.F.p. = 21,750 cals.; H.F.v. = 21,170 cals.; H.C.p. 2 = 11,930 cals. (Thomsen, Th. 4, 50); H.C.p. = 213,500 cals. (Berthelot, Ann. Chim. Phys. [v.] 23, 179). 1 vol. of water at $t°$ absorbs $0{\cdot}05449-0{\cdot}001807t+0{\cdot}00001028t^2$ vols. of marsh gas, 1 vol. of alcohol at $t°$, $0{\cdot}522586-0{\cdot}0028655t+0000142t^2$ vols. (Bunsen).

Marsh gas is emitted from the surface of the ground in many parts of the world, notably in Italy, North America, and in the vicinity of the Caspian Sea. It is formed by the putrefaction of vegetable matter under water, and hence occurs in marshy places. It is evolved in large quantities from the mud volcanoes of Sicily, Italy, and the Crimea. It also occurs in the coal measures, and, in small quantities, in the gases of the human intestines (Ruge, J. 1862, 528), and in the breath of calves and sheep (Reiset, J. 1863, 638).

It is formed by the putrefaction of cellulose. According to Hoppe-Seyler, this is due to the action of a fungus (*Amylobacterium*, Van Tieghem, Compt. rend. 88, 205), and cellulose (sterilised filter-paper was used) is converted into a non-reducing sugar $C_6H_{12}O_6$, which splits up into $3CO_2$ and $3CH_4$; this action is stopped by a temperature above 60°.

Marsh gas is also produced by the destructive distillation of carbonaceous matter—*e.g.* wood or coal—and hence occurs, to the extent of about 40 p.c. by volume, in coal gas.

It can be obtained from chloroform or carbon tetrachloride by passing the vapour, mixed with hydrogen, through a hot tube, or by heating with copper, potassium iodide, and water (Berthelot, J. 1857, 267). Also by passing a mixture of the vapour of carbon disulphide and sulphuretted hydrogen over heated copper or iron (Berthelot, Ann. Chim. Phys. [iii.] 53, 69). Also by the action of the silent electrical discharge upon a mixture of hydrogen and carbon monoxide (Brodie, Proc. Roy. Soc. 21, 245), and by the direct combination of carbon and hydrogen at 1200° (Bone and Jerdan, Chem. Soc. Trans. 1897 42), and also by the action of water on aluminium carbide (Moissan, Bull. Soc. chim. [iii.] 11, 1012; 15, 1285).

Preparation.—By heating potassium acetate with caustic potash

$$KC_2H_3O_2+KOH=K_2CO_3+CH_4.$$

Sodium acetate and a mixture of equal volumes of calcined soda and powdered lime are heated in an iron or copper vessel (Schorlemmer, Chem. News, 29, 7), hydrogen and ethylene are also produced in this reaction (Kolbe); the latter may be removed by means of sulphuric acid.

It can also be obtained by the action of the copper-zinc couple upon a mixture of equal volumes of alcohol and methyl iodide (Gladstone and Tribe, Chem. Soc. Trans. 1884, 154). Pure methane is obtained by the decomposition of zinc methyl with alcohol or water.

Properties.—Methane is colourless and odourless, and forms an explosive mixture with air ('firedamp'). It is very stable, and is not affected by phosphorus pentoxide or antimony pentachloride, or even by strong nitric acid. Dry chlorine has no action in the dark, but in sunlight the mixture explodes; in diffused daylight chloro substitution derivatives are formed. When passed through a hot tube, a very small portion is converted into naphthalene, but the greater portion remains unaltered. It is very gradually absorbed by cold fuming sulphuric acid (Worstall, J. Amer. Chem. Soc. 1899, 246). It may be oxidised to methyl alcohol and formaldehyde (*see Methyl alcohol*).

It forms a hydrate with water at −2° or −3° under a pressure of 30 atmospheres. Tension of dissociation at 0° = 27·5 atmospheres; crit. temp. = 21·5° (Villard, Compt. rend. 107, 395).

Methyl iodide CH_3I; b.p. 42·3° corr. (Perkin, Chem. Soc. Trans. 1884, 459); 44·3° (Pierre, Annalen, 56, 147), sp.gr. 2·28517 at 15°/15° (P.); 2·2677 at 15° (Bardy and Bordet, Ann. Chim. Phys. [v.] 16, 569). Formed by the action of phosphorus and iodine upon methyl alcohol (Dumas and Péligot, Annalen, 15, 30).

Preparation.—In a similar manner to that of ethyl iodide (*q.v.*). 35 parts methyl alcohol, 100 parts iodine, and 10 parts of phosphorus are the proportions usually employed. These substances are allowed to remain in contact for some hours; the methyl iodide is then distilled off, washed with dilute caustic soda solution, and dried by means of calcium chloride. The preparation from an iodide of an alkali or alkaline earth by the action of methyl sulphate is patented by Weinland and Schmidt (D. R. P. 175209, 1905). A yield of 94 p.c. is obtained by dissolving yellow phosphorus in methyl iodide, and adding iodine to the liquid, and slowly dropping methyl alcohol into the cooled mixture (Walker and Johnson, Chem. Soc. Trans. 1905, 1595).

It forms a colourless liquid which turns brown on exposure to light owing to the liberation of iodine. It is extensively used in the preparation of various aniline colours owing to the ease with which it undergoes decomposition; it thus affords a ready means of introducing the methyl group into other compounds.

Methyl nitrate CH_3NO_3; b.p. 65°; sp.gr. 1·2167 at 15°/15° (Perkin, Chem. Soc. Trans. 1884, 682).

Preparation.—200 c.c. pure wood spirit are distilled with 40 grams urea nitrate and 150 c.c. pure nitric acid (sp.gr. 1·31) until two-thirds have distilled off; to the residue 170 c.c. of methyl alcohol and 130 c.c. nitric acid are added, again distilled, and then 150 c.c. methyl alcohol, 110 c.c. nitric acid, and 10 grams urea nitrate are added to the residue, and distillation again continued (C. Lea, J. 1862, 387).

Can also be prepared by mixing methyl alcohol and sulphuric acid, and adding 2 parts of this liquid to a mixture of 1 part nitric acid and 2 parts sulphuric acid. The distillate is washed with potassium carbonate solution. Delépine recommends the following. A mixture of 50 c.c. strong sulphuric acid and 150 c.c. methyl alcohol cooled to 12° are carefully added to a mixture of 100 c.c. strong sulphuric acid and 150 c.c. nitric acid (36°), cooled to 12°, so that the temperature does not rise above 15°. Afterwards the whole is shaken with 100 c.c. strong sulphuric acid. After a few minutes' standing the ester is separated off (Bull. Soc. chim. [iii.] 13, 1044).

Methyl nitrate is a colourless liquid with a pleasant smell; explodes when heated to 150°, or by percussion.

Methyl nitrite CH_3NO_2; b.p. −12°; sp.gr. of liquid 0·991 at 15°/. A gas, prepared by treating 1 molecule methyl alcohol with 1 molecule *iso*amyl nitrite (Bertoni, Gazz. chim. ital. 12, 438). Also by the action of nitric acid upon copper (or arsenious acid) and methyl alcohol, or by the action of nitric acid upon brucine (Strecker, Annalen, 91, 76).

Methyl oxalate $(CH_3)_2C_2O_4$; m.p. 54°; b.p. 163·3° corr. (Weger, Annalen, 221, 86). Oxalic acid (dried at 100°) is mixed with boiling methyl alcohol, and on cooling the crystals separate out (Erlenmeyer, J. 1874, 572).

Forms monoclinic plates, which, by action of chlorine yield, first, an oily liquid of the composition $C_2O_4(CHCl_2)_2$ (Malaguti, Annalen, 32, 49), and by prolonged action in sunlight, a body $C_2O_4(CCl_3)_2$, which crystallises in leaflets (Cahours, *ibid.* 64, 313).

Methyl hydrogen oxalate $H(CH_3)C_2O_4$. When oxalic ethyl ester is treated in methyl alcoholic solution with potassium methoxide, potassium methyl oxalate is thrown out in the form of fine leaves (Salomon, Ber. 8, 1509). Methyl hydrogen oxalate is a solid of low melting-point which boils at 108°–109°/ 12 mm. (Anschütz and Schönfeld, Ber. 19, 1442).

Methyl oxide, Dimethyl ether $(CH_3)_2O$,; b.p. −23·65° (Regnault, J. 1863, 70); −21° (Berthelot); sp.gr. (air=1) 1·617.

Formed by heating methyl alcohol with sulphuric acid (Dumas and Péligot, Ann. Chim. Phys. [ii.] 58, 19), or with boron trioxide (Ebelmen, *ibid.* [iii.] 16, 138; Annalen, 57, 328).

1·3 parts of wood alcohol are mixed with 2 parts of sulphuric acid, and heated to 140°. The gas evolved is passed into strong sulphuric acid, which absorbs 600 times its volume; the gas is then set free by diluting the acid with an equal volume of water (Erlenmeyer and Kriechbaumer, Ber. 1874, 699).

Methyl ether is a colourless gas with a pleasant odour; 1 vol. of water at 18° absorbs 37 volumes of the gas (Dumas and Péligot). It unites with hydrochloric acid to form a compound $(CH_3)_2O{\cdot}HCl$, which boils at 2° (Friedel, Bull. Soc. chim. [ii.] 24, 160, 241).

Chlorine Substitution Products.

Chlormethyl ether $CH_2Cl{\cdot}O{\cdot}CH_3$; b.p. 59·5° at 759 mm.; formed by bringing together, in diffused daylight, chlorine and excess of methyl oxide (Friedel, Bull. Soc. chim. [ii.] 28, 171). It is decomposed by water into hydrochloric acid, trioxymethylene $(CH_2O)_3$ and methyl alcohol.

Dichlormethyl ether $(CH_2{\cdot}Cl)_2O$; b.p. 105°; sp.gr. 1·315 at 20°; formed by the action of chlorine upon methyl oxide (Regnault, Annalen, 34, 31).

Tetrachlormethyl ether $(CHCl_2)_2O$; b.p. 130°; sp.gr. 1·606 at 20° (Regnault).

Perchlormethyl ether $(CCl_3)_2O$; b.p. 100° (with decomposition); sp.gr.=1·597; by the action of chlorine upon methyl oxide in sunlight (Regnault). Decomposed by heat, yielding carbon tetrachloride and carbonyl chloride. (*See also* de Sonay, Ber. 1894, Ref. 337.)

Methyl phosphates.

1. *Normal methyl phosphate* $(CH_3)_3PO_4$; b.p. 197·2° (corr.); sp.gr. 1·2378 at 0° (Weger, Annalen, 221, 89). From methyl iodide and silver phosphate (Hall, Chem. Soc. Trans. 51, 754).

2. *Dimethyl phosphoric acid* $(CH_3)_2HPO_4$; a syrupy liquid, produced when phosphoryl chloride $POCl_3$ is dropped into methyl alcohol (Schiff, Annalen, 102, 234). The salts are very soluble in water.

3. *Monomethyl phosphoric acid* $CH_3H_2PO_4$ is produced when methyl alcohol is dropped into phosphoryl chloride (Schiff, Annalen, 102, 337).

Methyl phosphites.

Monomethyl phosphite $CH_3H_2PO_3$, a syrupy liquid formed by the action of phosphorus trichloride upon methyl alcohol (Schiff, Annalen, 103, 164). It is miscible with ether, and forms salts which are amorphous, and decomposed by water into methyl alcohol and phosphites.

Trimethyl phosphite $P(OCH_3)_3$ is a liquid boiling with partial decomposition at 185°. It is prepared by the action of phosphorus trichloride on sodium methoxide. Sp.gr. 1·1785 at 15° (Jaehne, Annalen, 256, 281).

Methyl sulphates.

1. *Hydrogen methyl sulphate, methyl sulphuric acid* CH_3HSO_4. The free acid is an oily body, which remains liquid at $-30°$. Obtained from methyl alcohol and sulphuric acid (Dumas and Péligot, Annalen, 15, 40), or from methyl alcohol and chlorsulphonic acid in the cold (Claesson, J. pr. Chem. [ii.] 19, 240).

Preparation.—One part of methyl alcohol is mixed with two parts of concentrated sulphuric acid, allowed to stand in a warm place for some hours, diluted with water and neutralised with barium carbonate, filtered and the barium precipitated by the proper quantity of sulphuric acid. Methyl sulphuric acid forms salts with the metals, which are soluble and readily crystallise. On distillation it decomposes into dimethyl sulphate and sulphuric acid (Claesson).

Chloride of methyl sulphuric acid CH_3SO_3Cl. *Methyl chlorosulphonate* is obtained by dropping methyl alcohol into sulphuryl chloride in molecular proportions (Behrend, J. pr. Chem. [ii.] 15, 32), or by passing sulphur dioxide into methyl hypochlorite (Sandmeyer, Ber. 1886, 861). It is an oily liquid with pungent smell; decomposed by water into methyl sulphuric and hydrochloric acids.

2. *Dimethyl sulphate* $(CH_3)_2SO_4$; b.p. 188°; sp.gr. 1·33344 at 15° (Perkin, Chem. Soc. Trans. 1886, 785). By distilling wood spirit with 8 or 10 parts of sulphuric acid (Dumas and Péligot, Ann. Chim. Phys. [iii.] 58, 54) or by distilling anhydrous methyl sulphuric acid, best *in vacuô* (Claesson, J. pr. Chem. [ii.] 19, 244). Methyl sulphate is best prepared by bringing together methyl alcohol (27 grams) and chlorsulphonic acid (100 grams) at $-10°$ and then distilling the mixture under 20 mm. pressure at 140°. The yield is 80–83 p.c. theoretical. Nordhausen sulphuric acid gives a yield of only 42 p.c. (D. R. P. 113239). The Société Anonyme des Produits Chimiques de Fontaines in Lyon-Monplaisir uses practically the same process with carbon tetrachloride as a diluent (D. R. P. 193830). It is extensively used as a methylating agent for aromatic amines, the reaction being:

$$Me_2SO_4+2R{\cdot}NH_2=RNH_2{\cdot}MeHSO_4+R{\cdot}NHMe$$

(Ullmann, Annalen, 327, 103), *cf.* however, Claesson and Lundvall (Ber. 13, 1699). Quinoline and quinaldine are both quantitatively converted into their ammonium bases by treatment with methyl sulphate in benzene solution (Ullmann, *l.c.*). It is also a very convenient reagent for esterifying acids (Carl Graebe, *ibid.* 344, 244). On distillation under reduced pressure of the products obtained by the action of methyl sulphate on alcoholic solutions of sodium penta-, tetra-, or tri-sulphide *methyl trisulphide*, Me_2S_3, has been obtained by Strecker (Ber. 1908, 1105. *Cp.* also Klason, Chem. Soc. Abstr. 1888, 356). A colourless liquid with odour like that of peppermint.

Methyl sulphides.

1. *Hydrogen methyl sulphide, methyl mercaptan, methyl sulphydrate,* CH_3SH (Gregory, Annalen, 15, 239); b.p. 5·8° at 752 mm. (Klason, Ber. 20, 3407). By heating potassium hydrogen sulphide with potassium methyl sulphate (Dumas and Péligot). It is a colourless liquid with a disagreeable odour and forms a crystalline hydrate with water. By the action of chlorine upon carbon disulphide containing a little iodine, *Perchlormethyl mercaptan* CCl_3ClS, a liquid (b.p. 146°–148° corr.; sp.gr. 0°1·712 at 12·8°) is obtained (Rathke, Annalen, 167, 195). This substance is decomposed by heating to 200° into carbon tetrachloride and sulphur chloride.

2. *Dimethyl sulphide* $(CH_3)_2S$; b.p. 37·1°–37·3° at 754·7 mm. (Beckmann, J. pr. Chem. [ii.] 17, 453); b.p. 37·2° at 758 mm. (Klason, Ber. 20, 3407). Sp.gr. 0·845 at 21° (Regnault, Annalen, 34, 26). From potassium sulphide and methyl chloride (Regnault, Ann. Chim. Phys. [ii.] 71, 391).

Preparation.—500 c.c. methyl alcohol are treated with 750 c.c. sulphuric acid, and a solution of 2·75 kilos. sodium carbonate (crystals) is added, and the solution concentrated until the sodium sulphate crystallises out. To the solution of sodium methyl sulphate 500 grams of potash dissolved in water and half saturated with sulphuretted hydrogen are added. The yield is about 150 grams (Klason, Ber. 1887, 3407; Chem. Soc. Trans. 1888, 356). Methyl sulphide is a colourless liquid with an unpleasant smell. It combines directly with chlorine to form oily substitution products $(CH_2Cl)_2S$, $(CHCl_2)_2S$, and $(CCl_3)_2S$ (Riche, Ann. Chim. Phys. [iii.] 43, 283). Bromine unites with it to form a crystalline bromide $(CH_3)_2SBr_2$ (Cahours, Annalen, 135, 355). It also forms many crystalline compounds with various salts, *e.g.*

$$(CH_3)_2S{\cdot}HgCl_2;$$

$2(CH_3)_2S{\cdot}PtCl_4)$, &c. (Loir, Ann. Chim. Phys. [iii.] 39, 448; 54, 42). It combines at ordinary temperatures with methyl iodide to form *trimethyl sulphine iodide* $(CH_3)_3SI$, which crystallises in prisms.

By the action of moist silver oxide upon this compound there is formed *trimethyl sulphine hydroxide* $(CH_3)_3S{\cdot}OH$, an oily liquid which possesses strongly basic properties and forms characteristic salts with the acids. Sulphuretted hydrogen reacts with the base, yielding the *hydrosulphide* $[(CH_3)_3S]SH$, which on treating with one molecular proportion of the hydroxide yields the *normal sulphide* $[(CH_3)_3S]_2S$, which resembles in its reactions the sulphides of the alkalis (Brown and Blackie, Chem. News, 37, 130; 39, 51).

Methyl trisulphide $(CH_3)_2S_3$ has been prepared by Strecker (*see* above *Dimethyl sulphate*).

Methyl sulphite $(CH_3)_2SO_3$ or $SO(OCH_3)_2$; b.p. 121·5°; sp.gr. 1·0456 at 16·2°/4°. Obtained from methyl alcohol and sulphur chloride S_2Cl_2 (Carius, Annalen, 110, 209; 111, 96). Is isomeric with ethyl sulphurous acid $OH{\cdot}SO{\cdot}OC_2H_5$, and ethyl sulphonic acid $C_2H_5SO_2{\cdot}OH$.

Methyl sulphonic acid $CH_3SO_2{\cdot}OH$, a syrupy liquid decomposed at about 130°. By the action of nitric acid upon methyl thiocyanate or disulphide (Muspratt, Annalen, 65, 261). Also by heating methyl iodide with sodium sulphite solution to 120° (Collmann, *ibid.* 148, 105), and by the reduction of trichloromethane sulphonic acid (Kolbe, *ibid.* 54, 174), and also by the action of chloride of lime on methyl thiocyanate (de Coninck, Compt. rend. 126, 828). It forms stable crystalline salts which are very soluble in cold water but almost insoluble in alcohol. The potassium compound $CH_3\cdot SO_2\cdot OK$, is decomposed by heating with caustic potash—

$$CH_3\cdot SO_2OK+3KOH=3H_2+K_2CO_3+K_2SO_3$$

(Berthelot, J. 1869, 336).

Methyl sulphonic chloride $CH_3\cdot SO_2Cl$; b.p. 150°–153° (Carius); 160° (Nithack); sp.gr. 1·51 (Gowan, J. pr. Chem. [ii.] 30, 281). By the action of phosphorus pentachloride upon methyl sulphonic acid (Carius, Annalen, 114, 142). It is not acted upon by sulphuretted hydrogen or potassium cyanide in alcoholic solution. Ammonia forms an amide

$$CH_3\cdot SO_2\cdot NH_2$$

which crystallises in long prisms (Gowan, *l.c.*, also Chem. Soc. Trans. 48, 367).

Chlormethyl sulphonic acid $CH_2Cl\cdot SO_2\cdot OH$, an acid syrup obtained by the action of nascent hydrogen upon trichlormethyl sulphonic acid (Kolbe, Annalen, 54, 168).

Dichlormethyl sulphonic acid $CHCl_2\cdot SO_2\cdot OH$, an unstable body formed by the action of zinc upon trichlormethyl sulphonic acid (Kolbe, Annalen, 54, 164); also by heating chloroform with a solution of potassium sulphite to 180° (Strecker, *ibid.* 148, 92). The *chloride*

$$CHCl_2\cdot SO_2Cl$$

(b.p. 170°–180°, sp.gr. 1·71) is formed by the action of phosphorus pentachloride upon the acid (Gowan, J. pr. Chem. [ii.] 30, 399), or by reducing, by means of sulphur dioxide or stannous chloride, trichlormethyl sulphonic chloride (Kolbe).

Trichlormethyl sulphonic acid

$$CCl_3\cdot SO_2\cdot OH,H_2O;$$

m.p. 130°. The free acid is obtained from the chloride by treatment with baryta, and precipitation of the dissolved barium by means of sulphuric acid, the excess of sulphuric acid is then removed by means of lead carbonate and excess of lead by means of sulphuretted hydrogen (Gowan, J. pr. Chem. [ii.] 30, 284).

It forms small prisms which are very stable and insoluble in water, but soluble in alcohol or ether. It has strong acid properties and is not affected by nitric acid, aqua regia, or chromic trioxide.

Trichlormethyl sulphonic chloride $CCl_3\cdot SO_2Cl$ (m.p. 135°, b.p. 170°) forms camphorlike crystals, and is obtained by the action of moist chlorine upon carbon disulphide (Berzelius and Marcet, Gilbert's Annalen, 48, 161). Bassett (Chem. News, 54, 79) recommends the following process: 100 grams of powdered potassium chlorate, 200 c.c. hydrochloric acid, 400 c.c. water and 50 c.c. carbon disulphide are mixed together and allowed to stand for some days until the carbon disulphide becomes solid; the white solid is then removed by filtration and washed; the yield is 63 grams. It is very stable and reacts with difficulty or not at all with aromatic amines. With secondary and tertiary organic bases it yields colouring matters. It also oxidises leuco bases and their sulphonic acids to colouring matters (Espenschied, D. R. P. 14621).

Methyl thiocyanate $CH_3\cdot S\cdot CN$; b.p. 132·9° at 757·2 mm.; sp.gr. 1·088 at 0° (Pierre, J. 1851, 51). H.C.=398·95 cals. (Thomsen, Th. 4, 196). By heating methyl sulphide with cyanogen bromide to 100° (Cahours, J. 1875, 257). By distilling a concentrated solution of equal parts of potassium thiocyanate and calcium methyl sulphate (Cahours, Annalen, 61, 95). Calcium methyl sulphate may be replaced with advantage by methyl sulphate in theoretical proportions.

If heated to 180°–185° it is partially converted into the *iso*thiocyanate. By the action of chlorine in daylight cyanuric chloride $Cl_3(CN)_3$, thiocarbonyl chloride $CSCl_2$ and thiocarbonyl tetrachloride $CSCl_4$ are obtained (James, Chem. Soc. Trans. 51, 272). By heating with methyl iodide to 100° trimethyl sulphine iodide $(CH_3)_3SI$ is produced (Cahours, J. 1875, 257).

Methyl *iso*thiocyanate $CH_3\cdot NCS$, *methyl mustard oil*; m.p. 34°; b.p. 119° (Hofmann, Ber. 1, 172). By heating the silver salt of methyl thiocarbamic acid $CS(NH\cdot CH_3)SH$ with water. This acid is formed by the action of carbon disulphide upon methylamine. Methyl mustard oil forms white crystals which have a smell resembling that of horseradish.

Methyl selenide $(CH_3)_2Se$; b.p. 58·2°. Obtained by distilling a solution of sodium selenide (prepared from phosphorus pentaselenide and caustic soda), with potassium methyl sulphate (Jackson, Annalen, 179, 1). A disagreeably smelling liquid; with platinum tetrachloride forms a yellow compound $2(CH_3)_2Se\cdot PtCl_4$, soluble in alcohol. It also unites with chlorine and bromine $(CH_3)_2SeCl_2$, m.p. 59·5°; $(CH_3)_2SeBr_2$, m.p. 82°.

Methyl diselenide $(CH_3)_2Se_2$, a heavy, reddish yellow liquid with very unpleasant odour, formed when potassium diselenide is heated with potassium methyl sulphate (Wöhler and Dean, Annalen, 97, 5; Rathke, *ibid.* 152, 211).

METHYLAMINES.

These are compounds with strongly marked basic properties, derived from ammonia by the replacement of one, two, or three atoms of hydrogen by an equal number of methyl groups.

Methylamine $(CH_3)NH_2$, *monomethylamine*; b.p. −6° to −5·5° at 768·35 mm., sp.gr. 0·699 at −10·8° (Hofmann, Ber. 22, 699).

Occurrence.—In the oil yielded by the dry distillation of bone (Anderson, Annalen, 88, 44). In the plants *Mercurialis annua* (Linn.) and *M. perennis* (Linn.) (Reichardt, J. 1865, 457). In herring brine (Tollens, Zeitsch. Chem. 1866, 516) and in the products of the putrefaction of fish. In crude wood spirit (Commaille, J. 1873, 686; Vincent, Ann. Chim. Phys. [v.] 1, 444). In the products of the dry distillation of the residues from beet-sugar 'vinasses' (Duvillier and Buisine, Ann. Chim. Phys. [v.] 23, 317).

In the products of distillation of bran with lye (Laycock, Chem. News, 1898, 78, 210, 223). In the products yielded by the decomposition of fibrin by *streptococci* (Emmerling, Ber. 1897, 30, 1863).

Formation.—By the action of caustic potash upon methyl *iso*cyanate or *iso*cyanurate (Wurtz, Ann. Chim. Phys. [iii.] 30, 443). From ammonia and methyl iodide (Hofmann, Phil. Trans. 1851, 381) or methyl nitrate (C. Lea, Chem. News, 6, 46; Juncadella, Compt. rend. 48, 342). By heating wood spirit with sal ammoniac to 300° (Berthelot, Ann. Chim. Phys. [iii.] 38, 69).

By heating caustic potash with certain alkaloids—*e.g.* morphine, codeïne, creatine, &c. (Wertheim, Annalen, 73, 210; Dessaignes, J. 1855, 331). By the action of chlorine upon caffeïne or theobromine (Rochleder, J. 1850, 435). By the action of nascent hydrogen, from zinc and sulphuric acid, upon hydrocyanic acid (Mendius, Annalen, 121, 139). By passing a stream of hydrogen and hydrocyanic acid gas over platinum black, heated to 110° (Debus, Chem. Soc. Trans. 16, 249).

By the reduction of hexamethylene tetramine with zinc dust and hydrochloric acid (D. R. P. 73812); of formamide with sodium in amyl alcohol solution (Guerbet, Bull. Soc. chim. [iii.] 21, 780); or of nitromethane electrolytically in sulphuric acid solution at 70°–75° (Pierron, *ibid.* 783).

Preparation.—Equal molecules of methyl nitrate and ammonia dissolved in methyl alcohol are heated to 100°. The product is decomposed by caustic soda, and the base combined with hydrochloric acid, the dried chloride is then heated with caustic soda, and the liberated methylamine passed into sulphuric acid, the sulphate is dried at 110° and treated with absolute alcohol in which the di- and tri-methylamine salts are soluble; the insoluble monomethylamine sulphate is then decomposed by potash, and the free methylamine passed into a cooled solution of ethyl oxalate. The resulting di-methyl oxamide is dissolved in hot water, filtered and recrystallised, then decomposed by caustic potash, and the gas passed into absolute alcohol (Duvillier and Buisine, Ann. Chim. Phys. [v.] 23, 324; *v.* also Muller, Bull. Soc. chim. [ii.] 42, 202; Chem. Soc. Trans. 48, 501).

It can also be prepared by the interaction of acetamide and bromine in caustic potash solution (Hofmann, Ber. 1882, 15, 765; 1885, 18, 2741; François, Compt. rend. 1908, 147, 680). By heating phosphorus with excess of methyl alcohol solution under pressure at 225° (D. R. P. 64346), or by heating formaldehyde with ammonium chloride at 40°–95°.

Methylamine can be prepared electrolytically, cheaply and conveniently, according to the following process: An electrolytic cell, provided with a diaphragm separating the cathode and anode, is filled with a solution of sodium sulphate, and 140 grams hexamethylene tetramine is added. The electrolysis is carried out by means of lead electrodes and a current of 3 amperes per square decimetre. The alkali formed at the cathode is neutralised by the careful addition, drop by drop, of dilute sulphuric acid. The temperature must be kept at about 20°. Methylamine and trimethylamine are thus formed, and can be separated in the ordinary way. Ammonium sulphate can replace the sodium sulphate (D. R. P. 148054; Frdl. 1902–04, 26; *see* also D. R. P. 143197; Frdl. 1902–04, 25).

Commercial methyl sulphate is added in small portions at a time to excess of a 10 p.c. aqueous solution of ammonia at −5°. The product is then added to an excess of a 30 p.c. aqueous solution of sodium hydroxide, and the mixture is distilled, the issuing gas being collected in 20 p.c. hydrochloric acid. The methylamine hydrochloride is separated from the ammonium chloride by fractional crystallisation, and is finally purified by recrystallisation from alcohol (Burmann, Bull. Soc. chim. 1906, [iii.] 35, 801).

According to Bertheaume (*ibid.* 1908, 146, 1215) this method of separation is of very little use (Fleck, J. Amer. chem. Soc. 1896, 18, 670).

A better method of separating the three amines than the one given above, is to treat the concentrated solution of their hydrochlorides with caustic soda and collect the gas evolved in formaldehyde. The liquid is now treated with an equal weight of caustic potash, whereby the greater part of the trimethylamine is evolved, whilst the methylene derivatives of mono- and di-methylamine remain in solution, and can be fractionated by distillation. The amines are regenerated by boiling the condensation products with alcoholic hydrochloric acid (Delépine, Compt. rend. 1896, 122, 1064; Ann. Chim. Phys. 1896, [vii.] 8, 439).

Methylamine may be separated from ammonia by shaking the aqueous mixture of the two substances with yellow mercuric oxide during an hour. The liquor is then decanted and distilled when pure methylamine is obtained, providing no other nitrogenous bases are present in the impure liquor (François, J. Pharm. Chim. 1907, 25, 517, 523; Compt. rend. 1907, 144, 567; *ibid.* 1908, 147, 428).

To distinguish the three amines from ammonia the solution is neutralised with hydrochloric acid and evaporated to dryness. The residue is dissolved in 95 p.c. alcohol, and 5 c.c. of the solution is heated at 70°–75° with a few grammes of tetrachlorobenzoquinone. If any of the amines are present a violet colouration is produced, whereas ammonia gives no colouration (Tsalapatini, Chem. Zentr. 1908, i. 299). For the detection and estimation of ammonia in the methylamines, *see* François (Compt. rend. 1907, 144, 857). Methylamine can be distinguished from the di- and tri-amines by treatment with Nessler's reagent, with which it gives a yellow precipitate insoluble in excess of water and reagent. The other two amines form a white precipitate, which disappears on addition of water (Delépine, Compt. rend. 1896, 122, 1272).

Properties.—Methylamine is a colourless gas with a strong ammoniacal smell. It is very inflammable and burns with a yellow flame; it is decomposed at a red heat into ammonia hydrocyanic acid, hydrogen, and marsh gas. It is very soluble in water, 1 volume of water at 12·5° dissolving 1150 volumes and 959 volumes at 25°. The solution behaves like *liquor ammoniæ* and yields crystallisable salts on neutralisation with acids.

Heat of neutralisation with hydrochloric acid =25·9 cals. (Muller, Ann. Chim. Phys. 1888, [vi.] 15, 517). For salts of methylamine, which, as a rule, resemble those of ammonia, *v.* Wurtz, *ibid.* [iii.] 30, 443; Topsoë, J. 1883, 618; Bailey, Chem. Soc. Trans. 45, 692; Petit and Polonowsky, Bull. Soc. chim. [iii.] 9, 1013; Brochet and Cambier, *ibid.* 13, 536; Jarry, Compt. rend. 1897, 124, 964; Cook, Amer. Chem. J. 1899, 22, 437; Ragland, *ibid.* 417; Lenher, J. Amer. Chem. Soc. 1898, 20, 572; Dunstan and Goulding, Chem. Soc. Trans. 1897, 579; Ladenburg, Ber. 1896, 29, 2711; Wende, *ibid.* 2719; Ristenpart, *ibid.* 2530; Partheil and Broich, *ibid.* 1897, 30, 618; Fenner and Tafel, *ibid.* 32, 3228; Delépine, Ann. Chim. Phys. [vii.] 8, 461; Compt. rend. 1896, 122, 1272; Hofmann and Marburg, Annalen, 1899, 305, 191; Lang, Chem. Soc. Trans. 1903, 724; Rengade, Compt. rend. 1905, 140, 246; François, *ibid.* 1906, 142, 1199; Litterschild, Arch. Pharm. 1904, 242, 37; Guareschi, Chem. Zentr. 1891, ii. 620; Christensen, J. pr. Chem. [ii.] 45, 356; Gutbier and Woernle, Ber. 1906, 39, 4134.

Methylamine, like ammonia, in aqueous solution precipitates metallic hydroxides from solutions of many salts; but, unlike ammonia, dissolves, when in excess, the hydroxide of aluminium, whereas it fails to dissolve the hydroxides of cadmium, nickel, and cobalt.

When methylamine is oxidised with monopersulphuric acid (Caro's acid), according to Bamberger and Seligman, it undergoes the following changes

$$CH_3NH_2 \rightarrow CH_3{\cdot}NH{\cdot}OH \rightarrow CH_2{:}NOH \rightarrow \text{either}$$
$$OH{\cdot}CH{:}NOH \text{ or } CH_2NH{\cdot}OH \rightarrow CH_3NO_2,$$

hydrogen cyanide also being formed (Ber. 1902, 35, 4299). Unlike the di- and tri-amines, it is readily decomposed by chromic acid with evolution of nitrogen (Coninck and Combe, Compt. rend. 1898, 127, 1221; 128, 682).

Methylamine interacts with cyanogen chloride in cold ethereal solution forming principally *s*-dimethylguanidine hydrochloride and also methylcyanamide (Kaess and Gruszkiewicz, Ber. 1902, 35, 3598).

It also reacts slowly with sodium phosphate and magnesium sulphate in dilute aqueous solution, forming methylamine magnesium phosphate (François, J. Pharm. Chim. 1908, 28, 86). Neither di- nor tri-methylamines react thus.

Liquid methylamine is a very good solvent for organic compounds, and combines readily with both organic and inorganic compounds, forming addition products (Gibbs, J. Amer. Chem. Soc. 1906, 28, 1395; Hochstetter and Kohn, Monatsh. 1903, 24, 773). For a number of addition products with inorganic substances, *see* Bonnefoi, Compt. rend. 1897, 124, 773; 127, 516; Jarry, *l.c.*; and Ann. Chim. Phys. [vii.] 27, 376; Matthews, J. Amer. Chem. Soc. 1898, 20, 826; Lenher, *ibid.* 1900, 23, 486; Moissan, Compt. rend. 128, 26; Lang and Jolliffe, Chem. Soc. Proc. 1903, 147; Ephraim and Weinberg, Ber. 1909, 42, 4447; Ekeley, J. Amer. Chem. Soc. 1909, 31, 664.

In the presence of soil, calcium carbonate and oxygen, methylamine is converted into ammonia, and finally into nitrites and nitrates (Demoussy, Compt. rend. 1898, 126, 253).

Under the influence of the silent electric discharge methylamine evolves nitrogen (Berthelot, *ibid.* 775; *see* also Mixter, Amer. J. Sci. 1898, [iv.] 6, 217).

Methyl chloramine Me·NHCl is obtained by distilling methylamine hydrochloride with sodium hypochlorite (Berg. Compt. rend. 1893, 116, 887). It is a colourless volatile oil with a piquant irritating odour.

Methyl dichloramine $MeNCl_2$ is obtained by leading chlorine into aqueous methylamine (Köhler, Ber. 1878, 12, 771) or by the distillation of methylamine hydrochloride with bleaching powder (Bamberger and Renauld, Ber. 1895, 28, 1683). It is a golden-yellow liquid, b.p. 59°–60°. Similar bromo and iodo compounds are also known (Dehn, J. Amer. Chem. Soc. 1909, 31, 123).

Methyl nitramine MeN_2O_2H is obtained by treating δ-dimethyl dinitro-oxamide with barium hydroxide (Franchimont, Rec. trav. chim. 1894, 13, 313; 321, 331; also v. Pechmann, Ber. 1897, 30, 647). It forms long needles, m.p. 38°, readily soluble in water and in alcohol. On reduction with aluminium amalgam and aqueous alcohol it yields diazomethane, whilst with zinc and hydrochloric acid it is reduced to methylamine, hydrazine and methylhydrazine (Thiele and Meyer, Ber. 1896, 29, 962). When heated with β-naphthol, β-naphthol methyl ether is formed with evolution of nitrogen (Franchimont and Umbgrove, Rec. trav. chim. 1897, 15, 215). It forms a number of metallic salts (Franchimont, *l.c.*; Ley and Kissel, Ber. 1899, 32, 1364). The *potassium* salt $KMeO_2N_2$, m.p. 220°, explodes on heating or on being struck.

Thionylmethylamine MeN : SO is an oil which fumes in air, b.p. 58°–59° (Michaelis and Storbeck, Annalen, 1893, 274, 187). Methylamine derivatives of various aliphatic acids are described by Duden, Bock and Reid (Ber. 1905, 38, 2036); Fosse (Compt. rend. 1906, 143, 914); Tafel and Wassmuth (Ber. 1907, 40, 2831); Benary (Ber. 1909, 42, 3912); Gansser (Zeitsch. physiol. Chem. 1909, 61, 16); Fourneau (Bull. Soc. chim. 1909, [iv.] 5, 229); also D. R. PP. 198306, 1908; 202167, 1909.

Methylaminoanthraquinones are prepared by dissolving a mixture of the desired amino-derivative of anthraquinone and formaldehyde in concentrated sulphuric acid and warming to 55°–60° (D. R. P. 156056, 1905).

α-Methylaminoanthraquinone, m.p. 167°, is obtained by treating α-mononitroanthraquinone with methylamine solution (D. R. P. 144634; Frdl. 1902–04, 201).

1-Methylaminoanthraquinone-5-sulphonic acid

$$SO_3H{\cdot}C_6H_3{<}\begin{smallmatrix}CO\\CO\end{smallmatrix}{>}C_6H_3NHMe,$$

and also the diamino compound

$$NHMe{\cdot}C_6H_3(CO)_2C_6H_3NHMe,$$

are formed by treating potassium 1 : 5-anthraquinonedisulphonate with aqueous methylamine at 150°. The potassium salt of the former crystallises from water in violet brown needles. Other methylamine anthraquinone sulphonic acids are obtained similarly (D. R. P. 186722, 1907).

For other derivatives of methylamine anthraquinone which are used as dyes, *see* D. R. PP. 156759, 164791; Frdl. 1905–07, 293, 280; D. R. PP. 212470, 1909; 220314; Chem. Zentr. 1910, i. 1306).

Methylaminoacetocatechol

$$C_6H_3(OH)_2CO{\cdot}CH_2{\cdot}NHMe$$

is formed by warming gently chloroacetocatechol with an excess of methylamine. It is a white crystalline powder darkening at 200° and decomposing at about 230°. Ferric chloride gives an emerald-green colour (D. R. P. 152814; Dakin, Chem. Soc. Proc. 1905, 154). When reduced and then treated with ammonia, it yields methylamino-*o*-dihydroxyphenylethanol, m.p. 208°, which is an astringent, and has hæmostatic properties (J. Soc. Chem. Ind. 1909, 1005). The ethanol yields a hydrochloride, m.p. 157° (D. R. P. 202169).

Methylaminoquinones are described by Fichter (Annalen, 1908, 361, 363).

2-Methylamino-8-methoxyquinoline crystallises in silver prisms, m.p. 151°, and forms a crystalline nitrosamine, m.p. 180° (Fischer, Ber. 1902, 35, 3674).

Methylaminocamphene has b.p. 202°–203°/756 mm. $[\alpha]_D+28{\cdot}7°$ (Forster and Micklethwait, Chem. Soc. Trans. 1904, 334).

Methylaminocoumarins are described by v. Pechmann and Schaal (Ber. 1899, 32, 3690, 3696); and by Morgan and Micklethwait (Chem. Soc. Trans. 1904, 1238).

Methylaminothiazoles are described by Young and Crookes (Chem. Soc. Trans. 1906, 68). *Uracils* by Wheeler and Jamieson (Amer. Chem. J. 1904, 32, 342).

Dimethylamine $(CH_3)_2NH$; b.p. 7·2°–7·3° at 764·1 mm.; sp.gr. 0·6865 at −5·8° (Hofmann, Ber. 1889, 22, 699). From methyl iodide and ammonia (Hofmann, J. 1862, 329). In small quantity by distilling the compound of aldehyde ammonia and sulphurous acid with caustic lime (Petersen, Annalen, 1857, 102, 317). In the putrefaction of fishes; occurs in herring brine (Bocklisch, Ber. 18, 87, 1924). Is obtained together with methylamine in the action of methyl alcohol on phospham (*see Methylamine;* also Vidal, Chem. Zentr. 1897, ii. 517).

Preparation.—The product of the action of ammonia upon methyl iodide (consisting of the hydriodides of mono-, di- and tri-methylamine and tetramethylammonium iodide) is treated with alcohol in order to remove the last-mentioned compound. The residue on treatment with caustic potash yields the free bases which can be partially separated by condensation, the more volatile monomethylamine escaping condensation may be received in hydrochloric acid.

The mixture of the free bases is then treated with ethyl oxalate, the trimethylamine remains unacted upon, the dimethylamine is converted into the ethyl ester of dimethyl oxamic acid, whilst the mono- base is converted into dimethyl oxamide. The latter is difficultly soluble in cold water, and is thus separated from the dimethylamine compound which is then distilled with potash

$$(CH_3)_2N{\cdot}C_2O_2(OC_2H_5)+2KOH = (KO)_2C_2O_2+C_2H_5OH+(CH_3)_2NH.$$

The alcoholic solution is then neutralised with hydrochloric acid, evaporated to dryness, and decomposed by caustic potash. The hydrochloride of dimethylamine can be freed from admixed ammonium chloride by treatment with chloroform, in which the latter is insoluble (Behrend, Annalen, 1883, 222, 119).

By the reduction of a mixture of formaldehyde and methylamine with zinc-dust and hydrochloric acid (D. R. P. 73812).

Dimethylamine can be obtained by heating thiodimethylamine (185 grammes) with sulphuric acid chlorhydrin (130 grammes), the temperature being raised gradually and the mass finally heated for 2–3 hours at 130°–150°. On cooling the product is shaken with ether to remove benzenethiochloride, and the residue is treated with water, made alkaline, and the dimethylamine is separated by distillation in steam (D. R. P. 105870; Frdl. 1897–1900, 34).

An almost theoretical yield of dimethylamine hydrochloride is obtained by adding powdered nitrosodimethylaniline hydrochloride and a few zinc shavings to a nearly boiling, dilute aqueous solution of sodium hydroxide, the amine being absorbed in concentrated hydrochloric acid contained in a Péligot's U-tube (Menschutkin, J. Russ. Phys. Chem. Soc. 1898, 30, 243; Norris and Laws, Amer. Chem. J. 1898, 20, 54).

The free base can be liberated by treatment with caustic soda.

Properties.—Dimethylamine is a colourless, inflammable liquid with a strong ammoniacal smell. Bromine acts upon an aqueous solution forming dimethylamine hypobromite and bromide $N(CH_3)_2H{\cdot}HBrO$ and $NH(CH_3)_2{\cdot}HBr$; or, if the bromine be in excess, the unstable tribromide $N(CH_3)_2Br_3$, a yellow flocculent precipitate, is obtained (Raschig, Ber. 1885, 18, 2250).

At 0° it combines directly with two atoms of bromine (Remsen and Norris, Amer. Chem. J. 18, 94).

When oxidised with hydrogen peroxide it yields nitrous acid, formaldehyde and formic acid (Dunstan and Goulding, Chem. Soc. Trans. 1899, 1009). With Nessler's reagent, dimethylamine gives a white precipitate.

When heated with hydrogen at 820°–1120°, hydrocyanic acid, methane and ammonia are formed, the relative quantities of the products depending on the quantity of hydrogen present (Voerkelius, Chem. Zeit. 1909, 33, 1025, 1078, 1090).

Dimethylamine forms salts resembling those of ammonia (Topsoë, J. 1883, 618; Delépine, Ann. Chim. Phys. [vii.] 8, 459; Norris and Laws, *l.c.*; and 490; Ragland, *l.c.*; Cook, *l.c.*; Jörgensen, Zeitsch. anorg. Chem. 1906, 48, 374).

Dimethylamine dihydrochloride is a white crystalline substance formed by passing dry hydrogen chloride into the base or into the normal hydrochloride (Kaufler and Kunz, Ber. 1909, 42, 385).

Dimethylchloramine Me_2NCl, b.p. 46°/765 mm., is obtained in the same way as the monomethyl derivative, and has similar properties (Berg, *l.c.*). The corresponding bromo derivative has b.p. 64°–66° (Seliwanoff, Ber. 1893, 26, 423; Willstätter and Hottenroth, Ber. 1904, 37, 1775).

Other halogen derivatives are described by Cohn (J. pr. Chem. 1897, [ii.] 56, 345) and Knorr (Ber. 1904, 37, 3504).

Dithiodimethylamine $S_2(NMe_2)_2$ is a reddish-yellow liquid, b.p. 82°–83°/22 mm., 170°–180°/760 mm. (decomp). It is decomposed by acids into the amine, sulphur, and sulphur dioxide (Michaelis and Luxembourg, Ber. 1895, 28, 165).

Dimethylnitramine $Me_2O_2N_2$ forms bright colourless needles, whilst the *isonitramine* is a liquid, b.p. 112° (Franchimont and Umbgrove, *l.c.*; Lachman, Amer. Chem. J. 1899, 21, 483; Bamberger, Ber. 1895, 28, 402; Kirpal, *ibid.* 537).

Dimethylamine acetone $NMe_2{\cdot}CH_2{\cdot}COMe$ is prepared by adding chloracetone to an aqueous 30 p.c. solution of dimethylamine. It is a colourless oil, b.p. 123°, miscible with water, yielding a platinochloride, which forms beautiful crystals, m.p. 176° (decomp.). It also yields a hydrochloride; an aurichloride (m.p. 145°–146°); a methiodide (m.p. 168°); and an oxime, m.p. 99° (Stoermer and Dzimski, Ber. 1895, 28, 2220; 1896, 29, 866).

Methyl dimethylaminoacetate is a volatile oil, boiling at 135°. The corresponding ethyl compound boils at 149°–150°.

Methyl β-dimethylaminopropionate

$$NM_2{\cdot}CH_2{\cdot}CH_2{\cdot}CO_2Me,$$

b.p. 154·5°, yields a methiodide, m.p. 191°–192° (decomp.), which, when warmed with alkalis, gives acrylic acid and trimethylamine, whilst with silver oxide it gives β-trimethylpropiobetaine (Willstätter, Ber. 1902, 35, 584).

Methyl-γ-dimethylaminobutyrate has b.p. 171·5°–173°, and yields a crystalline aurichloride and picrate.

Dimethylaminodimethylacetal is a colourless mobile liquid, b.p. 137·5°, which has no reducing properties. Other dimethylamino derivatives of aliphatic acids have also been prepared (Willstätter, Ber. 1902, 35, 1378).

Dimethylamino derivatives of aliphatic hydrocarbons are described by Willstätter (Ber. 1901, 34, 129; Annalen, 1903, 326, 1); Duden and Lemme (Ber. 1902, 35, 1335); Hochstetter and Kohn (Monatsh. 1903, 24, 773); Bouveault (Bull. Soc. chim. 1904, [iii.] 31, 1306, 1322).

A number of methyl and dimethyl aminocarbinol derivatives of the type

$$R_1R_2C(OH)CH_2NR_3R_4$$

(where R_1,R_2=alkyl or aryl groups R_3= methyl or other alkyl and R_4=an alkyl group or hydrogen) are obtained by the action of methyl or dimethylamine on an ethylene oxide  $R_1R_2C\overset{O}{\text{——}}CH_2$ (D. R. P. 199148; Frdl. 1908–10, 975; also D. R. P. 173610; Knorr and Matthes, Ber. 1901, 34, 3482).

These substances, which have valuable anæsthetic properties, and are less toxic than cocaine or eucaine, can also be obtained by treating aminoacetones or esters of amino acids containing a tertiary amino group with magnesium organo compounds of the type $R{\cdot}Mg{\cdot}X$ (D. R. PP. 169819, 169746; Frdl. 1905–07, 1029, 1033).

Esters having pronounced saporific properties and a low toxicity are produced by condensing alkyl dimethylaminohydroxy*iso*butyrates with anhydrous chloral (D. R. PP. 203643, 198306, 202167; Frdl. 1908–10, 980, 984, 1000).

For other dimethylamino compounds used in medicine, *see* D. R. PP. 121051, 129967; Frdl. 1900–02, 1219, 1226; J. Soc. Chem. Ind. 1909, 491.

Dimethylaminoparaxanthine known in commerce as *paraxine*, is an energetic diuretic (D. R. P. 156901, 1905) and is decomposed into

2:6-Dioxy-8-dimethylamino-7-methylpurine, m.p. above 319°, a crystalline substance which can be separated from the urine and has also a strong diuretic action (Forschbach and Weber, Arch. exp. Path. Pharm. 1907, 56, 186).

Dimethylamine reacts in equimolecular proportion with polyhydroxyaromatic compounds forming addition products with an alkaline reaction which can be used for developing in photography without further addition of alkali (D. R. P. 141101; Frdl. 1900–02, 1217).

Dimethylamine is used in the production of a large number of valuable dyestuffs; thus violet to blue dyestuffs are obtained by heating gallocyanine with mono- di- or tri-methylamine (D. R. PP. 57459, 65000; Frdl. 1890–94, 367).

Blue dyes are also obtained by the action of dimethylamine on the dyes of the oxazine series. The substances so obtained differ from the parent dye in giving purer colours and in being stable towards alkalis (D. R. P. 54658; Frdl. 1890–94, 373).

See also Freund and Wirsing, Ber. 1907, 40, 204; D. R. PP. 172079, 161665; the article on AMINES and the various parent dyes.

When dimethylamine is heated with *p*-aminophenol-azo-β-naphthol and formaldehyde, a dark-brown powder is obtained, which is a good dye for tannined cotton (D. R. P. 95546; Frdl. 1897–1900, 555).

3-Dimethylaminoanthraquinone is obtained when dimethylaminobenzoylbenzoic acid (1 part) is heated with concentrated sulphuric acid (10 parts) at 175°–180°. It forms red needles, m.p. 181°. When 12 parts of sulphuric acid is used, and the temperature is kept at 80°, dimethyl-aminoanthranol is formed, but is readily oxidised to the anthraquinol, by ferric chloride (Haller and Guyot, Compt. rend. 1898, 126, 1544; D. R. P. 108837).

1-Dimethylamino-5-phenoxyanthraquinone m.p. 147°–149°, and similar compounds which form important materials for the manufacture of dye-stuffs, have been obtained by treating the corresponding anthraquinone derivative with the desired mono- or di-alkylamine in pyridine solution at 110°–115° (D. R. P. 165728; Frdl. 1905–7, 289).

For other dimethylaminoanthraquinone derivatives, *see* Severin, Compt. rend. 1906, 142, 1274; D. R.PP. 136777, 136778; Frdl. 1900–02, 374; D. R. P. 146691; Frdl. 1902–04; D. R. PP. 146691, 1904; 205096, 1909).

Dimethylamine, when heated with fluorescein chloride or dichlorofluorescein chloride in presence of zinc chloride at 160°–170°, gives derivatives of chloroaminofluoran, whilst at higher temperatures rhodamines are produced (D. R. P. 139727, 1903).

Chloromethyl- and dimethyl-aminofluoran form pink crystals, melting at 168° and 218° respectively.

Dimethylaminocamphor is a colourless oil, b.p. 241°/758 mm. It does not reduce Fehling's solution, and is only slowly acted on by silver nitrate. It forms a picrate, m.p. 220° (decomp.); hydriodide, m.p. 251° (decomp.); a platinichloride, m.p. 211° (decomp.); and acetate, m.p. 251°, with evolution of gas (Forster, Chem. Soc. Trans. 1905, 240; Rabe and Schneider, Ber. 1908, 41, 872).

5-Dimethylaminouracil

$$NH\left\langle\begin{matrix}CO\text{——}NH\\CO{\cdot}C(NMe_2)\end{matrix}\right\rangle CH$$

is formed by treating 5-bromouracil with dimethylamine, and forms colourless plates, m.p. 297° (decomp.) (Wheeler and Jamieson, Amer. Chem. J. 1904, 32, 342).

Trimethylamine $N(CH_3)_3$; b.p. 3·2°–3·8° at 764·6 mm., sp.gr. 0·662 at −5·2° (Hofmann, Ber. 22, 699; sp.gr. 0·673 at 0° (Bleunard). Does not solidify at −75° under a pressure of 10 mm.; forms a crystalline hydrate with 7 molecules of water, melting at 4·3°. Occurs in certain plants, *e.g.* *Chenopodium Vulvaria* (Linn.), *Arnica montana* (Linn.), hawthorn blossom, pear and wild cherry blossom, in ergot (Dessaignes, J. 1857, 481; Walz, J. 1852, 552), in certain lichens such as the *Sticta fuliginosa*, in hops and in cod liver oil, in bone oil and guano (Zopf, Annalen, 1897, 297, 272). It also occurs in various animal fluids, *e.g.* in calves' blood (Dessaignes), and in human urine (Filippi, Zeitsch. physiol. Chem. 1906, 49, 433). Also in large quantities in herring brine, which owes to it its peculiar smell (Wertheim, J. 1851, 480).

It is also a product of the decomposition of fibrin by *streptococci* (Emmerling, Ber. 30, 1863).

It is obtained by treating methyl iodide with ammonia (Hofmann), by the distillation of tetramethylammonium hydroxide (Hofmann, Annalen, 93, 325); by distillation of narcotine (Wertheim, *ibid.* 73, 208), or codeïne (Anderson, *ibid.* 77, 367), with potash.

By the action of methyl alcohol on magnesium nitride (Szarvasy, Ber. 1897, 30, 305). By the reduction of trimethyloxamine with zinc-dust (Hantzsch and Hilland, Ber. 1898, 31, 2058; Dunstan and Goulding, *l.c.*). By the interaction of hexamethylenetetramine with formaldehyde (Eschweiler, Ber. 1905, 38, 880).

By the putrefaction of yeast or of wheat meal (Hesse, J. 1857, 403). Also by the dry distillation of 'vinasses' from the beetroot sugar manufacture (Vincent, Bull. Soc. chim. [ii.] 27, 150).

Preparation.—The crude methylamine from the distillation of the 'vinasse' is treated with sulphuric acid, the solution evaporated to a syrup and treated with absolute alcohol, the monomethylamine sulphate is thus precipitated. The filtrate is treated with the proper amount—1 molecule for every 2 molecules of primary amine present—of ethyl oxalate, and allowed to stand for 24 hours. The precipitate, consisting of a mixture of di-*iso*butyl oxamide and di-*iso*propyl oxamide, is filtered off and the filtrate distilled; the residue is then decomposed by potash, the free bases received in alcohol, and the alcoholic solution mixed at 0° with ethyl oxalate (1 molecule to each molecule of free base) and allowed to stand for a day. The mixture is then distilled, and the triethylamine obtained pure. The non-volatile residue is made slightly alkaline with milk of lime and evaporated, calcium *iso*propyl oxamate first crystallises out, and then calcium ethyl oxamate. The mother liquor, on addition of alcohol, gives a precipitate of calcium methyl oxamate, whilst calcium dimethyl oxamate remains in solution (Duvillier and Buisine, Ann. Chim. Phys. [v.] 23, 299).

A mixture of herring pickle and lime is subjected to distillation, the alkaline distillate is neutralised with hydrochloric acid, evaporated to dryness, and the residue treated with alcohol, which leaves the ammonium chloride undissolved. The solution is evaporated, the residue dissolved in a little water, and redistilled with lime, the vapours being led through an empty bottle to separate less volatile constituents, and then conducted into water or condensed with ice.

50 grammes of ammonium chloride are heated with 440 grams of 40 p.c. formaldehyde solution in an autoclave at 120°–160°.

Trimethylamine can more readily be obtained in a pure state by the distillation of tetramethylammonium hydroxide (Schmidt, Annalen, 1892, 267, 254).

Properties.—Trimethylamine is a volatile liquid with a strong, fish-like smell. It is very soluble in water, and possesses strong basic properties, although it can be displaced from its compounds by either mono- or di-methylamine.

When heated at 800°–1000° it decomposes almost quantitatively into hydrocyanic acid and methane, whilst at 600°, *tetramethyl hydrazine* is formed (Voerkelius, Chem. Zeit. 1909).

When passed through a hot tube with hydrogen it decomposes, forming dimethyl dimethylene diamine $(CH_2)_2(CH_3)_2N_2$, ammonia, cyanogen, and other products (Romeny, Ber. 11, 835). It forms salts with acids, of which the hydrochloride is of some importance; it has been suggested to employ it in the manufacture of potassium carbonate from potassium chloride by a process analogous to the Solvay ammonia soda process. Ammonia cannot be employed in this process, since ammonium chloride has only about the same solubility as potassium hydrogen carbonate, whilst trimethylamine hydrochloride is very much more soluble.

For a number of salts formed by trimethylamine with inorganic salts, *see* Guareschi, *l.c.*; Christensen, *l.c.*; Ragland, *l.c.*; Cook, *l.c.*; Hofmann and Marburg, *l.c.*; Mylius and Foerster, Ber. 24, 2424; Wiede, *ibid.* 31, 3140; Michael and Hibbert, Annalen, 1909, 364, 64.

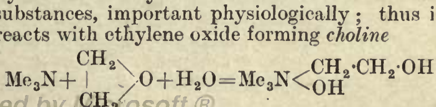
Trimethylamine dibromide NMe_3Br_2 is formed by passing dry trimethylamine into ice-cold bromine, or by heating trimethylamine hydrobromide (1 molecule) with a small quantity of hydrogen bromide and bromine (1 molecule). Similar iodine, chlorine, and mixed halogen derivatives have also been obtained (Remsen and Norris, Amer. Chem. J. 1896, 18, 90; *see* also Hantzsch and Graf, Ber. 1905, 38, 2154; Norris, *ibid.* 3904). They are crystalline unstable substances.

For other halogen and halogen acid compounds of trimethylamine, *see* Gabriel and Stelzner, Ber. 1895, 28, 2929; Delépine, Compt. rend. 1896, 122, 272; Ann. Chim. Phys. 1896, [vii.] 8, 439; Norris, Amer. Chem. J. 1898, 20, 51; Pictet and Krafft, Bull. Soc. chim. [iii.] 7, 72; Hantzsch, Ber. 1905, 38, 2161; Kaufler and Kunz, *ibid.* 1909, 42, 2482).

Trimethylamine combines with carbon disulphide to form a colourless crystalline compound $N(CH_3)_3{\cdot}CS_2$, m.p. 125°, which is somewhat unstable; it is soluble in chloroform, and combines with dilute acids, but is decomposed by strong acids into its constituents.

Trimethyloxamine (*Trimethylamine oxide*) $Me_3N{:}O,2H_2O$ forms needle-shaped crystals m.p. 96°, and is best obtained by the action of hydrogen peroxide on an aqueous solution of trimethylamine (Dunstan and Goulding, Chem. Soc. Trans. 1899, 794, 1005; Mamlock and Wolffenstein, Ber. 1901, 34, 2499).

Trimethylamine, like dimethylamine, enters into the constitution of a number of important dyes. It also yields derivatives which form substances, important physiologically; thus it reacts with ethylene oxide forming *choline*

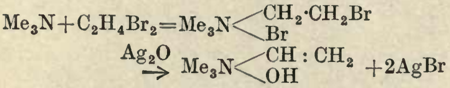


$$Me_3N + \begin{array}{l} CH_2 \\ | \\ CH_2 \end{array}\!\!\!>O + H_2O = Me_3N\!<\!\begin{array}{l} CH_2{\cdot}CH_2{\cdot}OH \\ OH \end{array}$$

With monochloracetic acid producing *betaine*

$$Me_3N+ClCH_2{\cdot}CO_2H=Me_3N{\cdot}CH_2{\cdot}CO+HCl.$$
$$\underbrace{\qquad\qquad\qquad}_{O}$$

With ethylene dibromide, to form *neurine*



$$Me_3N+C_2H_4Br_2=Me_3N\begin{cases}CH_2{\cdot}CH_2Br\\Br\end{cases}$$
$$\xrightarrow{Ag_2O} Me_3N\begin{cases}CH:CH_2\\OH\end{cases}+2AgBr$$

***iso*Crotyltrimethylammonium bromide**

$CMe_2:CH{\cdot}NMe_3Br$,

obtained by the interaction of *iso*butylene bromide and trimethylamine, is homologous with neurine bromide, and, like valeryltrimethyl ammonium bromide, closely resembles it in its physiological action. Dibrom*iso*butyl trimethyl ammonium bromide and dibrom*iso*butyltrimethyl ammonium dibromide and other similar compounds have also been prepared (Kleine, Chem. Zentr. 1894, i. 16).

Ethylene bromide reacts with trimethylamine in molecular proportion at 100°, yielding tetramethylammonium bromide, trimethylvinylammonium bromide (neurine bromide), dimethylamine bromide, and other compounds.

Propylene and amylene bromides also react with trimethylamine, yielding a number of methylammonium compounds (Kleine, *l.c.*).

Trimethylamine reacts with halogen ketones, forming ketonic bases (Schmidt, Arch. Pharm. 1898, 236, 334).

Trimethylacetonylammonium chloride (coprine chloride) $AcCH_2{\cdot}NMe_3Cl$ is a crystalline substance which gives a platinochloride, yellowish red needles, m.p. 238°–240°; an aurichloride, beautiful yellow needles, m.p. 139·5°; and an oxime, colourless plates, m.p. 212° (Furnée, Arch. Pharm. 1898, 236, 343).

Trimethylacetonylammonium bromide melts at 190°, and at 195° it gives rise to a yellow distillate, and tetramethylammonium bromide (Brendler and Tafel, Ber. 1898, 31, 2683).

For the interaction of trimethylamine with other aliphatic compounds, *see* Malbot, Bull. Soc. chim. [iii.] 6, 845, 709, 711; *ibid.* 7, 213; Duvillier, *ibid.* [iii.] 23, 507; Menozzi and Pantoli, Gazz. chim. ital. 23, ii. 209; Hartmann, Chem. Zentr. 1896, i. 999; André, Compt. rend. 1898, 126, 1107; Benary, Ber. 1908, 41, 2399; D. R. P. 195813; Frdl. 1908–10, 990.

In France and in Russia trimethylamine has been employed successfully in medicine, but English and American doctors have not obtained such good results. For the physiological effects of trimethylamine, *see* Combemale and Brunelle, Compt. rend. Soc. Biol. 1891, 175).

Methylammonium cobaltinitrite

$(MeNH_3)_3CO(NO_2)_6$

is prepared by adding to a nearly saturated solution of methylamine hydrochloride, a nearly saturated solution of pure sodium cobaltinitrite. It is a yellow powder, stable when dry, but slowly decomposing in the presence of moisture or on heating. When treated with strong mineral acids it decomposes violently (Cunningham and Perkin, Chem. Soc. Trans. 1909, 1564).

Monomethylammonium hexabromoplatinate $(NH_3Me)_2PtBr_6$ and the corresponding di- and tri-methyl compounds are all crystalline substances (Gutbier and Bauriedel, Ber. 1909, 42, 4243).

Magnesium methylammonium arsenate

$NH_3Me{\cdot}MgAsO_4,8H_2O$

and the trimethylammonium compound

$NHMe_3{\cdot}MgAsO_4,6H_2O$

are white crystalline powders (Brisac, Bull. Soc. chim. 1903, [iii.] 29, 591). Similar methylammonium phosphates have also been prepared (Porcher and Brisac, *ibid.* 587). For other methyl ammonium compounds, *see* Reynolds, Chem. Soc. Trans. 1891, 394; François, Compt. rend. 1905, 140, 1697; Gutbier, Zeitsch. physikal. Chem. 1909, 69, 304.

Tetramethylammonium $N(CH_3)_4$, *tetramethylium*, according to Palmaer (Zeitsch. Elektrochem. 1902, 8, 729) is produced when a solution of tetramethylammonium chloride or hydroxide in liquid ammonia is electrolysed between platinum electrodes, but it could only be observed as giving a transient blue colouration and could not be isolated.

The base, **Tetramethylammonium hydroxide** NMe_4OH is formed as the pentahydrate

$NMe_4OH,5H_2O$,

m.p. 62°–63°, by the action of a methyl alcohol solution of potassium hydroxide on a similar solution of tetramethyl ammonium chloride. When this hydrate is desiccated it forms a trihydrate, m.p. 59°–60°, and a monohydrate which decomposes at 130°–135° without melting (Walker and Johnson, Chem. Soc. Trans. 1905, 955). The hydroxides are hygroscopic, strongly alkaline, and readily absorb carbon dioxide when exposed to the air. When heated they decompose forming methyl alcohol and trimethylamine. The *iodide* $N(CH_3)_4I$ is the main product of the action of ammonia upon methyl iodide (Hofmann, Proc. Roy. Soc. 1851, 381), or by heating trimethylazonium iodide with methyl iodide at 125°–130° (Harries and Haga, Ber. 31, 59). It forms quadratic prisms soluble in hot water, but only slightly in cold water; sp.gr. 1·84 (Schröder, Ber. 12, 562). Similar chlorine and bromine compounds are also known.

Tetramethylammonium pentaiodide NMe_4I_5, m.p. 126°–127°, is obtained by the action of methyl iodide on nitrogen iodide (Silberrad and Smart, Chem. Soc. Trans. 1906, 173).

Tetramethylammonium forms many salts which have the power of producing crystalline double compounds with many metallic salts (*v.* Topsöe, J. 1883, 619; Risse, Annalen, 107, 223; Lossen, *ibid.* 181, 374; Ragland, *l.c.*; Prescott, J. Amer. Chem. Soc. 1898, 20, 96; Wiede, *l.c.*; Auld and Hantzsch, Ber. 1905, 38, 2685; Milbauer, Zeitsch, anorg. Chem. 1907, 53, 135; Schmidt, Chem. Zentr. 1907, ii. 1593; Braun, Ber. 1908, 41, 2123; Kaufler and Kunz, *l.c.*).

Tetramethylammonium formate (*Forgenine*) $H{\cdot}CO_2{\cdot}N(CH_3)_4$ is obtained by the action of tetramethylammonium iodide on silver formate. It is a white crystalline, odourless, hygroscopic substance, stable in dry air and in solution, decomposing above 200°, and giving the reactions of formates (Vanzetti, Chem. Zentr. 1906, ii. 1347).

Forgenine is employed in medicine, but in large doses it is toxic, and may even prove fatal (Piccinini, Chem. Zentr. 1907, i. 651).

α-Methyl hydroxylamine $MeO{\cdot}NH_2$ is formed by treating methyl ethyl benzhydroxamate with hydrochloric acid (Lossen and Zanni, Annalen, 1876, 182, 225). The hydrochloride forms prisms, m.p. 149°, and gives an orange-red crystalline platinochloride (Lossen, Ber. 1883, 16, 827; Petraczek, *ibid.* 827).

β-Methyl hydroxylamine MeNH·OH is formed by heating benz*syn*aldoxime methyl ether or its nitro derivative with hydrochloric acid (Dittrich, Ber. 1890, 23, 3598; Kjellin, *ibid.* 1893, 26, 2382), but is best prepared by the electrolytic reduction of nitromethane in alcoholic sulphuric acid solution at 15°–20° (Pierron, Bull. Soc. chim. [iii.] 21, 783; *see* also Bamberger, Ber. 1894, 27, 1350; Kirpal, *ibid.* 1892, 25, 1715). It forms long prisms, m.p. 42°, b.p. 62·5°/15 mm., sp.gr. 1·0003 at 20°/4°. It is readily soluble in water and alcohol, decomposes on standing, and is reduced to methylamine by hydriodic acid.

The *hydrochloride* has m.p. 88°–90°; the *picrate* m.p. 128°–130°.

α-Methyl β-ethyl hydroxylamine NHEtOMe is a colourless alkaline liquid, b.p. 60°–61°, readily soluble in water and does not reduce silver nitrate. It forms a hydrochloride and a platinichloride. *β-Methyl α-ethyl hydroxylamine* has b.p. 65°–65·5° and similar properties to the α-methyl β-ethyl compound (Jones, Amer. Chem. J. 1907, 38, 253).

αβ-Dimethylhydroxylamine hydrochloride
NHMe·OMe,HCl
forms long prismatic needles m.p. 115°–116°. It is volatile at 100°, does not reduce Fehling's solution or silver nitrate. The platinochloride forms red prismatic crystals which melt at 180° (decomp.). The free base is a colourless volatile liquid, b.p. 42·2°–42·6° (Jones, Amer. Chem. J. 1898, 20, 1).

Methyl hydrazine $CH_3HN{\cdot}NH_2$ is prepared by the reduction of diazomethane with sodium amalgam and alcohol or by agitating methyl iodide with excess of methylhydrazine in aqueous solution (Pechmann, Ber. 1895, 28, 859; Harries and Haga, *ibid.* 1898, 31, 56). A colourless liquid with ammoniacal smell. The sulphate $NHCH_3{\cdot}NH_2,H_2SO_4$, a crystalline compound, is obtained from methyl hydrazine carbamide which results from the action of nascent hydrogen upon nitroso-methyl carbamide $NH_2{\cdot}CO{\cdot}N(CH_3)NO$ (Brüning, Ber. 21, 1809). The oxalate has m.p. 166°. Methyl hydrazine gives benzoyl and other derivatives (Michaelis and Hadanck, Ber. 1908, 41, 3285).

as-**Dimethyl hydrazine** $(CH_3)_2N{\cdot}NH_2$; b.p. 62·5° at 717 mm.; sp.gr. 0·801 at 2·2°; b.p. 63·9° at 752·5 mm.; sp.gr. 0·7914 at 22·3°/0° (Brühl, Ber. 1897, 30, 160); from nitroso-dimethylamine and nascent hydrogen (zinc-dust and acetic acid) in alcoholic solution (Renouf, Ber. 1880, 13, 2171), or by the dry distillation of trimethylazonium hydroxide (Harries and Haga, *l.c.* 58). It has a strong ammoniacal smell, and is very soluble in water, alcohol, and ether. It is decomposed by nitrous acid into nitrous oxide and dimethylamine.

The *oxalate* has m.p. 142°–143°. The *cyanide* crystallises in beautiful needles and decomposes at 0°–10° (Peters, Ber. 1906, 39, 2784).

sym-**Dimethylhydrazine** MeNH·NHMe is obtained by the action of methyl iodide on potassium or lead diformyl hydrazine (Harries and Klamt, Ber. 1895, 28, 504; Harries and Haga, *l.c.* 63), or by boiling the methyl iodide salt of methyl pyrazole with strong potassium hydroxide (Knorr and Köhler, Ber. 1906, 39, 3257; Knorr, *ibid.* 3265). It is a mobile, colourless, fuming liquid, b.p. 81°/747 mm., with the characteristic odour of aliphatic hydrazines. It dissolves in water with evolution of heat, attacks cork, rubber, and the epidermis, and its vapour, when mixed with air, burns with a faintly luminous flame, depositing soot, and is liable to explosion. It is a fairly strong reducing agent, and forms salts with mineral and organic acids. It also forms a semicarbazide and a phenylthiosemicarbazide, m.p. 115°; a dibenzoyl derivative, m.p. 85°; a dimethyl picrazide, m.p. 141°, and other derivatives (Knorr and Köhler, *l.c.*).

Trimethylazonium iodide $NH_2{\cdot}NMe_3I$ is obtained by agitating an aqueous solution of hydrazine hydrate with methyl iodide and caustic potash. It resembles ammonium chloride in crystalline structure, and has m.p. 235° (decomp.). It is converted into hydrochloride when acted on by silver chloride, and into the hydroxide by its interaction with silver oxide (Harries and Haga, *l.c.*).

Tetramethyl tetrazone $(CH_3)_2N{\cdot}N{:}N{\cdot}N(CH_3)_2$, b.p. 130°; a yellow explosive oil, slightly soluble in water. It is a strong base, and its salts are very soluble in water; it reduces silver solution with formation of a mirror (Renouf).

Methylene Compounds.

Methylene CH_2, a dibasic radicle not known in the free state.

Methylene diacetate $CH_2(C_2H_3O_2)_2$. B.p. 170°; from methylene iodide and silver acetate (Butlerow, Annalen, 107, 111); from chlormethyl acetate $C_2H_3O_2{\cdot}CH_2Cl$ and potassium acetate (Henry, Ber. 1873, 739). A liquid decomposed by water at 100° into acetic acid and trioxymethylene.

Methylene bromide CH_2Br_2, *Dibromomethane.* B.p. 96·5°–97·5° corr.; sp.gr. 2·4985 at 15°/15°, 2·47745 at 25°/25°; Perkin, Chem. Soc. Trans. 1884, 520). Obtained by the action of bromine upon methylene iodide under water (Butlerow, Annalen, 111, 251); from methyl bromide and bromine at 250° (Steiner), or by the action aluminium bromide heated to 100° on trioxy methylene (Gustavson).

A liquid which, by the action of water and excess of lead oxide at 150° gives ethylene glycol (Eltekoff, Ber. 6, 558).

Methylene chloride CH_2Cl_2, *Dichlormethane.* B.p. 41·6° corr.; sp.gr. 1·37777 at 0°/4° (Thorpe, Chem. Soc. Trans. 1880, 195); b.p. 40°; sp.gr. 1·33771 at 15°/15°, 1·32197 at 25°/25° (Perkin, *ibid.* 1884, 527). From methane and chlorine after preliminary formation of methyl chloride (Regnault, Annalen, 33, 328); from methylene iodide and chlorine (Butlerow, Annalen, 111, 251).

Preparation.—A mixture of chloroform (1 vol.), zinc, and alcohol (3 vols.) is gradually treated with hydrochloric acid and distilled; the distillate, consisting of chloroform and methylene chloride, is rectified, and the residue boiling above 53° is again treated with zinc (Greene, Chem. News, 50, 75). It may also be prepared by treating methylene iodide under water with chlorine.

Properties.—A colourless liquid with a pleasant smell, resembling that of chloroform.

When heated with water to 200°, hydrochloric and formic acids and methyl chloride are produced; the latter, on further heating, forming methyl alcohol and hydrochloric acid. With aqueous ammonia at 140° it forms ammonium chloride, methylamine hydrochloride, and formic acid (André, Compt. rend. 102, 1474). When treated with ammonia, dissolved in methyl alcohol, hexamethylene tetramine is obtained.

Methylene chlorobromide CH_2ClBr, *Chlorobromomethane.* B.p. 68°–69° at 765 mm.; sp.gr. 1·9907 at 19°/19°; V.D.=4·43 (Henry, Compt. rend. 101, 599). Obtained by the action of bromine upon chloriodomethane. A mobile colourless liquid, with agreeable smell. It gives rise when treated with 2 mols. of ammonia in saturated methyl alcohol solution for 2 hours at 60°–70° to hexamethylene tetramine hydrobromide, ammonium chloride and ammonium bromide.

Methylene chlorofluoride CH_2ClF, *Chlorfluormethane.* A gas, sp.gr. 34·18 (calc. 34·25). From methyl fluoride and chlorine in sunlight. Is colourless, and slightly soluble in, and slowly decomposed by, water; burns with difficulty in oxygen (Collie, Chem. Soc. Trans. 1889, 112).

Methylene chloroiodide CH_2ClI, *Chloriodomethane.* B.p. 109°–109·5° at 760·4 mm.; sp.gr. 2·444 at 14·5°/14·5°; V.D. 88·14. An oily liquid obtained by the action of iodine monochloride upon methylene iodide (Sakurai, Chem. Soc. Trans. 1885, 198); also by action of iodine in potassium iodide solution upon monomercuric methylene chloriodide (*ibid.* 1882, 362).

Methylene iodide CH_2I_2, *Diiodomethane.* M.p. 4°; b.p. 180°, with partial decomposition; sp.gr. 3·3326 at 15°/15° (Perkin, Chem. Soc. Trans. 1896, 1173); M.M. at 15°=18·827 (Perkin, *ibid.* 45, 464). From iodoform and sodium ethoxide (Butlerow, Ann. Chim. Phys. [iii.] 53, 313); by heating iodoform either alone or with iodine (Hofmann, Annalen, 115, 267; Dunn, Chem. Soc. Proc. 1910, 116); from chloroform or iodoform and hydriodic acid (Leben, Zeitsch. Chem. 1868, 712). By the action of iodine on diazomethane dissolved in ether (*v.* Pechmann, Ber. 1894, 1889). A yellow liquid which, when heated with water and copper to 100°, yields ethylene (Butlerow, Annalen, 120, 356). With zinc ethyl it forms butane. With silver acetate yields methylene acetate; combines with mercury to form mercuric methylene iodide CH_2I,HgI. It dissolves phosphorus very readily at ordinary temperatures (more than 1 : 1). An attempt to prepare the radicle methylene (CH_2), by heating with silver powder produces carbon methane and ethane and other products (Sudborough, Chem. Zentr. 1897, ii. 180). It is considerably used in the construction of sp.gr. columns for rock analysis by the density method, the usual diluents being benzene or ether.

Methylene oxide CH_2O *v.* FORMALDEHYDE.

Methylene sulphides.

Trimethylene sulphide $(CH_2S)_3$, *Parathioformaldehyde.* B.p. 216°; sublimes without decomposition. Formed by the action of sulphuretted hydrogen upon a solution of formaldehyde. Also by reducing, by means of zinc and hydrochloric acid, carbon disulphide (Girard, Annalen, 100, 306), potassium thiocyanate, or allyl mustard oil (Hofmann, Ber. 1, 176). It also results from the action of potassium sulphide on methylene iodide (Husemann, Annalen, 126, 294; Mansfeld, Ber. 1886, 698). It crystallises from benzene, carbon disulphide, or chloroform in quadratic prisms which are insoluble in water and possess a penetrating odour. It forms crystalline compounds with many salts, *e.g.* $C_3H_6S_3{\cdot}HgCl_2$, needles, insoluble in water; $2C_3H_6S_3{\cdot}PtCl_4$, golden-yellow needles.

Metathioformaldehyde $(CH_2S)x$ is formed by leading sulphuretted hydrogen for 10 hours into a boiling solution of hexamethylenetetramine saturated with ammonia (Wohl, Ber. 1886, 2345). The precipitate is purified by washing with water and hydrochloric acid, and by boiling with alcohol and glacial acetic acid. It has a characteristic odour, melts at 175°–176°, is not volatile without decomposition, and does not form salts with mercuric or platinic chlorides.

Methylene hydrogen sulphide $CH_2(HS)_2$, *thiomethylene glycol*, is not known in the free state. The diethyl ether, $CH_2(SC_2H_5)_2$, b.p. 184°, sp.gr. 0·987 at 20°, is obtained by the treatment of sodium mercaptide with methylene iodide (Claesson, J. pr. Chem. [ii.] 15, 176).

Methylene sulphonic acid $CH_2(SO_3H)_2$, *Methane disulphonic acid*, forms very unstable needle-like crystals. Produced in small quantity by the action of sulphur trioxide upon ether (Liebig, Annalen, 13, 35; Strecker, *ibid.* 100, 199); by the oxidation of methylene thiocarbonate (Husemann, *ibid.* 126, 293); from chloroform and potassium sulphite solution at 180° or from iodoform and potassium sulphite at 150° (Strecker, *ibid.* 148, 92).

Preparation.—Lactic acid or calcium lactate is heated with fuming sulphuric acid until sulphur dioxide begins to be evolved; the mixture is then neutralised with barium carbonate. It can also be prepared by heating 2 volumes of acetamide with 1 volume of fuming sulphuric acid (Buckton and Hofmann, Annalen, 100, 133). For salts *v.* Hofmann, Strecker, *l.c.*, also Monari (Ber. 1885, 1343).

Hexamethylenetetramine, *hexamethyleneamine, formamine, ammonio-formaldehyde, ammonaldehyde, cystamin, cystogen, formin, metramine, urisol, uritone, urotropine, vesalvine* $(CH_2)_6N_4$, is prepared by the action of ammonia on trioxymethylene (Butlerow, Annalen, 115. 322); from alcoholic ammonia and methylene chloride at 125° (Höland, *ibid.* 240, 225); or by passing formaldehyde vapour into a concentrated solution of ammonia, evaporating to a syrupy consistency and pouring into alcohol (Wohl, Ber. 1886, 1842). It forms rhombohedral crystals from alcohol, is insoluble in ether, but readily in water and chloroform. It can be sublimed *in vacuô.* Thioformaldehyde is produced by treating it with H_2S in the warm. It is precipitated from its aqueous solution by bromine as an orange-red tetrabromide

$$C_6H_{12}N_4Br_4,$$

which, when kept over potash, loses two atoms of bromine; the resulting dibromide melts at 198°–200°. This dibromide when boiled with water is decomposed into formaldehyde, water, ammonia, and hexamethylenetetramine. Hexamethylenetetramine is also precipitated from its solutions by mercuric chloride quantitatively. In the presence of ammonium salts it may be estimated by expelling the ammonia by heating with strong potash, by which it is unaffected, until all ammonia is expelled, then making acid and boiling to decompose the hexamethylene tetramine and subsequently making alkaline and estimating the ammonia in the usual way (Puckner and Hilpert, J. Amer. Chem. Soc. 1908, 1471). The purity of a specimen is readily examined qualitatively by means of Nessler's solution, which shows the presence of ammonia and ammonium salts by the usual yellow colour or brown precipitate, and of formaldehyde by a precipitate of mercury (Wöhlk, Zeitsch. anal. Chem. 1905, 765). Many compounds and derivatives of hexamethylene tetramine have been prepared and patented. The compounds with halogen pyrroles and aromatic sulphuric acids by Stange (Eng. Pat. 4804, 1899); with phenol and phenol mono- and poly- sulphuric acids and their halogen derivatives by the Chemische Fabriken vonn Weiler-ter-Meer (D. R. P. 124231); basic compounds by Karl Hock (D. R. P. 139394); cystopurin, a compound of 1 mol. hexamethylenetetramine and 2 mols. sodium acetate by Bergell and Wülfing (Eng. Pat. 29093, 1906; U.S. Pat. 852993, 1907; Chem. Zentr. 1907, i. 487); the chloral, bromal, and butyl chloral derivatives by Lederer (Eng. Pat. 17693, 1897); the quinate by Wichmann and Gabler (U.S. Pat. 690804, 1902; Zimmermann, Eng. Pat. 14834, 1899); the salicylic acid compound by O. Imray (Eng. Pat. 22481, 1895); a powerfully astringent compound resulting from the condensation with tannin by H. E. Newton (Eng. Pat. 10790, 1898); 'ammonium compounds' by Farbenfabriken von Baeyer & Co. (D. R. P. 164510); the borate by Aktien Gesellschaft für Anilinfabriken (Fr. Pat. 363764, 1906; U.S. Pat. 869636; Eng. Pat. 5039, 1906). In addition the following derivatives have been prepared: salts of inorganic acids and compounds with metallic salts by B. Grützner (Chem. Zentr. 1898, ii. 663); halogen derivatives by Horton (Ber. 1888, 1999), and Höhnel (Chem. Zentr. 1900, i. 409); bromoiodides and chloroiodides by Mouneyrat (Compt. rend. 136, 1472); the chromate by K. A. Hofmann (Ber. 1906, 3181). The products of decomposition have been studied by Ischidzu and Inouye (Chem. Zentr. 1906, i. 1087), Grassi-Cristaldi; and Di Franco by the catalytic hydrogenation with reduced nickel has obtained trimethylamine, ammonia, and methane (*ibid.* 1907, i. 237).

Methylene tetramethyl diamine

$CH_2[N(CH_3)_2]_2$

is prepared from formaldehyde and dimethylamine (Henry). It boils at 85°, and has sp.gr. 0·7491 at 18·7°.

Methylene tetraethyl diamine $CH_2[N(C_2H_5)_2]_2$, b.p. 166°–169° (168° Henry). Formed by the action of trioxymethylene, 6·5 parts, upon diethylamine, 29·2 parts (Kolotoff, J. Russ. Phys. Chem. Soc. 17, 244). It is an unpleasant-smelling liquid, insoluble in water, but very soluble in alcohol; sp.gr. 0·8105 at 18·7° (Henry, Ber. 1893 (Ref.) 934).

Methylene tetrapropyl diamine

$CH_2[N(C_3H_7)_2]_2$,

boils at 225°–230° with decomposition; sp.gr. 0·8014 at 18° (Henry).

Methylene thiocarbonate CH_2CS_3. A yellowish-white, amorphous powder insoluble in water, almost insoluble in alcohol, ether, or carbon disulphide, obtained by the action of methylene iodide upon sodium thiocarbonate in alcoholic solution (Husemann, Annalen, 126, 292). Is decomposed by ammonia into ammonium thiocyanate and methylene sulphide $(CH_2S)_3$.

Methylene thiocyanate $CH_2(CSN)_2$, m.p. 102°. From methylene iodide and potassium thiocyanate in alcoholic solution (Lermontoff, Ber. 1874, 1282). It forms needles or prisms which are almost insoluble in cold, moderately soluble in warm water, and easily soluble in alcohol or ether. By oxidation, *e.g.* by nitric acid, it yields methylene disulphonic acid.

Dimethylene dimethyl diamine

$(CH_2)_2N_2(CH_3)_2$.

A crystalline non-volatile body obtained by passing trimethylamine and hydrogen through a heated tube (Romeny, Ber. 1878, 835).

Dimethylene diethyl diamine

$(CH_2)_2N_2(C_2H_5)_2$,

b.p. 205°–208°. Obtained by heating in a sealed tube a mixture of trioxymethylene with ethylamine (Kolotoff, J. Russ. Phys. Chem. Soc. 17, 231). An oily liquid with an unpleasant odour, soluble in cold water or in alcohol. Is decomposed by hydrochloric acid into trioxymethylene and ethylamine.

β-METHYLADIPIC ACID *v.* PIMELIC ACID.

METHYLAL *v.* SYNTHETIC DRUGS.

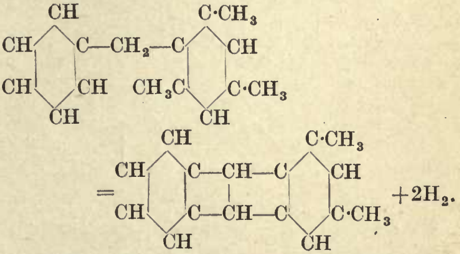
METHYLALLOXAN *v.* ALLOXAN.

METHYL-ANTHRACENE AND OTHER ALKYL DERIVATIVES OF ANTHRACENE. In order to obtain the higher homologues of anthracene, it has been found necessary in most cases to resort to synthetical methods, as very few of these substances have been met with in coal tar.

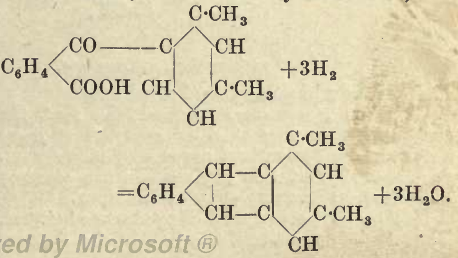
The methods usually employed are the following:—

(1) Elimination of hydrogen from the hydrocarbons of the C_nH_{2n-14}, or C_nH_{2n-16} series, by passing them through red hot tubes.

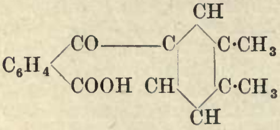
Benzyl mesitylene is thus converted into dimethylanthracene.



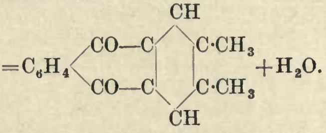
(2) By distilling *o*-ketonic acids with zinc-dust (Gresly, Annalen, 234–238); *m*-xyloyl-*o*-benzoic acid yields *m*-dimethylanthracene,



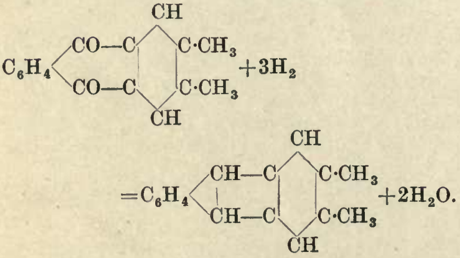
(3) By the action of sulphuric acid on *o*-ketonic acids (at about 125°), and subsequent reduction with zinc-dust and ammonia (Elbs, J. pr. Chem. 1890, 41, 1, &c.).



o-Xyloyl-*o*-benzoic acid.



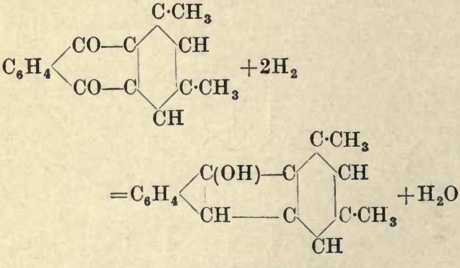
o-Dimethylanthraquinone.



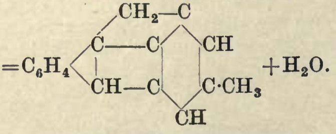
o-Dimethylanthracene.

This reaction cannot be successfully employed in a number of cases where one of the methyl groups is attached to the carbon atom next to the carbonyl group, as under these conditions anthracylene derivatives frequently result (*v.* Elbs, *l.c.* pp. 15–18).

Thus *m*-dimethylanthraquinone, on reduction with zinc-dust and ammonia, yields *m*-dimethylanthracylene and not *m*-dimethylanthracene.



m-Dimethylanthranol.

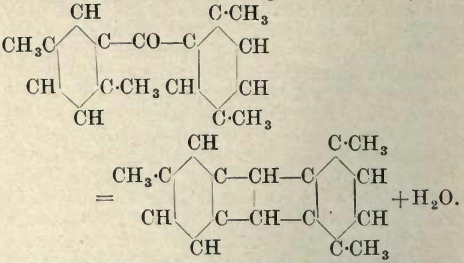


m-Dimethylanthracylene.

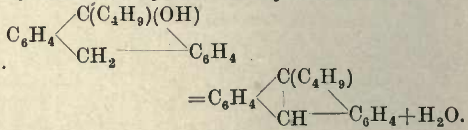
And similarly in a number of other cases.

It should, however, be remarked that the results of a number of Elbs' analyses of these anthracylene derivatives agree only so very approximately that this explanation can scarcely be looked on as completely satisfactory.

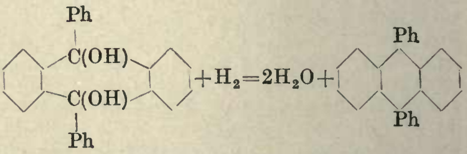
(4) By the prolonged boiling of some ketones. Thus di-*p*-xylyl ketone, when boiled for 6 hours on a reversed condenser yields (1,4,7) trimethylanthracene (Elbs and Olberg, Ber. 19, 409).



(5) The homologues of anthracene of the formula $C_6H_4(C_2HC_nH_{2n+1})C_6H_4$ are produced by boiling the alkylhydroanthranol with alcohol, hydrochloric acid, or picric acid. Thus *iso*butyl hydranthranol yields *iso*butylanthracene.

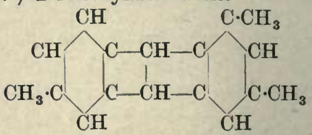


(6) Homologous arylanthracenes substituted in the γ position arise when the carbinols resulting from the action of magnesium aryl halogen compounds on anthraquinone and its derivatives are reduced. Thus diphenyl anthracene results when the corresponding carbinol is treated with zinc and acetic acid.

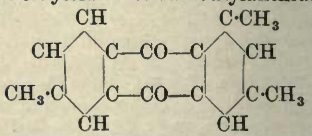


In their properties and reactions the homologues of anthracene behave very similarly to anthracene itself. On oxidation with chromic acid they yield corresponding anthraquinone derivatives, but in most cases the oxidation goes further and converts a portion of the anthraquinone into mono-, di-, or tricarboxylic acid, according to the number of side chains present, thus

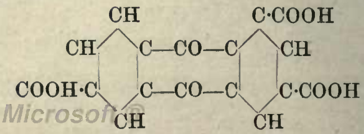
(1,3,6¹) Trimethylanthracene



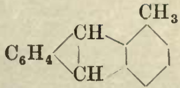
on oxidation yields first trimethylanthraquinone



and ultimately (1,3,6¹) anthraquinone tricarboxylic acid



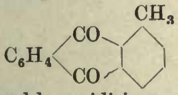
α-Methyl anthracene



According to Birukoff (Ber. 20, 2069), α-methyl anthracene may be prepared by the distillation of methyl erythroxy anthraquinone with zinc-dust. O. Fischer and Sapper (J. pr. Chem. 1911, [ii.] 83, 201), obtained only a small yield of the substance in this manner, the main product was anthracene. The best method of preparation, according to these authors, consists in heating 4-chloro-1-methylanthraquinone with zinc-dust at a very low red heat. α-methylanthracene crystallises in long, colourless needles, has m.p. 85°–86°, and is much more soluble in most solvents than anthracene or β-methylanthracene. Its solution in alcohol exhibits blue fluorescence. With picric acid, α-methylanthracene forms a compound crystallising in red needles, having m.p. 113°–115°.

4-Chloro-1-methyl anthracene is obtained on boiling 4-chloro-1-methylanthraquinone with zinc-dust and aqueous ammonia. It melts at 112° and, unlike the corresponding quinone, does not part with halogen on distillation with zinc-dust.

α-Methyl anthraquinone

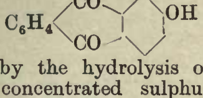


is readily prepared by oxidising α-methylanthracene with chromic acid in acetic acid solution, only small quantities of anthraquinone carboxylic acid being produced.

α-Methylanthraquinone crystallises from dilute acetic acid in small white needles, which, when exposed to light, become reddish-coloured. It melts at 170°–171°, is very readily soluble in alcohol or benzene, but difficultly soluble in glacial acetic acid.

It differs from its 4-hydroxy derivative in that it does not lose its methyl group on distillation with zinc dust. Since α- and β-methylanthracene are obtained on submitting many natural products to zinc-dust distillation, it is of importance to be able to distinguish between them. α-Methylanthraquinone differs from the corresponding β- compound in turning red on exposure to light. Moreover it is oxidised by dilute nitric acid at 160° to anthraquinone-1-carboxylic acid, which develops a rose coloration when heated with soda lime. Under these conditions anthraquinone-2-carboxylic acid gives a blue colour.

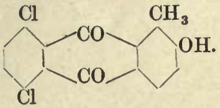
2-Hydroxy-1-methylanthraquinone



is obtained by the hydrolysis of its methyl ether with concentrated sulphuric acid. It crystallises from acetic acid in yellow needles which melt above 300°. Its red violet potassium salt is sparingly soluble in water.

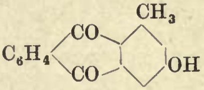
Methyl ether. This is the product of the action of sulphuric acid at 155° on 4′-methoxy-5′-methyl-2-benzoylbenzoic acid. It crystallises in canary yellow needles from methyl alcohol and melts at 184°. The substance is soluble in acetic acid or ethyl alcohol and may be sublimed. It forms a monobrom derivative, melting at 228°, and when dissolved in fuming nitric acid, yields a nitro-methoxy-methylanthraquinone which forms canary yellow needles, melting at 179°. The latter on reduction with stannous chloride in alkaline solution is converted into the corresponding amino compound. This amino-methoxy-methyl anthraquinone separates from methyl alcohol in bright red needles of m.p. 187°. Acetamino-methoxy-methyl anthraquinone crystallises from acetic acid in brown needles, melting at 204°. On energetic nitration, 2-methoxy-1-methylanthraquinone yields a trinitro derivative (Bentley, Gardner and Weizmann, Chem. Soc. Trans. 91, 1626).

5:8-dichlor-2-hydroxy-1-methylanthraquinone

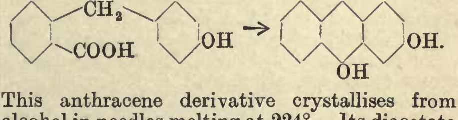


3 : 6 : dichlorphthalic anhydride condenses with *o*-tolyl methyl ether in presence of aluminium chloride and the product is probably 3 : 6-dichlor-3′-hydroxy-2-*o*-toluoyl benzoic acid. This acid on heating with fuming sulphuric acid and boric acid, is converted to the quinone which separates from acetic acid as a yellow flocculent powder, decomposing at 249°. It should be remarked that in the above methyl hydroxy compounds, the methyl group may have the position 3 (Walsh and Weizmann, Chem. Soc. Trans. 97, 691).

3-Hydroxy-1-methylanthraquinone



This quinone has been synthesised by the following series of operations (Bistrzycki and Yssel de Schepper, Ber. 31, 2795). The condensation of phthalic anhydride and *m*-cresol yields a benzoyl benzoic acid which, on reduction, furnishes 4-hydroxy-2′-methyl diphenyl methane carboxylic acid. This compound, on treatment with sulphuric acid, is changed with loss of the elements of water into 1-methyl-3 : 10-dihydroxy anthracene thus :—



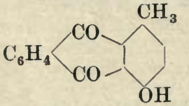
This anthracene derivative crystallises from alcohol in needles melting at 224°. Its diacetate forms microprisms from benzene and melts at 171°–173°. On oxidation with chromic acid in acetic acid solution, this diacetate yields the acetyl derivative of 3-hydroxy-1-methyl anthraquinone. The derivative crystallises from alcohol in yellow needles, melting at 130°–135°. and on hydrolysis with alcoholic potash the parent quinone is produced.

3-hydroxy-1-methylanthraquinone occurs in needles, sublimes at 200° and melts at 299°–300°. It dissolves in ammonia to an orange solution.

5 : 8 - dichlor - 3 - methoxy - 1 - methylanthraquinone (Walsh and Weizmann, *l.c.*) is obtained

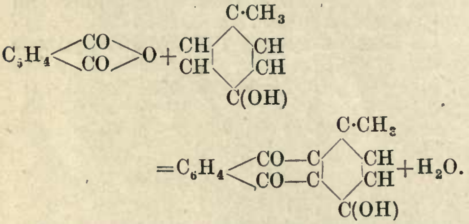
in small yield by treatment of the benzoyl benzoic acid from dichlorphthalic anhydride and *m*-tolyl methyl ether with sulphuric acid. The yellow compound crystallises from acetic acid and decomposes at 236°.

4-Hydroxy-1-methylanthraquinone



(Methyl erythroxyanthraquinone)

is produced when a mixture of phthalic anhydride and *p*-cresol is heated with concentrated sulphuric acid (Birukoff, *l.c.*).



Preparation.—5 parts of phthalic anhydride, 2 parts of *p*-cresol, and 15 parts of concentrated sulphuric acid are heated to 160° for ten minutes, the product poured into water, the precipitate well washed with boiling water, and extracted with boiling dilute caustic potash solution. 4-Hydroxy-1-methylanthraquinone is obtained from the alkaline solution by the addition of hydrochloric acid in yellow flocks, which are readily purified by recrystallisation from glacial acetic acid. The pure substance is thus obtained in beautiful dark-brown needles, melting at 175°.

This quinone may also be obtained by the hydrolysis of its methyl ether, either by means of acetic acid and hydrochloric acid at 100° under pressure or with concentrated sulphuric acid. Further, the condensation of phthalic anhydride and *p*-cresol is well effected by fusion with boric acid. A benzoyl benzoic acid results, and this, by further treatment with sulphuric acid, yields the quinone (Bentley, Gardner and Weizmann, *l.c.*).

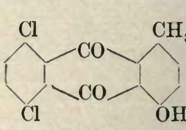
4-Hydroxy-1-methylanthraquinone is almost insoluble in ammonia and sodium carbonate solution, readily soluble in caustic potash solution with a red coloration; with baryta or lime-water insoluble brick-red lakes are produced. It dissolves in sulphuric acid with an orange-yellow colour, sublimes very easily, and in all its reactions, and also in its absorption spectrum, shows great similarity with erythroxyanthraquinone.

Fusion with potash converts it with difficulty into a colouring matter which is probably α-methylalizarin.

The *acetate* crystallises from acetic acid in yellow needles, which melt at 179°–180°.

Methyl ether. O Fischer and Sapper (J. pr. Chem. 1911, [ii.], 83, 201) obtained this substance by the action of methyl alcoholic potassium hydroxide at 100° under pressure on 1-methyl-4-chloroanthraquinone. They described it as consisting of yellow needles of m.p. 128° and reddening under the action of light. Bentley, Gardner and Weizmann (*l.c.*) condensed phthalic anhydride with *p*-tolylmethylether and so obtained 2′-methoxy-5′-methyl-2-benzoyl benzoic acid. The action of sulphuric acid at 150° on this compound led to the formation of the methyl ether of 4-hydroxy-1-methyl-anthraquinone described as orange-yellow needles from methyl alcohol, melting at 171°.

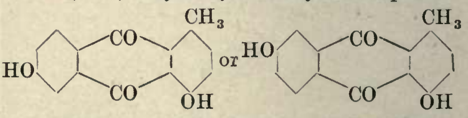
5 : 8-dichlor-4-hydroxy-1-methylanthraquinone



3 : 6 : dichlorphthalic anhydride was condensed by means of aluminium chloride with *p*-tolyl methyl ether. The resulting 3 : 6 : dichloro-5′-hydroxy-2-toluoyl-benzoic acid was heated with fuming sulphuric acid (10 p.c. SO_3) in presence of boric acid for a few minutes at 130°. The quinone separates from acetic acid in micro-needles of m.p. 259°. Its brilliant red solution in concentrated sulphuric acid exhibits purple fluorescence. Its acetyl derivative forms lemon-yellow needles, melting at 181°.

When heated with sodium phenoxide and copper powder, one chlorine atom is replaced by phenoxyl.

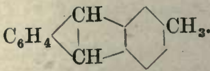
4:6-(or 7) dihydroxy-1-methylanthraquinone



4-Hydroxyphthalic acid or its anhydride, when fused with boric acid and *p*-cresol, yields a benzoyl benzoic acid from which, by the further action of sulphuric acid, this quinone is obtained. The substance crystallises as a yellow powder from alcohol, and melts at 244°–246°.

A methyl dimethoxy anthraquinone, which is probably, although not necessarily, the dimethyl ether of the above quinone, is obtained by condensing 4-methoxy phthalic anhydride with *p*-tolylmethyl ether by means of aluminium chloride and subsequently treating the benzoyl benzoic acid so produced with sulphuric acid (containing 60 p.c. SO_3) in presence of boric acid below 40°. The substance crystallises from acetic acid and melts at 141°. One methoxyl group is hydrolysed by the action of sulphuric acid at 110°.

β-Methylanthracene



This hydrocarbon is found in varying quantities, together with anthracene and phenanthrene, in the fraction of coal tar which distils above 340°.

It may be synthetically prepared by the following reactions.

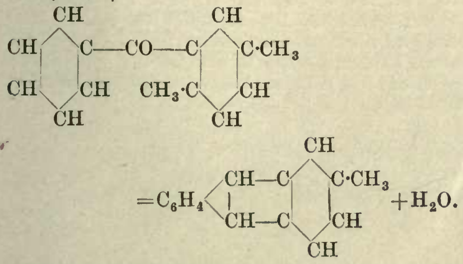
1. By passing the vapours of ditolylmethane (Weiler, Ber. 7, 1185) $CH_2(C_6H_4CH_3)_2$, ditolylethane (Fischer, *ibid.* 7, 1195),

$$CH_3\text{-}CH(C_6H_4CH_3)_2,$$

or of oil of turpentine (Schultz, *ibid.* 10, 117) through a red-hot tube.

It is best in this reaction to employ ditolylethane since the hydrocarbon from ditolylmethane is mixed with anthracene.

2. By boiling *p*-xylylphenylketone for several days on a reflux apparatus (Elbs, J. pr. Chem. 1890, 41, 3).



3. By the distillation of chrysophanic acid $C_{15}H_{10}O_4$, emodin $C_{15}H_{10}O_5$ (Liebermann, Annalen, 183, 163), colophonium, benzoe resin (Ciamician, Ber. 11, 273), chrysarobin $C_{30}H_{26}O_7$ (Liebermann and Seidler, Annalen, 212, 34) and methylquinizarine $C_{15}H_{10}O_4$ (Nietzki, Ber. 10, 2013) with zinc-dust.

Preparation (Japp and Schultz, Ber. 10, 1049). The high boiling distillate of coal tar, known as crude phenanthrene, is freed from the greater part of the anthracene it contains by oxidation with potassium dichromate and sulphuric acid. The dark-brown mass is extracted with hot alcohol, the well-cooled solution allowed to deposit as much anthracene and phenanthrene as possible, the mother-liquors which contain the methylanthracene evaporated and the residue repeatedly recrystallised from alcohol.

β-Methylanthracene crystallises from alcohol in pale yellow needles and melts at 202°–203°. It sublimes readily when heated continuously at 100°. It is difficultly soluble in ether, alcohol, glacial acetic acid, acetone, and light petroleum, readily soluble in benzene, chloroform, and carbon disulphide.

Oxidation with nitric acid converts it into methylanthraquinone

$$C_6H_4\!<\!\begin{matrix}CO\\CO\end{matrix}\!>\!C_6H_3\cdot CH_3.$$

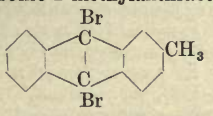
Chromic acid oxidises it for the most part direct to anthraquinone-2-carboxylic acid

$$C_6H_4\!<\!\begin{matrix}CO\\CO\end{matrix}\!>\!C_6H_3\cdot COOH.$$

Methylanthracene combines with picric acid, forming a compound which crystallises in large red needles; alcohol and water decompose this compound.

When sunlight acts on a benzene solution of the hydrocarbon, a dimeride, bisβ-methylanthracene, is formed (Orndorff and Megraw, Amer. Chem. J. 22, 152). It crystallises in rhombic crystals from toluene and melts at 228°. The substance is sparingly soluble and is converted on melting or solution in xylene into β-methylanthracene.

9 : 10-**Dibromo-2-methylanthracene**

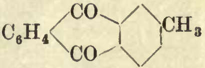


is produced by treating methylanthracene in CS_2 with bromine; it crystallises from glacial acetic acid in yellow needles, m.p. 142°–143°.

The position of the halogen atoms is proved by the oxidation of the substance to 2-methylanthraquinone.

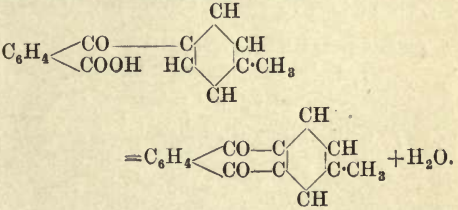
Tetrabromomethylanthracene $C_{15}H_8Br_4$ is formed when dibromomethylanthracene is treated with bromine. It crystallises from toluene in yellow needles. Oxidation with nitric acid converts this compound into dibromomethylanthraquinone $C_{15}H_8Br_2O_2$.

β-Methylanthraquinone



(O. Fischer, Ber. 8, 675) is obtained by boiling methylanthracene in alcoholic solution with nitric acid, or by carefully oxidising the hydrocarbon with CrO_3, in which latter case, however, considerable quantities of anthraquinone and anthraquinone carboxylic acid are also formed.

It has also been isolated from the by-products which accumulate in the manufacture of anthraquinone (Wachendorff and Zincke, Ber. 10, 1485; Börnstein, *ibid.* 15, 1820). This substance is identical with the methylanthraquinone which is obtained synthetically by heating *p*-methyl benzoylbenzoic acid with concentrated sulphuric acid (Gresly, Annalen, 234, 239).



This latter preparation is carried out in the following manner:—

The powdered acid is slowly added to 7 or 8 times its weight of concentrated sulphuric acid, and the mixture gradually heated until at the end of half an hour the temperature has risen to 120°–125°.

The clear dark brownish-red coloured solution is kept at this temperature for about an hour, allowed to cool and poured into much water. Steam is passed through the liquid for some time, the precipitate collected, washed well first with water, and lastly with dilute ammonia, dried, and the greenish-yellow mass purified by recrystallisation from a mixture of xylene and alcohol. Yield 70–75 p.c. of theory.

β-Methylanthraquinone sublimes in yellow needles, m.p. 176°–177°; moderately soluble in ether, acetone, chloroform, or hot alcohol; difficultly soluble in glacial acetic acid and benzene.

Dibromomethylanthraquinone is obtained by the action of bromine at 130°–140° on β-methylanthraquinone. It is colourless and melts at 219°–220° (O. Fischer, J. pr. Chem. 1909, [ii.] 79, 555).

ω-Dichloro-β-methylanthraquinone is obtained by chlorination of methyl anthraquinone. The substance melts at 200° and is converted by the action of sulphuric acid (66° Baumè) at 130° into β-anthraquinone aldehyde (Badische Anilin und Soda Fabrik, D. R. P. 174984).

Methylanthraquinone disulphonic acid (O. Fischer, *l.c.*) $C_{15}H_8(HSO_3)_2O_2$.

Preparation. — Methylanthraquinone is heated with 5–6 parts of fuming sulphuric acid for several hours at 250°–270°. The alkali salts and the barium and calcium salts of this acid are soluble in water. Fusion with potash converts the acid into methylalizarin.

Nitromethylanthraquinone

$C_{15}H_9NO_4$ or $CH_3{\cdot}C_{14}H_6(NO_2)O_2$.

Preparation.—Methylanthraquinone (2 parts) is dissolved in concentrated H_2SO_4 (12–14 parts), and to the resulting solution KNO_3 (1 part) is slowly added. The product after standing 24 hours is carefully mixed with water, the precipitate collected, and extracted repeatedly with alcohol until the filtrate is only slightly yellowish-coloured. The resulting nitromethylanthraquinone is purified by recrystallisation from acetic acid (Römer and Link, Ber. 16, 695), from which solvent it is obtained in yellow needles melting at 269°–270°. It is difficultly soluble in alcohol, ether, benzene, chloroform, glacial acetic acid, and ethyl acetate, readily soluble in nitrobenzene. It dissolves in sulphuric acid, producing a yellow solution which on warming turns brown. Water precipitates from this solution a purple precipitate, which dissolves in alkalis with a violet-blue colour. Nitromethylanthraquinone sublimes in small almost colourless needles. It is not decomposed by boiling caustic potash solution.

Aminomethylanthraquinone

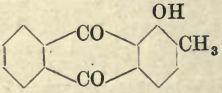
$C_{15}H_{11}NO_2$ or $CH_3{\cdot}C_{14}H_6(NH_2)O_2$

is readily produced by the reduction of nitromethylanthraquinone with $SnCl_2$ (Römer and Link, *l.c.*). The freshly precipitated nitro compound is added in small quantities at a time to a dilute solution of $SnCl_2$ in KOH, and the product heated nearly to boiling. The resulting precipitate, which must dissolve completely in excess of cold HCl, is purified by recrystallisation from dilute HCl.

Aminomethylanthraquinone crystallises in glittering red needles which melt at 202°, and sublime on heating in long dark-red needles. It is almost insoluble in water, readily soluble in alcohol, ether, chloroform, benzene, and glacial acetic acid. Boiling with hydriodic acid and phosphorus converts it into aminomethylanthranol; at 150°, however, aminomethylanthracenedihydride $CH_3{\cdot}C_{14}H_{10}NH_2$ results.

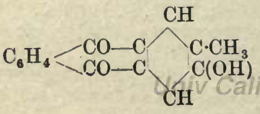
The *acetyl-derivative* $CH_3{\cdot}C_{14}H_6O_2NH(C_2H_3O)$ crystallises from glacial acetic acid in yellow needles, m.p. 176°–177°.

1-Hydroxy-2-methylanthraquinone (Weizmann, Bentley and Gardner, *l.c.*)

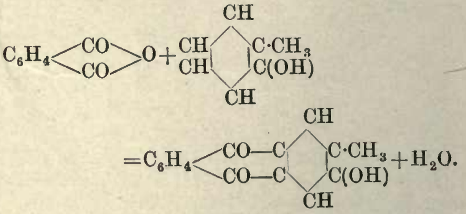


Phthalic anhydride condenses with orthocresol in presence of boric acid at 170° and yields 2′-hydroxy-3′-methyl-2-benzoylbenzoic acid. The yellow solution of this substance in concentrated sulphuric acid goes red on heating and yields on dilution this hydroxyanthraquinone. It forms yellow needles on crystallisation from acetic acid and melts at 184°–185°.

3-Hydroxy-2-methylanthraquinone

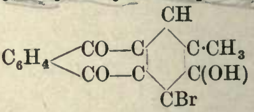


Preparation (Fraude, Annalen, 202, 613).—By heating 2 parts of *o*-cresol, 3 parts phthalic anhydride, and 100 parts of sulphuric acid at 160° for two days. The product is poured into water, extracted repeatedly with ether; the ether distilled off, the residue dissolved in dilute soda, acidified with HCl, and the precipitate purified by sublimation and recrystallisation from alcohol.



Hydroxymethylanthraquinone melts at 260°–262°, is readily soluble in alcohol, ether, and acetic acid; it dissolves in alkalis, also in lime and baryta water, forming a dark reddish-brown solution. When strongly heated it sublimes in golden-yellow leaflets.

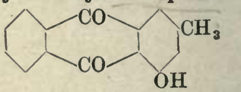
Bromohydroxymethylanthraquinone



is obtained by heating 4 parts of dibromo-*o*-cresol phthaleïne ($C_{22}H_{16}Br_2O_4$) with 1 part of phthalic anhydride and 200 parts of sulphuric acid at 150° for five hours.

Small yellow needles, m.p. 205°. Fusion with potash converts this substance into *α*-methylalizarin.

4-Hydroxy-2-methylanthraquinone



Bentley, Gardner and Weizmann (*l.c.*) obtained this quinone in a manner analogous to the preparation of 1-hydroxy-2-methylanthraquinone, by substituting *m*- for *o*-cresol. It melts at 178° and consists of yellow needles which are crystallised from acetic acid. A quinone probably identical was obtained by Römer and Link (Ber. 16, 700) from the aminomethylanthraquinone described above.

Preparation.—Aminomethylanthraquinone is dissolved in sulphuric acid, the solution mixed with small quantities of water until the resulting precipitate becomes reddish-coloured.

The well-cooled product is slowly mixed with a solution of KNO_2 until the precipitate becomes light yellow and free nitrous acid is evolved, then an equal volume of water is added and the whole heated to boiling.

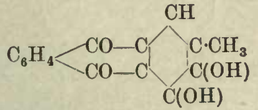
The precipitate is collected, dissolved in boiling dilute caustic potash solution, precipitated with HCl, and recrystallised from alcohol.

Hydroxymethylanthraquinone crystallises from alcohol in orange-yellow needles which melt at 177°–178°, and sublime in long thin yellow plates when carefully heated. It is almost insoluble in water, difficultly soluble in alcohol, readily soluble in ether, and benzene. Cold caustic potash solution dissolves it sparingly.

Fused with potash a small quantity of a colouring matter is produced which dissolves in alkalis with colorations similar to those produced by alizarin. Hydroxymethylanthraquinone, if freshly precipitated, dissolves in boiling lime or baryta water, but is insoluble in sodium carbonate or solution of alum. Its alcoholic solution is not precipitated by alcoholic lead acetate.

The *acetate* $C_{17}H_{12}O_4$ or $CH_3{\cdot}C_{14}H_6O_2(C_2H_3O_2)$ crystallises from alcohol in orange-yellow plates which melt at 177°.

Dihydroxymethylanthraquinone (*a*-methylalizarin)



is readily prepared by fusing methylanthraquinone disulphonic acid (O. Fischer, *l.c.*), hydroxymethylanthraquinone, or bromohydroxymethylanthraquinone (Fraude, Annalen, 202, 166) with potash. The mass is dissolved in water, acidified with HCl, and the precipitate purified by sublimation. Orange-yellow needles, m.p. 250°–252°, moderately soluble in alcohol, ether, and acetone. The calcium and barium salts are insoluble blue precipitates.

The absorption spectrum of a solution of this substance in concentrated sulphuric acid is represented in Fig. 1.

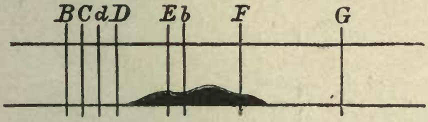


FIG. 1.

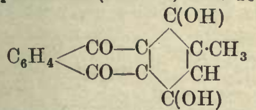
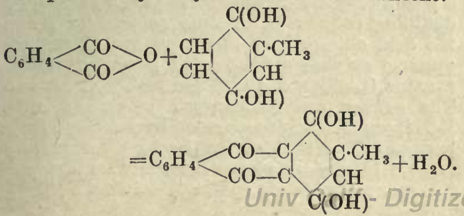
It corresponds very closely with that of alizarin itself (Liebermann and Kostanecki, Ber. 19, 2330). Methylalizarin dyes mordanted cloth similarly to alizarin, but according to some authorities the tinctorial power of methylalizarin is much inferior to that of alizarin, hence the introduction of this substance into artificial alizarin is avoided by the alizarin manufacturer as much as possible.

Methylquinizarin (Nietzki, Ber. 10, 2012)



This isomeride of methylalizarin is produced by heating a mixture of hydrotoluquinone and phthalic anhydride with 8–10 parts of sulphuric acid at 130°–150° for two to three hours. The product is treated with water, the precipitate repeatedly extracted with boiling water, and purified by recrystallisation from benzene.



Methylquinizarin crystallises in long fine bent needles which melt at 160° and sublime with slight decomposition. The solutions in ether and alcohol are fluorescent. Distilled with zinc-dust methylanthracene is formed.

The absorption spectrum of methylquinizarine dissolved in sulphuric acid is represented in Fig. 2—

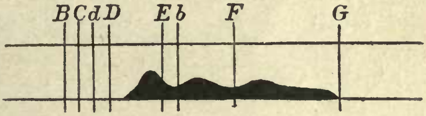


FIG. 2.

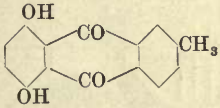
and is very closely allied to that of quinizarin itself.

Methylquinizarin when treated with acetic anhydride yields a *diacetate* $C_{15}H_8(C_2H_3O)_2O_4$, which crystallises in yellow needles, m.p. 185°.

5 : 8-Dihydroxy-2-methylanthraquinone (von Niementowski, Ber. 33, 1634).



This substance is prepared by heating together equimolecular quantities of 1-methyl-3 : 4-phthalic anhydride and hydroquinone with 6 parts of concentrated sulphuric acid for 5 to 10 hours at 140°–160°. It forms orange leaflets from alcohol mixed with benzene, or it may be crystallised from a large quantity of alcohol and obtained in beautiful ruby-red needles. It has the curious property of melting at 165°, resolidifying and melting again at 175°. The sublimed quinone melts at 175°. The solution in dilute caustic soda is violet red.

Diacetyl derivative.—This is readily produced by the action of sodium acetate and acetic anhydride. It crystallises from benzene, is intensely yellow, and melts at 204°.

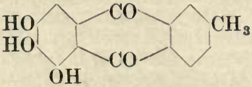
6 : 7-Dihydroxy-2-methylanthraquinone and **5 : 6- (or 7 : 8) dihydroxy-2-methylanthraquinone** (Niementowski, *l.c.*).

The 6 : 7-dihydroxy compound is the main product when catechol is substituted for hydroquinone in the above preparation. It crystallises from acetic acid in yellow micro-needles and melts with decomposition at 320°–340°. Its diacetate forms straw-yellow needles from alcohol, m.p. 208°. The 5 : 6- (or 7 : 8) dihydroxy compound is produced in small quantities in the same reaction. It crystallises from a little benzene in orange-red needles and melts and sublimes at 216°. Its diacetate crystallises from alcohol in groups of transparent yellow needles; m.p. 176°.

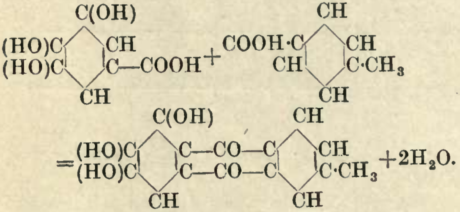
4 : 6- (or 7 :) **Dihydroxy-2-methylanthraquinone** (Bentley, Gardner, and Weizmann, *l.c.*).

4-Hydroxyphthalic anhydride and *m*-cresol, when fused with boric acid at 180°, yield a benzoyl benzoic acid in which the cresolic hydroxyl is in the ortho- position to carboxyl. With fuming sulphuric acid the substance condenses to the quinone, which separates from glacial acetic acid as a yellow crystalline powder of m.p. 284°.

β-Methylanthragallol, 5:6:7-trihydroxy-2-methylanthraquinone



Formation.—By heating a mixture of gallic acid and *p*-toluic acid to 130° (Cahn, Annalen, 240–284):



Sublimes in orange-red needles, m.p. 275°. Its other properties are very similar to those of anthragallol itself. The absorption spectrum of its solution in sulphuric acid is shown in Fig. 3.

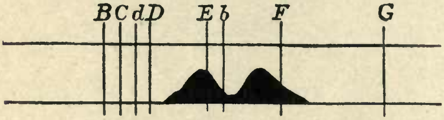


Fig. 3.

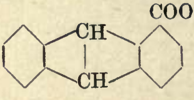
Considerable confusion exists in the literature with respect to the anthracene and anthraquinone carboxylic acids.

Anthracene-10-carboxylic acid (Liebermann, Graebe, Ber. 2, 678)  $C_6H_4\left\langle\begin{matrix}C(COOH)\\ |\\ CH\end{matrix}\right\rangle C_6H_4$. The chloride of this acid is produced by heating anthracene with $COCl_2$ to 180°–200°.

The acid crystallises from alcohol in long, silky, pale-yellow needles, which melt at 206° with decomposition. It is almost insoluble in cold water, readily soluble in alcohol. On distillation with soda lime it decomposes into CO_2 and anthracene. The salts are mostly soluble in water.

Anthracene-1-carboxylic acid

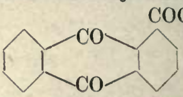


The nitrile of this acid is produced by distilling sodium anthracene α-monosulphonate with potassium cyanide (Liebermann and Pleus, Ber. 37, 646; see also Liebermann and Rath, *ibid.* 8, 246, and Dienel, *ibid.* 39, 926). The nitrile crystallises from alcohol in yellow leaflets, m.p. 126°, and is slowly hydrolysed by alcoholic potash with formation of the potassium salt of anthracene-1-carboxylic acid.

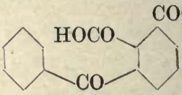
The acid may also be prepared by the reduction of anthraquinone-1-carboxylic acid with zinc-dust and ammonia (Graebe and Blumenfeld, *ibid.* 30, 1118). The acid forms yellow needles or prisms on crystallisation from alcohol and melts at 245°. It sublimes undecomposed in needles, is sparingly soluble in benzene and ether, readily soluble in alcohol and glacial acetic acid, insoluble in water. Distillation with soda lime decomposes it into CO_2 and anthracene. Chromic acid oxidises it to anthraquinone carboxylic acid $C_{15}H_8O_4$. The acid and its salts possess a blue fluorescence; the latter are mostly readily soluble in water. The Ba and Ca salts dried at 130° are yellow amorphous powders. The Pb salt is a flocky precipitate.

The amide of the acid is produced by the action of ammonia on the yellow oily chloride. It crystallises from alcohol and melts at 260° (Graebe, Blumenfeld), 256° (Dienel).

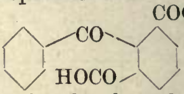
Anthraquinone-1-carboxylic acid



This acid is prepared by oxidising 1-methylanthracene with chromic acid (Liebermann and Bischoff, Ber. 13, 49), or by the hydrolysis of its nitrile (see below). A method which leaves no doubt as to its constitution has also been employed (Graebe and Leonhardt, Annalen, 290, 231; Graebe and Blumenfeld, Ber. 30, 1115). Hemimellitic anhydride and benzene in presence of aluminium chloride yield a mixture of 3-benzoylphthalic acid



and 2-benzoyl*iso*phthalic acid



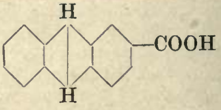
Each of these acids, when heated with sulphuric acid at 145°–150°, is changed to anthraquinone-1-carboxylic acid.

It crystallises from glacial acetic acid in long pale-yellow needles, which melt at 293°–294°. With caustic potash and zinc-dust, it develops a blood-red coloration. The barium salt is sparingly soluble. Its methyl ester is sparingly soluble in cold methyl alcohol and has m.p. 189°. The ethyl ester from the acid and alcoholic hydrochloric acid has m.p. 169°.

Nitrile (Dienel, Ber. 39, 926). This derivative is obtained by the distillation of sodium anthraquinone α-sulphonate with potassium cyanide, or by oxidising the nitrile of anthracene-1-carboxylic acid. It forms gold yellow leaflets of m.p. 216°–217°.

The amide has m.p. 280°.

Anthracene-2-carboxylic acid



The nitrile of this acid is obtained (together with a small quantity of the nitrile of the 1-acid) by distilling sodium anthracene sulphonate (from the acid obtained by the reduction of anthraquinone sulphonic acid) with potassium ferrocyanide (Liebermann and Bischoff, Ber. 13, 47). The nitriles are decomposed by boiling with KOH, and the acids separated by means of their barium salts; that of the 1-acid being readily soluble in water, whereas barium anthracene 2-carboxylate is very sparingly soluble.

The same acid is produced by the reduction of anthraquinone-2-carboxylic acid

$$C_6H_4<\begin{matrix}CO\\CO\end{matrix}>C_6H_3COOH$$

with zinc-dust and ammonia (Börnstein, Ber. 16, 2610).

Anthracene-2-carboxylic acid crystallises from alcohol in small yellow plates, which melt at about 280°, and sublime at a higher temperature in plates. It is sparingly soluble in $CHCl_3$, almost insoluble in CS_2 and benzene, less soluble in alcohol and glacial acetic acid than the β-acid. The alcoholic solution possesses an intense blue fluorescence. Reduction with sodium amalgam or hydriodic acid converts this acid into three acids, $C_{15}H_{12}O_2$, $C_{15}H_{14}O_2$, and $C_{15}H_{16}O_2$. Chlorine led into the solution in $CHCl_3$ produces first γ-chloranthracene carboxylic acid and then dichloranthracene (m.p. 209°). Bromine behaves similarly.

The *Sodium salt* is difficultly soluble in cold water, and crystallises in glittering flakes. The solutions fluoresce blue.

The *Barium salt* is almost insoluble in cold water, and only very sparingly soluble in hot.

Methyl ester (Behla, Ber. 20, 703)

$$C_{15}H_9O_2CH_3$$

crystallises in yellow prisms; m.p. 111°.

Ethyl ester (Liebermann, Bischoff, Ber. 13, 49) $C_{15}H_9O_2C_2H_5$ melts at 134°, and is readily soluble in alcohol. Both these salts distil without decomposition.

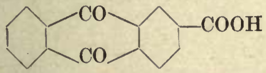
Chloride (Börnstein, *l.c.*) $C_{15}H_9OCl$ crystallises from benzene in yellow warts; m.p. not given. Readily soluble in alcohol, ether, $CHCl_3$ and CS_2. Decomposed only by boiling water.

Amide $C_{15}H_9ONH_2$ crystallises from glacial acetic acid in plates; m.p. 293°–295°. Insoluble in water, CS_2, $CHCl_3$, or benzene. Difficultly soluble in alcohol. The solutions fluoresce blue.

γ-Chloranthracene carboxylic acid (Behla, *l.c.*) (*v. supra*) crystallises from benzene in needles; m.p. 258°–259°, being at the same time decomposed into chloranthracene and CO_2.

γ-Bromanthracene carboxylic acid (Behla, *l.c.*) crystallises from alcohol in long, greenish-yellow needles; melts at 266°, being converted into CO_2 and bromoanthracene.

Anthraquinone-2-carboxylic acid



is produced by oxidising 2-methylanthracene or the corresponding quinone or carboxylic acid (Liebermann, Rath, Ber. 8, 248). It may also be obtained by the oxidation of anthranol β-carboxylic acid with potassium permanganate in alkaline solution (Limpricht, Annalen, 309, 122).

According to the Höchster Farbwerke (D. R. P. 80403), it is conveniently prepared by heating benzophenone-2 : 4′-dicarboxylic acid with sulphuric acid.

Preparation.—Methylanthraquinone (1 part) is dissolved in concentrated sulphuric acid (6 parts), mixed then with water (1 part), and $K_2Cr_2O_7$ ($2\frac{1}{2}$ parts) slowly added. The mass is warmed to 110°–120° for a short time, filtered, the precipitate washed with water, and boiled out with dilute ammonia. The excess of ammonia is evaporated off, the solution filtered, and precipitated with HCl (Börnstein, Ber. 16, 2609; *v.* also Liebermann and Glock, *ibid.* 17, 888).

Anthraquinone-2-carboxylic acid crystallises from alcohol in yellow prisms, which melt at 290°–292°, and sublime undecomposed when carefully heated. It is almost insoluble in ether, benzene, chloroform, and excess of caustic soda, difficultly soluble in glacial acetic acid and absolute alcohol, readily soluble in acetone. Gives with zinc-dust and KOH the anthraquinone reaction; reduction with zinc-dust and ammonia converts it into anthracene-2-carboxylic acid. Distillation over red-hot asbestos decomposes it into CO_2 and anthraquinone. It dissolves in sodium acetate and ammonium oxalate, and is not reprecipitated on the addition of acetic acid. Fusion with soda converts it into oxyanthraquinone carboxylic acid $C_{15}H_8O_5$.

The *Calcium salt* $Ca(C_{15}H_7O_4)_2$ and the *barium salt* $Ba(C_{15}H_7O_4)_2$ are sparingly soluble.

Ethyl ester (Liebermann and Glock, Ber. 17, 890) $C_{15}H_7O_4{\cdot}C_2H_5$ is formed by the action of alcohol on the chloride. It crystallises in needles, melts at 147°, and is readily soluble in alcohol.

Chloride $C_{15}H_7O_3Cl$ is produced by treating the acid with PCl_5. Crystallises from benzene in needles which melt at 147°.

Amide $C_{14}H_7O_2CONH_2$ is obtained by passing NH_3 into a benzene solution of the chloride. It crystallises from a mixture of glacial acetic acid and benzene in needles, which melt at 280°, and are difficultly soluble in alcohol and benzene.

Anilide crystallises from xylene in needles, m.p. 258°–260°.

Nitroanthraquinone carboxylic acid

$$C_{14}H_6(NO_2)O_2{\cdot}COOH$$

is produced by mixing the solution of the acid in concentrated sulphuric acid with nitric acid. Crystallises from glacial acetic acid in small needles, which melt above 300°. Gives with sulphuric acid a violet colouring matter.

Dinitroanthraquinone-2-carboxylic acid (Limpricht, Annalen, 309, 122) is obtained by the oxidation of the corresponding anthranol with chromic acid in acetic acid solution. It forms yellow needles from alcohol and melts at 315°.

Under the heading methylanthracene, besides *o*- and *m*-methylanthracene two other substances are to be found in chemical literature.

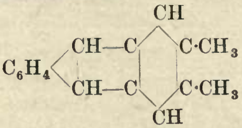
*iso***Methylanthracene** (Börnstein, Ber. 15, 1821) obtained by digesting *iso*methylanthraquinone with zinc-dust and ammonia, and by distilling *p*-toluene phthaloylic acid (Gresly, Annalen, 234, 238), with zinc-dust, is evidently identical with *m*-methylanthracene.

Methanthrene $C_{15}H_{12}$ (Oudemans, J. pr. Chem. [ii.] 9, 416), obtained by distilling podocarpinic acid $C_{17}H_{22}O_3$ with zinc-dust, is probably not an anthracene derivative at all. It melts at 117°, and gives on oxidation with CrO_3 and acetic acid, methanthraquinone $C_{15}H_{10}O_2$ which crystallises from 70 p.c. alcohol in orange-red needles melting at 187°.

It therefore possesses more the properties of a phenanthrene than of an anthracene derivative.

Dimethylanthracenes.

o-Dimethylanthracene

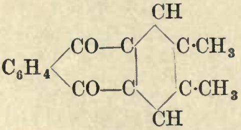


(Elbs, J. pr. Chem. 1890, 41, 5) is readily prepared by the reduction of the corresponding (2, 3) dimethylanthraquinone with zinc-dust and ammonia.

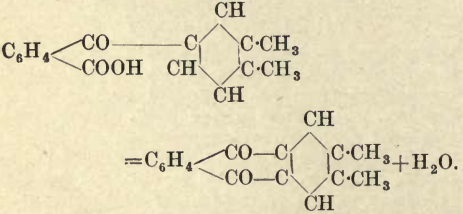
5 grams of the quinone, 30 grams zinc-dust, and 500 c.c. aqueous ammonia (equal parts of concentrated ammonia solution and water), are heated to boiling until the red liquid which is produced at first has become colourless. The mass is then filtered, the residue washed with hot water, dried in a water oven, and repeatedly extracted with boiling alcohol. The clear alcoholic extract deposits on cooling yellowish plates of dimethylanthracene. o-Dimethylanthracene melts at 246°, and sublimes in colourless plates which possess a bluish-green fluorescence. It is readily soluble in benzene and hot alcohol, but difficultly soluble in cold alcohol.

The picric acid compound crystallises in long garnet-red needles; it is readily decomposed by alcohol.

o- or (2, 3) **Dimethylanthraquinone**

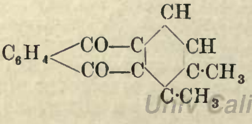


is obtained synthetically by heating o-xyloyl-o-benzoic acid with H_2SO_4.



1 part of o-xyloyl-o-benzoic acid is dissolved in 6 parts of warm concentrated H_2SO_4, and the mixture heated at 128° for a quarter to half an hour, the dark-coloured solution poured into a dish, and placed next to a dish of water. As the solution becomes dilute the quinone crystallises out, the operation being complete in 3–4 days.

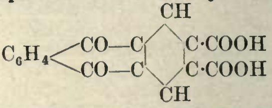
The precipitate is collected, washed with water and dilute ammonia, and purified either by sublimation or recrystallisation from xylene; o-dimethylanthraquinone is thus obtained in long yellow needles which melt at 183°. It is readily soluble in hot xylene, benzene, and alcohol, and is readily reduced by zinc-dust and ammonia to o-dimethylanthracene, hence its constitution is probably that given above, and not



(Compare action of zinc-dust and ammonia on dimethylanthraquinones with a CH_3 group in the 1 or 4 position.)

A dimethyl anthraquinone, which is probably identical with this, is obtained by oxidising dimethyl anthranol with chromic acid in acetic acid solution (Limpricht and Martens, Annalen, 312, 103). It forms yellow needles from alcohol and melts at 200°.

Anthraquinone-2 : 3-dicarboxylic acid



is produced by heating o-dimethylanthraquinone (3 grams) with 20–25 c.c. of nitric acid (sp.gr. 1·1) in a sealed tube at 210°–220° for five hours. It crystallises in yellow needles, melts at 340°, and when strongly heated sublimes in yellow plates, which melt at 290°, and consist now of anthraquinone dicarboxylic anhydride.

$$C_6H_4{<}\begin{matrix}CO\\CO\end{matrix}{>}C_6H_2{<}\begin{matrix}CO\\CO\end{matrix}{>}O.$$

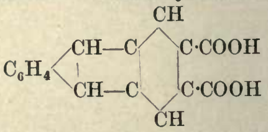
Ammonium salt. Red amorphous mass, easily soluble in water.

Calcium salt. Light red precipitate, almost insoluble in water.

Lead salt. Light red precipitate, almost insoluble in water.

Silver salt. Light red precipitate; is decomposed on heating into CO_2, Ag, and anthraquinone.

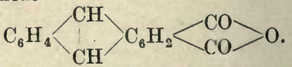
Anthracene-2 : 3-dicarboxylic acid



is readily prepared by treating the solution of the ammonium salt of anthraquinone dicarboxylic acid with zinc-dust and ammonia until the red solution becomes yellowish-green coloured; and then precipitating the clear solution with HCl.

Anthracene-o-dicarboxylic acid crystallises from alcohol in small yellowish-green crystals, which melt at 345°. It is insoluble in water, readily soluble in alcohol. The solution in dilute ammonia fluoresces blue-green, that in dilute NaOH blue.

The acid, if carefully heated, gives a yellowish-red sublimate of anthracene-o-dicarboxylic anhydride



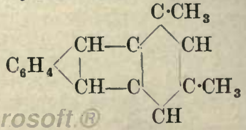
$$C_6H_4{<}\begin{matrix}CH\\CH\end{matrix}{>}C_6H_2{<}\begin{matrix}CO\\CO\end{matrix}{>}O.$$

Calcium salt. Brownish-green precipitate, almost insoluble in water.

Lead salt. Yellowish precipitate, insoluble in water.

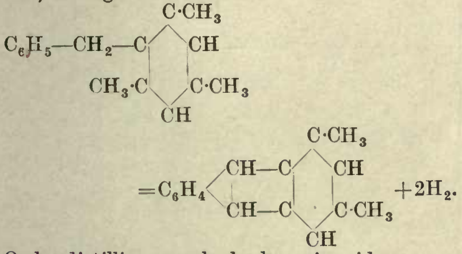
Silver salt. Yellowish-brown precipitate, insoluble in water; decomposes on distillation into CO_2, Ag, and anthracene.

m-**Dimethylanthracene**

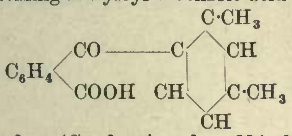


(Elbs, J. pr. Chem. 1890, 41, 13). This hydrocarbon cannot be produced by the reduction of *m*-methylanthraquinone with zinc-dust and ammonia.

It is obtained by passing mesitylphenyl methane (Louise, Ann. Chim. Phys. [vi.] 6, 187, 193) through a red-hot tube



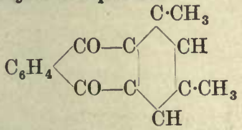
Or by distilling *m*-xyloyl-*o*-benzoic acid



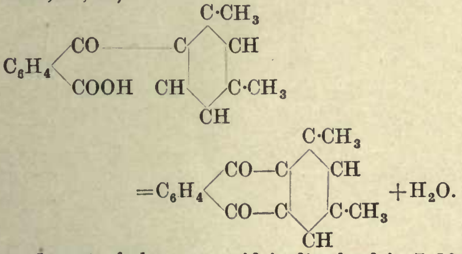
with zinc-dust (Gresly, Annalen, 234, 238).

m-Dimethylanthracene crystallises from alcohol in colourless plates, which melt at 202°–203°. Gives with bromine γ-brom-*m*-dimethyl anthracene tetrabromide (m.p. 175°–180°).

m-Dimethylanthraquinone



is prepared by the action of sulphuric acid on *m*-xyloyl-*o*-benzoic acid (Elbs, J. pr. Chem. 1890, 41, 13).



1 part of the pure acid is dissolved in 7–10 parts of concentrated sulphuric acid, the clear solution heated at 110°–125° for half an hour, the product poured in a thin stream into water, and the precipitate treated as described under *m*-methylanthraquinone. Yield 60–70 p.c. of theory. *m*-Dimethylanthraquinone crystallises in small needles which melt at 162°. It dissolves with difficulty in alcohol and benzene. Zinc-dust and ammonia reduces it to *m*-dimethylanthracylene $C_{16}H_{12}$, and not to dimethylanthracene.

m-Dimethylanthracylene

$C_{16}H_{12}$ or  (?)

Preparation.—*m*-Dimethylanthraquinone (5 grams), finely powdered, is mixed with zinc-dust (30 grams) and concentrated aqueous ammonia (200 c.c.), and a solution (5 c.c.) of basic copper carbonate in ammonia added. The product is well agitated, and gently warmed until it has assumed a light green colour, then boiled for six hours with the addition from time to time of small quantities of copper carbonate dissolved in ammonia. The mass is filtered, the precipitate washed with water, dried at the ordinary temperature, and extracted with boiling alcohol. The alcoholic solution on cooling deposits a small quantity of crystals, which are filtered off. The mother liquor is partially evaporated, again allowed to stand, filtered from the crystals which form, and this operation repeated until oily drops appear. The remainder of the hydrocarbon present in the mother liquor is purified by conversion into the picric acid compound and decomposing this with ammonia or sodium hydroxide solution (Elbs, *l.c.*).

m-Dimethylanthracylene crystallises from alcohol in groups of colourless plates which melt at 85°. It is readily soluble in hot alcohol and glacial acetic acid, difficultly soluble in cold alcohol.

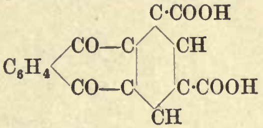
With picric acid it forms a deep garnet-red compound $C_{16}H_{12}$-$C_2H_2(NO_2)_3OH$, which is not decomposed by alcohol. M.p. 135°.

Treated with bromine in CS_2 solution (4 at. Br. to 1 mol. $C_{16}H_{12}$) an unstable dibromo compound

$C_{16}H_{10}Br_2$ or  (?)

is produced, which crystallises from CS_2 in sulphur-yellow prisms, which melt at 175° with decomposition.

Anthraquinone-*m*-dicarboxylic acid



This acid is produced quantitatively by the oxidation of *m*-dimethylanthraquinone with dilute nitric acid (for details, *v.* the *o-dicarboxylic acid*). It crystallises in fine yellow needles, which sublime above 330° without melting. It is almost insoluble in water, and difficultly soluble in the ordinary organic solvents.

Ammonium salt. Reddish warty masses, easily soluble in water.

Potassium salt. Reddish gelatinous mass, which becomes crystalline on standing, and contains then 2 mol. of water of crystallisation.

Sodium salt. Reddish crystalline crusts, contains 9 mol. of water of crystallisation.

Calcium salt. Light-red powder, insoluble in water and alcohol.

Barium salt. Light-violet powder, contains 1 mol. of water of crystallisation.

Lead salt. Red powdery precipitate, insoluble in water and alcohol.

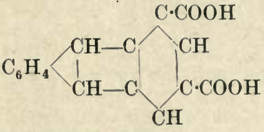
Copper salt. Dark-green crystalline powder, contains 1 mol. of water of crystallisation, insoluble in water and alcohol.

Silver salt. Pinkish precipitate, almost insoluble in water and alcohol. Decomposes on heating into CO_2, Ag, and anthraquinone.

Anthraquinone-*m*-dicarboxyl chloride is obtained by warming the acid (5 grams) with phosphorus pentachloride (7·5 grams), distilling off the phosphorus oxychloride at 140°, and shaking the residue with water and chloroform. The chloroform solution is dried over $CaCl_2$ and evaporated, when the acid chloride remains behind as a reddish mass, which showed little tendency to crystallise.

The *acid amide* prepared by treating the chloride with ammonia is also difficult to obtain in a crystalline condition.

Anthracene-*m*-dicarboxylic acid



is prepared by reducing anthraquinone-*m*-dicarboxylic acid with zinc-dust and ammonia (for details, *v.* the *o*-dicarboxylic acid). Crystallises in brownish-yellow masses, which do not melt at 330°. It is almost insoluble in water, difficultly soluble in most other solvents.

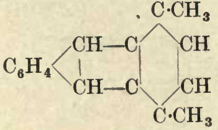
Ammonium salt. Greyish-green crystalline powder, readily soluble in water, difficultly soluble in dilute alcohol.

Copper salt. Dirty-green precipitate, almost insoluble in water and alcohol. Dissolves in ammonia, producing a yellow solution with a strong blue fluorescence (characteristic).

Silver salt. Light-brown powder. Dissolves in ammonia, producing a yellow solution with a blue fluorescence.

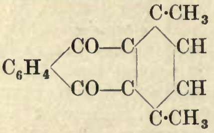
The chloride of the acid has the same properties and is produced in the same manner as the chloride of anthraquinone-*m*-dicarboxylic acid.

***p*-Dimethylanthracene**

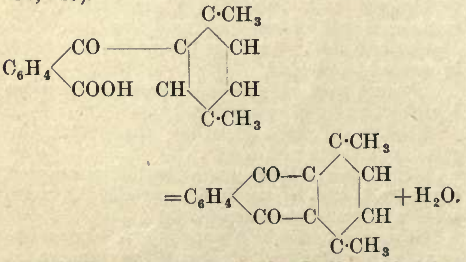


has not yet been prepared.

***p*-Dimethylanthraquinone**

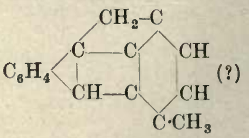


is produced by the action of H_2SO_4 on *p*-xyloyl-*o*-benzoic acid, at a temperature of 125° (Elbs, J. pr. Chem. 1890, 41, 27; Gresly, Annalen, 234, 240).



The details of the preparation and purification are the same as those of the ortho derivative. Yield 50–65 p.c. of the theoretical. *p*-Dimethylanthraquinone crystallises from xylene in yellow needles, which melt at 118°–119°. It is readily soluble in benzene and xylene, sparingly soluble in alcohol.

***p*-Dimethylanthracylene**

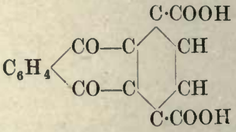


is produced when *p*-dimethylanthraquinone is reduced with zinc-dust and ammonia (*v.* *m*-dimethylanthracylene).

It crystallises from alcohol in plates which melt at 63°.

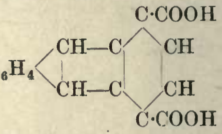
The picrate $C_{16}H_{12}{\cdot}C_6H_2(NO_2)_3OH$ crystallises from alcohol in dark-red needles, which melt at 129°.

Anthraquinone-*p*-dicarboxylic acid



is prepared by oxidising *p*-dimethylanthraquinone with dilute nitric acid (for details, *v.* the *o*- and *m*- derivatives). Yield nearly quantitative. It crystallises in small yellow crystals, which are difficultly soluble in water, but readily soluble in alcohol. The melting-point lies above 300°. The salts are similar to those of the *o*- and *m*- derivatives.

Anthracene-*p*-dicarboxylic acid

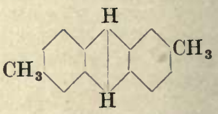


is obtained in the same way as its isomerides, by reducing anthraquinone *p*-dicarboxylic acid with zinc-dust and ammonia.

It crystallises from alcohol in the form of a light-brown crystalline powder which melts at about 320°. It is readily soluble in alcohol, but almost insoluble in water.

The salts are similar to those of the *o*-acid.

2 : 6-Dimethylanthracene



Friedel and Crafts (Ann. Chim. Phys. [vi.] 11, 265) obtained an unseparated mixture of dimethylanthracenes and other substances by each of two reactions, namely by the action of aluminium chloride on toluene and methylene chloride, or on toluene and acetylene tetrabromide.

Lavaux (Compt. rend. 139, 976) isolated from this product, benzene, xylene, dimetatolylmethane, diparatolylmethane, β-methylanthracene, and three isomeric dimethylanthracenes, having m.ps. 240°, 244·5°, and 86°

respectively. The substance of m.p. 244·5° is 2 : 6-dimethylanthracene and the constitution is proved by the following synthesis taken in conjunction with the other evidence:

m-Tolyl *m*-4 xylylketone (Seer, Monatsh. 32, 143), from *m*-toluoyl chloride and *m*-xylene, when boiled for five days is changed to 2 : 6-dimethylanthracene of m.p. 243°.

The hydrocarbon can also be prepared (Anschütz, Annalen, 235, 319) by distilling the tetrahydride of the tetramethylanthracene of Anschütz with zinc-dust. This preparation harmonises better with the constitution 2 : 4 : 6 : 8 for the latter hydrocarbon than for the 1 : 3 : 6 : 8 structure assigned by Dewar and Jones (*v. infra*).

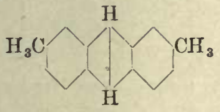
The substance crystallises from benzene in greenish yellow plates and is readily soluble in benzene, difficultly so in alcohol.

2 : 6-Dimethylanthraquinone is produced by the oxidation of the anthracene derivative by chromic acid in acetic acid solution. It is also obtained in 19 p.c. yield by heating *m*-toluoyl chloride and aluminium chloride at 130° for two hours and then at 130°–140° for 16 hours. It is very sparingly soluble and crystallises from acetic acid, nitrobenzene, or in the form of long silky needles, from alcohol. It melts at 236°.

Anthraquinone-2 : 6-dicarboxylic acid is obtained when the above quinone is boiled with chromic acid and acetic acid for 60 hours. It forms a chloride which has m.p. 197°–198°, and this with alcoholic ammonia yields an amide $C_{16}H_{10}O_4N_2$, infusible at 370°.

2 : 6-Di-α-naphthoylanthraquinone $C_{36}H_{20}O_4$, m.p. 183°–185°, is obtained from the chloride, naphthalene, and aluminium chloride in nitrobenzene at 75°–80° after 20 hours.

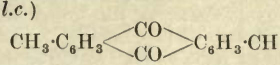
2 : 7-Dimethylanthracene (α and γ-dimethylanthracenes)



This hydrocarbon is produced (Elbs and Wittich, Ber. 18, 348) when a mixture of 3 parts toluene, 3 parts carbon disulphide, and 1 part chloroform is treated with 2 parts of aluminium chloride. It is formed further (1) together with ditolylmethane $C_{15}H_{16}$ and *m*- and *p*-xylene, by treating a mixture of toluene and methylene chloride with aluminium chloride (Friedel and Crafts, Bull. Soc. chim. [ii.] 41, 323); (2) by treating xylyl chloride $CH_3\cdot C_6H_4\cdot CH_2Cl$ with aluminium chloride (Friedel and Crafts, *ibid.* [ii.] 41, 326); (3) by treating toluene and acetylene tetrabromide with aluminium chloride (Anschütz and Immendorff, Ber. 17, 2816; Annalen, 235, 172); (4) by treating toluene with nickel carbonyl and aluminium chloride. In this reaction, *p*-tolualdehyde is a by-product (Dewar and Jones, Chem. Soc. Trans. 85, 212).

It is identical with the hydrocarbon isolated by Zincke and Wackendorff (Ber. 10, 1481) from the higher boiling fractions of coal tar. It crystallises from alcohol in glittering yellowish plates which melt at 215° (Elbs, *l.c.*; Dewar and Jones, *l.c.*); 224°–225° (Friedel and Crafts, *l.c.*). It sublimes readily, is moderately soluble, and yields the following oxidation products.

γ-Dimethylanthraquinone (Zincke and Wackendorff, *l.c.*)



$$CH_3\cdot C_6H_3\left<\begin{matrix}CO\\CO\end{matrix}\right>C_6H_3\cdot CH_3$$

is produced by the oxidation of the above hydrocarbon with CrO_3 and acetic acid; it crystallises from dilute alcohol in small straw-yellow needles, which melt at 155°.

It sublimes in almost colourless flat needles, is moderately soluble in alcohol, ether, benzene, glacial acetic acid, and hot light petroleum.

Methylanthraquinone carboxylic acid,

$$CH_3\cdot C_3H_3\left<\begin{matrix}CO\\CO\end{matrix}\right>C_6H_3\cdot COOH,$$

is produced by the oxidation of γ-dimethylanthracene (m.p. 224°–225°) with CrO_3 and acetic acid. It crystallises in flocks, which melt at 244°–246°, and sublime, when strongly heated, in small needles.

Anthraquinone dicarboxylic acid

$$COOH\cdot C_6H_3\left<\begin{matrix}CO\\CO\end{matrix}\right>C_6H_3\cdot COOH$$

is formed, together with dimethylanthraquinone and methylanthraquinone carboxylic acid, by oxidising γ-dimethylanthracene with CrO_3. It crystallises in small warty masses (m.p. not given). It is readily separated from methylanthraquinone carboxylic acid by treatment with concentrated NaOH, in which the sodium salt of the dicarboxylic acid is readily soluble, but that of the monocarboxylic acid sparingly soluble. The solution of the acid in KOH becomes violet on exposure to the air. The Ba and Ca salts are gelatinous and insoluble.

DIMETHYL ANTHRACENE DERIVATIVES.

Nitro compounds. 4-nitro-1 : 3-dimethylanthraquinone of m.p. 234° is obtained by boiling 1 : 3-dimethylanthraquinone with nitric acid (sp.gr. 1·37) for 10 hours. It is reduced by alkaline hyposulphite to the amino compound which has practically the same m.p. 4-Iodo-1 : 3-dimethylanthraquinone, m.p. 118°, is produced when the diazotised amine is treated with potassium iodide (Scholl and Potschiwauscheg, Ber. 43, 346). 2 : 4-Dinitro-1 : 3-dimethylanthraquinone melts at 283°–285°, and is produced by agitating the quinone for many hours with fuming nitric acid (sp.gr. 1·52).

1 : 5-Dinitro-2 : 6-dimethylanthraquinone (?) (Seer, *l.c.*) is obtained by the nitration of 2 : 6-dimethylanthraquinone with sulphuric acid and potassium nitrate. It forms colourless needles and on reduction with alkaline hyposulphite yields the corresponding diamine, dark-red needles, melting at 255°–256°. The corresponding diiodo compound, obtained in the usual way, forms orange-yellow needles, m.p. 273°.

Chloro derivatives (Harrop, Norris, and Weizmann, Chem. Soc. Trans. 95, 1312).

3 : 6-Dichlorophthalic anhydride was condensed with the three xylenes by means of aluminium chloride in carbon disulphide solution.

The benzoyl benzoic acids were converted to the corresponding quinones by heating with sulphuric acid containing boric acid and 10 p.c. of sulphur trioxide for 10 minutes at 120°.

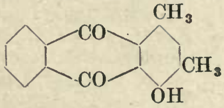
5 : 8 - Dichloro - 1 : 2 - dimethylanthraquinone from *o*-xylene crystallises from acetic acid in greenish-yellow needles and melts at 269°–270°. Its colour in sulphuric acid is orange red.

5 : 8 - **Dichloro - 1 : 3 - dimethylanthraquinone** is produced in poor yield. It crystallises from xylene in light yellow needles and melts at 208°.

5 : 8 - **Dichloro - 1 : 4 - dimethylanthraquinone** melts at 244°. When these chloro compounds are heated with aniline, sodium phenoxide, or phenyl mercaptan and caustic soda, the chlorine atoms are replaced by the groups —NHPh, —OPh, and —SPh respectively.

Hydroxy derivatives.

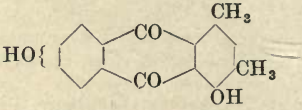
4-Hydroxy - 1 : 3 - dimethylanthraquinone (Bentley, Gardner and Weizmann, *l.c.*)



Phthalic anhydride and *m*-4-xylenol, when fused together with boric acid, yield a benzoyl benzoic acid which, on further treatment with sulphuric acid, changes to this quinone. It crystallises in needles from acetic acid and melts at 173°–175°.

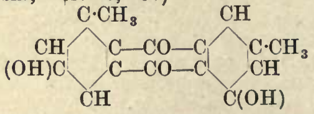
Methyl ether. Phthalic anhydride and *m*-4 : xylyl methyl ether in presence of aluminium chloride yield 2′-methoxy - 3′ : 5′-dimethyl - 2 - benzoyl benzoic acid. The latter, on treatment with sulphuric acid, yields 4 : methoxy : 1 : 3 : dimethylanthraquinone, yellow needles from acetic acid, m.p. 176°–177°.

4 : 6 - (or 7) **Dihydroxy-1 : 3-dimethylanthraquinone.**

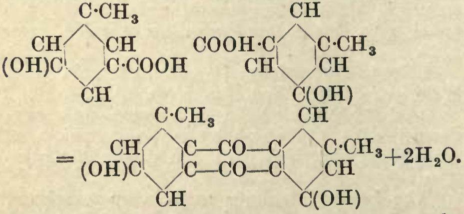


This quinone is obtained direct by the condensation of 4-hydroxyphthalic anhydride with *m*-4 - xylenol by means of boric acid. It crystallises in yellow needles from acetic acid and melts at 270°. Its solution in sulphuric acid is intensely bluish-red (Bentley, Gardner and Weizmann, *l.c.*).

Dimethylanthrarufin (Kostanecki and Niementowski, Ber. 18, 250)



is obtained, together with small quantities of two other isomers, by heating symmetrical *m*-hydroxytoluic acid with sulphuric acid.



The crude product is poured into water, the precipitate collected, washed with water, and treated with baryta water, which leaves the dimethylanthrarufin undissolved. The baryta extract is precipitated with HCl, the precipitate extracted with alcohol. Dimethylbenzdihydroxyanthraquinone dissolves, whereas dimethylanthraflavic acid is insoluble (*v. infra*).

Dimethylanthrarufin crystallises from benzene in yellow silky needles, which melt at 300° and sublime in orange-red needles. It does not dye mordanted cloth. The solution in sulphuric acid is cherry-red coloured, and similar to that of anthrarufin in H_2SO_4. The *diacetate*

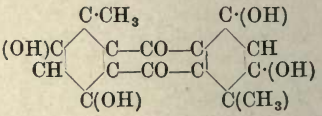
$$C_{16}H_{10}O_2(C_2H_3O_2)_2$$

crystallises in yellow plates, m.p. 236°–237°.

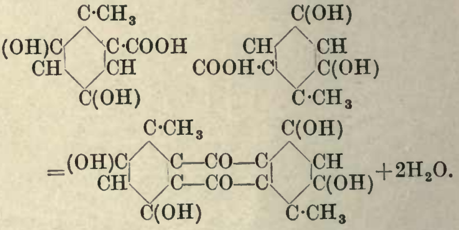
Dimethylanthraflavic acid (for preparation, *v. Dimethylanthrarufin*). It sublimes in yellow needles which do not melt at 360°. It is insoluble in benzene, difficultly soluble in alcohol and glacial acetic acid; it dissolves in alkalis and sulphuric acid with a yellow colour like anthraflavic acid. It does not dye mordanted cloth. The *diacetate* crystallises in needles which melt at 223°.

Dimethylbenzdihydroxyanthraquinone (for preparation, *v. Dimethylanthrarufin*). It crystallises from alcohol in yellow needles which melt at 213°. It dissolves in glacial acetic acid, but is sparingly soluble in alcohol and benzene. It does not dye mordanted cloth. The *diacetate* melts at 188°.

Dimethylanthrachrysone (Cahn, Annalen, 240, 280)



is prepared by heating cresorsellinic acid (1 part) with concentrated sulphuric acid (10 parts) to 100°.

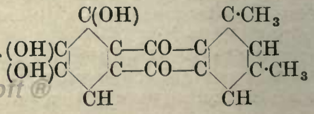


It crystallises from alcohol in bronze-coloured needles which do not melt when heated to 360°. It sublimes with difficulty, and then with considerable decomposition. It is insoluble in water, benzene, and light petroleum, sparingly soluble in alcohol and CS_2, readily soluble in $CHCl_3$, acetone, and glacial acetic acid. It is soluble in solutions of the alkalis and alkaline earths, with a yellowish-red colour. The solution in sulphuric acid is magenta-coloured, and shows two absorption bands in the green. It does not dye mordanted cloth.

The *tetraacetyl derivative* $C_{16}H_8O_2(C_2H_3O_2)_4$ crystallises in yellowish needles which melt at 234° and are readily soluble in hot alcohol, glacial acetic acid, and benzene.

Dimethylanthragallol (Birukoff, Annalen, 240, 287)

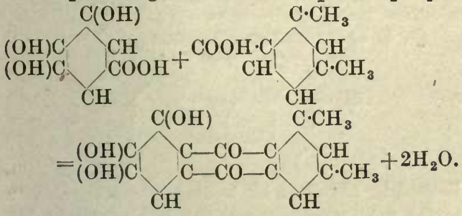
$C_{16}H_{12}O_5$ or



is obtained by heating a mixture of 5 parts xylylic acid

$C_6H_3(COOH)(CH_3)(CH_3),(COOH : CH_3 : CH_3=1, 2, 4)$

with 3 parts of gallic acid and 40 parts H_2SO_4.

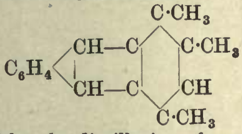


The product is mixed with water, the precipitate collected, washed with water, dissolved in absolute alcohol (in which small quantities of accompanying rufigallic acid are insoluble); evaporated and the residue extracted with benzene; again evaporated, and the product recrystallised from acetone. Glittering reddish-yellow needles (no m.p. given). Distilled with zinc-dust, dimethylanthracene (m.p. 224°) results. The absorption spectrum of a solution of dimethylanthragallol in concentrated sulphuric acid is almost identical with that of anthragallol itself.

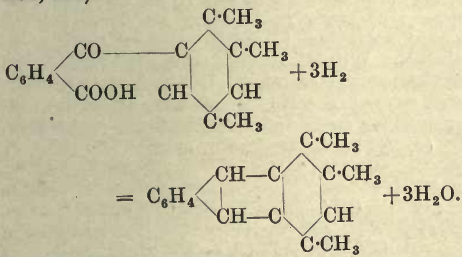
This substance should, from its method of preparation, be a derivative of *m*-dimethylanthracene, which, however, melts at 202°–203°, whereas the dimethylanthracene obtained from dimethylanthragallol melts at 224°, and is evidently identical with that obtained from coal tar by Zincke and Wackendorff. This point requires investigation.

Trimethylanthracenes (Elbs, J. pr. Chem. 1890, 41, 121).

(1, 2, 4) **Trimethylanthracene**



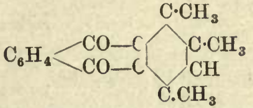
is produced by the distillation of pseudocumoyl-*o*-benzoic acid with zinc-dust (Gresly, Annalen, 234, 241).



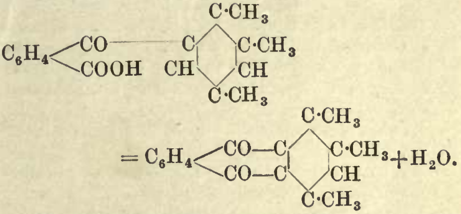
Preparation.—5 grams of the powdered acid are intimately mixed with 10 grams of zinc-dust, and distilled from a retort, the temperature being raised very gradually. The greenish-coloured oil which first passes over is separated from the reddish-coloured oil, which distils last and crystallises on cooling; the latter is dissolved in boiling light petroleum, and the crystals which separate out on cooling purified by recrystallisation.

Trimethylanthracene crystallises in white plates, possessing a blue fluorescence, and which melt at 244°. The picrate crystallises from benzene in brownish-red needles, which melt at 145° and are decomposed by alcohol.

(1, 2, 4) **Trimethylanthraquinone**



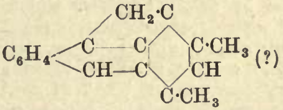
is obtained by the action of dehydrating agents on pseudocumoyl-*o*-benzoic acid.



In order to obtain a good yield of this substance, the following directions must be carefully observed.

10 grams of powdered *pseudo*cumoyl-*o*-benzoic acid are dissolved in 100 c.c. of concentrated sulphuric acid, and the product gently warmed. The solution, which becomes clear and cherry-reddish coloured at 60°, is heated at 115° for one hour, allowed to cool to 70°–80°, and then mixed with 10 grams of phosphorus pentoxide, the temperature being allowed to rise gradually to 115°–120° during the addition, at which temperature it is kept for further two hours. The well-cooled product is poured in a thin stream into water, the precipitate collected, washed with water, and then with cold carbonate of soda solution; dried at 100°, and recrystallised from a mixture of alcohol and xylene. Trimethylanthraquinone crystallises in long yellow needles which sublime readily and melt at 162°–163°. It is readily soluble in ether, benzene, and xylene; sparingly soluble in alcohol.

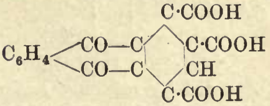
(1, 2, 4) **Trimethylanthracylene**



results from the action of zinc-dust and ammonia on trimethylanthraquinone (for details, *v.* dimethylanthracylene). It crystallises from alcohol in colourless plates which melt at 64° and resemble naphthalene in appearance. The picrate $C_{17}H_{14}{\cdot}C_6H_2(NO_2)_3OH$ melts at 134°, and is decomposed by alcohol.

Bromine converts the hydrocarbon into its unstable dibromo-trimethylanthracylene.

Anthraquinone-1 : 2 : 4-Tricarboxylic acid



is produced by the oxidation of (1, 2, 4) trimethylanthraquinone with dilute nitric acid (*v. Anthraquinone dicarboxylic acids*). It crystallises from alcohol in yellowish-white warty masses, which do not melt at 320°. It is almost insoluble in water.

The *ammonium* salt separates from its

solution in reddish amorphous crusts, which dissolve in water with a deep-red colour.

The *primary sodium salt*

$$C_6H_4\genfrac{}{}{0pt}{}{\diagup CO \diagdown}{\diagdown CO \diagup}C_6H(COOH)_2(COONa),2H_2O$$

crystallises in yellow plates, readily soluble in hot, but difficultly in cold water.

Secondary sodium salt

$$C_6H_4\genfrac{}{}{0pt}{}{\diagup CO \diagdown}{\diagdown CO \diagup}C_6H(COOH)(COONa)_2,3H_2O$$

crystallises in yellowish-red plates, more soluble in water than the primary salt.

Tertiary sodium salt is very readily soluble in water, and difficult to obtain in a crystalline form.

Neutral calcium salt. Rose-red plates from water.

Neutral copper salt. Light-green precipitate, very difficultly soluble in water.

Neutral lead salt. Yellow powdery precipitate insoluble in water.

Neutral silver salt. Reddish powdery precipitate which, when heated to a high temperature, decomposes into CO_2, Ag, and anthraquinone.

The *triethyl ester*

$$C_6H_4\genfrac{}{}{0pt}{}{\diagup CO \diagdown}{\diagdown CO \diagup}C_6H(COOC_2H_5)_3$$

crystallises from alcohol in glittering white plates, which melt at 125°.

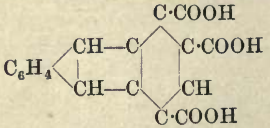
When treated with nitric acid and sulphuric acid trimethyl anthraquinone yields three nitro-derivatives which, on oxidation, yield two mononitro- and one dinitro-anthraquinone tricarboxylic acids.

I. *Mononitro-anthraquinone* (1, 2, 4) *tricarboxylic acid*, $C_{12}H_4(CO)_2(COOH)_3(NO_2)$, crystallises in small yellow crystals which melt at 308°–310°. It is soluble in alcohol, ether, acetone, glacial acetic acid, and benzene, insoluble in water.

II. *Mononitroanthraquinone tricarboxylic acid* crystallises in small crystals, which melt at 360°–370° with decomposition, is readily soluble in alcohol, ether, and benzene, insoluble in water. The copper salts of these two acids differ very distinctly. That of acid I. crystallises in green needles, which dissolve in ammonia with a green colour; that of acid II. crystallises in red needles which dissolve in ammonia, forming a red solution.

Dinitro anthraquinone (1, 2, 4) *tricarboxylic acid*, $C_{12}H_3(NO_2)_2(CO)_2(COOH)_3$, melts at 340°–360° with decomposition.

Anthracene-1 : 2 : 4-tricarboxylic acid

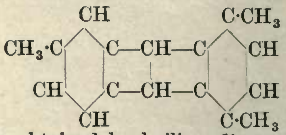


is readily obtained by reducing anthraquinone (1, 2, 4) tricarboxylic acid with zinc-dust and ammonia (for details, see the corresponding dicarboxylic acids). It is readily soluble in benzene and light petroleum, still more readily in alcohol, with a yellowish-green colour, insoluble in water. No sharp m.p. was observed, as the acid sublimed above 260°, being converted probably into the anhydride.

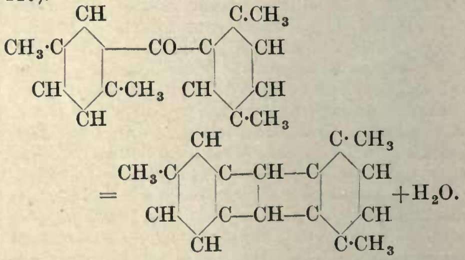
The *alkali salts* are very readily soluble in water, and do not crystallise readily.

The *silver salt* is a yellowish-green precipitate which, on heating, is decomposed, yielding a sublimate of anthracene.

(1, 4, 7) Trimethylanthracene



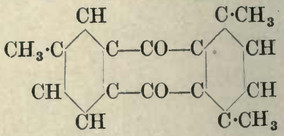
is readily obtained by boiling di-*p*-xylylketone under a reflux apparatus for 6 hours (Elbs, *l.c.* 140).



The yield is about 20–25 p.c. of the theoretical.

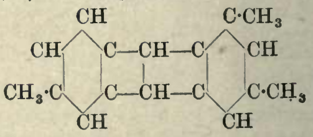
It crystallises in thin colourless plates, which fluoresce bluish-green, melt at 227°, and sublime with great readiness, even at 100°. It is difficultly soluble in cold alcohol, more readily soluble in hot alcohol, benzene, and ether.

(1, 4, 7) Trimethylanthraquinone

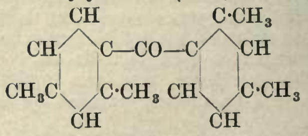


is obtained by oxidising (1, 4, 7) trimethylanthracene with the theoretical quantity of CrO_3 in glacial acetic acid solution. The yield is almost quantitative. It crystallises in yellow needles, which melt at 184°, and sublime with great readiness. It dissolves readily in glacial acetic acid, but is only sparingly soluble in alcohol. With zinc-dust and KOH it gives the anthraquinone reaction. On further oxidation this substance yields a mixture of carboxylic acids which could not be satisfactorily separated.

(1, 3, 6) Trimethylanthracene



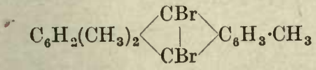
is synthetically prepared by the action of heat on di-*m*-xylylketone (Elbs, *l.c.* 142).



(*v. supra*).

The yield is 20–25 p.c. of the theoretical. It crystallises from a mixture of alcohol and acetone in plates which melt at 222°, is difficultly soluble in alcohol and light petroleum, more readily in ether and glacial acetic acid, very readily in CS_2, acetone, and benzene.

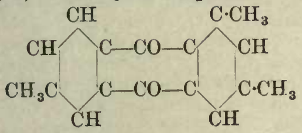
γ-*Dibromo* (1, 3, 6) *trimethylanthracene*



$$C_6H_2(CH_3)_2 \Big< \begin{matrix} CBr \\ | \\ CBr \end{matrix} \Big> C_6H_3{\cdot}CH_3$$

results when trimethylanthracene (1 mol.) dissolved in CS_2 is treated with bromine (2 mol.). On evaporation a brownish-yellow crystalline mass is obtained, which crystallises from acetone in rosettes of yellow plates which melt at 142°.

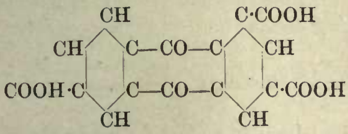
(1, 3, 6) **Trimethylanthraquinone**



is produced by oxidising (1, 3, 6) trimethylanthracene with the calculated quantity of chromic acid in acetic acid solution.

It crystallises in yellow needles which melt at 190°, are readily soluble in glacial acetic acid, difficultly soluble in alcohol. It sublimes readily and gives with zinc-dust and potash a deep-red solution.

Anthraquinone (1, 3, 6) **tricarboxylic acid**



To prepare this substance 0·5 gram (1, 3, 6) trimethylanthracene is heated with 15 grams HNO_3 (sp.gr. 1·1) in a sealed tube 10 hours to 180°, then 10 hours to 210°–220°. The tricarboxylic acid crystallises out in yellow plates. It is scarcely soluble in water, and very difficultly soluble in other solvents; it does not melt when heated to 300°.

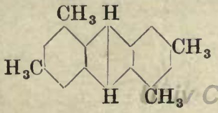
The *ammonium salt* is readily soluble in water, and crystallises in flesh-coloured plates.

The *barium salt* is a cherry-red crystalline precipitate, very sparingly soluble in water.

Tetramethylanthracene (Anschütz, Annalen, 235, 174) $C_{14}H_6(CH_3)_4$ is formed in small quantity, together with toluene and trimethylbenzene, by the action of aluminium chloride on a mixture of acetylenetetrabromide and *m*-xylene; m.p. 280°. If *o*-xylene be used in the place of *m*-xylene in the above reaction, a tetramethylanthracene, which melts above 280°, is obtained; in the case of *p*-xylene being used the tetramethylanthracene obtained melts at about 280°.

Since there are only two isomeric tetramethylanthracenes derivable from *m*-xylene, namely 1 : 3 : 6 : 8 and 2 : 4 : 6 : 8, and the former is chosen for the quinone described below, the hydrocarbon of Anschütz is probably 2 : 4 : 6 : 8-tetramethylanthracene.

1 : 3 : 6 : 8-**Tetramethylanthracene**

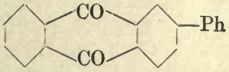


Dewar and Jones (Chem. Soc. Trans. 1904, 85, 212) obtained this hydrocarbon by the action of nickel carbonyl on *m*-xylene in presence of aluminium chloride.

The hydrocarbon is purified by successive crystallisation from hot benzene and acetic acid. It forms beautiful lustrous plates, melts at 280°, is very pale yellow, and exhibits green fluorescence.

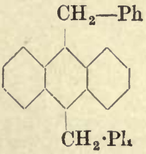
1 : 3 : 6 : 8-**Tetramethylanthraquinone** is obtained from the hydrocarbon in the usual manner. It crystallises in pale yellow prisms of m.p. 228°–230°.

2-**Phenylanthraquinone** (Scholl and Neovius, Ber. 44, 1075).



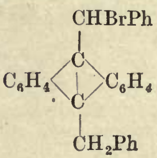
Phthalic anhydride condenses with diphenyl in presence of aluminium chloride in carbon disulphide solution, and the product is exclusively diphenyl-4-phthaloylic acid. When heated with zinc chloride at 280°, 2-phenylanthraquinone is obtained. The product is purified by reduction with alkaline hyposulphite, filtering the alkaline solution and oxidising by a current of air. The substance crystallises in yellow needles and melts at 160°–161°. The quinone may also be obtained by reducing diphenyl-4-phthaloylic acid to the corresponding diphenyl methane carboxylic acid, and this with zinc chloride at 185° is changed to 2-phenyl-9-anthrone which, on oxidation with chromic acid, yields 2-phenylanthraquinone.

9 : 10-**Dibenzylanthracene** (Lippmann and Fritsch, Monatsh. 25, 793).



This interesting hydrocarbon is prepared by heating anthracene (100 grams), benzyl chloride (145 grams), and zinc-dust (10 grams) with carbon disulphide (1 litre) on the water bath, and with continual passage of carbon dioxide, until the evolution of hydrogen chloride ceases. The substance forms blue fluorescent needles, crystallises from acetic acid and melts at 241°. It has a peculiar odour resembling carbylamine.

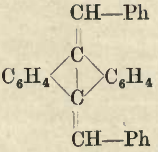
Monobromodibenzylanthracene

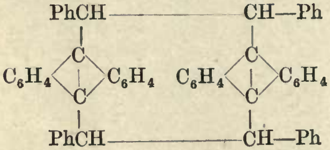


$$C_6H_4 \Big< \begin{matrix} CHBrPh \\ | \\ C \\ | \\ C \\ | \\ CH_2Ph \end{matrix} \Big> C_6H_4$$

This derivative is obtained by the action of bromine on dibenzylanthracene in carbon disulphide solution. The bromine is carried into the liquid mixed with carbon dioxide. The product crystallises from carbon disulphide or benzene in yellow prisms, melting, when quickly heated, at 187°.

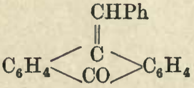
Uni- and bi-molecular **dibenzylidenedihydroanthracene**



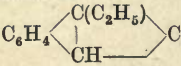


Unimolecular. Monobromodibenzylanthracene is boiled in benzene solution with aqueous potassium acetate, or the bromide is heated with a small excess of acetic anhydride. The substance melts at 234°–236°, and is soluble in chloroform with blue fluorescence.

Bimolecular $C_{56}H_{40}$. Monobromodibenzylanthracene is boiled with quinoline in benzene solution for 20 hours. It forms yellow crystals of m.p. 184° and is soluble in hot benzene or chloroform with red fluorescence. It is easily distinguished from the monomolecular compound in that its solution in sulphuric acid is green.



Benzylidene anthrone $C_6H_4<\begin{array}{c}\overset{\overset{CHPh}{\|}}{C}\\CO\end{array}>C_6H_4$ (Haller and Padova, Compt. rend. 141, 857) is closely related to the above benzal dihydroanthracenes. It is obtained by the condensation of anthranol with benzaldehyde in pyridine solution containing piperidine. The yield is 36 p.c. of that demanded by theory. The substance crystallises in yellow needles, and is readily soluble in chloroform, benzene, and acetone, sparingly so in ligroin. It melts at 126°–127°. The corresponding anisylidene and *m*-nitrobenzylidene derivatives melt at 141° and 166° respectively. The benzylidene anthrone is also easily obtained on passing hydrochloric acid into the acetic acid solution of *benzyl oxanthranol*. The latter is prepared by the action of magnesium benzyl chloride on anthraquinone. It forms colourless crystals from alcohol and melts at 146°.



Ethylanthracene (Liebermann, Annalen, 212, 109) $C_6H_4<\begin{array}{c}C(C_2H_5)\\|\\CH\end{array}>C_6H_4$ is formed by boiling ethyl hydranthranol with alcohol and hydrochloric or picric acid.

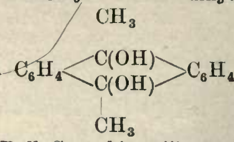
$$C_6H_4<\begin{array}{c}C(C_2H_5)OH\\CH_2\end{array}>C_6H_4 \text{ or } C_{16}H_{14},H_2O.$$

It crystallises from alcohol in large concentrically grouped plates which melt at 60°–61°. The picrate melts at 120°.

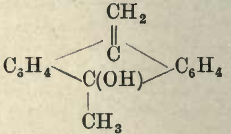
Ethylhydranthranol

$$C_6H_4<\begin{array}{c}C(C_2H_5)OH\\CH_2\end{array}>C_6H_4$$

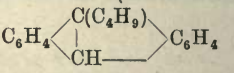
is produced by heating anthraquinone (3 parts) with zinc-dust (10 parts), caustic soda solution (10 p.c.), and ethyl bromide (2–4 parts).



9 : 10 - Dimethyl - 9 : 10 - dihydroxydihydroanthracene $C_6H_4<\begin{array}{c}\overset{CH_3}{C}(OH)\\\underset{CH_3}{C}(OH)\end{array}>C_6H_4$ (Guyot and Staehling, Bull. Soc. chim. [iii.] 33, 1152). This substance is prepared by the action of magnesium methyl iodide on anthraquinone. It crystallises from methyl alcohol in colourless prisms containing solvent of crystallisation. Some of this it loses on exposure to the air, but the last molecule is not driven off unless the substance is exposed *in vacuô* to a temperature of 100°. The anhydrous compound melts at 181° and dissolves in sulphuric acid with a green colour, changing on standing to yellow. When treated with alcohols the corresponding ethers are produced. Thus ethyl alcohol yields the diethyl ether of the anthracene derivative.



9 - Methyl - 9 - hydroxy - 10 - methenedihydroanthracene $C_6H_4<\begin{array}{c}\overset{\overset{CH_2}{\|}}{C}\\\underset{CH_3}{C}(OH)\end{array}>C_6H_4$ is obtained when the dihydroxy compound (*v. supra*) is boiled with acetic acid. It is a canary yellow crystalline powder melting at 223°, and sparingly soluble in organic solvents. It dissolves in sulphuric acid to a clear yellow solution.



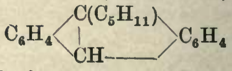
*iso***Butylanthracene** (Liebermann, Annalen, 212, 107) $C_6H_4<\begin{array}{c}C(C_4H_9)\\|\\CH\end{array}>C_6H_4$ is obtained by boiling an alcoholic solution of *iso*butyl hydranthranol ($C_{18}H_{19}OH$) with picric acid or hydrochloric acid. It crystallises from alcohol in fluorescent needles; m.p. 57°. The picrate crystallises in long brownish-red needles.

*iso***Butylhydranthranol**

$$C_6H_4<\begin{array}{c}C(C_4H_9)(OH)\\CH_2\end{array}>C_6H_4$$

is prepared by boiling 3 parts anthraquinone with 10 parts of zinc-dust, 50 parts of caustic soda solution (10 p.c.), and 2·4 parts of *iso*butyl bromide. It crystallises in needles, which melt at 71°–72°.

*iso***Amylanthracene** (Liebermann, *l.c.*)

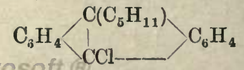


$$C_6H_4<\begin{array}{c}C(C_5H_{11})\\|\\CH\end{array}>C_6H_4$$

is prepared from *iso*amylhydranthranol (*v. Isobutylanthracene*). Long, colourless sea-green needles, m.p. 59°. Very soluble in benzene, CS_2,$CHCl_3$ light petroleum, and hot alcohol; difficultly soluble in cold alcohol. The solutions fluoresce blue. The solution in sulphuric acid is green; on warming it becomes red. Chromic acid oxidises it to *iso*amyloxanthranol

$$C_6H_4<\begin{array}{c}C(C_5H_{11})(OH)\\CO\end{array}>C_6H_4.$$

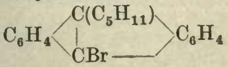
Chlor*iso*amylanthracene



$$C_6H_4<\begin{array}{c}C(C_5H_{11})\\|\\CCl\end{array}>C_6H_4$$

is obtained by passing chlorine into a solution of *iso*amylanthracene in chloroform. It crystallises from alcohol in pale-yellow needles, which melt at 70°–71°. The solutions fluoresce blue. The picrate crystallises in red needles, which melt at 108°.

Bromo*iso*amylanthracene



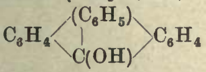
is obtained by adding the calculated quantity of bromine to the solution of the hydrocarbon in 20–30 parts of CS_2. Orange-yellow needles, m.p. 76°. The picrate crystallises in orange-yellow needles, which melt at 110°.

***iso*Amylhydroanthranol**

(*v. Isobutylhydranthranol*). Needles, m.p. 73°–74°. Very readily soluble in alcohol; insoluble in water.

Phenylanthracene  is obtained by distilling phenylanthrol (Baeyer, Annalen, 202, 61) $C_{20}H_{13}(OH)$ with zinc-dust; also, but in very small quantity, by distilling diphenylphthalid  or triphenylmethane carboxylic acid $C_{20}H_{16}O_2$ with zinc-dust. It is also produced, together with anthracene and other hydrocarbons, by the action of aluminium chloride on a mixture of chloroform and benzene (Friedel and Crafts, Ann. Chim. Phys. [vi.] 1, 495). It crystallises from alcohol in plates which melt at 151°–153°, and boil at 417°. It is readily soluble in hot alcohol, ether, CS_2, $CHCl_3$, and benzene, the solutions possessing a blue fluorescence. Oxidation with CrO_3 and acetic acid converts it into phenyloxanthranol . The *picrate* crystallises in red needles. Reduction with hydriodic acid converts it into a dihydride $C_{20}H_{16}$, which melts at 120°–120·5°.

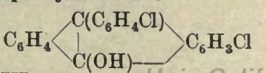
Phenylanthranol (Baeyer, *l.c.*)



is formed by dissolving triphenylmethane carboxylic acid $(C_6H_5)_2CH{\cdot}C_6H_4{\cdot}COOH$ in 3 parts of sulphuric acid and pouring the mass into water. The precipitate is collected, washed with dilute sodium carbonate, and recrystallised from alcohol. Yellow needles, which melt at 141°–144°, with slight decomposition. It dissolves readily in ether, forming a yellowish solution, which possesses a greenish-yellow fluorescence. It dissolves also in hot alcohol, petroleum spirit, and acetone. Oxidation with CrO_3 converts it into phenyloxanthranol

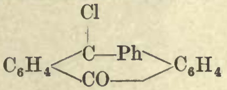
The *acetate* $C_2H_3O_2{\cdot}C_{20}H_{13}$ crystallises from alcohol in yellow needles which melt at 165°–166°.

Dichlorophenylanthranol



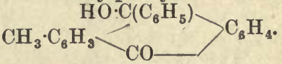
is formed by boiling phenolphthalideïn chloride  with zinc-dust and acetic acid. It crystallises from alcohol in needles, which melt at 170°. It is very sparingly soluble in alcohol, moderately soluble in acetone and ether, readily soluble in benzene or CS_2, forming bluish-green fluorescent solutions.

Phenyloxanthranolchloride

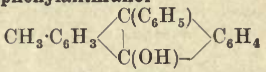


(Haller and Guyot, Bull. Soc. chim. 1897, [iii.] 17, 873) is obtained by warming diphenylphthalide with phosphorus pentachloride. It crystallises from benzene in large, colourless, transparent prisms, melting at 164°. Water changes it to phenyloxanthranol, whilst with methyl alcohol it yields phenyloxanthranol methyl ether.

Methylphenylanthracene (Hemilian, Ber. 16, 2367)  is formed by the distillation of methylphenylanthranol with zinc-dust (*v. infra*). It crystallises from alcohol in yellow crystalline masses (melting-point not given). The alcoholic solution fluoresces greenish-blue. It is readily oxidised by CrO_3 and acetic acid to methylphenyloxanthranol



Methylphenylanthranol

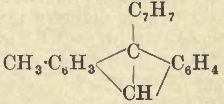


is similarly prepared by heating methyltriphenylmethane carboxylic acid

$$(C_6H_5)_2CH{\cdot}C_6H_3(CH_3)COOH$$

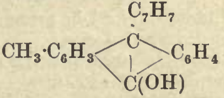
with sulphuric acid to 100°. It crystallises from alcohol in glittering plates, which on heating become brown at 130°, and melt at 156°–157°. It is readily soluble in ether, boiling alcohol, and glacial acetic acid.

Methyl-*p*-tolylanthracene



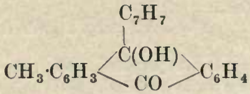
(Limpricht, Annalen, 299, 291) is obtained by the distillation of methyl-*p*-tolyloxanthranol with zinc-dust in a stream of hydrogen. It forms yellow needles of m.p. 191°. On oxidation with chromic acid in acetic acid solution, it yields methyl-*p*-tolyloxanthranol.

Methyl-*p*-tolylanthranol



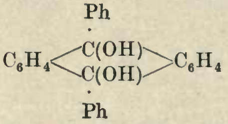
This substance is easily produced by dissolving di-*p*-tolylphenyl methane *o*-carboxylic acid in concentrated sulphuric acid. On pouring the solution into water, small yellow crystals, melting at 117°, separate. The compound is easily changed to

Methyl-*p*-tolyloxanthranol



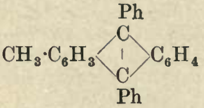
by oxidation with chromic acid. This derivative crystallises from toluene in colourless needles, melting at 206°.

9 : 10 - **Diphenyl** - 9 : 10 - **dihydroxydihydroanthracene**



(Haller and Guyot, Compt. rend. 138, 327). This compound is produced in 10 p.c. yield by the action of magnesium phenyl bromide on anthraquinone. It crystallises from methyl alcohol in colourless needles, containing solvent of crystallisation. This is lost on exposure to air, the crystals falling to a white powder, melting at 247°. The solution in sulphuric acid is indigo blue, changing to orange-yellow on heating. The colourless solution in glacial acetic acid exhibits blue fluorescence.

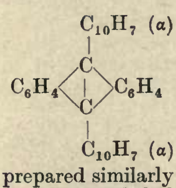
2-**Methyl**-9 : 10-**diphenylanthracene**



(Guyot and Staehling, Bull. Soc. chim. [iii.] 33, 1104). When phenyl magnesium bromide acts on 2-methylanthraquinone the product varies according to the conditions employed. If the organo-metallic derivative is slowly added to a benzene solution of the quinone, then Hemilian's 2-methyl-9-phenyloxanthranol (*v. supra*) is the main product. On boiling the quinone with a solution of magnesium phenyl bromide for many hours, then 2-methyl-9 : 10 - diphenyl - 9 : 10 - dihydroxydihydroanthracene is produced. This crystallises in cubes and melts at 240°. On treatment with zinc-dust in acetic acid solution it is reduced to 2-methyl-9 : 10-diphenylanthracene.

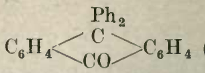
The latter crystallises from benzene and alcohol in yellow green dichroic plates, melting at 213°, and soluble in organic solvents with intense violet-blue fluorescence. Chromic acid changes it to 2-methyl-9 : 10-diphenyl-9 : 10-dihydroxydihydroanthracene.

Di-α-naphthylanthracene



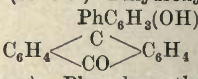
(Guyot and Staehling, *l.c.*) is prepared similarly to the above diphenyl derivative. α-Naphthyl magnesium bromide and anthraquinone yield 9 : 10 - di-α-naphthyl - 9 : 10 - dihydroxydihydroanthracene, which forms colourless crystals from toluene, and contain 1 molecule of toluene of crystallisation. It dissolves in sulphuric acid with a malachite-green colour. Di-α-naphthylanthracene is obtained from this di-ol by reduction with zinc and acetic acid. It forms yellow crystals, soluble in benzene, and exhibiting a most intense violet fluorescence.

Diphenylanthrone



(Haller and Guyot, Bull. Soc. chim. 1897, [iii.] 17, 873). This compound is obtained by the action of aluminium chloride on a benzene solution of phthalyltetrachloride. The latter may be replaced by anthraquinone chloride or phenyloxanthranol chloride, which are probably intermediate products of the reaction. The substance crystallises from acetic acid in colourless needles, or from benzene in large transparent prisms, melting at 192°. Although undoubtedly a ketone, it does not react with phenylhydrazine. It forms a molecular compound with nitrobenzene.

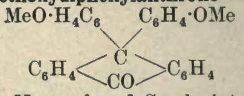
2′ : 4′- (or 3′5′) **Dihydroxy** - 9 : 9 - **diphenylanthrone**



(Liebermann and Lindenbaum). Phenyloxanthranol chloride (*v. supra*) furnishes this substance when it is treated with resorcinol in boiling benzene solution. Other phenols react similarly. The resorcinol derivative crystallises from alcohol in the form of colourless needles, which, when heated, lose solvent at 125°, and then melt at 259°–261°. The solution in concentrated sulphuric acid is yellow. On boiling with acetic anhydride and sodium acetate a diacetate is produced, and this compound crystallises from alcohol in plates and melts at 191°.

Scharwin and Kusnezof (Ber. 36, 2020) have condensed anthraquinone with phenols and with resorcinol, using for the former condensation, tin tetrachloride, and for the latter, zinc chloride. The substances produced are hydroxy derivatives of diphenylanthrone.

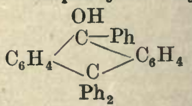
***p*-Dimethoxydiphenylanthrone**



(Scharwin, Naumof and Sandurin).

Anthraquinone chloride condenses with anisole to form this substance, when the solution of the mixture in carbon disulphide is treated with aluminium chloride. It crystallises from alcohol in yellow rhombohedra of m.p. 208°. It is soluble in the usual organic solvents, and in sulphuric acid with red-violet colour. On hydrolysis with aluminium chloride it yields phenolanthraquinone identical with the product obtained by Scharwin and Kusnezof (*l.c.*) from anthraquinone and phenol.

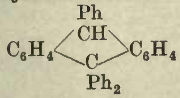
9 : 10 : 10 - **Triphenyl** - 9 - **hydroxydihydroanthracene**



(Haller and Guyot, Compt. rend. 139, 9). This substance can be obtained by dropping a benzene solution of diphenylanthrone (*v. supra*) into an ethereal solution of magnesium-phenyl bromide. After the addition of water, and acidification, the solvent is evaporated, when the carbinol crystallises in colourless voluminous needles, which contain 1 molecule of ether of crystallisation. This is removed at 120°, and the substance then melts at 200°. It dissolves in sulphuric acid with orange-red colour.

The methyl ether is obtained by adding methyl alcohol containing hydrochloric acid to the boiling toluene solution of the carbinol. The colourless leaflets melt at 218°. The corresponding ethyl ether melts at 250°.

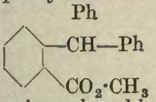
Triphenyldihydroanthracene



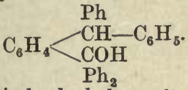
is prepared—

(*a*) By boiling the above carbinol or its ethers with zinc-dust and acetic acid.

(*b*) Methyltriphenylmethane-*o*-carboxylate



reacts with magnesium-phenyl bromide, yielding the tertiary alcohol and



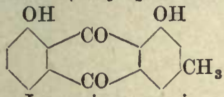
$$C_6H_4 \langle \begin{matrix} \overset{Ph}{CH}—C_6H_5. \\ \underset{Ph_2}{COH} \end{matrix}$$

This crystallises from methyl alcohol as its methyl ether, m.p. 215°. The orange-red solution of this methoxyl compound in sulphuric acid quickly becomes colourless, and on dilution triphenyldihydroanthracene is precipitated. This last change is still better effected by the agency of hydrochloric acid in glacial acetic acid solution.

Triphenyldihydroanthracene forms colourless crystals from a mixture of benzene and alcohol, and melts at 220°. Its solution in sulphuric acid is colourless.

METHYLANTHRACENE DERIVATIVES OCCURRING IN NATURE.

Chrysophanic acid (*Chrysophan, Chrysophanol*)



Occurrence.—In various species of lichens, *Parmelia parietina* (Ach.), *Lecanora* (*Placodium*) *elegans* (Ach.), *Cassia speciosa* (Schrad.), *Rhamnus frangula* (L.), *Rhamnus Purshiana* (D.C.), (as glucoside), in the root of *Rumex obtusifolius* (L.), in senna leaves, and in Chinese rhubarb. From this latter source a definite glucoside chrysophanein $C_{21}H_{20}O_9$ has been isolated by Gilson (Arch. internat. de Pharmako-dynamie et de Therapie, 1905, vol. 14, 487).

Preparation.—Chrysophanic acid is usually obtained by the oxidation of chrysarobin (*v. infra*) (Liebermann, Seidler, Annalen, 212, 36), which is mixed with dilute potassium hydroxide solution and a current of air passed until the liquid has acquired a deep reddish colour. The quinone is precipitated into HCl and extracted with ligroin (b.p. 50°–60°). On evaporation of the solvent a yellow residue is obtained which can be crystallised from alcohol. The melting-points found for chrysophanic acid by various authors range from 154° to 190°, and this has been shown to be due to the fact that the substance commonly contains an admixture of its methyl ether. Repeated crystallisation leads to a product containing only 0·36 p.c. methoxyl, and this melts at 188°. Oesterle (Arch. Pharm. 243, 434) obtained a methoxyl free chrysophanol by treatment with anhydrous aluminium chloride in benzene solution. After crystallisation from ligroin, alcohol, and benzene, the pure chrysophanol melted at 196°. This melting-point was also found by Gilson (*l.c.*) for the hydrolysis product of the pure glucoside chrysophanein. The analysis of the pure substance agreed excellently with the formula $C_{15}H_{10}O_4$. As ordinarily obtained chrysophanol crystallises in orange needles, which sublime, partially with decomposition, in the same form. The methoxyl free substance consists of shining brown-yellow leaflets, when crystallised from benzene. It is almost insoluble in water, but soluble in ether, benzene, and glacial acetic acid. It is difficultly soluble in ammonia and alkaline carbonates, but readily so in potassium hydroxide, forming a deep-red solution. Distilled with zinc-dust chrysophanic acid yields methylanthracene (Liebermann, Annalen, 183, 169).

The absorption spectrum of a solution of chrysophanic acid (Liebermann and Kostanecki, Ber. 19, 2330) in sulphuric acid, which resembles very closely that of chrysazin, is shown in Fig. 4.

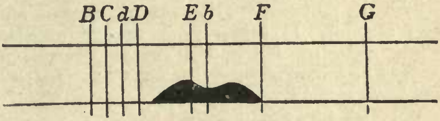


FIG. 4.

Since chrysophanic acid diacetate is converted by oxidation, with chromic acid in acetic acid and acetic anhydride solution, into diacetyl rhein, the positions of the groups are evidently identical in the two substances.

Derivatives of chrysophanic acid. *Tetranitrochrysophanic acid* (Liebermann and Giesel, Annalen, 183, 175) is obtained when chrysophanic acid is warmed with concentrated nitric acid. It occurs in yellow micro leaflets, which decompose on heating. The substance is quite insoluble in water, soluble in acetic acid, and behaves as a strong acid. It resembles chrysammic acid.

Amino derivatives. Aminodeoxychrysophanic acid (Liebermann and Giesel, *l.c.*) was obtained by heating chrysophanic acid with concentrated ammonia at 200°, or by leaving the acid with strong ammonia for a long time at the ordinary temperatures (Hesse, Annalen, 309, 32). It is a cherry-red powder forming easily soluble purple-violet salts with alkalis. It is sparingly soluble in ether, comparatively readily so in alcohol. In this compound, either one of the hydroxy groups of the chrysophanic acid is replaced by amino, or one of the carbonyl oxygens by imino.

Diamino-de-dioxy-chrysophanic acid (Liebermann and Giesel, *l.c.*) is obtained when chrysophanic acid is heated at 150° with a small quantity of aqueous ammonia. Since this substance is soluble in alkalis it may probably be more correctly designated as diiminochrysophanic acid. On boiling with acetic anhydride it yields acetylchrysophanic acid imide (so called) having the composition $C_{15}H_8(C_2H_3O)NO_2$. This substance crystallises from chloroform in violet needles, having a metallic reflex.

Monoacetylchrysophanic acid $C_{15}H_9(C_2H_3O)O_4$ (Hesse, *l.c.*) is obtained by the action of acetic anhydride on chrysophanic acid. It is dissolved by gently warming and then allowed to remain 48 hours. It crystallises from acetic acid in yellow needles of m.p. 152°.

Diacetylchrysophanic acid $C_{15}H_8(C_2H_3O)_2O_4$ (Liebermann, *l.c.*) is the product when chrysophanic acid is boiled with sodium acetate and acetic anhydride. Oesterle (*l.c.*) gives the melting-point of the pure substance as 208°. It crystallises in light yellow leaflets, and can be oxidised by chromic acid to diacetyl rhein (Fischer, Falco and Gross, J. pr. Chem. 1911, [ii.] 83, 208).

Dibenzoylchrysophanic acid $C_{15}H_8(C_7H_5O)_2O_4$ (Warren de la Rue and Müller, J. 1862, 323) obtained by the Schotten-Baumann reaction, crystallises in pale yellow needles, melting at 200°–208° (Tutin and Clewer, Chem. Soc. Trans. 99, 956).

Chrysophanic acid monomethyl ether

$$C_{15}H_8O_2(OH)(OCH_3)$$

(Oesterle, *l.c.*) is the main product when chrysophanic acid is methylated by means of methyl sulphate and potassium hydroxide. After a process of purification, it can be crystallised from alcohol. It forms clear orange needles which melt at 204°. Its acetyl derivative consists of lemon yellow needles when crystallised from alcohol, m.p. 204°.

Chrysophanic acid dimethyl ether

$$C_{15}H_8O_2(OCH_3)_2$$

is also produced when the acid is treated with a large excess of methyl sulphate and alkali. It crystallises in orange needles, m.p. 195°, either from acetic acid or aqueous alcohol. It dissolves with red colour in concentrated sulphuric acid.

Chrysophanein (Gilson, *l.c.*) is as already mentioned the glucoside of chrysophanic acid. It crystallises in needles from 92 p.c. alcohol and melts at 242°–249°. It is tasteless, and this in conjunction with its other properties renders the formulation of barbaloin as a glucoside of aloemodin and arabinose open to criticism.

Chrysophanhydranthrone $C_{15}H_{12}O_3$. Since chrysarobin (*see* below) gave chrysophanic acid on oxidation, attempts were made to realise the reverse process. Liebermann (Ber. 21, 436) reduced chrysophanic acid with tin and hydrochloric and acetic acids, and obtained a compound which crystallised from benzene in yellow leaflets and melted at 196°. It was not chrysarobin and was termed chrysophanhydranthrone. Hesse (Annalen, 284, 194) obtained the same substance by heating chrysophanic acid with hydriodic acid. Jowett and Potter (Chem. Soc. Trans. 1902, 1584) obtained in this reaction chrysarobin; but Hesse obtained chrysophanhydranthrone by heating chrysarobin with concentrated hydrochloric or hydriodic acid. The melting-point of the pure hydranthrone is 205°–210°. On distillation with zinc-dust β-methylanthracene is obtained. It yields a diacetyl derivative which crystallises from acetic acid in needles of m.p. 238°–240°.

Chrysarobin $C_{15}H_{12}O_3$ (?). This derivative of chrysophanic acid is a remedy indispensable to the dermatologist, and was first obtained from Goa powder by Attfield (Pharm. J. 5, 721) by extraction with chloroform. Liebermann and Seidler (Annalen, 212, 34) prepared the compound in a pure condition. The so-called Goa powder separates out in the pith hollows of certain trees belonging to the genus *Andira* in Brazil and India. It is extracted with benzene, the solution evaporated, and the residue repeatedly crystallised from glacial acetic acid. Small yellow needles, m.p. 170°–178°. Insoluble in water and ammonia, difficultly soluble in alcohol and ether, more readily soluble in benzene, glacial acetic acid, and chloroform. Insoluble in very dilute potassium hydroxide, but soluble with a dark-green fluorescence in strong solutions. This solution is readily oxidised by the oxygen of the air, yielding chrysophanic acid. Distilled with zinc-dust, chrysarobin yields methyl anthracene. Chrysarobin has no dyeing properties. It may be the anthranol of chrysophanic acid, although a double molecular formula has been ascribed to it by several authors.

The acetyl derivatives of chrysarobin and of the dichrysarobin obtained by heating the solution in acetic acid have been carefully investigated by Hesse (Annalen, 309, 60).

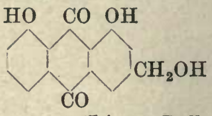
Monoacetyl derivative is obtained by 3–4 hours' boiling with acetic anhydride. The yellow leaflets obtained on crystallisation from acetic acid melt at 188°–190°.

Diacetyl derivative is produced when chrysarobin is boiled 6 hours with acetic anhydride. It crystallises in rhombic prisms, m.p. 216°; the solutions fluoresce blue. A β-diacetate of m.p. 265°–270° has also been isolated.

Triacetyl chrysarobin can be prepared by heating either chrysarobin or chrysophanhydranthrone with acetic anhydride and sodium acetate for 1 hour. It crystallises in prisms, m.p. 234°.

Hexaacetyl dichrysarobin is produced by boiling chrysarobin with sodium acetate and acetic anhydride for many hours. It is amorphous, and melts at 125°.

Aloemodin



Aloemodin occurs (Léger, Bull. Soc. chim. [iii.] 23, 785) together with barbaloin and *iso*-barbaloin in Barbados aloes, and in smaller quantities in all other varieties of aloe.

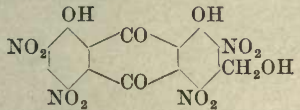
It may be prepared best by the action of alcoholic hydrochloric acid on barbaloin (Oesterle, Arch. Pharm. 237, 699). The dried reaction product is extracted with hot toluene, the solution treated with animal charcoal and concentrated; when on cooling orange-yellow needles separate. The substance is purified by many recrystallisations from toluene and from acetic acid. After sublimation the pure aloemodin melts at 224°. Léger, and Jowett and Potter have obtained aloemodin by the oxidation of barbaloin with sodium peroxide. Tetrachloraloemodin and tetrabromaloemodin are produced by the oxidation of tetrachlor- and tetrabrombarbaloins with the same reagent.

When heated with a little sulphuric acid and subsequently treated with dilute ammonia solution, aloemodin gives a violet colour; frangula emodin under the same conditions gives a cherry red. Aloemodin when oxidised with chromic acid in acetic acid solution yields rhein $C_{15}H_8O_6$. This is a carboxylic acid, so that aloemodin $C_{15}H_{10}O_5$ must be recognised as the corresponding primary alcohol, and further as hydroxychrysophanic acid.

Diacetylaloemodin $C_{15}H_8O_5(COCH_3)_2$ is obtained by boiling aloemodin with acetic anhydride and sodium acetate for an hour. It crystallises from acetic acid in small yellow needles, m.p. 177°–178°. Although aloemodin yields a diacetate, tetrachloraloemodin has three hydroxyl groups which can be acetylated.

Tribenzoyl aloemoin $C_{15}H_7O_5(COPh)_3$ is obtained by the Schotten-Baumann reaction. It crystallises well from ethyl acetate as greenish-yellow micro leaflets, m.p. 235°.

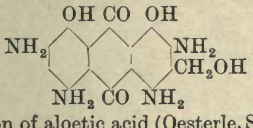
Tetranitroaloemodin



is the so-called *aloetic acid,* which is obtained together with chrysammic acid, by the action of nitric acid on barbaloin. The substance was first obtained by Scheele, who termed it aloë bitter, and subsequently by a number of chemists, but it was first isolated in the pure condition by Mulder (Annalen, 1849, 72, 286). Oesterle proved that the substance is tetranitroaloemodin since he applied to it the process by which Liebermann and Giesel (Annalen, 183, 184) converted chrysammic acid into chrysazin, and obtained aloemodin.

Aloetic acid is a yellow crystalline powder which becomes red on standing in the air. It is fairly soluble in water to an intense red solution. It is also soluble in ether, chloroform, alcohol, benzene, and ethyl acetate. Léger (Compt. rend. 1911, 153, 114) finds that on further oxidation with nitric acid, aloetic acid yields chrysammic acid and 2 : 4 : 6-trinitrometahydroxybenzoic acid.

Hydroaloetic acid



The reduction of aloetic acid (Oesterle, Schweizer Wochenschr. f. Ch. u. Ph. 1906, No. 31) is accomplished by an aqueous solution of potassium hydrogen sulphide. Hydroaloetic acid is a blue-black amorphous substance very sparingly soluble in most solvents. The solution of the substance in concentrated sulphuric acid was treated with nitrous fumes and then boiled with an excess of alcohol. It was found possible to isolate aloemodin by acetylating the product, purifying the diacetate and hydrolysing with alcoholic potash. The aloemodin obtained melted at 223°.

Frangula emodin (emodin)

$C_{15}H_{10}O_5$, or $C_{14}H_4(CH_3)(OH)_3O_2$

(position of OH groups unknown, but probably the same as those in flavopurpurine).

Occurrence.—In rhubarb root, the bark of the alder tree, in *Rhamnus Purshiana* (D.C.) (cascara sagrada) and *Rhamnus cathartica* (Linn.).

Preparation.—Alder bark is extracted with dilute sodium hydroxide, the solution precipitated with HCl, and the precipitate purified by repeated recrystallisation from absolute alcohol.

Orange-red, silky needles, m.p. 245°–250° (Liebermann, Annalen, 183, 161).

Moderately soluble in benzene, more readily so in alcohol and acetic acid; soluble in dilute ammonia, forming a cherry-red solution. Does not dye mordanted cloth. Distilled over zinc-dust β-methylanthracene results. The absorption spectrum of a solution in concentrated sulphuric acid is shown in Fig. 5 (Liebermann and Kostanecki, Ber. 19, 2330):

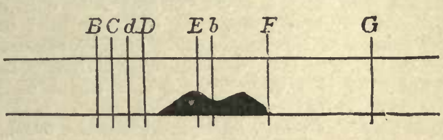


FIG. 5.

and closely resembles that of flavopurpurin.

The triacetate (Liebermann, *l.c.*)

$C_{15}H_7(C_2H_3O)_3O_5$

crystallises from acetic acid in yellow needles, m.p. 190°.

Tribenzoate. Tutin and Clewer (Chem. Soc. Trans. 99, 954) obtained this derivative by applying the Schotten-Baumann reaction to emodin. It crystallises from glacial acetic acid in small pale yellow needles, and melts at 186°.

Dibenzoyl emodin, m.p. 225°, has also been described, but there appears to be some uncertainty as to its existence.

Emodinmonomethyl ether

$CH_3{\cdot}C_{14}H_4O_2(OH)_2OCH_3$

was found by Perkin and Hummel in *Ventilago maderaspatana* (Chem. Soc. Trans. 65, 940), by Tutin and Clewer in rhubarb root and in *Rumex Ecklonianus* (Meissn.), whilst Oesterle and Johann (Arch. Pharm. 1910, 248, 476) show that it is the methylated compound usually associated with chrysophanic acid.

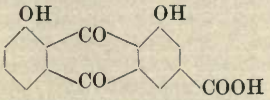
Jowett and Potter (Chem. Soc. Trans. 1903, 77, 1330) obtained the substance by heating the potassium salt of emodin with methyl iodide. It crystallises from benzene in long, orange-red needles, m.p. 200°. It is sparingly soluble in alcohol or acetone. A nitro derivative melts at 217°, and a tetranitro derivative at 275° with decomposition. The former is obtained by using nitric acid of sp.gr. 1·42, the latter when nitric acid (sp.gr. 1·54) is employed.

Its diacetate crystallises in golden needles, m.p. 185°, and the dibenzoate prepared by the Schotten-Baumann method melts at 228°.

Frangulin. This emodin derivative was first obtained in a pure condition by Casselmann (Annalen, 104, 77), although Binswanger (Repert, Pharm. 104, 151) had previously obtained it in a crude state from the bark of *Rhamnus frangula* (Linn.). It crystallises from alcohol in lemon-yellow, silky needles, melting at 226°. Acids hydrolyse it with formation of emodin and rhamnose so that the body is a rhamnoside of emodin. Its precise composition is at present uncertain. *Polygonin* is another glucoside of emodin, although the nature of the sugar is unknown. It was extracted by A. G. Perkin from *Polygonum cuspidatum* (Sieb. et Lucc).

(Chem. Soc. Trans. 67, 1084). It crystallises in slender, orange-yellow needles, m.p. 202°–203°.

Rhein



Rhein occurs in rhubarb, from which it was first isolated by Hesse (Annalen, 1899, 309, 43). He gave it the formula $C_{15}H_{10}O_6$, and considered it a tetrahydroxymethylanthraquinone. Tschirch and Heuberger (Arch. Pharm. 1902, 240, 611), however, made analyses from which they concluded that rhein is $C_{15}H_8O_6$, and since only a diacetate could be prepared, they assigned to the substance the constitution of a methylene ether of a tetrahydroxyanthraquinone. In support of this view it was also urged that on distillation with zinc-dust rhein yields anthracene. Oesterle and Tisza (Schweiz. Woch. Chem. Pharm. 1908, 46, 701) carefully purified rhein, by crystallisation from pyridine, and sublimation in cathode ray vacuum, and support the empirical formula of Tschirch and Heuberger. Rhein is best prepared by the oxidation of barbaloin or the acetyl derivative of barbaloin. Oesterle (Schweiz. Woch. f. Chem. Pharm. 1903, 50) obtained a small yield by oxidising barbaloin with chromic acid in aqueous solution, but when tetraacetylbarbaloin is oxidised with chromic acid in acetic anhydride solution, a 50 p.c. of diacetylrhein is easily obtained, and rhein is thus shown to be a dihydroxyanthraquinone carboxylic acid (Robinson and Simonsen, Chem. Soc. Trans. 95, 1085). Rhein crystallises from pyridine in combination with a molecule of the solvent in glistening orange needles. These fall to a powder at 130°, and the pure rhein then melts at 318° (Tutin and Clewer, *l.c.*). Oesterle's purest rhein melted at 321°–321·5°. It is sparingly soluble in organic solvents, but dissolves readily in sodium carbonate solution. It dyes both mordanted and unmordanted wool clear yellow shades.

Diacetate. Various melting-points have been assigned to this substance ranging from 236° to 258°. The latter value is probably correct, and was obtained by Tutin and Clewer (*l.c.*), who prepared this derivative by heating rhein with a large excess of acetic anhydride and a little camphor sulphonic acid. After concentration the compound separates in rosettes of pale yellow needles, m.p. 258°. It is soluble in sodium carbonate solution, and on hydrolysis with alcohol and sulphuric acid yields the ester of rhein.

Dibenzoyl rhein (Tutin and Clewer, *l.c.*) obtained by the Schotten-Baumann reaction, crystallises from acetic acid in yellow-brown prisms, m.p. 262°.

Rhein methyl ester $C_{14}H_5O_2{\cdot}(OH_2){\cdot}CO_2Me$ (Robinson and Simonsen, *l.c.*) forms deep orange needles by crystallisation from methyl alcohol, and melts at 174°. It is insoluble in sodium carbonate solution.

Rhein ethyl ester $C_{14}H_5O_2{\cdot}(OH)_2CO_2Et$ is obtained by esterifying either rhein or diacetyl rhein with alcohol and sulphuric acid. Orange needles from alcohol, m.p. 159°. It yields a diacetate, melting at 170°, which is quite insoluble in cold aqueous potash.

Dimethylrhein $C_{14}H_5O_2(OMe)_2COOH$ (Robinson and Simonsen, *l.c.*) is prepared by treating an alkaline solution of rhein with methyl sulphate in the cold. The substance was isolated by means of its sparingly soluble potassium salt. It crystallises from alcohol in light brown needles, and melts when pure at 283°–284°. It dissolves in alkali to orange-yellow solutions, and can be neither acetylated nor benzoylated. Its ethyl ester melts at 185°–187°, and is insoluble in alkalis.

Dimethyl rhein chloride $C_{14}H_5O_2(OMe)_2COCl$ is produced from the acid by the action of thionyl chloride. It is crystallised by adding ligroin to its solution in chloroform. Canary-yellow prisms melting at 190° are obtained. On treatment with ammonia—

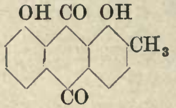
Dimethyl rhein amide

$$C_{14}H_5O_2(OMe)_2{\cdot}CO{\cdot}NH_2$$

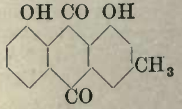
is obtained. This very insoluble substance can be crystallised from a large quantity of ethyl acetate. It occurs in microscopic hexagonal plates, m.p. 287°. It is a fact of great importance that this amide undergoes the Hofmann reaction, and can be converted in this way into an aminodimethoxyanthraquinone, which, after removal of the amino group and demethylation, yields chrysazin. Rhein is thus chrysazin carboxylic acid.

CONSTITUTION OF CHRYSOPHANIC ACID, ALOEMODIN, AND RHEIN.

The relationship of chrysophanic acid, aloemodin, and rhein is expressed by the scheme, RCH_3, $RCH_2{\cdot}OH$, RCOOH, since both chrysophanic and and aloemodin yield rhein on oxidation and rhein is a carboxylic acid (Robinson and Simonsen, *l.c.*). Now chrysophanic acid is derived from β-methylanthracene whilst rhein can be degraded to chrysazin. Accepting the usual 1 : 8-configuration for chrysazin, this leaves two possible formulæ for chrysophanic acid, namely—



and



That the latter (and therefore the corresponding formulæ for aloemodin and rhein) must be taken as correct is proved by the fact that aloetic acid (*see* above) is oxidised by nitric acid with formation of 2 : 4 : 6-trinitro-*m*-hydroxybenzoic acid. W. H. P. & R. R.

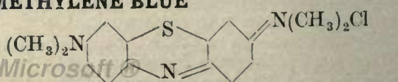
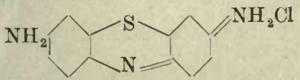
METHYLDIPHENYLAMINE *v.* DIPHENYLAMINE.

METHYLENE BLUE

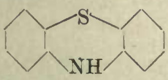


A colouring matter first obtained by Caro in

1876 by the oxidation of dimethyl-*p*-phenylenediamine in presence of sulphuretted hydrogen. By treating *p*-phenylenediamine with sulphuretted hydrogen and oxidising agents, or by heating it with sulphur and subsequently oxidising, Lauth obtained a violet basic colouring matter containing sulphur, known as 'Lauth's violet' or thionine.



The comparatively small yield of the colouring matter (15–20 p.c. of the *p*-phenylenediamine taken), together with the difficulties attending the preparation of the materials required, prevented its manufacture on the large scale. Lauth's reaction, however, became of industrial importance through Caro's discovery of the method of manufacture of nitrosodimethylaniline whereby it was readily possible to obtain dimethyl-*p*-phenylenediamine. This compound, when treated by Lauth's reaction, gave rise to a methylated Lauth's violet, which differed from the parent substance in being of a pure blue colour, and also in being more easily obtained and in much larger quantity. The new colouring matter came into commerce under the name of *Methylene blue.*[1] Its constitution, together with its relation to Lauth's violet (thionine), was first established by Bernthsen (Annalen, 1885, 230, 73). He showed that both these substances were derived from thiodiphenylamine



from which by nitration, reduction, and subsequent oxidation, Lauth's violet could be obtained, methylene blue being the tetramethyl derivative.

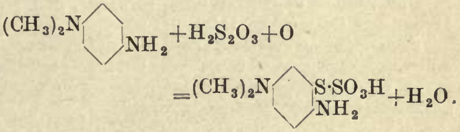
The method of manufacturing methylene blue formerly adopted by the Badische Anilin und Soda-fabrik (Eng. Pat. 3751, 1887; D. R. P. 1886; Amer. Pat. 204796; *cf.* also Mühlhäuser, Dingl. poly. J. 1886, 262, 371) consists in reducing nitrosodimethylaniline $NO{\cdot}C_6H_4{\cdot}N(CH_3)_2$, made by the action of sodium nitrite on dimethylaniline by means of zinc or sulphuretted hydrogen; the dimethyl *p*-phenylenediamine so obtained is treated in dilute acid solution with sulphuretted hydrogen and some oxidising agent (*e.g.* ferric chloride)

$$2C_8H_{12}N_2+H_2S+3O+2HCl$$
$$=C_{16}H_{18}N_3SCl+NH_4Cl+3H_2O.$$

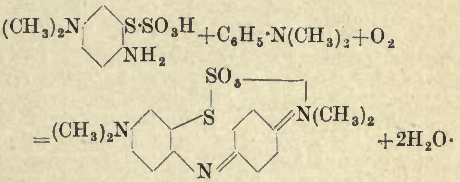
By the gradual addition of the ferric chloride the liquid becomes deep blue, and the resulting colouring matter is 'salted out' by adding common salt and zinc chloride, and purified by re-solution in water and 're-salting out.' This double salt, which constitutes the methylene blue of commerce, crystallises in copper-coloured crystals, readily soluble in pure water, but sparingly soluble in solution of zinc chloride.

Tetramethyldiaminodiphenylamine when oxidised in presence of sulphuretted hydrogen yields only traces of methylene blue. Similarly in the simultaneous oxidation of dimethyl-*p*-phenylenediamine and dimethylaniline in presence of sulphuretted hydrogen, the dimethylaniline enters but slightly into the reaction. On the other hand, if the tetramethyldiaminodiphenylamine, or the mixture of dimethyl-*p*-phenylenediamine and dimethylaniline, is oxidised in presence of sodium thiosulphate, a peculiar sulphoacid results, which on boiling with acids decomposes into sulphur dioxide and *leuco-methylene blue.* By the oxidation of this body methylene blue is readily obtained (Ulrich, Eng. Pat. 43, 1886; D. R. PP. 38573, 39757). According to D. R. P. 38573 a mixture of the neutral salts of aminodimethylaniline and dimethylaniline is oxidised in presence of the thiosulphate; in No. 39757 a solution of nitrosodimethylaniline hydrochloride is heated with dimethylaniline and sodium thiosulphate.

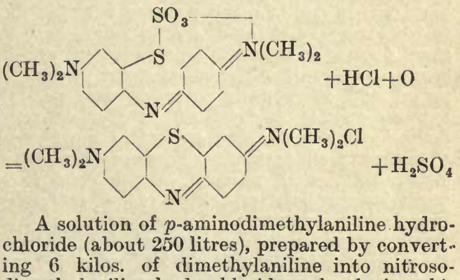
The process by which methylene blue is now manufactured (Eng. Pat. 10314, 1888; 8221, 1893; D. R. PP. 45839, 46085, 47374) is as follows: *p*-aminodimethylaniline (dimethyl-*p*-phenylenediamine) is mixed with sodium thiosulphate and the mixture oxidised by potassium dichromate to the thiosulphonic acid, thus—



Dimethylaniline is now added and the indamine is formed by oxidation with dichromate



The indamine is now boiled with dilute acid or zinc chloride solution whereby the colouring matter is formed



A solution of *p*-aminodimethylaniline hydrochloride (about 250 litres), prepared by converting 6 kilos. of dimethylaniline into nitrosodimethylaniline hydrochloride and reducing this with zinc-dust, is neutralised at 18°–20° with sodium hydroxide solution until a faint turbidity is produced. 16 kilos. of aluminium sulphate are now added, the mixture stirred for half an hour and then a concentrated solution of 13 kilos. of sodium thiosulphate is quickly poured in, followed at once by a solution of 4·8 kilos. of potassium dichromate in 75 litres

---

[1] Methylene blue appears on the market under this name and also with the following marks: 2B (Badische Co.); 2B powder extra (Berlin Co.); DBB zinc-free (Cassella & Co.); BG conc. zinc salt (Ter Meer); 4BE (Poirrier). It is manufactured in England by Read Holliday and Sons, Ltd., Huddersfield, and Claus and Co., Ltd., Manchester.

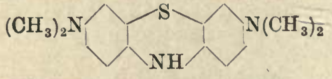
of water. In order to complete the formation of the thiosulphonic acid the mixture is stirred for an hour. The whole is diluted to 600 litres and 6 kilos. of dimethylaniline hydrochloride are added. For the preparation of the indamine a saturated solution of 14 kilos. of potassium dichromate is now run in quickly at a temperature of 10°–12°, the whole being well stirred, 75 kilos. of a solution of zinc chloride (sp.gr. 1·53) added and the mixture heated for half an hour to 100°. On cooling the precipitated methylene blue is filtered off and purified by redissolving and precipitating with zinc chloride. (The amount of potassium dichromate added in the last operation is sufficient both to form the indamine and to oxidise the leuco-methylene blue produced.)

By using methylethylaniline instead of dimethylaniline a much greener dyestuff is obtained (*Methylene blue, M.E.* Cain, 7th Int. Cong. App. Chem. London, 1909, sect. iv. B, 95).

(For the preparation of methylene blue on the laboratory scale see Cain and Thorpe, Synthetic Dyestuffs, 1905, 258; Möhlau and Bucherer, Farbenchemisches Praktikum, 1908, 262.)

Methylene blue may be estimated by titrating a boiling solution with titanous chloride in a current of carbon dioxide (Knecht, J. Soc. Dyers and Colourists, 1905, 21, 9).

Concentrated sulphuric acid dissolves methylene blue with a green colour. By reducing agents it is readily transformed into its leuco base, *tetramethyldiaminothiodiphenylamine*



This substance forms yellow needles, melting at 185° (Landauer and Weil, Ber. 1910, 43, 198); it rapidly oxidises on exposure to moist air, and is transformed into methylene blue.

Methylene blue is, with the exception of Victoria blue, the only basic blue colouring matter which has any technical importance, and it is preferable to Victoria blue on account of its greater fastness to light. It resists the action of neutral soaps and dilute solutions of chloride of lime. It is largely used in cotton-yarn dyeing and in calico-printing with tannin, or with tannin and tartar emetic mordants. It gives a greenish-blue inclining to indigo, and is frequently shaded with methyl violet, malachite green, and other basic colouring matters. It has no special applications in silk or wool dyeing. For pure blue cotton is mordanted with aluminium acetate, aged, passed through a chalk bath, well washed, passed through a weak tannin bath and dyed at a gradually increasing temperature. The colour is added in small portions to the dye-bath, which should not be warmer than 20°–25° at the beginning, and after some colour has been taken up it should be heated very gradually to 70°–80°, or higher if required; a small amount of acetic acid in the dye-bath acts favourably for level dyeing. For very dark indigo shades cotton, mordanted with tannin and antimony, may be passed through a weak solution of pyrolignite of iron; or a bath of pyrolignite of iron (6° Tw.) may be substituted for tartar emetic; after the treatment with iron liquor the cotton should be passed through weak lime water and finally well washed before dyeing (Knecht, Rawson and Loewenthal, A Manual of Dyeing, 2nd ed., 1910, 484). For method of detection on dyed fabrics, *v.* vol. ii. p. 298.

Methylene blue is of considerable value as a staining material in bacteriological and histological research; *v.* Ehrlich, Centralb. Medic. Wissensch. 1885; Dresser, Zeitsch. Biol. 1885, 41; A. B. Lee, The Microtomist's Vade-Mecum; J. W. H. Eyre, The Elements of Bacteriological Technique. J. C. C.

METHYLENE GREEN. A substance obtained by treating methylene blue with nitrous acid, or with nitric acid in sulphuric or acetic acid solution. It is a mono-nitro derivative of methylene blue. The leuco compound forms brown needles melting at 146°–147°. It is applied to cotton in the same way as methylene blue, and gives a full bluish-green shade.

METHYL*iso*PROPYL PROPIONIC ACID *v.* HEPTOIC ACIDS.

METHYLMALIC ACID *v.* MALIC ACID.

METHYLNAPHTHALENES. α- and β-methylnaphthalene occur in creosote oil (Schulze, Ber. 1884, 17, 842, 1527), and, together with naphthalene and di-, tri-, and tetra-methylnaphthalene, in crude petroleum or naphtha (Tammann, D. R. P. 95579, 1897). The separation of these substances from their homologues can be effected either by fractional sulphonation or distillation, and their purification by means of picric acid (Tammann, *l.c.*; Wichelhaus, Ber. 1891, 24, 3918; Wendt, J. pr. Chem. 1892, [ii.] 46, 319). The azo dyes prepared from aminomethylnaphthalenes (Akt-G., D. R. P. 15647; Eng. Pat. 750, 1881) have no technical value.

α-Methylnaphthalene, b.p. 240°–242°, forms a *picrate* crystallising in needles, m.p. 116°–117° (Ciamician, Ber. 1878, 11, 272); a *nitro* derivative, b.p. 194°–195° under 27 mm. (Scherler, Ber. 1891, 24, 3932); and two isomeric *sulphonic acids*, separable by means of their barium salts (Wendt, *l.c.*).

β-Methylnaphthalene, monoclinic prisms, m.p. 32·5°, b.p. 240°–242°, forms a *picrate* crystallising in needles, m.p. 115° (Schulze, *l.c.*);

a *nitro* derivative, needles, m.p. 81° (*ibid.*), and two isomeric *sulphonic acids*, separable by means of their barium slats (Wendt, *l.c.*).

METHYL ORANGE *v.* Azo- colouring matters.

METHYLPHENYL HYDRAZINE *v.* Hydrazines.

METHYLPHENYL HYDRAZONES *v.* Hydrazones.

METHYL VIOLET *v.* Triphenyl methane colouring matters.

METHOXYBENZENE *v.* Anisole.

METOL. Trade name for methyl-*p*-aminophenol sulphate. Used as a photographic developer.

METOQUINONE. Trade name for a photographic developer obtained by the action of methyl-*p*-aminophenol sulphate (metol) on hydroquinone (quinol).

METTERNICH GREEN. A double salt of zinc chloride with the chlormethyl-hexamethyl rosaniline hydrochloride. Known also as *iodine green* or *night green.* Obtained by the action of methyl iodide or chloride upon rosaniline (Hofmann and Girard, Ber. 2, 442; Appenzeller, *ibid.* 6, 965).

MEXICAN ELEMI *v.* Oleo-resins.

MEXICAN MYRICA WAX *v.* Waxes.

MEZEREON RESIN *v.* Resins.

MIARGYRITE. Silver sulphantimonite $AgSbS_2$, occurring as small, usually indistinct, monoclinic crystals. These are black and opaque, with a metallic lustre, but thin splinters transmit a deep crimson colour; streak dark cherry-red; sp.gr. 5·2. Crystals were formerly found at Bräunsdorf, near Freiberg in Saxony, and compact masses of some size are met with in the silver mines of Bolivia. L. J. S.

MICA (Ger. *Glimmer*). A name applied to a group of minerals characterised by the facility with which they split into thin laminæ, which are flexible and more or less elastic. It is now believed that all micas belong to the monoclinic system, but the crystals often affect a hexagonal habit. The perfect cleavage, on which the micaceous structure depends, is parallel to the basal plane. A similar structure is seen in the group of chlorites, but their laminæ, though flexible, are not elastic. The hardness of the micas is between 2 and 3; while their sp.gr. ranges from 2·7 to 3·1. The optical characters and chemical composition are subject to considerable variation in different species. Broadly speaking, there is a group of potash-micas, generally of pale colour, and having the optic axes separated by wide angles; and a group of magnesian, or ferro-magnesian, micas, usually of dark colour, with the optic axes in some cases so close that the mineral becomes apparently uniaxial. On sharply striking a plate of mica with a needle-point, a six-rayed star is produced (*percussion-figure*); while pressure with a blunt instrument develops a similar figure (*pressure-figure*), having each ray at right angles to one in the percussion-figure.

All the micas are complex silicates, containing aluminium and potassium, generally with magnesium, but rarely with calcium. The potassium is frequently replaced in part by lithium and sodium, while iron may be substituted for the magnesium and aluminium. Water is always present, and many micas contain fluorine. The chemical constitution of the group of micas has been discussed by Rammelsberg (Min. Chem.) and by Tschermak (Zeitsch. Kryst. 1878, 2, 14; 1879, 3, 122), and later by F. W. Clarke (Amer. Chem. J. 1889, 38, 384; Bull. United States Geol. Survey, 1895, No. 125). The following analyses will serve to illustrate the composition of the principal species:—

—	I	II	III	IV
Silica . .	46·74	50·43	44·81	40·91
Alumina .	35·10	28·07	10·87	17·79

	102·21	98·94	99·17	98·72

I. Muscovite from Easton, Pennsylvania, by Rammelsberg. II. Lepidolite from Rozena, Moravia, by Reuter. III. Phlogopite from Edwards, St. Lawrence Co., New York, by Penfield; notable for the absence of fluorine. IV. Biotite from Vesuvius, by Chodnew.

Muscovite, or potash-mica $H_2KAl_3(SiO_4)_3$, is the common species widely distributed as a constituent of granite, gneiss, and mica-schist. It is usually white, grey, or yellow; and the angle of the optic axes may be as much as 70°. Some forms of muscovite have been mistaken for talc, as in the granitic rock of the Alps called protogine, and in certain so-called talc-schists. *Sericite* is a silky talc-like mica, occurring in the schists of the Taunus. A rare variety of muscovite containing 6 p.c. of baryta has been called *oellacherite* or baryta-mica. *Fuchsite*, or chrome-mica, of a bright-green colour, is a variety containing about 4 p.c. of chromic oxide. The *paragonite* of St. Gotthard, closely related to muscovite, is a soda-mica $H_2NaAl_3(SiO_4)_3$.

Lepidolite, or lithia-mica, with the approximate formula $KLi[Al(OH,F)_2]Al(SiO_3)_2$, is generally of peach-blossom colour, but sometimes grey or white, with a pearly lustre. It occurs in certain granites, especially with minerals containing fluorine, like topaz and tourmaline. Small amounts of rubidium and cæsium are sometimes present in lepidolite. The best-known locality for the typical kind is near Rozena in Moravia, where it forms a beautiful rock, occasionally polished as an ornamental stone. During recent years lepidolite has been extensively mined at Pala in California for the supply of lithium salts largely used in the manufacture of lithia-water. *Zinnwaldite* is a greyish lithia-bearing mica, occurring in the tin-mining districts of Saxony, Bohemia, and Cornwall.

Phlogopite $[H,K,(MgF)]_3Mg_3Al(SiO_4)_3$ includes certain magnesian micas, usually of reddish or bronze colour, occurring in crystalline limestone and in serpentine. The angle of the optic axes ranges from 0° to 17°. It is notable that certain phlogopites exhibit by transmitted light luminous stars, due to the presence of multitudes of included acicular crystals definitely orientated; the best examples of this asteriated mica being yielded by some of the Laurentian limestones of Canada. The mica mined in Canada and Ceylon for commercial purposes is phlogopite.

Biotite includes a number of magnesian and ferro-magnesian micas, generally of dark colour, and transparent only in thin laminæ. Frequently occurring in six-sided plates, and having a very small optic angle, they were formerly referred to the hexagonal system. In thin sections they exhibit strong pleochroism. They are generally denser than muscovite, and their cleavage-laminæ are less elastic. Biotite is often found, in association with muscovite, in granite, gneiss, and mica-schist, and the two micas are sometimes closely intergrown. The biotitic micas also occur in mica-syenite, mica-porphyry, and trachyte; while sharply developed crystals are not uncommon in the ejected blocks of Monte Somma. The Vesuvian dark micas were termed by Breithaupt *meroxene*, and this name has been revived by Tschermak for all the true biotites, while he uses the term *anomite* to distinguish a similar mica, differing only in optical characters. *Rubellane*, an opaque red mica from certain volcanic rocks, is merely an altered biotite, which has lost its elasticity. In *lepidomelane*, the aluminium of an ordinary biotite is largely replaced by iron, and the mica becomes black and is attracted by a powerful magnet. Heddle's *haughtonite*, of the Scottish granites, differs from biotite by containing less magnesium, and from lepidomelane by having most of its iron in the condition of FeO, the average percentage of this oxide being 17·22.

The vanadium-mica, or *roscoelite*, occurring with gold ores in California and Colorado, contains as much as 28·85 p.c. V_2O_3. *Margarite*, or lime-mica, $H_2CaAl_4Si_2O_{12}$ is sometimes placed in the mica group, though more usually it is classified with the clintonites or 'brittle micas.'

The mica of commerce comes mostly from India, the United States, and Canada. Large sheets of sufficient purity to be profitably worked are of very limited occurrence; they are usually found in veins of pegmatite or giant granite, where the constituents crystallise on a large scale, and are often associated with rare minerals such as beryl and columbite. In India the chief mica-mining districts are those of Hazáribágh in Bengal and of Nellore in Madras; from the former the mica (muscovite) is usually of a pale ruby tint, and from the latter of a greenish shade. In the Inikúrti mine, Nellore, 'books' of mica measuring 10 feet across the basal plane and up to 15 feet across the folia have been found. Rectangular sheets measuring 30×24 inches and free from flaws have frequently been obtained. A single mica crystal from North Carolina has been known to weigh nearly 2000 pounds. Mica has been worked at Alstead, in New Hampshire, where sheets have been found measuring 4 feet across. Mining for mica has also been carried on in the Black Hills of South Dakota, in Virginia, and in New Mexico. Several mines have now been opened up in the Uluguru Mountains, in German East Africa.

Of the various micas, muscovite and phlogopite are the only ones of commercial importance; and these, strangely enough, often pass in trade under the name of 'talc.' Muscovite was formerly called 'Muscovy glass,' in allusion to its use in Russia as a substitute for window-glass. At the present day it is employed chiefly as a transparent fire-resisting medium in the doors of stoves and furnaces, and for lamp-shades and gas-covers. It is also used for the dial-plates of compasses, while in the East, especially in India, it is applied to various ornamental purposes. Paintings on mica, executed by native artists, are well known to collectors. Sheets of mica, used as a decorative material, have been found in the prehistoric mounds of the Mississippi Valley.

The preparation of mica for the market is very simple. The blocks of rough mica, having been freed from associated minerals, or dressed, are split into plates, which are then 'scribed,' or marked out into patterns, and along this scribing the mineral is cut by means of shears. A good deal of refuse is necessarily produced. This mica-waste is ground and used as a lubricating agent, and as an absorbent for nitroglycerin in the preparation of certain explosives; it has also been employed in the ornamentation of wall-papers, and to a limited extent as a substitute for asbestos.

Many other practical uses of mica might be mentioned. Its most extensive application at the present day depends on the fact that it is a bad conductor of electricity. The smooth, flexible sheets are used in the construction of the armatures of dynamos and in other parts of electrical machinery. Extensive use is also made for insulating purposes of a manufactured material known as *micanite* or *micanite cloth*. This consists of scraps of mica cemented by shellac on to cloth or paper.

MICA POWDER *v.* Explosives.

MICACEOUS IRON ORE *v.* Hæmatite; also Iron.

MICHLER'S KETONE *v.* Ketones.

MICROBALANCE. Nernst and Riesenfeld (Ber. 1903, 36, 2086) described a torsion balance sensitive to 0·0005 mgrm. with a load of several milligrams (for applications of same, *v.* Jänecke, Zeitsch. anal. Chem. 1904, 43, 547; Brill, Ber. 1905, 38, 140; Brill and Evans, Chem. Soc. Trans. 1908, 93, 1442). The zero of this balance is inconstant, and its sensitiveness varies greatly with the load. Ordinary gravity balances have been made by Steele and Grant (Proc. Roy. Soc. 1909, A. 82, 580), and modified by Gray and Ramsay (*ibid.* 1911, A. 84, 536; 1912, A. 86, 270) to carry loads ranging from 1 or 2 mgrms. to 1 decigram with a sensitiveness of 1×10^{-7} to 4×10^{-9} grm. The zeros of these balances remain constant over long periods of time.

The beam (Fig. 1) consists of a framework of thin silica rods, total length 10 cms. (Fig. 2 (*a*) shows a more rigid beam); it turns on a compound quartz knife-edge resting on a quartz plate A at the top of the brass pillar B. The vibrations of the balance are followed by passing a beam of light, from a Nernst lamp, through the window C in the side of the air-tight brass case, on to a tiny platinised quartz mirror, sealed to the balance frame at D so that it revolves with the latter without undergoing displacement. The light is reflected on to a mm. scale some distance away. The three-way tap E allows the interior of the balance case to be put into communication with either the atmosphere or a vacuum pump; the manometer F records the pressure within the case. A fine quartz thread fused to the beam at G supports (i.) a quartz bulb H of known volume V c.c. (either filled with air or vacuous), (ii.) the scale-pan J, and (iii.) a quartz counterpoise K. The whole hangs within the tube L (fitted to the case by the ground-glass joint M), and is counterpoised by a solid bead of silica at N. A little uranium oxide inside the case ionises the air and eliminates disturbing electrical effects; and calcium chloride in L keeps the interior dry.

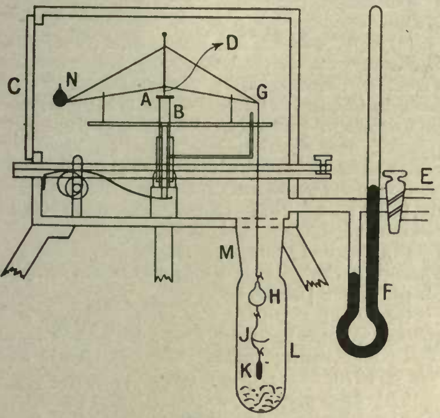

FIG. 1.

To perform a weighing, the pressure in the case is suitably lowered (to P_1 at temp. T_1 abs.), and the position of the reflected spot of light on the scale taken as the zero. The substance is then placed on the pan J, and a new pressure (P_2 at temp. T_2 abs.) determined under which the zero of the balance is recovered. The weight of the substance is then given by the expression (σ_0=wt. of 1 c.c. air at N.T.P.)

$$\frac{273V\sigma_0}{760}\left(\frac{P_2}{T_2}-\frac{P_1}{T_1}\right)$$

The usual vacuum correction is, of course, necessary. Only weights less than the weight of air that the bulb H can hold may be thus determined. To measure greater weights, the counterpoise K is replaced by a lighter one; a series of such counterpoises is required, and the differences between their weights may be measured on the microbalance itself. It is convenient (Fig. 2*b*) to make the bead N counterpoise the bulb, scale-pan, and a set of weights (ranging from 2 to 0·1 mgm.; made from capillary quartz tubing, and calibrated on the balance). In weighing a substance, weights are removed to obtain a coarse adjustment; the pressure within the case is then altered, thereby making the (variable) buoyancy of the air on the bulb H effect the fine adjustment. The absolute accuracy of the weighings is limited to the accuracy with which V may be determined; their relative accuracy is much greater.

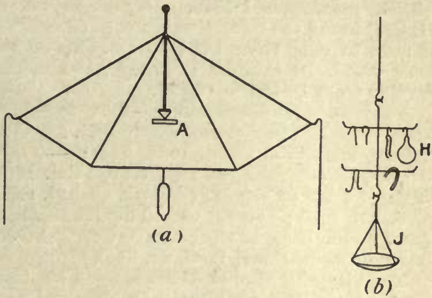

FIG. 2.

In a balance constructed by Steele and Grant, the beam, &c. weighed 0·93 grm., the bulb H had a capacity of 0·422 c.c. and contained $5{\cdot}04\times10^{-4}$ grms. of air; the balance had a period of 33 secs., and was sensivitive to 4×10^{-8} grm.

MICROCLINE *v.* FELSPAR.

MICROCOSMIC SALT. *Ammonium sodium hydrogen phosphate* $NH_4{\cdot}NaHPO_4,4H_2O$, used as a flux in blow-pipe tests.

MICROSAL. Trade name for a disinfectant made by mixing a solution of crude sulphophenolic acid with copper carbonate.

MIDDLETONITE *v.* RESINS.

MIEMITE. A dolomite of an asparagus-green colour found in Tuscany, *v.* DOLOMITE.

MIKADO ORANGE, -YELLOW *v.* AZO-COLOURING MATTERS.

MILK. Milk is the term usually restricted to the liquid secreted by the mammary glands of the class of animals called mammalia. Certain secretions, however, which are produced by birds and by some species of plants more or less resemble ordinary milk in their general physical and chemical characters.

Milk is generally white in colour, with a faint yellow or bluish tinge; it is homogeneous and opaque, the opacity being due to particles of fat (milk globules) and to casein, the characteristic protein of milk, which in combination with lime and calcium phosphate exists in pseudo solution. When fresh it has a characteristic aroma. Immediately after drawing, it has in addition a faint odour of an exhalation from the skin which disappears on exposure to the atmosphere. The sp.gr. of milk in general varies between 1·018 and 1·045 (Scherer); that of human milk averages 1·032 (Simon), 1·03267 (1·02561–1·04648) (Vernois and Becquerel), 1·0313 (1·0353–1·0260) (Leeds, Chem. News, 50, 263); that of cow's milk varies between 1·029 and 1·033 (Bouchardat and Quevenne). The average of English cows' milk is 1·0322 (Vieth), of German cows 1·031 (Fleischmann).

The specific heat of milk is 0·96, varying slightly according to the percentage of fat (Richmond) and 0·9457 (Fleischmann, J. Landw.

1902, 50, 33), and it attains its maximum density between 0° and 1° (Fleischmann, L. V. S.[1] 17, 251). The refractive index of cow's milk was found by Valentin (Pfl. Arch. 1879, 78) to average 1·35 with Abbe's refractometer. The refractive index of human milk varies from 1·3475 to 1·3494, maximum 1·3518. Jorgenssen (L. J. 11, 699) found the refractive index of 23 samples of milk to vary from 1·347 to 1·3515; on the other hand, 29 samples of whey gave indices varying from 1·3465 to 1·3433.

The freezing-point of milk is —0·54° to —0·58° mean —0·554° (Beckmann, Milch. Zeit. 23, 702; Lajoux, J. Pharm. Chim. 1905, 577); —0·556° to —0·574° (Hamburger, Rec. trav. chim. 1896, 349); —0·55° to —0·57° (Winter, Compt. rend. 1895, 121, 696); —0·55° to —0·59° (Carlinfanti, Gazz. chim. ital. 1897, 460); —0·55° ±0·03° (Atkins, Chem. News, 1908, 97, 241).

The viscosity of milk depends upon the temperature, but the diminution in viscosity with rise of temperature is much more rapid in milk than in water.

The reaction with litmus varies according to the species. Human milk is normally alkaline, whilst that of the carnivora is generally acid; cow's milk may appear faintly alkaline or faintly acid, or show both reactions (amphoteric).

Abnormally, milk may be bluish-white, deep-yellow, brown, pinkish-red, blue, or black in colour, watery, slimy, stringy, sandy, or heterogeneous in consistency, putrid or otherwise offensive in odour, and salty, sour, bitter, or astringent in taste.

The liquid secreted by the female immediately before or after parturition is termed colostrum or beestings, and differs considerably from normal milk in both physical and chemical characters.

Reaction.—Soxhlet (J. pr. Chem. [ii.] 6, 1) has shown that cow's milk, in common with all liquids containing both neutral and acid phosphate in solution, is amphoteric—*i.e.* it will exhibit both acid and alkaline reactions. With the recognition of the facts that litmus is an acid of appreciable strength, and that the change of colour is due to a setting up of equilibrium between the bases combined with the phosphoric acid and litmus respectively, the amphoteric reaction of milk is simply explained. All milks are acid to phenolphthalein, the average degree of acidity of cow's milk being about equal to 20 c.c. of normal acid per litre; the exact degree varies slightly according to the amount of phenolphthalein used, and the temperature.

Composition.—The ancients were acquainted with only three of the constituents of milk, viz. fat, caseïn, and water. Bartoletus of Bologna (1619) discovered a fourth constituent, the 'nitrum seri lactis,' afterwards renamed by Testi (1698) *zucchero di latte* (sugar of milk). Geoffrey (1737) separated the soluble salts and identified sodium chloride among them. Scheele (1780) found calcium phosphate in the ash.

At the present time the following substances are stated to be normal constituents of fresh milk.

(*a*) *Proteins*: Caseïn, opalisin (Wroblewski, Zeitsch. physiol. Chem. 1898, 308); and the mucoid-protein of Storch (Analyst, 1897, 148); albumin (lactalbumin); globulin (Sebelien, Zeitsch. Chem. 9, 445; Hewlett, J. Physiol. 1892, 13, 798; Arthus, Arch. Physiol. 1893, 673).

(*b*) *Extractive matters*: Urea (Lefort, Compt. rend. 62, 190); creatinine (Weil, Ber. 11, 2175); traces of lecithin, cholesterol, and hypoxanthine (Schmidt-Muhlheim, P. Arch. 30, 379).

(*c*) *Organic acids*: Lactic acid (Marchand, J. Pharm. Chim. [iv.] 29, 311; Hoppe-Seyler, Virch. Arch. 17, 443; Manetti and Musso, Zeitsch. Chem. 16, 397), though it is doubtful if this exists in perfectly fresh milk; citric acid (Henkel and Soxhlet, Bied. Zentr. 17, 787); acetic acid (Béchamp, Compt. rend. 76, 836); orotic acid (Biscaro and Belloin, Mon. Scient. [iv.] 19; i. 384; and Ann. Soc. Chim. Milano, 11, 1905).

(*d*) *Carbohydrates*: Sugar of milk, and a second carbohydrate discovered by Ritthausen, (J. pr. Chem. [i.] 57, 348).

(*e*) *Other organic bodies*: Alcohol (Béchamp, Compt. rend. 76, 836); lactochrome, an organic colouring matter (Blyth, Chem. Soc. Trans. 1879, 531); and a bitter principle.

(*f*) *Inorganic acids* (*in combination*): Phosphoric, hydrochloric, sulphuric (Musso and Schmidt, Bied. Zentr. 1179, 865); thiocyanic (Musso); but its presence is accidental from mustard oil in food (Stoecklin and Crochetelle, Compt. rend. 1910, 150, 1530).

Enzymes.—A proteoclastic enzyme (Babcock and Russell, 14th Ann. Report, Wisconsin Exp. Stat. 1897); an oxydase, a catalase (Loew, Zeit. Biol. 1902, 256; Wender, Chem. Zentr. 1903, i. 592), a reductase (Schardinger, Zeitsch. Nahr. Genussm. 1902, 1113; Reiss, Chem. Zentr. 1905, i. 604), and a kinase (Hongardy, Bull. acad. Roy. Belg. 1906, 888). Wohlgemuth and Strich (Sitzungsber. K. Akad. Wiss. Berlin, 1910, 520) state that carbohydrate and fat splitting enzymes are present, also oxydase, reductase and catalase, but show that proteoclastic enzyme is due to bacteria; there is a glycyltryptophan enzyme. Tromsdorff (Centr. Bakt. Par. 1909, 1, 291) finds no reductase in quite fresh sterile milk. Bordas and Touplain (Compt. rend. 1909, 1057) reject the enzyme nature of peroxydase, and state that the reactions are due to casein.

(*g*) *Bases*: Potash, soda, lime, ferric oxide, magnesia, ammonia (Latschenberger, J. 14, 222).

(*h*) *Gases* (*in solution*); carbon dioxide, oxygen, nitrogen.

Microscopic characters.—Viewed under the microscope fresh milk appears as a clear colourless liquid in which are suspended—(*a*) milk globules and more rarely (*b*) granular bodies, the so-called colostrum corpuscles. Haidenhain (Handb. der Phys.) states that the following morphological structures have been observed in human and to a less extent in cow's milk:—

(1) Semiglobular fat drops with a finely granular substance.

(2) Clear cells containing one or two fat drops and an eccentric nucleus.

(3) Round clear bodies easily coloured by eosin and picrocarmine, supposed to be free nuclei.

(*a*) The milk globules may vary in diameter from 0·01 to 0·0015 mm., but generally range from 0·005 to 0·0033 mm.

---

[1] L. V. S. = Landwirthschaftliche Versuchs-Stationen.

According to Bohr (J. 1880, 183) the diameter may vary from 0·0063 to 0·00014 mm.

Under the highest powers of the microscope they appear merely as more or less irregularly shaped globules of fat, without the faintest trace of a limiting membrane; nevertheless, all the earlier observers (Henle, Mitscherlich, Lehmann, Moleschott, &c.) believed in the existence of an external envelope, principally because ether, when shaken up with milk, will not dissolve out the fat unless acetic acid or potash is previously added. These substances were supposed to dissolve the enveloping membrane of the globules and release the fat. This view has been again advocated by Struve (J. pr. Chem. [ii.] 27, 249), who thinks the globules have a coat of insoluble casein; by Babcock (Milch.-Zeit. 17, 809), who states they are covered with an envelope of milk-fibrin, and by Béchamp (Compt. rend. 107, 772). Storch (Analyst, 1897, 198) affirms the existence of a semi-gelatinous membrane; but his conclusions have been adversely criticised by Richmond (Analyst, 1897, 207; 1904, 183) and Wood (American Medicine, 1907, 416).

The weight of evidence appears, however, to be against the existence of a solid membrane. Soxhlet holds that the milk is a simple emulsion of fat particles with casein, calcium phosphate, &c., and that the addition of acetic acid or sodium carbonate deprives the casein of its emulsifying power. He found that when a small quantity of ether was added it also entered into an emulsion with the fat and casein, &c., and only separated out with extreme slowness. If a large excess of ether or a mixture of ether and alcohol is shaken up with milk, the fat is completely extracted, without any previous addition of acid or alkali, whereas benzene and chloroform, which are equally good solvents for fat, will not extract it from the globules even after the addition of potash. If acetic acid is added to the milk in quantity just sufficient to convert the phosphates present into acid phosphates, but not to coagulate the milk, the fat cannot be extracted with ether. If a current of CO_2 is then passed through the milk, coagulation ensues and the fat can very readily be extracted with ether. The CO_2 cannot be supposed to be capable of dissolving any membrane (L. V. S. 19, 118). If milk be dried in a vacuum over H_2SO_4 the fat can easily be extracted from the residue with ether, but if the residue is redissolved in water the solution resists the action of the ether.

Duclaux (Chem. Biol. 667) finds that if the globules are kept warm while under the microscope, they may be squeezed out and broken by pressing on the cover glass, the altered globules only differing in size from the original ones. Babcock (Milch.-Zeit. 15, 393) also found that if milk be heated to 100° and whipped, the globules are doubled in number but present the same microscopic outline as before. By passing milk through small orifices under great pressure (homogenising) the fat globules can be broken up into very minute particles. From the above facts it is certain that the only membrane is a liquid layer condensed round the globules by the surface tension. Refer also to De Sinety (Arch. de Phys. 1874, 479), Herer (J. 1871, 120), Hoppe-Seyler (Arch. Path. Anat. 17, 417). The milk globules consist mainly of various fats, but analysis shows the presence of traces of cholesterol, lecithin, and of a yellow colouring matter spectroscopically identical with luteïn.

(*b*) The colostrum cells or corpuscles occur very sparingly in normal milk, but abundantly in the colostrum. They consist of irregular conglomerations of very small fat vesicles embedded in a granular protoplasmic matrix; occasionally one or more eccentric nuclei may be observed. They are about four or five times as large as the milk globules, the diameter varying from 0·014 to 0·055 mm. Heidenhain (Handb. der Phys.) finds that if a drop of warm perfectly fresh milk be examined on a Strecker's warm stage, and the temperature regulated to 38°C. amœboid movements of these cells can be observed resembling in all respects those of the white blood corpuscles, from which indeed Heidenhain considers them to be derived by a process of infiltration with milk fat.

The fat of these corpuscles is much more readily dissolved by ether than that of the milk globules. They are disintegrated by potash or acetic acid, iodine water colours them intensely yellow, hence they consist of very small globules of fat embedded in an albuminous substance.

Abnormal milk may contain hematin, biliary colouring matters, mucin, blood corpuscles, pus, mucus, fibrous clots, and many varieties of fungi and bacteria.

Changes in milk.—Milk commences to undergo change from the moment it is drawn. If left exposed to the air it very soon loses its dissolved CO_2 and takes up oxygen. Cow's milk, in which the alkaline reaction is said to be more distinct whilst in the udder, soon shows the acid reaction markedly. On standing for a time a thick yellowish-white stratum, rich in fat, collects on the surface (cream), whilst the lower portion becomes bluish-white, poorer in fat, and increases in sp.gr. Recknagel (Bied. Zentr. 1884, 16) finds that 2 or 3 hours after the milk has been drawn the sp.gr. commences to rise, the milk attaining its maximum density in 6 hours if the temperature is kept down to 5°, but only after the lapse of 2 or 3 days at 15°. This property he considers to be due to the swelling up of the casein suspended in the milk. Vieth (Milch.-Zeit. 18, 141) found the average sp.gr. of 15 samples to be 1·0296, half an hour after milking, and 1·0309, 16 hours later.

This phenomenon is chiefly, if not wholly, due to the slow solidification of the fat globules; fat in the liquid state has a density of 0·92, and when solid of 0·93, and the experiments of H. D. and S. O. Richmond (Dairy Chemistry, 338; and Analyst, 1901, 117) prove that the fat melts at about 32°–34°, and the liquid globules slowly solidify if cooled below this temperature.

If milk is cooled to 10° it acquires a viscous consistency which increases rapidly as the temperature falls. Hoppe-Seyler (Ph. C. 723) states that on standing the quantity of albumin falls and that of casein increases.

On boiling, CO_2 is expelled, and it is stated that H_2S is also given off (Schreiner, L. V. S. 22, 60; Rettger, Amer. J. Physiol. 1902, 450; Utz, Milch.-Zeit. 1903, 354). Arnold (Bied. Zentr. 1882, 131) states that unboiled milk colours tincture of guaiacum blue, but that boiled milk does not; potassium iodide and starch are rapidly turned blue by unboiled milk, but only slowly by boiled milk.

These reactions are due to the oxydase present in milk; there are, however, a large number of other reagents, which, when added to fresh milk, give on addition of a little hydrogen peroxide coloured oxidation products; among these may be mentioned paraphenylene diamine (Dupuoy, J. Pharm. Chim. 1897, 397; Storch, Bied. Zentr. 1898, 711; Leffmann, Analyst, 1898, 85); metaphenylene diamine (Richmond and Rosier, Analyst, 1900, 231); ortol (ortho methylamino phenol and quinol); Saul (Brit. Med. J. 1903, 664); benzidine (Wilkinson and Peters, Zeitsch. Nahr. Genussm. 1908, 172); most photographic developers (Macadie, Pharm. J. 1907, 207; *cf.* also Siegfeld, Zeitsch. angew. Chem. 1903, 764).

As in all fairly alkaline liquids, the alkaline reaction in cow's milk becomes more evident while hot (Soxhlet, J. pr. Chem. [ii.] 6, 1), but recovers its previous intensity on cooling. Boiled milk also coagulates less readily, and is less sensible to the action of ferments and bacilli (Richet, Compt. rend. 88, 750). Very considerable chemical change must therefore have taken place, but it is still not very clear what is the nature of this change.

If heated over 60° milk acquires a slimy consistency, which has also been attributed to a change in the state of the suspended casein; this sliminess retards the subsequent separation of cream.

By heating milk to 100° (or even to lower temperatures) the rising of cream is hindered (Cazeneuve and Haddon, Bull. Soc. chim. 1895, 13, 500; Richmond and Boseley, Analyst, 1897, 95).

When milk is evaporated in a vacuum at the ordinary temperature, or at the ordinary pressure at a temperature of 50°, a skin gradually forms on the surface and is renewed as often as it is removed. This skin is due to the desiccation of the proteins by the surface evaporation, and to the concentration of the hydrogen ions. It was formerly thought to consist of albumin only (Hoppe-Seyler, Virch. Arch. 17, 417), and the statement was made that, on boiling milk, the albumin separated out; but Sembritzki (Pogg. Ann. 37, 460) found that by continually removing the skin, he could obtain 1·023 p.c. of the milk in that form. Since the albumin is not present in such quantity, it follows that some other body such as casein must enter into its composition.

When milk is heated for a long time at a high temperature it coagulates; Cazeneuve and Haddon (Compt. rend. 1895, 120, 1272) attribute this to the formation of formic acid by the action of heat on lactose; but Bardach (Monatsh. 1897, 199) shows that the formic acid produced is insufficient in quantity for this, and find that it is due to complex changes in the caseïn.

On slowly freezing milk, the ice first formed contains a greater proportion of fat, but the mother liquor contains more casein, milk-sugar, and salts, but if the freezing takes place quickly the fat is equally distributed (Kaiser and Schmeider, Bied. Zentr. 1887, 267).

For composition of ice found on freezing milk, *cf.* Vieth, Analyst, 1891, 65; Bordas and de Raczkowski, Compt. rend. 1901, 133, 759; Richmond, Analyst, 1893, 53.

If, however, the milk is agitated, the milk-ice is richer than the mother liquor in slow freezing, but more watery and poorer in both solids and fat when quickly frozen (Henzold, Milch.-Zeit, 15, 461).

Souring of milk.—Under certain circumstances, the homogeneous structure of milk undergoes a change, and a curd is thrown down in the form of a flocculent or compact precipitate. This change is termed curdling or coagulation, and is caused by the development of lactic acid by the action of micro-organisms, *e.g.* the *B. acidi lactici*, which are constantly present in milk, even when drawn from the udder (Hueppe, Bied. Zentr. 85, 408), and precipitation of the caseïn.

Spontaneous coagulation is characterised by the gradual souring and thickening of the milk; it takes place more readily when the temperature is raised, and when the atmosphere is charged with electricity.

Soxhlet found fresh milk to coagulate in 19 hours at 39°; in 29 hours at 25°; in 48 hours at 20°; in 63 hours at 17·5°; in 88 hours at 15°; in 99 hours at 10°; and he kept milk for 14 days without much change in taste at 1°–2°.

Though the nature of the organisms varies the amount of acid produced in a given time at any temperature is fairly constant (*cf.* Thorner, Chem. Ziet. 1891, 1108; Van Slyke and Hart, Amer. Chem. J. 1904, 145). Richmond and Miller (Analyst, 1907, 144) have plotted out a curve showing the relation of acidity and time at 20°, and state that at other temperatures the form of the curve remains the same, but the time taken to reach a given point increases (or decreases) 2·075 times for each 10° above or below 20°. The curve is logarithmic up to 45° acidity, at which point a break occurs; this appears to be due to this being the point at which the micro-organisms do not increase (Revis and Payne, J. Hygiene, 1906, 216); from this point the development of acidity is expressed by another parabolic curve. Revis and Payne (*l.c.*) conclude that as milk turns sour, calcium phosphate is split off from the casein complex, and when curdling takes place practically all the calcium phosphate is removed.

Though the lactic fermentation is the most common in milk, other substances are produced by the action of micro-organisms; both *d*- and *l*-lactic acids are produced, and acetic, propionic, and butyric acids may be formed (*cf.* Kozai, Bied. Zentr. 1903, 273; Tissier and Gastling, Ann. Inst. Pasteur, 1903, 540; v. Freudenreich and Jensen, Centr. Bakt. Par. 1906, 529; Thorpe Chem. Soc. Trans. 1905, 206; Richmond and Miller, Analyst, 1906, 317; Beyerinck, Proc. K. Akad. Wetensch. Amsterdam, 1907, 17), and succinic acid, together with ammonia and trimethylamine has been found in two cases by Kozai (*l.c.*). Alcohol in small quantities is almost always present in sour milk, and usually proteolysis occurs (*cf.* Kozai, and Richmond and Miller, *l.c.*; Pennington, J. Biol. Chem. 1908, 353).

When milk is boiled for some time, *most* of the organisms contained in it are destroyed, and spontaneous coagulation cannot occur unless it is again impregnated by contact with the air.

A temperature of 100° is, however, insufficient to destroy all the organisms present in milk.

Duclaux (Le Lait, Paris, 1887) kept milk unchanged for 5 years by removing all the air from the vessel, and subsequently by heating to 120° for some time.

Spontaneous coagulation is retarded by the addition of antiseptics, which inhibit the action of the bacilli themselves, and also by alkaline substances which merely neutralise the acid formed by their action. As antiseptics the following substances are sometimes added to milk, viz. boric acid, salicylic acid, formaldehyde, benzoates &c. (For a quantitative study of the action of preservatives, *cf.* Richmond and Miller, Analyst, 1907, 144.)

Coagulation by acids.—Most acids coagulate milk in the cold, more readily when heated. 1 p.c. of acetic acid is required to precipitate milk fully at the ordinary temperature, but 0·4 p.c. is sufficient at 35° and 0·2 p.c. at 100°. Even carbonic acid will coagulate milk at an elevated temperature. Duclaux (*Le lait*) found that on saturating milk in the cold with CO_2 and heating it in a closed vessel at 115°–120°, coagulation ensued.

Many salts such as NaCl, $MgSO_4$, &c., coagulate milk. Alcohol and acetone act in a similar manner.

Coagulation by rennet.—This is by far the most important of all the methods of coagulating milk, and the phenomena merit the closest attention. Unfortunately the action is very complex, and there still exists some divergence of opinion as to its nature. The old theory, that coagulation was in this case also preceded by the formation of lactic acid, held by Simon, Liebig, Soxhlet, &c., is now entirely abandoned, and it is generally admitted that the action of rennet depends upon the specific property of a chemical ferment present in it. This was first isolated by Deschamps (Dingl. poly. J. 1840, 445), who termed it *chymosin.* Hammarsten (Bull. Soc. chim. [ii.] 22, 352) fully investigated the properties of this ferment. He found that it does not give the xanthoprotein reaction, is not precipitated by nitric acid, alcohol, iodine, tannin, nor by neutral acetate of lead, but it is precipitated by basic lead acetate. It is not coagulated at 100°, but its efficiency is destroyed. It is soluble in water and glycerol; the latter solution is precipitated by alcohol.

Hammarsten (J. Pharm. Chim. 5, 267) further proved that it could coagulate milk even in the absence of acids or of milk sugar, and that the precipitate obtained differed in many important particulars from that thrown down by acids. Heintz showed that rennet could produce coagulation even in solutions rendered alkaline with sodium carbonate, provided the temperature were raised to 65°.

The ferment is inactive in the cold, and when present in only very small quantity. Hammarsten has proved that it cannot precipitate a solution of casein unless a small amount of certain soluble salts is present; the salt may be phosphate or chloride or sulphate, but it is essential to have it in solution; calcium phosphate in suspension is entirely useless. Small quantities of sodium phosphate, potassium chloride, the soluble barium, strontium, calcium, and magnesium salts promote the action of the ferment; larger quantities have, however, an adverse influence. The great majority of the sodium, potassium, and ammonium salts invariably retard the action of rennet.

Halliburton (J. Physiol. 1890, 11, 448) and Ringer (*ibid.* 1891, 12, 164) have shown that the ferment splits up the protein, and the curd is precipitated owing to its insoluble lime salt.

The presence of alkalis and alkaline carbonates either delays or entirely prevents coagulation. Small quantities of acids, on the other hand (except boric), hasten the action (A. Weitzel, Arbeiten a. d. Kais. Gesundheitamt, 1902, 19, 126). 1 p.c. of lactic acid greatly accelerates coagulation (Engling, L. V. S. 31, 391).

Pawlow and Parastchouk (Verb. d. Vers. Nordicher Naturfor. u. Äntze in Helsingfors, 1902, 28) have put forward the view that as many ferments contain a rennet-like body, rennet is not a special ferment at all, but that the property of curdling milk is shared by all proteoclastic enzymes.

Constitution of milk.—Chemists have hitherto been unable to agree with regard to the constitution of milk. According to some it is a solution, according to others an emulsion, and others consider it to be a mere mixture.

On filtering milk through a porous cell, the following substances occur in the filtrate in solution:—

The whole of the milk sugar, albumin and extractive matters, soda, potash, hydrochloric and citric acids (in combination), the greater part of the magnesia, about one-third the lime, and one-half the phosphoric acid present in the milk (Richmond, Analyst, 1901, 313, however, found that the albumin was removed). The bulk of the milk solids—viz. the fat, casein, lime, and phosphoric acid—fails to pass through.

The question whether the fat exists in an emulsified state, or in morphologically differentiated structures has already been noticed (*v. Microscopic characters*). The state of the casein, lime, and phosphoric acid, now claims our attention.

Hammarsten (J. Pharm. Chim. 5, 267) found that perfectly pure casein is insoluble in water, and possesses a strongly acid character. It dissolves in the phosphates and carbonates of the alkalis; in the latter case CO_2 is expelled. It also dissolves in a solution of caustic soda, in lime water, and in baryta water. If the solution in lime water is neutralised with phosphoric acid and kept for some time at about 40°, it becomes milk-white in appearance, behaves on filtration like natural milk, and is coagulated by acids or rennet. Other solutions of casein were not affected by rennet, unless calcium and phosphoric acid or a few other substances were introduced.

Hammarsten also observed that milk-casein precipitated by rennet constantly contained 4–5 p.c. of tricalcium phosphate, whilst that precipitated by acids contained a lesser and more variable percentage; the serum obtained from rennet also contained more proteins than that obtained from other precipitants. From these facts he concluded that casein was held in solution in milk by the neutral phosphates of the alkalis, and that the casein thus dissolved was able to take up the insoluble di- and tri-calcium phosphates and enter with them into a turgid, highly hydrated, and colloid condition which he considered the characteristic state of milk-casein, both in his artificial compound and in natural milk.

Coagulation by acids is according to this theory due to the conversion of the neutral phosphates of the alkalis into acid phosphates, which are unable to hold the casein in solution, but at the same time the acids convert part of the insoluble di- and tri-calcium phosphates, into the soluble mono-calcium salts. The milk-casein precipitated by acids is therefore poor in calcium phosphate.

Coagulation by rennet is due, according to Hammarsten, to the decomposition of the milk-casein into two proteins, one of which passes into perfect solution, whilst the other forms an insoluble compound with tricalcium phosphate (cheese). The approximate constancy of the percentage of calcium phosphate in the coagulum, and the excess of proteins in the serum, are thus accounted for (*cf.* Harris, J. Anat. and Physiol. 1894, 188).

On heating milk with an oxalate, calcium oxalate is precipitated; fluorides also easily precipitate the calcium (Arthus, Arch. Physiol. 1893, 673; Ringer and Hammarsten, *l.c.*).

Milk-casein, according to Engling (L. V. S. 31, 391), is casein-tricalcium-phosphate, and is completely decomposed by acids, casein being precipitated and more or less of the calcium phosphate taken up into solution. Rennet again only partially decomposes the casein-tricalcium-phosphate. A portion of the protein is detached and goes into perfect solution as acid albuminate, and as soon as a certain quantity of this is formed its acid character determines the precipitation of the bulk of the casein and tricalcium phosphate as a *basic* salt (cheese).

Hammarsten (*l.c.*) has studied the properties of the soluble portion, which he calls whey-protein; it has the properties of an albumose.

Söldner (L. V. S. 35, 351) made the observation that although the reaction of milk is amphoteric, the bases in the ash of milk are very largely in excess of the acids. It seemed to him *à priori* improbable that a strongly acid body like casein should exist in milk in combination with neutral tricalcium phosphate, and that a quantity of base should be simultaneously present with no acid to neutralise it, and without imparting a basic reaction to the liquid. Hammersten (*l.c.*) had found that casein was soluble in lime-water and Söldner found he could obtain two compounds of casein and lime; one containing 2·36 p.c. CaO reacts alkaline with litmus, but not with phenolphthaleïn, and dissolves in water to form an opalescent fluid which is not coagulated by rennet. The other compound containing 1·55 p.c. CaO, has a slight acid reaction; its solution in water forms after some time a milk-white fluid which is coagulated by rennet. Hammarsten had observed that pure casein contains 0·847 p.c. of phosphorus, and Söldner has proved that a solution of pure casein in lime-water leaves on ignition a residue of calcium pyrophosphate. Söldner therefore concludes that milk-casein is the *unsaturated compound of casein and lime* (1·55 p.c. CaO), and that it does not enter into combination with, nor has any specific solvent power for the insoluble di- and tri-calcium phosphates as such, these salts merely existing *in suspension* in the milk.

The power that *free casein* posessses of dissolving di- and tri-calcium phosphates is due to the acid nature of free casein. Just as it expels CO_2 from carbonates, &c., like other acids, so it abstracts part of the base from the insoluble phosphates, forming a soluble lime-casein compound.

According to Richmond (Analyst, 1900, 116; 1901, 313; 1902, 241) the state in which casein exists in milk has been elucidated by the study of the composition of the substance removed by filtration through a porous cell, and by the action of acids and of rennet.

There is little doubt that casein is a substituted phosphoric acid, and the amount of base in combination with the substance separated by porous earthenware is equal to one atom of sodium and one of calcium, together with half a molecule of tribasic calcium phosphate. The minimum amount of acid necessary to curdle milk on boiling is 8·3 c.c. normal hydrochloric or sulphuric acids per litre, and slightly greater amounts of weaker acids; this quantity is almost exactly equal to that required to combine with the sodium, and the precipitate contains the same amount of calcium, and calcium phosphate as the substance removed by a porous cell; the acidity of the serum is moreover equal to that of the milk. The behaviour of two acids is, however, anomalous, very much larger amounts of oxalic and phosphoric acids being required to curdle milk on boiling, the average quantities being 28·5 c.c. N-oxalic acid, and 35 c.c. N-phosphoric acid per litre; if we consider that oxalic acid removes calcium from milk as insoluble calcium oxalate, and phosphoric acid would form acid phosphates with calcium phosphate, it appears that these two acids break up the sodium-calcium-casein-calcium-phosphate complex.

The action of rennet, though chiefly on the protein portion of the complex, presents many analogies to that of acids on boiling; a portion of the casein molecule is split off as 'whey protein,' and the residue is also a substituted phosphoric acid; the proportion of calcium and calcium phosphate to organic phosphorus in the precipitated curd is the same as that found in the substance separated by porous earthenware, and in the precipitate formed by the minimum quantity of acid on boiling; the sodium is, however, removed, and the difference between the acidities of the milk and the whey is almost exactly 8·3 c.c. N-acid per litre. It appears probable that the action of rennet is even more analogous to that of the minimum quantity of acid on heating, as the amount of protein precipitate in the latter case is never quite equal to that of the casein, indicating that a portion of the protein molecule is removed on boiling; further evidence that this is the case is shown by the fact that while mercury salts are very perfect precipitants of the casein of milk, they do not remove the whole of the casein from a solution that has been heated, a lævo-rotatory substance which is precipitated by phosphotungstic acid remaining dissolved.

By heating milk alone, or by centrifuging, practically no calcium or phosphoric acid is removed, without a corresponding amount of organic phosphoric acid.

The action of acids in the cold is different from that on boiling; at ordinary temperatures at least 6 times the quantity required on boiling is necessary before a precipitate is obtained, and nearly the whole of the calcium and calcium phosphate is removed. At intermediate temperatures the amount of acid is less, and the removal of the inorganic constituents proportionately less.

These facts show that casein exists in milk as a complex of a sodium calcium salt combined with a molecular proportion of calcium phosphate, and that the simple derivatives consist of a similar complex, and are precipitated as acid salts, the sodium being removed. The older view that calcium phosphate was entangled or loosely combined appears to be untenable. This complex forming a solution resembling milk can be artificially prepared, and behaves towards rennet in a manner similar to milk. Casein in solution in alkalis is not curdled by rennet, but the molecule is split up, the hydrolysis proceeding much further than when rennet acts on the complex which exists in milk. This indicates that the final product of the action of rennet on the casein as it exists in milk is determined by a simple derivative which forms an insoluble acid salt.

It is not known in what state the albumin exists in the milk; it is not coagulated by raising the temperature to 70°, though it has been shown by Faber (Analyst, 1889, 144) and Stewart (Brit. Med. J. 1896, 626) that at this temperature it is converted into a form which is precipitated by acids or magnesium sulphate.

It has been stated that it is in combination with the casein, but the experiments of Richmond (Analyst, 1902, 240) appear to negative this view.

Lecithins, which are compounds of choline, glyceryl-phosphoric acid, and fatty acids such as stearic, are found in milk, and are probably of considerable importance in nutrition. They have been studied by Bordas and de Raczkowski (Compt. rend. 1902, 134, 1592; 135, 302, and 354) who state that the greatest amount is found in the first month; they show that by removing 98 p.c. of the cream 69 p.c. of the lecithin is removed, and this is confirmed by Glikin (Biochem. Zeitsch. 1909, 348). Nerking and Haensel give the quantity as 0·0109–0·0833 p.c. (Biochem. Zeitsch. 1908, 348).

Citric acid. Henkel (Bied. Zentr. 17, 787) found that on saturating the serum left after removing proteins, &c., with calcium salts, and slowly evaporating, a crystalline deposit of calcium citrate was formed. The amount of citric acid was estimated from this as 0·08–0·12 p.c.; but the quantity present is probably considerably greater.

Söldner (L. V. S. 35, 351) estimates it as 0·25 p.c., and Richmond (Analyst, 1901, 316) as 0·264 p.c.

It evidently exists as a soluble salt, since the same quantity separates out from whey and from serum (by cell filtration). The concretions in condensed milk consist of pure calcium citrate.

Salts. These consist principally of phosphates, chlorides, and citrates of the alkalis and alkaline earths. Musso also found 0·0391–0·0831 gram of sulphuric acid per litre. This would amount to 0·558–1·19 p.c. of SO_3 in the ash. Musso also found 0·0021–0·0046 gram NaCNS per litre of milk.

The amount of ash in cow's milk varies from 0·65 to 0·85 p.c.; generally from 0·7 to 0·8 p.c.

The ratio of ash : proteins : sugar is very constantly 2 : 9 : 13 in cow's milk, 1 : 5 : 10 in human, 1 : 6 : 23 in mare's milk (Vieth, Analyst, 13, 49). The following are average analyses of milk-ash:

	Percentage in milk	Percentage in ash
K_2O	0·1728	24·5
Na_2O	0·0868	11·0
CaO	0·1608	22·5
MgO	0·0243	2·6
Fe_2O_3	0·0005	0·3
P_2O_5	0·1922	26·5
Cl	0·1146	15·6
SO_3	0·0061	1·0

(Fleischmann).

More sulphuric acid is actually found in the ash than that shown, but it is due to the oxidation of the sulphur in the albuminoids; only that determined by Musso is taken into account. On the other hand, a deduction must be made for increase of weight by oxidation. Fleischmann deducts 3·5 p.c. of the weight of the ash for this error.

Söldner has shown (L. V. S. 35, 351) that, owing to the excess of base present in milk-ash, the whole of the phosphorus in the casein is oxidised to phosphoric acid, and appears in the ash as calcium phosphate. From 25 to 40 p.c. of the P_2O_5 in the ash may be due to this source. The composition of the ash therefore still requires revision.

Söldner (*supra*) has made an estimate of the amounts of salts as actually existing in the milk. Assuming the presence of 0·25 p.c. citric acid, he calculates:

Sodium chloride	0·962
Potassium chloride	0·830
Monopotassium phosphate	1·156
Dipotassium phosphate	0·835
Potassium citrate	0·495
Dimagnesium phosphate	0·336
Magnesium citrate	0·367
Dicalcium phosphate	0·671
Tricalcium phosphate	0·806
Calcium citrate	2·133
Lime (in combination with casein)	0·465

Rona and Michaelis (Biochem. Zeitsch. 1909, 114) state that 40–50 p.c. of the calcium is diffusible, and that much of it is combined with proteins. Richmond (Analyst, 1901, 310) considers that the citrates exist in milk as dibasic salts and gives the following as the distribution of the phosphoric acid in milk:

	P.c.
P_2O_5 as casein combined with CaNa	0·0605
„ $Ca_3(PO_4)_2$	0·0625
„ R_2HPO_4	0·077
„ RH_2PO_4	0·020

Latschenberger (Monatsh. 5, 129) found 0·02106 p.c. of ammonia in milk. Sherman, Berg, Cohen, and Whitman (J. Biol. Chem. 1907, 171) give the amount as 0·004 p.c.

Schrödt and Hansen (L. V. S. 31, 55) found the amount of chlorine in the ash to be greater at the end than at the beginning of the period of lactation (17·63 p.c.). There was also relatively more soda than potash, though the total alkalis were the same.

The ash is almost always 8 p.c. of the solids not fat (Vieth, Analyst, 13, 63).

Gases in Milk.—Pflüger (Pafl. Arch. 2, 166) found:

	O	CO_2 (pumped out)	CO_2 (expelled by phosphoric acid)	N
1.	0·1	7·6	0·00	0·7
2.	0·09	7·4	0·2	0·8

v. also Hoppe-Seyler (Virch. Arch. 17, 417); Setchenow (Zeit. rat. Med. 1861, 285).

Colostrum is, immediately after parturition, a yellow or brownish-yellow dirty-looking liquid, slimy, viscous, and often heterogeneous in consistency. It has a peculiar smell, a stale salty taste, and generally a slight acid reaction. It coagulates on boiling. The sp.gr. at 15° varies from 1·040 to 1·080.

The presence of colostrum corpuscles is characteristic (*v. Microscopic characters*).

The character of colostrum rapidly changes, and the following analyses by Engling (Bied. Zentr. 1879, 214) will show this:

Time after calving.	Sp.gr.	Total solids	Fat	Casein	Albumin	Sugar	Ash
Immediately	1·068	26·93	3·54	2·65	16·56	3·00	1·18
10 hours	1·046	21·23	4·66	4·28	9·32	1·42	1·55
24 „	1·043	19·37	4·75	4·50	6·25	2·85	1·02
48 „	1·042	14·19	4·21	3·25	2·31	3·86	0·96
72 „	1·035	13·36	4·08	3·33	1·03	4·10	0·82

Cf. also Vaudin (J. Pharm. Chim. 1894, 30, 337) and Sutherst (Chem. News, 1902, 1) who states that what is called albumin by Engling contains a large proportion of globulin; he finds 5·32 p.c. of this on the first day, and 2·05 p.c. on the second.

The proteins in colostrum vary greatly. Casein is always somewhat greater than in normal milk; albumin varies from a little above that of ordinary milk to over three times that amount. Globulin is always an essential constituent. Extractive N is a little higher than in ordinary milk. Engling (*l.c.* 96) states that at first colostrum contains no milk sugar, but only carbohydrates, resembling grape sugar. Sebelien and Sunde (Zeitsch. angew. Chem. 1908, 2546) find that the sugar is chiefly lactose, and suggest the presence of 0·05 p.c. of arabinose. The colostrum fat differs from ordinary butter in smell, taste, consistency, and melting-point. It melts at 40°–44°. This is due, according to Nilsson (Bied. Zentr. 17, 171) to the smaller quantity of volatile acids. Nuclein has been found up to 2 p.c. Cholesterol and lecithin also occur in some quantity. Urea is higher than in ordinary milk.

Engling found the ash of colostrum to consist of

K_2O	Na_2O	CaO	MgO	Fe_2O_3	P_2O_5	SO_3	Cl
7·23	5·72	34·85	2·06	0·52	41·43	0·16	11·25

The higher percentage of phosphoric acid and lime, and the low alkalis, are particularly noteworthy.

ABNORMAL MILK.

Blue milk. This is characterised by the appearance of blue spots, which gradually increase till the whole surface is covered. It is due to a bacillus (*B. cyanogenus*). If the reaction of the milk is acid the colouration is deep blue; in other cases it is a slaty blue, changing to deep blue on addition of acids. The colouring matter is identical with triphenylrosaniline (Martiny and Fürstenberg, Milch.-Zeit. 10, 594).

Stringy milk. Some milk, on standing for a short time, becomes thick and stringy. It is due to a special ferment, which sets up mucic fermentation. Sound milk is infected by addition of a little of the stringy milk, but the ferment can be destroyed by heating to 65° or by the addition of strong antiseptics.

Red milk is due either to colouring matter in the food of the animal or more frequently to the presence of blood from the rupture of a small blood vessel in the udder; on warming the milk and centrifuging the blood may be separated and identified by the usual methods.

Bitter milk is principally due to the food, but it is occasionally obtained from cows just before the end of lactation.

For particulars of other abnormalities in milk, *v.* Kirchner's Milchwirthschaft. For milk in disease, *v.* Blyth's Foods, where other references will be found.

ANALYSIS OF MILK.

Specific gravity. This may be determined by the lactodensimeter, the pyknometer, or by the Westphal balance.

The lactometer or lactodensimeter. This is merely a special form of hydrometer with a large bulb and a slender stem, which is graduated from 15°–45° corresponding to sp.grs. of 1·015 to 1·045; in some forms the range is even less. The milk should be at 60°F., or if the determination is made at another temperature, the readings of the lactometer should be corrected by means of a table.

The milk should be stirred, and the instrument very gently lowered till it sinks no further. The reading of the lower edge of the meniscus should be taken.

The form of pyknometer which gives the best results with milk is the Sprengel tube—a U-tube with narrow capillary ends; this should be filled with milk, immersed in a vessel of water at 60°F. till the volume is constant, and weighed. The weight of milk divided by the weight of water at 60°F. will give the specific gravity.

The Westphal balance consists of a counterpoised thermometer of exactly 5 or 10 c.c. displacement, suspended by a fine platinum wire from one end of a graduated lever. The thermometer or plummet is immersed in the milk at 15° and equilibrium restored by suspending a series of riders from the lever, which is graduated for the direct reading of the sp.gr.

Determination of the total solids. About 5 grams of milk are rapidly weighed out into a tared platinum, porcelain, nickel, or aluminium dish, and dried on a water-bath till successive weighings at one hour's interval differ by less than a milligram. This generally occupies 4–5 hours.

Richmond (Analyst, 14, 121) states that the most satisfactory results are obtained by taking not more than 2 grams of milk, and drying for 1½ hours in a wide, flat-bottomed basin.

Babcock (Dept. Agric. Rept. 13, pt. i. 81) dries the milk on asbestos, and very accurate results are thus obtained. For the rapid determination of total solids, Revis (Analyst, 1907, 284) adds 1 c.c. of acetone to 2·5 grams of milk in a wide basin and dries for 2 hours.

Determination of the ash. The total solid matter obtained by evaporating a portion of the milk to dryness is ignited at the lowest possible temperature until the ash is perfectly white; a barely visible red heat should be employed. If the temperature is raised to a visible red heat, serious loss may be incurred owing to the volatility of the chlorides in the ash. In a series of experiments Vieth (Analyst, 12, 60) found that the ash lost 25 p.c. in weight after heating at a bright red heat for half an hour. On heating for 5, 10, and 20 minutes respectively, the ash lost 6, 19, and 24 p.c. in weight. The percentage of chlorine in the ash was simultaneously reduced by $15\frac{1}{2}$, 69, and 96 p.c. of its total amount, so that over two-thirds of the chlorides volatilise in 10 minutes, and nearly the whole in 20 minutes. The ash must not be kept even at the lower temperature longer than necessary. Vieth found that it lost 6 p.c. in weight in 30 minutes when kept at a dark-red heat.

Determination of the milk-fat. The fat is the most valuable and important constituent of milk, and its determination with exactness is therefore indispensable for commercial and analytical purposes. Formerly the dried milk solids were exhausted with ether or petroleum, the ether evaporated from the solution obtained and the fat weighed. This method is almost entirely abandoned, as 20–25 p.c. of the fat is left unextracted, and concordant results are unattainable.

The following methods are now in use:—

Gravimetric methods. In consequence of the discrepancies between the results obtained by different analysts by processes in general use in 1884–5 (Wanklyn, or modifications), the Society of Public Analysts appointed a committee to compare the principal methods then known. The report of the committee, presented in 1886, and adopted by the society, stated that 283 comparative analyses had been made, and that the most concordant, and most trustworthy results had been obtained by the use of *Adams's process.* It was accordingly resolved that public analysts should use that process in preference to any other. The advent of methods such as Schmidt's and Gottlieb's has, however, caused this recommendation to be generally ignored.

Adams's process. The original method (Analyst, 85, 48) as modified by Allen and Chattaway (*ibid.* 86, 74) is carried out as follows. A strip of blotting paper 22 inches long, $2\frac{1}{2}$ inches wide, is thoroughly exhausted with ether and dried at 100°C. to constant weight. It is then rolled up into a coil of about 1 inch diameter with a piece of thin string (previously boiled with sodium carbonate) placed in a cap of (fat free) filter paper, and attached to it by means of the ends of the string. 5 c.c. of milk are distributed with a pipette over the upper surface of the coil, it is then transferred to the water oven and roughly dried on a glass plate. The dry coil is transferred to a 'Soxhlet's extractor,' and exhausted with ether, light petroleum, or carbon disulphide for $1\frac{1}{2}$ to 3 hours, the fat solution evaporated to dryness and weighed.

If the milk is sour it is preferable to mix it well, transfer a portion into a tared basin, weigh, pour it on to the coil, wash out the basin with 2 or 3 drops of water, adding these also to the coil, then proceed as above.

Sour milk may also be rendered homogeneous by adding a few drops of ammonia. A definite volume may then be used (the sp.gr. being known).

There is some difficulty in completely exhausting the blotting paper before use. Richmond (Analyst, 14, 123) states that this can be very perfectly done by treating for 3 or 4 hours with alcohol containing 10 p.c. of acetic acid, in a large Soxhlet extractor.

Adams's method gives low results if the fat is in a finely divided condition, *e.g.* in homogenised milk.

Storch's method. 10 grams of milk are evaporated on pumice, which is then ground to a fine powder, and extracted in a Soxhlet extractor; the pumice is then dried and reground and further extracted. Many other substances can be used in place of pumice; thus plaster of Paris was used for many years, and if the fine grinding (the essential part of the method) is adhered to, gives excellent results, but if only broken up roughly the results are low. Nilsson recommends kaolin (Chem. Zeit. 1891, 37), but the substance which gives the best results is kieselguhr (Analyst, 14, 124).

Schmidt (Zeitsch. anal. Chem. 27, 464) takes a test tube of 50 c.c. capacity, graduated in the upper part to $\frac{1}{10}$ c.c., introduces 10 c.c. of milk, adds 10 c.c. of strong HCl, boils with shaking until the liquid turns dark brown, cools the tube in cold water, adds 30 c.c. of ether, shakes round, and, after standing, measures the volume of the ethereal solution and draws off 10 c.c. This he evaporates down in a weighed porcelain capsule on the water-bath, and finally in the air-bath at 100°C. He then weighs and calculates for the original quantity of the ethereal solution. If the process has been properly conducted, the ether separates from the aqueous solution quite clear, without the slightest turbidity. The ethereal solution as it flows out from the pipette should not show any watery drops. With proper arrangements the operations can be carried out in 15 minutes. Stokes, who has devised special forms of tube for this method (Analyst, 14, 30), finds the results by this method agree with those obtained by Adams's process.

Instead of taking an aliquot portion of the ethereal solution, as much as possible should be withdrawn, and the tube washed out with successive portions of ether; the whole of the fat is thus obtained and weighed.

Gottlieb's method (L. V. S. 40, 1). This is a modification of the method of Röse (Zeitsch. angew. Chem. 1888, 4), and is thus carried out: 10 c.c. of milk are measured into a tall, narrow cylinder, graduated in 0·5 c.c., and holding 100 c.c., 1 c.c. of ammonia (sp.gr. 0·96) is added, and then 10 c.c. of alcohol; the mixture is well shaken. 25 c.c. of ether, which need not be dry, are added, and the contents of the tube well mixed; finally 25 c.c. of light petroleum are added and the mixture again well shaken. It is essential that the contents of the tube be mixed after the addition of each reagent, or the results may be very low. The cylinder is then left for 6 hours, the volume of the ethereal solution measured, and 50 c.c. removed, evaporated, and the fat dried and weighed .Popp (Milch.-Zeitung, 1904, 20) states that 1 hour is sufficient for the separation, and that the sp.gr. of the ammonia may be varied between 0·91 and 0·96 without affecting the results.

A more rapid procedure is to follow the method as above described, as far as the addition of the light petroleum (the quantities being halved throughout if desired, though it is essential to adhere to the proportions given); the contents of the tube are mixed, allowed to stand a minute or two till separation takes place, again mixed, and allowed to separate. As much as possible of the ethereal layer is removed, and the residue of the fat extracted by three further shakings with a mixture of equal quantities of ether and light petroleum (the recovered solvent answers admirably for this purpose). The combined ethereal extracts are evaporated in a wide-necked flask, and the fat dried in the water oven, with frequent blowing in of air until the weight is constant. The fat is then washed out of the flask with a little light petroleum, and the flask with any small residue of non-fatty substance again weighed (Fahrion, Chem. Zeit. 1906, 267; Richmond, Analyst, 1908, 389). This last procedure should be applied to the fat determinations by all methods, especially the Schmidt method, if accurate results are to be obtained.

Gottlieb's method is perhaps the easiest and best of all the methods of fat estimation, and is probably destined to supplant all the others; it is applicable with certain obvious modifications to all milk products.

Siegfeld (Milchw. Zentr. 1906, 1) finds that 0·0029–0·0036 p.c. cholesterol and 0·0079–0·0166 p.c. lecithin are contained in the fat separated by Gottlieb's method.

The maceration method being particularly suited to the analysis of sour milk will be described later.

Volumetric methods. A number of methods have been described in which the milk is treated with a solvent which dissolves everything in the milk except the fat, and this is separated by centrifugal force into the narrow graduated neck of a bottle, and there measured. Of these it is only necessary to describe the Gerber acid method, and to mention the Sinacid and Sal alkali methods.

Gerber's acid method. The reagents employed are sulphuric acid (first proposed by Babcock, Seventh Ann. Rep. Agr. Expt. Stat. Univ. Wisconsin, 1889, 98) to dissolve the casein, and amyl alcohol the use of which was introduced by Leffmann and Beam (Analyst, 1892, 83), to assist the separation of the fat. Gerber has worked out the various details (Milch.-Zeit. 1892, 891; 1893, 363, 656; and 1895, 169), and at the present time is worked as follows: 10 c.c. of sulphuric acid (commercial sp.gr. 1·820–1·825; 90–91 p.c. H_2SO_4) are measured into a bottle with a long graduated stem called a butyrometer; 11 c.c. of milk are added, and 1 c.c. of amyl alcohol (sp.gr. 0·815, b.p. 128°–130°C.). It is important that this order be adhered to, as if the sulphuric acid and amyl alcohol be allowed to mix before the acid is diluted with the milk, an action resulting in the formation of amylene and other products takes place, which substances increase the apparent volume of the fat (Richmond and O'Shaughnessy, Analyst, 1899, 146; Siegfeld, Molkerei-Zeitung, 1899, 433). The butyrometer is closed by a rubber cork, and the contents well mixed by shaking, and inverting several times so that the liquid in the neck becomes thoroughly warm; the fat is brought up into the neck by centrifuging for several minutes at a speed of at least 1000 revolutions per minute. Unless the bottles have been kept warm during centrifuging, by the use of a steam turbine to drive the machine or other device, they must be placed in a water-bath at a temperature of 60°–65° for several minutes. The percentage of fat is read off directly on the scale; to facilitate reading, the bottom of the fat column can be adjusted to one of the main percentage lines, by pushing in or pulling out the rubber cork to a small extent.

There are many types of butyrometers, differing chiefly in the construction of the graduated stem, this being round, square, or flat, or with eccentric bore to magnify the fat layer; for the trained chemist the round stem is the best, and gives the most accurate readings, but to the untrained eye the lateral magnification of the scale appears to be more easy to read. A number of appliances for automatically measuring the sulphuric acid and amyl alcohol have been devised, which are fully described and illustrated in the various manufacturers' catalogues.

With care this method gives good results, usually agreeing within 0·1 p.c. of the figures given by gravimetric analysis. The usual faults made by untrained persons are: (i) insufficient mixing, which may lead to a clear fat layer not being obtained; (ii) insufficient centrifuging, leading to low results; and (iii) unsuitable strength of acid, which may give rise to a dark, fat layer, and to errors in the result.

The layer measured is not pure fat (Richmond, Analyst, 1905, 326), partial hydrolysis takes place, and a portion of the soluble fatty acids is dissolved in the aqueous liquid; a small amount of amyl ester is formed, and also a sulpho-acid. If the conditions of the process are adhered to the volume of the fatty layer is but very slightly in excess of the true fat of the milk. As the whole of the amyl alcohol dissolves in the acid to form amyl hydrogen sulphate, a considerable margin of error in the measurement of the alcohol is without appreciable influence on the result.

The 'Sinacid' and 'Sal' methods. As strong sulphuric acid has certain disadvantages as a reagent, especially in the hands of inexperienced persons, the use of alkaline solutions to dissolve the casein has been introduced by Sichler (Milch.-Zeit. 1904, 417, Sinacid process), and Gerber (*ibid.* 1906, 4, Sal method).

The former method employs a solution containing sodium hydroxide, Rochelle salt, and sodium sulphate, whilst sodium chloride is substituted for the sulphate in the Sal method. Butyrometers, which are practically the same as those used in Gerber's acid method, are employed, and 11 c.c. of alkaline solution, 10 c.c. of milk, and 0·6 c.c. of *iso*butyl alcohol are measured into the boules. The mixing and centrifuging are performed as in the acid method, but the temperature of the water-bath is 45°. The *iso*butyl alcohol used in this method, which is usually coloured red, blue, or green, does not dissolve in the aqueous liquid, but passes into the fat, and hence the measurement must be exact. A drawback is that the corks become slippery, and tend to come out of the bottles.

The 'Neusal' method. A solution containing sodium salicylate, a carbohydrate and *iso*butyl alcohol is employed, and 4 c.c. of this are added to 9·7 c.c. of milk, mixed, warmed to 45° and centrifuged. The results are good, but Golding (Analyst, 1911, 203) has shown that variations in the mixture give erroneous results.

Determination of milk-fat from formulæ. It has been found that the sp.gr. of milk, solids not fat, and the fat are dependent upon each other, so that if two of these quantities are known, the third can be calculated.

Numerous formulæ have been worked out to express the relations between the three data, many of them applicable only to particular methods of analysis, which have now been shown to be incorrect. Owing to the natural variation in composition and specific gravity of the fat and solids not fat, the method is only an approximate one.

The following formula, which, though scientifically incorrect, is simple, gives results which are near the truth :

$$\text{S.n.F.} = \frac{G}{4} + 0{\cdot}2F + 0{\cdot}14 \text{ or } T = \frac{G}{4} + 1{\cdot}2F + 0{\cdot}14.$$

G=lactometer degrees, F=Fat, S.n.F.=solids not fat, T=total solids (Richmond, Analyst, 1905, 57).

A slide rule called the milk scale has been devised to perform the calculation (Analyst, 1898, 2); a scale for the correction of specific gravity for temperature is also included.

Determination of the milk-sugar.—(1) *Gravimetrically, by Soxhlet's method.*—25 c.c. of milk are weighed out, diluted to 400 c.c. ; 10 c.c. of a solution of copper sulphate (69·28 grams per litre) are added, then 6·5–7·5 c.c. of a solution of caustic soda standardised to precipitate an equal volume of the copper solution. The solution should still be slightly acid after the addition of the soda, and contain traces of copper. Scheibe (Milch.-Zeit. 1901, 113) recommends that 20 c.c. of a cold, saturated solution of sodium fluoride should also be added to remove lime salts. It is diluted to 500 c.c., filtered ; 100 c.c. are transferred to a beaker, 50 c.c. of Fehling's solution are added, the whole boiled for 6 minutes, filtered through asbestos, washed with hot water, then twice with absolute alcohol and twice with ether. A special filter is used consisting of a calcium chloride tube, the bulb half filled with asbestos and previously dried and weighed. The tube containing the asbestos and precipitate is cleared of ether by blowing air through, and a stream of hydrogen passed through, whilst the bulb is gently heated for 5 minutes. The reduced copper is allowed to cool in a stream of hydrogen, and weighed. Soxhlet gives the following table :—

Copper obtained (milligrams)	Amount of milk-sugar (milligrams)
392·7	300
363·6	275
333·0	250
300·8	225
269·6	200
237·5	175
204·0	150
171·4	125
138·3	100

The intermediate values are obtained by interpolation.

(2) *By polarisation.*—The proteins in milk affect the determination, and must first be eliminated. This may be done—

By mercuric nitrate (Wiley, Amer. Chem. J. 6, 289).—Mercury is dissolved in double its weight of HNO_3 (sp.gr.=1·42), and an equal volume of water added to the solution.

Vieth (Analyst, 1888, 63) gives the following directions : to 100 c.c. of milk 3 c.c. of this solution are added, the mixture well shaken and filtered. The clear filtrate is polarised, and the percentage of anhydrous milk sugar deduced. If a 200 mm. tube is used, the reading in angular degrees, is multiplied by

$$0{\cdot}95 \times \frac{1}{1{\cdot}05} \times \frac{100 - 1{\cdot}057F}{100} \times \frac{1}{\text{sp.gr.}}$$

This expression reduces the readings to their value in anhydrous milk sugar ; corrects for the volume of the fat (the volume of the proteins is taken as 3 c.c.), and converts percentages by volume into percentages by weight.

Richmond and Boseley (Analyst, 1897, 98) add to 100 c.c. of milk (if a 200 mm. tube is used):

3 c.c. mercuric nitrate solution,

10·85 c.c. of water to reduce angular degrees to percentages of anhydrous milk sugar,

$F \times 1{\cdot}11$ c.c. of water to correct for the volume of fat,

Lactometer degrees $\times \frac{1}{10}$ to convert volume into weight percentages.

The reading in angular degrees gives the percentage direct.

Richmond (Analyst, 1910, 516) has lately shown that mercury salts do not precipitate the whole of the proteins, and recommends the addition of phosphotungstic acid to the mercuric filtrate. With whole milk the error is very small, but is important with dried milks, &c.

Patein (J. Pharm. Chim. 1904, 501) states that milk sugar cannot be estimated polarimetrically in human milk, as this contains a lævorotatory substance not precipitated by mercuric nitrate nor picric acid.

The volume of the precipitate of fat and proteins may be estimated by the method of double dilution, *i.e.* making up the same quantity of milk to two different volumes, one being preferably twice the other; formulæ for correction have been worked out by Bigelow and McElroy (Amer. Chem. J. 25, 694), Wiley and Ewell (Analyst, 1896, 186), and Schiebe (Milch.-Zeit. 1901, 113). Mercuric iodide, and acetate, sodium metaphosphate, picric acid, and zinc ferrocyanide have also been proposed to precipitate the proteins (*cf.* Thibault, J. Pharm. Chim. 1896, 5; Carrez, Ann. Chim. anal. 1909, 187).

The temperature during the process must be kept constant and within 15°–25° (Wiley, Analyst, 13, 196).

Stokes and Bodmer (*ibid.* 10, 12) recommend the use of Pavy's solution (*v.* p. 101).

100 of milk-sugar have the same reducing power as 52 of glucose or 49·4 of cane-sugar. By this method a fair determination may be made by merely diluting the milk so that 6–12 c.c. decolourise about 40 c.c. of Pavy's solution.

Determination of the total proteins.—Ritthausen's method (Zeitsch. anal. Chem. 1878, 241).—The proteins are precipitated by copper sulphate and soda solution (*v. Determination of milk-sugar*). The precipitate is collected on a weighed filter, washed with a little of the clear filtrate, allowed to drain, washed with 80–100 c.c. of hot water, dried, the fat extracted, dried again at 125°–150° and weighed. The precipitate is ignited and the ash deducted. Sebelien (Zeitsch. Chem. 13, 135) points out that this method is not exact, since copper hydroxide does not give up all its water at 125°, but only on ignition. This error is avoided if at least 0·6 gram of protein is present in solution, and the ratio between the copper oxide used and the amount of protein falls between 1·3 and 1·35.

Fleischmann (Lehrbuch der Milchwirtschafe, 1907, 70) states that the error introduced is 0·038 p.c. for each 1 p.c. of protein.

Almen's method. This method gives very exact results, and is particularly recommended by Sebelien (Zeitsch. physiol. Chem. 13, 135). 3–5 grams of milk are taken (2 grams of colostrum, 10 of whey), diluted with 3–4 vols. water; a few drops of solution of some salt (NaCl, $MgSO_4$, &c.), then excess of solution of tannin, is added in the cold. (The tannin solution consists of 4 grams tannin added to 8 c.c. of 25 p.c. acetic acid and 190 c.c. of 40–50 p.c. alcohol.) The precipitate is thoroughly washed with *cold* water, and the nitrogen in the filter and precipitate estimated by Kjeldahl's process. The result, after subtraction of the N in the filter, gives the protein N, and this ×6·38=total proteins (since both casein and albumin contain 15·7 p.c. N); for whey the factor 6·96 gives the most exact results.

Phospho-tungstic acid may also be used to precipitate the proteins.

Total nitrogen. The total nitrogen in milk is best determined directly by Kjeldahl's method. The digestion must be somewhat prolonged to obtain the best results (Kreusler, L. V. S. 31, 248). In absolutely accurate determinations it is not advisable to calculate the total proteins from total N by multiplication by 6·37, because of the presence of nitrogenous extractive matters in the milk. Schmidt-Muhlheim found an average of 0·04–0·05 p.c. of extractive N. This is confirmed by Sebelien (*l.c.*), who finds the same average, with a minimum of 0·03 p.c. and an exceptional maximum (in colostrum) of 0·08 p.c.

(N−0·04)×6·38 gives a very close approximation (Sebelien).

Separate determination of the proteins (casein, albumin, globulin, &c.). Hoppe-Seyler (Handb. der Phys. Chem. Anal.) proceeds as follows. 20 c.c. of milk are diluted with water to 400 c.c., transferred to a deep beaker, and very dilute acetic acid added until a flocculent precipitate just appears. Carbon dioxide is then passed for ¼–½ hour, and the precipitate allowed to subside for 12 hours. The solution, which should be perfectly clear, is passed through a weighed filter, the precipitate washed on with a little of the clear filtrate, allowed to drain, and washed once with distilled water. The precipitate=casein+fat. The latter is extracted as usual. The filtrate is boiled for a few minutes, when the albumin separates out; if the precipitate is not very flocculent, a few drops of very dilute acetic acid may be added. It is collected on a weighed filter, washed with cold water, and dried at 120°–125°.

The filtrate and wash-water are evaporated to the consistency of a thin syrup, the precipitate which settles out gathered on a small weighed filter, well washed with cold water, and weighed.

Van Slyke (Amer. Chem. J. 1894, 712) adds to 10 grams of milk + 90 c.c. of water at a temperature of 40°–42°, 1·5 c.c. of 10 p.c. acetic acid, and allows the liquid to stand 5 minutes; the precipitate of casein is washed, and the nitrogen estimated by Kjeldahl's method. The albumin is precipitated by boiling the filtrate, the nitrogen being estimated in the precipitate. This method has been extended by Van Slyke and Hart (Amer. Chem. J. 1903, 150).

This method cannot be used for human milk nor for that of the mare and ass, because on dilution and treatment with acetic acid and CO_2 the caseïn separates in such a finely divided condition that it cannot be filtered. Blyth (Food: Lond. 88) uses the following modification for human milk; 100 c.c. are diluted to 400 c.c., acidified with dilute acetic acid, saturated with CO_2, and transferred to a tall beaker. A small cylindrical porous battery cell, closed by a perforated plug connected with a mercury pump, is immersed in the liquid. A good vacuum is maintained, and ultimately the whole of the solution passes through. The caseïn is left behind, and is washed, dried, and weighed. The albumin is precipitated by boiling, &c.

Pfeiffer and Schmidt (Zeitsch. Chem. 23, 445) modify Hoppe-Seyler's method in the following way for human milk: 20 c.c. of milk are diluted to 400 c.c., heated to 40°, acetic acid added drop by drop till a granular precipitate commences to form; CO_2 is then passed in for half an hour and the precipitate allowed to subside for 24 hours. The caseïn is then weighed, and the filtrate treated in the ordinary way.

Tolmatscheff's method.—(1) *Casein.* 20 c.c. of milk are saturated in the cold with crystallised $MgSO_4$ (it is best to make the crystals into a paste with water), 100 c.c. of a very concentrated solution of $MgSO_4$ are added, the precipitate filtered off, well washed with a concentrated solution of $MgSO_4$, the fat extracted, and the residue dried, weighed, and the ash deducted.

(2) *Albumin.* The filtrate and wash-water from the caseïn are acidified with dilute acetic acid, heated to boiling, filtered, washed, with water and alcohol, dried at 120°–125°, and weighed. Sebelien (*l.c.*) advises that in each case the N should be determined in the precipitate by Kjeldahl's process, and the albuminoid found by multiplication by 6·37. The results are accurate.

The following scheme is recommended for scientific purposes (Sebelien):—

(1) Determine total N by Kjeldahl's method.

(2) Total proteins by precipitation with tannin (N by Kjeldahl).

(3) Casein+globulin by precipitation with $MgSO_4$ (N by Kjeldahl).

(4) Casein by precipitation with dilute acetic acid (N by Kjeldahl).

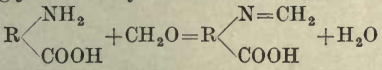
The difference between (2) and (3) gives the albumin, between (3) and (4) the globulin, between (1) and (2) the non-protein or extractive N. The latter may also be determined directly by Kjeldahl's method, in the filtrate from the tannin (2).

Opalisin, which is scanty in cow's milk, but abundant in human milk, is estimated by precipitation of the casein by acetic acid, and saturation of the filtrate by sodium chloride (Wroblewski, Zeitsch. physiol. Chem. 1898, 308).

Schlossmann (*ibid.* 1896, 197) precipitates casein with a little saturated alum solution at 37°, globulin in the filtrate by saturating with magnesium sulphate, and estimates albumin from the difference between the total protein nitrogen and that of the casein and albumin.

For general review of the methods of protein estimation, *cf.* Simon, Zeitsch. physiol. Chem. 1901, 466.

Rapid estimation of proteins.—The aldehyde method. Steinegger proposed that the acidity developed in milk by the addition of formaldehyde should be used as an analytical method (Zeitsch. Nahr. Genussm. 1905, 659), and showed that it was due to the conversion of the practically neutral amino-acid groups into strongly acid methylene-amino-acid radicles.



$$R\begin{cases}NH_2\\COOH\end{cases}+CH_2O=R\begin{cases}N{=}CH_2\\COOH\end{cases}+H_2O$$

Richmond and Miller (Analyst, 1906, 224) studied the method, and pointed out that the value depended on the nature of the base used for titration, the use of soda giving lower results than strontia, which they recommend (*cf.* also Sorensen, Biochem. Zeitsch. 1907, 45).

The method is as follows: to 10 or 11 c.c. of milk (the latter volume is convenient if the Gerber fat estimation is performed) at least 1 c.c. of 0·5 p.c. phenolphthalein solution is added, and the milk neutralised with N/11 (approx.) strontia; to the faintly pink solution 2 c.c. of 40 p.c. formaldehyde solution is added, and the titration continued till a faint pink colour again appears; the acidity of the formaldehyde added is deducted, and the aldehyde figure is calculated as c.c. of N acid per litre; this multiplied by 0·170 gives the percentage of proteins in normal cow's milk. On no account must the formaldehyde solution be neutralised previous to use with soda, as the strong neutral solution becomes very appreciably alkaline on dilution; the same figure for acidity of the formaldehyde is, however, obtained when strontia is used whatever the dilution. The factor for converting aldehyde figure to proteins varies with different milks and milk products; thus it is 0·125 for whey, 0·136 for human milk, and 0·154 for asses' milk. When milk turns sour the aldehyde figure rises (Analyst, 1906, 328; and 1908, 115), due to proteolytic fermentation. The method, although extremely rapid, and approximately accurate, must be used with reservation.

Acidity. By titration of milk with an alkali solution using phenolphthalein solution as indicator, a measure of the acidity is obtained; unfortunately there are several modes of expression of acidity. Soxhlet and Henkel (Chem. Zentr. 1887, 229) titrate 50 c.c. of milk with N/4 soda solution, and call the number of cubic centimetres of soda used degrees of acidity; Thörner (Milch.-Zeit. 1893, 58) dilutes 10 c.c. of milk with 20 c.c. of distilled water, and titrates with N/10 soda, and expresses as degrees of acidity the number of c.c. of normal solution required per litre of milk; many others use 10 c.c. of milk undiluted and titrate with N/10 solution, and express the acidity in the same terms as Thörner, but as the sodium salts of the acids present in milk dissociate on dilution the degrees determined by Thörner's method do not agree with those determined by using undiluted milk. It is not unusual, though of course incorrect, to express the acidity as grams of lactic acid per 100 c.c., and Dornic (Le Contrôle du Lait, 1897) proposes the use of N/9 soda solution (1 c.c. = 0·01 gram lactic acid), and calls the grams of lactic acid per litre degrees. The amount of phenolphthalein used and the temperature have some influence on the end-point of neutrality (Richmond and Miller, Analyst, 1907, 152).

Experience has shown that the most satisfactory and concordant results are obtained by the use of strontia solution (about N/11) as the alkali at the ordinary room temperature (15°–20°), and employing at least 0·005 gram phenolphthalein for 10 c.c. of milk, and the most convenient mode of expression is c.c. of N acid per litre or degrees. The tint equal to that produced by 1 drop of an 0·01 p.c. alcoholic solution of rosaniline acetate added to 11 c.c. of milk may be taken as a standard. The normal acidity of cow's milk is about 20 degrees, and the acidity is nearly always within 2 degrees of the aldehyde figure (*q.v.*; Richmond, Analyst, 1908, 115); in a few abnormal cases it is much lower.

Analysis of sour milk. A practical method for the analysis of sour milk, by means of which the composition, when fresh, can be deduced, has been devised at the Government Laboratory. Originally described by Bell (Food and its Adulterations, 1883, pt. 2), it has been modified and placed on a scientific basis by Thorpe (Chem. Soc. Trans. 1905, 206); Richmond and Miller (Analyst, 1906, 317) have examined and criticised the method, and while suggesting a few minor modifications, agree in the main with Thorpe as to its substantial accuracy. The following is an abridged description, but for full working details the original papers should be consulted.

Maceration method for fat and solids not fat. 10 grams (*circa*) are weighed into a flat-bottomed platinum dish provided with a flattened glass stirrer, neutralised with strontia solution, using phenolphthalein as indicator, and evaporated to a stiff paste on a steam-bath; the residue is treated with successive quantities of ether, and ground up to a fine powder under the ether, which is passed through a weighed filter, and collected in a flask; the ether is evaporated and the fat dried and weighed. The fat should be washed out of the flask with light petroleum, and the residue of phenolphthalein subtracted from the weight (R. and M.). It is advisable to continue the extraction with ether and the grinding of the solids not fat till no more fat is obtained. The solids not fat in the basin and on the weighed filter are dried to constant weight in the water oven. A correction is made or the added alkali by deducting 0·00428 gram or each c.c. of N/10 strontia added.

Corrections for loss owing to decomposition.—(*a*) *The alcohol correction.* 75 grams (more or less according to the amount of sample available) are half neutralised with soda and distilled, the distillate is neutralised, using litmus paper as indicator, and redistilled a convenient volume (say 25 or 50 c.c.) being collected, and the density taken; the difference between the density found and 1000, multiplied by 0·977, will give the quantity of anhydrous milk-sugar equivalent to the alcohol per 100 c.c. of distillate.

(*b*) *Volatile acid correction.* 10 grams of milk are half neutralised with N/10 soda, and a little phenolphthalein added; the mixture is evaporated to dryness with frequent stirring, taken up with 20 c.c. of boiling water, and titrated with N/10 soda. The difference between volume of N/10 soda used for the original acidity, and that after evaporation multiplied by 0·0255 gives the correction due to loss of milk-sugar p.c. by conversion into volatile acids.

If the milk has undergone the butyric acid fermentation, which is not common, but which is easily recognised, this method gives totally erroneous results, and the methods described by Thorpe or Richmond and Miller (*l.c.*) must be substituted.

(*c*) *Ammonia correction.* 2 grams of milk are made up to 100 c.c. with ammonia free water, and filtered clear; the ammonia is estimated by Nesslerising in 10 c.c. of the dilute solution, the standard solution receiving an addition of 10 c.c. of a clear solution of 2 c.c. of fresh milk slightly acidified in 100 c.c. of water. The ammonia found multiplied by $500 \times 5{\cdot}2$ will give the loss of casein p.c. The three corrections, of which that due to alcohol is generally by far the largest, are added to the solids not fat to obtain the solids not fat in the fresh milk.

Richmond and Miller introduce some further corrections for lactic acid, aldehyde taken up from the ether, loss of butyric acid (if present) on drying, and for hydrolysis of the proteins, but these, except in special cases, are small, and tend in opposite directions; they may be omitted, as a rule, without greatly affecting the results. Specific gravity of sour milk may be determined by adding ammonia to dissolve the curd, and making a correction for the density of the added ammonia (*cf.* Weibull, Milch.-Zeit. 1894, 247, and 413; Richmond and Harrison, Analyst, 1900, 207).

ADULTERATIONS.

The principal adulterations practised are the addition of water and the removal of cream. Carbonates of the alkalis and borax, or boric acid, formaldehyde, and more rarely, salicylic acid, are also introduced to keep milk from souring.

The addition of water or removal of cream is shown by the analysis.

Clause 4 of the Sale of Food and Drugs Act, 1899, gives power to the President of the Board of Agriculture to fix limits below which a presumption is raised till the contrary is proved that the milk is not genuine; these limits are 8·5 p.c. of solids not fat and 3·0 p.c. of fat. It sometimes happens that genuine milk yields a percentage of fat below 8·5 p.c. of solids not fat (*cf.* Wauters, Rev. internal. Falsific. 1902, 67; Malpeaux and Dorez, Ann. Agronom. 1901, 449; and Billitz, Milchw. Zentr. 1905, 113). Richmond (Analyst, 1893, 271) considered that genuine milks of this character contained above 0·7 p.c. of ash and 0·5 p.c. of nitrogen, but as he has himself found lower percentages of nitrogen (Analyst, 1903, 281, and 1910, 231) his views have undergone modification. His present view is that normal milk should contain at least 4·5 p.c. of lactose, 0·5 p.c. nitrogen, and 0·7 p.c. ash, and that abnormal milks low in solids not fat should conform to these limits in at least two of the constituents.

For the monthly variations of the composition of milk, the daily variations and the variation between morning and evening milk, *see* numerous papers in the Analyst since 1882, by Vieth and Richmond.

Soxhlet has proposed the following direct test for the addition of water, based upon the presence of nitrates in water and their total absence in milk.

The milk is coagulated by a solution of calcium chloride free from nitrate; the serum is now treated with a solution of diphenylamine in concentrated H_2SO_4, in the same way as with the ferrous sulphate test. This test has frequently been rediscovered. Szilasi (Ann. Chim. Phys. 33) measures out 1 c.c. of a solution of diphenylamine sulphate into a porcelain dish, and adds a few drops of milk; nitrates gradually give a blue colouration. These tests are not sufficiently delicate for pure water.

Fritzmann (Chem. Zentr. 1898, i. 218) adds formaldehyde and pure sulphuric acid; in the presence of nitrates a blue colour is developed.

Richmond (Analyst, 1894, 83) has found nitrates in the milk of cows that received 1 gram of potassium nitrate with their food.

Carbonates of the alkalis are best determined by taking 500 grams of milk and determining the CO_2 in the ash. The ash of pure milk should not contain more than 2 p.c.

Boric acid is detected by Meissl as follows. 100 c.c. are made alkaline with milk of lime, evaporated and incinerated. The ash is dissolved in as little concentrated HCl as possible, filtered, the filtrate evaporated to dryness, and the HCl expelled. The residue is moistened with a drop or two of an alcoholic extract of turmeric and evaporated on the water-bath. Mere traces of boric acid give a cinnabar or cherry-red colouration.

A more rapid though less delicate test consists in neutralising a quantity of milk with caustic soda, using phenolphthalein as indicator; portions of this are poured into the test tubes, and to one an equal volume of water is added, and to the other an equal volume of neutral 50 p.c. glycerol. In the presence of boric acid the glycerol tube will be much lighter in colour, usually quite white.

Salicylic acid is detected by Pellett by mixing 100 c.c. of milk, 100 c.c. of water at 60°, 5 drops acetic acid, 5 drops of a solution of mercuric nitrate, filtering off the proteins, shaking with 50 c.c. of ether, allowing to settle, removing the ether, evaporating to dryness, dissolving the residue in a few drops of water, and adding ferric chloride. The quantity of salicylic acid can be approximately known by comparing the violet colouration produced with a series of standard solutions.

Boric acid is estimated (Richmond and Miller, Analyst, 1907, 144) by adding to milk half its volume of 0·5 p.c. phenolphthalein solution, and neutralising to a faint pink colour while boiling; at least 30 p.c. of glycerol is now added, and the boric acid titrated with N/10 alkali (1 c.c. = 0·0062 gram H_3BO_3). R. T. Thomson (Analyst, 1893, 184) neutralises first to methyl orange, and then titrates in the presence of glycerol to phenolphthalein. Another method, due originally to Gooch, depends on the volatilisation of boric acid as methyl borate by distillation with methyl alcohol (*cf.* Cassal, Analyst, 1890, 230, and Hehner, *ibid.* 1891, 141). Formaldehyde may be detected by numerous methods, the most simple of which is due to Hehner (*ibid.* 1896, 94); when strong sulphuric acid is added to milk it forms a violet-blue colouration at the junction of the two liquids in the presence of formaldehyde, provided that a small quantity of an oxidising agent be present. Leonard (Analyst, 1896, 157) and Farnsteiner (Chem. Zentr. 1897, i. 133) have shown that ferric chloride is the best oxidising agent, and Rosenheim (Analyst, 1907, 106) has pointed out that this last is a tryptophan reaction.

Other tests are those of Trillat with dimethylaniline (Compt. rend. 1892, 891), Richmond and Boseley with diphenylamine (Analyst, 1895, 155), Rideal with Schiff's reagent (*ibid.* 1895, 158; *cf.* Richmond and Boseley, *l.c.*, and Hehner, *l.c.*), Mitchell with Nessler's reagent (Analyst, 1897, 97), Jorissen with morphine (Bull. Soc. chim. 1897, 17, 167), Vanino with phloroglucinol (Chem. Zentr. 1899, i. 710), Gabutti with carbazole (Boll. Chim. Farm. 1907, 349).

Preservation of Milk.

To preserve milk for any length of time at the ordinary temperature it must be sterilised. This may be done either by means of antiseptics, such as salicylic acid, borax, or boric acid, &c. —the presence of which is highly undesirable in food—or, as is more generally practised, by the agency of heat. For the action of drugs, *v.* Soxhlet, J. Pharm. Chim. 6, 118; Mayer, Milch.-Zeit. 1882, 321. A temperature of 100° is insufficient to sterilise milk completely. Dietzell found that milk heated for 20 minutes to 105°–110° only kept sweet for a few weeks, whilst that heated to 100°–115° for 20 minutes (5 minutes at 115°) was perfectly sweet 3 years later.

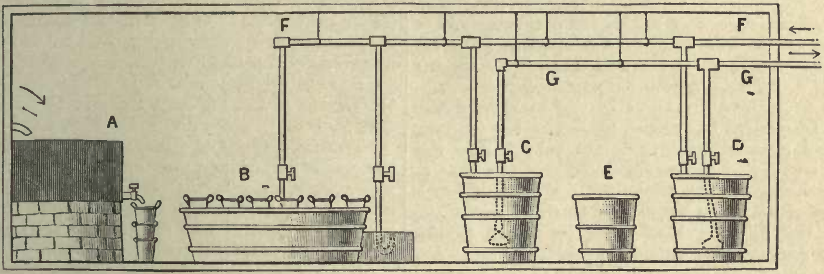


Fig. 1.

Duclaux kept milk unchanged for 5 years by exhausting the air from the containing vessel and subsequently heating to 120°.

Milk can, however, be preserved unchanged by mixing it with a considerable percentage (not less than 12 p.c. of its weight) of sugar, evaporating to a semi-solid mass, and excluding the air.

Fleischmann gives the following account of the process of manufacture of condensed milk *with* addition of sugar. The milk on delivery is weighed, filtered through a wire sieve, and thrown into a reservoir communicating with the tank A (Fig. 1), tapped into cans 20–30 inches deep. A number of these are placed in the water-bath B which is heated by steam from a perforated coil at the bottom, communicating with the steam-pipe F. (Beside each water-bath is a smaller bath for cleaning the cans.) When the milk has attained a temperature of 87°–94° it is transferred to the vats C or D, which have false copper bottoms, into which steam can be introduced to prevent the milk from cooling. The vat E contains the necessary quantity of *cane-sugar*—12 p.c. of the weight of the milk, hot milk is thrown in, stirred, and passed back to C through a filter, and this is repeated till all the sugar is dissolved.

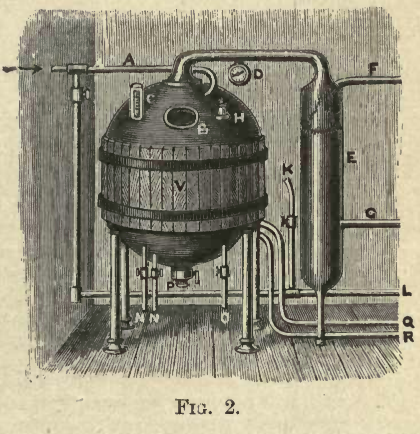

Fig. 2.

The milk in C is then sucked up by the pipe G, which terminates in a sieve, into the vacuum V (Fig. 2). This is a spherical copper vessel, with a wooden jacket round the middle and with a false bottom, into which either steam or cold water can be introduced. There is also a copper coil inside the vacuum, into which steam and cold water can be passed. A (Fig. 2) is the pipe through which the sugared milk is introduced; B is a sight-hole, hermetically closed with a thick glass plate; C is a thermometer; D a manometer; E a condenser; F the cold-water pipe for the condenser; G the pipe leading to the air-pumps; H an air-cock; I is an exhaust pipe for the condensed water; K and L are cold-water pipes for clearing the vacuum; M an exhaust pipe for the waste water from the space between the two bottoms; N an exhaust pipe for the coil inside the vacuum; O a pipe for drawing samples of milk; P the delivery pipe for the condensed milk; Q a steam pipe for supplying the space under the false bottom; R a supply pipe for the coil. On the other side of the vacuum there is another sight-hole resembling B, behind which a light is placed, whilst the progress of the operation is continually watched through B. The air-pumps are set to work, but no steam is passed in until the milk is seen to be *boiling briskly*; the temperature is then regulated to 60°. The pressure inside the vacuum is generally 60–100 mm.

When a sample taken out and cooled is of the right consistency, cold water is turned on in both the coil and false bottom, and after a short time the milk is run out and quickly cooled to 15°. It is then tapped into canisters; the covers, which are pierced with a fine hole, are soldered on—the heat of the operation causes the greater part of the residual air to be expelled; the hole is then quickly soldered over.

Various modifications of the above process are adopted. In some places, for instance, special precautions are taken to regulate the temperature of the water-bath, and the heat is not allowed to rise above 60°–75°; in others a series of ledges are arranged in the vacuum, so that the milk trickles down from one to the other and is more quickly condensed, &c., &c. Grandeau and Kramer (J. Pharm. Chim. 16, 267) state that at Zurich the addition of sugar is made to the milk heated to 35°, and the temperature in the vacuum is not allowed to rise above 52°.

In many cases part of the cream is removed before condensation.

ANALYSIS OF CONDENSED MILK (SWEETENED).

MILK CONDENSED WITHOUT ADDITION OF SUGAR.

In America the milk is filtered, heated to 60° or 70°, filtered again and condensed in a vacuum at 40°–45° to about ⅓ of its bulk. A portion of the cream is often abstracted before condensation.

This milk will not keep for more than a few days. The milk prepared at Romanshorn (Switzerland) keeps better, but the process of manufacture is not known. It is believed that the milk is heated to about 120° in its preparation, as about ⅔ of the albumin is coagulated, whilst in ordinary (sweetened) condensed milk only about half the albumin is coagulated. A portion of the cream is abstracted before condensation on account of the rancidity which a large amount of fat quickly occasions.

Scherff's process, which is in use at Stendorff, consists in first sterilising the milk by heating it to 100°–113° for 1–2 hours in sealed vessels under a pressure of 2–4 atmospheres. It is then condensed either to ½ or to ⅓ of its bulk in a partial vacuum at a temperature of 65°–70° and a pressure of 11 mm.

Voelcker gives the following analyses of unsweetened milk:

	I	II
Water . . .	57·96	51·72
Fat . . .	16·02	14·33
Casein . . .	8·50	11·69
Milk-sugar . .	16·32	19·51
Ash . . .	2·20	2·75

KEPHIR.

Milk does not readily undergo the alcoholic fermentation by the action of yeast, though a small amount of alcohol is formed during the lactic fermentation.

In the Caucasus a special ferment (kephir grains) is used which has the property of speedily inducing alcoholic fermentation in milk. Kern (Biol. Zentr. 2, 137) found in the grains two of the organisms of ordinary yeast (*Saccharomyces cerevisiæ*) and a bacillus (*Dispora caucasica*).

For the manufacture of kephir, *v.* Krannhals (J. Pharm. Chim. 14, 191), Haccius (Bied. Zentr. 1885, 265).

The milk-sugar is changed by the action of the grains partly into carbon dioxide and alcohol and partly into lactic acid; small quantities of glycerol, acetic, succinic, and butyric acids are also formed. The casein and albumin are partly peptonised.

Kephir is an agreeable nourishing drink with a slightly sour taste. It is best relished when two days old, and three days after preparation it is decidedly sour and stronger in alcohol.

König gives the following average composition of kephir:

Water	91·21
Alcohol	0·75
Fat	1·44
Sugar	2·41
Lactic acid	1·02
Casein	2·83
Albumin	0·36
Hemialbumose . . .	0·26
Peptone	0·039
Total proteins . . .	3·49
Ash	0·68

A simple method of making kephir consists in taking some of the good 3-days' old product, adding 4–5 parts of cow's milk, and allowing it to ferment for 2 days with occasional shaking. The consumption of kephir has made considerable progress, and it is now the custom to take it medicinally, although its preparation in reference to the production and significance of the so-called kephir grains is still obscure. In the Caucasus kephir is prepared from milk, particularly sheep's and goat's milk, in peculiar leather pipes (*burdinks*) by adding to it kephir grains as ferment. Struve has investigated the formation of this ferment and studied its properties. Since the augmentation of the kephir grains takes place when the milk is kept in leather pipes their growth must necessarily be affected by the milk constituents, and although it was *à priori* impossible to determine what changes the ingredients consumed during this process undergo, it was assumed that the substances belonging to the group of proteins would maintain their general type to a greater or less degree. 100 parts of the grain dried in the air gave :

Water	11·21
Fat	3·99
Peptones soluble in water .	10·98
Proteins soluble in ammonia .	11·32
Proteins soluble in potash .	30·39
Insoluble residue . . .	33·11

On digesting the insoluble residue in a dilute solution of potash and subjecting it to microscopical examination, it showed an intimate mixture of yeast fungi with the bacteria described by Kern under the name of *Dispora caucasica.* Struve concludes that only 33·11 p.c. of the total substance of the grains constitutes the active ferment. With kephir grains of the above composition a drink is prepared which, according to Podwisozky, contains only traces of alcohol after 24 hours' bottling, whilst in 48 hours it becomes brisk and contains a considerable amount of alcohol, the latter increasing still further after the lapse of another 24 hours. On subjecting the three drinks characterised by the difference in the duration of the fermentation to analysis it was found that although the percentage of casein was the same in each case, the latter was not completely soluble in a mixture of dilute ammonia and potash. In the solution of the casein of the kephir of one day's fermentation only traces of a precipitate were observed ; the kephir 2 days old gave 0·05 p.c. and that 3 days old 0·22 p.c. of residue. Microscopical examination of the residues showed that yeast fungi only were present, bacteria or other forms of fungi being entirely absent. From this Struve infers that the fermentation of the milk is dependent upon the growth of the yeast fungus (*Saccharomyces mycoderma, Mycoderma cerevisiæ et vini*) contained in the kephir grains, whilst the bacteria *Dispora caucasica* take no active part in the fermentation. This conclusion is confirmed by the fact that the finished kephir is capable of fermenting fresh portions of milk. From the results of this investigation Struve concludes (1) During the fermentation the yeast fungus, under the influence of the power of vegetation and of osmotic laws, enters into animal as well as vegetable tissues, and disposes them to a variety of changes. (2) The development of the yeast fungus in the interior of organic tissues may, under favourable conditions, assume the character of a special process of fermentation. (3) The effects of such a process are increased when the evolution of carbon dioxide is retarded. (4) Animal tissues into which the yeast fungus has entered exhibit in sugar solutions as well as in milk all appearances of vinous fermentation. They can therefore be used instead of kephir grains for the preparation of kephir. (5) The formation of the kephir ferment is the cause of a peculiar growth of the yeast fungus within the tissues of the leather pipes during the process of fermentation, its fungoid form being due to the development of carbon dioxide. (6) The bacteria *Dispora caucasica* must be regarded as residues of fibrils of the tissues of the leather pipes (Ber. 17, 1364 ; J. Soc. Chem. Ind. 3, 493).

Milk powder. By evaporating condensed milk in a vacuum chamber it is reduced to a solid form. Many patents have been taken out for drying milk ; Just and Hatmaker use rollers heated by steam above the temperature of 100°, the milk being fed on to them at such a rate that it is nearly dry by the time that the adhering film reaches knives touching the surface of the rollers, that remove it continuously. A small quantity of alkali is added to render the milk powder soluble in water. The rollers may be surrounded by a jacket through which a current of air passes, or from which the air is exhausted, in which case the temperature of the rollers is not so high, and a more soluble product is obtained.

Under the Stauf, Merrell-Soule, and Bevenot de Neveu patents, milk is sprayed through small orifices under pressure, into a large chamber through which warm air is passed ; evaporation takes place, and the solid milk falls in very minute particles ; this method produces a very soluble powder, without the addition of alkali, and the fat does not separate in oily globules, as it does from milk powders prepared by other methods. Milk powders prepared from skim milk keep well, but those containing the fat have a tendency to turn rancid or tallowy ; this is partly due to oxidation, a large surface of the fat being exposed to the air, and partly to the action of the neutral enzymes of the milk, which are not destroyed at the temperatures employed.

The following are typical analyses of milk powders :

Designation	Moisture	Fat	Milk sugar	Proteins	Mineral matter
Enriched .	1·4	36·8	33·8	22·8	5·2
Full cream	4·7	29·2	35·7	24·8	5·6
Half cream	4·9	16·4	43·6	28·5	6·6
Skim .	3·4	2·1	54·5	31·8	8·2
Whey .	2·7	0·7	76·5	14·0	8·1
Sweetened	1·6	17·7	22·6 cane sugar 38·9	15·6	3·6

Cream. On allowing milk to stand, the fat globules rise to the surface, and form a layer of cream on the surface ; under the influence of gravity the rate of rise of the fat globules is slow, and the whole of the cream cannot be obtained before the milk turns sour. By centrifugal force the rate of motion of the fat globules can be much increased, and practically the whole of the cream removed ; the modern cream separator consists of a steel bowl rotated at a high rate of speed (5000–10,000 revolutions per minute) into which the milk is fed by a central inlet tube ; from this it passes to a series of chambers (usually formed by a number of conical discs—the Alfa device), in which the heavier portion—the skim milk—pass to the outside of the bowl, while the lighter fat globules collect in the centre, and escape by an outlet at the top of the bowl, the skim milk being removed from near the periphery by a series of tubes or a special chamber, and discharged at a lower level. Provision is made by an adjustment of the cream outlet for varying the proportion of skim milk and cream removed, and thus the thickness of the cream.

Qualitatively cream has the same composition as milk, but differs quantitatively in containing a very much larger percentage of fat; the other constituents, except those soluble in the fat (lecithin), or those existing in the solid form (the cellular elements) are depressed in proportion to the increase of the fat.

Clotted or Devonshire cream is prepared by setting milk in pans, and when a layer of cream has risen to the surface, heating on a water-bath nearly to boiling; the cream is removed on the following day. As evaporation takes place from the surface, not only is the percentage of fat raised, but the non-fatty solids are proportionately high.

COMPOSITION OF MAMMALIAN MILK.

HUMAN MILK.

Human milk differs in important particulars from that of the cow. It is not curdled by rennet, appears thinner, and contains more sugar and less proteins.

Fat. The fat of human milk contains a very much smaller quantity of volatile acids than that of cow's milk, and a larger amount of unsaturated acids (Laves, Zeitsch. physiol. Chem. 19, 369; Ruppel, Zeit. Biol. 31, 1; Pizzi, Staz. Sper. Ag. 1894, 615; Sauvaitre, Ann. Chim. Anal. 1902, 143). The refractive index is higher, and decreases as lactation advances and free fatty acids are present (Carter and Richmond, B. M. J. 1898, 199).

Sugar. According to Radenhausen (Zeitsch. Chem. 5, 13) and Denigès (J. Pharm. Chim. [v.] 27, 413), the sugar of human milk is lactose; the last author, however, states that there is another carbohydrate which modifies the properties, whilst Denigès finds a second dextrorotatory carbohydrate present. Carter and Richmond (*l.c.*) give the specific rotatory power as 48·7°, and state that it crystallises in rhomboid plates; they consider that more than one sugar is present.

Proteins. The casein of human milk, though closely related, differs from that of cow's milk; it is not curdled by rennet, does not exist in combination with calcium phosphate, and is thrown down by acids in a very finely divided state. Dogiel (Zeitsch. Chem. 9, 591) attributes this to the small amounts of salts present; if the salts are raised to the standard of cow's milk, the casein comes down in flakes. Kobrak (Pfluger's Archiv. 1900, 69) says that it is less acid, and by repeated precipitation with acid and solution in dilute alkali, a product like the casein of cow's milk is obtained; he considers it as a nucleo- protein plus histon or protamine. Lehmann and Hempel (Pfluger's Archiv. 1894, 56, 558) find 1·09 p.c. of sulphur and 3·2 p.c. ash, as against 0·72 and 6·47 p.c. respectively in the casein of cow's milk. Sikes (J. Physiol. 1906, 464) gives the proportion of Ca to proteins as 1·06 : 100. Wroblewski (Diss. Berne, 1894) also finds more sulphur, and states that no nuclein is present. Abderhalden and Schittenhelm (Zeitsch. physiol. Chem. 1906, 458) find that whilst biological tests show that the casein of human milk differs from that of the cow, the proportion of amino-acids is very similar (*cf.* also Tangl and Czókás, Pfluger's Archiv. 1908, 534; also Abderhalden and Langstein, Zeitsch. physiol. Chem. 1910, 8, find no difference in yield of amino-acids).

Wroblewski (*ibid.* 1898, 308) states that the amount of opalisin (*q.v.*) is abundant in human milk. Camerer and Soldner (Zeitsch. Biol. 1898, 277) find 40 p.c. of unknown protein in human milk. The ratio of protein nitrogen to total nitrogen is 0·88 (Camerer and Söldner, *l.c.*), 0·91 (Munk, Virchow's Archiv. 134, 501).

Salts. Human milk contains only about 0·03 p.c. calcium and 0·029 p.c. P_2O_5 (Sikes, *l.c.*), or 0·044 p.c. P_2O_5, according to Stoklasa (Zeitsch. physiol. Chem. 1897, 343); of the P_2O_5 0·012 p.c. belongs to the proteins (Sikes). These quantities are very much lower than those found in cow's milk. Citric acid is present.

Gases. Külz (Zeitsch. Biol. 1895, 180) finds O 1·07–1·44, CO_2 2·35–2·87, and N 3·37–3·81 p.c. by volume.

Enzymes. Oxydase does not appear to be normally present in human milk, but there is much catalase, which is destroyed at 75° (Jolles, Zeitsch. Biol. 1903, 248). A proteoclastic enzyme is also found. Béchamp (Compt. rend. 76, 836) describes an amylolytic ferment.

Composition.—The most extensive studies of the composition of human milk are those of Leeds (Chem. News, 50, 263, 280), Pfeiffer (J. Pharm. Chim. 13, 163), Carter and Richmond (*l.c.*), Lehmann and Hempel (*l.c.*), Szilasi (Chem. Zeit. 14, 1202), Camerer and Söldner (Zeitsch. Biol. 1896, 43 and 535), and V. and J. S. Adriance (Pamphlet Abstr. J. Chem. Soc. 1899, ii. 115).

It is difficult to deduce a mean composition from the results, as human milk appears to undergo a progressive change of composition; the table below is an abstract of the results of the observers:

Date from birth	Total solids	Fat	Sugar	Proteins	Ash
1st day (colostrum)	15·7	3·0	4·0	8·3	0·4
1st week . .	12·9	3·5	6·1	3·0	0·3
2nd week . .	12·35	3·35	6·6	2·15	0·25
3rd & 4th weeks .	12·1	3·4	6·75	1·75	0·22
After 1st month .	11·8	3·3	6·8	1·5	0·2

The fat is the most variable of the constituents, the maximum found being 9·05 (P.) and the minimum 0·47 (C. and R.). Forster (Ber. 14, 591) states that the last portions drawn from the lowest are richer than those preceding, 1·71, 2·77, and 4·5 p.c. being found in three successive samples. Carter and Richmond, however, find, from the examination of 37 samples taken before suckling and 37 after, that there is little difference in the fat; in 15 cases the fat was higher, and in 21 cases lower, while in one (where the reaction was excessive) the composition before and after suckling was identical. The maximum difference (with a very deficient supply) was shown in a case where 0·98 p.c. was found before suckling and 4·07 p.c. after. The cases in which the fat was found higher before suckling generally occurred when the mother was lying down, and hence it would seem that the separation of cream was largely mechanical.

When lactation is established the sugar usually varies between 6 and 7 p.c., though Carter and Richmond record a sample containing 8·89 p.c. and the proteins between 1 and 2 p.c.

Reaction.—Human milk always appears alkaline to litmus, and the acidity to phenolphthalein averages 3 c.c. N acid per litre.

Healthy children of both sexes discharge, from their seventh to their twelfth day from birth, a white secretion from the breast (*Haeenmilch*), which resembles human milk in composition

MILK OF OTHER ANIMALS.

Mare's milk is white, sp.gr. 1·035 (1·034–1·036). It is much sweeter than cow's milk, but contains less fat and proteins. Mare's milk is distinguished from all others by its small amount of fat.

Koumiss is a vinous liquor made by the Tartars by the fermentation of mare's milk. It is a white, sweetish, effervescing liquid, somewhat sour when old. The sugar gradually diminishes with age, whilst the alcohol and the lactic acid increase.

It is prepared by adding 1 part of old koumiss to 10 of fresh milk, and warming for 2–3 hours to 20°–25°. Carbon dioxide then comes off, and the liquid is bottled and left to mature. (For manufacture and analyses, *v.* Vieth, Analyst, 13, 2; L. V. S. 31, 353; Biel, J. 4, 166.) A similar preparation in imitation of the true Russian koumiss is made in Switzerland and in this country from cow's milk by adding a small quantity of sugar and yeast to skim milk; it contains more sugar and less lactic acid than old Russian koumiss, and on account of the much greater proportion of casein contained in cow's milk differs considerably from that prepared from mare's milk (Phil. Trans. [iii.] 1, 861, 888).

H. Suter-Naef (Ber. 5, 286) gives the composition of Swiss koumiss (sp.gr. 1·1286), manufactured at Davos, as follows:

	In 100 grams	Per litre
Water	90·346	1019·64 grams.
Alcohol	3·210	36·23 ,,
Lactic acid	0·190	2·14 ,,
Sugar	2·105	23·75 ,,
Albuminates	1·860	20·99 ,,
Butter	1·780	20·09 ,,
Inorganic salts	0·509	5·74 ,,
Free carbonic acid	0·177	2·00 ,,

For observations on the changes and action of Russian koumiss *v.* Jagielski (Pharm. J. [iii.] 1, 861, 885); J. T. George (Phil. Trans. [iii.] 3, 544).

Ass's milk is white, and sweeter than cow's milk. Sp.gr. between 1·023–1·035.

It readily turns acid, and easily undergoes fermentation. (For composition, *v.* Table, p. 540.)

Goat's milk is white, of insipid, sweetish taste and peculiar odour. It is a little richer in solids than cow's milk. Sp.gr. 1·030–1·035. On coagulation its casein forms thick clots. (For composition, *v.* Table p. 540.)

Sow's milk. Petersen and Oekhen (Bied. Zentr. 1897, 711; and Milch.-Zeit. 1896 ,655), Henry and Woll (Ann. Rep. Ag. Exp. Stat. Wisconsin, 1897, 10), and Woll (Exp. Stat. Record, 1900, 84) have examined the milk. The average composition is

Fat	Sugar	Proteins	Ash	Solids not fat	Sp.gr.
6·71	4·97	5·96	1·02	11·95	1·0389

The fat varies from 2·4 to 12·1.

Sheep's milk. Besana (Staz. Sper. Ag. Ital. 1892, 572), Hucho (Landw. Jahr. 1897, 497), Trillat and Forestieri (Compt. rend. 1902, 134, 1517; Ann. Chim. anal. 1902, 321; Bull. Soc. chim. 1903, 29, 286), Pizzi (Staz. Sper. Ag. Ital. 1894, 615; Fleischmann (Book of the Dairy, 1896, 56). Mean composition:

Fat	Sugar	Protein	Ash	Solids not fat	Sp.gr.
6·86	5·23	6·52	0·98	11·83	1·0385

Buffalo's milk. F. Strohner (Zeitsch. Nahr. Genussm. 1888, 88), W. Fleischmann (Book of the Dairy, 1896, 57), A. Pizzi (Staz. Sper. Ag. Ital. 1894, 615), Windisch (Zeitsch. Nahr. Genussm. 1904, 273), Leather (Analyst, 1901, 200, Indian Buffalo), Pappel and Richmond (J. Chem. Soc. Trans. 1891, 246, Egyptian Buffalo).

H. D. R.

MILK-TREE WAX, COW-TREE WAX, *v.* WAXES.

MILLERITE. Native nickel sulphide. Occurs in brass-yellow capillary crystals *v.* NICKEL.

MILLET. A name somewhat loosely applied to many species of grasses, growing in tropical or sub-tropical countries. As examples may be given the following:—

Great millet, *Sorghum vulgare* (Pers.). Other names given to varieties of this plant are dhurra or durra, African millet, Kaffir corn, millo maize. American broom corn and joar.

Little millet, *Panicum miliare* (Lam.).

Common millet or **Indian millet,** *Panicum miliaceum* (Linn.).

Texas millet, *Panicum texanum* (Vasey).

Sauwa millet, *Panicum frumentaceum* (Roxb.).

Japanese broom corn, *Panicum Crus-galli* (Linn.).

Golden or **Italian millet,** *Setaria italica* (Beauv.). Varieties of this constitute German millet or Hungarian grass, Japanese millet, Boer manna, and Californian green molia.

Pearl millet, *Pennisetum typhœdeum* (Rich.). Also known as Egyptian or cat's tail millet.

Polish millet, *Panicum sanguinale* (Linn.).

Koda millet, *Paspalum scrobiculatum* (Linn.).

The seeds of some varieties are used as human food, also in the preparation of certain fermented drinks, and as food for horses, cattle, and poultry. Broom corn is so called because its seed heads, after being deprived of the seeds, are employed in making brooms. The whole plants, cut green, are employed either as green fodder, or hay for farm animals.

Many of the millets grow to a height of only 2–4 feet, but Pearl millet sometimes attains 6 feet, while great millet or Kaffir corn reaches 8 or even 10 feet.

The following analyses, many of them by Church (Food Grains of India, 1886 and 1891), will serve to show the composition of the seeds of many 'millets.'

Species	Water	Protein	Fat	N-free extract	Crude fibre	Ash
Sorghum vulgare .	12·5	9·3	2·0	72·3	2·2	1·7
,, *saccharatum*	12·8	11·8	3·0	68·3	3·0	1·1
Pennisetum typhoideum .	11·3	10·4	3·3	71·5	1·5	2·0
Setaria italica[1] .	10·2	10·8	2·9	73·4	1·5	1·2
Panicum miliare .	10·2	9·1	3·6	69·0	4·6	3·5
,, *miliaceum*[1]	12·0	12·6	3·6	69·4	1·0	1·4
,, *frumentaceum*	12·0	8·4	3·0	72·5	2·2	1·9
,, *sanguinale* .	13·4	14·9	4·1	64·5	1·1	2·0
,, *texanum* .	(?)	4·7	2·1	47·1	23·2	(?)
Paspalum scrobiculatum[1]	11·7	7·0	2·1	77·2	0·7	1·3
'Rangoon millet' .	12·4	10·6	3·1	70·3	1·4	2·2
'Millet' . .	12·9	11·1	4·5	59·5	7·5	4·5
Dhurra . .	11·5	9·0	3·8	70·1	3·6	2·0
Sorghum vulgare .	15·2	9·3	3·3	68·0	2·5	1·7
Pearl millet[2] .	9·2	12·9	5·1	68·5	2·1	2·2

The various millets are largely used as fodder plants, but cases of death among animals fed upon young plants (of *Sorghum* in particular) have been numerous. It has been shown by Dunstan and Henry (Phil. Trans. 1902, A, 399) that the young leaves and shoots of *Sorghum vulgare* contain a glucoside, *dhurrin*, which readily hydrolyses by the action of an enzyme also present in the plant, yielding *p*-hydroxybenzaldehyde, *d*-glucose, and hydrocyanic acid. Brünnich (Chem. Soc. Trans. 1903, 788) obtained as much as 2·44 grains of hydrocyanic acid from 1 lb. of green sorghum at 5 weeks old, corresponding to 13·38 grains per 1 lb. of dry matter. The amount rapidly diminishes as the plant grows: at 9 weeks old, the same sorghum only yielded 0·20 grain per 1 lb. of green material (0·76 grain HCN per 1 lb. dry matter).

Brünnich was also able to detect hydrocyanic acid in several other varieties of millet.

When sufficiently grown, however, the various millets afford good fodder, and the smaller varieties, nutritious and palatable hay. The following are analyses of some millet hays grown in the Transvaal:—

	Water	Protein	Fat	N-free extract	Crude fibre	Ash
Boer manna . .	7·2	4·9	1·5	43·0	36·5	6·9
Golden millet . .	7·9	11·1	1·0	29·5	41·0	9·5
Californian green moba	8·0	10·5	1·2	35·6	35·6	9·3
Jap. broom corn .	9·6	6·8	1·2	38·8	34·8	8·8

H. I.

MILLON'S REAGENT *v.* Albuminoids.

MILORY GREEN. *Chrome green v.* Pigments.

MIMOSA *v.* Primuline and its Derivatives.

MIMOSA BARK *v.* Tannins.

MINERAL ACIDS. Acids of inorganic origin, *e.g.* sulphuric, nitric, hydrochloric, phosphoric, &c.

MINERAL ALKALI. A term originally given to soda in contradistinction to potash, which was termed the *vegetable alkali*.

MINERAL BLUE. *Antwerp blue v.* Pigments.

MINERAL CAOUTCHOUC. Syn. with *Elaterite* (*q.v.*).

MINERAL CARBON. *Anthracite v.* Fuel.

MINERAL CHAMELEON. *Sodium* or *potassium manganate v.* Manganese.

MINERAL COTTON. A name given to slag-wool.

MINERAL GREEN. *Scheele's green, Hydrocupric arsenite* $CuHAsO_3$ *v.* Arsenic.

MINERAL INDIGO. A name given to the blue oxide of molybdenum *v.* Molybdenum.

MINERAL KERMES. Amorphous antimony sulphide containing the trioxide (*v.* Antimony).

MINERAL OILS *v.* Petroleum.

MINERAL PURPLE. *Purple of Cassius v.* Gold, purple.

MINERAL TALLOW. *Hatchettine.* A variety of fossil resin or wax resembling dysodil, ozokerite, &c.

MINERAL TURPETHUM. *Mercuric sulphate v.* Mercury.

MINERAL WATERS *v.* Aerated waters; also Water.

MINERAL YELLOW. A term occasionally given to lead oxychlorides when used as pigments *v.* Lead.

MINIUM *v.* Lead.

MINJAK-LAQAM *v.* Oleo-resins.

MINJAK TENGKAWANG *v.* Borneo tallow.

MIRBANE, ESSENCE OF. A trade name for nitrobenzene as used in perfumery.

MISPICKEL, Arsenopyrite, or **Arsenical pyrites** (Ger. *Arsenikkies*). A mineral consisting of iron sulpharsenide of FeAsS, crystallising in the orthorhombic system. The crystals are usually quite simple in form, being bounded by a longer or shorter rhombic prism and terminated by dome faces. They are isomorphous with marcasite (*q.v.*). When not tarnished, the material is tin-white in colour with a brilliant metallic lustre. Sp.gr. 6·1; hardness 6. Granular and compact masses are frequent. A cobaltiferous variety (4–10 p.c. cobalt replacing iron) is known as *danaite*. The mineral is sometimes highly auriferous, and it is then a valuable ore of gold, as in New South Wales, California, and Alaska.

Mispickel occurs chiefly in mineral-veins. Large quantities are found in the silver-lead veins of Freiberg, Saxony, and in the tin veins of Cornwall and Devon. White arsenic is obtained as a by-product when these ores are roasted.

L. J. S.

MITIS GREEN. *Copper aceto-arsenate, Schweinfurth green v.* Arsenic.

MITTLER'S GREEN. Sny. with *Guignet's green*, art. Chromium.

MOCHA-STONE *v.* Agate.

MOIRÉE MÉTALLIQUE. The term given to the variegated arborescent or crystalline appearance given to the surface of tin plate produced by heating the plate and applying to it some dilute *aqua regia* for a few seconds, washing it with water, drying and coating it with lacquer.

MOLASSES *v.* Sugar.

MOLYBDENITE. A mineral consisting of molybdenum disulphide MoS_2, crystallising in the form of six-sided scales or short prisms, the system of crystallisation being possibly

---

[1] The samples were deprived of their husks before analysis.

[2] A sample grown in South Africa, highly prized as food for ostriches.

hexagonal. There is a perfect cleavage parallel to the base, and the laminæ are very flexible but not elastic. The mineral is very soft (H.$=$1), sectile, and greasy to the touch, and it readily marks paper. The colour is lead-grey with a bluish tinge and a metallic lustre. Sp.gr. 4·7. In its scaly form and general appearance molybdenite bears a striking resemblance to graphite, differing from this, however, in the bluish tinge of its colour. It is, of course, readily distinguished from graphite by its greater density and by its chemical reactions. The name molybdenite (from μόλυβδος, lead or lead-ore) itself bears witness to the confusion between this mineral and black-lead or plumbago (graphite); and, indeed, the two minerals were not distinguished until Scheele in 1778 obtained molybdic acid from one of them.

As isolated scales disseminated through crystalline rocks of various kinds (granite, gneiss, marble, &c.), molybdenite is of wide distribution, though only in small amounts. It is also found in metalliferous veins and in quartz-veins. In small quantities it has been won by mining at Altenberg in Saxony, near Flekkefjord and Egersund in Norway, Kingsgate in New South Wales, the Hodgkinson mining district in north Queensland, in Canada, and in the State of Washington. It is used for the preparation of molybdenum compounds employed in the laboratory; for the preparation of a fine blue pigment for dyeing fabrics; and for the manufacture of ferro-molybdenum, which, combined with chrome-steel, gives a self-hardening product, especially suitable for tools.

L. J. S.

MOLYBDENUM. Sym. Mo. At.wt. 96·0 (Seubert and Pollard). This metal, the presence of which in molybdenite was first pointed out by Scheele in 1778, and which is said to have been isolated by Hjelm in 1790, is grouped under Mendeléeff's classification with chromium, tungsten, and uranium, but, from the technical point of view, it may be regarded as a member of a group of heavy metals, including columbium, tantalum, tungsten, uranium, vanadium, and titanium, which occur in the oldest plutonic rocks and schists, and are capable of imparting special properties to steel when added to it in extremely small proportions.

Molybdenum owes its name to the word *molybdaena*, under which title most minerals resembling lead in appearance were formerly known, and its nature and value are even now so little recognised that its principal source, the sulphide (MoS_2) is frequently passed over by the prospector as being merely graphite, which it closely resembles. The writer has, in fact, seen it employed as blacklead in the north of Newfoundland within the last 20 years.

Molybdenum occurs in *Molybdenite* MoS_2, *Wulfenite* $PbMoO_4$, and *Molybdic ochre* MoO_3 (usually containing a considerable amount of Fe_2O_3), and as the extremely rare minerals, *Powellite* $Ca(Mo{\cdot}W)O_4$, *Belonesite* $MgMoO_4$, and *Pateraite* $FeCo(Mo)O_4$. It also occurs in small quantities in other minerals containing the rare heavy metals of the same group, but is probably more an accidental occurrence than an essential constituent. The purest molybdenum metal is produced from wulfenite, but practically the whole of the world's supply of the metal and its compounds is obtained from molybdenite. Until within the last 5 years, most of this mineral was produced by hand-picking from pegmatite and other granitic rocks, and from schists in which it occurs as sparsely distributed flakes resembling high-grade graphite in appearance and general physical properties. It was only purchased when of high quality (90–95 p.c. of MoS_2 equivalent to 54–57 p.c. Mo), and commonly by inspection and not on assay. It is now, however, in increasing demand, and is purchased on the usual commercial basis of so much per unit per cent. of Mo or of its equivalent in MoO_3 with a guarantee of not more than so much per cent. of arsenic, phosphorus, antimony, or copper. The limit fixed for these objectionable metals is always subject to special agreement, and is becoming more elastic on account of the increasing demand and the small supply, and from the fact that in modern smelting methods, in which the electric furnace is employed, they are, to a great extent, eliminated. Lower-grade molybdenite concentrates are also obtained by the treatment of ores in which it occurs in small flakes to the extent of even less than 2 p.c., by ordinary washing plants or by electrostatic or oil flotation processes.

Metallic molybdenum may be prepared by reduction of molybdic acid MoO_3, or, preferably, of the less volatile dioxide MoO_2, with pure carbon or by the alumino-thermic process or by heating one of the oxides or chlorides in a current of hydrogen. It has a sp.gr. of about 9 (after melting), and, when pure and free from more than a trace of carbon, is softer than steel, malleable and capable of being forged and welded. Its fusing-point is about 2000°, slightly below that of tungsten. It is attacked by the halogens and by most acids and fused salts, and has not so far been applied to any practical use, except in alloy with other metals, and is prepared for the manufacture of such alloys, by direct reduction of the sulphide in the electric furnace under conditions which eliminate the bulk of the sulphur and other non-metallic impurities, partly through the high temperature obtained and partly by the use of basic materials in the furnace charge or linings. Similarly, ferro-molybdenum and other alloys are produced by the direct electric furnace reduction of molybdenite in admixture with oxide of iron, chromium, nickel, or tungsten, the only metals with which it is at present alloyed for technical use.

The addition of molybdenum to steel in the form of the pure metal or one of the above alloys, largely increases its tensile strength, toughness, and fineness of grain and its retention of magnetism. For the production of high-grade tool steel, it has a value similar to, but greater than, that of tungsten. At present, it is mainly employed in crucible steel, and, like many of the steels now being prepared for special purposes, molybdenum steels and molybdenum alloys must be regarded as still on trial as compared with others, although the fact that they are of great value is beyond doubt.

Molybdenum is now prepared for addition to steel, as 90–98 p.c. molybdenum powder or fused lump practically free from carbon, as ferro-molybdenum containing 10, 25, 50, and

80–85 p.c. molybdenum, and as an alloy with tungsten, chromium, or nickel.

The following are typical analyses of ferro-molybdenum as now made by the electric furnace:—

Mo . .	85·80	80·00	85·00	50·00
Fe . .	10·96	16·50	14·20	49·30
C . .	3·07	3·24	0·50	0·35
Si . .	0·11	0·21	0·25	0·30
S . .	0·05	0·02	0·03	0·03
P . .	0·01	0·03	0·02	0·02
	100·00	100·00	100·00	100·00

The two low-carbon alloys were probably produced by the refining of crude cast ferro-molybdenum by a modification of the process of Moissan, who removes the excess of carbon by heating the powdered metal with molybdenum dioxide or calcium molybdate, with the addition of alumina for production of slag.

Molybdenum combines with the halogens to form a large variety of compounds, including many double halogen salts and various oxy-salts. It forms compounds with phosphorus, boron, silicon, and sulphur, which are of no technical interest except in so far as their presence in molybdenum or ferro-molybdenum is objectionable. Similarly, molybdenum carbides can be produced, and one of the difficulties in obtaining metallic molybdenum and ferro-molybdenum by direct reduction of the oxide with carbon, is the fact that too large a proportion of the latter is commonly contained in them to permit of their use in steel making without further de-carburising treatment. G. T. H.

COMPOUNDS OF MOLYBDENUM.

Oxides. Molybdenum forms a series of oxides, which, during their formation in solution, often show changes of colour through various shades of blue to black or violet-black. The following are the best known oxides:—

The sesquioxide Mo_2O_3, formed when one of the higher oxides is treated with sodium amalgam or zinc, is a black powder, which forms black or dark grey salts. These salts give black or dark purple solutions when concentrated, but on dilution, the solutions become transparent and of a purple tint. They have a styptic taste, oxidise somewhat in the air, and are precipitated by alkalis forming the brownish-black hydroxide $Mo(OH)_3$ (Muthmann and Nagel, Ber. 1898, 31, 2009).

Molybdenum dioxide MoO_2 is formed by heating the sesquioxide in air or by heating the trioxide in a current of hydrogen at 470° and in other ways (Guichard, Compt. rend. 1899, 129, 722; *ibid.* 1900, 131, 998; Friedheim and Hoffmann, Ber. 1902, 35, 791; Chapman and Law, Analyst, 1907, 32, 250). It is a brown or violet-brown crystalline powder, which, like the other oxides, is reduced to metallic molybdenum when heated at 600° in hydrogen. It gives unstable salts, the concentrated solutions of which are black, but turn, successively, bluish-green, greenish-yellow, red and yellow on dilution. The hydroxide $Mo(OH)_4$ is dark red and forms a yellow or red colloidal solution in water.

Molybdenum trioxide MoO_3 is usually found with molybdenite and occurs as molybdic ochre, either as an earthy powder or incrustation, or in crystalline masses. It is obtained by roasting the powdered mineral with quartz sand, treating the mass with ammonia, and after removing impurities, converting the ammonium molybdate thus formed into the trioxide by decomposition and evaporation with nitric acid (Wöhler, Annalen, 1856, 100, 376; Muthmann, *ibid.* 1887, 238, 117; Eng. Pat. 5821, 1909). It is a white powder, which becomes yellow on heating, melts at 791° to a yellow liquid, and readily volatilises in the air (Groschuff, Zeitsch. anorg. Chem. 1908, 58, 113). Towards strong acids the trioxide acts as a base (Guichard, Compt. rend. 1906, 143, 744), but generally it behaves as an acid forming oxide.

Molybdic acid $H_4Mo_2O_5$ or $MoO_3{\cdot}2H_2O$ (Mylius, Ber. 1903, 36, 638; Rosenheim and Bertheim, Zeitsch. anorg. Chem. 1906, 50, 320; Graham, Journ. Franklin Inst. 1907, 163, 69) is obtained as yellow crusts, and forms colloidal, or, according to Wöhler and Engels (Zeitsch. Elektrochem. 1910, 16, 693) semi-colloidal solutions (Graham, Chem. Soc. Trans. 1864, 326: Sabanéeff, J. Russ. Phys. Chem. Soc. 21, 515). When reduced by metallic molybdenum, in neutral or faintly acid solution, the blue oxide or molybdenum molybdate is formed, but if the solution is strongly acid a brown oxide appears (Guichard, *l.c.*).

The normal molybdates are unstable and readily form polymolybdates by uniting with further molecules of the trioxide and also with other acidic oxides to form a large number of complex molybdates. A large number of alkaline and other molybdates are known, some of which are used for the production of pigments and dyes, in pottery glazes and in analytical work.

Molybdenum molybdate (molybdenum blue or molybdenum indigo) is obtained by reducing molybdic acid as above or with other reducing agents or by adding a cold dilute hydrochloric acid solution of molybdenum dioxide to a similar solution of ammonium molybdate and washing with sodium chloride (Guichard, Compt. rend. 1900, 131, 389, 419). Its solubility, and possibly its composition, depends on the mode of formation (Klason, Ber. 1901, 34, 158). It is said to form a useful, though somewhat expensive, pigment for india-rubber (Gummi Zeit. 1903, 17, 418).

Phosphomolybdic acid $H_3PO_4,12MoO_3$ is formed by treating its ammonium salt with *aqua regia* (Finkener, Ber. 1878, 11, 1638; Levi and Spelta, Gazz. chim. ital. 1903, 33, i. 207; Miolati, *ibid.* ii. 335) is employed as a reagent for alkaloids. Its ammonium salt $(NH_4)_3PO_4,12MoO_3$ is a canary-yellow crystalline powder almost insoluble in water and in dilute acids.

Permolybdic acid $H_2MoO_5xH_2O$ is an orange-red amorphous powder, formed by treating the trioxide with hydrogen peroxide (Muthmann and Nagel, *l.c.* 1836); a number of permolybdates have been prepared.

Sulphides. *Molybdenum sesquisulphide* M_2S_3 forms steel-grey needles of sp.gr. 5·9 at 15°, and is obtained by heating the disulphide in the electric furnace (Guichard, Compt. rend. 1900, 130, 137).

Molybdenum disulphide MoS_2 occurs native as *molybdenite* in foliated scales or in tabular hexagonal prisms, and can be obtained artificially by fusing the trioxide with sulphur or by heating it in sulphuretted hydrogen. It is very similar to graphite in appearance, possessing a metallic lustre and a lead-grey colour, but it is incombustible in the blowpipe. It is oxidised with evolution of sulphur dioxide when heated in the air, and when treated with nitric acid or *aqua regia*.

Molybdenum trisulphide MoS_3, obtained by the action of sulphuretted hydrogen on a concentrated molybdate solution, is a black-brown powder, which combines with basic sulphides to form thio molybdenum salts (Annalen, 1884, 225, 1; Hofmann, Zeitsch. anorg. Chem. 1896, 12, 55). Molybdenum tetra-sulphide and thiomolybdic acids are also known.

Halides and other compounds. Molybdenum forms a large number of halogen, mixed and double halogen, and oxyhalogen salts (Muthmann and Nagel, *l.c.*; Guichard, Compt. rend. 1896, 123, 821; Bull. Soc. chim. 1901, [iii.] 25, 188; Klason, *l.c.* 148; Nordenskjöld, Ber. 1901, 34, 1572; Ruff and Eisner, *ibid.* 1907, 40, 2926, 3931). Molybdenum combines with silicon to form silicides (Vigouroux, Compt. rend. 1899, 129, 1238; Defacqz, *ibid.* 1907, 144, 1424; Bull. Soc. chim. 1908, [iv.] 3577; Watts, Trans. Electro. J. 1906, 9, 105; Hönigschmid, Monatsh. 1907, 28, 1017); with boron to form borides (Tucker and Moody, Chem. Soc. Trans. 1902, 16; Binet du Jassonneix, Compt. rend. 1906, 143, 169); with carbon to form carbides (Moissan and Hoffmann, *ibid.* 1904, 138, 1558); and with carbon monoxide forming a carbonyl compound (Mond, Chem. Soc. Trans. 1910, 798).

Molybdenum cyanides and thiocyanates and their complex salts with a number of organic compounds have been prepared (Rosenheim, Zeitsch. anorg. Chem. 1906, 49, 148; *ibid.* 1907, 54, 97; Ber. 1908, 41, 2386; *ibid.* 1909, 42, 149, 2295; Sand and Maas, *ibid.* 1907, 40, 4504; *ibid.* 1908, 41, 1500, 1861, 3367; *ibid.* 1909, 42, 2642; Chilesotti, Gazz. chim. ital. 1904, 34, ii. 493). A number of salts of molybdenum with organic acids have also been prepared (Rosenheim, Ber. 1895, 26, 1191; Zeitsch. anorg. Chem. 1903, 34, 427; Grossman and Krämer, *ibid.* 1904, 41, 43; Ber. 1903, 34, 1606; Henderson and Barr, Chem. Soc. Trans. 1896, 1455; Orr and Whitehead, *ibid.* 1899, 546; Mazzucchelli, Atti. R. Acad. Lincei. 1909, [v.] 18, ii. 259).

Molybdamide $OH{\cdot}MoO_2{\cdot}NH_2$ is obtained by treating a chloroform solution of molybdic chloride with ammonia. A black precipitate of the diamide is obtained, which, when extracted with alcohol, is converted into the brownish-red amorphous monamide.

The *monoethylamide* $OH{\cdot}MoO_2\,HNEtH_2O$, a white powder and the *diethylamide*

$$MoO_2(NHEt)_2,$$

a reddish-brown powder are formed readily by the action of molybdenum chloride on ethylamine. The diamide reacts violently with nitric acid, and gives a deep blue solution with strong sulphuric acid (Fleck and Smith, Zeitsch. anorg. Chem. 1894, 7, 351).

Molybdenum tannate is of a deep yellow colour, soluble, and has a great affinity for vegetable fibre. It produces fast shades on leather, and in conjunction with logwood extracts a variety of shades may be obtained (Pozzi-Escot, Compt. rend. 1902, 135, 880).

Nicotine ammonium molybdate, prepared by the action of ammonium molybdate on nicotine in the presence of acetic acid is a white powder, sp.gr. 2·5407, and is intensely poisonous. On oxidation in acid solution it yields nicotinic acid, but in alkaline solution dipyridine is formed. (Meszlényi, Landw. Versuchs.-Stat., 1905, 61, 321).

MONAZITE. A mineral consisting essentially of phosphate of the cerium metals $(Ce,La,Di)PO_4$, crystallising in the monoclinic system. Several other elements (yttrium, silicon, iron, calcium, tin, &c.) are usually present in small amounts, and in particular thorium (ThO_2 1–11 p.c.). The commercial value of the mineral depends on its use as a source of thoria for the manufacture of mantles for incandescent gas-lighting (*q.v.*). Crystals of monazite are yellowish-brown and translucent, or dull brown and opaque, with a lustre inclining to resinous. Sp. gr. 4·9–5·3; hardness 5½. Monazite gives the absorption-spectrum characteristic of didymium salts, and this affords a ready means of detecting the mineral.

Dull crystals of monazite of fair size are found in the pegmatite-veins of the Ilmen mountains in the southern Urals, and at several places in the south of Norway. Small, brilliant crystals are occasionally met with in crevices in the gneissic rocks of the Alps. As small grains embedded in gneissic and granitic rocks monazite has a very wide distribution, though only in relatively very small amounts. With the weathering and breaking down of such rocks, the monazite is accumulated with the other heavy minerals in the beds of streams. Under these circumstances it is often met with in alluvial gold washings. The careful examination of the heavy residues of river sands rarely fails to reveal the presence of some grains of this mineral. Occurrences of this kind have been recorded from all parts of the world, but it is only in Brazil and in North and South Carolina that the deposits are sufficiently rich to be worked commercially.

In Brazil, monazite-bearing sands are found on the seashore at certain spots near Alcobaca and Prado in the south of the State of Bahia, and at various points along the coast of the States of Espirito Santo and Rio de Janeiro. The amount exported annually is about 5000 tons. In the Carolinas, alluvial deposits are worked in the valleys of the several streams draining the South Mountains, an eastern outlier of the Blue Ridge. These sands contain monazite in amounts reaching to 1–2 p.c., and they are concentrated by the washing methods of the gold miner. Magnetite and other ferriferous minerals are extracted by an electro-magnet, and the product contains 65–70 p.c. of monazite mixed with other heavy minerals, such as zircon, garnet, rutile, corundum, &c. This cleaned monazite-sand is fine in grain, and of a resinous yellow colour with darker specks of other minerals. The production amounts to about 200 tons per annum, but it is now decreasing. At the felspar quarries of the south of Norway the isolated crystals of monazite are picked out by hand, about a ton per annum being so collected.

L. J. S.

MOND GAS *v.* Fuel.

MONEL METAL. An alloy of nickel and copper made from the nickel-copper ores of Ontario; contains, in addition to copper, about 68 p.c. of nickel and a slight amount of iron. Combines a strength approaching that of steel with the non-corrosive qualities of copper or brass: used for roof covering, pump-rods, marine propellers, &c. The cast metal has a tensile strength of 82,500 lbs. per square inch. Elastic limit 37,500 lbs. per square inch, and elongation 44 p.c. The modulus of elasticity is from 22,000,000 to 23,000,000 lbs. as against 30,000,000 lbs. for steel and 13,000,000 lbs. for manganese bronze; m.p. 1360°, sp.gr. (cast) 8·87. Electrical conductivity 4 (copper 100). An important characteristic is the retention of the mechanical properties at high temperatures, which has led to the adoption of the alloy for locomotive fire-boxes in Germany (J. E. Thompson, Eng. and Min. J. 1911, 91, 223; J. Soc. Chem. Ind. 1911, 30, 287).

MONOBROMO-CAMPHOR *v.* Camphors.

MONTANIN. Trade name for a solution of hydrofluosilicic acid; used as a disinfectant.

MONTAN WAX is a bituminous substance extracted by various solvents from *pyropissite*, obtained from the lignites of Saxony and Thuringia. The crude substance is hard and odourless, resembling ozokerite in appearance, and having m.p. 80°–90°. Montan wax comes into commerce as a white, high-melting candle-like material. It is not a paraffin, but consists of two compounds, *montanic acid*, $C_{29}H_{58}O_2$, m.p. 83°–84°, and an alcohol, m.p. 60° (*v.* Boyen, Zeitsch. angew. Chem. 1901, 14, 1110; *cf.* Marcusson, Chem. Rev. Fett- u. Harz. Ind. 1908, 15, 193; Eisenreich, *ibid.* 1909, 16, 211). Asher (D. R. P. 207488 of 1907) purifies the crude substance by heating twice with nitric acid of sp.gr. 1·2–1·4, then washing and melting it, whereby the asphaltic or resinous matter separates out. It may also be purified by dissolving in a suitable organic solvent and then heating with alcoholic alkali. After separation of the saponified matter, the wax is finally treated with concentrated sulphuric acid at 100° (D. R. P. 220050 of 1906). The aluminium salts of montanic acid have been prepared for use as impregnating materials (D. R. P. 221888 of 1908).

Similar waxes have been extracted from Irish peat, and are sold under the names of *montana wax* and *montanin wax* (Ryan and Dillon, Proc. Roy. Dublin Soc. 1909, 12, 202).

MOONSTONE *v.* Felspar.

MORDANT ROUGE. *Aluminium acetate v.* Acetic acid.

MORIN *v.* Old Fustic.

MORINDA CITRIFOLIA. The roots of *Morinda citrifolia* (Linn.) and *M. tinctoria* (Roxb.), known as 'Morinda Root,' are extensively employed in various parts of India under the general trade name of *Suranji*, more especially for dyeing reds, purples, and chocolates. These plants, the native names for which are *Aal, A'l, Ach,* or *Aich*, are to be met with in nearly all the provinces of India, either wild as in the jungles of Bengal, or cultivated in small patches in betelnut plantations, or near the homesteads of the dyers. In Bengal the plant is usually propagated by slips or cuttings, but in other parts it is raised from seed, as well as from cuttings. When the plants have attained a height of from 5 to 6 feet, that is, as a rule, about the end of the third year, the straight spindle-shaped roots which extend into the ground to a depth of 3 or 4 feet, are dug out and the upper portions of the plant are cut into slips to serve for the propagation of the next crop.

The colouring matter is found principally in the root bark, and is developed in greatest quantity at about the end of 3 or 4 years, depending upon the character of the soil. After this time the dyeing principle gradually disappears, and the matured trees, which eventually attain the height of a mango tree, contain hardly a trace of it. The thin roots are most valuable, roots thicker than half an inch being thrown away as worthless. They are mainly used for dyeing the thread or yarn from which the coloured borders of the cotton garments worn by the lower classes are woven, but they are also employed for dyeing the coarse cotton fabric called 'Khárva,' or for dyeing the silk thread, which forms the border of the silk fabric known as 'Endi cloth.' The colours given by A'l range from a reddish-yellow through pink and various shades of red to a dark brown red. The tint seems to depend primarily upon the age of the root, and upon the proportion of root-bark to stem which is employed. The root bark gives the best reds; the dye in the woody part of the root is yellow, and hence when the wood preponderates over the bark, the resulting dye is reddish-yellow.

About 1790 some of the powdered root under the name of 'aurtch' came into the hands of Dr. Bancroft, who found little or no difficulty in applying it to both wool and cotton. At that time he considered that it might be profitably imported into Europe.

In 1832 Schwartz and Koechlin also examined the root under the names 'Nona' and 'Hachrout,' and reported on its dyeing properties to the Industrial Society of Mulhouse. They referred to the fact that of all the Indian *rubiaceæ* examined by them, it contained the largest quantity of certain yellow principles of an acid character which not only necessitated the washing of the root with cold water before dyeing, but also made it requisite to add a certain proportion of sodium carbonate to the dyebath in order to have a perfectly neutral bath. Their conclusion was that since morinda root only possessed one-third the dyeing power of a medium quality of madder, it could never compete with the latter in the European market.

About 1848 some morinda root was submitted for trial to some of the most experienced and skilful calico printers of the Glasgow district, all of whom concurred in declaring it not to be a dye at all.

In 1848 Anderson (Annalen, 71, 216)

isolated from the root of the *M. citrifolia* by extraction with alcohol, a crystalline yellow substance which he named *Morindin*, and to which he assigned the formula $C_{28}H_{30}O_{15}$. This substance, when strongly heated, gave a crystalline sublimate *morindon*, and Anderson pointed out the great similarity, on the one hand, between morindin and ruberythric acid, and on the other between morindon and alizarin.

Rochleder (Annalen, 1852, 82, 205) gave it as his opinion that morindin and morindon were identical with the ruberythric acid and alizarin derived from madder, and Stokes (Chem. Soc. Trans. 2, [2] 333) by examining the absorption spectra of solutions of alizarin and morindon in sodium carbonate and in ether, came also to the conclusion that these two colouring matters consisted of one and the same substance. Stenhouse (J. 1864, 17, 543) formed a similar opinion, and pointed out that morindin not only gives morindon by heating, but also when digested with boiling dilute mineral acids.

On the other hand, Stein (J. 1866, 19, 645) found that the absorption spectra of alizarin and morindon are not identical, and that ruberythric acid and morindin are distinct substances, although the latter resemble each other in the respect that both are glucosides. The distinction between these compounds was rendered much clearer by the work of Thorpe and Greenall (Chem. Soc. Trans. 1887, 51, 52), and Thorpe and Smith (*ibid.* 1888, 53, 171), who showed that morindon possesses the formula $C_{15}H_{10}O_5$; on distillation with zinc dust it gave methylanthracene (m.p. 190°–191°), and was evidently a derivative of methylanthraquinone. To morindin, the glucoside, the formula $C_{26}H_{28}O_{14}$ was assigned.

Somewhat later Perkin and Hummel (Chem. Soc. Trans. 65, 851), during an examination of the *Morinda umbellata* (Linn.) (*see* below), proved that morindon contains three hydroxyl groups, and that Thorpe and Smith's hydrocarbon was β-methylanthracene.

Oesterle and Tisza (Arch. Pharm. 1907, 245, 534) consider that the true formula of morindin is $C_{27}H_{30}O_{15}$, and that its hydrolysis with acid can be expressed as follows:

$$C_{27}H_{30}O_{15}+2H_2O=2C_6H_{12}O_6+C_{15}H_{10}O_5.$$

The sugar thus formed is not fermented by yeast and yields an osazone melting at 197°.

Morindin crystallises from 70 p.c. alcohol in glistening yellow needles, which melt at 245°, and dissolve in alkaline solutions with a red colour. It does not dye mordanted fabrics.

Nono-cetylmorindin $C_{27}H_{21}O_{15}(COCH_3)_9$ (O. and T.), citron yellow needles, melts at 236°.

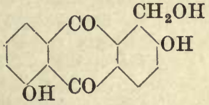
Nono-benzoylmorindin $C_{27}H_{21}O_{15}(CO{\cdot}C_6H_5)_9$ (O. and T.), yellow needles, melts at 186°.

Morindon, the colouring matter of *Morinda citrifolia*, which is obtained by the hydrolysis of morindin, and also exists as a rule to some extent in the free state in this root, consists of orange-red needles, melting at 271°–272°. It is soluble in alkaline liquids, with a blue-violet tint, somewhat bluer than the corresponding alizarin solutions, which, when treated with baryta water, give a cobalt-blue precipitate of the barium derivative. Its solution in sulphuric acid is blue-violet.

Triacetylmorindon $C_{15}H_7O_5(COCH_3)_3$ crystallises in citron-yellow needles, melting at 222°.

Morindon trimethyl ether $C_{15}H_7O_2(OCH_3)_3$ consists of a yellow crystalline powder, melting at 229°.

The exact constitution of morindon has not yet been determined, but it appears probable that if this compound contains in reality three phenolic hydroxyls, it is most likely to consist of a methyl anthragallol. If, on the other hand, as is quite probable, morindon contains an alcoholic group, which, according to Robinson and Simonsen, occurs in the isomeric emodin



then its constitution will be represented as alizarin in which one of the three β-positions is occupied by CH_2OH. Such a constitution would appear to harmonise well with the present known properties of morindon.

In many respects the *Morinda citrifolia* resembles chay-root and madder, for, in addition to morindin and morindon, it contains a large quantity of *chlorogenin*, and certain yellow non-tinctorial substances derivatives of anthraquinone. The preparation of morindon in quantity can be conveniently carried out by extraction with sulphurous acid, according to the details given in the articles on MADDER and CHAY ROOT, for the isolation of natural alizarin. The non-tinctorial yellow compounds, which are obtained as by-products by this method, have not yet been studied in the case of the *Morinda citrifolia*, but in the case of the *Morinda umbellata* have been partially investigated (*see* below).

From the alcoholic extract of the *Morinda citrifolia*, Oesterle (Arch. Pharm. 1907, 245, 287) has isolated a small quantity of a substance which has the constitution of a *monomethyl ether* of a *trihydroxymethylanthraquinone*. It consists of yellow crystals, melting at 216°, soluble in hot alkaline solutions, with a yellowish-red colour. It is not, as this author suggested, identical with the emodin methyl ether which exists in the *Ventilago maderaspatana* (A. G. Perkin, Chem. Soc. Trans. 1907, 2074).

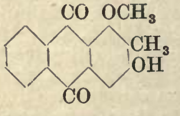
Dyeing properties.—In Dr. G. Watts' Dictionary of the Economic Products of India, Dr. J. Murray has written under the head of *Morinda*, not only a most complete account of the more important species, but full details of the native methods of dyeing with them. These methods of dyeing vary considerably in detail in different parts of India, but they are all similar in general principles, and are practically crude processes of the turkey-red dyeing known in Europe. An extended series of dyeing experiments in connection with morinda root have been carried out by Hummel and Perkin (J. Soc. Chem. Ind. 1894, 13, 346), who find that by adopting certain precautions this dyestuff possesses a dyeing power which is greater than madder itself.

To obtain good results it is necessary, as previously indicated by the work of Schwartz and Koechlin (*l.c.*), to neutralise, or better still to remove, the free acid which exists in considerable quantity in the roots. Experiments also with the powdered morinda root which had been allowed to ferment, or had been digested with boiling dilute acid, as in the preparation of 'garancine' from madder, showed that these preparations dyed exceedingly well when 1 p.c. of chalk was added to the dye-bath. It was found, for instance, that 7·5 grams of a sample of washed morinda root (equivalent to 10 grams of the unwashed root) had a dyeing power equal to 15 grams madder root of good quality.

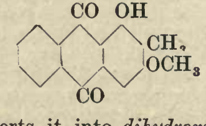
The reds and pinks obtained on alumina mordant are yellower than the corresponding madder colours, the chocolate presents a similar difference in tone, and hence again appears fuller than a madder chocolate, whilst the lilac is distinctly redder. Oil prepared calico mordanted as for turkey-red gives a very bright orange-red or scarlet similar in shade to that given by flavopurpurin, and fast to clearing with soap and stannous chloride. Chromium mordant on similarly prepared calico gives a full rich chocolate, and iron mordant yields colours varying from dull purple to black, according to the intensity of the mordant. On wool and silk, mordanted according to the usual methods, good chocolate browns are obtained with chromium, orange-reds with alumina, bright orange with tin, and dark purple and black with iron mordant. All the colours referred to are as fast to soap as the corresponding madder colours. With respect to wool and silk in the unmordanted condition, these fibres may be readily dyed both with the washed and unwashed root, more or less rich orange or yellow colours, the brightness of which is enhanced by the addition of a little acetic acid to the dye-bath. These colours, however, which appear to originate from the glucoside morindin itself, are of a sensitive character towards alkalis, and of little value. A. G. P.

MORINDA LONGIFLORA, known as 'Ojuologbo' (woody vine) (Journal Society of Arts, 1905, 53, 1069), is a native of West Africa and considered to be one of the most valuable medicinal plants of that region. It is fully described in the Flora of Tropical Africa (1877, III. 192), where it is stated to be known under the native name of 'Mibogga.'

According to Barrowcliff and Tutin (Chem. Soc. Trans. 1907, 91, 1909) the root of the *M. longiflora* (G. Don) contains an hydroxymethoxymethyl anthraquinone and an alizarin-monomethyl ether, although morindin, the common constituent of the roots of the *M. citrifolia*, *M. tinctoria*, and *M. umbellata*, is absent. The *hydroxymethoxymethylanthraquinone* $C_{16}H_{12}O_4$, yellow needles, melts at 290°, and the *acetyl* derivative at 173°. Heated with 70 p.c. sulphuric acid it gives the 1 : 3-*dihydroxy*-2-*methylanthraquinone* of Schunck and Marchlewski (Chem. Soc. Trans. 1894, 65, 182). Accordingly it possesses one of the following formulæ—

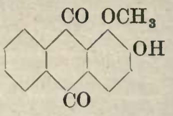


or



Hydriodic acid converts it into *dihydroxymethylanthranol* $C_{15}H_{12}O_3$ (m.p. 235°), and by methylation 1 : 3-*dimethoxy*-2-*methylanthraquinone* (m.p. 181°) is produced.

The *monomethyl ether of alizarin*.



is identical with the compound isolated by Perkin and Hummel (Chem. Soc. Trans. 1893, 63, 1174) from chay root (*Oldenlandia umbellata* [Linn.]).

The leaves of the *M. longiflora* also contain the above-mentioned hydroxymethoxymethylanthraquinone, and in addition a crystalline alcohol *morindanol* $C_{38}H_{62}O_4$, which melts at 278°, and has $[\alpha]_D + 65{\cdot}9°$. With sodium methoxide and methyl iodide it yields *methylmorindanol* $C_{38}H_{61}O_3{\cdot}OCH_3$ (m.p. 116°).

'Ojuologbo' does not appear to contain an alkaloid, and extracts of the leaves and root were not found to possess any pronounced physiological action (B. and T.). A. G. P.

MORINDA UMBELLATA or **MANG-KOUDU.** The dyeing material, variously named oung-koudou, jong-koutong, &c., is the root-bark of *Morinda umbellata* (Linn.), and is met with in Eastern commerce in the form of small, reddish-brown, irregular rolls of bark, much wrinkled in appearance. Its cost is about 6*d*. per lb. In Java it is largely used for producing the fast reds in the native calico prints, well known under the name of 'baticks.'

Although the shrub from which the root-bark is obtained is met with in Ceylon and the hilly regions of Eastern, Southern, and South-Western India, as well as in the Malay Peninsula and Java, the material does not appear to be considered as of any special importance by the Hindoo dyers, unless, indeed, as is very probable, they use the root as a whole under the general designation ál root, of which it must simply be regarded as a variety.

The following are a few of its Indian vernacular names: Âl (*Bomb.*); núna (*Tamil*); múlúghúdú (*Telugu*); mang-kudu (*Malay*).

The literature connected with mang-koudu is extremely limited, brief references to its dyeing properties only being found in the following publications: Philosophy of Permanent Colours (1813), Bancroft; Bulletin de la Société Industrielle de Mulhouse (1832), E. Schwartz and D. Koechlin; L'Art dela Teinture des Laines (1849), Gonfreville; Monograph on the Dye-stuffs and Tanning Matters of India, &c. (1878), T. Wardle; Watt's Dictionary of the Economic Products of India (1891), J. Murray.

The examination of this dyestuff by Perkin and Hummel (Chem. Soc. Trans. 65, 851) has indicated its close chemical resemblance to the *M. citrifolia.* It contains a glucoside of the nature of morindin, which yields by hydrolysis morindon, but which, according to Perkin (Chem. Soc. Proc. 1908, 24, 149), is best represented by the formula $C_{26}H_{28}O_{14}$, and is identical with that suggested by Thorpe and Greenall (Chem. Soc. Trans. 1887, 51, 52) for the morindin derived from the *M. citrifolia.* The acetyl derivative $C_{26}H_{20}O_{14}(C_2H_3O)_8$ is very sparingly soluble in alcohol, and melts at 246°–248°, and the sugar produced from the glucoside yields an osazone melting at 202°–203°, which is not readily dissolved by alcohol.

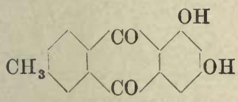
This root bark contains a considerable quantity of *chlorogenin* (*cp.* MADDER), together with a small amount of non-tinctorial yellow derivatives of anthraquinone. A quantitative extraction of 200 grams of the material with sulphurous acid (*cp.* MADDER) gave

9·47 grams of green precipitate, which yielded :

Crude chlororubin 8·075 grams = 4·03 p.c.
Pure morindon . 1·187 „ = 0·59 „
Yellow substances 0·208 „ = 0·104 „

These yellow substances proved to consist of a mixture of at least six distinct compounds. The main constituent isolated in yellow needles, melting at 171°–173°, possessed the formula $C_{16}H_{12}O_5$, and had properties in harmony with those required by a *monomethyl ether* of a *trihydroxymethylanthraquinone.* The *diacetyl* derivative $C_{16}H_{10}O_5(C_2H_3O)_2$ melts at 148°.

A second compound $C_{15}H_{10}O_4$, crystallised in yellow needles, melting at 269°, and was found to consist of the *methylpurpuroxanthin* prepared synthetically (Marchlewski, Chem. Soc. Trans. 1893, 63, 1142) by the condensation of metadihydroxybenzoic acid with paramethylbenzoic acid.



The remaining yellow substances (*a*) $C_{16}H_{12}O_6$, orange-red needles, m.p. 258°, (*b*) $C_{16}H_{10}O_5$, lemon-yellow needles, m.p. 198°–199° ; (*c*) $C_{16}H_{10}O_5$, needles, m.p. 208°, were isolated in such small amount that a determination of their constitution could not be attempted.

Dyeing properties.—This dyestuff is largely employed by the Javanese for producing the fast reds in their celebrated 'baticks.' The colours it yields are practically identical with those given by morinda root, but much fuller, a fact not to be wondered at, for it is well known that in ordinary morinda root the colouring principle is situated chiefly in the root bark. In its ordinary condition mangkudu is not useful in dyeing, but as in the case of *ál* root, a preliminary washing or steeping in water suffices to remove the deleterious acid principles present, and thus to transform it into a valuable red dyestuff. A. G. P.

MORINDIN *v.* MORINDA, and GLUCOSIDES.

MORITANNIC ACID *v.* OLD FUSTIC.

MORPHINE *v.* VEGETO-ALKALOIDS.

MORPHOSAN *v.* SYNTHETIC DRUGS.

MORTAR *v.* CEMENTS.

MORTAR, HYDRAULIC, *v.* CEMENTS.

MOSAIC GOLD. *Ormolu*, *v.* GOLD, MOSAIC.

MOTHER-LIQUOR. The liquid which remains after the crystallisation of a salt or other solid.

MOTHER-OF-PEARL. This is the nacreous lining of the shell of various molluscs, notably that of the large pearl-oyster *Meleagrina margaritifera* (Lam.). The nacre is secreted by the mantle of the mollusc, and consists mainly of calcium carbonate (the orthorhombic modification corresponding with the mineral aragonite) associated with organic matter (up to 12 p.c. of conchiolin). On digesting the nacre in a dilute acid, all the calcareous salt may be dissolved, leaving a coherent pellicle of connective tissue which retains the iridescence until disturbed by pressure. The iridescence is due to the interference of light reflected from the microscopic corrugated edges of the delicate layers of nacre. In consequence of its pleasing lustre, mother-of-pearl is largely employed for buttons, counters, card-cases, knife-handles, and a great variety of trivial ornaments. Large quantities are used by the manufacturers of Birmingham and Sheffield. An important use is that of inlaying papier-maché work, while it is also used in the ornamentation of Moorish and other Oriental furniture. Mother-of-pearl is sometimes decorated by engraving, especially by the Chinese, or by having a pattern etched upon it by means of acid. In trade three varieties of shell are recognised—namely, the white, the gold-edged, and the black-edged. Dark shells are known generally as 'smoked pearl.' The principal fisheries for pearl-shell are in Torres Straits, off the north-west coast of Western Australia, in the Sooloo Archipelago, in the Persian Gulf and Red Sea, and round Tahiti and some other islands of the South Pacific. The shell is commonly known in the market by the name of its place of shipment, such as 'Manila' and 'Egyptian' shells. In the Bay of California and the Gulf of Panama mother-of-pearl shell is obtained from the *Meleagrina californica* (Cpr.), and passes in trade as 'bullock shell.' The brilliant shells of the *Haliotis* and certain species of *Turbo* are also used for inlaid papier-maché and other ornamental purposes. *V.* W. H. Dall, Amer. Nat. 1883, 27, 579 ; and E. W. Streeter, Pearls and Pearling Life, London, 1886 ; G. F. Kunz and C. H. Stevenson, The Book of the Pearl, New York, 1908. L. J. S.

MOTTRAMITE *v.* VANADIUM.

MOULDS, fermentations produced by, *v.* FERMENTATION.

MOUNTAIN ASH, *Sorbus Aucuparia* (Linn.) or [*Pyrus Aucuparia* (Gaert.)] *Service tree, Rowan.* The fruit of this plant affords one of the best natural sources of malic acid (*q.v.*) and of sorbitol. A partial analysis of the berries by Kelhofer (Chem. Zeit. 1895, 19, 1835) shows them to contain 2·78 p.c. free malic acid, 0·49 p.c. tannin, and 6·27 p.c. of sugar. Sorbinose is not present in the juice of the ripe berries, but on dilution and keeping for some months, is produced by the oxidation of the sorbitol (Freund, Monatsh. 1891, 11, 560). This oxidation is effected by a specific bacterium (Bertrand, Compt. rend. 1898, 127, 124, and 728). H. I.

MOUNTAIN BLUE. Syn. with *Azurite* $Cu(HO)_2{\cdot}2CuCO_3$, *v.* COPPER.

MOUNTAIN CORK, FLAX, LEATHER, WOOD. See ASBESTOS.

MOUNTAIN GREEN. Syn. with *Malachite* (*q.v.*, also *v* COPPER). The term is also applied to a mixture of Schweinfurth green with gypsum or heavy spar ; *v.* ARSENIC.

MOUNTAIN SOAP. *Steatite v.* TALC.

MOWRAH SEED OIL *v.* BASSIA OIL.

MUCIC ACID *v.* CARBOHYDRATES.

MUCIC FERMENTATION GUM *v.* GUMS.

MUCILAGE. The older writers made a distinction generally between gums which, like arabic and tragacanth, are obtained as a solid exudate, and the gum which is almost a universal constituent of plants, especially of some seeds

and roots, and may be extracted by treatment with water (*cf.* Gm. 15, 209). The latter was termed *mucilage*, or *vegetable mucilage*, or *pflanzenschleim* (Ger.). Among the more important sources of this gum are marshmallow, salep, fleawort, linseed, and quince; *v.* Gums.
A. S.

MUKOGEN *v.* Synthetic drugs.

MULBERRY, *Morus* spp. The name of several varieties of trees, grown for fruit, ornament, timber, shade, or for the sake of the leaves, which form the best food for silkworms. Many species and varieties are known, the three best known types being *M. alba* (Linn.), *M. nigra* (Linn.), and *M. rubra* (Linn.). Fresenius (Annalen, 185, 101, 219) found in the fruit of black mulberries—

Water	Protein	Free acid	Invert sugar	Pectins	Seeds and fibre	Ash
84·71	0·39	1·86	9·19	2·03	1·16	0·65

The leaves contain from 62 to 73 p.c. of water, and the dry matter contains from 3·8 to 6·1 p.c. of nitrogen and from 7 to 8·5 p.c. of ash (Sestini, Versuchs. Stat. Organ. 15, 286). Alpe (Bied. Zentr. 1900, 29, 422) estimates that in Italy about 20 kilos. of wood and 25 kilos. of leaves are removed from each tree annually, and that this robs the soil of about 510 grammes of N, 172 grammes of P_2O_5, and 486 grammes of CaO, a loss which could be made good by about 100 kilos. of farm-yard manure to each tree. Menozzi (Chem. Soc. Abstr. 1899, ii. 682) found the dry matter of mulberry leaves to contain 5·0 p.c. of pentosans and 11·2 p.c. of cellulose.
H. I.

MULBERRY PAPER. The inner bark of *Broussonetia papyrifera* (Vent.) contains bast-fibres which are used in China and Japan for the preparation of a kind of paper, and in Polynesia for the manufacture of a fabric.

MULHOUSE BLUE *v.* Triphenylmethane colouring matters.

MUNDIC. The name given by the Cornish miners to iron pyrites. Similarly mispickel arsenical pyrites is known as 'arsenical mundic.'

MUNJEET or **MANJEET.** The *Rubia cordifolia* (Linn.) was formerly extensively cultivated in India, particularly in the mountainous districts, for the sake of the colouring matters contained in its stem or roots. In the Dárjéling district it occurs as a small climber common all over the hills, at elevations varying from 3000 to 7000 feet, but most abundant between 5000 and 6000 feet, and is found either creeping along the ground or climbing the trunks of trees in large festoons. In Bengal it would seem that the dye of munjeet is extracted mainly from the stem, and only occasionally from the root, as is the case in the North-Western Provinces and elsewhere in India. The munjeet of Bengal is apparently rather the *Rubia munjista* of Roxburgh than the *Rubia cordifolia.* This species of Roxburgh is, however, reduced to *Rubia cordifolia* in Hooker's Flora of British India. To prepare the dye the wood of the munjeet is first dried, then crushed and pounded, and then generally boiled with water, but sometimes merely left to steep in cold water. The solution obtained is of a deep red, and is used generally to dye coarse cotton fabrics, or the thread which is to be woven into such fabrics. Alum appears to be generally employed as a mordant, although myrabolans also are used in the Dárjéling district, and other astringents in the Maldah district. In the latter district munjeet is used in conjunction with iron salts to produce a deep purple, and in the Dárjéling district is mixed with indigo to form a maroon (McCann, Dyes and Tans of Bengal). The red and chocolates of East Indian chintzes were formerly entirely obtained from munjeet. The colours produced from munjeet are bright, but not so durable as those from ordinary madder, the inferiority being due, according to Stenhouse (Pharm. J. 13, 148), to the presence of purpurin and an orange dye munjistin (purpuroxanthin carboxylic acid). Runge, who examined the tinctorial power of munjeet, concluded that it contained twice as much available colouring matter as madder; but later experiments have shown that the colouring power is actually less. Stenhouse found that munjeet garancine has only half the colouring power of garancine made from Naples roots, but that munjeet yields (according to Higgin) from 52 to 55 p.c. of garancine, whereas madder yields only 30–33 p.c.

When madder was so much in vogue, munjeet was employed to some extent in this country, because it was considered that a good quality of this material contains as much colouring matter as madder, and could be applied by exactly the same methods.

The important colouring matter of munjeet is *purpurin*, and no alizarin is present in this root, and it is therefore interesting to note that whereas chay root contains alizarin, and munjeet purpurin, in madder both these substances exist together.

For the analysis of the phenolic constituents of munjeet, a modification of the method of Stenhouse, who first submitted this plant to examination, is to be recommended.

The ground dyestuff is digested with boiling alum solution for 5 hours, and the deep red extract treated with acid and allowed to cool. The red precipitate is collected, washed, and dried, and then extracted with boiling toluene (carbon disulphide was employed by Stenhouse), by which means the colouring matters pass into solution, and a resinous impurity remains undissolved. The colouring matters are now removed from the toluene by agitation with dilute potassium hydroxide solution, the alkaline liquid is acidified, and the precipitate collected, washed, and dried. In order to separate the constituents of this product it is extracted about 10 times with boiling dilute acetic acid, and the dark red residue consisting of *purpurin* is crystallised from alcohol.

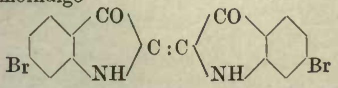
The earlier acetic acid extracts are mixed with hydrochloric acid, and the yellowish-red deposits are crystallised from alcohol. The product consists of orange-coloured leaflets, and is *purpuroxanthin carboxylic acid* or *munjistin*, as it was termed by Stenhouse, its discoverer, who first obtained it from munjeet. The properties of this compound have already been given in detail in the article upon Madder.

Munjeet has also been examined by Perkin and Hummel, who, in addition to the above constituents, detected the presence of a trace of *purpuroxanthin* (Chem. Soc. Trans. 1893, 63, 115).
A. G. P.

MUNTZ METAL *v.* Zinc.

MUREX *v.* Purple of the Ancients.

The Tyrian or antique purple was mainly obtained from shell-fish, especially from *Murex brandaris.* Friedländer (Monatsh. 1907, 28, 991; 29, 247) has isolated 1·4 grams of a pure purple dye from 12,000 specimens of *Murex brandaris*, and has shown that it is identical with 6:6′-dibromoindigo



(Sachs and Kempf, Ber. 1903, 36, 3303) *v.* Indigo, synthetic, and Punicin.

MUREXAN *v.* Uramil.

MUREXIDE, *ammonium hydrogen purpurate* $C_8H_8O_6N_6,H_2O$. The formation of a red residue when a solution of uric acid in nitric acid is evaporated to dryness, was first observed by Scheele in 1776, and forms the basis of the well-known *murexide test* for uric acid and compounds related thereto. In 1818 Prout (Ann. Chim. Phys. 11, 48) obtained the coloured principle in a crystalline form, and regarded it as the ammonium salt of a hitherto unknown acid, which he named *purpuric acid;* and by double decomposition prepared several other red purpurates. Liebig and Wöhler (Annalen, 1838, 26, 319) showed that the compound obtained by the action of mineral acids on ammonium purpurate, and regarded by Prout as the free acid, was in reality 'murexan' (afterwards identified by Beilstein with *uramil*), which, together with alloxan, form the chief products of decomposition of purpuric acid by mineral acids. These authors therefore gave the name of *murexide* to the compound, regarding it as having more of the nature of an acid amide than of a true ammonium salt. Subsequent work has, however, not justified this conclusion, since purpuric acid mixed with ammonium chloride can be obtained by the action of dry hydrogen chloride on murexide suspended in hot anhydrous acetic acid; it is an orange-red powder, and forms soluble salts with organic bases such as methylamine, ethylamine, pyridine, quinoline, and aniline (Möhlau and Litter, J. pr. Chem. 1906, [ii.] 73, 449).

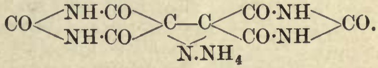
Preparation.—(1) From uric acid, by oxidising with nitric acid and subsequent treatment with ammonia or ammonium carbonate (Prout, *l.c.*; Liebig and Wöhler, *l.c.*; Kodweiss, Pogg. Ann. 19, 12; Fritzsche, Annalen, 1839, 32, 316).

(2) From alloxantin or alloxan by the action of ammonium salts in solution (Fritzsche, *l.c.*; Liebig, *l.c.*; Gregory, J. pr. Chem. [i.] 22, 374); or by passing dry ammonia over finely powdered alloxantin at 100° (Gmelin, Hand. f. Chem. 1856, iv. 195). According to Piloty and Finckh (Annalen, 1904, 333, 22), a yield of 80 p.c. of pure murexide can be obtained by adding 5 grams of alloxantin in 200 c.c. of water to a mixture of 25 grams of ammonium acetate in 100 c.c. water and 15 c.c. of 10 p.c. ammonia saturated with carbon dioxide; the solutions are mixed at 80° and the murexide crystallises out. The alloxantin may be replaced by a mixture of ammonium dialurate and alloxan. Hartley (Chem. Soc. Trans. 1905, 1791) prepared spectroscopically pure murexide by passing a stream of dry ammonia into finely-powdered alloxantin mixed with 100 times its weight of boiling absolute alcohol, for 3 hours or more. The precipitated anhydrous murexide is washed with absolute alcohol and dried at 100°, or in a vacuum.

(3) From uramil by oxidation with mercuric oxide in the presence of ammonia (Liebig and Wöhler, *l.c.*; Beilstein, Annalen, 1858, 107, 176); or by adding alloxan to a saturated solution of uramil in hot ammonia solution (Liebig).

The formation of murexide by the interaction of aqueous solutions of alloxan and amino acids was first observed by Strecker (Annalen, 1862, 123, 363). The reaction has been more closely investigated by Piloty and Finckh (*ibid.* 1904, 333, 22), and by Hurtley and Wootton (Chem. Soc. Trans. 1910, 99, 288). According to the latter authors, the amino acid is oxidised by the alloxan to the next lower aldehyde with the elimination of carbon dioxide and ammonia; the alloxan is reduced to dialuric acid, which combines with the unchanged alloxan to form alloxantin, and this, with the ammonia, forms murexide. The red stain caused by alloxan on the skin is probably due to a similar reaction, and it is suggested that alloxan may prove a suitable reagent for the detection of amino acids.

Constitution.—Matignon (Ann. Chim. Phys. 1893, [vi.] 28, 347) regarded purpuric acid as the imino derivative of alloxantin and expressed the constitution of its ammonium salt, murexide, by the formula



$$\mathrm{CO}<\begin{matrix}\mathrm{NH{\cdot}CO}\\ \mathrm{NH{\cdot}CO}\end{matrix}>\underset{\mathrm{N.NH_4}}{\mathrm{C{-}C}}<\begin{matrix}\mathrm{CO{\cdot}NH}\\ \mathrm{CO{\cdot}NH}\end{matrix}>\mathrm{CO.}$$

Slimmer and Stieglitz (Amer. Chem. J. 1904, 31, 661) showed that the molecule of murexide could not have a symmetrical structure, since the ammonium dimethylpurpurates obtained by the condensation of 1:3-dimethyluramil and alloxan, and of uramil and 1:3-dimethylalloxan are isomerides and not identical as would be the case if Matignon's formula were correct. These authors therefore suggest that the constitution of purpuric acid is best expressed by the formula

$$\mathrm{CO}<\begin{matrix}\mathrm{NH{\cdot}CO}\\ \mathrm{NH{\cdot}CO}\end{matrix}>\mathrm{CH{\cdot}N:C}<\begin{matrix}\mathrm{CO{\cdot}NH}\\ \mathrm{CO{\cdot}NH}\end{matrix}>\mathrm{CO,}$$

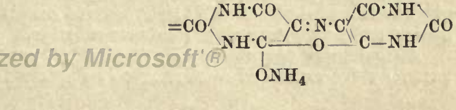
or in the hydrated form

$$\mathrm{CO}<\begin{matrix}\mathrm{NH{\cdot}CO}\\ \mathrm{NH{\cdot}CO}\end{matrix}>\mathrm{CH{\cdot}NH{\cdot}C(OH)}<\begin{matrix}\mathrm{CO{\cdot}NH}\\ \mathrm{CO{\cdot}NH}\end{matrix}>\mathrm{CO,}$$

the salts being derived from the *pseudo* form of the acid

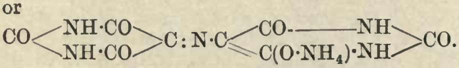
$$\mathrm{CO}<\begin{matrix}\mathrm{NH{\cdot}CO}\\ \mathrm{NH{\cdot}C(OH)}\end{matrix}>\mathrm{C{\cdot}N:C}<\begin{matrix}\mathrm{CO{\cdot}NH}\\ \mathrm{CO{\cdot}NH}\end{matrix}>\mathrm{CO.}$$

Piloty and Finckh (Annalen, 1904, 333, 22), having regard to the intense colour of murexide, assign to alloxan a quinonoid structure and to murexide that of a diureide oxazonium ammonium salt, and express its formation from uramil, alloxan, and ammonia by the following scheme

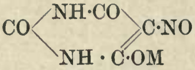


Möhlau and Litter (Ber. 1904, 37, 2686; J. pr. Chem. 1906, [ii.] 73, 449) represent murexide as a ketoimide having an unsymmetrical structure such as may be expressed by the formulæ

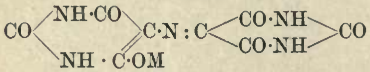
or



The second of these is identical with that proposed by Slimmer and Stieglitz (*l.c.*); and deduced by Hartley (Chem. Soc. Trans. 1905, 87, 1794) from a study of the action of alcoholic ammonia on alloxantin. Hantzsch and Robison (Ber. 1910, 43, 92) point out the correspondence between their formula for the coloured salts of violuric acid and the above formula for murexide



Violurate.



Purpurate.

the oxygen of the nitroso group of the violurate, being replaced by a malonylurea residue.

Murexide crystallises in short four-sided garnet-red prisms, with gold-green reflex. The anhydrous salt forms a brownish powder which assumes a green metallic lustre when rubbed. Its molecular heat of combustion is 736·7 cal. (Matignon, Ann. Chim. Phys. 1893, [vi.] 28, 346), it is sparingly soluble in cold, more readily so in hot water, insoluble in alcohol or ether. The absorption spectrum shows two absorption bands, one in the visible spectrum and one in the ultraviolet (Hartley, Chem. Soc. Trans. 1887, 199; 1905, 1805).

Solutions of murexide dye silk, wool, cotton, or leather red to purple shades in the presence of mercury salts, or orange to yellow shades in the presence of zinc salts, and at one time the compound was prepared on a commercial scale, as a dyestuff, from uric acid extracted from guano. The fugitiveness of the colours in the presence of even sulphurous acid, and the superiority of the aniline dyes have caused it to be entirely superseded.

In addition to murexide, the following salts of purpuric acid have been described: *sodium hydrogen salt* $C_8H_4NaO_6N_5$, dark brick-red solid; *potassium hydrogen salt* $C_8H_4KO_6N_5$, dark red microcrystalline solid, prepared like the other salts from murexide by double decomposition, also by oxidising dipotassium uramil with iodine in ethereal solution (Piloty and Finckh, Annalen, 1904, 333, 22); di-*potassium salt* $C_8H_3K_2O_6N_5$, dark blue solid, formed by dissolving the mono-potassium salt in potassium hydroxide (Fritzsche); *calcium salt* $C_8H_3CaO_6N_5$, dark green crystalline precipitate (Beilstein); *barium salt*

$$Ba(C_8H_4O_6N_5)_2,3H_2O,$$

dark green precipitate, very sparingly soluble in water (Fritzsche); *silver salt* $C_8H_4AgO_6N_5,1\frac{1}{2}H_2O$, bright purple powder; a solution of murexide gives a red precipitate with lead acetate and a bronze red precipitate with mercuric chloride.

Methylamine purpurate $C_9H_{10}O_6N_6,H_2O$, prepared by the action of methylamine on alloxan and alloxantin, forms red microscopic rhombic crystals, loses H_2O at 110°, decomposes at 210°, and when heated with water yields 7-methyluramil, alloxantin, alloxan, and methylamine.

Ethylamine purpurate $C_{10}H_{12}O_6N_6,H_2O$ decomposes at 205° (Möhlau and Litter, J. pr. Chem. 1906, [ii.] 73 449).

Other derivatives of purpuric acid are: *ammonium*-1:3-*dimethylpurpurate*

formed from 1:3-dimethyluramil and alloxan in the presence of ammonium carbonate, crystallises in small four-sided prisms, is slightly yellower in colour than murexide, and closely resembles its isomeride *ammonium* 1′:3′-*dimethylpurpurate*

similarly obtained from uramil and 1:3-dimethyl alloxan.

5-*Methylpurpuric acid*

prepared from methyl iodide and anhydrous potassium purpurate; the isomeric O-4-*methylpurpurate*

obtained from methyliodide and silver purpurate is unstable (Slimmer and Stieglitz, Amer. Chem. J. 1904, 31, 661). M. A. W.

MUREXOÏN (*tetramethylmurexide ?*)

$$C_{12}H_{16}O_6N_6$$

is prepared by the action of air and ammonia on dry or moist amalic acid (tetramethylalloxantin) (Rochleder, J. 1850, 436; Brunn, Ber. 1888, 21, 514); or by treating desoxyamalic acid with bromine, and afterwards with ammonia (Fischer and Ach, Ber. 1895, 28, 2477). It forms cinnabar-red four-sided prisms reflecting a golden yellow light from two faces, it sublimes at 230°, and decomposes without previous fusion at a higher temperature. It is sparingly soluble in alcohol or water, forming deep purple-red solutions. It is decomposed on warming with hydrochloric acid, but the only product of the reaction that has been identified is dimethylparabanic acid (cholestrophan) (Brunn, *l.c.*). M. A. W.

MURIATIC ACID *v.* Chlorine.

MUSCARINE

the chloride of dimethyl phenyl-*p*-ammonium-β-hydroxynaphthoxazine obtained by the action of nitrosodimethylaniline hydrochloride on α-dihydroxyhaphthalene. A colouring matter introduced by Durand and Huguenin. Is a brownish-violet powder, sparingly soluble in cold water but readily soluble in hot water with a bluish-violet colour. Alkalis precipitate the base as a yellow-brown powder. Dyes cotton mordanted with tannin and tartar emetic a blue colour *v.* Oxazine colouring matters.

MUSCARINE *v.* Ptomaïnes.

MUSCOVADA. The unrefined brown or raw sugar of commerce *v.* Sugar.

MUSCOVITE or **MUSCOVY GLASS.** A term occasionally applied to mica (*q.v.*).

MUSHROOM, the name given to various species of edible fungi. Species of *Agaricus*, *Lactarius*, and *Coprinus*, and popularly even of *Boletus*, *Polyporus*, and *Morchella*, furnish most of the edible mushrooms, although some species of the same genera are poisonous. The following analyses, chiefly from König, are of edible fungi :—

	Water	Protein	Fat	Mannitol	Glucose	Other N-free extract	Crude fibre	Ash
Psalliota (Agaricus) campestris (Quél.) . . .	89·7	4·9	0·2	0·4	0·7	2·5	0·8	0·8
Cantharellus cibarius (Fries.)	91·4	2·6	0·4	0·7	0·3	2·8	1·0	0·7
Boletus edulis (Bull.) .	87·1	5·4	0·4	0·4	2·2	2·6	1·0	1·0
,, *luteus* (Linn.) .	92·6	1·5	0·3	2·0		2·0	1·2	0·5
Lactarius deliciosus (Fries.)	88·8	3·1	0·7	2·2		0·9	3·6	0·7
(?) *Polyporus ovinus* (Schäff.)	91·6	1·0	0·6	2·6		1·7	1·8	0·7
Morchella esculenta (Pers.)	90·0	3·3	0·4	0·7	0·1	3·7	0·8	1·0
Coprinus comatus (Pers.)	94·3	2·0	0·1	2·9			0·2	0·5

Mushrooms are liable to considerable variation in composition according to the age at which they are gathered and to the character of the soil or other medium on which they are grown. The nitrogenous matter and crude fibre are the most variable constituents. Owing to the very large proportion of nitrogenous substances in the dry matter, mushrooms are usually considered to be highly nutritious, but, according to the investigations of Saltet (1885), Uffelmann, Strohmer (1886), and Mendel (1898), the nitrogenous matter has a low digestibility, about 33 p.c. of the pure proteids usually being indigestible. Of the total nitrogen, from 60–80 p.c. exists as proteid, 6–13 p.c. as amino acids, 11–17 p.c. as acid amides, and about 0·2 p.c. as ammonia. Choline occurs to the extent of 0·01 p.c. in *Cantharellus cibarius*, 0·015 p.c. in *Psalliota campestris*, and 0·0056 p.c. in *Boletus edulis* (Polstorff, Chem. Zentr. 1909, ii. 2014).

Lietz (Zeitsch. Nahrungm. Unters. Hygiene u. Waarenk. 1893, 7, 223) found that 19 varieties of mushrooms contained, in the dry matter, from 0·08 to 1·64 p.c. lecithin, and from 0·11 to 3·08 p.c. of combined phosphorus pentoxide.

Gilson (Compt. rend. 1895, 120, 1000) obtained from various species, a substance identical with chitin, the horny external covering of insects. The fat consists of phytosterol and a dark brown oil, about half of which consists of free fatty acids, the remainder being neutral fat (Opitz, Arch. Pharm. 1895, 229, 290).

The non-nitrogenous extract of mushrooms consists chiefly of mannitol, trehalose (or mycose), inulin and pentosans. According to Bourquelot (Compt. rend. 108, 568) mannitol is largely produced from the trehalose during the after-ripening and drying, whilst the trehalose itself is formed from some dextrin-like carbohydrate, which constitutes the tissue of the fungus. The proportion of pentosans is small; Wittmann found about 0·1 p.c., whilst Menozzi (Chem. Soc. Abstr. 1899, ii. 683) found, in the dry matter of *Boletus edulis*, 1·9 p.c.

The ash varies in amount and composition; it forms from 5 to 9 p.c. of the dry matter, and usually contains about 50 p.c. K_2O, 30 p.c. P_2O_5, with smaller quantities of lime, magnesia, soda, silica, and chlorine. Alumina is often present, in some cases to the extent of 5–7 p.c. A poisonous fungus, *Amanita muscaria* (Pers.), contains an isomeride of betaine, *muscarine* $CH(OH)_2CH_2{\cdot}N(CH_3)_3OH$, which acts like a ptomaine. One of the edible fungi *Gyromitra* (*Helvella*) *esculenta* (Fries.) in the fresh state, contains a poisonous constituent, helvellic acid $C_{12}H_{20}O_7$ (Böhm and Külz, Archiv. experimentelle Path. 19, 403). H. I.

MUSK. *Moschus.* (*Musc*, Fr.; *Moschus*, Ger.) Musk consists of the dried secretion of the preputial follicles of the musk deer, *Moschus moschiferus* (Linn.), which inhabits the mountainous districts of Central Asia. *Cf.* Pereira (Mat. Med. [iii.] 2, 2251). An analysis by Geiger and Reimann, quoted by Gmelin (Handb. Chem 2, 1449), shows that it contains cholesterol together with fatty, waxy, and albuminous substances. The well-known odour of musk is due to the presence of a ketone *muskone*. When distilled with steam crude musk yields 1·4 p.c. of a dark brown oil, about half of which distils at 200°–210° under 9 mm. pressure. Muskone $C_{15}H_{28}O$ or $C_{16}H_{30}O$ is obtained by treating the distillate with alcoholic potassium hydroxide and distilling the product at 160°–164° under 7 mm. pressure. It is a colourless, viscid oil, boils at 142°–143° under 2 mm., or with slight decomposition at 327°–330° under 752 mm. pressure. It is sparingly soluble in water, readily so in alcohol. The *oxime* melts at 46°. The *semicarbazone* melts at 133°–134°, and is odourless, but gives an odour of musk when heated with dilute sulphuric acid. The fraction of the oil boiling at 65°–106° under 7 mm. pressure obtained in the preparation of muskone has an unpleasant odour and gives the pine-wood reaction for pyrrole (Walbaum, J. pr. Chem. [ii.] 73, 488). Besides its use as a perfume, musk is employed in medicine as a nervous stimulant.

Compounds having the odour of musk have been prepared synthetically, but such substances have an entirely different chemical structure. These are, however, not poisonous, and are largely substituted in the cheaper forms of perfumery for the expensive natural product. The musk substitutes at present known are trinitro-*meta*-tertiarybutyltoluene and the corresponding compounds obtained from the homologues of toluene, and the dinitro derivatives of the ketones which are formed by the interaction of acyl chlorides on butyl derivatives of toluene and homologues (Baur, Compt. rend. 111, 238; Ber. 24, 2832; *ibid.* 31, 1344). A. S.

MUSK, ARTIFICIAL *v.* Butyl.

MUSK-ROOT *v.* Oleo-resins.

MUSTARD. Mustard is derived from the seed of an annual cruciferous plant which grows wild or is cultivated in Great Britain, and throughout Europe, the United States, and many other countries. It grows to a height of from 3 to 6 feet, has yellow flowers and lyrate leaves.

Two varieties are commonly used, *Sinapis alba* (Linn.) or white mustard, and *Brassica nigra* (Koch) or black mustard. These only are recognised by the British Pharmacopœia. The seeds of the former are spherical, 2 to 3 mm. in diameter, of a buff colour outside, with a finely granular surface. Those of black mustard are from 1 to 1·5 mm. in diameter, have a dark brown reticulated surface but are yellow within. Indian mustard is *Brassica juncea* (Coss.), and the Russian sarepta mustard is *B. Besseriana* (Andr.). The Dakota (wild) mustard or Charlock is *B. sinapistrum* (Boiss) (or *Sinapis arvensis* (Linn.)).

Preparation.—The ground farina is usually a mixture of the two varieties, and is prepared by crushing the seeds, winnowing out the husks, which form an obstacle to fine grinding, and sifting. A large proportion of the fixed oil is very generally removed by hydraulic pressure.

Composition.—The main constituent of the seed is the fixed oil, which is tasteless and nearly odourless, and is employed for mixing with other illuminating oils and sometimes for culinary purposes. This occurs in both varieties of the seed. The valuable and characteristic properties of mustard are due to the volatile oil, allyl *iso*-thiocyanate C_3H_5NCS, which, however, is not present in the mustard as such, but is formed by the action of water and an enzyme, *myrosin*, which is present in both kinds of seed, on a glucoside, potassium myronate $KC_{10}H_{18}NS_2O_{10}$, which is only found in the black variety. White mustard also contains a glucoside, *sinalbin* ($C_{30}H_{42}N_2S_2O_{15}$), which on hydrolysis forms an acrid pungent oil, *acrinyl iso-thiocyanate* (C_7H_7ONCS), which, however, is only slightly volatile with steam. Mustard seeds contain mucilage but no starch.

Fairly complete analyses by Piesse and Stansell gave the following results—

TABLE I.

—	Whole seed		Farina	
	White	Brown	White	Brown

Mustard is chiefly used as a condiment, but is also employed in medicine internally as an emetic and externally as a rubefacient and counter-irritant. The volatile oil is also official in the British Pharmacopœia, and is a powerful vesicant.

Adulteration.—Practically the only adulteration to which mustard is subject in this country is the addition of foreign starches, accompanied not unfrequently by turmeric or aniline dyes to restore the colour. Cayenne pepper is also said to be added to increase the pungency.

The addition of starch is defended on the ground that it confers better keeping properties on the preparation and prevents it caking. Provided the addition is notified and the amount moderate there is no objection; but in England, at all events, it is quite unnecessary.

In inferior grades traces of starch may be present owing to the accidental admixture of starch-bearing seeds during the gathering of the crop.

The removal of the fixed oil has been regarded by some as an adulteration, and at least one successful prosecution has been recorded in this country (British Food Journal, 1903, 278). The practice, however, is very general, especially on the Continent, and little can be said against it. The fixed oil adds nothing to the flavour, and is certainly liable to become rancid.

The admixture of ground hulls in excessive proportion has also been recorded.

In order to comply with the British Pharmacopœia definition both the black and the white varieties of mustard should be present, though no directions are laid down as to the proportions of each. The judicious mixture of the two kinds is advantageous in that, while the volatile oil, to which the characteristic aroma is mainly due, is only yielded by the black mustard, the latter is somewhat deficient in myrosin, and this deficiency is supplied by the white variety.

Detection of adulteration.—Added starch is detected by the microscope. If much is present the addition of iodine solution will stain the sample blue. As, however, the volatile oil absorbs iodine rapidly, it is desirable in the case of small quantities of starch, to prevent the formation of the volatile oil by previously boiling with potassium iodide (Amer. J. Pharm. 1898, 70, 433). The determination of the starch may be effected approximately by microscopical comparison of the sample with mixtures of mustard containing known weights of the particular starch ascertained to be present.

Methods based on the conversions of the starch into sugar and the estimation of the reducing power are not very satisfactory, owing to the presence of other reducing substances not derived from the starch. To obviate this as far as possible the conversion should be by diastase, and should be preceded by extraction with ether and 10 p.c. alcohol.

A method in which the starch is weighed as such is that of Kreis (Chem. Zeit. 1910, 1021), in which the substance is digested with alcoholic potash, the insoluble matter, after washing with alcohol, is heated with dilute sodium hydroxide, and the solution diluted and filtered and a portion of the filtrate treated with an equal volume of 95 p.c. alcohol. The precipitate is allowed to settle (aided by a centrifuge), filtered off, washed with 50 p.c., then with 95 p.c. alcohol, finally with ether and dried and weighed. An allowance of 3 p.c. should be made for non-starchy substances in the precipitate.

The proportion of added starch may also be calculated, in the absence of other adulterants, from the reduction in the percentage of nitrogen in the fat and water free sample. Methods based on the determination of the fixed oil are obviously unreliable.

Turmeric is detected by the microscope or by soaking a strip of filter paper in an alcoholic extract of the sample, then in a solution of borax, and finally acidifying with dilute (2 p.c.) hydrochloric acid. When dry the paper will assume a rose-red colour, which turns deep blue with ammonia or olive-green with dilute caustic potash.

The presence of an undue proportion of the hulls is at once apparent on microscopic examination, the most characteristic structures being the cellular epidermal layer with its mucilage, the sub-epidermal cells with their thickened angles in the case of white mustard; also the palisade cells, yellow and not reticulate in white mustard, and brown and reticulated in the black variety. As will be seen from Table II. the indications of the microscope may be confirmed by chemical analysis, the total nitrogen, fibre, and copper reducing power, after treatment with diastase, being the most useful determinations.

Table II.—Analysis of Mustard (Leach).

Cayenne pepper may be detected by the pungent taste of the residue obtained by evaporating the alcoholic extract on the water-bath, and the acrid fumes which it yields on gentle ignition.

The presence of unofficial species of mustard which are more likely to occur in foreign brands is almost entirely a matter of microscopical examination (*v.* Winton, Microscopy of Vegetable Foods; also Pammel, Amer. Monthly Micr. Journal, 17, 206, and 213; Pharm. J. 1905, [74] 719).

As the efficiency of mustard for medicinal purposes depends on the proportion of volatile mustard oil, its determination is of some importance. Roeser's method (J. Pharm. Chim. 1902, 361) is carried out as follows: 5 grammes of the sample are mixed with 60 c.c. of water and 15 c.c. of 60 p.c. alcohol, allowed to stand for 2 hours and distilled into 10 c.c. of ammonia until two-thirds of the liquid has passed over; 10 c.c. of N/10 silver nitrate are added, and after standing for 24 hours the solution is diluted to 100 c.c. To 50 c.c. of the filtered solution are added 5 c.c. of N/10 potassium cyanide, and the excess of cyanide determined by titration with standard silver nitrate, using slightly ammoniacal 5 p.c. potassium iodide as indicator. The percentage of volatile oil is obtained by multiplying the number of c.c. of silver nitrate used up by the oil by 0·6274 (*v.* also German Pharmacopœia). (For proportion of volatile oil yielded by various kinds of mustard oil, *see* Ann. Falsi. 1909, 2, 215, and 12, 372.)

Standards.—United States Dept. of Agriculture. Mustard seeds should be those of *S. Alba*, *B. Nigra*, and *B. Juncea*. Ground mustard should consist of powdered mustard seeds with or without a portion of the hulls having been removed and from which a portion of the fixed oil has been expressed. Standard ground mustard is mustard yielding not more than 2·5 p.c. of starch by the diastase method and not more than 8 p.c. of ash. Leach (J. Amer. Chem. Soc. 1904, 26, 1210) suggests ash and starch as above, crude fibre not exceeding 5 p.c., nitrogen not less than 8 p.c. C. H. C.

MUSTARD OIL *v.* Oils, Essential.

MYCOSE, TREHALOSE, *v.* Carbohydrates.

MYDROL. Trade name for iodomethylphenyl pyrazolone. A white, odourless powder, with a bitter taste, soluble in water (*v.* Synthetic drugs).

MYOSIN *v.* Proteins.

MYRICA WAX (MEXICAN) *v.* Waxes.

MYRICA NAGI (Thunb.). This is an evergreen tree belonging to the *Myricaceæ* met with in the sub-tropical Himalaya from the Ravi eastwards, also in the Khasia mountains, the Malay Islands, China, and Japan. It is the box-myrtle or *yangmae* of China, and is synonymous with *M. sapida* (Wall.), *M. rubra* (Sieb. and Zucc.), and *M. integrifolia* (Roxb.). The bark is occasionally used as a tanning agent, and is said to have been exported from the North-West Provinces to other parts of India to the extent of about 50 tons per annum. In Bombay it is met with under the name of *kaiphal*, and in Japan as *shibuki*.

Myricetin $C_{15}H_{10}O_8,H_2O$, the colouring matter can be isolated from an aqueous extract of the plant by a similar method to that which is serviceable for the preparation of fisetin (see article Young Fustic) but is more readily obtained in quantity from the Japanese commercial 'shibuki' extract (Perkin and Hummel, Chem. Soc. Trans. 1896, 69, 1287; and Perkin, *ibid.* 1902, 81, 204).

The extract is treated with ten times its weight of hot water to remove tannin, and when cold the clear liquid is decanted off, the residue washed twice in a similar manner, and well drained. The product is extracted with boiling alcohol, and the solution evaporated until crystals commence to separate. On cooling these are collected (the filtrate A being reserved), and washed first with strong and then with dilute alcohol. A complete purification is best effected by converting the colouring matter into its acetyl derivative, and when pure hydrolysing this in the usual manner. Myricetin crystallises in yellow needles, melting at about 357°, and closely resembles quercetin in appearance. Dilute potassium hydroxide solution dissolves myricetin with a green colouration, which, on standing in air, becomes first blue, then violet, and eventually brown coloured. Alcoholic lead acetate gives an orange-red precipitate, and ferric chloride a brown-black colouration.

With mineral acids in the presence of acetic acid the following compounds which crystallise in orange-red needles have been prepared:

Myricetin sulphate $C_{15}H_{10}O_8 \cdot H_2SO_4$, *myricetin hydrochloride* $C_{15}H_{10}O_8 \cdot HCl$, *myricetin hydrobromide* $C_{15}H_{10}O_8 \cdot HBr$, and *myricetin hydriodide* $C_{15}H_{10}O_8 \cdot HI$. Alcoholic potassium acetate yields monopotassium myricetin $C_{15}H_9O_8K$. Bromination in the presence of alcohol gives *tetrabrom-myricetin ethyl ether* $C_{15}H_5O_8Br_4Et$, colourless needles, m.p. about 146° (Perkin and Phipps, *ibid.* 1904, 85, 62), and this is analogous to the behaviour of morin under similar circumstances. By the action of bromine in acetic acid *tetrabrom-myricetin* $C_{15}H_6O_8Br_4$, brown-red needles, m.p. 235°–240° is produced.

When fused with alkali myricetin gives *phloroglucinol* and *gallic acid. Hexa-acetyl myricetin* $C_{15}H_4O_8(C_2H_3O)_6$, colourless needles, m.p. 211°–212°; *hexabenzoyl myricetin*

$$C_{15}H_4O_8(C_7H_5O)_6,$$

colourless needles; *myricetin pentamethyl ether* $C_{15}H_5O_3(OCH_3)_5$, pale yellow needles, m.p. 138°–139°; *acetylmyricetin pentamethyl ether* $C_{15}H_4O_3(OCH_3)_5C_2H_3O$, colourless needles, m.p. 167°–170°; *myricetin hexamethyl ether,*

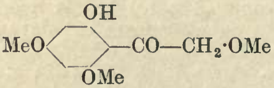
$$C_{15}H_4O_2(OCH_3)_6,$$

colourless needles, m.p. 154–156; and *myricetin hexaethyl ether* $C_{15}H_4O_2(OC_2H_5)_6$, almost colourless needles, m.p. 149°–151°, have been prepared.

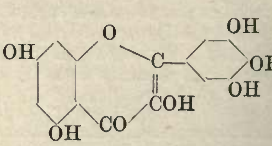
Myricetin dyes mordanted woollen cloth the following shades, which are practically identical with those given by quercetin:

Chromium.	*Aluminium.*	*Tin.*	*Iron.*
Red-brown.	Brown orange.	Bright red orange.	Olive black.

On digestion with alcoholic potash at 170° myricetin pentamethyl ether, gives *gallic acid trimethyl ether* and *phloroglucinol monomethyl ether*, whereas myricetin hexaethyl ether gives *gallic acid triethyl ether* and *phloroglucinol diethyl ether.* With boiling alcoholic potash myricetin hexamethyl ether gives gallic acid trimethyl ether and 2-*hydroxy-fisetol trimethyl ether* (Perkin, Chem. Soc. Trans. 1911, 100, 1721)



Myricetin hexaethyl ether behaves similarly with production of gallic acid triethyl ether and 2-*hydroxy-fisetol triethyl ether,* prismatic needles, m.p. 96°–97° (Perkin and Wilkinson, *ibid.* 1902, 81, 590). Myricetin is therefore a *hydroxyquercetin,* and possesses the following constitution:



Myricitrin $C_{21}H_{22}O_{13},H_2O$, the glucoside, is present in the alcoholic filtrate A, from the crude myricetin, from which it separates on standing. The crystals are collected, washed first with alcohol, then with dilute alcohol, crystallised from water, from alcohol, and finally from water. Myricitrin forms pale yellow, almost colourless, leaflets, melting at 199°–200°, and is soluble in alkalis with a pale yellow tint. Aqueous lead acetate gives an orange-yellow precipitate, and alcoholic ferric chloride a deep greenish-black colouration. In appearance it cannot be distinguished from quercetin and the shades given by the two substances on mordanted woollen cloth are practically identical.

Chromium.	*Aluminium.*	*Tin.*	*Iron.*
Full brown yellow.	Full golden yellow.	Lemon yellow.	Brown olive.

When hydrolysed with dilute sulphuric acid myricitrin yields rhamnose and myricetin, according to the equation

$$C_{21}H_{22}O_{13}+H_2O=C_{15}H_{10}O_8+C_6H_{14}O_6$$

and is analogous to quercitrin which in a similar manner gives rhamnose and quercetin. In addition to myricetin the *Myrica nagi* contains a trace of a glucoside of second colouring matter, which is probably *quercetin.*

The dyeing properties of myrica bark are generally similar to those of other yellow mordant dyestuffs. On wool with chromium mordant it gives a deep olive-yellow, and with aluminium a dull yellow, similar to the colours obtained from quercitron bark, but much fuller; with tin mordant it gives a bright red-orange, redder in hue than that given by quercitron bark; with iron mordant it gives a dark greenish olive like that obtained from quercitron bark but again fuller.

On cotton with aluminium and iron mordants it dyes colours which are more similar to those obtained from old fustic than from quercitron bark. Some specimens of myrica bark are exceedingly rich in colouring matter, and a sample examined by Hummel and Perkin (J. Soc. Chem. Ind. 1895, 14, 458) possessed much stronger dyeing power than old fustic.

OTHER SOURCES OF MYRICETIN.

Sicilian sumach the leaves of the *Rhus Coriaria* (Linn) contain myricetin, probably as glucoside (Perkin and Allen, *ibid.* 69, 1299). This colouring matter also exists in Venetian sumach *R. cotinus* and this is interesting, because the wood of this tree constitutes 'young fustic,' and contains fisetin. Among other plants myricetin has been isolated from the *Myrica Gale* (Linn), the leaves of *Pistacia Lentiscus* (Linn.), the leaves of the logwood tree *Hæmatoxylon campechianum* (Linn), and in conjunction with quercetin in the leaves of the *Coriaria myrtifolia* (Linn.), and the *Rhus Metopium* (Linn.).

MYRICIN. The more difficultly soluble portion of beeswax, consisting mainly of myricyl palmitate *v.* WAXES.

MYRICYL ALCOHOL *v.* WAXES.

MYRISTIC ACID $C_{13}H_{27}\cdot COOH$, discovered by Playfair in nutmeg butter, from *Myristica moschata* (Annalen, 37, 155); is found also in otoba fat from *M. otoba* (Görgey, *ibid.* 66, 314); in Dika bread (Oudemans, J. 1860, 322); in cocoa-nut oil; in butter; in the oil from quince seeds (Hermann, Arch. Pharm. 237, 367), and in wool fat (Darmstädter and Lifschütz, Ber. 1896, 620; 1898, 97), and may be obtained by melting stearolic acid with potash. It crystallises in needles, m.p. 53·8°, b.p. 121°–122° (0 mm.) and 250·5° (100 mm.), sp.gr. 0·8622 at 53·8°/4°.

Trimyristin or *trimyristil glyceride*

$$C_3H_5(C_{14}H_{27}O_2)_3$$

in which form myristic acid occurs in the various *Myristica* fats, crystallises from ether in needles, m.p. 55°.

MYRISTICA FATS comprise a number of fats belonging to the family of *Myristicaceæ.* They are all characterised by a preponderant proportion of myristin and hence by high saponification values. Some of these fats, like ochoco fat, consist almost entirely of myristin. The following fats—arranged, as far as is possible at present, in the order of the iodine values—include the better known members of this group: (*a*) nutmeg butter, mace butter; (*b*) Papua nutmeg butter; (*c*) fat from *Myristica malabarica*; (*d*) Kombo fat; (*e*) fat from *Myristica canarica*; (*f*) fat from *Myristica guatemalensis*, 13·8 p.c.; (*g*) Ucuhuba fat, Bicuhyba fat; (*h*) Ochoco fat.

In addition to the foregoing members there must be also included in this group the fats from: (1) *Myristica otoba* (Humb. and Bonp.), which yields the commercial otoba fat or otoba wax; (2) *Virola sebifera* (Aubl.), a fat used in Guiana in the manufacture of soaps and candles; (3) *Myristica ocuba* (Humb. and Bonp.), known commercially as ocuba wax, used in Para as a candle-making material; (4) *Virola Micheli* (Heckel), occurring in French Guiana; (5) *Staudtia kamerunensis* (Warb.).

(*a*) **Nutmeg butter,** mace butter, is obtained from the seeds of *Myristica officinalis* (Linn.) (*S. moschata* [Thunb.]. *S. fragrans* [Houtt.]), a tree growing wild on the islands of the Indian Archipelago, notably Celebes, Sumatra, Java, Molucca, and the Banda Islands. The tree (or at least varieties thereof) is also cultivated in Ceylon, in the West Indies, Brazil, and Guiana. The pericarp of the seed yields the arillus (mace) which is used in pharmacy, as a condiment for culinary purposes, and for the preparation of the ethereal oil contained in it. Formerly the small, as also the worm-eaten, rejected nuts which could not be exported were worked up for mace butter on the islands of the Indian Archipelago. The nuts were ground to a coarse meal, filled into sacks, and steamed for about 6 hours over boiling-pots. The sacks were then placed in a strong press and subjected to pressure. The butter so obtained represented a brownish mass. This was exported in the shape of bars (resembling soap bars) wrapped in cocoa-nut tree leaves (hence these bars were termed 'soap of Banda'). At present mace butter is chiefly obtained in European works (Holland, Germany) where the nuts are powdered and expressed when hot. The fat is also prepared in small quantities by extraction with light petroleum or common ether, in pharmaceutical laboratories.

The world's annual production of nutmegs does not exceed 1500 tons. Only a small quantity is used in the manufacture of nutmeg butter, so that the price of the fat is somewhat high. The seeds contain 38–40 p.c. of fat. Nutmeg butter has the consistence of soft tallow, is of a yellowish colour, and has the strong taste and odour of nutmegs.

The commercial fat varies considerably in composition. It contains from 4 to 10 p.c. of an ethereal oil (hence its saponification value does not exceed 190, and falls to as low a figure as 154) and contains chiefly trimyristin, in addition to a liquid fat and free fatty acids.

Cold alcohol dissolves the liquid fat, the free fatty acids, and the ethereal oil (unsaponifiable matter), leaving about 45 p.c. undissolved. The undissolved portion yields, on crystallisation from ether, pure trimyristin, melting at 55°.

Boiling alcohol dissolves nutmeg butter almost completely. The solubility in alcohol is not only due to the high percentage of free fatty acids contained in the commercial samples, but also to the ready solubility of myristin itself in alcohol.

Investigation of genuine mace butter obtained from Ceylon nutmegs by Power and Salway (Chem. Soc. Trans. 1907, 1653) afforded the following composition of the specimen examined:

Essential oil	12·5 p.c.
Trimyristin	73·0 ,,
Oleic acid, as glyceride . .	3·0 ,,
Linolenic acid, as glyceride .	0·5 ,,
Formic, acetic, and cerotic acids (very small amounts) . .	—
Unsaponifiable matter . .	8·5 ,,
Resinous material . . .	2·0 ,,
	99·5 ,,

The unsaponifiable matter consisted of a substance of the formula $C_{18}H_{22}O_5$ (amounting to about 5 p.c. of the expressed oil) and some myristicin $C_{11}H_{12}O_3$ and a very small amount of alcohol $C_{20}H_{34}O$, melting at 134°–135°. This alcohol is described as a 'phytosterol;' it differs from the ordinary phytosterol (sitosterol) by its different chemical composition, although it has the same melting-point.

Owing to the proportion of ethereal oil, which the genuine mace butter contains, the refractive index is very high. Various specimens examined in the butyro-refractometer indicated from 77·5 to 85 scale divisions. The iodine value varied from 77 to 80, the Reichert-Meissl value was 4·1–4·2, and the melting point only 25°–26°.

(*b*) **Papua nutmeg butter.** In consequence of the large demand for mace butter (nutmeg butter), this butter is frequently substituted by fats from other species of *Myristica*. Recently Papua nutmeg butter, the fat from *Myristica argentea* (Warb.) from the so-called 'Papua nutmeg,' which grows wild in Dutch New Guinea is substituted for genuine mace butter. Papua butter chiefly differs from genuine mace butter in that it contains no ethereal oil.

(*c*) **Fat from Myristica malabarica** (Lam.) is obtained from the seeds of *Myristica malabarica*, a tall evergreen tree growing in the forests of Konkan, Kanara, Malabar, and Travancore. The seeds contain 32 p.c. of shells, and yield 40·76 p.c. of fat and resins. The mace from these seeds differs entirely from that of the genuine mace in that it contains no ethereal oil. These seeds, sold as 'Bombay seeds' ('Kaiphal') have been frequently confounded with the genuine seeds from *Myristica officinalis*. The fat from the kernels of 'Bombay seeds' differs entirely from the fat from *Myristica officinalis*, for its saponification value is about 190; it melts at 31°, has an iodine value of 50·4, and a Reichert-Meissl value of 1·1 only. In the butyro-refractometer it only indicates 48–49 scale divisions at 30°.

(*d*) **Kombo fat, kombo butter** is obtained from the seeds of *Myristica angolensis* (Welw.), *Pycnanthus Kombo* [Baillon] (Warb.). This tree is widely distributed in the Gaboon (known there as 'arbre à suif du Gabon,') in the Congo, Angola, and in Southern and Northern Nigeria. The fruit breaks up easily into two thick hard pieces of husk and an inner nut covered with a false arillus; hence the seeds which are frequently mistaken for nutmegs can be easily differentiated from official nutmegs. The saponification value of a specimen (determined in the Imperial Institute) was 183, the iodine value 33·7. The numbers refer to a fat refined from crude fat by treatment with alkali in order to remove the fatty acids. The original crude fat had the iodine value 65·4, and the saponification value 275, in the presence of about 14 p.c. of fatty acids.

(*e*) The seeds of **Myristica canarica** are derived from the 'candle nut tree,' growing in India on the Western Ghats, from the Konkan southwards. The entire seeds yield 49·4 p.c. of fat; the mace, 54·6 p.c. of fat; the kernels separated from the shells furnish 64·76 p.c. of fat. The fat examined by D. Hooper (Agric. Ledger, 1907, No. 3) was light brown and crystalline, and gave, in the cold, with strong sulphuric acid a carmine-red colour. The saponification value was 215·02, the iodine value 26·64. The proportion of myristic acid amongst the fatty acids is stated to be about 70 p.c. Possibly identical with the fat last named is the fat from *Myristica surinamensis* (Roland) (*Virola surinamensis* [Warb.]), and perhaps also the fat from *Virola guatemalensis* (Warb.), obtained from 'wild nutmegs,' which do not contain an ethereal oil. These are occasionally imported into this country under the name 'oil nuts,' from Africa, as also from South America. The iodine value of a specimen of fat from *V. guatemalensis* ('African oil nut') examined by Grimme was 13·8, and its saponification value 244, and the proportion of unsaponifiable matter 1·13 p.c.

(*g*) **Ucuhuba fat, Urucaba fat, Bicubyba fat** is obtained from the nuts of *Myristica* (*Virola*) *bicuhyba* (Humb.). It is stated that the fat from *Virola bicuhyba* is usually mixed in Brazil with that from *Myristica officinalis*, but genuine specimens submitted to the author do not bear this out. Owing to the crude method employed in its preparation, the fat brought into the market is yellowish-brown, and has an aromatic odour (due to a small quantity of an ethereal oil), recalling that of coco-nut oil. Ucuhuba fat consists of myristin and olein (about 20 p.c.), small quantities of an ethereal oil, of a resinous substance, and of a wax-like compound: The resinous substance is soluble in ether, hot alcohol, light petroleum and chloroform. Genuine specimens examined in the author's laboratory melted from 35°–44·7°, had the saponification value 218·8, the iodine value 18·5, Reichert-Meissl value 2·68, lactones 3·15 p.c., unsaponifiable matter 3·05 p.c., and insoluble fatty acids 89·37 p.c..

(*h*) **Ochoco fat** is contained in the seeds of *Scyphocephalium ochocoa* (Warb.), a tree indigenous to the west coast of Africa. From a description published by Pierre it appears that the nuts have no arillus, and that they are non-dehiscent. The specimens examined by the author were identified by the Kew authorities as the kernels of *Scyphocephalium ochocoa* The average weight of the kernels is 10 grams; the smallest weighing 5 grams, and the largest 12·5 grams. The kernels, together with the thin husks surrounding the endocarp, yield 58·8 p.c. of fat. By whatever process the fat is prepared, a dark brown colouring matter is at the same time extracted, which is so tenaciously retained by the fat, that the author has hitherto been unable to remove this colouring matter. Similar difficulties were met with by Heckel and his collaborators. This dark colouring matter is not only contained in the husks, but also in the membranous extension of the husk (spermoderm) which passes through the whole of the endosperm, in the form of irregular lamellæ radiating from the chalaza. As the examination of the dark fat offered some difficulties, the only way to obtain a fat free from colouring matter was to cut out the white endosperm carefully by hand. The amount of endosperm so obtained formed 84·7 p.c. of the kernels. These 84·7 p.c. contained 69·4 p.c. of fat.

The white endosperm, on being extracted in the usual manner, yielded a perfectly white fat of the saponification value 238·5, the iodine value 1·72, and Reichert-Meissl value 0·65. The fat may therefore be considered as consisting of practically pure myristin, or at most of 98 p.c. of myristin and 2 p.c. of olein.

The natives apply the name 'ochoco' indiscriminately to several edible fruits, such as the fruits from *Lophira alata* (Banks.) ('niam fat'). J. L.

MYRISTICA SURINAMENSIS. The fruit of the *Myristica surinamensis* (Roland), is imported into Germany under the name of 'oil nut.' The nuts have the size and form of a cherry, with a dark-grey brittle shell inclosing a hard kernel. The kernels freed from shell, ground to powder, and extracted with ether, give 73 p.c. of fatty extract. The crude fat contains resin and a free acid. 100 parts of crude fat contain therefore 87 parts of pure substance. The pure fat has the formula $C_{45}H_{86}O_6$, which agrees with that of trimyristin. Like tristearin and tripalmitin, this body exists in different modifications with different melting-points. The trimyristin, saponified with alcoholic potash, yields myristic acid $C_{14}H_{28}O_2$. No other glycerides exist in this fat. The free acid in the crude fat was found to be myristic acid. Owing to the purity of the fat, and the absence of other glycerides, Reimer and Will recommend it as a source of pure myristic acid (J. Soc. Chem. Ind. 4, 746).

MYRISTICOL *v* CAMPHORS.

MYROBALANS *v* TANNINS.

MYRRH, MYRRHIN, MYRRHOL *v.* GUM RESINS.

MYRTLE BERRY WAX *v.* Waxes.

MYRTLE OIL and **MYRTOL** (Umney, Imp. Inst. Jour. Scient. & Tech. Research Dept. 1896, 302; Schimmel. Chem. Zentr. 1910, i. 1719). This oil as used medicinally begins to boil at 160° and about 80 p.c. distils over up to 240°. The residue consists of high-boiling terpenes, partly resinised and partly polymerised. From the portion boiling between 160°–240° by repeated fractional distillation the following constituents can be separated :—

A terpene $C_{10}H_{16}$ boiling between 158° and 160°, and having a specific rotation $[\alpha]_D = +36{\cdot}8^\circ$. According to Bartolotti (Gazz. chim. ital. 21, 276) the b.p. is 154°–155°, $[\alpha]_D + 59{\cdot}3^\circ$. Its properties led Jahns to believe it to be right-handed pinene.

Cineol $C_{10}H_{18}O$, which, purified by Wallach's method, boiled constantly at 176°.

A camphor probably of the formula $C_{10}H_{16}O$, in small quantity, boiling at 195°–200°, $[\alpha]_D$ 24·8° (Bartolotti, *l.c*). The therapeutic value of the myrtle oil is dependent on the amount of cineol present in it, the latter substance being identical with cajeputol and eucalyptol (E. Jahns, Arch. Pharm. 27, [iii.] 174; J. Soc. Chem. Ind. 8, 721).

According to Semmler and Bartelt (Ber. 1907, 40, 1363), myrtle oil contains in its high boiling fraction the ester of an alcohol $C_{10}H_{16}O$, which is called *myrtenol* and has b.p. 222°–224°/760 mm., sp.gr. 0·9763 at 20°, $[n]_D$ 1·49668 and $[\alpha]_D$ (in 100 mm. tube) $+ 45^\circ\ 45'$ (according to Soden and Elze b.p. 220°–221°, $[\alpha]_D$ 49°25′). With phosphorus pentachloride it yields *myrtenyl chloride* $C_{10}H_{15}Cl$, b.p. 90°/12 mm., and on reduction with sodium, *d*-pinene is formed. On oxidation with chromic acid myrtenol yields an aldehyde *myrtenal* $C_{10}H_{14}O$, b.p. 87°–90°/10 mm., which yields an oxime, m.p. 71°–72° and a nitrile, b.p. 100°–102°/10 mm. On hydrolysing the nitrile *myrtenic acid* $C_{10}H_{14}O_2$, b.p. 148°/9 mm., m.p. 45°, is produced. By reduction of the acid *dihydromyrtenic acid* $C_{10}H_{16}O_2$, b.p. 142°–144°/8 mm. is formed. When oxidised with alkaline permanganate myrtenol yields *d*-pinic acid $C_9H_{14}O_4$, b.p. 212°–216°/10 mm.

The characteristic odour of myrtle oil is due chiefly to the ester in the fraction of the oil boiling at 160°–180° (von Soden and Elze, Chem. Zeit. 1905, 29, 1031; Bartolotti, *l.c.*).

Myrtle seed oil forms a yellow oil of characteristic flavour, is readily soluble in ether and turpentine, but less so in alcohol. It contains glycerides of oleic, linoleic, myristic, and palmitic acids (Scusti and Perciabosco, Gazz. Chim. ital. 1907, 37, 483).

MYRTLE WAX (*Laurel wax, Bayberry tallow*) is obtained from the berries of various species of *Myrica*. In North America where the *Myrica* shrubs are common along the Atlantic seacoast, the myrtle wax is obtained from *Myrica cerifera* (Linn.) and *Myrica carolinensis* (Willd.). In South America, notably in New Granada and Venezuela, it is obtained from *Myrica arguta* (Kunth), and *Myrica caracassana* (Humb., Bonpl. et K.), and in South Africa (Cape Colony) from *Myrica quercifolia* (Linn.), *Myrica cordifolia* (Linn.), *Myrica laciniata* (Willd.), and *Myrica serrata* (Lam.). In Abyssinia, myrtle wax is obtained from *M. ethiopica* (Linn.)

The myrica fruits are of the size of a pea, and are covered with a snow-white crust of fat, which is permeated with brown or black spots.

Myrtle wax is a glyceride and consists chiefly of palmitin with small quantities only of olein (Smith and Wade, Amer. Chem. J. 1903, 629). The iodine value of commercial samples varies between 2 and 4.

Myrtle wax worked up by itself does not yield useful candles; it can, however, be employed in the proportion of 20–25 p.c. as an addition to other candle material. In the United States 'beeswax' candles are made which contain a notable amount of myrtle wax. J. L.

N.

NAGYAGITE. Native lead and gold telluride, containing more or less sulphur, and occasionally antimony (*v.* Tellurium).

NAPHTHA. This term was originally applied to a number of volatile, more or less mobile, inflammable liquids, usually ethers obtained by distillation, e.g., *Naphtha vitrioli* (ethyl ether), *N. nitri* (nitrous ether), *N. aceti* (acetic ether). The term was subsequently restricted to the naturally occurring liquid hydrocarbons, but was afterwards extended to other hydrocarbons obtained by the destructive distillation of shale, coal, bone, &c.

NAPHTHACENE  is obtained by the distillation of dihydroxynaphthacene quinone (*iso*ethine diphthalide) with zinc-dust (Gabriel and Leupold, Ber. 1898, 31, 1272; Fr. Pat. 320327, 1902; J. Soc. Chem. Ind. 1903, 22).

It forms orange-yellow to red-yellow leaflets, m.p. about 335°, which sublime forming a greenish-yellow vapour. It gives a green solution with sulphuric acid, and is insoluble in benzene. When treated with fuming nitric acid it yields naphthacenequinone.

Dihydronaphthacene  is formed by the distillation of naphthacene or of dihydroxynaphthacene quinone over zinc-dust; or by heating dihydroxy- or dichloronaphthacene quinone with hydrogen iodide and phosphorus (Gabriel and Leupold, *l.c.*). It forms flat needles, m.p. 206°–207°, b.p. about 400°. It gives a green solution in sulphuric acid with evolution of sulphur dioxide; is sparingly soluble in boiling alcohol, but more readily so in benzene, glacial acetic acid, and other organic solvents. It is oxidised by chromic acid, forming naphthacenequinone, whilst with concentrated nitric acid it yields a nitronaphthacenequinone.

NAPHTHACENEQUINONE *v.* Quinones.

NAPHTHALENE $C_{10}H_8$.[1]

History.—The production of naphthalene in the manufacture of coal-gas seems to have been noticed first by Clegg (*cf.* Brande, Quart. Journ. Sci. 1820, 8, 287); the discovery of its presence in coal-tar, however, was made simultaneously in 1819 by Garden (Annals Phil. 1820, 15, 74) and Brande (*l.c.*), the latter regarding it as a hydrocarbon (*cf.* Thomson, Schweig. J. 47, 337). It was further examined by Kidd, who named it 'naphthaline' (Phil. Trans. 1821, 209), by Ure (*ibid.* 1822, 473), and by Chamberlain (Annals Phil. 1823, [2] 6, 135); but its composition was determined first by Faraday in the course of his investigation of its isomeric monosulphonic acids (Phil. Trans. 1826, 159) and later by Laurent (Annalen, 1832, 3, 11). A bibliography of the early history of the subject is given in Gmelin (Eng. ed. 14, 1).

Formation and sources.—Naphthalene is almost invariably a constituent of the products obtained when organic substances are heated at a comparatively high temperature. For example, it is formed in small quantity, with other aromatic hydrocarbons, when marsh gas or acetylene (Berthelot, Bull. Soc. chim. 1867, [2] 7, 306), or the vapour of alcohol, acetic acid (Berthelot, Ann. Chim. Phys. 1850, [2] 33, 295), toluene, xylene, or cumene, or of a mixture of benzene, styrene or anthracene, with ethylene (Berthelot, Compt. rend. 1871, 63, 790, 834; Bull. Soc. chim. 1866, [2] 6, 268; 1867, 7, 218, 278, 285), is passed through porcelain tubes filled with pumice and heated to redness. It is present in small quantity in oil gas tar (Armstrong and Miller, Chem. Soc. Trans. 1886, 49, 80), and is produced when the vapour of toluene, or ethylbenzene, or of a mixture of toluene and ethylene is passed through a red-hot tube (Ferko, Ber. 1887, 20, 660). Berthelot's results have not been confirmed in every instance by later investigators (*cf.* Graebe, Ber. 1874, 7, 49; Lorenz, *ibid.* 1097; Carnelley, Chem. Soc. Trans. 1880, 37, 705; Ferko, *l.c.*), but this lack of confirmation may have been due to a difference in the conditions employed. Naphthalene is a constituent of brown coal tar (Heusler, Ber. 1897, 30, 2744); also of the tar produced when turpentine vapour is led through a red-hot iron tube (Schultz, *ibid.* 1877, 10, 116), and is formed when colophony or gum benzoin is distilled with zinc-dust (Ciamician, *ibid.* 1878, 11, 269).

With the object, primarily, of obtaining benzene, toluene, and anthracene, petroleum residues and the high-boiling oils of wood tar and brown coal tar have been passed, as in Berthelot's experiments, through red-hot tubes filled with charcoal, pumice, &c. The tars formed under these conditions from the residues of Baku petroleum (Letny, Ber. 1878, 11, 1210; Dingl. poly. J. 1878, 229, 355; Lissenko, Ber. 1878, 11, 342; Rudnew, Dingl. poly. J. 1881, 239, 72), and from the high-boiling oils of brown coal tar (Liebermann and Burg, Ber. 1878, 11, 723; Salzmann and Wichelhaus, *ibid.* 1431), and pinewood tar (Atterberg, *ibid.* 1222) contain considerable quantities of naphthalene, and in general resemble coal tar. Nevertheless, the production of valuable aromatic hydrocarbons on the large scale from petroleum residues, either under these conditions (Greiff, Chem. Ind. 1879, 2, 185; Liebermann, Dingl. poly. J. 1882, 246, 429; Redwood, J. Soc. Chem. Ind. 1885, 4, 79) or by the later methods patented by Hlawaty (D. R.-P. 51553 of 1888; Eng. Pat. 2242 of 1890), and Nikiforoff (D. R.-P. 143549; Eng. Pat. 21874 of 1901; Eng. Pat. 17450 of 1907; *cf.* Oglobine, Zeitsch. angew. Chem. 1905, 18, 406) is more costly than their isolation from coal tar, and at present of no commercial value.

Naphthalene is a constituent of the principal varieties of tar produced from coal in the manufacture of gas and coke; it is also present in coal gas, although the amount is kept as small as possible, to avoid blocking of the service pipes during cold weather (*cf.* Smith, J. Soc. Chem. Ind. 1889, 8, 949; Young, *ibid.* 1899, 18, 1109; 19, 813; Irwin, *ibid.* 19, 314; also, art. Gas, Coal). The proportion in gas tar varies considerably with the different kinds of coal employed (*cf.* Smith, J. Soc. Chem. Ind. 1889, 8, 951), and is greater the higher the temperature used during carbonisation (Smith, *ibid.* 1884, 3, 64), amounting usually to 4–6 p.c. (*ibid.* 1890, 9, 446), but in some cases to as much as 10 p.c. (Lewis, J. Gas Lighting, 47, 1248). In coke-oven tars, the proportion of naphthalene, as of other aromatic hydrocarbons, depends on the type of oven used (*cf.* Smith, J. Soc. Chem. Ind. 1883, 2, 404). With closed ovens, the tars do not differ greatly from gas tar, thus Watson Smith found from 1 to 10·17 p.c. in tars from Simon-Carvès ovens working with different kinds of coal (*ibid.* 2, 500; 3, 104, 508; J. Iron and Steel Inst. 1885, 103), and 'an equal amount to that contained in gas tar' in the tar from an Otto oven

[1] The following abbreviations are employed for the names of firms to which frequent reference is made in the text of this article:—

Aktienges.	Aktiengesellschaft für Anilinfabrikation in Berlin.
Badische	Badische Anilin- und Soda-Fabrik in Ludwigshafen a. Rh.
Bayer	Farbenfabriken vorm. F. Bayer & Co. in Elberfeld.
Bindschedler	Basler chemische Fabrik, vorm. Basler chem. Fabrik Bindschedler in Basel.
Brönner	Farbfabrik vorm. Brönner in Frankfurt a. M.
Cassella	Anilinfarbenfabrik von L. Cassella & Co. in Frankfurt a. M.
Dahl	Dahl & Co. in Barmen.
Geigy	Anilinfarben- und Extrakt-Fabriken vorm. J. R. Geigy in Basel.
Gesellsch.	Gesellschaft für chemische Industrie in Basel.
Griesheim	Chemische Fabrik Griesheim-Elektron in Frankfurt a. M.
Heyden	Chemische Fabrik von Heyden, Aktiengesellschaft in Radebeul bei Dresden.
Höchst	Farbwerke vorm. Meister, Lucius & Brüning in Höchst a. M.
Kalle	Kalle & Co., Aktiengesellschaft in Biebrich a. Rh.
Landshoff	Chemische Fabrik Grünau, Landshoff und Meyer.
Leonhardt	Farbwerk Mülheim, vorm. A. Leonhardt & Co., in Mülheim bei Frankfurt.
Sandoz	Chemische Fabrik vorm. Sandoz in Basel.
Schöllkopf	Schöllkopf Aniline and Chemical Co., Buffalo (U.S.A.).
Verein	Verein chemischer Fabriken in Mannheim.

(J. Soc. Chem. Ind. 1884, 3, 508); Knublauch obtained from 4·27 to 5·27 p.c. in tars from Otto-Hoffmann ovens (Dingl. poly. J. 1884, 254, 37); whilst Lunge found 7·69 p.c. of the crude hydrocarbon in tars from Otto-Hoffmann ovens, and 6·7 p.c. of the crude hydrocarbon in tars from Otto-Hilgenstock ovens, as against 7·4 p.c. in gas tar from the same coal (J. Soc. Chem. Ind. 1887, 6, 583). Blast-furnace tar contains only a very small proportion of naphthalene (Smith, *ibid.* 1883, 2, 495), and it could not be detected in Sutherland gas-producer tar (Smith, *ibid.* 3, 10).

Synthetical methods of preparing naphthalene have been described by Aronheim (Ber. 1873, 6, 67), Wreden and Znatowicz (*ibid.* 1876, 9, 1606), Brunner and Brandenburg (*ibid.* 1878, 11, 698), and Baeyer and Perkin (*ibid.* 1884, 17, 448). It has also been obtained by heating barium carbide with barium hydroxide at 800°–1000° (Bradley and Jacobs, D. R.-P. 125936; Eng. Pat. 26061 of 1898).

Isolation and purification (Lunge, Coal Tar and Ammonia, 4th ed. 1909, 643 *et seq.*).—Naphthalene occurs in the coal tar fraction boiling at 180°–250°, and is present, therefore, in the 'light oil' (b.p. 110°–210°), and 'creosote oil' (b.p. 240°–270°), but most abundantly in the 'carbolic oil' (b.p. 210°–240°) of the tar distiller. From the carbolic oil the crude hydrocarbon crystallises out to a large extent on cooling, and can be freed from the accompanying oil by draining and subsequent hot-pressing. It is then stirred for some time with hot caustic soda solution of convenient strength to remove phenolic constituents; and, after the alkaline liquor has been run off, is washed with hot water. Next, it is heated for about an hour with 5–10 p.c. of concentrated sulphuric acid (sp.gr. 1·7–1·84)[1] at about 100°, to remove both basic substances and residual phenols as soluble sulphonic acids. It is then washed several times with hot water, afterwards with weak alkali, and again with hot water, and finally is either sublimed or preferably distilled, pure naphthalene being collected between 210° and 235°, or so long as a sample solidifies on cooling, and gives only a faintly-coloured solution when dissolved in hot sulphuric acid.

Properties.—Purified naphthalene is usually found in commerce in white crystalline masses or thin scales. It crystallises from alcohol in scales or monoclinic prisms (Groth, Ber. 1870, 3, 453), melts at 79°, solidifies at 79·6°–79·8° (Weger, Zeitsch. angew. Chem. 1909, 22, 341), and boils at 217·5° at 750·5 mm., or 218·5° at 767·6 mm. (Crafts, Bull. Soc. chim. 1883 [2], 39, 282). Its sp.gr. is 1·1517 at 18·75° (Vohl, J. pr. Chem. 1867, 102, 30), or 0·9774 in the liquid state at 79·2° (Kopp, Annalen, 1855, 95, 335; *cf.* Schiff, *ibid.* 1884, 223, 261). Naphthalene has a characteristic, penetrating, tarry odour, a pungent taste, and burns with a very smoky flame. It is only sparingly soluble in light petroleum, but very soluble in benzene or ether, and miscible in all proportions with hot toluene or absolute alcohol. According to Bechi (Ber. 1879, 12, 1978), 100 parts of toluene dissolve 31·94 parts of naphthalene at 16·5°, and 100 parts of absolute alcohol dissolve 5·29 parts at 15°; according to Smith 100 parts of benzene, toluene, 'xylene,' and 'cumene' dissolve 45·8, 32·0, 31·5, and 30·1 parts of naphthalene respectively at 15° (J. Soc. Chem. Ind. 1902, 21, 1225). Naphthalene volatilises at temperatures considerably below its boiling-point, and is readily volatile with steam, alcohol vapour, or the vapour of tar oils of low boiling-point. Naumann (Ber. 1877, 10, 2016; 11, 33) has determined the vapour-tension of naphthalene to be 2 mm. at 15°, 9 mm. at 78°, and 20·5 mm. at 100°, and finds that when steam is passed into it naphthalene distils with water in the following ratios:—

Barometer (cor.)	Temperature of liquid	Temperature of vapour	Ratio of naphthalene to water in distillate
mm.			
759·5	97·8°	99·2°	100 : 520
757·0	97·7°	99·1°	100 : 570
733·0	—	98·2°	100 : 555

Reactions.—(1) When heated with amorphous phosphorus and hydriodic acid, naphthalene yields a *tetra-*, *hexa-*, *octo-*, or *deka- hydride* (*cf.* Graebe and Guye, Ber. 1883, 16, 3028); with sodium and ethyl alcohol a *dihydride* (Bamberger and Lodter, Annalen, 1895, 288, 75); and with sodium and amyl alcohol a *tetrahydride* (Bamberger and Kitschelt, Ber. 1890, 23, 1561).

(2) On oxidation with potassium permanganate in aqueous solution (Tscherniac, D. R.-P. 79693 of 1894; Procházka, Ber. 1897, 30, 3109; Graebe and Trümpy, *ibid.* 1898, 31, 369; Daly, J. Physical Chem. 1907, 11, 93) or, better, with potassium manganate (Tscherniac D. R.-P. 86914 of 1895) naphthalene is converted into *phthalonic acid* with only a small proportion of *phthalic acid* (*cf.* Lossen, Annalen, 1867, 144, 71), but with acidified permanganate into *phthalic acid* (Tscherniac, *l.c.*). With dilute nitric acid (of sp.gr. 1·15) at 130°, *phthalic acid* is the product (Beilstein and Kurbatow, Annalen, 1880, 202, 215; *cf.* Boswell, J. Physical Chem. 1907, 11, 129); with chromic acid mixture, *phthalic acid* (Lossen, *l.c.*) in 32 p.c. yield (Heller, Ber. 1912, 45, 674, footnote); but with chromic acid in acetic acid solution, [α-]*naphthaquinone* (Groves, Chem. Soc. J. 1873, 26, 209) and *phthalic acid* (Beilstein and Kurbatow, *l.c.*). Oxidation in acid solution with ceric salts (Höchst, D. R.-P. 158609 of 1902) or electrolytic oxidation (de Bottens, Zeitsch. Electrochem. 1902, 8, 673) in presence of cerous salts (Höchst, D. R.-P. 152063; Eng. Pat., 19178 of 1902) also converts it into [α-]-*naphthaquinone* and *phthalic acid.* It is oxidised also, when heated with 15 times its weight of 100 p.c. sulphuric acid (monohydrate) and half its weight of mercuric sulphate at 200°, yielding *phthalic acid* in large amount, mixed with some *sulphophthalic acid* (Badische, D. R.-P. 91202; Eng. Pat. 18221 of 1896).

(3) With chlorine, *naphthalene dichloride* (Fischer, Ber. 1878, 11, 735, 1411), and *tetrachloride* (*q.v.*) are formed, which, by elimination of hydrogen chloride are converted into mono- and di-chloronaphthalenes (Faust and Saame,

---

[1] To obtain naphthalene which will remain permanently white an oxidising agent—for example, about 5 p.c. of finely-ground pyrolusite, or of Weldon-mud—may be used with the acid (Lunge, Ber. 1881, 14, 1756; Chem. News, 1881, 44, 65).

Annalen, 1871, 160, 66; Krafft and Becker, Ber. 1876, 9, 1088; Widmann, *ibid.* 1882, 15, 2162; Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 85). With bromine, it forms a *tetrabromide*, but only at low temperatures (Orndorff and Moyer, Amer. Chem. J. 1897, 19, 262), and under ordinary conditions gives rise to substitution derivatives (Laurent, Ann. Chim. Phys. 1835, [ii.] 59, 216; Glaser, Annalen, 1865, 135, 40; Guareschi, *ibid.* 1884, 222, 265; Armstrong and Wynne, *l.c.*).

(4) Fuming nitric acid, or a mixture of nitric and sulphuric acids, converts naphthalene into *mono-*, *di-*, *tri-*, or *tetra-nitro-* derivatives; with sulphuric acid, according to the quantity, concentration, or temperature employed, *mono-*, *di-*, *tri-*, or *tetra- sulphonic acids*, or *sulphones*, are formed.

(5) When its vapour is passed through a red-hot iron tube, naphthalene yields about 15 p.c. of $\beta\beta$-dinaphthyl, and, when mixed with ethylene, gives in addition a very small quantity of acenaphthene and phenanthrene (Ferko, Ber. 1887, 20, 662).

(6) Naphthalene combines with trinitro-derivatives of benzene (Hepp, Annalen, 1882, 215, 380), toluene (Hepp, *l.c.*), aniline (Liebermann and Palm, Ber. 1875, 8, 377), phenol (Henriques, Annalen, 1882, 215, 332), or cresol (Noelting, Ber. 1882, 15, 1862; 17, 271), forming crystalline molecular compounds of varying stability. Of these, the *compound* with picric acid, $C_{10}H_8+C_6H_2(NO_2)_3{\cdot}OH$, crystallises in golden-yellow needles, m.p. 149°, and dissolves in alcohol, ether, or benzene without decomposition (Fritzsche, Jahresb. Chem. 1857, 456).

Tests.—Commercial naphthalene should melt at 79°,[1] boil at 217°–218° at 760 mm., volatilise without leaving a residue, and be white and free from phenols or quinoline bases. When heated with concentrated sulphuric acid at 170°–200° it should at most colour the acid grey (Witt, Chem. Ind., 1887, 10, 216), or faintly purple, and when left in contact with nitric acid (sp.gr. 1·42) should remain white for at least half an hour (Lunge, Coal Tar and Ammonia, *l.c.*).

The presence of phenols can be detected by boiling the sample with dilute caustic soda solution, cooling, filtering, and adding to the filtrate bromine water and hydrochloric acid, when any phenols present will be precipitated in the form of brominated compounds. Quinoline bases are detected by dissolving the sample in warm concentrated sulphuric acid, pouring the solution into water, filtering, rendering the filtrate alkaline and distilling, when any quinoline bases present will pass over with the steam, and will be recognised by their characteristic odour (Lunge, *l.c.*).

Estimation.—The proportion of naphthalene in commercial samples can be determined in many cases by sublimation. According to Küster (Ber. 1894, 27, 1101) an acidimetric method, based on the formation of the insoluble picrate, can be used for determining naphthalene. In this process a saturated solution of picric acid is employed, the excess of which is afterwards found by titration with standard baryta, using lacmoid as indicator; but as acenaphthene, chrysene, and the naphthols, also form insoluble compounds with picric acid, the method is valueless if they are present in the sample. In modified forms Küster's method has been employed for estimating the amount of naphthalene in coal gas by Colman and Smith (J. Soc. Chem. Ind. 1900, 19, 128) and by Gair (*ibid.* 1905, 24, 1279; 26, 1263).

Uses.—Until the discovery of the eosins about 1874, and of the azo- dyes about 1876, naphthalene had but a limited use, and was either employed as a fuel, or burned for soot. Now a large proportion of the output is utilised in the manufacture of (*a*) the phthalic acid required in the production of dyestuffs of the phthaleïn group and of indigo, (*b*) the naphthylamines and naphthols used in the azo- dye industry.

To a limited extent it finds employment as a disinfectant and insecticide, and in the enrichment of gaseous fuels, but its use as a carburettor for coal gas in the albo-carbon burner, with the object of increasing the illuminating power, has been much restricted, if not abandoned, as a consequence of the introduction of incandescent lighting (*cf. inter alia* Livesey and Kidd, Eng. Pat. 244; D. R.-P. 2075 of 1878; Kidd and Vale, Eng. Pat. 2135 of 1880; Vale, D. R.-P. 32255 of 1884; Lunge, *l.c.*).

CONSTITUTION OF NAPHTHALENE AND NAPHTHALENE DERIVATIVES.

The naphthalene compounds of greatest technical importance in connection with the manufacture of azo dyes are the naphthylamines, naphthols, aminonaphthols, and the derived isomeric sulphonic acids. These substances are by no means equally valuable as sources of dyes; some, for example, do not couple with diazotised bases, or form only aminoazo compounds, others yield azo dyes which are not fast to soap, or are valueless on account of their shade, insolubility, or instability,[2] and only a comparatively small number form azo dyes which answer all the requirements of the dyer so far as fastness, tinctorial power, and delicacy of shade are concerned. A knowledge of the constitution of the naphthalene derivatives employed in the colour industry is thus a question of much importance, as may be judged from the frequent references in this article to Patent specifications where no inconsiderable amount of the chemistry of naphthalene is to be found.

Constitution of naphthalene.—The Erlenmeyer-Graebe formula for naphthalene, proposed by Erlenmeyer (Annalen, 1865, 137, 346 (footnote)), but first made probable on the basis of experimental evidence by Graebe (*ibid.* 1869,

---

[1] In practice, the temperature at which the sample solidifies is preferred to the melting point, the determination, if made in Shukoff's apparatus, being accurate to 0·1° (Chem. Zeit. 1901, 25, 1111).

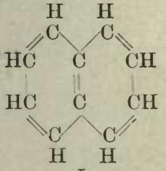
[2] For example: each of the following acids (2 mols.) coupled with diazotised benzidine (tetrazodiphenyl), gives worthless azo-dyes of the shades indicated:—

(*a*) β-Naphthylaminesulphonic acids:—5-[γ-] acid, sparingly soluble orange yellow; 6- [β-] acid, insoluble reddish brown; 7- [δ- or F-] acid, red changing to brown by action of atmospheric carbon dioxide; 8- [α-] none, but a yellow diazoamino- compound;

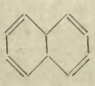
(*b*) β-Naphthylaminedisulphonic acids:—3 : 6- (amino-R-] acid, red of little tinctorial power; 6 : 8- [γ-, or amino-G-] acid, yellow and fugitive.

On the other hand, β-naphthylamine-3 : 7-disulphonic acid gives a red dye, remarkably fast towards light and acids (Cassella, D. R.-P. 46711 of 1888).

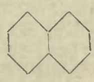
149, 22), represents the molecule as composed of two six-membered rings having two carbon atoms in common. This arrangement is shown in formula I, with which formula II, or, conventionally, when the object is merely to show the relative position of substituents in the molecule, formula III is equivalent :—



I

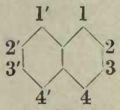


II

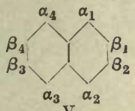


III

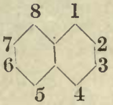
To save the labour of writing the symbol each time it is desired to indicate the orientation of a substituent, several methods for distinguishing the positions have been devised, of which three are shown in the symbols IV–VI :—



IV



V

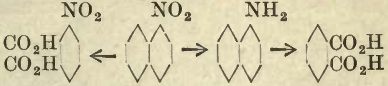


VI

Of these the last (VI), originally proposed by Graebe in 1869, and adopted by the Geneva Congress on Nomenclature in 1892 (Chem. News. 65, 280), is the only one now in use.[1]

With one exception (Wreden, Ber. 1876, 9, 950) all the formulæ proposed for naphthalene[2] show two six-membered rings in the same plane,[3] but differ from one another, and from the Erlenmeyer-Graebe symbol, in the mode of distribution of the fourth valency of each carbon atom, on which the unsaturation of the molecule, and the properties distinguishing naphthalene compounds from those of benzene probably depend. These six-membered rings have been termed benzene or benzenoid rings, but under a misapprehension : neither ring has the properties of benzene until the unsaturation of the other has been destroyed.

That naphthalene contains one six-membered ring is shown by its synthesis from benzene derivatives ; that it contains two, having two carbon atoms in common is demonstrated most convincingly, perhaps, by the production of 3-nitrophthalic acid from α-nitronaphthalene (Beilstein and Kurbatow, Annalen, 1888, 202, 217) and of phthalic acid from α-naphthylamine (Monnet, Reverdin and Noelting, Ber. 1879, 12, 2306) by the use of the same oxidising agent.



Incidentally, the production of 3-nitrophthalic acid fixes the α-position[4] relatively to the central carbon atoms in the formula (Reverdin and Noelting, Ber. 1880, 13, 36). As phthalic acid and nitrophthalic acid are benzene derivatives, it is evident that each six-membered ring of naphthalene becomes a benzene ring on disruption of the other by oxidation. Bamberger has shown that a similar result follows from the saturation of either ring by hydrogen.

The problem of the internal structure of the naphthalene molecule—in other words, the distribution of the fourth valency of each carbon atom—has been attacked both by chemical and physical methods with results which suggest that a complete solution has not yet been found. To be satisfactory on chemical grounds, the naphthalene formula must account for :—

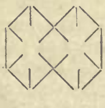
(i.) The symmetry of the molecule, in the sense that its two halves are alike as shown, for example, by the existence of four similar α- and four similar β- positions ;[5]

(ii.) The reduction, effected easily, of naphthalene derivatives to homonucleal tetrahydro-compounds with the loss of the properties distinguishing them from benzene derivatives ;

(iii.) The occurrence of substitution and of reduction initially in α- positions ;

(iv.) The difference between the four contiguous αβ- positions [1 : 2, 3 : 4, 5 : 6, 7 : 8] and the two contiguous ββ- positions [2 : 3, 6 : 7] of which the former alone have properties corresponding with those associated with the *ortho-* position in benzene. Only one 2 : 3-derivative, namely 3-hydroxy-β-naphthoic acid, is known to be formed by substitution from a β-mono- derivative, and the number formed in other ways is relatively very small.

Two formulæ, proposed respectively by Bamberger (*l.c.*) and by Thiele (*l.c.*), are of interest as designed to exhibit or account for some, if not all, of these requirements. Bamberger's formula (VII), based on Armstrong's centric formula for benzene, satisfies requirements (i.) and (ii.), and Thiele's formula (VIII), developed from his benzene formula with its conjugated double linkings, accounts also for requirements iii. and iv. by reference to the residual valencies shown in α- positions.



VII

VIII

---

[1] To distinguish the relative positions in disubstitution derivatives otherwise than by the use of numbers, Erdmann (Annalen, 1893, 275, 188) has proposed the adoption of the italicised prefixes in addition to those (shown in Roman type) which were previously in use :

1 : 4 para-	1 : 2 ortho-	1 : 7 *kata-*
1 : 5 *ana-*	1 : 3 meta-	2 : 6 *amphi-*
1 : 8 peri-	1 : 6 *epi-*	2 : 7 *pros-*

The suggestion was made by him that 2 : 3-derivatives should also be distinguished as *ortho-*, but as they are essentially different in properties from 1 : 2-compounds, confusion would arise from its adoption.

[2] *Cf.* Berthelot, Compt. rend. 1866, 73, 788, 834 ; Wichelhaus, Ber. 1868, 2, 107 ; Wreden (second formula), *l.c.* ; Claus, Ber. 1882, 15, 1827 ; Bamberger, Annalen, 1890, 257, 44 ; Armstrong, Chem. Soc. Proc., 1890, 6, 102 ; Thiele, Annalen 1899, 306, 138 ; Knoevenagel, *ibid.* 1900, 311, 194 ; Hartley, Chem. Soc. Trans. 1905, 87 ; Baly and Tuck, *ibid.* 1908, 93, 1905 ; Willstätter and Waser, Ber. 1911, 44, 3423 ; *cf. ibid.* 1912, 45, 1481.

[3] Kaufler (Annalen, 1907, 351, 154) has proposed a formula with the two rings in different planes.

[4] The use of the terms α and β for the isomeric naphthalenemonosulphonic acids was introduced by Merz (Zeitsch. Chem. 1868, [ii.] 4, 394) without reference to the naphthalene symbol.

[5] The existence of these two sets of interequivalent positions follows from the recognition of three isomeric αα-dichloronaphthalenes (Atterberg, Ber. 1877, 10, 547), and of three isomeric ββ-dichloronaphthalenes (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 83). For the interequivalence of the 2 : 7-position, compare Beschke (Annalen, 1909, 369, 157).

As against these and other theories of the structure of the naphthalene molecule, the Erlenmeyer-Graebe formula still commands the largest measure of assent. It contains the five double linkings, the presence of which is probable on physical grounds (*cf.* Brühl, Ber. 1887, 20, 2307); it shows clearly the difference between $\alpha\beta$- and $\beta\beta$- positions in the same nucleus; and, in common with Bamberger's or Thiele's formula, it accounts for the assumption of benzenoid properties when one of the two rings is saturated by hydrogen. It is also the formula which agrees best with the conclusions to be drawn from (*a*) the synthesis of α-naphthol by heating phenyl*iso*crotonic acid (Fittig and Erdmann (Annalen, 1885, 227, 242):

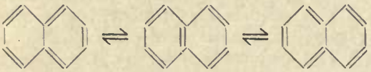
(*a*)

and (*b*) the production of carboxy-*o*-cinnamic acid from β-naphthol by oxidation (Ehrlich and Benedikt, Monatsh. 1888, 9, 527):

(*b*)

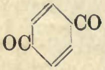
as in both of these compounds an $\alpha\beta$- double linking is present in the side chain.

Oscillation formulæ of the type suggested by Kekulé for benzene have been proposed also for naphthalene (*cf.* Erdmann, Annalen, 1893, 275, 191; Hartley, Chem. Soc. Trans. 1905, 87, 1828):—



but they would predicate a similarity in the properties of contiguous $\alpha\beta$- and $\beta\beta$- positions which does not exist. On the contrary, evidence from the chemical side (*cf.* Marckwald, Annalen, 1893, 274, 373; 1894, 279, 5) points to fixity of structure,[1] which finds its expression in the central double linking of the Erlenmeyer-Graebe formula.

That the internal structure of the naphthalene molecule can undergo modification under some conditions, just as that of benzene does, is clear from the existence of 2 : 6-naphthaquinone (Willstätter and Parnas, Ber. 1907, 40, 1406, 3971)

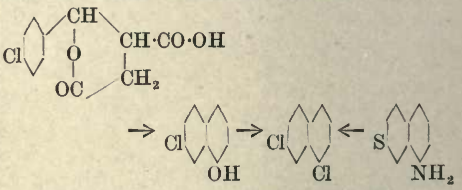


but this change—of much interest on other grounds—has no obvious connection with the question of a fixed or oscillatory structure for either hydrocarbon.

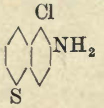
The mono-, di-, and tri-chloronaphthalenes furnish an argument in support of the symbol, for the investigation of all the substances described as di- and tri-chloro- derivatives has shown that the number is ten for the one and fourteen for the other[2] in agreement with the number of isomerides predicted from the formula. In no other series of tri-derivatives have all the possible isomerides been isolated, and as, by well-known reactions, it is not difficult in most cases to connect a naphthalene derivative under investigation with one or other of the chloronaphthalenes, this group of substances serves as a standard to which the orientation of other di- and tri- derivatives is referred.

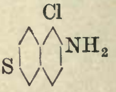
The constitution of the chloronaphthalenes has been ascertained mainly by two independent methods of investigation,[3] of which only an outline can be given here.

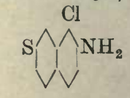
In one of them the isomeric sulphonic acids of α-naphthylamine (Erdmann, Annalen, 1888, 247, 306; 1893, 275, 192; Erdmann and Süvern, *ibid.* 275, 230) and α-nitronaphthalene were converted into dichloronaphthalenes, and the constitution of these determined by comparison with heteronucleal dichloronaphthalenes obtained synthetically from chlorophenylparaconic acids (Erdmann and Kirchhoff, Annalen, 1888, 247, 366; Erdmann, *ibid.* 1893, 275, 255)



In the other method use was made of 1-chloro-β-naphthylamine and its three heteronucleal sulphonic acids. Each of these acids was converted respectively into a chloro- and an amino-naphthalenesulphonic acid by eliminating (*a*) the NH_2-radicle, (*b*) the chlorine atom, and these in turn into dichloronaphthalenes. These dichloronaphthalenes, five in number and necessarily heteronucleal, contained each a chlorine atom derived from, and occupying the same position as either the Cl or the NH_2 radicle of 1-chloro-β-naphthylamine, and two isomerides were obtained from each acid. Thus their constitution was ascertainable, and that of the acids shown to be (S being used for SO_3H):—







---

[1] That part of Marckwald's objection to oscillation formulæ which is based on the assumed impossibility of preparing 2 : 3-naphthaquinone, seems no longer to be valid owing to the isolation of the 2 : 3-quinone of 1-methylnaphthalene in the form of a halogen derivative (Fries and Empson, Ber. 1909, 42, 3375). But the argument drawn from the impossibility of coupling β-naphthol with diazotised bases in the contiguous β-position still remains, and is supported, for example, by the results of experiments on the etherification of β-naphthol derivatives (Davis, Chem. Soc. Trans., 1900, 77, 44).

[2] When the substituents are not alike the number of isomerides is greater; thus the existence of 14 naphtholsulphonic acids, of 42 naphtholdisulphonic acids, and of 84 aminonaphtholsulphonic acids is deducible from the naphthalene symbol, and Ray has calculated the total number of substitution derivatives of which it allows to be 10,766,600 (Ber. 1900, 33, 1910; *cf.* Kauffmann, *ibid*, 2131).

[3] The agreement between the conclusions reached by these methods excludes the possibility that intramolecular change may have occurred at any stage of the work, and strengthens the evidence derived from many sources, that high temperature reactions which, in the case of benzene, are untrustworthy for the purpose of ascertaining structure, give with naphthalene derivatives consistent results. For example, the SO_3H radicle of naphthalene-, naphthylamine-, and naphtholsulphonic acids can be exchanged for OH by fusion of the acids with caustic alkali (*cf.* Erdmann, Annalen, 1889, 247, 308), and by distillation of hydroxy- or nitro- or sulphonic derivatives with phosphorus pentachloride, OH, or NO_2, or SO_2Cl radicles can be exchanged for Cl without any change in orientation.

(Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 34, 48; 6, 77). By an extension of this method the constitution of the fourteen trichloronaphthalenes also was ascertained (*ibid.*, Chem. Soc. Proc. 1895, 11, 84).

Reference to the following tables shows that in several instances di- and tri-chloronaphthalenes respectively have nearly the same melting points, and as they cannot easily be identified by their crystalline form, other means of characterising them are necessary. By sulphonating the dichloronaphthalenes with chlorosulphonic acid, and the trichloronaphthalenes with 10 p.c. anhydrosulphuric acid, sulphonic acids are formed, of which the chlorides and amides, each with a definite melting point, differ sufficiently among themselves to render identification complete (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 77; 1895, 11, 84).

Throughout this article the constitution of a substance is indicated by numerals, except in those cases where the use of α- and β-, as equivalent to the 1- and 2- positions, is commonly employed, *e.g.* α-naphthol instead of the less familiar 1-hydroxynaphthalene. When it has been necessary to use the letters α, β-, γ- . . . to distinguish isomerides, of which the constitution is unknown, the plan adopted by Ladenburg (Handwörterbuch, art. NAPHTALIN) of placing the letters in brackets (*e.g.* [α-]) to indicate that they bear no reference to the constitution of the compounds, has been followed.

SUBSTITUTION IN THE NAPHTHALENE SERIES.

A full discussion of the laws of substitution in the naphthalene series, and of the theories which have been proposed to account for or explain them, lies outside the scope of this article, but a summary of what is known or surmised in connection with nitration and sulphonation may be attempted in view of the importance of these processes in the manufacture of naphthalene derivatives for use in the colour industry.

The existence of two series of mono- substitution derivatives in the naphthalene series, and the fact that substitution tends to occur mainly in the α- position have long been recognised. For example, by chlorination, bromination, or nitration, naphthalene yields α-chloro-, α-bromo- or α-nitro-naphthalene; whilst, by nitration, α-chloronaphthalene yields three, α-nitronaphthalene two, naphthalene-α-sulphonic acid three, and naphthalene-β-sulphonic acid three α-nitro- derivatives. Owing to the very small proportion in which the β-isomeride is formed, the separation of β-chloro-, β-bromo-, or β-nitronaphthalene from the respective mono- substitution products was not achieved until recently, and the only recorded attempt to increase this proportion, by nitrating naphthalene at 200°–300° instead of at the ordinary temperature, led to negative results (Nägeli, Bull. Soc. chim. 1899, [iii.] 21, 786).

With sulphuric acid as the agent very different results are obtained, as β-isomerides can be prepared easily and in large amount. Faraday, who was the first to study the action of sulphuric acid on naphthalene, isolated the barium salts of the two monosulphonic acids, known now as the α- and β- acids, and later investigations have not only confirmed his discovery, but shown that the β- compound increases in amount as the temperature of sulphonation is raised until at 160° it constitutes almost the sole product (*v. Naphthalene-α-sulphonic acid*). This increase in the amount of the β-, accompanied by a corresponding diminution in that of the α- acid is shown clearly by the following numbers, obtained with many others by Euwes (Rec. trav. chim. 1909, 28, 298) in a quantitative study of the molecular reaction expressed by the equation:—

$$C_{10}H_8 + H_2SO_4 \rightarrow C_{10}H_7 \cdot SO_3H + H_2O$$

t°	P.c. $C_{10}H_8$ recovered [1]	P.c. in product		Disulphonic acid	Sulphone
		α-acid	β-acid		
80°	27·0	96·4	3·6	—	—
100°	20·0	83·2	16·8	—	—
129°	10·0	44·4	55·6	—	1·0
138·5°	8·6	28·4	71·6	—	(?)
150° [2]	6·4	18·3	81·7	—	3·2

According to Euwes, when equilibrium is attained, the relative proportion of α- and β-acid is fixed for any given temperature; thus

---

[1] It should be noted that this decrease in the amount of naphthalene recovered at the higher temperatures does not harmonise with Merz and Weith's results (*v. Naphthalene-α-sulphonic acid*).

[2] At temperatures above 160°, disulphonic acid was formed, but the data given do not show to what extent, if any, the consequent increase in dilution of the sulphuric acid influenced the relative proportion of α- and β-monosulphonic acids.

with 90 p.c., 96 p.c., and 100 p.c. sulphuric acid at 129°, the proportion of α-acid in the product was 44·6–44·4 p.c., the recovered naphthalene being 32 p.c., 23 p.c., and 10 p.c. respectively.

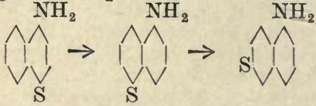
It has long been known that sulphonation is a reversible process, and, in the naphthalene series that α-sulphonic acids are hydrolysed at lower temperatures than β-sulphonic acids under conditions otherwise comparable. To Noelting is due the suggestion that naphthalene, regenerated by hydrolysis of its α-sulphonic acid at the high temperature is at this high temperature resulphonated, but in the β-, not the α-position (Ber. 1875, 8, 1095). This explanation, which does not account for the presence of β-acid at the lowest temperature of sulphonation, or for its progressive increase as the temperature rises, seems to have been accepted (*cf.* Weinberg, Ber. 1887, 20, 3354; Bender, *ibid.* 1889, 22, 994) until Erdmann published the first detailed study of an example of sulphonation.

Briefly, Erdmann's results, which were obtained with α-naphthylamine, showed that:—

(i.) When heated with 5 times its weight of 95–96 p.c. sulphuric acid at 130°, the base was rapidly converted into the 4-acid, with a small amount of the 5-acid, and traces of the 6-acid.

(ii.) The product at the end of 20 minutes was soluble in water, but contained some α-naphthylamine;

(iii.) The amount of naphthylamine increased, with simultaneous formation of the 4:7-disulphonic acid, as the heating at 130° was prolonged, the 5-acid, and afterwards the 6-acid, becoming the chief product:



To explain these facts, Erdmann modified Noelting's view by the assumption that the 4-, 5-, and 6-acids are produced simultaneously but in widely differing amounts. The formation of water by the further sulphonation of the 4-acid $NH_2{\cdot}C_{10}H_6{\cdot}SO_3H + H_2SO_4 = NH_2{\cdot}C_{10}H_5(SO_3H)_2 + H_2O$ disturbs the equilibrium which otherwise would be attained, and brings about the hydrolysis first of the 4-acid, and then of the 5-acid. Thus he accounted for the increase in the amount of α-naphthylamine; of the 5-acid; and finally of the 6-acid—the least easily hydrolysed of the three acids—in the product.

While this view accounts for the phenomena observed by Erdmann, and evidently implies that the introduction of a sulphonic group, like other processes of substitution, takes place mainly in α- and only to a small extent in β-positions at whatever temperature it may be effected—the subsequent change in the proportion of the isomerides being due to hydrolysis mainly of α-acid and resulphonation—it does not furnish a general theory of sulphonation. For example, it leaves unexplained:

(*a*) The transference of the SO_3H radicle S to a β- position under the influence of 30–40 p.c. anhydrosulphuric acid at 130°–180° in cases such as the following [1]—

I. 
II. 
III. 
(*b*) The rare occurrence of acids in which two SO_3H radicles occupy contiguous positions, and the non-occurrence of acids in which they occupy relatively 1:4- or 1:8- positions, even when on general grounds the occurrence of such acids in the sulphonation melt might be expected.[2]

The acids, five in number, in which two SO_3H radicles occupy contiguous positions, are each obtained by the aid of 40 p.c. anhydrosulphuric acid at 130°. Four of them are the β-naphthylamine- and β-naphthol- sulphonic acids of the orientation [R being NH_2 or OH]:

and the fifth is an α-naphthasultamtrisulphonic acid, in which contiguity occurs either in a ββ- or in a αβ- position.

If, with so great a wealth of material as is indicated—at least in part—in this article, the absence of a comprehensive theory of sulphonation should invite comment, the difficulties of separating the mixtures of soluble acids or salts, and of recognising the presence or demonstrating the absence in a melt of those small amounts of isomeric acids on which the validity of any theory must ultimately rest, should not be forgotten. These difficulties, as all experience would suggest, may not be insuperable, but until they have been overcome the prospect of more adequate views on the mechanism of this highly important industrial process seems to be remote.

Laws of Substitution in the Naphthalene Series.

Reference has been made to the fact that monosubstitution occurs mainly in the α-position. When a second radicle enters the

---

[1] Until their nature and the operative conditions are better understood, changes of this type can be classified only as intramolecular or isomeric. Apart from the many cases of "isomeric change" among sulphonic acids, two others are sufficiently remarkable to merit reference, viz. the conversion of naphthalene-α-sulphohydroxamic acid $C_{10}H_7{\cdot}SO_2{\cdot}NH{\cdot}OH$ into naphthalene-β-sulphinic acid and of dinaphthalene-α-sulphohydroxamic acid $(C_{10}H_7{\cdot}SO_2)_2N{\cdot}OH$ into the β-compound by dilute alkali solutions at the ordinary temperature (Angeli, Angelico and Scurti, Gazz. chim. ital. 1903, 33, ii. 296).

[2] The existence of 1:2-, 1:4-, and 1:8-naphthalenedisulphonic acids, prepared by indirect methods, makes the "invincible objection" of sulphonic groups to assume, or to remain in, these positions during sulphonation the more remarkable (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 133; 1893, 9, 166). With nitric acid, no such difficulty is encountered (*v. Di-* and *tri-nitronaphthalenes*). The similarity in the orientating effect of the NO_2 and SO_3H radicles in benzene does not extend without modification to naphthalene.

molecule it may do so in the same ring as the first—homonucleally—or in the other ring—heteronucleally. As in the case of benzene, it is possible to indicate in general terms the directing influence of the radicle already present on the position taken up by the entering substituent, but a comparison of the laws of the two series, benzene and naphthalene, shows important differences. Summarised with reference only to the naphthalene derivatives which find a place in this article, the laws are as follows :—

Homonucleal substitution in position 4, or in positions 2 and 4 occurs—

(i.) When Cl, OH, or NHAc [1] is already present in the *α*- position;

but in position 1, or in positions 1 and 4—

(ii.) When OH or NHAc is already present in the *β*- position.

Heteronucleal substitution in position 5, or in positions 5 and 8, occurs—

(i.) When NO_2 or SO_3H is already present in either the *α*- or the *β*- position.

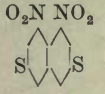
(ii.) When Cl or NH_2 is already present in the *β*- position.

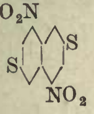
Tri-substitution. The evidence of directing influence obtained in the course of the production of tri- from di-substitution derivatives does not admit, at present, of broad generalisation, but from the facts accumulated about nitration and sulphonation, two deductions can be drawn :—

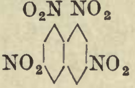
(i.) The non-existence of derivatives in which SO_3H groups occupy relatively the 1 : 2-,[2] 1 : 4-, or 1 : 8- position, has its counterpart in the rare occurrence of nitro- compounds containing NO_2 groups relatively in the 1 : 2- or 1 : 4- position. The analogy does not extend to the 1 : 8- position, many 1 : 8- dinitro-derivatives being known.

(ii.) The inhibition of 1 : 2-disulphonation and largely of 1 : 2- dinitration extends to the sulphonation of nitro- compounds, and to the nitration of sulphonic acids. No case is known in which a NO_2 and a SO_3H group occupy relatively the 1 : 2- or the 2 : 1- position.

As an illustration of the effect of these restrictions on the orientation of nitration products, the constitution of the following substances, said to be the only dinitration products of naphthalene-2 : 6-, and -2 : 7-disulphonic acids, and of 1 : 8-dinitronaphthalene, may be quoted :



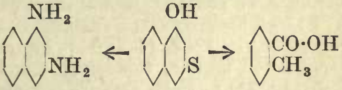




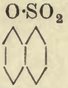
Properties peculiar to 1 : 3- *and* 1 : 8- *Derivatives.*

While the properties of the 1 : 2- and 1 : 4-derivatives of naphthalene resemble, in the main, those of the corresponding *ortho*- and *para*- derivatives of benzene, there is no such agreement between the properties of 1 : 3-derivatives in the two series. For this reason the use of the prefix *meta*- for naphthalene compounds of this orientation is apt to be misleading. Moreover, from the point of view of substitution, it is evident (*v. supra*) that the 5- and 8- positions, more nearly than the 3-position, in naphthalene have the functions of the *meta*- position in benzene.

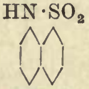
As examples of properties peculiar to di- (and tri-) derivatives of naphthalene containing the radicles OH, NH_2, or SO_3H relatively in the 1 : 2- position, reference may be made to the conversion of *α*-naphthol- or *α*-naphthylamine-3-sulphonic acid [3] into 1 : 3-diaminonaphthalene by interaction with ammonia, and into *o*-toluic acid by fusion with caustic potash.



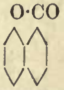
Turning to 1 : 8- or *peri*- derivatives, certain of these furnish internal condensation products, *e.g.* naphthalic anhydride, recalling the behaviour of some 1 : 2- or *ortho*- derivatives under similar conditions. But, as condensation in each of these positions is dependent on the possibility of a 5- or 6- membered ring being formed, many of the products arise from reactions applicable only to the one series or the other, but not to both. For example, among the well-known *ortho*- condensation products, anhydrides of the following types obtained with *peri*-derivatives are not represented :



Sultone.



Sultam.



Lactone.

DEVELOPMENT OF NAPHTHALENE CHEMISTRY SINCE 1890.

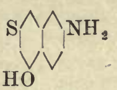
During the interval since the publication of the first edition of this Dictionary, the chemistry of naphthalene has been explored with a degree of completeness which seems to suggest that little of technical importance remains to be discovered. Most of the work dealing with the production of substances of possible or actual value in the manufacture of azo- dyes is to be found in Patents published before the end of last century, and much of it has been accomplished by applications or variations of well-known processes to which reference is not necessary in this place. But there are three subjects sufficiently remarkable in themselves to call for more extended notice than is possible in the summaries prefacing the various sections of this article, namely :—

(i.) 2-Amino-5-naphthol-7-sulphonic or J- acid as a source of direct cotton dyes;

(ii.) The bisulphite reaction, confined almost entirely to naphthalene derivatives;

(iii.) The naphthazarin reaction, elucidated first in connection with compounds of the hydroxyanthraquinone series.

2-Amino-5-naphthol-7-sulphonic acid. Among isomeric aminonaphtholsulphonic acids, the chief interest attaches to the 2 : 5 : 7- or J- acid, which, unlike all other aminonaphthol derivatives, resembles *para*diamines (benzidine, &c.) and sulphur bases (dehydrothiotoluidine, primuline, &c.) in endowing most of the azo dyes of



J- acid.

---

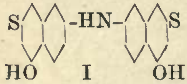
[1] Reference to *α*-naphthylamine derivatives will show that a summary of the directing influence of the NH_2 radicle in *α*-compounds cannot easily be made.

[2] *α*-Naphthasultamtrisulphonic acid (*q.v.*) is a possible exception.

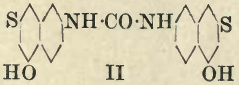
[3] The *β*-naphthol- and *β*-naphthylamine-4-sulphonic acids yield the toluic acid but not the diamine.

which it is a component with the valuable property of dyeing unmordanted cotton.[1] This fact was recognised first of all[2] in disazo-dyes containing the N-ethyl derivative of J-acid as end component (*cf.* Leonhardt, D. R.-P. 95624; Eng. Pat. 10699 of 1895), then in those from its N-phenyl derivative, from J-acid itself (*ibid.* D. R.-P. 114248 of 1896), and also from 2-amino-5-naphthol-7 : 1-disulphonic acid (*ibid.* D. R.-P. 117950 of 1896). Nevertheless, the utilisation of this discovery seems to date from the introduction of direct cotton dyes produced from 5 : 5′-dihydroxy-2 : 2′-dinaphthylamine-7 : 7′-disulphonic acid (I *infra*) by coupling with diazotised aniline, toluidine, &c. (Bayer, D. R.-P. 114841; Eng. Pat. 24296 of 1899), followed by a series of direct cotton monoazo dyes (*ibid.* D. R.-P. 122905; Eng. Pat. 2683 of 1900), disazo dyes (*ibid.* D. R.-P. 129494 of 1900; Gesellsch., D. R.-P. 126802 of 1901), and trisazo dyes (Bayer, D. R.-P. 121867; Eng. Pat. 3673 of 1900) obtained from J-acid itself.

Experience showed that the affinity for unmordanted cotton was increased by the substitution of acyl radicles in the amino- group of J-acid,[3] and, of the many derivatives examined, the azo dyes from the substituted ureas (II) gave, perhaps, the best results in this respect.

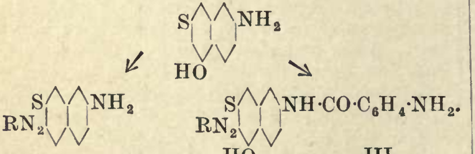


I



II

But these dyes, although pure in shade and fast to acids, were less fast to alkalis. By transference of the diazotisable amino- group in the monoazo dyes of J-acid from the naphthalene nucleus to a benzene ring present in the acyl radicle (III), fastness to alkalis also was secured (*cf.* Gesellsch., D. R.-P. 151017; Eng. Pat. 13778 of 1902; D. R.-P. 170045; Eng. Pat. 24936 of 1903).



III

These aminoarylacyl-2-amino-5-naphthol-7-sulphonic acids when coupled in alkaline solution give monoazo- dyes which can be diazotised on the fibre, and, without any essential alteration in shade, developed with β-naphthol and thereby rendered fast to washing.[4] By appropriate substitution, therefore, it is possible to obtain from J-acid direct cotton dyes of any desired degree of intensity, purity of shade, or fastness.

The bisulphite reaction.—For more than forty years Piria's discovery of the reduction of α-nitronaphthalene to α-naphthylaminesulphamic (thionaphthamic) acid and naphthionic acid by aqueous alcoholic ammonium sulphite (Annalen, 1851, 78, 31), remained an isolated fact. The interest attaching to the reaction is nevertheless considerable, as the conversion of α-naphthylamine into naphthionic acid by the usual method requires both concentrated sulphuric acid and a high temperature.

From the patents of Fischesser & Co. (D. R.-P. 76438 of 1893; 79577 of 1894), it is evident that the method is of restricted application, but can be used for the simultaneous reduction and sulphonation of α-nitronaphthalene-3 : 8-disulphonic acid, and of 1 : 5-dinitro- or (*cf.* Höchst, D. R.-P. 215338 of 1908) of 1 : 8-dinitro-naphthalene by the aid of sodium bisulphite solution. Further, α-nitronaphthalene with a large excess of bisulphite yields not Piria's compounds, but α-naphthylamine-2 : 4-disulphonic acid[5] (Höchst, D. R.-P. 92082 of 1895).

In none of these cases is the nitrogen atom eliminated from the molecule as the result of the interaction with bisulphite, but in the last recorded application of the process—conversion of 1 : 8-dinitronaphthalene-3 : 6-disulphonic acid into 1-amino-8-naphthol-3 : 6-disulphonic acid (Bayer, D. R.-P. 113944 of 1899; *cf.* Bucherer, J. pr. Chem. 1904, [2] 70, 349), replacement of a NO_2 (or NH_2) group by OH was observed, and a new field for investigation opened up.

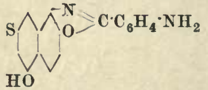
---

[1] Certain disazo dyes, with J-acid as middle component and nitro-*o*-diazophenols as end components are unsuitable for dyeing unmordanted cotton (Oehler, D. R.-P. 151332; Eng. Pat. 8575 of 1903).

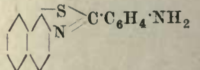
[2] J-acid, obtained from Armstrong and Wynne's β-naphthylamine-5 : 7-disulphonic acid (Badische, D. R.-P. 75469; Eng. Pat. 2614 of 1893), was employed originally for the production of direct cotton dyes by coupling with diazotised *para*diamines (*ibid.*), or dehydrothiotoluidine (*cf.* Bayer, D. R.-P. 88846, 92708; Eng. Pat. 10629 of 1894), its specific cotton fixing capacity being thereby obscured.

[3] The following acyl and other derivatives have been studied in this connection, R being J-acid in the amino- group of which substitution has occurred:
CH_3·CO·R (Bayer, D. R.-P. 119828; Eng. Pat. 2683 of 1900).
C_6H_5·CO·R (*ibid*, D. R.-P. 127141 of 1900).
R·C(NH)·R (*ibid.* D. R.-P. 129417, 132537; Eng. Pat. 18939 of 1900).
R·CH_2·CO·R (*ibid.* D. R.-P. 126443, 128195; Eng. Pat. 18939 of 1900).
R·CH_2·CH_2·R (*ibid.* D. R.-P. 129478, 126801; Eng. Pat. 18939 of 1900).
R·CS·R (*ibid.* D. R.-P. 116201, 122286, 126133 of 1899; Eng. Pat. 3615 of 1900).
R·CO·R (*ibid.* D. R.-P. 116200, 122904 of 1899; Eng. Pat. 3615 of 1900).

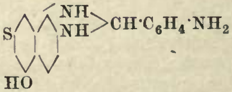
[4] In the other naphthalene derivatives which have been found to give cotton dyeing powers to azo dyes of which they are components, this method of securing fastness to alkalis without alteration in shade, is also used. Compare, for example:—



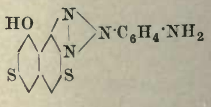
(Bayer, D. R.-P. 165102 of 1904; Eng. Pat. 1675 of 1905).



(Bayer, D. R.-P. 166903: Eng. Pat. 27843 of 1905).



(Cassella, D. R.-P. 209110 of 1907).



(Gesellsch., D. R.-P 146375 of 1902).

[5] Bucherer (J. pr. Chem. 1904, [2] 69, 50) makes the interesting statement that occasionally a small quantity of α-naphthol-4-sulphonic acid is formed in this reaction.

Two nitroso-compounds, α-nitroso-β-naphthol and β-nitroso-α-naphthol, also undergo this type of change with sodium bisulphite solution, furnishing the corresponding aminonaphtholsulphonic acids (Böniger, Ber. 1894, 27, 23).

Slightly earlier in date than this patent of Bayer & Co., is one in which it is shown that the conversion of α-naphthylamine- into α-naphthol- derivatives can be achieved under the influence of sodium bisulphite solution in open vessels at the boiling-point (Bayer, D. R.-P. 109102 of 1899). With β-naphthylamine derivatives, unless a large excess of bisulphite is used (Badische, D. R.-P. 134401 of 1899; *cf.* Bucherer and Stohmann, J. pr. Chem. 1905, [2] 71, 436), condensation to ββ′-dinaphthylamine derivatives occurs (Bayer, D. R.-P. 121094 of 1900).

The clue to these results was supplied by the discovery that in this reaction a highly soluble intermediate compound is formed, which, although stable towards acids, is decomposed by alkalis with the production of ammonia and the naphthol.[1] This intermediate compound is a sulphite (Badische, D. R.-P. 126136 of 1899), identified as a naphthyl sulphite, as it does not couple with diazotised bases, and can be obtained from the corresponding naphthol derivative by interaction with bisulphite (Badische, D. R.-P. 115335 of 1899).

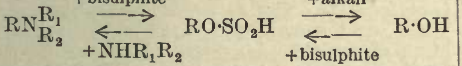
I. $R\cdot NH_2+2NaSO_3H\rightarrow RO\cdot SO_2H+Na_2SO_3+NH_3$
II. $R\cdot OH+2NaSO_3H\rightarrow RO\cdot SO_2H+Na_2SO_3+H_2O$

The naphthyl sulphite, which by alkalis is hydrolysed forming the naphthol, regenerates the naphthylamine by interaction with ammonia; the reversal of the reaction discovered by Bayer & Co. can therefore be effected (Badische, D. R. P. 117471 of 1899)—

III. $RO\cdot SO_2H+3NH_3\rightarrow R\cdot NH_2+(NH_4)_2SO_3$.

Usually ammonium sulphite replaces sodium bisulphite in the first stage (II), and the conversion of the naphthol into naphthylamine derivative is conducted at 100° in pressure vessels (to prevent escape of ammonia), the yield being almost quantitative, as against 30–65 p.c. when the naphthol derivative is heated with ammonia and ammonium chloride at a high temperature.

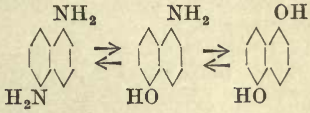
By the use of methylamine, aniline or their homologues in place of ammonia in reaction III, alkylated α- and β-naphthylamines (Badische, D. R.-P. 121683 of 1900) and arylated β-naphthylamines (Badische, D. R.-P. 122570 of 1900) can be obtained. In the Patent literature and in the papers published by Bucherer (J. pr. Chem. 1904, [ii.] 69, 47; 70, 345; 1905, [ii.] 71, 433), to whom the detailed study of the reaction is due, a convenient expression for the bisulphite reaction is given, which shows clearly the reversible nature of the change:—



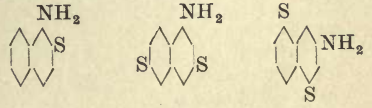
$$RN\begin{matrix}R_1\\R_2\end{matrix}\ \underset{+NHR_1R_2}{\overset{+\text{bisulphite}}{\rightleftarrows}}\ RO\cdot SO_2H\ \underset{+\text{bisulphite}}{\overset{+\text{alkali}}{\rightleftarrows}}\ R\cdot OH$$

in which R is a naphthyl radicle and R_1R_2 are hydrogen, alkyl, or (for β- compounds only) aryl radicals.

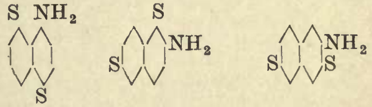
With the exception of derivatives of *m*-dihydroxy- and *m*-diamino-benzene the bisulphite reaction is confined to the naphthalene series, and it is dependent on the use of a large excess (3–5 mols.) of the reagent. It is applicable to diaminonaphthalene, aminonaphthol and dihydroxynaphthalene derivatives as well as to the naphthylamines and naphthols,



its technical importance being therefore evident. But it is subject to restrictions; for example, it does not succeed with α- derivatives in which a substituent is present in the 2- or 3- position, or with β- derivatives in which a substituent is present in the 4- position, such as the acids:

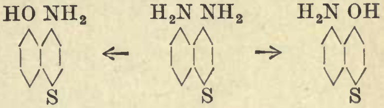


although it takes place easily with acids in which these respective positions are not occupied:

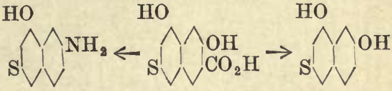


Many interesting applications of the reaction are to be found in the literature, from which two may be taken by way of illustration:

(*a*) 1:8-Diaminonaphthalene-4-sulphonic acid will furnish either the 4- or the 5-sulphonic acid of 1-amino-8-naphthol according as the process is conducted in the presence or absence of acetone (Badische, D. R.-P. 120016 of 1900):—



(*b*) Two formulæ are possible for the aminonaphtholsulphonic acid, and two for the dihydroxynaphthalenesulphonic acid obtained respectively by fusing β-naphthylamine- and β-naphthol-6:8-disulphonic acids with caustic potash. That these acids have the formulæ I and II, and not the alternative formulæ,



I Nigrotic acid. II

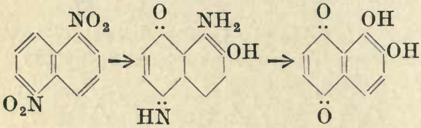
is established by the fact that they can be formed from nigrotic acid by interaction with sodium bisulphite and with ammonium sulphite respectively (Bucherer, J. pr. Chem. 1907, [2] 75, 287).

The naphthazarin reaction. Naphthazarin is formed when a solution of 1:5-dinitronaphthalene in sulphuric acid or anhydro-acid is heated with a reducing agent, such as sulphur or zinc, and the blue solution formed by pouring the product into water is boiled until the colour has changed to red. Although the constitution of naphthazarin was determined finally in 1895 to be 5:6-dihydroxy[α]-naphthaquinone (Will, Ber. 1895,

---

[1] This process differs essentially from that in which the exchange of NH_2 for OH is effected at high temperatures under the influence of water or mineral acids. The end products of the two reactions are usually the same, but differences between them are not unknown, *e.g.* naphthionic acid is converted almost quantitatively by the bisulphite method into α-naphthol-4-sulphonic acid, but by the acid method into α-naphthol.

28, 2234) by production of the substance from 1 : 2 : 5 : 8-tetranitronaphthalene, that of the 'intermediate product' which dissolves in water with the blue colour first observed by Aguiar (Ber. 1871, 4, 439) has not been established by direct experiment. As reference to naphthazarin (p. 656) will show, the numerous patents of the Badische Company and of other firms taken out in 1896–1900, together with the investigations of Graebe (Ber. 1899, 32, 2876; *cf.* Graebe and Oeser, Annalen, 1904, 335, 153; Badische, D. R.-P. 91391 of 1896) and of Friedlaender (Ber. 1899, 32, 3528) on the nitronitrosonaphthols isolated from the naphthazarin melt, suggest a close resemblance to the reaction between 1 : 5-dinitroanthraquinone, anhydrosulphuric acid and sulphur at 50° which leads to the formation of a soluble bluish 'intermediate' product identified as 1-nitro-5-nitroso-8-hydroxyanthraquinone (Bayer, D. R.-P. 104282 of 1898; *cf.* 105567 of 1897). By analogy, the naphthazarin reaction therefore is represented by the formulæ:



I II

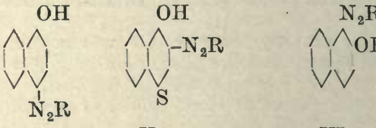
The 1-nitro-5-nitroso-8-hydroxynaphthalene (nitronitrosonaphthol) is formed at relatively low temperatures, but the 'intermediate product' (I) at higher temperatures, passing when boiled with dilute acids into naphthazarin (II), with elimination of the NH_2 radicle as ammonia.

Diazo and Azo Compounds.

Without exception, diazotised bases couple homonucleally with naphthols, naphthylamines, or their sulphonic acids,[1] and in the formation of azo dyes from the β- compounds, the remarkable difference between contiguous homonuclear αβ- and ββ- positions, to which reference has been made (p. 563), is constantly in evidence. For example:

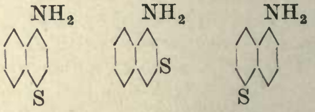
α-Naphthol will couple in the 4- position, and its derivatives in this position also if it be not occupied (I), otherwise they couple in the 2- position (II); but

β-Naphthol and its derivatives will couple only in the contiguous 1- position (III):

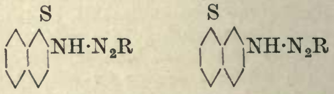


I II III

To this generalisation there are exceptions, due probably to steric hindrance, among amino- and hydroxy-naphthalenesulphonic acids of certain configurations. Thus the α-naphthylamine- or α-naphthol-sulphonic acids of the formulæ:



couple in the 2- position, although in one of them only is the 4- position occupied; and β-naphthylamine-8-sulphonic acid and its derivatives, like the 1-sulphonic acids, furnish diazo amino- compounds instead of azo derivatives:



Other examples of this deviation from the general rule will be found among sulphonic acids of the diaminonaphthalenes, aminonaphthols, and dihydroxynaphthalenes.

The position of the azo group in azo dyes can be determined either by reduction, *e.g.* with stannous chloride (Witt, Ber. 1888, 21, 3471), or with sodium hypo- ('hydro-') sulphite (Grandmougin, *ibid.* 1906, 39, 2494, 3561, 3929), whereby the base used for diazotisation and an amino derivative of the second component are obtained; or by fission with cold fuming nitric acid (Schmidt, *ibid.* 1905, 38, 3202; *cf.* Meldola and Hanes, Chem. Soc. Trans. 1894, 65, 841), whereby the diazo compound used and nitro derivative of the second component are formed. The former of these processes has found some application in the preparation of aminonaphthalene derivatives (*v. Diaminonaphthalene-* and *aminonaphthol-sulphonic acids*).

---

[1] The following trivial names are given to sulphonic acids employed in the manufacture of azo dyes:—

Naphthylaminesulphonic acids [$NH_2 : SO_3H$]
[1 : 4] Naphthionic [2 : 6] Brönner
[1 : 5] Laurent [2 : 7] F-acid
[1 : 8] S or Schöllkopf [2 : 8] Badische

Naphthylaminedisulphonic acids [$NH_2 : SO_3H : SO_3H$]
[1 : 3 : 8] ε-disulpho. [2 : 3 : 6] Amino-R
[1 : 4 : 8] Disulpho. S [2 : 3 : 7] Disulpho. F
[2 : 4 : 8] Disulpho. C
[2 : 6 : 8] Amino-G

Naphtholsulphonic acids [$OH : SO_3H$]
[1 : 4] Nevile & Winther [2 : 6] Schaeffer
[1 : 5] L-acid [2 : 7] F-acid
[1 : 8] S-acid [2 : 8] Croceïc-acid

Naphtholdisulphonic acids [$OH : SO_3H : SO_3H$]
[1 : 3 : 8] Disulpho. E [2 : 3 : 6] R-acid
[1 : 4 : 8] Disulpho. S [2 : 3 : 7] F-acid
[2 : 4 : 8] C-acid
[2 : 6 : 8] G-acid

Aminonaphtholsulphonic acids [$NH_2 : OH : SO_3H$]
[1 : 5 : 7] M-acid [2 : 3 : 6] R-acid
[1 : 7 : 3] B-acid [2 : 5 : 7] J-acid
[1 : 8 : 3] H-monosulpho. [2 : 7 : 3] F-acid
[1 : 8 : 4] S-acid [2 : 8 : 6] G-acid
[2 : 8 : ?] V-acid

Aminonaphtholdisulphonic acids [$NH_2 : OH : SO_3H : SO_3H$]
[1 : 8 : 2 : 4] S-acid [1 : 8 : 4 : 6] K-acid
[1 : 8 : (2) : ?] L-acid [1 : 8 : (5) : ?] D-acid
[1 : 8 : 3 : 5] B-acid
[1 : 8 : 3 : 6] H-acid [2 : 8 : 3 : 6] 2 R-acid

Dihydroxynaphthalenesulphonic acids [$OH : OH : SO_3H$]
[1 : 5 : 2] C-acid [2 : 3 : 6] R-acid
[1 : 7 : 3] G-acid [2 : 7 : 3] F-acid
[1 : 8 : 3] ε-acid
[1 : 8 : 4] S-acid

Dihydroxynaphthalenedisulphonic acids [$OH : OH : SO_3H : SO_3H$]
[1 : 3 : 5 : 7] Yellow acid (Gelbsäure)
[1 : 5 : 3 : 7] Red acid (Rotsäure)
[1 : 7 : 3 : 6] A-acid
[1 : 8 : 2 : 4] S-acid [1 : 8 : ? : ?] I-, G-, and R-acids
[1 : 8 : 3 : 5] K-acid [2 : 3 : 6 : 8] B-acid
[1 : 8 : 3 : 6] Chromotrope acid

Dihydroxynaphthalenecarboxylic acids [$OH : OH : CO_2H$]
[1 : 7 : 6] S-acid [2 : 6 : 3] L-acid

Carbodihydroxynaphthalenesulphonic acid [$OH : OH : CO_2H : SO_3H = 1 : 7 : 6 : 3$] Nigrotic acid.

Reference is made in the article Azo- colouring matters (*q.v.*) to the differing capacity of isomeric naphthylamine- and naphthol-sulphonic acids for combination with diazotised bases. This property can be utilised in appropriate cases for the separation of isomeric sulphonic acids. For example:

(i.) The sulphonation product of β-naphthol at 50°–60° contains Schaeffer's and croceïc acids, of which the latter only is of value for the manufacture of croceïn-scarlet. Schaeffer's acid couples with diazotised benzidine, whereas croceïc acid does not; hence by fractional precipitation (as a disazo compound) the former can be removed, leaving the latter in a state of purity (Bayer, D. R.-P. 30007; Eng. Pat. 8495 of 1884).

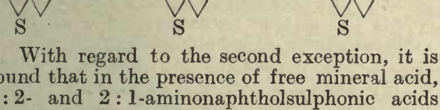
(ii.) β-Naphthylamine-3:6-disulphonic acid, obtained by heating β-naphthol-3:6-disulphonic acid (R-acid) with ammonia under pressure, can be freed from any unchanged hydroxy acid (which spoils the shade of azo- dyes formed from the amino- acid) by fractional treatment with diazobenzene or diazoxylene (Cain, *priv. comm.*).

Diazo-oxides.—The formation of diazo compounds by interaction of naphthylamine- or aminonaphthol-sulphonic acids with nitrous acid proceeds normally except with:—

(*a*) Naphthylaminesulphonic acids containing one SO_3H group in the ortho- (1- or 2-) position relatively to the amino- radicle;

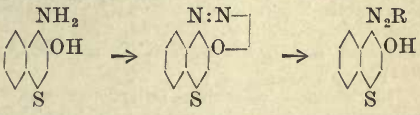
(*b*) 1:2- and 2:1-aminonaphtholsulphonic acids or their derivatives.

With respect to the first exception, it is found that when warmed with solutions of alkali carbonates or acetates, to remove free mineral acid, diazotised α- or β-naphthylamine-*ortho*-sulphonic acids (Badische, D. R.-P. 145906; Eng. Pat. 6615 of 1902; D. R.-P. 156440; Eng. Pat. 27372 of 1903; 160536; Eng. Pat. 4997 of 1904; 162009; Eng. Pat. 21638 of 1904; Höchst, D. P. Anm. F. 16863; Eng. Pat. 23993 of 1902), also diazotised 1-chloro-β-naphthylaminesulphonic acids (Badische, D. R.-P. 145906; 148882 of 1902), and 2:4-dichloro-α-naphthylaminesulphonic acid (Badische, D. R.-P. 153298; Eng. Pat. 16995 of 1903), furnish anhydrides (diazo oxides) of hydroxydiazonaphthalenesulphonic acids, *e.g.* for β- compounds:



With regard to the second exception, it is found that in the presence of free mineral acid, 1:2- and 2:1-aminonaphtholsulphonic acids are not diazotised by nitrous acid (Witt, Ber. 1888, 21, 3475), but oxidised to [β-]naphthaquinonesulphonic acids (Böniger, *ibid.* 1894, 27, 24; *cf.* Badische, D. R.-P. 153298; Eng. Pat. 16995 of 1903). By removal of free mineral acid, diazotisation of these aminonaphthols to diazo oxides has been rendered possible (Weiler-ter Meer, D. R.-P. 155083 of 1903; Badische, D. R.-P. 157325 of 1903), and almost quantitative in the presence of cupric and ferric salts (Geigy, D. R.-P. 171024; Eng. Pat. 10235 of 1904; D. R.-P. 172446 of 1904), zinc salts (Kalle, D. R.-P. 175593; Eng. Pat. 23034 of 1904), nickel salts (*ibid.*, D. R.-P. 178621 of 1905), or mercuric salts (*ibid.*, D. R.-P. 178936 of 1905). But as these salts are found to spoil the brightness and solubility of the derived azo dyes, they may with advantage be replaced by salts of the alkali or alkaline earth metals (Badische, D. R.-P. 189179; Eng. Pat. 10323 of 1906).

The diazo oxides form non-explosive, yellow, crystalline powders (Geigy, D. R.-P. 171024; Eng. Pat. 10235 of 1904); they can be chlorinated (Kalle, D. R.-P. 246574 of 1911); brominated (Sandoz, D. R.-P. 236656 of 1910); nitrated by nitrosulphuric acid without decomposition (Geigy, D. R.-P. 164655; Eng. Pat. 15418 of 1904; Kalle, D. R.-P. 176619 of 1905); and sulphonated by anhydrosulphuric acid (*ibid.* D. R.-P. 176618, 176620 of 1905). Their coupling capacity, probably as the result of their structure:



is not pronounced, except for resorcinol (Badische, D. R.-P. 148881 of 1902); the derived *ortho*-hydroxyazo-dyes give fast bluish black shades on chromed wool.

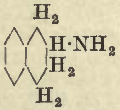
Tetrahydronaphthalene Derivatives.

On reduction in boiling amyl alcohol solution with sodium, naphthalene (Bamberger and Kitschelt, Ber. 1890, 23, 1561) and the naphthylamines and naphthols (Bamberger, Annalen, 1890, 257, 2) are converted into tetrahydro-derivatives, of which two types exist:—

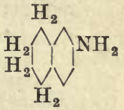
(1) Those termed *alicyclic* (or *ac.*-) derivatives, in which both the substituent and the four added hydrogen atoms are in the same ring.

(2) Those termed *aromatic* (or *ar.*-) derivatives, in which the substituent is in one and the four added hydrogen atoms in the other ring.

With α-naphthylamine and α-naphthol, 'aromatic' derivatives are exclusively formed, but with β-naphthylamine and β-naphthol both types of derivative are obtained, the 'alicyclic' compound forming about 95 p.c. of the product:



(*ac.*-derivative.)



(*ar.*-derivative.)

The specific properties which distinguish corresponding derivatives of naphthalene and benzene are suppressed in the tetrahydronaphthalene derivatives, and, in connection with the naphthalene theory, it may be noted that 'alicyclic' compounds display the characters of the secondary amines and alcohols of the fatty series, whereas 'aromatic' compounds show a close analogy in properties with the *o*-xylidines and *o*-xylenols of the benzene series. Physiologically *ac.*-tetrahydro-β-naphthylamine ('Thermine,' *cf.* J. Soc. Chem. Ind. 1890, 9, 888) and its alkyl-derivatives are interesting on account of their powerful mydriatic properties (Bamberger and Filehne, Ber. 1889, 22, 777).

I. Chloro-Derivatives.

Introductory.—Naphthalene derivatives, in which chlorine is associated with the carbon atoms of the nucleus, are of two kinds: additive compounds (*e.g.* naphthalene dichloride and tetrachloride) and those in which substitution of chlorine for hydrogen has taken place, viz. the chloronaphthalenes.

The formation of chloronaphthalenes can be achieved by the following methods:

(1) By chlorination of naphthalene or chloronaphthalenes (*cf.* Faust and Saame, Annalen, 1871, 160, 65; E. Fischer, Ber. 1878, 11, 735; Widman, *ibid.* 1882, 15, 2160; Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 85; Badische, D. R.-P. 234912 of 1910).

(2) From aminonaphthalenes by diazotisation and the Sandmeyer reaction (*cf.* Friedlaender and Szymanski, Ber. 1892, 25, 2081; Chattaway and Lewis, Chem. Soc. Trans. 1894, 65, 877).

(3) From nitro-, amino-, or hydroxynaphthalenesulphonic acids by conversion into chlorosulphonic acids and subsequent hydrolysis (*cf.* Cleve, Ber. 1892, 25, 2487).

(4) From naphthalenesulphonyl, or chloronaphthalenesulphonyl chlorides, by heating them with phosphorus pentachloride (*cf.* Carius, Annalen, 1860, 114, 145; Armstrong, Ber. 1882, 15, 205), or alone (*cf.* Armstrong and Wynne, Chem. Soc. Proc. 1895, 11, 80, 83; 1897, 13, 152).

(5) From nitronaphthalene (de Koninck and Marquart, Ber. 1872, 5, 11), and from nitronaphthalenesulphonyl chlorides (Erdmann and Süvern, Annalen, 1893, 275, 232, 252) by distillation with phosphorus pentachloride.

Allusion has been made to the complete series of mono-, di- and tri-chloronaphthalenes and to their use as reference compounds (p. 565). As sources of naphthol or naphthylamine derivatives certain of the α-chloronaphthalenesulphonic acids, viz. the 4- and 5- mono-, the 4 : 7-di- and the 2 : 4 : 7-tri- sulphonic acids (the last most readily) or 4-chloro- α-nitronaphthalene can be used, as in them the halogen can be exchanged for NH_2 or OH by digestion with caustic alkali or ammonia.

α-Chloronaphthalene is obtained when chlorine is passed into boiling naphthalene (Rymarenko) in the presence of ferric chloride (Oehler, D. P. Anm. O. 1921 of 1893) until the calculated increase in weight has been attained; when naphthalene dichloride is decomposed by heat or by alcoholic potash (Faust and Saame, Annalen, 1871, 160, 68; Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 85); or when diazotised α-naphthylamine hydrochloride is warmed with hydrochloric acid (Gasiorowski and Wayss, Ber. 1885, 18, 1940), or cuprous chloride solution (Atterberg, Bull. Soc. chim. 1894, [iii.] 65, 877). It boils at 263°, and has the sp.gr. 1·2025 at 15°.

Reactions.—(1) On nitration, it is converted into 4-*chloro-α-nitronaphthalene* (Atterberg, Ber. 1876, 9, 927), mixed with the 5- and 8- derivatives in small quantity (Griesheim, D. R.-P. 120585 of 1900).

(2) By sulphonation, it yields the 4-, 5-, 6-, and 7-*monosulphonic*, the 4 : 7- and a second *disulphonic* and the 2 : 4 : 7-*trisulphonic acids* (*v. infra*).

Dichloronaphthalenes. A mixture of 1 : 4- and 1 : 5- dichloronaphthalenes is obtained when naphthalene, with a carrier (ferric chloride, iodine, etc.), is chlorinated in carbon tetrachloride solution at −10° to 0°; the product contains small amounts of the 1 : 2- and 1 : 7-derivatives, which can be removed as sulphonic acids by sulphuric acid in the cold (Badische, D. R.-P. 234912 of 1910).

Perchloronaphthalene $C_{10}Cl_8$ is formed by exhaustive chlorination of naphthalene, finally in the presence of antimony trichloride (Berthelot and Jungfleisch, Bull. Soc. chim. 1868, [ii.] 9, 446). It crystallises in long needles, m.p. 203°, is moderately soluble in benzene or light petroleum, and when heated with 70 p.c. anhydro- acid at 50° is converted into a red dyestuff of unknown composition (Badische, D. R.-P. 66611 of 1892).

Naphthalene tetrachloride $C_{10}H_8Cl_4$ is formed together with oily impurities containing, according to the conditions employed, varying quantities of naphthalene dichloride, α-chloronaphthalene tetrachloride, and a dichloronaphthalene tetrachloride, by the action either of chlorine (Faust and Saame, Annalen, 1871, 160, 67), or of potassium chlorate and hydrochloric acid (E. Fischer, Ber. 1878, 11, 735) on naphthalene. According to Leeds and Everhart (J. Amer. Chem. Soc. 1880, 2, 208), the best yield (45 p.c.) is obtained by leaving naphthalene in thin layers in an atmosphere of chlorine until absorption is complete. Extraction of the product with light petroleum, to remove dichloride, and with alcohol, leaves the tetrachloride in a pure state. It crystallises from chloroform in large rhombohedra, m.p. 182°.

Reaction.—When heated at 100° with 8·7 times its weight of nitric acid (sp.gr. 1·45), it yields 2 : 3-*dichloro*-[*α*-]*naphthaquinone* (Helbig, Ber. 1895, 28, 505), or, boiled with ten times its weight, *phthalic acid* (Fischer, *l.c.*); but with chromic acid at 90° it gives 3 : 4-*dichloro-α-naphthol* (Helbig. *l.c.*).

α-Chloronaphthalenesulphonic Acids.

Introductory.—α-Chloronaphthalenesulphonic acids can be obtained by three methods:

(1) From the corresponding α-naphthylaminesulphonic acids by diazotisation and interaction with cuprous chloride solution.

(2) From α-chloronaphthalene by sulphonation, the products with sulphuric acid being successively the 4-, the 5-, and a mixture of the 6- and 7-monosulphonic acids as the temperature is raised gradually to 160°–170°, and the 4 : 7- (possibly also the 2 : 7-) disulphonic acid at 180°–190°.

(3) From sodium naphthalene-α- or β-sulphonate by chlorination.

When prepared by the last two methods, these acids can be used for the production of α-naphthylaminesulphonic acids, but the process has no technical importance.

(i.) α-**Chloronaphthalene-4-sulphonic acid** is the chief product when α-chloronaphthalene is sulphonated with chlorosulphonic acid in the cold (Armstrong and Wynne, Chem. Soc. Proc. 1900, 6, 86). Its *chloride* forms triclinic prisms, m.p. 95° (Cleve, Ber. 1887, 20, 73).

Reactions.—(1) When heated with 25 p.c. ammonia solution under pressure at 200°–210°, it is converted into *naphthionic acid* (Oehler, D. R.-P. 72336 of 1893).

(2) By digestion with 25 p.c. caustic soda solution under pressure at 200°–220°, it yields α-*naphthol*-4-*sulphonic acid* (Oehler, D. R.-P. 77446 of 1893).

(ii.) α-**Chloronaphthalene-5-sulphonic acid**, formed in small quantity when α-chloronaphthalene is sulphonated with chlorosulphonic acid in the cold, becomes almost the sole product when the sulphonation mixture is heated at 150° (Armstrong and Wynne, Chem. Soc. Proc. 1900, 6, 87). It can be obtained by chlorinating sodium naphthalene-α-sulphonate with a mixture of sodium chlorate and hydrochloric acid (Rudolph, D. R.-P. 103983; Eng. Pat. 19088 of 1898). Its *chloride* forms rhombic prisms, m.p. 95° (Cleve, Ber. 1887, 20, 73).

Reactions.—(1) When heated with 25 p.c. ammonia solution under pressure at 200°–210°, it is converted into α-*naphthylamine*-5-*sulphonic acid* (Oehler, D. R.-P. 72336 of 1893).

(2) By digestion with 8 p.c. caustic soda solution at 240°–250°, it yields α-*naphthol*-5-*sulphonic acid* (Oehler, D. R.-P. 77446 of 1893).

(iii.) α-**Chloronaphthalene-6-sulphonic acid**, mixed with the 7-*sulphonic acid*, is formed when α-chloronaphthalene is heated with 1–1·5 times its weight of sulphuric acid at 160°–170° for many hours (Oehler, D. R.-P. 76396 of 1893); or when a solution of sodium naphthalene-β-sulphonate is chlorinated by means of chlorine or of sodium chlorate and hydrochloric acid (Rudolph, D. R.-P. 101349; Eng. Pat. 19088 of 1898). By fractional crystallisation its calcium, barium, or sodium salt can be separated from the more soluble salt of the 7-acid. Its *chloride* forms scales, m.p. 114°–115° (Cleve, Ber. 1887, 20, 74); that of the 7-acid, prisms, m.p. 94° (Cleve, Ber. 1892, 25, 2481).

(iv) α-**Chloronaphthalene-4 : 6-disulphonic acid** (*cf.* Armstrong and Wynne, Chem. Soc. Proc. 1900, 6, 126) is formed when sodium α-chloronaphthalene-6-sulphonate is heated with 10 p.c. anhydro-acid at 110° (Rudolph, D. R.-P. 104902 of 1898).

Reaction.—When heated with caustic soda solution under pressure at 210°–230°, it yields 1 : 6-*dihydroxynaphthalene*-4-*sulphonic acid* (Rudolph, *l.c.*).

(v.) α-**Chloronaphthalene-4 : 7-disulphonic acid** is obtained when α-chloronaphthalene is sulphonated with 45 p.c. anhydro-acid at 20°, or with sulphuric acid at 180° [1] (Oehler, D. R.-P. 74744 of 1893); *or* when sodium α-chloronaphthalene-4-sulphonate is sulphonated with 20 p.c. anhydro-acid at 20° (Oehler, *l.c.*), or at 100° (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 18). The *barium* salt dissolves sparingly, but the *sodium* salt easily in water; the *chloride* forms prisms, m.p. 107° (Armstrong and Wynne, *l.c.*).

Reaction.—When heated with 30 p.c. caustic soda solution at 200°–210°, it yields α-*naphthol*-4 : 7-*disulphonic acid* (Oehler, *l.c.*).

(vi.) α-**Chloronaphthalene-2 : 4 : 7-trisulphonic acid** is the chief product of the sulphonation of α-chloronaphthalene with 45 p.c. anhydro-acid at 80°, *or* of sodium α-chloronaphthalene-4-sulphonate with 20 p.c. anhydro-acid at 170° (Oehler, D. R.-P. 76230 of 1893). Its *sodium* salt Na_3A+4H_2O forms small needles (Oehler, *l.c.*), and its *chloride* scales, m.p. 215° (Armstrong and Wynne, Chem. Soc. Proc. 1900, 6, 126).

Reaction.—When heated with 12 p.c. caustic soda solution under pressure at 150°, it yields α-*naphthol*-2 : 4 : 7-*trisulphonic acid* (Oehler, D. R.-P. 77996 of 1893).

II. NAPHTHALENESULPHONIC ACIDS.

Introductory.—Naphthalenesulphonic acids can be obtained by the following methods:—

(1) Action of sulphuric acid [2] on naphthalene or on naphthalenesulphonic acids.

(2) Elimination of the NH_2 radicle from naphthylaminesulphonic acids (*cf.* the 1 : 3-acid).

(3) From naphthylaminesulphonic acids by exchange of the NH_2 for the SH or SO_2H radicle, and oxidation of the resulting mercaptan or sulphinic acid (*v.* the 1 : 2-acid).

Of these methods the first is of technical importance, and by it ten naphthalenesulphonic acids (two mono-, four di-, three tri-, and one tetra-) have been obtained. As sulphonating agents,[2] sulphuric acid, anhydro-acid, chlorosulphonic acid, and anhydro-acid to which common salt has been added, are used, but the constitution of the product depends on the temperature and duration of the reaction as well as on the quantity and concentration of the acid. Attention has been called to the fact that sulphuric acid, unlike other substituting agents, gives rise to β- derivatives in large amount (p. 565). If the conditions leading to the production of naphthalene-β-sulphonic acid or of naphthalene-2 : 6-disulphonic acid, for example, are considered, they show that of the four factors named the concentration and temperature of the acid exercise a predominating influence on the relative positions in which the SO_3H radicles are found at the end of a sulphonation.

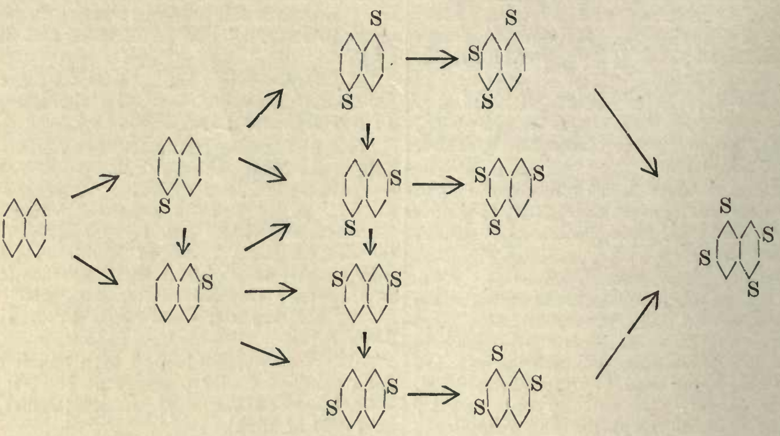
From the constitution of the acids obtained from naphthalene or from naphthalenesulphonic acids by sulphonation, it is evident that in no

---

[1] A second acid, possibly the 2 : 7-isomeride, is also formed under these conditions (Oehler, *l.c.*).

[2] In this article, '**sulphuric acid**,' when not otherwise distinguished, is ordinary concentrated sulphuric acid of sp.gr. 1·845; '**monohydrate**' is 100 p.c. sulphuric acid; and '**anhydro acid**' is fuming sulphuric acid containing dissolved sulphur trioxide, the proportion of which is given when known.

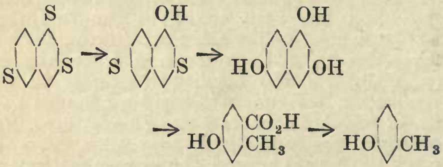
case has a product been isolated containing two sulphonic groups in positions relatively 1:2- (*ortho-*), 1:4- (*para-*), or 1:8- (*peri-*) to one another:



The sulphonic acids and their alkali salts are easily soluble in water, but the lead, barium, and calcium salts differ much in solubility, and in some cases afford a means of separating the constituents of a sulphonation melt. From the alkali salts, crystalline chlorides, amides, and anilides with definite melting-points, which serve to characterise the acids, can be prepared, and, from the chlorides, chloronaphthalenes which serve to fix their constitution.

By hydrolysis, or by sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3028) sulphonic groups in α- positions are more easily eliminated than those in β- positions.

When fused with caustic alkali, or digested under pressure with caustic alkali solution, naphthalenesulphonic acids give rise to hydroxy- compounds, in which one or more sulphonic groups have been exchanged for hydroxyl. The reaction takes place most readily with α-sulphonic groups. Should the naphtholsulphonic acid produced contain a sulphonic group in the 3- position relatively to the hydroxyl further change may occur and hydroxytoluic acids or *m*-cresols (from *m*-hydroxytoluic acids) be formed:



For technical purposes, naphthalenesulphonic acids are valuable as sources of the naphthols, of several naphtholsulphonic acids and of several nitronaphthalenesulphonic acids, furnishing in the last case by reduction naphthylaminesulphonic acids which are not formed from the naphthylamines by sulphonation.

The action of sulphuric acid on naphthalene leads also to the formation of small quantities of two dinaphthylsulphones—the αβ′- melting at 123°, and the ββ′- melting at 177° (Stenhouse and Groves, Ber. 1876, 9, 682; Hofmann, *ibid.* 1884, 17, 1921; Krafft, *ibid.* 1890, 23, 2364).

NAPHTHALENEMONOSULPHONIC ACIDS.

(i.) **Naphthalene-α-sulphonic acid** (sulphonaphthalic acid) $C_{10}H_7{\cdot}SO_3H$.

Formation.—Naphthalene on sulphonation with about its own weight of sulphuric acid yields a product containing varying proportions of α- and β- monosulphonic acids and a small quantity of at least one disulphonic acid, according to the conditions employed. Merz and Weith (Ber. 1870, 3, 195) state that a mixture of naphthalene and sulphuric acid in the proportion of 10:9 gave a product containing 80 p.c. of α-acid and 20 p.c. of β-acid when heated for 3 hours at 100°, but only 25 p.c. of α-acid with 75 p.c. of β-acid when heated for a further 4 hours at 170°, 15 p.c. of the naphthalene employed being recovered in the first case and 25 p.c. in the second. Also, that a mixture in the proportion 5:4 heated for 8 hours at 160° gave 80 p.c. of β-acid, 30 p.c. of the naphthalene employed being recovered. At temperatures below the melting-point of naphthalene—*e.g.* when finely powdered naphthalene is sieved into 1½–2 times its weight of sulphuric acid at 40°, and the mixture stirred continuously for many hours until everything has dissolved—α-acid is said to be the sole product, and the same result is obtained, but more rapidly, when sulphonation is effected by anhydro-acid in the cold (Landshoff, D. R.-P. 50411 of 1889). Sodium hydrogen disulphate, $NaH_3(SO_4)_2$, has been suggested as a sulphonating agent by Lambert (D. R.-P. 113784 of 1899).

Naphthalene-α-sulphonic acid, mixed with a small quantity of naphthalene-1:5-disulphonic acid, but free from β-sulphonic acid, is obtained, when slightly less than the calculated quantity of chlorosulphonic acid is added with continual shaking to a 10 p.c. solution of naphthalene in carbon disulphide (Armstrong and Wynne, Chem. Soc. Proc. 1887, 3, 146; *cf.* Armstrong, Chem. Soc. Trans. 1871, 24, 176).

Preparation.—Naphthalene is heated with an equal weight of sulphuric acid at 90°–95° for 2–3 hours, and the product poured into 6–8 times its bulk of water. The solution, separated from the 30 p.c. or so of unattacked naphthalene which solidifies on cooling, is neutralised with lime and the filtrate concentrated to remove the less soluble calcium salt of the β-acid. By further evaporation of the filtrate, the calcium salt of the α-acid can be separated, the final mother liquors containing the calcium salts of naphthalenedisulphonic acids in small quantity (Merz, Zeit. Chem. 1868, [ii.] 4, 394; Merz and Weith, *l.c.;* Merz and Mühlhäuser, Ber. 1870, 3, 710).

Identification.—The *acid* is a deliquescent substance sparingly soluble in slightly dilute sulphuric acid; the salts crystallise in scales.

Composition of salt (Merz)	1 part of the salt dissolves in	
	parts of water at 10°	parts of 85 p.c. alcohol at 10°
Potassium salt $+\frac{1}{2}H_2O$	13 (at 11°)	108 (at 11°)
Calcium „ $+2H_2O$	16·5	19·5
Barium „ $+H_2O$	87	350
Lead [1] „ $+3H_2O$	27	11

The *chloride*, which forms scales, m.p. 67° (Erdmann, Annalen, 1893, 275, 235), is reduced by zinc dust and dilute sulphuric to *thio-α-naphthol*, an oil b.p. 286° (Krafft and Schönherr, Ber. 1889, 22, 822).

Reactions.—(1) It is converted into a mixture of the 1 : 5- and 1 : 6-*disulphonic acids* by anhydro-acid in the cold, and into the 1 : 6-*disulphonic acid* by sulphuric acid at 110°.

(2) On fusion with caustic potash or soda it yields *α-naphthol* (Schaeffer, Annalen, 1869, 152, 281).

(ii.) **Naphthalene-β-sulphonic acid.**

Formation.—*v.* Naphthalene-α-sulphonic acid.

Preparation.—Naphthalene is heated with an equal weight of sulphuric acid at 160° during 3 hours, then at 170° during an hour, and finally at 180°, the operation being complete in about 8 hours. The product is either mixed with brine, whereby the less soluble β-salt is separated from the small amount of α-salt and disulphonate also present, or, after dilution with water, is neutralised by lime, and the calcium salt of the β-acid converted into sodium salt.

Identification.—The *acid* forms non-deliquescent scales; the salts crystallise in small scales, and, except those of the alkali metals, are sparingly soluble in cold water (*cf.* Burt, Boulton and Hayward, Eng. Pat. 4459 of 1894).

Composition of Salt (Merz)	1 part of the salt dissolves in	
	parts of water at 10°	parts of 85 p.c. alcohol at 10°
Potassium salt $+\frac{1}{2}H_2O$	15	115
Calcium „ (anhydrous) . . .	76	437
Barium „ $+H_2O$.	290	1950
Lead salt „ $+1\frac{1}{3}H_2O$	115 [2]	305

The *sodium* salt dissolves in 16·5 parts of water, and in 15·4 parts of N-, or 41 parts of 5N-hydrochloric acid at 23·9° (E. Fischer, Ber. 1906, 39, 4144). The *chloride* forms scales, m.p. 78° (E. Fischer and Bergell, Ber. 1902, 35, 3780), and, when reduced with zinc dust and dilute sulphuric acid, gives *thio-β-naphthol,* scales, m.p. 81°, b.p. 286° (Krafft and Schönherr, *ibid.* 1889, 22, 824).

Reactions.—(1) It is less readily hydrolysed than the α-acid. On sulphonation at 100° it yields the 1 : 6-, and at 160°–170° the 2 : 6- and 2 : 7-*disulphonic acids.*

(2) On fusion with caustic potash or soda it yields *β-naphthol* (Schaeffer, *l.c.*), for the preparation of which it is extensively employed.

Naphthalenedisulphonic Acids.

Introductory.—The four naphthalenedisulphonic acids obtained by sulphonation are the 1 : 5-, 1 : 6-, 2 : 6-, and 2 : 7- isomerides and are all heteronucleal. Their relationship is shown in the scheme on p. 574.

(i.) **Naphthalene-1 : 2-disulphonic acid** is formed from α-naphthylamine-2-sulphonic acid by conversion into the thionaphthol by Leuckart's method (Bayer, D. R.-P. 70296; Eng. Pat. 11465 of 1892; Armstrong and Wynne, Chem. Soc. Proc. 1893, 9, 168) or into the sulphinic acid (Gattermann, Ber. 1899, 32, 1156), and oxidation of these compounds by potassium permanganate in alkaline solution.

Identification.—The *potassium* salt ($+\frac{2}{3}H_2O$) forms very soluble flat prisms, and yields not a chloride but an *anhydride* (prisms, m.p. 198°, from benzene) by interaction with phosphorus pentachloride (Armstrong and Wynne, *l.c.*).

(ii.) **Naphthalene-1 : 3-disulphonic acid** is obtained from β-naphthylamine-6 : 8-disulphonic acid (amino-G-acid) or β-naphthylamine-5 : 7-disulphonic acid by boiling the corresponding hydrazines with copper sulphate solution (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 13, 129), *or* from amino-G-acid by boiling its diazo-compound with alcohol (*cf.* Badische, D. R.-P. 57910; Eng. Pat. 9537 of 1890).

Identification.—The *barium* salt, $BaA+4H_2O$, *potassium* salt, K_2A+2H_2O, and the *sodium* salt are crystalline and very soluble in water. The *chloride* forms easily soluble prisms, m.p. 137°, from benzene, convertible into 1 : 3-*dichloronaphthalene* (Armstrong and Wynne, *l.c.*).

Reactions.—Fusion with caustic soda at 200°–220° converts the sodium salt into *α-naphthol-3-sulphonic acid* (Badische, *l.c.*), but digestion with 60 p.c. caustic soda solution at 250°–300° under pressure gives *o-toluic acid* (Kalle, D. R.-P. 79028 of 1893; *cf.* Friedlaender and Rüdt, Ber. 1896, 29, 1611).

(iii.) **Naphthalene-1 : 4-disulphonic acid** is obtained from naphthionic acid, as described under the 1 : 2-acid (*cf.* also Bayer, D. R.-P. 95830; Eng. Pat. 26139 of 1896).

Identification.—The *potassium* $K_2A+1\frac{1}{3}H_2O$ and *sodium* salts are crystalline and easily soluble. The *chloride* forms four-sided plates, m.p. 160°, from benzene (Armstrong and Wynne, Chem. Soc. Proc. 1893, 9, 168).

(iv.) **Naphthalene-1 : 5-disulphonic acid** (so-called Armstrong's acid; naphthalene-[γ-]disulphonic acid of Armstrong and Wynne (Chem. Soc. Proc. 1886, 2, 231); naphthalene-[δ-]disulphonic acid of Beilstein, Schultz, &c.) is formed together with the 1 : 6-acid when naphthalene is mixed gradually with five times its

---

[1] According to Euwes (Rec. trav. chim. 1909, 28, 303) the *lead* salt is $PbA+2H_2O$, and 4·195 grams of it dissolve in 100 grams of water at 24·9°.

[2] According to Euwes (Rec. trav. chim. 1909, 28, 304), 0·407 gram of the lead salt of the β-acid dissolves in 100 grams of water at 24·9°.

weight of 23 p.c. anhydro-acid in the cold (Aktienges., D. R.-P. 45776; Eng. Pat. 4625 of 1888). If four times the weight of 30 p.c. anhydro-acid be used, and the product poured into 3–4 parts of water, a quantitative separation of the 1 : 5-acid is obtained (Ewer and Pick, D. P. Anm. E. 2619 of 1889). Or, as acid sodium salt, the 1 : 5-acid can be separated from the 1 : 6-isomeride by adding common salt to the sulphonation product. It is obtained free from its isomerides by the action of sulphuric anhydride (Armstrong and Wynne, Chem. Soc. Proc. 1887, 3, 42) or of chlorosulphonic acid in calculated quantity on naphthalene, or on naphthalene-*α*-monosulphonic acid (Armstrong and Wynne, *ibid.* 1886, 2, 231).

Preparation.—Dry sodium naphthalene-*α*-monosulphonate is stirred into twice its weight of anhydro-acid at 20°, and the mixture afterwards heated for an hour at 60°–70°. To the product, diluted with 5 times its weight of water, an equal volume of hot brine is added, and the acid sodium salt, which separates as the solution cools, is purified by recrystallisation (Schultz, Chemie d. Steinkohlenth., 3rd ed., 1, 189).

Identification.—The *acid* crystallises in very soluble lustrous, white, non-hygroscopic scales. The *lead* salt, $PbA+3H_2O$, *barium* salt, $BaA+4H_2O$, and *calcium* salt, $CaA+3H_2O$, are easily soluble in water, but when dehydrated dissolve only very slowly in it. The *potassium* salt, K_2A+2H_2O, in scales, dissolves in 8·04 parts of water at 12°; the *sodium* salt ($+2H_2O$), in scales dissolves in 8·78 parts of water at 16·5° (Armstrong and Wynne) or in 7·99 parts at 19° (Ewer and Pick, D. R.-P. 41934 of 1887). The *chloride* forms needles or small prisms, m.p. 183°, convertible into 1 : 5-*dichloronaphthalene* (Armstrong, Ber. 1882, 15, 205).

Reactions.—(1) On fusion with caustic soda, the sodium salt is converted into *α-naphthol*-5-*sulphonic acid* and 1 : 5-*dihydroxynaphthalene* (Ewer and Pick, *l.c.*; Armstrong and Wynne, Chem. Soc. Proc. 1887, 3, 43; Bernthsen and Semper, Ber. 1887, 20, 938).

(2) On nitration, the sodium salt yields as chief product *α-nitronaphthalene*-4 : 8-*disulphonic acid* (Bernthsen, Ber. 1889, 22, 3327; Schultz, *ibid.* 1890, 23, 77), together with *β-nitronaphthalene*-4 : 8-*disulphonic acid* (Cassella, D. R.-P. 65997 of 1890); and by further nitration 1 : 6-*dinitronaphthalene*-4 : 8-*disulphonic acid* (Kalle, D. R.-P. 72665 of 1893; Friedlaender and Kielbasinski, Ber. 1896, 29, 1982, 2574).

(v.) 1 : 6-**Naphthalenedisulphonic acid** (naphthalene-? : *β*-disulphonic acid of Armstrong and Wynne; naphthalene-[*γ*-]disulphonic acid of Beilstein and Schultz) is formed together with naphthalene-1:5-disulphonic acid when naphthalene is sulphonated with 23 p.c. anhydro-acid in the cold. It also occurs in the product formed when naphthalene is heated with 5 times its weight of sulphuric acid at 160° for 4 hours (Armstrong, Ber. 1882, 15, 204). A uniform acid is obtained when naphthalene is heated with 5 times its weight of monohydrate at 90°–110°, or with sulphuric acid at 90°, and subsequently with strong anhydro-acid at 110°–120° (Badische, D. P. Anm. B. 9514 of 1889; Bernthsen, Ber. 1889, 22, 3328; *cf.* Schultz, *ibid.* 1890, 23, 77).

Preparation.—Dry sodium naphthalene-*β*-sulphonate, mixed with twice its weight of 25 p.c. anhydro-acid, is heated on a water-bath, and the product is converted into sodium salt; on concentration of the solution to a relatively small bulk, this very soluble salt separates in characteristic needles (Ewer and Pick, D. R.-P. 45229 of 1887). A pure product is also obtained when an excess of chlorosulphonic acid is employed instead of anhydro-acid (Armstrong and Wynne, Chem. Soc. Proc. 1886, 2, 231; Armstrong, *ibid.* 1889, 5, 10).

Identification.—The *lead* salt, $PbA+3\frac{1}{2}H_2O$, *barium* salt, $BaA+4H_2O$, and *calcium* salt, $CaA+4H_2O$, are readily soluble in water; the *potassium* salt K_2A+H_2O dissolves in 3·4 parts and the *sodium* salt Na_2A+7H_2O in 3·34 parts of water at 16·5°. The *chloride* forms small prismatic aggregates from light petroleum, m.p. 129°, convertible into 1 : 6-*dichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1886, 2, 232; 1888, 4, 106).

Reactions.—(1) Fusion with caustic soda converts the sodium salt into 1 : 6-*dihydroxynaphthalene* (Ewer and Pick, *l.c.*).

(2) On nitration, the sodium salt yields, as chief product, *α-nitronaphthalene*-3 : 8-*disulphonic acid* (Aktienges., D. R.-P. 45776; Eng. Pat. 4625 of 1888; Ewer and Pick, D. R.-P. 52724 of 1888; Bernthsen, *l.c.*; Schultz, *l.c.*), the minor product being *β-nitronaphthalene*-4 : 7-*disulphonic acid* (Schultz, *l.c.*; Armstrong and Wynne, Chem. Soc. Proc. 1891, 7, 27), and by further nitration 1 : 6 - *dinitronaphthalene*-3 : 8 - *disulphonic acid* (Friedlaender and Kielbasinski, Ber. 1896, 29, 1980, 2574).

(vi.) **Naphthalene-1 : 7-disulphonic acid** can be obtained from *α*-naphthylamine-4 : 6-disulphonic acid (Dahl's No. II. acid) by boiling the corresponding hydrazine with copper sulphate solution (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 126).

Identification.—The *potassium* salt ($+H_2O$), is microcrystalline. The *chloride* forms scales from acetic acid, m.p. 122·5°, convertible into 1 : 7-*dichloronaphthalene.*

(vii.) **Naphthalene-1 : 8-disulphonic acid** is formed from *α*-naphthylamine-8-sulphonic acid by oxidation of the corresponding thionaphthol as described under the 1 : 2-acid (Bayer, *l.c.*; Armstrong and Wynne, *l.c.*).

Identification.—The *potassium* salt K_2A+H_2O forms sparingly soluble four-sided scales, and yields not a chloride, but an *anhydride* (sparingly soluble prisms, m.p. 227°, from benzene) by interaction with phosphorus pentachloride (Armstrong and Wynne, *l.c.*).

(viii.) **Naphthalene-2 : 6-disulphonic acid** ([*β*-] naphthalenedisulphonic acid of Ebert and Merz). For formation and preparation, *v.* naphthalene-2 : 7-disulphonic acid.

Identification.—The *acid* forms small, deliquescent scales, extremely soluble in water. The normal salts (*v.* 2 : 7-acid) contain less water of crystallisation, crystallise less readily, and are less soluble than the corresponding salts of the 2 : 7-acid; the lead, barium, and calcium salts of the 2 : 6-acid are characterised, moreover, by the slowness with which they again dissolve when once separated from solution. The *chloride* forms small needles, m.p. 226°, from benzene, convertible into 2 : 6-*dichloronaphthalene* (Ebert and Merz, Ber. 1876, 9, 598; Cleve, Bull. Soc. chim. 1876, [ii.] 26, 244;

Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 127).

Reactions.—(1) On fusion with caustic potash, the potassium salt is converted first into *β-naphthol-6-sulphonic acid* (Ebert and Merz, *l.c.*), and finally into 2 : 6-*dihydroxynaphthalene* (Armstrong and Graham, Chem. Soc. Trans. 1881, 39, 141; Emmert, Annalen, 1887, 241, 369).

(2) On nitration, this acid yields *α-nitro-3 : 7-disulphonic* and 1 : 5-*dinitro*-3 : 7-*disulphonic acids* (Cassella, D. R.-P. 61174; Eng. Pat. 15346 of 1890).

(ix.) **Naphthalene-2 : 7-disulphonic acid** ([α-] naphthalenedisulphonic acid of Ebert and Merz) is obtained, together with the 2 : 6-acid (Ebert and Merz, Ber. 1876, 9, 592), when naphthalene is heated above 150° with excess of sulphuric acid. These acids—distinguished as [α-] and [β-]—are formed in about equal amounts, when a mixture of 1 part of naphthalene and 5 parts of sulphuric acid is heated at 160° for 4 hours, the product being free from naphthalenemonosulphonic acids; when heated at 180° for 24 hours, however, the same mixture gives a product consisting almost entirely of the [β-]acid. Pure [α-]acid, also, is converted into [β-]acid by prolonged heating with sulphuric acid at this temperature. On repeating these experiments Armstrong found that the product formed by heating the mixture at 180° for 24 hours contains a smaller proportion of the [β-]acid than stated by Ebert and Merz; that a third acid, subsequently recognised as the 1 : 6-disulphonic acid is present in the 160° product; and that sulphonation at 140° leads to the formation of a product differing greatly from that obtained at 160°, owing, no doubt, to the presence of an increased proportion of the 1 : 6-acid and almost entire absence of the [β-]acid.

Preparation.—(1) Naphthalene is heated with 5 times its weight of sulphuric acid at 160° for 5 hours, and the product converted into calcium salt in the usual way. The separation of the isomeric disulphonic acids can be based on the very slight solubility in water of the calcium [β-]disulphonate, after it has been dehydrated at 200°–230° (Ebert and Merz, *l.c.*; *cf.* Freund, D. R.-P. 27346; Eng. Pat. 1069 of 1883). As an alternative, advantage may be taken of the difference in solubility of the calcium salts of the [α-], [β-], and 1 : 6-acids in concentrated brine, as the [β-]salt is practically insoluble in hot and cold, the [α-]salt tolerably soluble in hot but very sparingly soluble in cold, and the 1 : 6-salt fairly soluble in cold brine (Landshoff, D. R.-P. 48053 of 1888).

(2) Two methods, in neither of which is reference made to the occurrence of 1 : 6-acid in the sulphonation product, have been described by Baum (D. R.-P. 61730 of 1890) for the production and separation of the [α-] and [β-]acids:—

(*a*) Sodium naphthalene-β-sulphonate (230 kilos.) is stirred into monohydrate (500 kilos.) or sulphuric acid (600 kilos.) kept at 160°–170°, and afterwards heated at 180° for 6–8 hours. The product, converted into calcium salt, is concentrated until the solution contains about 30 p.c. of the salt and then allowed to cool. By this means the greater part of the [β-]salt (52 kilos.) is separated. The filtrate, converted into sodium salt, is evaporated to dryness, and the [α-]salt (200 kilos.) extracted by 2 parts of warm water, the solution being allowed to cool to 20° before filtration. The residue is a mixture of sodium [α-] and [β-] salts (80 kilos.).

(*b*) Potassium pyrosulphate (300 kilos.) is dissolved in fused naphthalene-β-sulphonic acid (250 kilos.) at 160°–165°, and the solution mixed with monohydrate (120 kilos.) also heated at 160°–170°. By fractional crystallisation of the potassium salts, the less soluble [β-]salt (54–60 kilos.) is separated from the [α-]salt (386–390 kilos.), the yield of the latter being much greater than in the first process.

Identification.—The *acid* crystallises in long, deliquescent needles, very soluble in water. The salts are more soluble and crystallise better than those of the [β-]acid; their composition, and the solubility of the anhydrous salts of both [α-] and [β-]acids in water at 18° are compared in the table (Ebert and Merz, *l.c.*):—

2 : 7 or [α-]		2 : 6 or [β-]	
$PbA+2H_2O$	easily	$PbA+H_2O$	sparingly
$BaA+2H_2O$	82·2 (19°)	$BaA+H_2O$	„
$CaA+6H_2O$	6·2	CaA	16·2
K_2A+2H_2O	1·4	K_2A	19·2
Na_2A+6H_2O	2·2	Na_2A+H_2O	8·4 (19°)

The *chloride* forms four- or six-sided prisms, m.p. 158°, from benzene, convertible into 2 : 7-*dichloronaphthalene* (Ebert and Merz, *l.c.*; Cleve, Bull. Soc. chim. 1876, [ii.] 26, 244; Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 12).

Reactions.—(1) Fusion of the sodium salt with caustic soda results in the production of *β-naphthol-7-sulphonic acid* ([δ-] or F- acid); Weinberg, Ber. 1887, 20, 2906; Cassella, D. R.-P. 42112; Eng. Pat. 12908 of 1886), or 2 : 7-*dihydroxynaphthalene* (Ebert and Merz, *l.c.*), according to the conditions employed.

(2) On nitration, it yields 1 : 8-*dinitro*-3 : 6-*disulphonic acid* (Cassella, D. R.-P. 67062 of 1890; Eng. Pat. 1742 of 1891; Bayer, D. R.-P. 69190 of 1891; Eng. Pat. 11522 of 1892).

NAPHTHALENETRISULPHONIC ACIDS.

Introductory.—According to Gürke and Rudolph, a naphthalenetrisulphonic acid is obtained by the sulphonation of naphthalene either with 8 times its weight of 24 p.c. anhydrosulphuric acid at 180°, or with 6 times its weight of 40 p.c. anhydro-acid at 80°–100°; also by the sulphonation of naphthalenemono- and disulphonic acids or their salts with a proportionately smaller quantity of anhydro-acid (D. R.-P. 38281; Eng. Pat. 15716 of 1885). Two acids, at least, are obtained by this process, the 1 : 3 : 5-acid being the chief product at the lower temperature, as Erdmann states (Ber. 1899, 32, 3188), and the 1 : 3 : 6-acid the chief product at the higher temperature. As a third acid, the 1 : 3 : 7-derivative, can be obtained by the sulphonation of naphthalene-3 : 7-disulphonic acid, its presence in the mixture, although not recorded, is at least probable.

The naphthalenetrisulphonic acids in which two of the three sulphonic groups are relatively in the *meta-* position yield hydroxytoluic acids by digestion with caustic soda solution at 250° (Kalle, D. R.-P. 91201 of 1893) and brown dyes, possibly derived from them, by digestion with sodium sulphide, sulphur and water at 240° (*ibid.* D. R.-P. 98439 of 1897).

(i.) **Naphthalene-1 : 3 : 5-trisulphonic acid** is formed when sodium naphthalene-1 : 5-disulphonate (2 pts.) is heated with monohydrate (2 pts.) and chlorosulphonic acid (8 pts.) at 160° (Fischesser & Co., D. P. Anm. F. 7059 of 1893); or, mixed with monohydrate (3 pts)., is heated with 70 p.c. anhydro-acid (2·5 pts.) at 80°–90° until a thin liquid is obtained (Kalle, D. P. Anm. K. 11104 of 1893; Eng. Pat. 1641 of 1894; D. R.-P. 82563 of 1893; *cf.* Bayer, D. P. Anm. F., 7004; Eng. Pat. 17141c of 1893; Erdmann, Ber. 1899, 32, 3188). It is also formed by oxidising β-thionaphthol-4 : 8-disulphonic acid with permanganate (Bayer, D. R.-P. 70296; Eng. Pat. 11465 of 1892).

Identification.—The *acid* is very soluble in water; the *sodium* salt Na_3A+4H_2O forms very soluble needles. The *chloride*, m.p. 146° (Gattermann, Ber. 1899, 32, 1159), is convertible into 1 : 3 : 5-*trichloronaphthalene* (Kalle, *l.c.*).

Reactions.—(1) When fused with caustic alkali it gives 1 : 5-*dihydroxynaphthalene*-3-*sulphonic acid* (Bayer, D. R.-P. 166768; Eng. Pat. 18569 of 1902), but when digested with strong caustic soda solution at 250° under pressure, it yields o-*hydroxy*-o-*toluic acid* (Kalle, D. R.-P. 91201 of 1893; Eng. Pat. 16559 of 1894).

(2) On nitration, it is converted into α-*nitronaphthalene*-4 : 6 : 8-*trisulphonic acid* (Kalle, D. R.-P. 82563 of 1893; Bayer, D. R.-P. 80741; Eng. Pat. 17141c of 1893).

(ii.) **Naphthalene-1 : 3 : 6-trisulphonic acid** is obtained when naphthalene in coarse powder is heated with 3½–4 times its weight of chlorosulphonic acid at 150°–155° for an hour (Armstrong and Wynne, Chem. Soc. Proc. 1887, 3, 146); or when sodium naphthalene-1 : 6- or 2 : 7-disulphonate is further sulphonated (*cf.* Bayer, D. R.-P. 63015 of 1891). It is formed also from α-naphthylamine-2 : 4 : 7-trisulphonic acid by boiling the hydrazine with copper sulphate solution (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 125).

Identification.—The *sodium* salt Na_3A+5H_2O forms very soluble needles. The *chloride* forms small prisms, m.p. 194°, from benzene (Armstrong and Wynne, *l.c.*).

Reaction.—When heated with caustic soda solution at 170°–180° under pressure, it yields α-*naphthol*-3 : 6-*disulphonic acid* (Friedlaender and Taussig, Ber. 1897, 30, 1462).

(iii.) **Naphthalene-1 : 3 : 7-trisulphonic acid** is obtained when sodium naphthalene-2 : 6-disulphonate (1 pt.), dissolved in monohydrate (3 pts.), is heated with 60 p.c. anhydro-acid (1 pt.) on a water-bath until a test, on addition of common salt, gives no separation of disulphonate (Cassella, D. R.-P. 75432 of 1891). It is also formed when the thionaphthols from α-naphthylamine-3 : 7-disulphonic acid and amino-G-acid are oxidised by alkaline permanganate (Bayer, D. R.-P. 70296; Eng. Pat. 11465 of 1892).

Reactions.—(1) When heated with 50 p.c. caustic soda solution at 260° under pressure, it yields p-*hydroxy*-o-*toluic acid* (Kalle, D. R.-P. 91201 of 1893; Eng. Pat. 16559 of 1894).

(2) By nitration it forms α-*nitronaphthalene*-3 : 5 : 7-*trisulphonic acid* (Cassella, *l.c.*).

(iv.) **Naphthalene-2 : 3 : 6-trisulphonic acid** is obtained when β-naphthylamine-3 : 6-disulphonic acid (amino-R-acid) is converted into the thionaphthol by Leuckart's method, and the latter oxidised by potassium permanganate in alkaline solution (Bayer, D. R.-P. 70296; Eng. Pat. 11465 of 1892; Armstrong and Wynne, Chem. Soc. Proc. 1893, 9, 168).

Identification.—The *potassium* salt ($+5H_2O$) is microcrystalline; the *chloride* forms flat prisms, m.p. 200° (Armstrong and Wynne, *l.c.*).

(v.–ix.) The sodium salts of the **naphthalene-1 : 2 : 5-, 1 : 2 : 6-, 1 : 3 : 8-, 1 : 4 : 7-, and 1 : 4 : 8-trisulphonic acids**, obtained, like the 2 : 3 : 6-acid, from the corresponding thionaphthol-α- or β-disulphonic acids are very soluble in water (Bayer, *l.c.*). The 1 : 4 : 8-*trisulphonyl chloride* forms clusters of needles, m.p. 156°–157° (Gattermann, Ber. 1899, 32, 1158).

NAPHTHALENETETRASULPHONIC ACIDS.

Introductory.—By heating naphthalene with 5 times its weight of 40 p.c. anhydro-acid at 160° for 9 hours, a product is obtained in which two naphthalenetetrasulphonic acids at least are stated to be present (Bayer, D. R.-P. 40893 of 1886). One of these acids, formed by sulphonation of naphthalene-2 : 6-disulphonic acid, is the 1 : 3 : 5 : 7 derivative (*ibid.* D. R.-P. 79054; Eng. Pat. 25074 of 1893), but the other, obtained by sulphonation of naphthalene-3 : 6-di- or 1 : 3 : 6-tri- sulphonic acid (*ibid.* D. R.-P. 80464; Eng. Pat. *l.c.*), has not been identified.

Two naphthalenetetrasulphonic acids are said to be formed when naphthalene is heated with sulphuric acid and phosphoric anhydride at 260° for 3–4 hours (Senhofer, Monatsh. 1882, 3, 111). Of these, one, forming the less soluble barium or copper salt, has been described by Senhofer as crystallising in very soluble prisms which retain $4H_2O$ at 100°. Its *copper* salt, Cu_2A+12H_2O; *barium* salt Ba_2A with 7, 10, 13, or $15H_2O$; *potassium* salt, K_4A+2H_2O; and *sodium* salt, Na_4A+10H_2O, are crystalline. The identity of this acid has not been established and little is known about the isomeride.

(i.) **Naphthalene-1 : 3 : 5 : 7-tetrasulphonic acid** is obtained when calcium naphthalene-2 : 6-disulphonate, dried at 200°, is heated with 3 times its weight of 25 p.c. anhydro-acid at 90° during 4 hours, whereby trisulphonic acid is formed, and then at 260° during 6 hours. The product is converted into sodium salt, which can be separated from a hot concentrated solution by common salt as a heavy, sand-like precipitate (Bayer, D. R.-P. 79054; Eng. Pat. 25074 of 1893). Instead of the 2 : 6-disulphonic acid, naphthalene-1 : 3 : 7-trisulphonic acid can be used (*ibid.* D. P. Anm. F. 7224; Eng. Pat. *l.c.*).

Identification.—The *chloride* forms compact, cubical crystals, m.p. 261°–262°, very sparingly soluble in benzene or acetone (Bayer, D. P. Anm. F. 7224 of 1893).

Reactions.—When heated with caustic soda solution under pressure, it yields α-*naphthol*-3 : 5 : 7-*trisulphonic acid*, and with a stronger (60 p.c.) solution the isomeric 1 : 3-*dihydroxy*-5 : 7-*disulphonic* (Gelbsäure) and 1 : 5-*dihydroxy*-3 : 7-*disulphonic* (Rotsäure) *acids* (Bayer, D. R.-P. 79054; Eng. Pat. *l.c.*), together with 1 : 3 : 5-*trihydroxynaphthalene*-7-*sulphonic acid* (*ibid.* Eng. Pat. 19624 of 1893).

(ii. and iii.) The following acids have been prepared by oxidation of the thionaphthols obtained by Leuckart's method from the corresponding β-naphthylaminetrisulphonic acids (Bayer, D. R.-P. 70296; Eng. Pat. 11465 of 1892):

Naphthalene-1 : 3 : 6 : 7-tetrasulphonic acid.

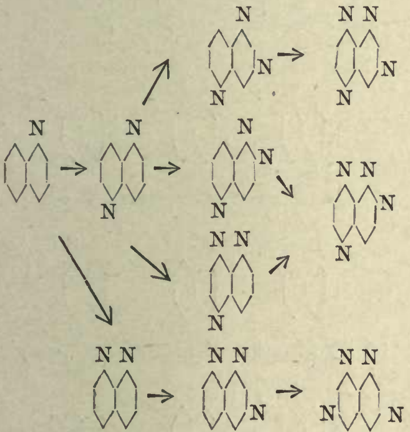
Identification.—The *sodium* salt forms a very soluble granular mass. The *chloride* forms needles, m.p. 309°–310°, sparingly soluble in benzene (Bayer, D. P. Anm. F. 7224 of 1893).

Naphthalene-1 : 3 : 6 : 8-tetrasulphonic acid.

Identification.—The *barium* salt is sparingly soluble, and the crystalline *sodium* salt easily soluble. The *chloride* forms short prisms, m.p., 282°–283°, very sparingly soluble in benzene, but more readily in acetone (*ibid.*).

III. NITRO- DERIVATIVES.

Introductory.—The first nitro- derivatives of naphthalene were prepared by Laurent (Ann. Chim. Phys. 1835, [ii.] 59, 376; 66, 152; *cf.* Lautemann and Aguiar, Bull. Soc. chim. 1865, [ii.] 3, 261) who described α-nitronaphthalene under the name nitronaphthalase. It is now recognised that one mono-,[1] two di-, four tri-, and three tetra-nitronaphthalenes can be obtained from naphthalene by nitration under suitable conditions, the relationship between them being shown in the scheme (N is used for NO_2):—



From this scheme it will be seen that, unlike SO_3H radicles in the presence of sulphuric acid, NO_2 radicles in nitration products of nitronaphthalene are found in 1 : 2-(*ortho-*), 1 : 4-(*para-*), and 1 : 8-(*peri-*) positions. Further, as illustrating the difference between nitrobenzene and nitro-α-naphthalene, it may be pointed out that the former yields *meta*dinitrobenzene as chief product, but the latter two *heteronucleal* αα-dinitronaphthalenes by further nitration.

The nitronaphthalenesulphonic acids are described in this section, the nitronaphthylamines and nitronaphthols in connection with the corresponding naphthylamines and naphthols (*q.v.*).

By reduction, usually with iron and dilute sulphuric acid, the nitronaphthalenesulphonic acids are converted into the corresponding naphthylaminesulphonic acids, which in not a few cases are of technical importance, being isomeric with those obtained from the naphthylamines by sulphonation.

NITRONAPHTHALENES.

(i.) α-**Nitronaphthalene.** In the laboratory, α-nitronaphthalene is best prepared by Piria's method, in which powdered naphthalene is nitrated with 5–6 times its weight of nitric acid of sp.gr. 1·33 in the cold, and the product extracted with carbon disulphide, to remove insoluble dinitronaphthalene (Annalen, 1851, 78, 32; *cf.* Beilstein and Kuhlberg, *ibid.* 1873, 169, 81).

On the large scale, finely-powdered naphthalene (2·5 pts.) is added gradually through a sieve to a mixture of nitric acid of sp.gr. 1·38 (2 pts.), sulphuric acid (2 pts.), and spent acid from a previous operation (6 pts.); the temperature being maintained at 45°–50° throughout the operation, and the nitration completed in one day. When cold, the spent acid is run off from the solid cake of nitronaphthalene, and the latter, after being washed with hot water, is either granulated by allowing it to flow in a thin stream into cold water (Witt, Chem. Ind. 1887, 10, 216) or crystallised from solution in one-tenth its weight of cumene or solvent naphtha (Paul, Zeitsch. angew. Chem. 1897, 146). The nitration can be effected by mixing naphthalene with powdered nitre, and stirring the mixture into sulphuric acid (Höchst, D. R.-P. 201623 of 1906, with sketch of nitration vessels). To avoid the use of sulphuric acid, and yet admit of the employment of a weaker nitric acid (below sp.gr. 1·33) than will attack naphthalene in its absence, an electrolytic method has been proposed (Tryller, D. R.-P. 100417 of 1897).

Properties.—α-Nitronaphthalene crystallises in long, slender, lustrous needles, m.p. 61° (Aguiar, Ber. 1872, 5, 371), b.p. 304° (Koninck and Marquart, *ibid.* 12), and is practically non-volatile with steam. It dissolves in 35·6 parts of 87·5 p.c. alcohol at 15°, and is readily soluble in benzene, carbon disulphide, ether or hot alcohol.

Reactions.—(1) With chromic acid in acetic acid solution it is oxidised to 3-*nitrophthalic acid* (Beilstein and Kurbatow, Annalen, 1880, 202, 217); with 5 p.c. potassium permanganate to 3-*nitrophthalonic acid* and 3-*nitrophthalic acid* (Friedlaender and Weisberg, Ber. 1895, 28, 1642); and with caustic soda solution at 170°–250° under pressure to both *phthalic* and *benzoic acids* (Bindschedler, D. R.-P. 136410, *cf.* 140999; Eng. Pat. 15527 of 1901).

(2) When boiled with ammonium sulphite it is converted into a mixture of '*thionaphthamic' acid*, $C_{10}H_7{\cdot}NH{\cdot}SO_3H$, and *naphthionic acid* (Piria, *l.c.*), but with sodium bisulphite into α-*naphthylamine*-2 : 4-*disulphonic acid* (Höchst, D. R.-P. 92082 of 1895).

(3) Reduction in acid solution converts it into α-*naphthylamine* (*q.v.*). In alcoholic solution with sodium amalgam *azoxynaphthalene* is formed (Jaworsky, J. pr. Chem. 1865, 94, 285). Distillation with zinc dust converts it into αβ-*naphthazine* (Laurent's naphthase; Doer, Ber. 1870, 3, 291; Klobukowsky, *ibid.* 1877, 10, 573; Witt, *ibid.* 1886, 19, 2794).

(4) On sulphonation with anhydro-acid it

---

[1] Accompanied by a very small amount of the isomeric β-mononitronaphthalene (*q.v.*).

yields a mixture of the *α-nitronaphthalene*-5-, 6-, and 7- *sulphonic acids*, the first named being the chief product (Palmaer, Ber. 1888, 21, 3260).

(5) When finely-divided sulphur is added carefully to about 4 times its weight of α-nitronaphthalene heated at 200°–220°, sulphur dioxide is evolved, and a green dye-stuff, 'naphthylthiazin,' is obtained (Bennert, Eng. Pat. 14646 of 1887; D. R.-P. 48802, 49966 of 1888).

(ii.) **β-Nitronaphthalene** has been separated in small quantity from crude mononitronaphthalene (Armstrong, *priv. comm.*), and its production in the nitration of naphthalene has long been inferred from the fact that technical α-naphthylamine contains β-naphthylamine in small quantity (Reverdin and Noelting, Sur la constitution de la naphtaline et de ses dérivés, ed. 1888, 33; Erdmann, Annalen, 1893, 275, 217; Chem. Fab. Weiler-ter Meer, D. R.-P. 205076 of 1906; Eng. Pat. 16446 of 1907; *cf.*, however, Witt, Chem. Ind. 1887, 10, 220).

Preparation.—It can be obtained from 2-nitro-α-naphthylamine by the diazo-reaction (Lellmann and Remy, Ber. 1886, 19, 236; Lellmann, *ibid.* 1887, 20, 891); in 7 p.c. yield from β-diazonaphthalene nitrite by treatment with cuprous oxide (Sandmeyer, *ibid.* 1887, 20, 1496); and, in 25 p.c. yield, from diazotised β-naphthylamine sulphate by interaction with cuprocupric sulphite and potassium nitrite solution at the ordinary temperature (Hantzsch and Blagden, *ibid.* 1900, 33, 2554).

Properties.—It crystallises from dilute alcohol in small yellow needles, melts at 79°, has an odour of cinnamon, and volatilises only slowly with steam.

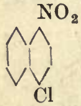
Reactions.—(1) On reduction it yields *β-naphthylamine* (Lellmann and Remy, *l.c.*).

(2) When warmed with methyl alcoholic potash it is converted into *2-nitroso-α-naphthol* (Meisenheimer and Witte, Ber. 1903, 36, 4167).

(3) On sulphonation with anhydro-acid it gives a mixture of the 5- and 8-*sulphonic acids* (Kappeler, Ber. 1912, 45, 633).

CHLORO-α-NITRONAPHTHALENES.

Introductory.—By nitration α-chloronaphthalene yields the three possible α-nitro- derivatives. Of these the 4-chloro-α-nitronaphthalene, unlike the 5- and 8-isomerides, but like 4- or *p*-chloronitrobenzene, exchanges the Cl for the NH_2 or OH radicle by interaction with ammonia or caustic alkali.



(i.) **4-Chloro-α-nitronaphthalene** is obtained as chief product, mixed with some of the 5-chloro- and a small quantity of the 8-chloro-α-nitronaphthalene, when α-chloronaphthalene is nitrated with nitric acid of sp.gr. 1·4 in the cold (Atterberg, Ber. 1876, 9, 927; Griesheim, D. R.-P. 120585 of 1900). It crystallises in yellow needles, m.p. 85°.

Reactions.—(1) When heated with 8 p.c. alcoholic ammonia under pressure at 150°–170°, it is converted into *4-nitro-α-naphthylamine* (Griesheim, D. R.-P. 117006; Eng. Pat. 7692 of 1900; *l.c.*).

(2) With solutions of alkali hydroxides, carbonates or acetates under pressure at 150°–155° it yields *4-nitro-α-naphthol* (*ibid.* D. R.-P. 117731; Eng. Pat. 7692 of 1900).

(ii.) **8-Chloro-α-nitronaphthalene** is formed as chief product, mixed with 5-chloro-α-nitronaphthalene, when α-nitronaphthalene is chlorinated at 40°–60° in the presence of ferric chloride, and separates as a crystalline magma from the product (Aktienges., D. R.-P. 99758 of 1897; Ullmann and Consonno, Ber. 1902, 35, 2808). It forms needles, m.p. 94°; the 5- *compound* has m.p. 111°.

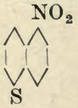
Reaction.—When heated with sulphuric acid at 80°, it is converted into *8-chloro-α-nitro-5-sulphonic acid*, whereas 5-chloro-α-nitronaphthalene does not undergo sulphonation under these conditions (Aktienges., D. R.-P. 103980 of 1897).

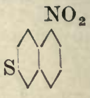
(iii.) **Dichloro-1 : 5-dinitronaphthalene**, also **chloro-** and **dichloro-1 : 8-dinitronaphthalene,** have been prepared by chlorinating the respective dinitronaphthalenes in a fused state in the presence of ferric chloride (Pollak, D. R.-P. 134306 of 1901).

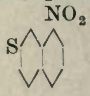
NITRONAPHTHALENEMONOSULPHONIC ACIDS.

Introductory.—The six nitronaphthalenemonosulphonic acids which are known with certainty are α- compounds, and are obtained either by the sulphonation of α-nitronaphthalene, or by the nitration of naphthalene-α- or β-monosulphonic acid. The products from each of these sources are:

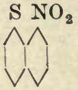
(*a*) By sulphonation of α-nitronaphthalene:

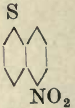


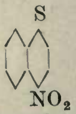




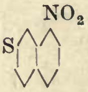
(*b*) By nitration of naphthalene-α-sulphonic acid:[1]

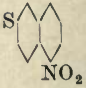


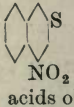




(*c*) By nitration of naphthalene-β-sulphonic acid:







The separation of the isomeric acids obtained by these methods is not easy, and for technical purposes is not attempted, as the naphthylaminesulphonic acids, for the production of which they are made, can be isolated from the reduction product with much less difficulty.

On comparing the products of the nitration of naphthalene-α- and β-sulphonic acids with those of naphthalenedi- and tri-sulphonic acids, it will be found that in the former case, isomerides are always, but in the latter only rarely formed; also that the NO_2 group can assume the 1 : 4- (*para-*) or the 1 : 8- (*peri-*) but not the 1 : 2- (*ortho-*) position relatively to the SO_3H group.

(i.) **α-Nitronaphthalene-3-sulphonic acid**

---

[1] According to Friedlaender (Heumann, Anilinfarben 1898, ii. 517), β-nitronaphthalene-4-sulphonic acid occurs in small quantity in the product from this source, but no description of the acid has been given.

(Cleve's [γ-]nitronaphthalenesulphonic acid[1]) is formed in small amount when sodium naphthalene-β-sulphonate is nitrated (*v.* the 6-acid), and is obtained from its chloride by boiling it with water (Cleve, Ber. 1886, 19, 2179; *cf.* Armstrong and Wynne, Chem. Soc. Proc. 1895, 11, 239).

Identification.—The *lead* salt PbA_2+3H_2O, *barium* salt BaA_2+3H_2O, and *potassium* salt KA, crystallise in sparingly soluble needles. The *chloride* forms needles, m.p. 140°, from acetic acid, convertible into 1 : 3-*dichloronaphthalene* (Cleve, *l.c.*). On reduction, it yields the [γ-] *α-naphthylamine-*3-*sulphonic acid* (Cleve, Ber. 1888, 21, 3271).

(ii.) α-**Nitronaphthalene-4-sulphonic acid** is formed in small quantity by the nitration of sodium naphthalene-α-sulphonate (*v.* the 8-acid), and is isolated from the product by means of its chloride (Cleve, Ber. 1890, 23, 959).[2]

Identification.—The *barium* salt BaA_2+H_2O forms needles soluble in 66 parts of cold and 33 parts of boiling water; the *calcium* salt CaA_2+2H_2O, scales soluble in 37 parts of water at 17° and 16 parts at 100°; the *potassium* salt, KA needles; and the *sodium* salt, $NaA+H_2O$ needles. The *chloride* forms prisms, m.p. 99°, from benzene. Reduction with ammonium sulphide converts the acid into *α-naphthylamine-*4-*sulphonic acid* (Cleve, *l.c.*).

(iii.) α-**Nitronaphthalene-5-sulphonic acid** (Cleve's [α-]acid). This acid is obtained as chief product (about 80 p.c.) when α-nitronaphthalene is sulphonated with anhydro-acid, and (*v.* the 8-acid) as minor product (about 20 p.c.) when sodium naphthalene-α-sulphonate is nitrated. It is said to be the only product of the interaction of α-nitronaphthalene and chlorosulphonic acid (Armstrong and Williamson, Chem. Soc. Proc. 1886, 2, 233).

Preparation.—(1) Finely divided dry α-nitronaphthalene (20 pts.) is added gradually to a mixture of sulphuric acid (35 pts.), and 24 p.c. anhydro-acid (25 pts.) at such a rate that the temperature does not rise above 90°, at which it is maintained during 8 hours or until sulphonation is completed. The product, poured on to an equal weight of ice, gives a crystalline separation of the pure 5-acid (Witt, Chem. Ind. 1887, 10, 218). From the mother liquor, the isomeric 6- and 7-acids can be isolated by conversion into and fractional crystallisation of the nitronaphthalenesulphonyl chlorides (Palmaer, Ber. 1888, 21, 3260).

(2) The formation of dark resinous substances, unavoidable when α-nitronaphthalene is sulphonated by anhydro-acid, does not occur if fused salt is added to the acid in quantity sufficient to convert the dissolved anhydride into chlorosulphonic acid. Thus, α-nitronaphthalene (10 pts.) is added to the mixed sulphuric and chlorosulphonic acids obtained from 20 p.c. anhydro-acid (26 pts.), and the mixture heated on a water-bath until sulphonation is complete (Erdmann, Annalen, 1888, 247, 311).

Identification.—The *acid* $HA+4H_2O$ crystallises in easily soluble pale-yellow needles, the *lead* salt PbA_2+3H_2O in scales; and the *barium* salt BaA_2+3H_2O in sparingly soluble needles (Cleve, Bull. Soc. chim. 1875, [2] 24, 510). The *calcium* salt CaA_2+2H_2O forms sparingly soluble needles; the *potassium* salt KA forms scales, or as $KA+H_2O$ hexagonal tables soluble in 25 parts of water at 17° (Erdmann, Annalen, 1893, 275, 247); the *sodium* salt $NaA+\frac{1}{2}H_2O$ forms very soluble tables (Cleve, *l.c.*). The *chloride* forms needles, m.p. 113°, from ether, convertible into 1 : 5-*dichloronaphthalene* (Cleve, *l.c.*).

Reactions.—On reduction with ammonium sulphide, or with iron and sulphuric acid, it is converted into *α-naphthylamine-*5-*sulphonic acid* (Cleve, *l.c.*; Erdmann, Annalen, 1888, 247, 316), with sodium amalgam it yields α-naphthylamine (Claus, Ber. 1877, 10, 1303); and electrolytically it forms 1-*amino-*4-*naphthol-*5-*sulphonic acid* (Bayer, D. R.-P. 81621 of 1893; Gattermann, Ber. 1893, 26, 1852).

(iv.) α-**Nitronaphthalene-6-sulphonic acid** (Cleve's [θ-] acid). A mixture of this acid with about an equal quantity of the 7-acid, forms almost the entire product of the nitration of sodium naphthalene-β-sulphonate, the 4-acid being present only in very small amount. A mixture of the two acids constitutes the minor product of the sulphonation of α-nitronaphthalene (*v.* the 5-acid).

Preparation.—(1) Sodium naphthalene-β-sulphonate (23 pts.) is stirred into sulphuric acid (115 pts.) at a temperature not exceeding 30°, the whole cooled to 0°, a mixture of nitric acid (7 pts.) and sulphuric acid then added at 0°–10°, the nitration being completed at this temperature (Cassella, D. R.-P. 67017; Eng. Pat. 6972 of 1891). The product is a mixture of the 6- and 7-acids (*ibid.* D. R.-P. 85058 of 1894).

(2) Sodium naphthalene-β-sulphonate is stirred into cold nitric acid of sp.gr. 1·3, and the mixture warmed to complete the nitration. By extraction of the barium salt with boiling water, the sparingly soluble 6-salt is obtained, the separation of the 6-, 7-, and 3-isomerides in the filtrate being effected by converting them into chlorides, extraction by carbon disulphide in which the 7-chloride is sparingly soluble, and fractional crystallisation of the residue (Cleve, Bull. Soc. chim. 1876, [2] 26, 444; 1878 [2], 29, 414; Ber. 1886, 19, 2179; *cf.* Erdmann and Süvern, Annalen, 1893, 275, 251).

Identification.—The *acid* crystallises in readily soluble brown needles; the *barium* salt BaA_2+H_2O in needles soluble in 782 parts of water at 22°; the *calcium* salt CaA_2+H_2O in scales; the *potassium* salt KA in tables soluble in 29 parts of water at 20°; the *sodium* salt, $NaA+3H_2O$, in crusts consisting of scales. The *chloride* forms prisms, m.p. 125·5°, from benzene, convertible into 1 : 6-*dichloronaphthalene* (Cleve, *l.c.*).

Reactions.—(1) On reduction with ammonium sulphide it is converted into *α-naphthylamine-*6-*sulphonic acid* (Cleve, *ibid.*); and electrolytically it forms 1-*amino-*4-*naphthol-*6-*sulphonic acid* (Bayer, D. R.-P. 81621 of 1893).

(2) On nitration the chloride is converted into 1 : 8-*dinitronaphthalene-*3-*sulphonyl chloride*, m.p. 145° (Hellström, Förhandl. 1888, 10, 613).

(v.) α-**Nitronaphthalene-7-sulphonic acid** (Cleve's [θ-] or [δ-]nitronaphthalenesulphonic

---

[1] In every case where the constitution of an α-nitronaphthalenesulphonic acid is given, the nitro- group is supposed to be in the position '1.'

[2] Erdmann and Süvern did not succeed in finding this acid among the nitration products of naphthalene-α-sulphonyl chloride (Annalen, 1893, 275, 249).

acid[1]) constitutes about one-half the product when sodium naphthalene-β-sulphonate (*v.* the 6-acid; *cf.* Cassella, D. R.-P. 85058 of 1894), or when naphthalene-β-sulphonyl chloride (Erdmann and Süvern, Annalen, 1893, 275, 238) is nitrated, but is formed only in small amount when α-nitronaphthalene is sulphonated (*v.* the 5-acid).

Identification.—The *acid* forms brown needles, very soluble in water, but, unlike the 6-acid, almost insoluble in concentrated hydrochloric acid, and less soluble than the 6-acid in 33 p.c. sulphuric acid. The *barium* salt $BaA_2+3\frac{1}{2}H_2O$ forms granular aggregates of needles, soluble, when anhydrous, in 377 parts of water at 17° but in 9·1 parts of boiling water; the *calcium* salt, very soluble needles; the *potassium* salt $KA+\frac{1}{2}H_2O$, needles readily soluble in water; the *sodium* salt, spherical aggregates of needles (Palmaer, Ber. 1888, 21, 3261). The *chloride* forms prisms, m.p. 169°, from acetic acid, dissolves very sparingly in carbon disulphide, and is convertible into 1 : 7-*dichloronaphthalene* (Cleve, Bull. Soc. chim. 1878, [ii.] 29, 414; Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 19).

Reaction.—On reduction (Cleve, Ber. 1888, 21, 3264) with iron and acetic acid (Erdmann, Annalen, 1893, 275, 272) it yields [δ-] or [θ-]α-*naphthylamine*-7-*sulphonic acid*, and electrolytically it forms 1-*amino*-4-*naphthol*-7-*sulphonic acid* (Bayer, D. R.-P. 81621 of 1893).

(vi.) α-**Nitronaphthalene-8-sulphonic acid** is obtained as chief product (60–70 p.c.) when sodium naphthalene-α-sulphonate is nitrated.

Preparation.—(1) Sodium naphthalene-α-sulphonate (4 pts.) is stirred into nitric acid of sp.gr. 1·45 (5 pts.), and the product converted into calcium salt. From the solution of the calcium salt, the greater part of the 5-salt is separated by concentration, the more soluble 8-salt being contained in the mother liquors (Cleve, Ber. 1890, 23, 958). For technical purposes the separation is unnecessary, as the corresponding naphthylaminesulphonic acids differ to a much greater degree in solubility, and are more easily isolated (*cf.* Schöllkopf, D. R.-P. 40571; Eng. Pat. 15775 of 1885).

(2) The acid can be obtained by stirring naphthalene-α-sulphonyl chloride into 3 times its weight of nitric acid of sp.gr. 1·475 at −5°; extracting the isomeric chlorides from the product by carbon disulphide; and hydrolysing the residue (Erdmann and Süvern, Annalen, 1893, 275, 237).

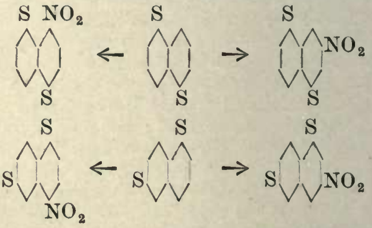
Identification.—The *acid* forms needles; the *barium* salt $BaA_2+2\frac{1}{2}H_2O$, crusts; the *calcium* salt $CaA_2+4\frac{1}{2}H_2O$, scales; the *potassium* salt $KA+H_2O$, needles, or $KA+2\frac{1}{2}H_2O$, scales, all easily soluble in water. The *chloride* forms prisms, m.p. 161°, from chloroform, but is almost insoluble in carbon disulphide (Erdmann and Süvern, *l.c.*).

Reaction.—On reduction, it yields α-*naphthylamine*-8-*sulphonic acid*, the S-acid of the Schöllkopf Co.'s D. R.-P. 40571 (Erdmann, Annalen, 1888, 247, 318).

(vii. and viii.) β-**Nitronaphthalene-5-sulphonic acid**, mixed with the 8-**acid**, is obtained by sulphonating β-nitronaphthalene with ice-cooled anhydro-acid, and is separated from it by fractional crystallisation of the mixed chlorides from benzene. The 5-*sulphonyl chloride*, prisms, m.p. 127°, is more soluble in benzene than the 8-*chloride*, needles, m.p. 169°–170° (Kappeler, Ber. 1912, 45. 634).

NITRONAPHTHALENEDISULPHONIC ACIDS.

Introductory.—The nitronaphthalenedisulphonic acids are obtained for the most part from naphthalenedisulphonic acids by nitration. In two cases, both α- and β-nitro-acids are formed, the α-nitro- derivative being the chief product:



but with the 1 : 4- (*cf.* Bayer, D. R.-P. 70857 of 1892), 2 : 6-, and 2 : 7-disulphonic acids only one, and that the α-nitro-acid is obtained.

(i.) α-**Nitronaphthalene-3 : 6-disulphonic acid** (Alén's [α-]acid) is obtained by nitration of naphthalene-2 : 7-disulphonic acid (Freund, D. R.-P. 27346; Eng. Pat. 1069 of 1883; *cf.* Armstrong and Wynne, Chem. Soc. Proc. 1895, 11, 82), and its chloride is formed, together with 1 : 8-dinitronaphthalene-3 : 6-disulphonyl chloride by nitrating naphthalene-2 : 7-disulphonyl chloride with nitrosulphuric acid at the ordinary temperature (Alén, Bull. Soc. chim. 1883, [2] 39, 63).

Identification.—The *acid* and salts crystallise in small needles; the *barium* salt, $BaA+5H_2O$, is sparingly; the *potassium* salt K_2A+3H_2O and *sodium* salt Na_2A+6H_2O are readily soluble in water. The *chloride* forms needles, m.p. 140°–141°, from benzene, convertible into [θ-] or 1 : 3 : 6-*trichloronaphthalene* (Alén, Förhandl. 1884, 2, 95; Cleve, Ber. 1892, 25, 2487; Armstrong and Wynne, *l.c.*).

Reactions.—Reduction with ammonium sulphide converts it into α-*naphthylamine*-3 : 6-*disulphonic acid*, and with sodium amalgam into α-*naphthylamine* (Alén, Förhandl. 1883, 8, 3).

(ii.) α-**Nitronaphthalene-3 : 7-disulphonic acid** (Alén's [β-]acid). To prepare this acid, sodium naphthalene-2 : 6-disulphonate (33 pts.), dissolved in sulphuric acid (50 pts.), is nitrated in the cold with 50 p.c. nitric acid (25 pts.). If the melt, containing chiefly 2 : 6-disulphonic acid, which is formed by sulphonating naphthalene at 160°–200° be used for the nitration, the nitro-acid can be salted out from the product (Freund, D. R.-P. 27346; Eng. Pat. 1069 of 1883; *cf.* Cassella, D. R.-P. 61174; Eng. Pat. 15346 of 1890). Its chloride is formed, as sole product, when naphthalene-2 : 6 disulphonyl chloride is nitrated with nitro-

---

[1] This acid was originally termed [δ-] by Cleve, and is so described in his communication to the Paris Chemical Society (Bull. Soc. chim. 1878, [ii.] 29, 414). In the Swedish paper (Förhandl. 1878, 2, 32), which is practically identical with the French, the term [θ-] is employed, since 'the acid yields a new dichloronaphthalene which being the eighth known is distinguished as θ.'

sulphuric acid (Alén, Bull. Soc. chim. 1883, [ii.] 39, 64).

Identification.—The *barium* salt $BaA+2H_2O$, tablets; *calcium* salt $CaA+2H_2O$, needles; *potassium* salt K_2A, needles; and *sodium* salt Na_2A+2H_2O, needles, are less soluble than the salts of the 3 : 6-acid. The *chloride* (with 1 mol. C_6H_6), forms prisms, m.p. 190°–192°, from benzene, convertible into [η-] or 1 : 3 : 7-*trichloronaphthalene* (Alén, Förhandl. 1884, 2, 95; Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 13).

Reactions.—Reduction with ammonium sulphide converts it into *α-naphthylamine*-3 : 7-*disulphonic acid*, and with sodium amalgam into *α-naphthylamine* (Alén, Förhandl. 1883, 8, 21).

(iii.) α-**Nitronaphthalene-3 : 8-disulphonic acid** is formed as chief product, together with some β-nitronaphthalene-4 : 7-disulphonic acid (Schultz, Ber. 1890, 23, 77; *cf.* Armstrong and Wynne, Chem. Soc. Proc. 1891, 7, 27), by nitrating naphthalene-1 : 6-disulphonic acid or its salts.

Preparation.—Sodium naphthalene-β-sulphonate (50 pts.), sulphonated with 2½–3 times its weight of 20 p.c. anhydro-acid at 100°, is cooled to 10°–15°, and nitrated below 25° with nitric acid of sp.gr. 1·4 (22·5 pts.). After dilution, the nitro-acid can easily be separated owing to its sparing solubility in alkalis or brine (Ewer and Pick, D. R.-P. 52724 of 1888).

It is also obtained, together with α-nitronaphthalene-4 : 8-disulphonic acid, when the product formed by sulphonating naphthalene (10 pts.) with 23 p.c. anhydro-acid (50 pts.) at 15° is nitrated with nitric acid of sp. gr. 1·45 (7 pts.) (Aktienges., D. R.-P. 45776 of 1887; Eng. Pat. 4625 of 1888). Or, the product obtained by sulphonating naphthalene with 5 times its weight of sulphuric acid at 90°–110° is nitrated, and poured into brine to separate the nitro-acid (Badische, D. P. Anm. B. 9514, B. 9548 of 1889; Bernthsen, Ber. 1889, 22, 3328).[1]

Salts.—The salts crystallise in easily soluble needles; the *potassium* salt K_2A is almost insoluble in dilute caustic potash solution (Friedlaender, Ber. 1895, 28, 1535).

Reactions.—(1) On reduction in acid solution it is converted into [ε-]*α-naphthylamine*-3 : 8-*disulphonic acid* (Bernthsen, *l.c.*); but in neutral solution with sodium bisulphite it yields *α-naphthylamine*-3 : 6 : 8-*trisulphonic acid* (Fischesser & Co., D. R.-P. 76438 of 1893; Eng. Pat. 7046 of 1894).

(2) When heated with concentrated caustic soda solution it yields the basic sodium salt of 4-*nitroso-α-naphthol*-2 : 5-*disulphonic acid* (Friedlaender, Ber. 1895, 28, 1535).

(iv.) α-**Nitronaphthalene-4 : 8-disulphonic acid** is obtained, together with the 3 : 8-acid, as already described (Aktienges., D. R.-P. 45776 of 1887; Eng. Pat. 4625 of 1888). It is also formed, together with β-nitronaphthalene-4 : 8-disulphonic acid, by nitration of naphthalene-1 : 5-disulphonic acid, and separated from it by the greater solubility of the sodium α-salt in brine (Cassella, D. R.-P. 65997 of 1890).

(v.) α-**Nitronaphthalene-5 : 8-disulphonic acid** is formed when barium naphthalene-1 : 4-disulphonate (5 pts.), mixed with sulphuric acid (30 pts.), is nitrated at 10°–15° with 25 p.c. nitric acid (3 pts.). The product is free from isomerides (Bayer, D. R.-P. 70857 of 1892).

(vi.) β-**Nitronaphthalene-4 : 7-disulphonic acid** is formed, together with α-nitronaphthalene-3 : 8-disulphonic acid, by nitration of naphthalene-1 : 6-disulphonic acid (Schultz, Ber. 1890, 23, 77; Armstrong and Wynne, Chem. Soc. Proc. 1891, 7, 27).

(vii.) β-**Nitronaphthalene-4 : 8-disulphonic acid** is obtained when naphthalene-1 : 5-disulphonic acid (28 pts.), suspended in well-cooled sulphuric acid (90 pts.), is nitrated with a mixture of nitric acid of 90°(? 40°) Bé. (10 pts.) and sulphuric acid (10 pts.). The product is poured on to ice, and soda (40 pts.) added to separate the β-salt from the more soluble α-salt (Cassella D. R.-P. 65997 of 1890).

Nitronaphthalenetrisulphonic Acids.

(i.) α-**Nitronaphthalene-3 : 5 : 7-trisulphonic acid** is formed when sodium naphthalene-1 : 3 : 7-trisulphonate, dissolved in sulphuric acid, is nitrated at 15°–20° with nitrosulphuric acid containing 43 p.c. nitric acid, and the crystalline nitro-acid separated by the addition of salt to the product after dilution with water (Cassella, D. R.-P. 75432 of 1891).

(ii.) α-**Nitronaphthalene-3 : 6 : 8-trisulphonic acid** is obtained by the nitration of naphthalene-1 : 3 : 6-trisulphonic acid, dissolved in sulphuric acid (Koch, D. R.-P. 56058; Eng. Pat. 9258 of 1890).

Reactions.—On reduction in acid solution it yields *α-naphthylamine*-3 : 6 : 8-*trisulphonic acid* (Koch, *l.c.*), but when heated with ammonia at 150°–170° it is converted into *β-naphthylamine*-3 : 6 : 8-*trisulphonic acid* with elimination of nitrogen (Kalle, D. R.-P. 176621 of 1905).

(iii.) α-**Nitronaphthalene-4 : 6 : 8-trisulphonic acid** is produced by the nitration of sodium naphthalene-1 : 3 : 5-trisulphonate (10 pts.), dissolved in monohydrate (30 pts.), with 25 p.c. nitric acid (6·1 pts.), at 40°–50° (Kalle, D. P. Anm. K. 11104 of 1893; Eng. Pat. 1641 of 1894; D. R.-P. 82563 of 1893; Bayer, D. R.-P. 80741; D. P. Anm. F. 7004; Eng. Pat. 17141c of 1893).

Dinitronaphthalenes.

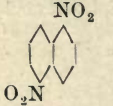
Introductory.—Two dinitronaphthalenes, the 1 : 5- and 1 : 8- compounds, are obtained when naphthalene or α-nitronaphthalene is nitrated with strong nitric acid or with a mixture of nitric and sulphuric acids. The proportion in which they are formed varies to some extent, but may be taken as 1 to 2 (Friedlaender and Scherzer, Chem. Zentr. 1900, i. 410), although according to Gassmann, who used more concentrated acid mixtures, the best yield of 1 : 8-dinitronaphthalene (about 70 p.c.) is obtained only when the temperature beyond the stage of mononitronaphthalene is the lowest possible (Ber. 1896, 29, 1244, 1521).

(i.) **1 : 3-Dinitronaphthalene** ([γ-]dinitronaphthalene) is prepared by boiling diazotised 2 : 4-dinitro-α-naphthylamine with alcohol. The statement that it is a product of the nitration of naphthalene (Höchst, D. R.-P. 96227 of

---

[1] According to Friedlaender (Heumann, Anilinfarben, 1898, ii. 518), the product obtained by any of these methods contains at least four nitro-acids, of which the α-nitronaphthalene-3 : 8-disulphonic acid constitutes only about 40 p.c.

1897) has been shown to be erroneous by Friedlaender (Ber. 1899, 32, 3531). It crystallises from dilute alcohol in bright yellow needles, m.p. 144° (Liebermann and Hammerschlag, Annalen, 1876, 183, 274; *cf.* Friedlaender, Ber. 1895, 28, 1951).



(ii.) 1 : 5-**Dinitronaphthalene** ([α-] or *ana*-dinitronaphthalene) is obtained as minor product, together with the 1 : 8-compound, when α-nitronaphthalene, dissolved in sulphuric acid (4–5 pts.) is nitrated at 0° by the calculated quantity of a mixture of nitric acid, sp.gr. 1·4 (1 pt.) with sulphuric acid (2 pts.). The solution, at first red, becomes white owing to the separation of the dinitronaphthalenes as a thick magma. When dry, the product is dissolved in 6 parts of boiling pyridine, and from the solution, when cold, almost the whole of the 1 : 5-isomeride separates in the pure state (Friedlaender, Ber. 1899, 32, 3531). Or, by increasing the proportion of sulphuric acid, and, at the close of the nitration, heating the mixture at 80°–90° until dissolved, and afterwards cooling to 20° an almost complete separation of the 1 : 5-isomeride is achieved (Friedlaender, *l.c.*; Kalle, D. R.-P. 117368 of 1899).

The separation from the 1 : 8-derivative can also be effected by extraction of the washed and dried nitration product with acetone (Beilstein and Kurbatow, Annalen, 1880, 202, 219), chloroform (Darmstaedter and Wichelhaus, *ibid.* 1869, 152, 301), benzene (Aguiar, Ber. 1870, 3, 29; Beilstein and Kuhlberg, Annalen, 1873, 169, 85), or acetic acid (Aguiar, Ber. 1872, 5, 372), in which the 1 : 5-compound is only sparingly soluble.

Properties.—1 ·5-Dinitronaphthalene crystallises from acetic acid in six-sided yellow needles and melts at 216° (Aguiar, Ber. 1872, 5, 372). It is only sparingly soluble in the ordinary solvents, and practically insoluble in carbon disulphide or cold nitric acid. With phosphorus pentachloride it yields 1 : 5-*dichloronaphthalene* (Atterberg, Ber. 1876, 9, 1188, 1730).

Reactions.—(1) Reduction with alcoholic ammonium sulphide converts it into 5-*nitro-α-naphthylamine* and 1 : 5-*diaminonaphthalene* (Beilstein and Kuhlberg, Annalen, 1873, 169, 87), but with tin and hydrochloric acid only into the latter (Erdmann, *ibid.* 1888, 247, 360).

(2) When boiled with ammonium sulphite or sodium bisulphite solution it yields 1 : 5-*diaminonaphthalenedisulphonic acid* (Fischesser & Co., D. R.-P. 79577 of 1894), but if reducing agents, such as glucose, milk sugar, sodium stannite, &c., be present, brown *dyestuffs* are formed (Badische, D. R.-P. 92538; Eng. Pat. 20250 of 1896).

(3) When heated with 12–23 p.c. anhydrosulphuric acid at 40°–50°, it is converted into 8-*nitro*-4-*nitroso-α-naphthol* (Badische, D. R.-P. 91391; Eng. Pat. 14955 of 1896; Graebe, Ber. 1899, 32, 2879; Friedlaender, *ibid.* 3528; Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339).

If, however, a reducing agent, such as sulphur or zinc be present, a *naphthazarin intermediate product* is formed (*cf.* Bayer, D. R.-P. 71386, 77330; Eng. Pat. 17673 of 1892).

By the use of boric acid, instead of reducing agents, with monohydrate at 200°–300°, two dyestuffs are obtained which dye chromed wool black (Bayer, D. R.-P. 82574 of 1894).

(iii.) 1:6-**Dinitronaphthalene** ([δ-]dinitronaphthalene) is obtained by boiling diazotised 1 : 6-dinitro-β-naphthylamine with alcohol. It crystallises from alcohol in bright-yellow needles, m.p. 161·5° (Graebe and Drews, Ber. 1884, 17, 1170; *cf.* Kehrmann and Matis, *ibid.* 1898, 31, 2419).

(iv.) 1 : 8-**Dinitronaphthalene** ([β-] or *peri*-dinitronaphthalene) is the major product of the dinitration of naphthalene. For its purification, *v.* 1 : 5-dinitronaphthalene.

Properties.—1 : 8-Dinitronaphthalene crystallises in large, yellow rhombic tables, and melts at 170° (Aguiar, Ber. 1872, 5, 372). In ordinary solvents, and in concentrated sulphuric acid it is more soluble than the 1 : 5- compound. According to Beilstein and Kuhlberg (Annalen, 1873, 169, 86), one part dissolves in 91·4 parts of chloroform, in 530 parts of 88 p.c. alcohol, or in 139 parts of benzene at 19°; and according to Friedlaender (Ber. 1899, 32, 3531), 1 part dissolves in 10 parts of cold and in 1·5 parts of hot pyridine. With phosphorus pentachloride it yields 1 : 8-*dichloronaphthalene* in small quantity, the chief product being 1 : 4 : 8-*trichloronaphthalene* (Atterberg, Ber. 1876, 9, 1188, 1732).

Reactions.—(1) Reduction with phosphorus iodide and water (Aguiar, Ber. 1874, 7, 309; Meyer and Muller, *ibid.* 1897, 30, 775), or with tin and hydrochloric acid (Ladenburg, *ibid.* 1878, 11, 1651; Erdmann, Annalen, 1888, 247, 363), converts it into 1 : 8-*diaminonaphthalene*.

(2) When digested with sodium or ammonium sulphite at 70°–90°, the alkali set free being removed as formed, it is converted into *α-naphthylsulphamino*-4 : 7-*di-* and 2 : 4 : 7-*trisulphonic acids* (Höchst, D. R.-P. 215338 of 1908), but when boiled with sodium bisulphite solution, it yields 1 : 8-*diaminonaphthalenetrisulphonic acid* (Fischesser & Co., D. R.-P. 79577; Eng. Pat. 13156 of 1894).

(3) Blue, violet, or black dyestuffs are obtained when it is heated with alkali, sodium bisulphite, and reducing agents, such as glucose (Badische, D. R.-P. 79208; Eng. Pat. 10996 of 1893; D. R.-P. 88236 of 1895; Eng. Pat. 7766 of 1896), milk sugar, sodium stannite, or sodium sulphide (*ibid.* D. R.-P. 92471; Eng. Pat. 20250 of 1896); or, omitting alkali, with sodium sulphide (*ibid.* D. R.-P. 84989; Eng. Pat. 10996 of 1893; D. R.-P. 88847; Eng. Pat. 22603 of 1894), or sodium disulphide (Höchst, D. R.-P. 117188, 117189 of 1898).

(4) When heated with 12–23 p.c. anhydroacid, it yields 5-*nitro*-4-*nitroso-α-naphthol* (Badische, D. R.-P. 90414 of 1895; Eng. Pat. 14955 of 1896; Graebe, Ber. 1899, 32, 2877; Friedlaender, *l.c.*; Friedlaender and Scherzer, *l.c.*).

By heating it with sulphuric acid and reducing agents, such as aniline or tin or iron (Badische, D. R.-P. 76922 of 1893; Eng. Pat. 3828 of 1894), or electrolysing its solution in sulphuric acid (*ibid.* D. R.-P. 79406; Eng. Pat. *l.c.*) it forms a *naphthazarin intermediate product* isomeric with that obtained from 1 : 5-dinitronaphthalene.

If sulphuretted hydrogen or antimony sulphide be used with the sulphuric acid, black dyestuffs are formed (Badische, D. R.-P. 114264 of

1899; Eng. Pat. 890 of 1900), which by interaction with sodium thiosulphate give violet shades (*ibid.* D. R.-P. 147945; Eng. Pat. 1864 of 1903).

(5) When it is heated in caustic soda solution with phenols (Höchst, D. R.-P. 122476 of 1900) or aminophenols or phenolcarboxylic acids (*ibid.* D. R.-P. 125133 of 1900), alkali soluble products are obtained.

DINITRONAPHTHALENEMONOSULPHONIC ACIDS.

(i.) 1:5-**Dinitronaphthalene**-3-[or 7-]**sulphonic acid** is obtained when α-nitronaphthalene-6-sulphonic acid, dissolved in sulphuric acid, is nitrated at 0°–15°, and salt is added to the product after dilution with water (Cassella, D. R.-P. 85058 of 1894). It is also stated to be formed when 1 : 5-dinitronaphthalene, dissolved in 6 times its weight of monohydrate, is heated at 100°–110° with rather more than twice its weight of 20 p.c. anhydro-acid (Höchst, D. R.-P. 117268 of 1900), but according to Eckstein (Ber. 1902, 35, 3403), 1 : 5-dinitronaphthalene is not sulphonated by 15–25 p.c. anhydro-acid at 140°, and at higher temperatures or with stronger acid is destroyed.

Identification.—The *sodium* salt forms needles, soluble in 12 parts of boiling water; the *chloride* prisms, m.p. 118°, from chloroform (Höchst, *l.c.*).

Reactions.—(1) With sodium sulphite or bisulphite solution it yields a *nitro-α-naphthylaminesulphonic acid* (Höchst, *l.c.*).

(2) Anhydro-acid in presence of a reducing agent converts it into a soluble blue "intermediate product," which yields a *naphthazarinsulphonic acid* when boiled with water (*ibid.*).

(ii.) 1 : 8-**Dinitronaphthalene** - 3 - [or 6 -] **sulphonic acid** is formed, together with the 1 : 5-dinitro-acid, when sodium naphthalene - β - sulphonate, dissolved in sulphuric acid, is dinitrated below 10°, and is precipitated by stirring the product into twice its volume of brine, the 1 : 5-isomeride remaining in solution (Cassella, D. R.-P. 67017; Eng. Pat. 6972 of 1891; D. R.-P. 85058 of 1894). It is also produced when 1 : 8-dinitronaphthalene, dissolved in monohydrate, is sulphonated at 100°–110° with twice its weight of 20 p.c. anhydro-acid (Höchst, D. R.-P. 117268 of 1900; Eckstein, Ber. 1902, 35, 3403).

Identification.—The *barium* salt BaA_2+5H_2O forms needles soluble in 8·5 parts of boiling or 20 parts of cold water (Eckstein); the *sodium* salt, needles soluble in 6·5 parts of boiling water. The *chloride* has m.p. 143°–144° (Höchst, *l.c.*; *cf.* Hellström, Förhandl., 1888, 10, 613).

(iii.) 1 : 8-**Dinitronaphthalene**-4-[or 5-] **sulphonic acid** is formed when the monosulphonation product of α-nitronaphthalene, consisting chiefly of the 5-acid, is nitrated at 15°–20°, and the 1 : 8-dinitro-acid separated by stirring the mixture into brine (Cassella, D. R.-P. 70019 of 1892; Eng. Pat. 4613 of 1893).

(iv.) 2 : 4-**Dinitronaphthalene** - 8 - **sulphonic acid** is obtained when naphthasultam or 2 : 4-dinitronaphthasultam is heated with fuming nitric acid (Dannerth, J. Amer. Chem. Soc. 1907, 29, 1327).

DINITRONAPHTHALENEDISULPHONIC ACIDS.

(i.) 1 : 5-**Dinitronaphthalene**-3 : 7-**disulphonic acid** is obtained when sodium naphthalene-2 : 6-disulphonate (or α-nitronaphthalene-3 : 7-disulphonate), dissolved in sulphuric acid, is dinitrated (or nitrated) at 20°–30°, and the product salted out (Cassella, D. R.-P. 61174; Eng. Pat. 15346 of 1890; *cf.* Oehler, D. P. Anm. O. 1430 of 1890; Bayer, D. R.-P. 126198 of 1900).

Reaction.—When dissolved in monohydrate, and heated at 50° with a solution of sulphur in 20 p.c. anhydro-acid, a blue mordant dye of the naphthazarin 'intermediate product' type is produced (Bayer, *l.c.*).

(ii.) 1 : 6-**Dinitronaphthalene**-3 : 8-**disulphonic acid**, obtained by nitration of α-nitronaphthalene-3 : 8-disulphonic acid or naphthalene-1 : 6-disulphonic acid (Friedlaender and Kielbasinski, Ber. 1896, 29, 1982) has not been characterised.

(iii.) 1 : 6-**Dinitronaphthalene**-4 : 8-**disulphonic acid** is obtained when sodium naphthalene-1 : 5-disulphonate (or its mononitration product), dissolved in monohydrate, is dinitrated (or nitrated) below 30°. The product is free from isomerides (Kalle, D. R.-P. 72665 of 1893; Friedlaender and Kielbasinski, *l.c.*).

(iv.) 1 : 8-**Dinitronaphthalene**-3 : 6-**disulphonic acid** is obtained free from isomerides when sodium naphthalene-2 : 7-disulphonate, dissolved in sulphuric acid, is dinitrated at 20°–30°. (Cassella, D. R.-P. 67062 of 1890; Eng. Pat. 1742 of 1891; Bayer, D. R.-P., 69190 of 1891; Eng. Pat. 11522 of 1892). Its chloride is formed, together with the mononitro- derivative, by nitrating naphthalene-2 : 7-disulphonyl chloride (Alén, Förhandl., 1883, 8, 13).

Identification.—The *barium* salt $BaA+5H_2O$ prisms, and the *potassium* salt needles, K_2A from hot, or K_2A+4H_2O from cold solution, are easily soluble. The *chloride* (with 1 mol. C_6H_6), has m.p. 218·5°–219·5° (Alén, *l.c.*).

Reactions.—(1) Reduction converts it into 1 : 8-*diaminonaphthalene*-3 : 6-*disulphonic acid* (Cassella, *l.c.*), but with sodium sulphite or bisulphite solution it yields 1-*amino*-8-*naphthol*-3 : 6-*disulphonic acid* (Bayer, D. R.-P. 113944; Eng. Pat. 21138 of 1899).

(2) Dilute caustic soda solution converts it into *sodium* 5-*nitro*-4-*nitroso*-α-*naphthol*-2 : 7-*disulphonate*, or 4 : 5-*dinitrosodihydroxynaphthalene*-2 : 7-*disulphonate*, or both (Kalle, D. R.-P. 113063 of 1899).

TRINITRONAPHTHALENES.

Three trinitronaphthalenes, the 1 : 2 : 5-, 1 : 3 : 5-, and 1 : 4 : 5- derivatives, are obtained by the nitration of 1 : 5-dinitronaphthalene, and a fourth, the 1 : 3 : 8- derivative, by the nitration of 1 : 8-dinitronaphthalene. The constitution of these compounds has been determined by oxidation to the respective nitrophthalic acids.

1:2:5- or [δ-]Trinitronaphthalene (Will, Ber. 1895, 28, 377) crystallises from alcohol in needles, m.p. 112°–113°.

1:3:5- or [α-]Trinitronaphthalene (Aguiar, Ber. 1872, 5, 373, 897) crystallises from alcohol in scales, m.p. 122°.

1:4:5- or [γ-]Trinitronaphthalene (Beilstein and Kuhlberg, Annalen, 1873, 169, 97; *cf.* Will, *l.c.*) crystallises from chloroform in bright yellow scales, m.p. 154° (Aguiar, *l.c.* 903).

1:3:8- or [β-]Trinitronaphthalene (Beilstein and Kuhlberg, *l.c.*; Friedlaender, Ber.

1899, 32, 3531; Kalle, D. R.-P. 117368 of 1889) crystallises in needles, m.p. 218°. It dissolves in cold sodium bisulphite solution without undergoing change, but is converted into *nitroaminonaphtholsulphonic acids* when the solution is warmed (Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339).

TETRANITRONAPHTHALENES.

Four tetranitronaphthalenes have been described, and to three of them constitutional formulæ have been assigned.

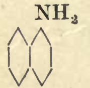
From 1 : 5-dinitronaphthalene, [α-]tetranitronaphthalene, which melts at 259° (Beilstein and Kuhlberg; Aguiar, *l.c.*); 1 : 2 : 5 : 8 or [δ-]tetranitronaphthalene, which decomposes at about 300° without fusion (Will, Ber. 1895, 28, 369); and 1 : 3 : 5 : 8- or [γ-]tetranitronaphthalene, which melts at 194°–195° (Will, *l.c.* 368) have been obtained; while, from 1 : 8-dinitronaphthalene, 1 : 3 : 6 : 8- or [β-] tetranitronaphthalene, which melts at 203°, has been prepared (Aguiar, *l.c.*; Will, *l.c.* 379).

IV. AMINO- DERIVATIVES.

Introductory.—α-Naphthylamine and several α-naphthylaminesulphonic acids are obtained by reduction of the corresponding α-nitro- derivatives with iron and dilute sulphuric acid. As β-nitro- derivatives are not readily accessible, β-naphthylamine and, with two exceptions, the β-naphthylaminesulphonic acids are prepared not by this reduction method, but by heating β-naphthol or the corresponding β-naphtholsulphonic acids with ammonia under pressure. α-Naphthylamine also can be prepared by heating α-naphthol with ammonia, although the yield is less satisfactory than in the case of the β-compound.

Secondary aminonaphthalenes are formed when the corresponding hydroxynaphthalenes are heated with primary amines under pressure.

AMINONAPHTHALENES.



(i.) α-**Naphthylamine** (α-aminonaphthalene; naphthalidam; naphthalidine) is formed by the reduction of α-nitronaphthalene with alcoholic ammonium sulphide (Zinin, J. pr. Chem. 1842, 27, 141; *cf.* Piria, Annalen, 1851, 78, 31); iron filings and acetic acid (Béchamp, Ann. Chim. Phys. 1854, [iii.] 42, 195; Balló, Ber. 1870, 3, 288, 673); tin and hydrochloric acid (Roussin, Compt. rend. 1861, 52, 797); zinc and hydrochloric acid (Böttger, Dingl. poly. J. 1870, 197, 458); alcoholic potash (Klobukowsky, Ber. 1877, 10, 571); zinc dust and aqueous calcium chloride (Dechend, D. R.-P. 43230 of 1887); or hydrogen and reduced copper at 330°–350° (Sabatier and Senderens, Compt. rend. 1902, 135, 225; *cf.* Senderens, D'Andoque, and Chefdebien, D. R.-P. 139457 of 1901).

It is also obtained when α-naphthol is heated with ammonia under pressure at 150°–160° for 60–70 hours (Badische, D. R.-P. 14612 of 1880). The yield may reach 70 p.c. of that calculated if the naphthol be heated with ammonia-calcium chloride at 270° for 8 hours, but dinaphthylamine is also formed in quantities varying with the conditions employed (Benz, Ber. 1883, 16, 14). Substitution of acetamide at 270° for ammonia gives a 50 p.c. yield of acet-α-naphthalide, together with about 15 p.c. of dinaphthylamine (Calm, Ber. 1882, 15, 615), but replacement of ammonia by sodamide at 220° leads to the production of 1-*amino*-5-*naphthol* (Sachs, D. R.-P. 181333 of 1905).

Preparation.—On the large scale α-naphthylamine is prepared by reducing granulated α-nitronaphthalene (15 pts.) with soft iron borings or 'swarf' (20 pts.) and hydrochloric acid (1 pt.)[1] at 50°–70° in an apparatus similar to that used in the manufacture of aniline, but provided with a wide exit-pipe for the escaping gases instead of a condenser. To remove the acid, milk of lime is added to the product, and the naphthylamine separated by distillation, superheated steam being used to drive the vapour into the condenser as rapidly as possible. The yield amounts to about 70 p.c. of that calculated.[2] The crude base is purified by a second distillation, but always contains appreciable quantities of naphthalene, owing to decomposition during the first distillation (Witt, Chem. Ind. 1887, 10, 218; Paul, Zeitsch. angew. Chem. 1897, 145). It also contains a small quantity of β-naphthylamine (*q.v.*).

To obtain α-naphthylamine free from the β- compound, the hydrochloride of the technical base can be fractionally crystallised to remove the more soluble β-salt (Reverdin and Noelting, Sur la constitution de la naphthaline, ed. 1888, 35), or the technical base can be (*a*) repeatedly crystallised from warm light petroleum (Erdmann, Annalen, 1893, 275, 217, footnote), or (*b*) fractionally crystallised from a relatively small quantity of xylene (Chem. Fab. Weiler-ter Meer, D. R.-P. 205076 of 1906; Eng. Pat. 16446 of 1907).

Identification.—α-Naphthylamine crystallises from most solvents in colourless scales or flat needles, melts at 50°, boils at 300° (Zinin, *l.c.*), and is but little volatile with steam. It is easily soluble in alcohol, ether, or aniline, but almost insoluble in water, of which 100 c.c. dissolve about 0·167 gram at the ordinary temperature (Balló, *l.c.*). On exposure to the air, the technical product changes colour gradually to greyish-violet, owing possibly to the presence of a small quantity of 1 : 8-diaminonaphthalene (Witt, *l.c.*). Its odour is characteristic and unpleasant.

The salts are for the most part sparingly soluble in water. The *hydrochloride* $B{\cdot}HCl$ and the *sulphate* $B_2{\cdot}H_2SO_4+2H_2O$ form scales; the *platinichloride* $(B{\cdot}HCl)_2PtCl_4$ is a crystalline powder. The *picrate*, $B{\cdot}HA$, forms sparingly soluble prisms, m.p. 161° (Smolka, Monatsh. 1885, 6, 923; *cf.* Suida, Ber. 1908, 41, 1913).

---

[1] Under these conditions, ferrous chloride in the presence of water is probably the reducing agent, thus:—

$$(1)\ 24FeCl_2 + 4C_{10}H_7{\cdot}NO_2 + 4H_2O = 12Fe_2Cl_4O + 4C_{10}H_7{\cdot}NH_2;$$

$$(2)\ 12Fe_2Cl_4O + 9Fe = 3Fe_3O_4 + 24FeCl_2.$$

[2] Other processes for the recovery of the base have been devised in which either the iron and iron oxide are removed electromagnetically from the reduction product fused at 50°–60° (Landshoff, D. R.-P. 83560 of 1895), or the reduction product is extracted by a relatively small quantity of a solvent, such as benzene (*ibid.* D. R.-P. 184497 of 1905).

Reactions.—(1) With nitrous acid, in the absence of sufficient mineral acid, it forms *aminoazonaphthalene*, m.p. 180°, as a brown precipitate (Liebermann, Annalen, 1876, 183, 265; Nietzki and Goll, Ber. 1885, 18, 298); but in acid solution the *diazo-* compound is produced, from which *α-naphthol* (Griess, Journ. Chem. Soc. 1867, 20, 89) and many *azo-* dyes have been obtained.

(2) Digestion with water under pressure at 200° converts it into *α-naphthol* (Höchst, D. R.-P. 74879; Eng. Pat. 14301 of 1892).

(3) When heated with potassium dichromate and dilute sulphuric acid it is oxidised to 1 : 4-[*α*]*naphthaquinone* and to *phthalic acid* (Monnet, Reverdin, and Noelting, Ber. 1879, 12, 2306).

(4) Oxidising agents such as ferric chloride, silver nitrate, mercuric chloride, or chromic acid when added to an α-naphthylamine salt in aqueous solution produce an azure-blue precipitate of *naphthameïn*, which rapidly becomes purple, dissolves in chloroform, and is not bleached by sulphurous acid (Piria, Annalen, 1851, 78, 64; Schiff, *ibid.* 1857, 101, 92; 1864, 129, 255).

(5) Reduction in boiling amyl alcohol solution with sodium converts it into ar.-*tetrahydronaphthylamine* (Bamberger and Althausse, Ber. 1888, 21, 1789).

(6) When heated with zinc chloride or calcium chloride at 280° it undergoes partial decomposition into *αα′-dinaphthylamine* and ammonia (Benz, *l.c.*).

Commercial tests.—Commercial α-naphthylamine should have the right melting-point and dissolve almost completely in dilute acids. The proportion of naphthalene present can be determined by distilling the sample with excess of hydrochloric acid in a current of steam and extracting the distillate with ether.

Acetyl derivatives.—Acetyl-α-naphthylamine (*acet-α-naphthalide*) $C_{10}H_7{\cdot}NH{\cdot}CO{\cdot}CH_3$ is formed by heating α-naphthol with ammonium acetate at 270°–280° (Calm, Ber. 1882, 15, 615), and prepared by boiling α-naphthylamine with 1·25 times its weight of glacial acetic acid for 4–5 days (Liebermann and Dittler, Annalen, 1876, 183, 229).

Properties.—It crystallises in needles, m.p. 159°, and is easily soluble in alcohol or acetic acid, but almost insoluble in cold water (Liebermann and Dittler, *l.c.;* Tommasi, Bull. Soc. chim. 1873, [ii.] 20, 20). On nitration in acetic acid solution it yields a mixture of 2-*nitroacet-α-naphthalide* and 4-*nitroacet-α-naphthalide* (Andreoni and Biedermann, Ber. 1873, 6, 342; Lellmann and Remy, *ibid.* 1886, 19, 797); and by further nitration 2 : 4-*dinitroacet-α-naphthalide* (Liebermann and Dittler, *l.c.* 274; Meldola and Forster, Chem. Soc. Proc. 1893, 9, 8).

Acetyl-α-naphthylaminesulphonic acids. Acet-α-naphthalide, when warmed with 20–25 p.c. anhydro-acid is converted chiefly into *acetyl-α-naphthylamine-5-sulphonic acid*, some 4-acid also being formed (Ewer and Pick, D. R.-P. 42874 of 1887; Schultz, Ber. 1887, 20, 3161). With 35 p.c. anhydro-acid below 30°, it yields the 5 : 7-*disulphonic acid* (Badische, D. R.-P. 69555 of 1892; Eng. Pat. 2370 of 1893).

The 2-, 4-, 5-, 6-, 7-, and 8-*sulphonic acids*, and the 3 : 6-, 4 : 6-, and 4 : 7-*disulphonic acids* can be prepared by heating solutions of the sodium salts of the respective α-naphthylamine-sulphonic acids at 50°–60° with acetic anhydride for a few minutes (Höchst, D. R.-P. 129000 of 1899; Eng. Pat. 17366 of 1898; *cf.* Nietzki and Zübelen, Ber. 1899, 22, 451; Cassella, D. R.-P. 74177; Eng. Pat. 15444 of 1893). Both acids and salts are very soluble in water, and each acid can be deacetylated by boiling it with water.

Alkyl derivates. *Methyl-α-naphthylamine* (Fischer, Annalen, 1895, 286, 159) is an oil, b.p. 293° (Landshoff, Ber. 1878, 11, 638); *dimethyl-α-naphthylamine* (Landshoff, *l.c.;* Hantzsch, Ber. 1880, 13, 1348) an oil, b.p. 272° (Friedlaender and Welmans, Ber. 1888, 21, 3124; *cf.* Bamberger and Helwig, *ibid.* 1889, 22, 1315; Pinnow, *ibid.* 1899, 32, 1406); *ethyl-α-naphthylamine* (Limpricht, Annalen, 1856, 99, 117; Friedlaender and Welmans, *l.c.*), an oil, b.p. 303° under 722·5 mm. (Bamberger and Helwig, *l.c.*); *diethyl-α-naphthylamine*, an oil, b.p. 283°–285° (Friedlaender and Welmans, *l.c.*).

Alkyl-α-naphthylaminesulphonic acids. Of these derivatives, *methyl-α-naphthylamine*-4-*sulphonic acid* has been made from α-naphthol-4-sulphonic acid by interaction with methylamine, and methylamine bisulphite at 150° (Badische, D. R.-P. 121683; Eng. Pat. 18726 of 1900), but *methyl-α-naphthylamine*-6-*sulphonic acid*, and *dimethyl-α-naphthylamine*-4-, 5-, 7-, and 8- *sulphonic acids* have been prepared by methylating the corresponding α-naphthylaminesulphonic acids (Füssganger, Ber. 1902, 35, 977). Dimethyl-α-naphthylamine-5-sulphonic acid, with an easily soluble isomeride, is obtained when dimethyl-α-naphthylamine is sulphonated with 95 p.c. sulphuric acid at 130° (Fussgänger, *l.c.*).

Aryl derivatives. *Phenyl-α-naphthylamine* forms prisms, m.p. 62°, b.p. 226° under 15 mm. (Girard and Vogt, Bull. Soc. chim. 1872, [ii.] 18, 68; Streiff, Annalen, 1881, 209, 152; Friedlaender, Ber. 1883, 16, 2077); o-*tolyl-α-naphthylamine*, needles, m.p. 94°–95° (Friedlaender, *l.c.*); p-*tolyl-α-naphthylamine*, prisms, m.p. 78°–79°, b.p. 236° under 15 mm. (Girard and Vogt, *l.c.*; Friedlaender, *l.c.*; Gnehm and Rübel, J. pr. Chem. 1901, [ii.] 64, 497).

Aryl-α-naphthylaminesulphonic acids. Of these derivatives, the phenyl- (*o*- or *p*-tolyl-) 3-, 4-, 5-, 6-, 7-, and 8-sulphonic acids have been prepared by heating the corresponding α-naphthylaminesulphonic acids with aniline (*o*- or *p*-toluidine) and its hydrochloride at 160°–170° (Bayer, D. R.-P. 70349, 71158, 71168; Eng. Pat. 7337A of 1892). Less satisfactory results are obtained when α-naphtholsulphonic acids (*cf.* Aktienges., D. R.-P. 38424 of 1886) are used instead of the α-naphthylamine compounds. The acids are very sparingly soluble in water; the sodium salts crystallise in scales, and, with the exception of the 3-, 7-, and 8-salts, are sparingly soluble (Bayer, *l.c.*).

Little is known of the aryl-α-naphthylamine-di- or tri-sulphonic acids. From two series of these acids, each containing SO_3H in the same nucleus as the NH_2 group, the corresponding aryl-derivative has not been isolated, but:

(*a*) Owing to the elimination of the 4-sulphonic group, *phenyl-* (p-*tolyl-*)*α-naphthylamine*-6-, 7- or 8-*sulphonic acid* is the product when α-naphthylamine-4 : 6-, 4 : 7-, or 4 : 8-disulphonic acid is phenylated (Aktienges., D. R.-P. 158923 of 1903; 159353; Eng. Pats. 15624, 24669 of 1904);

(*b*) Owing to the replacement of the 3-sulphonic group by the phenyl- (*p*-tolyl-) amino-group, *diphenyl*-(*di*-p-*tolyl*-)-1 : 3-*diaminonaphthalene sulphonic acids* result from phenylation of the acids derived from α-naphthylamine-3-sulphonic acid (Bayer, D. R.-P. 75296, 76414; Eng. Pat. 8898 of 1893).

α-NAPHTHYLAMINESULPHONIC ACIDS.

Introductory. — α - Naphthylaminesulphonic acids can be prepared by the following methods, of which the last two are technically unimportant:

(1) By the sulphonation of α-naphthylamine.

(2) By nitration of the corresponding naphthalenesulphonic acids and subsequent reduction.

(3) By sulphonation of α-naphthylamine-sulphonic acids obtained from nitronaphthalene-sulphonic acids.

(4) By heating α-naphtholsulphonic acids, other than those which contain sulphonic groups in the 2- or 3- position, with ammonium sulphite and ammonia at 100°–150°, and afterwards acidifying the products.

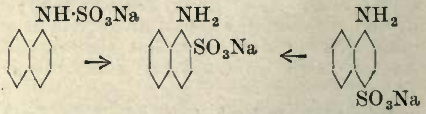
(5) By heating α-chloronaphthalenesulphonic acids with ammonia under pressure.

(6) By partial hydrolysis of α-naphthylamine-di- or tri-sulphonic acids.

Two of the monosulphonic acids, moreover, are obtained by methods applicable only to them:

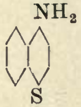
(*a*) Naphthionic acid, one of the three monosulphonic acids formed from α-naphthylamine by sulphonation, is obtained free from its isomerides by baking the acid sulphate of α-naphthylamine at 180°–200°;

(*b*) α-Naphthylamine-2-sulphonic acid is the only monosulphonic acid formed when sodium α-naphthylsulphamate or sodium naphthionate is heated at about 200°:

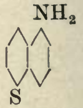


Three mono-, two di-, and two tri-sulphonic acids are known to be formed by the action of sulphuric acid on α-naphthylamine, and a third di- and third tri-sulphonic acid can be obtained by the sulphonation of α-naphthylamine-2-sulphonic acid, itself producible from α-naphthylamine and sulphuric acid, but only under special conditions (*v. supra*).

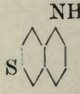
The nature of the sulphonation product depends on the four factors, concentration and relative quantity of the sulphuric acid, and temperature and duration of the reaction; but Erdmann (Annalen, 1893, 275, 192) has shown that it is possible to obtain, as chief product, successively the 4-, 5-, and 6-monosulphonic acid by prolonging the reaction without altering the temperature or the concentration of the sulphuric acid—



I.

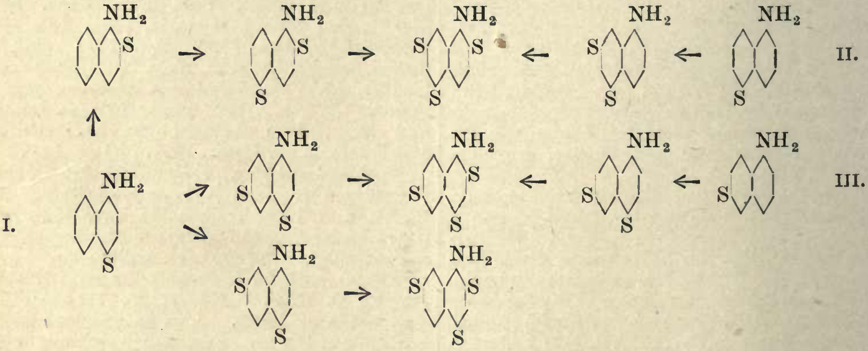


II.



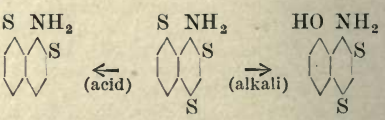
III.

From the scheme, which indicates the course of the sulphonation of α-naphthylamine, it will be seen that the 2- position is not occupied until trisulphonation occurs, and that neither the 3- nor the 8- position is attacked under any conditions—



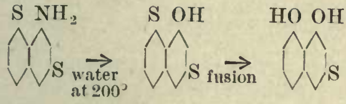
For the preparation of α-naphthylamine-8-sulphonic and 3 : 8-disulphonic acids, as well as of other acids not obtainable from α-naphthylamine by sulphonation, recourse is had to the second general method, in which the corresponding nitronaphthalenesulphonic acids are reduced.

As is usually the case, the sulphonic groups in α- are more easily eliminated than those in β-positions, whether the agent be caustic alkali, water, or dilute acid at high temperatures, or sodium amalgam in the cold. But the α-sulphonic groups differ in the degree of readiness with which they can be displaced; for example, the 4-sulphonic group is eliminated more easily than either the 5- or the 8- group by hydrolysis with dilute acids; but is replaced by hydroxyl least easily, and the 8-group most easily, of the three by fusion or digestion with caustic alkali—



If, instead of being fuesd or digested with caustic alkali at a high temperature, α-naphthylaminesulphonic acids be boiled with dilute caustic alkali solution and zinc dust, partial hydrolysis occurs, the α-sulphonic group eliminated being usually the one which, in the potash fusion, is exchanged for hydroxyl.

From α-naphthylaminesulphonic acids, the corresponding naphtholsulphonic acids can be obtained, not only by the diazo- reaction, but by heating the acids with water at 180°–200° under pressure. The latter reaction takes place most readily when sulphonic groups are present in the same nucleus as, or in the 8-position relatively to, the amino- group, and, as the example shows, the amino- group is replaced more readily than the α-sulphonic group by hydroxyl—



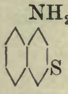
α-Naphthylaminesulphonic acids containing a 3-sulphonic group, by prolonged heating with caustic alkali solution at 260°–280°, yield hydroxytoluic acids, and, with ammonia (or aniline) at 180°, give 1 : 3-diaminonaphthalene derivatives.

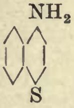
α-Naphthylamine-di- and tri-sulphonic acids containing an 8-sulphonic group are characterised by forming internal anhydrides (sultams), which yield yellow normal salts, and are less readily hydrolysed than the sultones derived from α-naphthol-8-sulphonic acids.

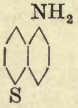
From solutions of the alkali monosulphonates the acids are precipitated, but from those of the di- and tri-sulphonates, acid salts separate on the addition of a mineral acid. A comparison of the relative strengths of the monosulphonic acids shows that the 2-acid is about 10 times as strong as the 4-, 5-, 6-, or 7-acid, and about 2000 times as strong as the 8-acid (Erdmann, Annalen, 1893, 275, 276).

A volumetric method for estimating α- (or β-) naphthylaminesulphonic acids, based on their different capacity for absorbing bromine has been devised by Vaubel (Chem. Zeit. 1893, 17, 1265). Most of these acids can be estimated accurately by titration with diazotised *p*-nitraniline (Bucherer, *cf.* J. Soc. Chem. Ind. 1907, 26, 818).

Azo- dyes of two types, *para-* and *ortho-*, can be obtained from α-naphthylaminesulphonic acids. Those usually formed are *para*-azo-dyes, but the sulphonic acids which contain one sulphonic group in the 3-, or 4-, or 5- position







do not form *para-* but *ortho*-azo- dyes (Gattermann and Schulze, Ber. 1897, 30, 50). In the production of azo-dyes, α-naphthylaminesulphonic acids are either themselves diazotised or are coupled as middle or end components with diazotised bases. Particularly valuable in the latter respect are the 6- and 7-monosulphonic acids, of which extensive use has been made in the series of disazo- and trisazo- dyes. In this article, however, it is not possible to refer, under each acid, to more than two or three typical illustrations of its application in the azo- dye industry.

α-Naphthylaminemonosulphonic Acids.[1]

(i.) **α - Naphthylamine - 2 - sulphonic acid** is obtained by heating sodium naphthionate at 200°–250° (Landshoff, D. R.-P. 56563; Eng. Pat. 6195 of 1890). The yield does not exceed 50 p.c., ammonia, α-naphthylamine, α-naphthylaminedisulphonic acids, sulphur dioxide and other substances being also formed (Erdmann, Annalen, 1893, 275, 225), but if the naphthionate is suspended in boiling naphthalene it becomes nearly quantitative, and the product contains as impurity only a small quantity of α-naphthylamine (Bayer, D. R.-P. 72833 of 1892). This acid is also formed when α-naphthylamine is heated with sulphanilic acid or its homologues at 180°–250° (*ibid.* D. R.-P. 75319 of 1892); or with naphthionic or β-naphthylamine-8-sulphonic acid at 160°–230° (*ibid.* D. R.-P. 77118 of 1892); or when α-naphthylsulphamic acid is heated at 170°–240° (Tobias, D. R.-P. 79132 of 1893; Eng. Pat. 15067 of 1894).

Identification.—The *acid* crystallises in needles, soluble in 244 parts of water at 20°, or in 31·3 parts at 100° (Doliński, Ber. 1905, 38, 1836). The *barium* BaA_2+H_2O and *calcium* CaA_2 salts form sparingly soluble scales; the *potassium* salt KA, needles sparingly soluble in cold water; the *sodium* salt NaA, scales soluble in 60 parts of cold water. It is convertible into *α-chloronaphthalene-2-sulphonyl chloride*, m.p. 80°, and into 1 : 2-*dichloronaphthalene*, m.p. 34° (Cleve, *ibid.* 1891, 24, 3472).

Reactions.—(1) From its sparingly soluble diazo- compound, Schaeffer's *α-naphthol-2-sulphonic acid* (Landshoff, *l.c.*), and *azo-* dyes (*cf.* Bayer, D. R.-P 66021; Eng. Pat. 5984 of 1891; D. R.-P. 75293 of 1892; Eng. Pat. 558 of 1893) have been obtained.

(2) On sulphonation with anhydro-acid, it yields *α-naphthylamine-*2 : 5-*disulphonic acid* (Landshoff, *l.c.*), and 2 : 5 : 7-*trisulphonic acid* (Bayer, D. P. Anm. F. 7001; Eng. Pat. 17141B of 1893).

(3) On fusion with caustic soda at 240°–270°, it is converted into 1-*amino*-5-*naphthol*-2-*sulphonic acid* (Landshoff, D. P. Anm. C. 4479 of 1892).

(ii.) **α-Naphthylamine-3-sulphonic acid** (Cleve's [γ-] acid) can be obtained by the reduction of α-nitronaphthalene-3-sulphonic acid with ferrous sulphate (Cleve, Ber. 1886, 19, 2181). It is also formed when sodium α-naphthylamine-3 : 8-disulphonate is boiled with 75 p.c. sulphuric acid (Kalle, D. R.-P. 64979 of 1892), or with zinc dust and 30 p.c. caustic soda solution (*ibid.* D. R.-P. 233934 of 1909), or is acted on by sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3032; *cf.* Bayer, Fr. Pats. 438737, 439010 of 1912; *v.* p. 592, footnote 1).

Identification.—The *acid* forms sparingly soluble needles; the *barium* BaA_2+H_2O in scales, *calcium*, *potassium*, and *sodium* NaA, salts are very soluble in water (Cleve, Ber. 1888, 21, 3271). It is convertible into *α-chloronaphthalene-3-sulphonyl chloride*, m.p. 106°, and into 1 : 3-*dichloronaphthalene*, (Cleve, *l.c.*; Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 18).

---

[1] In every case where the constitution of an α-naphthylaminesulphonic acid is given, the NH_2 group is supposed to be in the position '1.'

For phenyl- (or *p*-tolyl-)-α-naphthylaminesulphonic acids, see p. 587.

Reactions.—(1) From its diazo- compound *α-naphthol-3-sulphonic acid* has been obtained (Kalle, *l.c.*; Friedlaender, Ber. 1895, 28, 1952; Gattermann and Schulze, *ibid.* 1897, 30, 54).

It couples with diazotised bases[1] as the middle component of *disazo*-dyes (*cf.* Bayer, D. R.-P. 65262; Eng. Pat. 22641 of 1891; D. R.-P. 67261 of 1892), but has been little used for this purpose.

(2) Fused with caustic alkalis at 250°–260° it gives 1-*amino-3-naphthol* (Friedlaender, *l.c.*), and, in closed vessels at 250°–280°, o-*toluic acid* (Kalle, D. R.-P. 79028 of 1893).

(3) When heated with ammonia at 160°–180° it yields 1:3-*diaminonaphthalene* (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895); or with aniline (or *p*-toluidine) at 150°–170° it forms *diphenyl-(di-*p*-tolyl-)*-1:3-*diaminonaphthalene* (Bayer, D. R.-P. 75296; Eng. Pat. 8898 of 1893).

(iii.) α-**Naphthylamine**-4-**sulphonic acid** (naphthionic acid). Naphthionic acid, mixed with α-naphthylsulphamic acid, was first obtained by boiling α-nitronaphthalene with ammonium sulphite in alcoholic solution (Piria, Annalen, 1851, 78, 31). It is formed, with some of the more soluble 5-acid, when α-naphthylamine is sulphonated with 'fuming' sulphuric acid (*cf.* Erdmann, Annalen, 1888, 247, 315), and constitutes the sole product when it is heated with 4–5 times its weight of sulphuric acid at 100°–120°, or with 3 times its weight of acid at 130° until the product is soluble in alkali (Witt, Ber. 1886, 19, 57, 578; *cf.* Verein, Eng. Pat. 2237 of 1883). Pure naphthionic acid is obtained by 'baking' acid α-naphthylamine sulphate, or a mixture of α-naphthylamine and sulphuric acid in the proportion to form this salt, at 180°–200° (Nevile and Winther, Chem. Soc. Trans. 1880, 37, 632; Verein, *l.c.*), *or* by heating α-naphthylamine with 3 times its weight of potassium bisulphate at 200° (Bischoff and Brodsky, Ber. 1890, 23, 1914). It is also formed by boiling α-naphthylamine-4:8-disulphonic acid with zinc dust and dilute caustic soda solution (Kalle, D. R.-P. 233934 of 1909).

It is also formed when sodium α-naphthol-4-sulphonate is heated with 40 p.c. ammonium sulphite solution and 20 p.c. ammonia at 100°–150°, and the product acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900); *or* when sodium α-chloronaphthalene-4-sulphonate is heated with 25 p.c. ammonia at 200°–210° (Oehler, D. R.-P. 72336 of 1893).

Preparation.—According to Schultz (Chem. d. Steinkohlenth. 3rd ed., 1, 202), naphthionic acid is prepared by heating α-naphthylamine (50 kilos.) and sulphuric acid (36·5 kilos.) at 170°–180° until a homogeneous mass is obtained. Crystallised oxalic acid (2·5 kilos.) is then stirred in, and the frothy mass, spread on lead plates, is heated in an oven at 170°–180° during 8 hours. The porous product is converted into sodium naphthionate (64 kilos.) in the usual way.

Identification.—The *acid* $HA+\frac{1}{2}H_2O$ forms small lustrous needles, which dissolve in 3225 parts of water at 20°, or in 438·5 parts at 100° (Doliński, Ber. 1905, 38, 1836). The *barium* salt BaA_2+8H_2O in scales, *calcium* salt CaA_2+8H_2O in monoclinic tables, *potassium* salt KA in scales, and *sodium* salt $NaA+4H_2O$ in large monoclinic prisms, dissolve readily in water, and, like the acid, show marked blue fluorescence in dilute solution. It is convertible into *α-chloronaphthalene-4-sulphonyl chloride*, m.p. 95°, and into 1:4-*dichloronaphthalene* (Cleve, Ber. 1887, 20, 73).

Reactions.—(1) From its sparingly soluble, micro-crystalline, yellow *diazo-* compound, *α-naphthol-4-sulphonic acid* (Nevile and Winther, *l.c.*; Dahl, D. P. Anm. D. 1486 of 1883), *dinitro-α-naphthol* (Nevile and Winther, *l.c.*), and many *azo*-dyes (*cf.* Bayer, D. R.-P. 75293 of 1892; Eng. Pat, 558 of 1893), have been obtained.

It couples with diazotised bases (*cf.* Aktienges., D. R.-P. 58505 of 1890), forming ortho-*azo*-dyes, but is valueless as a middle component, owing to the amino- group, when in the *ortho-* position to the diazo-complex, being difficult to diazotise.

(2) When heated with 50 p.c. caustic soda solution at 240°–260° it is converted into *α-naphthol-4-sulphonic acid* (Aktienges., D. R.-P. 46307 of 1888).

(3) The sodium salt, when heated with sodium bisulphite solution at 85°–90° for 24 hours yields *α-naphthol-4-sulphonic acid* after the product has been acidified and boiled (Bayer, D. R.-P. 109102; Eng. Pat. 16807 of 1899).

(4) Prolonged heating with sulphuric acid at 130° converts it successively into the 5-acid and the 6-acid, and it is the most easily hydrolysed acid of the three (Erdmann, Annalen, 1893, 275, 193). Its sodium salt, when heated at 200°–250°, is converted into sodium α-naphthylamine-2-sulphonate (*q.v.*).

(5) The *acetyl* derivative, obtained by heating the sodium salt with acetic anhydride, yields, on nitration, the *acetyl* derivative of 5-*nitro-α-naphthylamine-4-sulphonic acid* (Nietzki and Zübelen, Ber. 1889, 22, 451; Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 221).

(iv.) α-**Naphthylamine-5-sulphonic acid** (Laurent's acid; Cleve's [α-]naphthalidinesulphonic acid).[2] This acid is obtained by reduction of α-nitronaphthalene-5-sulphonic acid (Laurent, Compt. rend. 1850, 31, 538; *cf.* Cleve, Förhandl., 1875, 9, 13; Bull. Soc. chim. 1875, [ii.] 24, 511; Erdmann, Annalen, 1893, 275, 264; Schöllkopf, D. R.-P. 40571; Eng. Pat. 15775 of 1885). It constitutes the chief product (*cf.* Erdmann, Annalen, 1888, 247, 315), naphthionic acid being the subsidiary product, when α-naphthylamine is warmed with twice its weight of 'fuming' sulphuric acid (Cleve, Förhandl., 1876, 7, 39; *cf.* Schmidt and Schaal, Ber. 1874, 7, 1367); *or* when α-naphthylamine hydrochloride is sulphonated in the cold with 20–25 p.c. anhydro-acid (Witt, Ber. 1886, 19, 578; Schultz, *ibid.* 1887, 20, 3161; Mauzelius, *ibid.* 3403); *or* when acet-α-naphthalide is sulphonated with 3–4 times its weight of 20–25 p.c. anhydro-acid and the product de-acetylated by boiling the melt with water (Lange, Ber. 1887, 20, 2940; Ewer and Pick, D. R.-P. 42874 of 1887;

---

[1] Diazobenzene chloride is an exception (*cf.* Gattermann and Schulze, Ber. 1897, 30, 54).

[2] The 'α-naphthylamine-[δ-]sulphonic acid' obtained by Hirsch by heating α-naphthylamine with 5 times its weight of sulphuric acid at 125°–130° for 8–9 hours (Hirsch, D. P. Anm. H. 7291 of 1887; Ber. 1888, 21, 2370), is a mixture of 5-acid with some 6-acid (Erdmann, Annalen, 1893, 275, 223).

Schultz, *l.c.*). It is also formed when sodium α-chloronaphthalene-5-sulphonate is heated with 25 p.c. ammonia solution at 200°–210° (Oehler, D. R.-P. 72336 of 1893).

Preparation.—The product obtained by sulphonating α-nitronaphthalene with 20 p.c. anhydro-acid, to which salt has been added (*v.* α-nitronaphthalene-5-sulphonic acid), is poured on to ice, reduced by iron, and converted into sodium salt in the usual way. Or the product of the sulphonation of acet-α-naphthalide or of α-naphthylamine hydrochloride with 20–25 p.c. anhydro-acid in the cold, is converted into the calcium salt and, by fractional crystallisation, separated from the more soluble naphthionate.

Salts.—The *acid* crystallises in anhydrous needles, soluble in about 940 parts of cold water. The *barium* salt BaA_2+6H_2O, in aggregates of small scales; *calcium* salt CaA_2+9H_2O, in tables; *potassium* salt $KA+H_2O$, in needles; and *sodium* salt $NaA+H_2O$, in aggregates of needles, dissolve readily in water; both acid and salts show greenish fluorescence in dilute aqueous solution (Cleve, Bull. Soc. chim. 1875, [ii.] 24, 511; Witt, *l.c.*; Mauzelius, Ber. 1887, 20, 3401). It is convertible into *α-chloronaphthalene-5-sulphonyl chloride*, m.p. 95°, and into 1 : 5-*dichloronaphthalene* (Erdmann, Annalen, 1888, 247, 353).

Reactions.—(1) From its sparingly soluble, yellow, crystalline *diazo-* compound *α-naphthol-5-sulphonic acid* (Cleve, *l.c.*; Erdmann, *l.c.* 343), and many *azo*-dyes (*cf.* Bayer, D. R.-P. 66693, 67259; Eng. Pat. 5984 of 1891), have been obtained.

It couples with diazotised bases (*cf.* Aktienges., D. R.-P. 58505 of 1890), forming ortho-*azo*-dyes (*cf.* the 4-acid).

(2) It yields 2 : 4-*dinitro-α-naphthol* when boiled with nitric acid (Witt, *l.c.*).

(3) Concentrated aqueous caustic soda at 240°–250° converts it into 1-*amino*-5-*naphthol* (Aktienges., D. R.-P. 49448 of 1889; *cf.* Friedlaender and Lagodzinski, J. Soc. Chem. Ind. 1897, 16, 793).

(4) On sulphonation with 35 p.c. anhydro-acid at 90°–120°, it yields *α-naphthylamine-*2 : 5 : 7-*trisulphonic acid* (Cassella, D. R.-P. 188505 of 1905). With 30 p.c. anhydro-acid in the cold and subsequent de-acetylation by boiling the melt with water, its acetyl- compound is converted into *α-naphthylamine*-5 : 7-*disulphonic acid* (Badische, D. R.-P. 69555 of 1892; Eng. Pat. 2370 of 1893).

(v.) α-**Naphthylamine-6-sulphonic acid** (Cleve's [β-]acid; Erdmann's μ-acid) is formed when the 4-acid or 5-acid is heated with sulphuric acid at 125°–130° for many hours (Erdmann, Annalen, 1893, 275, 200), and is prepared by reduction of α-nitronaphthalene-6-sulphonic acid by ammonium sulphide or by iron and dilute sulphuric acid (Cleve, Ber. 1887, 20, 74).

Identification.—The *acid*, $HA+2H_2O$, forms needles soluble in 1000 parts of water at 16°. The *barium* salt BaA_2+H_2O, in needles, is sparingly; and the *calcium* salt CaA_2+7H_2O in tablets; *potassium* salt $KA+H_2O$ in scales; and *sodium* salt $NaA+4\frac{1}{2}H_2O$ in thin tablets are easily soluble in water (Cleve, Förhandl. 1876, 7, 54; Bull. Soc. chim. 1876, [ii.] 26, 447; Erdmann, *l.c.*, 265). It is convertible into *α-chloronaphthalene-*6-*sulphonyl chloride*, m.p. 114–115° (Cleve, Ber. *l.c.*), and into 1 : 6-*dichloronaphthalene* (Erdmann *l.c.*).

Reactions.—(1) From its *diazo*-compound, *α-naphthol*-6-*sulphonic acid* (Erdmann and Süvern, Annalen, 1893, 275, 304), and many *azo*-dyes (*cf.* Bayer, D. R.-P. 67261 of 1892) have been obtained.

It couples with diazotised bases, and is of importance as the middle component (*cf.* Bayer, D. R.-P. 65262; Eng. Pat. 22641 of 1891; *ibid.* D. R.-P. 92799; Eng. Pat. 5112 of 1892, Cassella, D. R.-P. 83572 of 1891) or end component (*cf.* Cassella, D. R.-P. 121667, 127362; Eng. Pat. 23615 of 1898) of *disazo*-dyes.

(2) On fusion with caustic alkali, it yields 1-*amino*-6-*naphthol* (Bayer, D. R.-P. 74060; Eng. Pat. 11533 of 1892).

(3) The sodium salt, when heated with sodium bisulphite solution at 120°–150° for 15 hours, yields *α-naphthol*-6-*sulphonic acid*, after the product has been acidified and boiled (Bayer, D. R.-P. 109102; Eng. Pat. 16807 of 1899).

(4) When heated with anhydro-acid, it is converted into the 4 : 6-*disulphonic acid* (Cassella, D. P. Anm. C. 4021 of 1891), and the 2 : 4 : 6-*trisulphonic acid* (Bayer, D. P. Anm. F. 7016; Eng. Pat. 15223 of 1893).

(vi) α-**Naphthylamine-7-sulphonic acid** (Cleve's [θ-] or [δ-]acid; Cleve's acid) is obtained by the reduction of α-nitronaphthalene-7-sulphonic acid (Cleve, Ber. 1888, 21, 3264; Erdmann, Annalen, 1893, 275, 272); *or* by the partial hydrolysis of α-naphthylamine-2 : 7-disulphonic acid (Kalle, D. R.-P. 62634 of 1891); *or* from α-naphthol-7-sulphonic acid by the ammonium sulphite method (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *acid* $HA+H_2O$ forms scales soluble in 220 parts of water at 25°. The *barium* salt BaA_2 in needles, is sparingly, but the *calcium* salt CaA_2+2H_2O, *potassium* salt in scales, and *sodium* salt $NaA+\frac{1}{2}H_2O$ in needles, are easily soluble in water (Cleve, *l.c.*). It is convertible into *α-chloronaphthalene*-7-*sulphonyl chloride*, m.p. 94° (Cleve, Ber. 1892, 25, 2481), and into 1 : 7-*dichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 49).

Reactions.—(1) From its very soluble *diazo*-compound, *α-naphthol*-7-*sulphonic acid*, and (*cf.* Bayer, D. R.-P. 75293 of 1892; Eng. Pat. 558 of 1893) *azo*-dyes have been obtained.

It couples with diazotised bases, and is of much importance as a middle component (*cf.* Kalle, D. R.-P. 73901, 84460 of 1891; Eng. Pat. 2718 of 1892; Bayer, D. R.-P. 121421; Eng. Pat. 3673 of 1900; Cassella, D. P. Anm. C. 10219; Eng. Pat. 22306 of 1901) or the end component (*cf.* the 6-acid) of *disazo* or *trisazo*-dyes.

(2) When fused with caustic soda it yields 1-*amino*-7-*naphthol* (Cassella, D. R.-P. 69458 of 1891; Friedlaender and Zinberg, Ber. 1896, 29, 41).

(3) On sulphonation with anhydro-acid it is converted into the 4 : 7-*disulphonic acid* (Cassella, D. P. Anm. C. 3939 of 1891), and the 2 : 4 : 7-*trisulphonic acid* (Bayer, D. P. Anm. F. 6550; Eng. Pat. 15223 of 1893).

(vii.) α-**Naphthylamine-8-sulphonic acid** (Schöllkopf or S-acid) is obtained by reducing α-nitronaphthalene-8-sulphonic acid. Usually, however, the nitro-acid is not isolated but the nitration product of naphthalene-α-sulphonic acid, after dilution with water, is reduced by iron, neutralised by lime, and converted into sodium salt. The mixed sodium salts of the 8-acid and 5-acid thus obtained are easily separated owing to the sparing solubility of the 8-salt in water (Schöllkopf, D. R.-P. 40571; Eng. Pat. 15775 of 1885). It is also formed when sodium 1 : 8-naphthasultam-2 : 4-disulphonate is heated with 20 p.c. hydrochloric acid (Dressel and Kothe, Ber. 1894, 27, 2140).

Identification.—The *acid* $HA+H_2O$ forms needles soluble in 4800 parts of water at 21° or in 238 parts of boiling water; the *potassium* salt KA scales, soluble in 280 parts of water at 19°, or in 67 parts at 100°; the *sodium* salt NaA scales or tables, soluble in 885 parts of water at 24°, or in 375 parts at 100° (Erdmann, Annalen, 1888, 247, 320). It is convertible into *α-chloronaphthalene-*8*-sulphonyl chloride*, m.p. 101°, and into 1 : 8-*dichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1895, 11, 84).

Reactions.—(1) From its sparingly soluble *diazo-* compound *naphthasultone* (the anhydride of α-naphthol-8-sulphonic acid) has been obtained (Erdmann, *l.c.* 344).

It couples with diazotised bases, and has been used as end component in *disazo*-dyes (Bayer, D. R.-P. 96083 of 1892; Eng. Pat. 1851 of 1893), or, like its phenyl derivative (*ibid.* D. R.-P. 75571 of 1893), in the production of *monazo* dyes (Leonhardt, D. R.-P. 108546; Eng. Pat. 24830 of 1898).

(2) When heated at 130° with phosphorus oxychloride it gives *naphthasultam* (Dannerth, J. Amer. Chem. Soc. 1907, 29, 1320), and with 40 p.c. anhydro-acid at 80°–90° it forms 1 : 8-*naphthasultam*-2 : 4-*disulphonic acid* (Bayer, D. R.-P. 79566; Eng. Pat. 4979 of 1893).

(3) When heated with water at 200° under pressure it is converted into *α-naphthol*-8-*sulphonic acid* (Höchst, D. R.-P. 74644; Eng. Pat. 14301 of 1892); with 9 p.c. caustic soda solution at 220°–260° under pressure it yields 1 : 8-*dihydroxynaphthalene* (*ibid.* D. P. Anm. F. 6311 of 1892); and with fused alkali at 200° it gives 1-*amino*-8-*naphthol* (Badische, D. R.-P. 55404 of 1889; Eng. Pat. 9676 of 1890).

(4) On sulphonation with 10 p.c. anhydro-acid in the cold, it yields *α-naphthylamine*-4 : 8-*disulphonic acid* (Schöllkopf, *l.c.*). Its acetyl derivative with 25 p.c. anhydro-acid forms both the 4 : 8- and 6 : 8-*disulphonic acids* (Bayer, D. R.-P. 75084 of 1893).

α-NAPHTHYLAMINEDISULPHONIC ACIDS.[1]

(i.) **α-Naphthylamine-2 : 4-disulphonic acid** is formed[1] when α-nitronaphthalene is heated with sodium bisulphite solution at 100°. Its *sodium* salt is easily soluble in water.

Reactions.—From its *diazo-* compound, 2 : 4-*dinitro-α-naphthol* and *naphthalene*-1 : 3-*disulphonic acid* have been obtained (Höchst, D. R.-P. 92082 of 1895).

(ii.) **α-Naphthylamine-2 : 5-disulphonic acid** is obtained from α-naphthylamine-2-sulphonic acid by sulphonation with 10 p.c. anhydro-acid in the cold (Landshoff, D. R.-P. 56563; Eng. Pat. 6195 of 1890). It is easily soluble, but its acid salts are only very sparingly soluble in water.

Reactions.—(1) By the diazo- reaction, it yields *naphthalene*-1 : 6-*disulphonic acid* (Tobias, Ber. 1890, 23, 1631).

(2) By partial hydrolysis with dilute sulphuric acid at 160° it gives *α-naphthylamine*-5-*sulphonic acid* (Landshoff, *l.c.*).

(3) When heated with 50 p.c. caustic soda solution at 240°–270°, it is converted into 1-*amino*-5-*naphthol*-2-*sulphonic acid* (*ibid.*, D. P. Anm. C. 4479 of 1892; Eng. Pat. 6195 of 1890).

(4) On sulphonation with 40 p.c. anhydro-acid at 120°, it gives *α-naphthylamine*-2 : 5 : 7-*trisulphonic acid* (Bayer, D. P. Anm. F. 7001; Eng. Pat. 17141B of 1893).

(iii.) **α-Naphthylamine-2 : 7-disulphonic acid** is obtained by partial hydrolysis either of α-naphthylamine-2 : 4 : 7-trisulphonic acid with water at 230° under pressure (Kalle, D. R.-P. 62634 of 1891), *or* of α-naphthylamine-2 : 5 : 7-trisulphonic acid by boiling it with zinc dust and dilute caustic soda solution[1] (*ibid.* D. R.-P. 233934 of 1909). It crystallises in needles; its *barium* salt is very sparingly soluble in water, and solutions of its alkali salts show bluish-green fluorescence (Kalle, D. R.-P. 62634 of 1891).

Reactions.—By the diazo- reaction, it yields *naphthalene*-2 : 7-*disulphonic acid*, and, by partial hydrolysis with dilute sulphuric acid under pressure, it gives *α-naphthylamine*-7-*sulphonic acid* (Kalle, *l.c.*).

(iv.) **α-Naphthylamine-2 : 8-disulphonic acid** is obtained from naphthasultam-2 : 4-disulphonic acid by partial hydrolysis with 40 p.c. sulphuric acid at 110° (Cassella, D. R.-P. 75710 of 1893; *cf.* Dressel and Kothe, Ber. 1894, 27, 2140). It crystallises in moderately soluble needles; the solutions of its alkali salts show green fluorescence.

Reaction.—When fused with caustic soda, it yields 1-*amino*-8-*naphthol*-2-*sulphonic acid* (Cassella, *l.c.*).

(v.) **α-Naphthylamine-3 : 6-disulphonic acid** (Alén's [α-]acid) is obtained by reduction of α-nitronaphthalene-3 : 6-disulphonic acid (Alén, Förhandl., 1883, 8, 3; Freund, D. R.-P. 27346; Eng. Pat. 1069 of 1883;[2] Armstrong and Wynne, Chem. Soc. Proc. 1895, 11, 82); *or* by boiling α-naphthylamine-3 : 6 : 8-trisulphonic acid with zinc dust and 7 p.c. caustic soda solution (Kalle, D. R.-P. 233934 of 1909).

Identification.—The *acid* forms needles, and, like the *barium* $BaA+4H_2O$ and *calcium* $CaA+5H_2O$ in tablets, also the *acid potassium* $KHA+3H_2O$ and *acid sodium* $NaHA+3H_2O$ salts in needles, is easily soluble in water (Alén, *l.c.*). It is convertible into *α-chloronaphthalene*-3 : 6-*disulphonyl chloride*, m.p. 114° or 127°, and into 1 : 3 : 6-*trichloronaphthalene* (Armstrong and Wynne, *l.c.*).

Reactions.—(1) From its *diazo*-compound (Freund, *l.c.*), or when it is heated with water at 180° under pressure (Cassella, D. P. Anm.

---

[1] By electrolytic reduction in a divided cell, with its compartments connected by a layer of mercury and containing 25 p.c. caustic soda solution in the anode compartment, SO_3H in the position italicised is eliminated from the following naphthylaminesulphonic acids—1 : 3 : *8*, 1 : 4 : *8*, 1 : 2 : 4 : *6*, 1 : 2 : *5* : 7, 1 : 3 : *5* : 7, 2 : *4* : 8, 2 : *5* : 7, and from the naphtholsulphonic acid 1 : 3 : *8* (Bayer, Fr. Pat. 439010 of 1912, with sketch; *cf.* J. Soc. Chem. Ind., 1912, 31, 579).

[2] This acid, like the 3 : 7-acid, was regarded by Freund as a β-naphthylaminedisulphonic acid.

C. 4375 of 1892; Friedlaender and Taussig, Ber. 1897, 30, 1462), *α-naphthol*-3 : 6-*disulphonic acid* is obtained.

(2) When boiled with 75 p.c. caustic potash solution, it is converted into a mixture of 1-*amino*-3-*naphthol*-6-*sulphonic* and 1-*amino*-6-*naphthol*-3-*sulphonic acids* (Cassella, D. R.-P. 82676 of 1894).

(3) Ammonia at 180° under pressure converts it into 1 : 3-*diaminonaphthalene*-6-*sulphonic acid* (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895); aniline (or *p*-toluidine) at 150°–160° converts it into *diphenyl*-(*di*-p-*tolyl*-)-1 : 3-*diaminonaphthalene*-6-*sulphonic acid* (Bayer, D. R.-P. 76414; Eng. Pat. 8898 of 1893).

(vi.) **α-Naphthylamine-3 : 7-disulphonic acid** (Alén's [β-]acid) is prepared by reduction of α-nitronaphthalene-3 : 7-disulphonic acid (Freund, D. R.-P. 27346; Eng. Pat. 1069 of 1883; Cassella, D. R.-P. 57007, 58352 of 1890; Levinstein, Eng. Pat. 2682 of 1891), *or* by boiling α-naphthylamine-3 : 5 : 7-trisulphonic acid with zinc-dust and dilute caustic soda solution (Kalle, D. R.-P. 233934 of 1909; *cf.* p. 592, footnote 1). It is easily soluble in water, and, like its salts, shows blue fluorescence in solution. The *barium* salt $BaA + H_2O$, *calcium* salt $CaA + 2H_2O$, and *acid potassium* salt KHA form sparingly soluble needles (Alén, Förhandl. 1883, 8, 26).

Reactions.—(1) When heated with water at 180° under pressure it is converted into *α-naphthol*-3 : 7-*disulphonic acid* (Cassella, D. P. Anm. C. 5069 of 1892).

(2) Digestion with caustic soda solution at 200° converts it into a mixture of 1-*amino*-3-*naphthol*-7-*sulphonic acid* and 1-*amino*-7-*naphthol*-3-*sulphonic acid* (Cassella, D. R.-P. 57007 of 1890).

(3) Ammonia at 180° under pressure converts it into 1 : 3-*diaminonaphthalene*-7-*sulphonic acid* (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895); aniline (or *p*-toluidine) at 150°–160° converts it into *diphenyl*-(*di*-p-*tolyl*-)-1 : 3-*diaminonaphthalene*-7-*sulphonic acid* (Bayer, D. R.-P. 76414; Eng. Pat. 8898 of 1893).

(vii.) **α-Naphthylamine-3 : 8-disulphonic acid** ([ε-] acid) is obtained by reduction of α-nitronaphthalene-3 : 8-disulphonic acid. In practice, the mixture of this acid with α-nitronaphthalene-4 : 8-disulphonic acid, and some β-nitronaphthalenedisulphonic acids, obtained by nitrating a disulphonation melt containing the naphthalene-1 : 5- and 1 : 6-disulphonic acids, is freed from the excess of sulphuric acid by lime, reduced with iron, and converted into sodium salt. On concentration of the solution the first separations consist of the normal sodium salt of the 4 : 8-acid, the more soluble 3 : 8-salt which is retained in the mother liquor being precipitated from it as acid sodium salt by the addition of hydrochloric acid (Aktienges., D. R.-P. 45776; Eng. Pat. 4625 of 1888; Ewer and Pick, D. R.-P. 52724 of 1888; Bernthsen, Ber. 1889, 22, 3328; Schultz, *ibid.* 1890, 23, 77).

Identification.—The *acid* $H_2A + 3H_2O$ forms very soluble scales. The *barium* salt $BaA + 4H_2O$ forms needles sparingly soluble, and the *acid barium* salt $BaH_2A_2 + 5H_2O$, microscopic needles almost insoluble in cold water; the *normal sodium* salt $Na_2A + 6H_2O$ very soluble, and the *acid sodium* salt $NaHA + 2H_2O$, soluble in about 30 parts of cold water, crystallise in long needles or thin prisms (Bernthsen, *l.c.*). It is convertible into *α-chloronaphthalene*-3 : 8-*disulphonyl chloride*, m.p. 110°, and into 1 : 3 : 8-*trichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 16).

Reactions.—(1) The *diazo-* compound, when boiled with dilute sulphuric acid, yields *naphthasultone*-3-*sulphonic acid* (Ewer and Pick, *l.c.*; Bernthsen, *l.c.*).

(2) When heated with water at 180° under pressure it gives *α-naphthol*-3 : 8-*disulphonic acid* (Höchst, D. R.-P. 71494; Eng. Pat. 14301 of 1892), but yields *α-naphthylamine*-3-*sulphonic acid* when boiled with 75 p.c. sulphuric acid (Kalle, D. R.-P. 64979 of 1892), or by interaction with sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3032; *cf.* p. 592, footnote 1).

(3) Fusion with alkalis below 210° converts it into 1-*amino*-8-*naphthol*-3-*sulphonic acid* (Bayer, D. P. Anm. F. 4723; Eng. Pat. 13443 of 1890), but digestion with 9 p.c. caustic soda solution at 250° under pressure converts it into 1 : 8-*dihydroxynaphthalene*-3-*sulphonic acid* (Höchst, D. P. Anm. F. 7112 of 1892).

(4) Ammonia at 180° under pressure converts it into 1 : 3-*diaminonaphthalene*-8-*sulphonic acid* (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895); aniline (or *p*-toluidine) at 150°–160° converts it into *diphenyl*-(*di*-p-*tolyl*-)1 : 3-*diaminonaphthalene*-8-*sulphonic acid* (Bayer, D. R.-P. 75296; Eng. Pat. 8898 of 1893).

(viii.) **α-Naphthylamine-4 : 6-disulphonic acid** (Dahl's No. II acid)[1] constitutes about 30 p.c. of the product obtained by sulphonating naphthionic acid with 25 p.c. anhydro-acid in the cold (*v.* 4 : 7-acid), and is separated by extraction of the mixed calcium salts with 85 p.c. alcohol in which it is soluble (Dahl, D. R.-P. 41957 of 1886).

It is formed when α-naphthylamine-6-sulphonic acid is sulphonated with 10 p.c. (Cassella, D. P. Anm. C. 4021 of 1891) or 25 p.c. anhydro-acid (Bayer, D. P. Anm. F. 7016; Eng. Pat. 15223 of 1893), *or* when α-naphthylamine-4 : 6 : 8-trisulphonic acid is boiled with zinc dust and 7 p.c. caustic soda solution (Kalle, D. R.-P. 233934 of 1909); and can be obtained from α-naphthol-4 : 6-disulphonic acid by the ammonium sulphite method (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *calcium* salt $CaA + 5H_2O$ forms needles soluble in 85 p.c. but insoluble in 96 p.c. alcohol (Erdmann, Annalen, 1893, 275, 219), and, like the *potassium* and *sodium* salts, is very soluble in water; the *acid sodium* salt, in needles, is soluble in about 6 parts of water at 20° (Dahl, *l.c.*). It is convertible into *α-chloronaphthalene*-4 : 6-*disulphonyl chloride*, m.p. 126°–127°, and into 1 : 4 : 6-*trichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 126).

Reactions.—(1) From its moderately soluble *diazo-* compound *α-naphthol*-4 : 6-*disulphonic acid* (Dahl, *l.c.*), and *azo*-dyes (*cf.* Höchst, D. R.-P. 176640 of 1905; Eng. Pat. 7287 of 1906) have been obtained.

---

[1] In Dahl & Co.'s patent (D. R.-P. 41597 of 1886) an acid 'No. I' is described, the calcium salt of which is soluble in 96 p.c. alcohol. This acid, said to constitute 50 p.c. of the product when α-naphthylamine is heated with 4–5 parts of 25 p.c. anhydro-acid at 120°, could not be identified by Erdmann (Annalen, 1895, 275, 218), and is believed by him not to exist.

(2) By fusion with alkalis at 180°–200° it yields 1-*amino*-6-*naphthol*-4-*sulphonic acid* (Dahl, D. R.-P. 68232 of 1891; Friedlaender and Kielbasinski, Ber. 1896, 29, 1979), and at 200°–220° 1:6-*dihydroxynaphthalene*-4-*sulphonic acid* (Dahl, D. R.-P. 57114; Eng. Pat. 735 of 1890; *cf.* Friedlaender and Lucht, Ber. 1893, 26, 3034).

(3) When heated with aniline (or *p*-toluidine) at 180°, it forms *phenyl*- (or p-*tolyl*-)α-*naphthylamine*-6-*sulphonic acid* (Aktienges., D. R.-P. 159353; Eng. Pat. 24669 of 1904).

(4) Sulphonation with 35 p.c. anhydro-acid at 80°–90° converts it into α-*naphthylamine*-2 : 4 : 6-*trisulphonic acid* (Bayer, *l.c.*).

(ix.) α-**Naphthylamine**-4 : 7-**disulphonic acid** (Dahl's No. III acid) is obtained, mixed with about 30 p.c. of the No. II acid (*v.* 4 : 6-acid), by adding sieved naphthionic acid to 3·5 times its weight of 25 p.c. anhydro-acid below 30°. The product converted into dry calcium salt is extracted with 10 times its weight of 85 p.c. alcohol to remove No. II salt, the residue being No. III salt (Dahl, D. R.-P. 41957 of 1886).

It is also formed when α-naphthylamine-7-sulphonic acid is sulphonated with monohydrate at 100°–150° (Cassella, D. P. Anm. C. 3939 of 1891), or 25 p.c. anhydro-acid at 50°–60° (Bayer, D. P. Anm. F. 6550; Eng. Pat. 15223 of 1893); when 1 : 8-dinitronaphthalene is digested with sodium or ammonium sulphite solution at 70°–90°, and the crystalline α-naphthylsulphamino-4 : 7-disulphonate, which separates on cooling, is hydrolysed by a mineral acid (Höchst, D. R.-P. 215338 of 1908); or when sodium α-naphthol-4 : 7-disulphonate is heated with 40 p.c. ammonium sulphite solution and 20 p.c. ammonia at 100°–150°, and the product acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *barium* salt BaA, in needles, and *calcium* salt $CaA+H_2O$, are sparingly soluble in water; the *potassium* salt K_2A+3H_2O, in efflorescent prisms, and *sodium* salt Na_2A+3H_2O, in efflorescent needles, are readily soluble in water; the *acid sodium* salt in needles, is soluble in 140 parts of water at 20° or 20 parts at the boiling point, but, like the calcium salt, is insoluble in 85 p.c. alcohol (Dahl, *l.c.*; Erdmann, Annalen, 1893, 275, 220). The solutions of the acid and salts show blue fluorescence. It is convertible into α-*chloronaphthalene*-4 : 7-*disulphonyl chloride*, m.p. 107°, and into 1 : 4 : 7-*trichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 17).

Reactions.—(1) By the diazo- reaction (Dahl, *l.c.*), or by the bisulphite method (Bucherer, J. pr. Chem. 1904, [2] 70, 347), it yields α-*naphthol*-4 : 7-*disulphonic acid* convertible into 2 : 4-*dinitro*-α-*naphthol*-7-*sulphonic acid* (naphthol yellow S; *cf.* Armstrong and Wynne, *l.c.*).

(2) When heated with aniline (or *p*-toluidine) at 180°, it forms *phenyl*- (or p-*tolyl*-)α-*naphthylamine*-7-*sulphonic acid* (Aktienges., D. R.-P. 159353; Eng. Pat. 24669 of 1904).

(3) Sulphonation with 35 p.c. anhydro-acid at 80°–90° converts it into α-*naphthylamine*-2 : 4 : 7-*trisulphonic acid* (Bayer, *l.c.*).

(x.) α-**Naphthylamine**-4 : 8-**disulphonic acid** ([δ-] acid; disulpho-acid-S) is formed from α-naphthylamine-8-sulphonic acid by sulphonation with 3 times its weight of 10 p.c. anhydro-acid at first in the cold and afterwards at 100° (Schöllkopf. D. R.-P. 40571; Eng. Pat. 15775 of 1885); also, mixed with the 6 : 8-acid, when acetyl-α-naphthylamine-8-sulphonic acid is sulphonated with 25 p.c. anhydro-acid in the cold, the product deacetylated by boiling it with water, and the sodium salt separated from the more soluble 6 : 8-isomeride by fractional crystallisation (Bayer, D. R.-P. 75084 of 1893).

It can be obtained by reduction of α-nitronaphthalene-4 : 8-disulphonic acid, occurring, therefore, with the 3 : 8-acid (*q.v.*), in the product formed when the sulphonation melt containing naphthalene-1 : 5- and 1 : 6-disulphonic acids is nitrated, and the nitro-acids are reduced (Aktienges., D. R.-P. 45776; Eng. Pat. 4625 of 1888; Bernthsen, Ber. 1889, 22, 3327). Further, it can be made from α-naphthol-4 : 8-disulphonic acid by the ammonium sulphite method (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *normal sodium* salt, Na_2A+2H_2O, forms needles readily soluble in water (Bernthsen, Ber. 1890, 23, 3090, footnote); the *acid sodium* salt scales sparingly soluble in cold water. It is convertible into α-*chloronaphthalene*-4 : 8-*disulphonyl chloride*, m.p. 176°, and into 1 : 4 : 8-*trichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 126).

Reactions.—(1) By the diazo- reaction (Schöllkopf, *l.c.*), or by the bisulphite method (Badische, D. R.-P. 115335 of 1899; Eng. Pat. 1387 of 1900), it can be converted into α-*naphthol*-4 : 8-*disulphonic acid.*

(2) Fusion with caustic alkalis at 200°–210° converts it into 1-*amino*-8-*naphthol*-4-*sulphonic acid* (Bayer, D. R.-P. 75317; *cf.* 63074; Eng. Pat. 20275 of 1891), but with 60 p.c. caustic soda at 250° into 1 : 8-*dihydroxynaphthalene*-4-*sulphonic acid* (Bayer, D. R.-P. 71836 of 1890).

(3) When heated with aniline (or *p*-toluidine) at 180°, it yields *phenyl*- (or p-*tolyl*-)α-*naphthylamine*-8-*sulphonic acid* (Aktienges., D. R.-P. 158923 of 1903; Eng. Pat. 15624 of 1904).

(4) On sulphonation with 40 p.c. anhydro-acid, it forms *naphthasultam*-2 : 4-*disulphonic acid* (Bayer, D. R.-P. 79566; Eng. Pat. 4979 of 1893; Dressel and Kothe, Ber. 1894, 27, 2139).

(xi.) α-**Naphthylamine**-5 : 7-**disulphonic acid** is formed when acetyl-α-naphthylamine-5-sulphonic acid is sulphonated with 30 p.c., or acet-α-naphthalide with 35 p.c. anhydro-acid at 20°–30°, and the product deacetylated by boiling it with water (Badische, D. R.-P 69555 of 1892; Eng. Pat. 2370 of 1893; *cf.* Cassella, D. R.-P. 188505 of 1905). It can be obtained from α-naphthol-5 : 7-disulphonic acid by the ammonium sulphite method (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900). The *acid sodium* salt $NaH_3A_2+5H_2O$ forms very soluble needles and, in alkaline solution, couples with diazotised bases (*ibid.* D. R.-P. 69555 of 1892).

Reactions.—(1) By the diazo- reaction, or by the bisulphite method (Badische, D. R.-P. 115335 of 1899; Eng. Pat. 1387 of 1900), it yields α-*naphthol*-5 : 7-*disulphonic acid.*

(2) When heated with 75 p.c. caustic soda at 170°–180°, it yields 1-*amino*-5-*naphthol*-7-*sulphonic acid* (Badische, D. R.-P. 73276; Eng. Pat. 2370 of 1893).

(3) On sulphonation with 40 p.c. anhydro-acid at 120°–130°, it gives α-*naphthylamine*-

2 : 5 : 7-*trisulphonic acid* (Bayer, D. P. Anm. F. 7001; Eng. Pat. 17141 B of 1893).

(xii.) α-**Naphthylamine**-5 : 8-**disulphonic acid** is obtained from α-nitronaphthalene-5 : 8-disulphonic acid by reduction (Gattermann, Ber. 1899, 32, 1156); also from α-naphthol-5 : 8-disulphonic acid by the ammonium sulphite method (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900). Both the *acid* and the *acid sodium* salt $NaHA+1\frac{1}{2}H_2O$ form needles very sparingly soluble in water, but easily soluble in alkalis, giving greenish-yellow solutions (Bayer, D. R.-P. 70857 of 1892).

Reactions.—(1) When the *diazo-* compound is boiled with dilute sulphuric acid, *naphthasultone-5-sulphonic acid* is formed (Bayer, *l.c.*).

(2) When heated with 75 p.c. caustic potash at 150°–160°, it yields 1-*amino*-8-*naphthol*-5-*sulphonic acid* (Bayer, D. R.-P. 75055; Eng. Pat. 15269 of 1893), but with 60 p.c. caustic potash under pressure it gives 1 : 8-*dihydroxynaphthalene*-4-*sulphonic acid* (Bayer, D. R.-P. 77285 of 1892; Eng. Pat. 1227 of 1894).

(3) On sulphonation with 40 p.c. anhydro-acid at 80°–90°, it forms *naphthasultamdisulphonic acid*-D. (Bayer, D. R.-P. 79566; Eng. Pat. 4979 of 1893).

(xiii.) α-**Naphthylamine**-6 : 8-**disulphonic acid** can be obtained from α-naphthylamine-4 : 6 : 8-trisulphonic acid by boiling it with 75 p.c. sulphuric acid (Kalle, D. R.-P. 83146 of 1894); or from α-naphthol-6 : 8-disulphonic acid by the ammonium sulphite method (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900); and it is formed together with the 4 : 8-acid, when acetyl-α-naphthylamine-8-sulphonic acid is sulphonated with 25 p.c. anhydro-acid at the ordinary temperature, and the product boiled with water. Its *sodium* salt is much more soluble than that of the 4 : 8-acid, and in solution shows green fluorescence; its *acid sodium* salt, in needles, is easily soluble (Bayer, D. R.-P. 75084 of 1893).

Reactions.—(1) From its diazo- compound, *naphthasultone*-6-*sulphonic acid* and *naphthalene*-1 : 3-*disulphonic acid* have been prepared (Bayer, *l.c.*).

(2) When heated with 50 p.c. caustic potash solution at 180°–200°, it is converted into 1-*amino*-8-*naphthol*-6-*sulphonic acid* (Bayer, D. R.-P. 80853 of 1893).

α-Naphthylaminetrisulphonic Acids.

(i.) α-**Naphthylamine**-2 : 4 : 6-**trisulphonic acid** is formed when α-naphthylamine-6-sulphonic acid, or 4 : 6-disulphonic acid, is heated with 25 p.c. anhydro-acid (3·5 pts.) at 50°–60°, and afterwards with 70 p.c. anhydro-acid (1 pt.) at 80°–90° (Bayer, D. P. Anm. F. 7016; Eng. Pat. 15223 of 1893). The *acid sodium* salt forms needles, shows blue fluorescence in solution, and does not couple with diazotised bases.[1]

(ii.) α-**Naphthylamine**-2 : 4 : 7-**trisulphonic acid**. To obtain this acid, naphthionic acid is heated with 40 p.c. anhydro-acid at 120° (Höchst, D. R.-P. 22545; Eng. Pat. 2178 of 1882; *cf.* Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 125); *or* α-naphthylamine-7-sulphonic acid (or 4 : 7-disulphonic acid) is heated with 25 p.c. anhydro-acid (3·5 pts.) at 50°–60°, and afterwards with 70 p.c. anhydro-acid (1 pt.) at 80°–90° (Bayer, D. P. Anm. F. 6550; Eng. Pat. 15223 of 1893). It is also formed when 1 : 8-dinitronaphthalene is heated with sodium or ammonium sulphite solution at 70°–90°, and, after removal of the less soluble 4 : 7-compound, the α-naphthylsulphamino-2 : 4 : 7-trisulphonate is decomposed by a mineral acid (Höchst, D. R.-P. 215338 of 1908). The *acid sodium* salt forms small needles, shows blue fluorescence in alkaline solution, and does not couple with diazotised bases.

Reactions.—(1) Its *diazo-* compound, when warmed with dilute nitric acid, gives *naphthol-yellow*-S. (Höchst, *l.c.*).

(2) When heated with water at 230° it yields α-*naphthylamine*-2 : 7-*disulphonic acid*, but when boiled with 75 p.c. sulphuric acid, the 7-*monosulphonic acid* (Kalle, D. R.-P. 62634 of 1891).

(iii.) α-**Naphthylamine**-2 : 5 : 7-**trisulphonic acid** is obtained when α-naphthylamine-5-sulphonic acid is sulphonated with 35 p.c. anhydro-acid at 90°–120° (Cassella, D. R.-P. 188505 of 1905), *or* when α-naphthylamine-2 : 5- or 5 : 7-disulphonic acid is sulphonated with 40 p.c. anhydro-acid at 120°–130° (Bayer, D. P. Anm. F. 7001; Eng. Pat. 17141B of 1893). Its *acid sodium* salt forms needles easily soluble in water, and like the acid, shows green fluorescence in solution.

Reactions.—When heated with 50 p.c. caustic potash at 180°–200° under pressure, it yields 1-*amino*-5-*naphthol*-2 : 7-*disulphonic acid* (Bayer, *l.c.*; Cassella, *l.c.*); but when boiled with zinc dust and dilute caustic soda solution (Kalle, D. R.-P. 233934 of 1909) or reduced electrolytically (Bayer, Fr. Pat. 439010 of 1912)[1] it gives α-*naphthylamine*-2 : 7-*disulphonic acid*.

(iv.) α-**Naphthylamine**-3 : 5 : 7-**trisulphonic acid** is prepared by reduction of α-nitronaphthalene-3 : 5 : 7-trisulphonic acid (Cassella, D. R.-P. 75432 of 1891). Its salts are easily soluble and in solution show green fluorescence.

Reactions.—(1) By the diazo- reaction it can be converted into α-*naphthol*-3 : 5 : 7-*trisulphonic acid* (Kalle, D. P. Anm. K. 12732 of 1895).

(2) On fusion with caustic soda at 160°–170°, it yields 1-*amino*-5-*naphthol*-3 : 7-*disulphonic acid* (Cassella, *l.c.*).

(v.) α-**Naphthylamine**-3 : 6 : 8-**trisulphonic acid**, obtained by reduction of α-nitronaphthalene-3 : 6 : 8-trisulphonic acid (Koch, D. R.-P. 56058; Eng. Pat. 9258 of 1890), is also formed when sodium α-nitronaphthalene-3 : 8-disulphonate is warmed with sodium bisulphite solution (Fischesser & Co., D. R.-P. 76438 of 1893; Eng. Pat. 7046 of 1894). The *acid disodium* salt forms moderately soluble needles, and the *sodium* salt Na_3A+3H_2O easily soluble scales (Dressel and Kothe, Ber. 1894, 27, 2147).

Reactions.—(1) By the diazo- reaction it yields *naphthasultone*-3 : 6-*disulphonic acid* (Koch, *l.c.*), but when heated with water at 180°–250° under pressure, it gives α-*naphthol*-3 : 6 : 8-*trisulphonic acid* (Höchst, D. R.-P. 71495; Eng. Pat. 14301 of 1892).

(2) On fusion with caustic alkalis at 180°–190° it is converted into 1-*amino*-8-*naphthol*-3 : 6-*disulphonic acid* (Bayer, D. R.-P. 69722; Eng. Pat. 13443 of 1890).

(3) When heated with ammonia at 160°–180° under pressure it gives 1 : 3-*diaminonaphthalene*-

---

[1] For reduction product, *cf.* p. 592, footnote 1.

6 : 8-*disulphonic acid* (Kalle, D. R.-P. 90905; Eng. Pat. 9103 of 1895); and with aniline (or *p*-toluidine) at 150°–160° it yields *diphenyl*-(*di-p-tolyl*-)-1 : 3-*diaminonaphthalene*-6 : 8-*disulphonic acid* (Bayer, D. R.-P. 75296; Eng. Pat. 8898 of 1893; *cf.* Cassella, D. P. Anm. C. 13453 of 1905).

(4) By sulphonation with 25 p.c. anhydro-acid at 70°–80° it is converted into *naphthasultam*-3 : (4) : 6-*trisulphonic acid* (Bayer, D. R.-P. 84139 of 1894; Dressel and Kothe, *l.c.*).

(vi.) **α-Naphthylamine-4 : 6 : 8-trisulphonic acid** is obtained by reduction of α-nitronaphthalene-4 : 6 : 8-trisulphonic acid (Bayer, D. P. Anm. F. 7006; D. R.-P. 80741; Eng. Pat. 17141c of 1893; Kalle, D. R.-P. 82563 of 1893). Its solution in alkalis shows strong green fluorescence. It does not couple with diazotised bases.

Reactions.—(1) By the diazo- reaction (Bayer, D. P. Anm. 7004, 7006; Eng. Pat. 17141c of 1893), or by the bisulphite method (Bucherer, J. pr. Chem. 1904, [ii.] 70, 347), it gives *naphthasultone*-4 : 6-*disulphonic acid.*

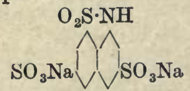
(2) When heated with water at 160°–220° under pressure it is converted into *α-naphthol*-6 : 8-*disulphonic acid* (Kalle, D. R.-P. 82563 of 1893), but when boiled with 75 p.c. sulphuric acid it gives *α-naphthylamine*-6 : 8-*disulphonic acid* (Kalle, D. R.-P. 83146 of 1894).

(3) On fusion with 70 p.c. caustic soda at 170°–175°, it is converted into 1-*amino*-8-*naphthol*-4 : 6-*disulphonic acid* (Bayer, D. R.-P. 80741; Eng. Pat. 17141c of 1893), and at a higher temperature into 1 : 8-*dihydroxynaphthalene*-3 : 5-*disulphonic acid* (Bayer, *l.c.*; *cf.* Cassella, D. R.-P. 108848 of 1895).

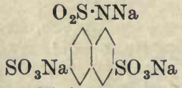
(4) On sulphonation with 25 p.c. anhydro-acid, it gives *naphthasultam*-(2) : 4 : 6-*trisulphonic acid* (Bayer, D. R.-P. 84140 of 1894).

NAPHTHASULTAM DERIVATIVES.

Introductory.—When warmed with anhydro-acid, α-naphthylaminesulphonic acids in which one of the sulphonic groups occupies the *peri*-position relatively to the NH_2 radicle may undergo dehydration, forming naphthasultams, in addition to further sulphonation. Contrasted with the sultones (p. 618), the stability of the sultams is remarkable. Neither by boiling a sultam with caustic alkali solutions, nor by heating it with ammonia is the anhydride ring attacked, although disruption of this ring (accompanied usually by partial de-sulphonation) can be effected if mineral acids be employed. These naphthasultamsulphonic acids, although not diazotisable, can be coupled with diazotised bases, provided the 4- position be free. The salts are of two types:



I. (acid)



II. (normal)

Those of type I are colourless, but those of type II are yellow and give yellow solutions, which show intense green or yellowish-green fluorescence.

(i.) **Naphthasultam** has been obtained from α-naphthylamine-8-sulphonic acid by dehydration with phosphorus oxychloride. It melts at 177°–178°, is converted into iso*naphthasultam* by acetic anhydride, and yields *nitronaphthasultam*, m.p. 253°, or 2 : 4-*dinitronaphthasultam*, m.p. 259°, on nitration (Dannerth, J. Amer. Chem. Soc. 1907, 29, 1320).

2 : 4-*Dinitronaphthasultam*, readily obtained from naphthasultam-2 : 4-disulphonic acid, has been introduced as a dyestuff. It is a pale-yellow powder, soluble in alkalis or alkali carbonates, but almost insoluble in water (Bayer, D. R.-P. 210222 of 1907).

(ii.) **Naphthasultam-2 : 4-disulphonic acid**-S, is obtained when α-naphthylamine-8-sulphonic or 4 : 8-disulphonic acid is sulphonated with 25–40 p.c. anhydro-acid at 80°–90° (Bayer, D. R.-P. 79566; Eng. Pat. 4979 of 1893; Aktienges., D. P. Anm. A. 3346; Eng. Pat. 2984 of 1893; Dressel and Kothe, Ber. 1894, 27, 2139), but the corresponding α-naphthylamine-2 : 4 : 8-trisulphonic acid is unknown.

Identification. — Naphthasultam-2 : 4-disulphonic acid forms a *disodium* salt Na_2HA+2H_2O in colourless needles, soluble in water without fluorescence, and a *trisodium* salt $Na_3A+8\frac{1}{2}H_2O$, in yellow scales, easily soluble in water with green fluorescence. It does not couple with diazotised bases.

Reactions.—(1) On fusion with caustic alkalis at 180°–200°, it yields 1-*amino*-8-*naphthol*-2 : 4-*disulphonic acid* (Bayer, *l.c.*; D. R.-P. 80668; Eng. Pat. 4979 of 1893; Aktienges., *l.c.*); and at 250°, 1 : 8-*dihydroxynaphthalene*-2 : 4-*disulphonic acid* (Bayer, *l.c.*; D. R.-P. 77703 of 1893; Cassella, D. R.-P. 81282 of 1893; Dressel and Kothe, *l.c.*).

(2) When heated at 110° with 40 p.c. sulphuric acid it gives *α-naphthylamine*-2 : 8-*disulphonic acid* (Kalle, D. R.-P. 75710 of 1893), but with 20 p.c. hydrochloric acid at 140°–150° *α-naphthylamine*-8-*sulphonic acid* is the product (Dressel and Kothe, *l.c.*).

(3) When heated in 50 p.c. sulphuric acid solution at 75°–80° with nitric acid of sp.gr. 1·2, it is converted successively into *nitronaphthasultamsulphonic acid* and 2 : 4-*dinitronaphthasultam* (Bayer, D. R.-P. 210222 of 1907).

(iii.) **Naphthasultam-3 : 6-disulphonic acid** is prepared by boiling the acid sodium salt of naphthasultam-3 : (4) : 6-trisulphonic acid with 20 p.c. sulphuric acid. The *trisodium* salt Na_3A+4H_2O forms easily soluble, small, yellow prisms. When boiled with 50 p.c. sulphuric acid it gives *α-naphthylamine*-3 : 6 : 8-*trisulphonic acid* (Bayer, D. R.-P. 84139 of 1894; Dressel and Kothe, Ber. 1894, 27, 2149).

(iv.) **Naphthasultamdisulphonic acid**-ε, obtained by heating sodium α-naphthylamine-3 : 8-disulphonate with 40 p.c. anhydro-acid at 80°–90°; and

(v.) **Naphthasultamdisulphonic acid**-D, obtained similarly from sodium α-naphthylamine-5 : 8-disulphonate, have been described (Bayer, D. R.-P. 79566; Eng. Pat. 4979 of 1893). On fusion with caustic alkali, each gives the corresponding 1-*amino*-8-*naphtholdisulphonic acid* (*ibid.* D. R.-P. 79566, 80668; Eng. Pat. 4979 of 1893).

(vi.) **Naphthasultam-3 : (4) : 6-trisulphonic acid** is formed when the acid sodium salt of α-naphthylamine-3 : 6 : 8-trisulphonic acid is heated with 25 p.c. anhydro-acid at 80° until a test no longer reacts with nitrite. The *acid sodium* salt Na_3HA+4H_2O forms easily soluble, minute needles; the *sodium* salt Na_4A+4H_2O, easily soluble, yellow granules; and the *barium* salt, a very sparingly soluble yellow powder (Bayer, D. R.-P. 84139 of 1894; Dressel and Kothe, Ber. 1894, 27, 2147).

Reactions.—(1) On digestion with 75 p.c. caustic potash solution at 130°, it yields 1-*amino*-8-*naphthol*-3 : 6-*disulphonic acid* (Bayer, *l.c.*; Dressel and Kothe, *l.c.*).

(2) When boiled with 20 p.c. sulphuric acid it is converted into *naphthasultam*-3 : 6-*disulphonic acid*; and with 50 p.c. sulphuric acid into *α-naphthylamine*-3 : 6 : 8-*trisulphonic acid* (Bayer, *l.c.*; Dressel and Kothe, *l.c.*).

(vii.) **Naphthasultam-(2) : 4 : 6-trisulphonic acid** is obtained when the acid sodium salt of α-naphthylamine-4 : 6 : 8-trisulphonic acid is heated with 25 p.c. anhydro-acid at 80°–90° until a test no longer reacts with nitrite (Bayer, D. R.-P. 84140 of 1894). The *acid sodium* salt forms easily soluble needles; the *sodium* salt Na_4A+6H_2O, easily soluble, minute yellow prisms. When heated with caustic alkali at 150°–160°, it is converted into 1-*amino*-8-*naphthol*-(2) : 4 : 6-*trisulphonic acid* (Bayer, D. R.-P. 84597 of 1894).

CHLORO-α-NAPHTHYLAMINES.

8-**Chloro-α-naphthylamine** can be obtained from 1 : 8-diaminonaphthalene by allowing its azimide to interact with copper powder or with cuprous salts and hydrochloric acid at 30°. The base forms needles, m.p. 98° (Badische, D. R.-P. 147852 of 1903; *cf.* Atterberg, Ber. 1876, 9, 1730).

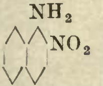
8-**Chloro-α-naphthylamine**-5-**sulphonic acid** is formed similarly from the azimide of 1 : 8-diaminonaphthalene-4-sulphonic acid (Badische, *l.c.*), and when heated with caustic soda solution under pressure at 190°–195° yields 1-*amino*-8-*naphthol*-5-*sulphonic acid* (Badische, D. R.-P. 112778 of 1899).

Several *α-chloro-α-naphthylaminesulphonic acids*, prepared by nitrating α-chloronaphthalenesulphonic acids and reducing the products, have been used in making azo- dyes, but not described in detail (Read, Holliday & Sons, Eng. Pats. 13999 of 1897; 11736 of 1898).

8-**Chloro-α-naphthylamine-3 : 6-disulphonic acid** is prepared similarly from the azimide of 1 : 8-diaminonaphthalene-3 : 6-disulphonic acid. With diazotised bases it forms *azo-* dyes; on fusion with caustic alkali it yields 1-*amino*-8-*naphthol*-3 : 6-*disulphonic acid*, and when heated with dilute sulphuric acid under pressure it is converted into 8-*chloro-α-naphthol*-3 : 6-*disulphonic acid*, from which 1 : 8-*dihydroxynaphthalene*-3 : 6-*disulphonic acid* can be obtained by fusion with alkali (Badische, D. R.-P. 147852 of 1903).

2 : 4-**Dichloro-α-naphthylaminesulphonic acid** is formed when 2 : 4-dichloroacet-α-naphthalide is sulphonated with 23 p.c. anhydro-acid below 45°, and the product deacetylated by boiling it with water. It is sparingly soluble in water; its *sodium* salt forms scales, and its *zinc* and *magnesium* salts long needles. When its sparingly soluble, crystalline *diazo-* compound is heated with sodium carbonate solution at 60°, it is converted into 4-*chloro*-1-*diazo-β-naphtholsulphonic acid* (Badische, D. R.-P. 153298; Eng. Pat. 16995 of 1903).

NITRO-α-NAPHTHYLAMINES.



(i.) 2-**Nitro-α-naphthylamine**, mixed with the 4-derivative, is obtained by nitrating acet-α-naphthalide in acetic acid solution. The product consists of crusts of a molecular compound (m.p. 171°) of the 2- and 4- derivatives mixed with needles of the 1 : 4- derivative, which can be separated mechanically and recrystallised from alcohol. By limited hydrolysis of the molecular compound with aqueous alcoholic caustic potash, 4-nitro-α-naphthylamine can be separated from the 2-nitroacet-α-naphthalide, which is most conveniently hydrolysed by boiling with alcoholic hydrochloric acid (Lellmann and Remy, Ber. 1886, 19, 797; Lellmann, *ibid.* 1887, 20, 892).

Properties.—It crystallises from alcohol in reddish-yellow, monoclinic prisms, m.p. 144° (Lellmann, Ber. 1884, 17, 112), and yields 2-*nitro-α-naphthol* when boiled with excess of caustic potash solution. Its *acetyl* derivative forms yellow needles, m.p. 199°.

(ii.) 4-**Nitro-α-naphthylamine,** prepared from 4-nitroacet-α-naphthalide (*v. supra*) by hydrolysis with alcoholic potash (Liebermann, Annalen, 1876, 183, 232), can also be obtained by mixing α-naphthyloxamic acid with nitric acid (sp.gr. 1·36) at 30°–40°, and hydrolysing the product with alkalis or mineral acids (Lange, D. R.-P. 58227 of 1890); *or* by heating 4-nitro-α-chloronaphthalene with 8 p.c. alcoholic ammonia at 150°–170° (Griesheim, D. R.-P. 117006; Eng. Pat. 7692 of 1900).

Properties.—It crystallises from alcohol in orange needles, m.p. 191°, and yields 4-*nitro-α-naphthol* when boiled with aqueous caustic potash (Andreoni and Biedermann, Ber. 1873, 6, 342). Its *acetyl* derivative forms yellow needles, m.p. 190°. From its *diazo-* compound, *azo-* dyes have been obtained (Höchst, D. R.-P. 68022; Eng. Pat. 18783 of 1891).

(*a*) 4-*Nitro-α-naphthylamine*-5-*sulphonic acid* is formed when α-naphthylamine-5-sulphonic acid, dissolved in 20 times its weight of sulphuric acid, is nitrated below 10°. It forms sparingly soluble, small needles, its *sodium* salt yellow scales (Bayer, D. R.-P. 133951; Eng. Pat. 9498 of 1899; *cf.* Levinstein, Eng. Pat. 13178 of 1899), and its *diazo-* compound furnishes *azo-* dyes (Bayer, D. R.-P. 118124, 119662; Eng. Pat. 9498 of 1899; Badische, D. R.-P. 151042 of 1903).

(*b*) 4-*Nitro-α-naphthylamine*-6-*sulphonic* and 7-*sulphonic acids* are obtained by the nitration of the corresponding α-naphthylaminesulphonic acids (Cassella, D. R.-P. 73502 of 1892), or their acetyl derivatives (*ibid.* D. R.-P. 74177; Eng. Pat. 15444 of 1893) in sulphuric acid solution. The 6-acid and salts are less soluble than the 7-isomerides. From the diazotised acids, *azo-* dyes have been obtained (*cf.* Bayer, D. R.-P. 118124; Eng. Pat. 9498 of 1899; Aktienges., D. R.-P. 222890 of 1908, 222931 of 1909).

(iii.) 5-**Nitro-α-naphthylamine** can be prepared by the partial reduction of 1:5-dinitronaphthalene with alcoholic hydrogen sulphide (Beilstein and Kuhlberg, Annalen, 1873, 169, 87); *or* by hydrolysis of 5-nitro-α-naphthylamine-4-sulphonic acid (Nietzki and Zübelen, Ber. 1889, 22, 452); *or*, mixed with the 4- and 8- compounds, by nitration of α-naphthylamine dissolved in 10 times its weight of sulphuric acid (Meldola and Streatfeild, Chem. Soc. Trans. 1893, 63, 1055).

Properties.—It crystallises in small, red needles, m.p. 119°. Its *acetyl* derivative forms large, brown prisms, m.p. 220° (Höchst, D. R.-P. 145191 of 1902), and its *sulphate* is less soluble than that of the 4- or 8-isomeride.

(*a*) 5-*Nitro-α-naphthylamine*-2-*sulphonic acid* can be prepared by nitrating α-naphthylamine-2-sulphonic acid in sulphuric acid solution below 15°. The acid and its *diazo-* compound are sparingly soluble (Cassella, D. R.-P. 70890 of 1892).

(*b*) 5-*Nitro-α-naphthylamine*-4-*sulphonic acid* is formed when acetyl-α-naphthylamine-4-sulphonic acid, mixed with sulphuric acid, is nitrated in the cold, and the product deacetylated by boiling it with dilute acid. The *acid* HA crystallises in needles; the *diazo-* compound forms *azo-* dyes (Nietzki and Zübelen, Ber. 1889, 22, 452).

(*c*) A *nitro-α-naphthylaminesulphonic acid*, probably isomeric with these acids, is said to be obtained by reduction of 1 : 5-dinitronaphthalene-3-sulphonic acid with sodium sulphite or bisulphite (Höchst, D. R.-P. 117268 of 1900).

(iv.) **8-Nitro-α-naphthylamine** occurs to the extent of 6–8 p.c. in the product obtained by the nitration of α-naphthylamine in sulphuric acid solution. It crystallises in red scales, m.p. 96°–97°, and its *acetyl* derivative in needles, m.p. 187°–188° (Meldola and Streatfeild, *l.c.*).

(v.) **2 : 4-Dinitro-α-naphthylamine** can be obtained from dinitroacet-α-naphthalide by hydrolysis with 50 p.c. sulphuric acid at 100° (Liebermann, Annalen, 1876, 183, 274; Meldola and Forster, Chem. Soc. Proc. 1893, 9, 8); or from 2 : 4-dinitro-α-naphthol by heating it with alcoholic ammonia under pressure at 190°–200° (Witt, Ber. 1886, 19, 2033). It crystallises in yellow needles, m.p. 237°; its *acetyl* derivative in yellow needles, m.p. 250°. When heated with aqueous alkalis, it is converted into 2 : 4-*dinitro-α-naphthol.*

(vi.) **4 : 5-Dinitro-α-naphthylamine** is formed by the nitration of 5-nitroacet-α-naphthalide suspended in sulphuric acid, and hydrolysis of the dinitroacet-α-naphthalide by boiling it with dilute acid. It crystallises in orange scales, m.p. 236°; its *acetyl* derivative in yellow needles, m.p. 244° (Badische, D. R.-P. 145191, 158499 of 1902).

(ii.) **β-Naphthylamine** (β-aminonaphthalene) was first prepared by reduction of 1-bromo-β-nitronaphthalene with tin and hydrochloric acid (Liebermann and Scheiding, Annalen, 1876, 183, 264). It is obtained, mixed with varying proportions of ββ′-dinaphthylamine, when β-naphthol is heated with ammonia at 160° under pressure for 60–70 hours (Badische, D. R.-P. 14612 of 1880), with twice its weight of ammonia-zinc chloride at 200°–210° for 2 hours (Merz and Weith, Ber. 1880, 13, 1300), or with 4 times its weight of anhydrous or hydrated ammonia-calcium chloride at 270°–280° for 8 hours, the yield being 80 p.c., and of ββ′-dinaphthylamine 12–14 p.c., under these conditions (Benz, *ibid.* 1883, 16, 19).

Preparation.—β-Naphthol is heated under pressure with 20–30 p.c. ammonia solution at 200° for a day (Schultz, Chemie des Steinkohlenth., 3rd ed., I, 85), or with caustic soda and ammonium chloride for 60–70 hours at 150°–160° (Badische, *l.c.*); or its dry sodium compound is heated with ammonium chloride at 200° for 24 hours (Oehler, Eng. Pat. prov. spec. 2516 of 1880). The crude product is extracted two or three times with hot caustic soda solution to remove unchanged β-naphthol, dried and finally distilled to remove ββ′-dinaphthylamine.

The conversion can be more easily achieved by the bisulphite method, β-naphthol (1 kilo.) being heated with 40 p.c. ammonium sulphite solution (1·5 litres) and 20 p.c. ammonia (1 litre) in an autoclave at 100°–150° until the change is complete. When cold the β-naphthylamine is separated by filtration, and the filtrate used for a subsequent operation. The product may contain small quantities of β-naphthol and ββ′-dinaphthylamine, which are easily removed, the yield of β-naphthylamine being almost quantitative (Bucherer, J.pr. Chem. 1904, [2] 69, 88; Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—It crystallises from alcohol in colourless, lustrous scales, melts at 112°, boils at 294° (Liebermann and Jacobson, Annalen, 1882, 211, 41), is only slightly volatile with steam, and dissolves easily in hot but only sparingly in cold water. The solutions of the base show blue fluorescence; those of its salts are non-fluorescent. Unlike α-naphthylamine, it gives no colour reactions with ferric chloride, chromic acid, bleaching powder, or nitrous acid. The *hydrochloride* $B{\cdot}HCl$ forms non-fluorescent scales, easily soluble, and the *nitrate* $B{\cdot}HNO_3$, and *sulphate* $B_2{\cdot}H_2SO_4$, scales sparingly soluble in water. The *platinichloride* crystallises in scales, and the *picrate*, from alcohol, in long yellow needles, m.p. 195°.

Reactions.—(1) From its *diazo-* compound *β-naphthol* (Liebermann, Annalen, 1876, 183, 268), and many *azo-* dyes have been obtained.

(2) On reduction in boiling amyl alcohol solution with sodium, it yields ac.-*tetrahydro-β-naphthylamine* (‘Thermine’) with about 3–4 p.c. of the *ar.*- derivative (Bamberger and Kitschelt, Ber. 1890, 23, 876).

(3) When heated alone, or with calcium or zinc chloride, it is converted partially into *ββ′-dinaphthylamine* and ammonia (Merz and Weith, Ber. 1881, 14, 2343; Benz, *l.c.*), but with sodamide, mixed with naphthalene, at 230° it gives 1 : 6-*diaminonaphthalene* (Sachs, *ibid.* 1906, 39, 3022).

(4) By digestion with bleaching powder and water at 40°–50°, it forms *αβ-naphthazine* (Claus and Jaeck, D. R.-P. 78748 of 1892).

Tests.—β-Naphthylamine should be free from β-naphthol and ββ′-dinaphthylamine, and therefore should be completely soluble in dilute hydrochloric acid. It should also have the right melting-point.

Acyl derivatives. Acetyl-β-naphthylamine (*acet-β-naphthalide*), obtained together with about 14 p.c. of ββ′-dinaphthylamine when β-naphthol is heated with ammonium acetate at 270°–280° for 8 hours (Merz and Weith, Ber. 1881, 14, 2343; Calm, *ibid.* 1882, 15, 610), is best prepared by boiling β-naphthylamine with 1·25–1·5 times its weight of glacial acetic acid for 12 hours, the ββ′-dinaphthylamine (about 10 p.c.) formed being readily separated by crystallisation from alcohol, in which it is only sparingly soluble

(Liebermann and Jacobson, Annalen, 1882, 211, 42).

Properties.—It crystallises in lustrous scales, m.p. 132° (Cosiner, Ber. 1881, 14, 59), dissolves readily in alcohol, sparingly in water, and is more easily hydrolysed by dilute acids than by alkalis (Calm, *l.c.*).

Acetyl-β-naphthylaminesulphonic acids. Two methods can be used for preparing these acids. In the first, acet-β-naphthalide is sulphonated with sulphuric acid, the product being *acetyl-β-naphthylamine*-5-*sulphonic acid* at 20°–30°, or *acetyl-β-naphthylamine*-7-*sulphonic acid* at 150°–160° (Kinzlberger & Co., D. P. Anm. K. 5732 of 1887). In the second, a solution of sodium β-naphthylamine- 5-, 6-, 7-, or 8-sulphonate is warmed with acetic anhydride at 50°–60° for a few minutes (Höchst, D. R.-P. 129000 of 1899; Eng. Pat. 17366 of 1898). The sodium salts obtained by salting out, and the derived acids, are crystalline but much more soluble in water than the corresponding naphthylamine compounds (Höchst, *l.c.*); they can be deacetylated by boiling the acids with water (Kinzlberger & Co., *l.c.*).

β-Naphthylsulphamic acid is formed when β-naphthylamine-1-sulphonic acid is heated at 230° (Tobias, D. R.-P. 74688; Eng. Pat. 15404 of 1893), and its *ammonium* salt when chlorosulphonic acid interacts with β-naphthylamine in chloroform solution, and the product is neutralised by ammonia (Traube, Ber. 1894, 24, 363). Fairly stable in neutral or alkaline solution, this substance decomposes, when warmed in acid solution, into β-naphthylamine and sulphuric acid.

β-Naphthylsulphamino-6:8-disulphonic acid is formed when β-naphthylamine-6:8-disulphonic acid is heated with 40 p.c. anhydro-acid at 90°. Its *barium* salt $Ba_3A_2+10H_2O$ forms sparingly soluble, orange-yellow needles; and the *potassium* salt K_3A+H_2O, orange-red needles. When its acid solution is warmed, it yields *β-naphthylamine*-6:8-*disulphonic* acid, while with 40 p.c. anhydro-acid at 130° it is converted into *β-naphthylamine*-3:6:8-*trisulphonic acid* (Dressel and Kothe, Ber. 1894, 27, 2153).

Alkyl derivatives.—*Methyl-β-naphthylamine*, an oil, b.p. 296° (Pechmann and Heinze, Ber. 1897, 30, 1785); *dimethyl-β-naphthylamine*, scales, m.p. 46°, b.p. 305° (Hantzsch, Ber. 1880, 13, 2054; Bamberger and Müller, *ibid.* 1889, 22, 1306; Pinnow, *ibid.* 1889, 32, 1405); *ethyl-β-naphthylamine* (Henriques, Ber. 1884, 17, 2668), an oil, b.p. 305° under 716 mm. (Bamberger and Müller, Ber. 1889, 22, 1297; O. Fischer, *ibid.* 1893, 26, 193) or 315°–316° under 760 mm. (Vaubel, Chem. Zeit. 1903, 27, 278); *diethyl-β-naphthylamine* (Morgan, Chem. Soc. Trans. 1900, 77, 823), an oil, b.p. 316° under 717 mm. (Bamberger and Williamson, Ber. 1889, 22, 1760).

Alkyl-β-naphthylaminesulphonic acids have been obtained by heating solutions of the respective sodium β-naphthylaminesulphonates with the alkyl chloride or sodium alkylsulphate under pressure (Bayer, D. R.-P. 41506 of 1886). The derived *disazo-* dyes are much bluer in shade than those from the non-alkylated acids (Bayer, D. R.-P. 41510, 41761, 42771; Eng. Pat. 17083 of 1886; D. R.-P. 43169, 43204 of 1887).

Ethyl-β-naphthylaminesulphonic acids. By sulphonating ethyl-β-naphthylamine with weak anhydro-acid at a moderate temperature, the 5-*sulphonic acid*, mixed with a small quantity of the 8-*acid*, is formed; with monohydrate at 140° the 7-*acid* is obtained; and with 20 p.c. anhydro-acid at 110°–120°, the 5:7-*disulphonic acid* is produced. The disulphonic acid, when fused with caustic alkali, yields *ethyl*-2-*amino*-5-*naphthol*-7-*sulphonic* acid (Leonhardt, D. R.-P. 95624; Eng. Pat. 10669 of 1895).

Aryl derivatives.—Phenyl- and tolyl-β-naphthylamines can be prepared by heating β-naphthol with the respective base (or its hydrochloride) under pressure at 200°–210° for 10 hours either alone (Graebe, Ber. 1880, 13, 1850; Badische, D. R.-P. 14612 of 1880; *cf.* Oehler, Eng. Pat. 2516 (prov. spec.) of 1880), or with the addition of ammonia-zinc chloride (Merz and Weith, Ber. 1880, 13, 1300). The yield is almost quantitative when β-naphthol (1 mol.), the base (2 mols.), and anhydrous calcium chloride (1 mol.) are heated together at 280° under pressure for 9 hours (Friedlaender, Ber. 1883, 16, 2077 *et seq.*). These products dissolve in the ordinary organic solvents, and, when heated with hydrochloric acid under pressure at 240°, regenerate β-naphthol and the base (Friedlaender, *l.c.*). *Phenyl-β-naphthylamine* forms needles, m.p. 108°, b.p. 395°–395·5° (Crafts, Annalen, 1880, 202, 5), and in solution shows blue fluorescence; o-*tolyl-β-naphthylamine* scales, m.p. 95°–96°; p-*tolyl-β-naphthylamine* scales, m.p. 104°, and in solution shows violet-blue fluorescence (Witt, Ber. 1887, 20, 578).

Phenyl- and (o- and p- *tolyl*)-*β-naphthylaminesulphonic acids.* Of these derivatives the 5-, 6-, 7-, or 8-sulphonic, and the 3:6- or 6:8-disulphonic acid can be obtained by heating the corresponding β-naphthylaminesulphonic acid with aniline (*o*- or *p*-toluidine) and its hydrochloride at 160°–170° (Bayer, D. R.-P. 70349, 71158, 71168; Eng. Pat. 7337A of 1892). They can also be obtained from the corresponding β-naphtholsulphonic acids by heating them with 40 p.c. sodium bisulphite solution and aniline (toluidine) in a reflux apparatus (Badische, D. R.-P. 122570; Eng. Pat. 18726 of 1900). Less satisfactory results follow when the corresponding β-naphtholsulphonic acid is heated with the base and its hydrochloride at 190°–200° (Aktienges., D. R.-P. 38424 of 1886). By sulphonation of phenyl-β-naphthylamine (Zimmer, D. R.-P. 45940; Eng. Pat. 13798 of 1888; Clayton Aniline Co., D. R.-P. 53649; Eng. Pat. 10934 of 1889) or of *o*-tolyl-β-naphthylamine (Clayton Aniline Co., D. R.-P. 57370 of 1889; Eng. Pat. 5155 of 1890), with 4 times its weight of monohydrate at temperatures below 50°, two isomeric sulphonic acids, A and B, result which have been identified as the 5- and 8- acids respectively (Lesser, Ber. 1894, 27, 2364; Bayer, *l.c.*).

ββ′-Dinaphthylamine[1] $(C_{10}H_7)_2NH$ is formed (3·5 p.c.) when β-naphthylamine is heated at 280°–300° during 8 hours (Benz, Ber. 1883, 16, 14); and in larger amount when it is heated with calcium chloride at 260°–280° (Merz and Weith, *ibid.* 1881, 14, 2343); also when it is

---

[1] *αα′-Dinaphthylamine*, obtained by heating α-naphthylamine with its hydrochloride at 150°, forms scales, m.p. 113° (Girard and Vogt, Bull. Soc. chim. 1872, [ii.] 18, 68; *cf.* Calm, Ber. 1882, 15, 615: Benz, *ibid.* 1883, 16, 16). *αβ′-Dinaphthylamine*, obtained by heating α-naphthylamine with β-naphthol and calcium chloride, forms prisms, m.p. 110°–111° (Benz, *l.c.*).

boiled with glacial acetic acid for some hours (Liebermann and Jacobson, Annalen, 1882, 211, 43), or heated at 170°–190° in a current of hydrogen chloride (Klopsch, Ber. 1885, 18, 1586). A secondary product in the manufacture of β-naphthylamine (*q.v.*), it is obtained in large amount when β-naphthol is heated with ammonia-zinc chloride at 280° (Merz and Weith, *l.c.*; Calm, Ber. 1882, 15, 614; Benz, *l.c.*), *or* with β-naphthylamine (Badische, D. R.-P. 14612 of 1880), *or* with β-naphthylamine and calcium chloride at 270°–280° (Benz, *l.c.*). It is also formed by heating β-naphthylamine (2 mols.) with sodium bisulphite solution (1 mol.) and alcohol at 90°–100° for 24 hours (Bayer, D. R.-P. 114974; Eng. Pat. 22804 of 1899).

Properties.—It crystallises in scales, m.p. 171°, b.p. 471° (Ris, Ber. 1887, 20, 2619). Dissolved in alcohol or benzene, it shows intense blue fluorescence. When heated with hydrochloric acid at 240° it yields β-naphthylamine and β-naphthol quantitatively (Ris, *ibid.* 1886, 19, 2017), and, with sulphuric acid, mixtures of the isomeric β-naphthylamine- and β-naphtholsulphonic acids (Sandoz, D. R.-P. 64859 of 1891).

ββ′-Dinaphthylamine-7 : 7′-*disulphonic acid* has been prepared from β-naphthylamine-7-sulphonic acid by the bisulphite method (Bayer, *l.c.*); 5 : 5′-*dihydroxy-ββ′-dinaphthylamine*-7 : 7′-*disulphonic acid* from 2-amino-5-naphthol-7-sulphonic acid by the bisulphite method (Bayer, *l.c.*), or by heating it with water under pressure at 200° (Bayer, D. R.-P. 121094 of 1900; Eng. Pat. 24296 of 1899); and the 8 : 8′-*dihydroxy*-6 : 6′-*disulphonic acid* from 2-amino-8-naphthol-6-sulphonic acid by the latter method (*ibid.*). The dihydroxy- compounds couple with diazotised bases, yielding *azo*- dyes (Bayer, D. R.-P. 114841; Eng. Pat. 24296 of 1899).

β-NAPHTHYLAMINESULPHONIC ACIDS.

Introductory. — β-Naphthylaminesulphonic acids are obtained by the following methods:—

(1) By sulphonation of β-naphthylamine or of the derived β-naphthylaminesulphonic acids. The product in most cases is a mixture of acids, from which the more soluble constituents cannot easily be obtained pure.

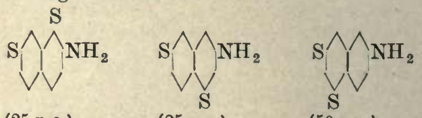
(2) By heating the sodium salts of the corresponding β-naphtholsulphonic acids with ammonia under pressure. Except with β-naphthol-1-sulphonic acid and its derivatives, this reaction gives a satisfactory yield of a pure product, and the ease with which it takes place increases with the number of sulphonic groups in the molecule.

(3) By heating the sodium salts of the corresponding β-naphtholsulphonic acids with ammonium bisulphite solution and ammonia at 100°–150°. The process is applicable to all acids which do not contain a 4-sulphonic group, and is of value for the production of the 6-, or 7-, or 8-monosulphonic acid, as each of the corresponding β-naphtholsulphonic acids is obtained in a pure state much more easily from β-naphthol than is the β-naphthylaminesulphonic acid from the mixed acids of the sulphonation melt (*cf.* Bucherer, J. pr. Chem. 1904, [ii.] 70, 357).

Four monosulphonic acids and one disulphonic acid, all of them heteronucleal, are known to be formed by the sulphonation of β-naphthylamine; six disulphonic acids by the sulphonation of monosulphonic acids; and six trisulphonic acids by the sulphonation of disulphonic acids. For the sulphonation of β-naphthylamine, sulphuric acid is used, but for that of the monosulphonic acids 20 p.c. anhydro-acid, and for that of the disulphonic acids 40 p.c. anhydro-acid are required, the end of the di- or tri-sulphonation being ascertained either by the solubility of the product or by the behaviour of the diazotised acid with R-salt. The effects of concentration of the acid, of temperature and of duration of the reaction on the nature of the product correspond with those traced out in other cases of sulphonation. It should be noted that sulphonation in the 1-position occurs only when at least one other sulphonic group is present in the molecule, and that the 1-sulphonic group when present is the first to be eliminated by hydrolysis.

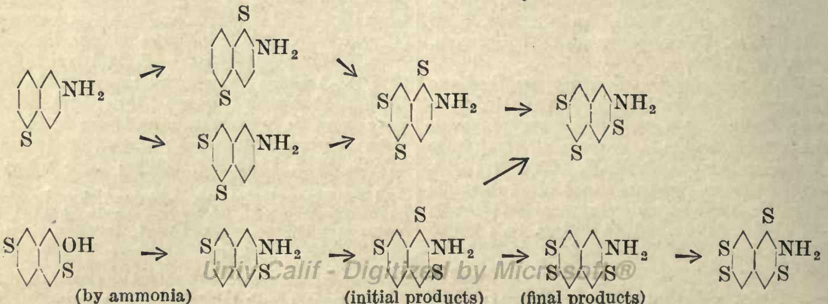
To illustrate the order in which sulphonic groups are introduced, the following examples of di- and of tri-sulphonation may be given:—

(*a*) When β-naphthylamine-7-sulphonic acid is sulphonated with 4 times its weight of 25 p.c. anhydro-acid at 15°, the products and their percentage amounts are—



(25 p.c.) (25 p.c.) (50 p.c.)

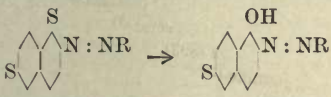
(*b*) When β-naphthylaminedisulphonic acids are sulphonated with 40 p.c. anhydro-acid at 140°, trisulphonic acids are formed, the nature of which depends on the duration of the reaction. In the scheme, two examples of the effect of prolonged heating are shown, the changes which the 1 : 3 : 7-trisulphonic acid undergoes in the presence of the anhydro-acid being particularly noteworthy—



(by ammonia) (initial products) (final products) β-Naphthylaminemonosulphonic acids are very sparingly soluble in water. The di- and tri-sulphonic acids dissolve easily in water, but their acid salts are less soluble, and are precipitated instead of the acids when a mineral acid is added to solutions of their alkali salts.

As sources of azo- dyes, the β-naphthylaminesulphonic acids are less important than the α- compounds. Many of the dyes obtained by coupling them with tetrazo- derivatives are of little value (*cf.* Cassella, D. R.-P. 46711 of 1888), and, moreover, the β-acids cannot be used as middle components in polyazo- dyes, as the NH_2 radicle, after coupling has taken place in the *ortho-* position relatively to it, does not admit of being itself diazotised (*cf.* Bayer, D. R.-P. 79816; Eng. Pat. 9972 of 1893).

β-Naphthylaminesulphonic acids containing either 1- or 8-sulphonic groups do not form azo-dyes, but diazoamino- compounds when coupled with diazotised bases. Those containing a 1-sulphonic group exchange it for hydroxyl, giving 2-diazo-α-naphthol-derivatives when diazotised and afterwards warmed at 50°–60° with excess (2 mols.) of sodium carbonate solution:



β-Naphthylaminesulphonic acids containing a 4-sulphonic group, like the *meta*-sulphonic acids from α-naphthylamine, yield hydroxytoluic acids by prolonged heating with caustic alkali solution at 280°, but, unlike them, are not converted into diaminonaphthalenes when heated under pressure with ammonia.

Unlike α-naphthylaminesulphonic acids which, when digested with caustic alkali solution, exchange the NH_2 for an OH radicle, β-naphthylaminesulphonic acids, under similar conditions, retain the amino- group, exchanging a SO_3H for the OH radicle, thus furnishing aminonaphtholsulphonic acids of which they are an important source.

β-Naphthylaminemonosulphonic Acids.[1]

(i.) β - **Naphthylamine - 1 - sulphonic acid** (Tobias's acid) is obtained when sodium β-naphthol-1-sulphonate is heated with 4–5 times its weight of 15–20 p.c. aqueous ammonia for 20 hours at 220°–230°. The β-naphthylamine, also formed, is removed from the cold product by filtration, and the acid separated from unchanged β-naphtholsulphonate by precipitation with hydrochloric acid (Tobias, D. R.-P. 74688; Eng. Pat. 15404 of 1893). The formation of β-naphthylamine can be avoided if the naphtholsulphonate be heated with 40 p.c. ammonium sulphite solution and 20 p.c. ammonia at 100°–150° until the reaction is complete, and the product afterwards acidified (Bucherer, J. pr. Chem. 1904, [ii.] 70, 357; Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *acid* separates in sparingly soluble anhydrous scales from hot, or in efflorescent hydrated needles from cold water; the *sodium* salt $NaA+H_2O$, in easily soluble scales which give a non-fluorescent solution (Tobias, *l.c.*). It is convertible into *β-chloronaphthalene-1-sulphonyl chloride*, m.p. 76° (Armstrong and Wynne, Chem. Soc. Proc. 1895, 11, 238), and into 1 : 2-*dichloronaphthalene* (Tobias, *l.c.*; Armstrong and Wynne, *l.c.*).

Reactions.—(1) From its sparingly soluble, crystalline *diazo-* compound, *β-naphthol-1-sulphonic acid* (Tobias) and *azo-* dyes (Badische, D. R.-P. 112833; Eng. Pat. 25511 of 1899) have been obtained.

(2) When heated at 230° in a dry, neutral atmosphere, the sodium salt is converted into *sodium β-naphthylsulphamate* (Tobias, *l.c.*).

(3) On sulphonation with 20 p.c. anhydro-acid it yields *β-naphthylamine-1 : 5-disulphonic acid* (Armstrong and Wynne, *l.c.*).

(ii.) β-**Naphthylamine-4-sulphonic acid** is obtained when β-naphthol-4-sulphonic acid is heated with ammonia under pressure (Kalle, D. R.-P. 78603 of 1893).

Identification.—The *acid* $HA+H_2O$ crystallises in sparingly soluble, long, white needles; the *potassium* salt $KA+1\frac{1}{2}H_2O$ in small needles; and the *sodium* salt $NaA+4H_2O$ in scales. The solution of the sodium salt shows violet fluorescence.

Reaction.—When heated with 60 p.c. caustic soda solution at 230°–280° under pressure, it is converted into *o-toluic acid* (Kalle, D. R.-P. 79028 of 1893).

(iii.) β-**Naphthylamine-5-sulphonic acid** ([γ-] acid; Dahl acid) constitutes about 40 p.c. of the product obtained when β-naphthylamine is heated with 3 times its weight of sulphuric acid at 100°–105° (*v.* 8-acid); about 55 p.c. of that obtained when β-naphthylamine sulphate is sulphonated at 15°–20° with 3 times its weight of sulphuric acid (Dahl, D. R.-P. 32276 of 1884); and 68–70 p.c. of that obtained when β-naphthylamine is sulphonated with 3 times its weight of 20 p.c. anhydro-acid at 70°–80° Dahl, D. R.-P. 29084; Eng. Pat. 7712 of 1884). It is also obtained when acet-β-naphthalide is sulphonated at 20°–30° with 5 times its weight of sulphuric acid, and the product deacetylated by boiling it with water (Kinzlberger & Co., D. P. Anm. K. 5732 of 1887).

Preparation.—β-Naphthylamine sulphate is stirred with 3 times its weight of sulphuric acid at 15°–20° during 48–70 hours until sulphonated. The product, converted into sodium salt, is extracted by boiling 90–95 p.c. alcohol; the alcoholic filtrate evaporated; and the residue, which contains small quantities of the 6- and 7-salts in addition to the 5-salt, is freed from these by conversion into and fractional crystallisation of the barium salts. As the barium or calcium salt of the 5-acid is easily soluble, a partial separation can be effected previous to the extraction with alcohol by converting the sulphonation product into the barium or calcium salt, and allowing the 6-, 7-, and 8-salts to separate, as far as possible, from the concentrated solution (Dahl, D. R.-P. 32271 of 1884).

Identification.—The *acid* HA forms needles or scales, soluble in 260 parts of boiling or 1300 parts of cold water. The salts crystallise well, dissolve easily in water, and, like the acid, show reddish-blue fluorescence in dilute solution.

---

[1] In every case where the constitution of a β-naphthylaminesulphonic acid is given, the NH_2 group is supposed to be in the position '2.'

The *barium* salt $BaA_2+2\frac{1}{2}H_2O$ forms granular aggregates; the *calcium* salt CaA_2+11H_2O, needles soluble in 11 parts of cold water, the *potassium* salt $KA+H_2O$, small rhombohedra, the *sodium* salt $NaA+5H_2O$, prisms, soluble in 10 parts of boiling 95 p.c. alcohol, the *ammonium* salt, plates (*cf.* Forsling, 1887, Ber. 20, 2103). It is convertible into *β-chloronaphthalene-5-sulphonyl chloride*, m.p. 70°, and into 1 : 6-*dichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 48; Cleve, Ber. 1892, 25, 2481; Forsling, *l.c.*).

Reactions.—(1) From the sparingly soluble *diazo-* compound, *β-naphthol-5-sulphonic acid* (Dahl, D. R.-P. 29084; Eng. Pat. 7712 of 1884), and *azo-* dyes (Dahl, D. R.-P. 30640; Eng. Pat. 11002 of 1884; Badische, D. R.-P. 120322; Eng. Pat. 2784 of 1900) have been obtained.

(2) Fusion with caustic potash at 260°–270° converts it into 2-*amino-5-naphthol* (Bayer, D. P. Anm. F. 7372; Eng. Pat. 5267 of 1894).

(3) When sulphonated with 4 times its weight of 20 p.c. anhydro-acid in the cold, it yields as chief product *β-naphthylamine-5* : 7-*disulphonic acid* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 128); and with 40 p.c. anhydro-acid, finally at 100°, *β-naphthylamine-1 : 5 : 7-trisulphonic acid* (Bayer, D. R.-P. 80878; Eng. Pat. 20580 of 1893).

(iv.) **β-Naphthylamine-6-sulphonic acid** ([β-] acid; Brönner acid) occurs to the extent of about 5 p.c. in the product obtained when β-naphthylamine is heated with 3 times its weight of sulphuric acid at 100°–105° for 6 hours (*v.* 8-acid), and of about 50 p.c. in that formed when β-naphthylamine sulphate, or β-naphthylamine-5- or 8-sulphonic acid, is heated with 3 times its weight of sulphuric acid at 160°–170° for 2 hours (*v.* 7-acid). It is also produced, mixed with a small proportion of the 7-acid (Bayer and Duisberg, Ber. 1890, 23, 1914), when an intimate mixture of β-naphthylamine and sulphuric acid, in the proportion necessary to form β-naphthylamine hydrogen sulphate, is baked at 200°–210° for 2 hours (Liebmann, D. P. Anm. L. 3205 of 1885); or when β-naphthylamine is heated with 3 times its weight of potassium bisulphate at about 230° (Bischoff and Brodsky, Ber. 1890, 23, 1914).

Preparation.—(1) β-Naphthylamine-6-sulphonic acid and its salts, being much less soluble in water than the 7- compounds (*q.v.*), can be separated without much difficulty by fractional crystallisation from the products obtained either by sulphonating β-naphthylamine under the conditions just described, or by heating β-naphthol-6-sulphonic acid, containing the 7-isomeride (*cf.* Green, Chem. Soc. Trans. 1889, 55, 37; Eng. Pat. 15849 of 1888), with ammonia. As with the 7-isomeride, the purity of the 6-acid can be judged from the appearance of its crystals, or of those of its ammonium salt, as they separate from solution (Green, *l.c.*).

(2) The pure acid[1] is obtained when ammonium or sodium β-naphthol-6-sulphonate is heated with aqueous ammonia at 180° under pressure (Brönner, D. R.-P. 22547; Eng. Pat. 3724 of 1882; *cf.* Landshoff, D. R.-P. 27378 of 1883; Ber. 1883, 16, 1932); or with 40 p.c. ammonium bisulphite solution and 20 p.c. ammonia at 100°–150°, the product afterwards being acidified (Badische, D. R.-P. 115335, 117471, of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *acid* $HA+H_2O$ crystallises in scales soluble in 630 parts of boiling water (Weinberg, Ber. 1887, 20, 2909), and, like its salts, shows blue fluorescence in solution. The *lead* salt PbA_2+2H_2O forms scales soluble in 670 parts of water at 1°; the *barium* salt BaA_2+6H_2O, long needles soluble in 450 parts of cold water; the *calcium* salt CaA_2+6H_2O, scales soluble in 225 parts of water at 5°; the *potassium* salt $KA+H_2O$, silky needles, soluble in 40–45 parts of cold water; the *sodium* salt $NaA+2H_2O$, silky needles, soluble in about 40 parts of cold water, and easily in hot 90 p.c. alcohol (*cf.* Forsling, Ber. 1887, 20, 77; Limpricht, quoted by Schultz, Chemie des Steinkohlenth, 3rd ed. 1, 209). The *ammonium* salt NH_4A+H_2O, large thin plates, is the least soluble of the ammonium β-naphthylaminesulphonates in cold water (Green, *l.c.*). It is convertible into *β-chloronaphthalene-6-sulphonyl chloride*, m.p. 109° (Forsling, *l.c.*), and into 2 : 6-*dichloronaphthalene* (Forsling, *l.c.*; Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 52).

Reactions.—(1) From its moderately soluble, yellow *diazo-* compound *azo-* dyes have been obtained (*cf.* Badische, D. R.-P. 120322 of 1900).

(2) When it is boiled with a large excess of 40 p.c. sodium bisulphite solution and the product acidified, *β-naphthol-6-sulphonic acid* is formed (Badische, D. R.-P. 134401 of 1899).

(3) On sulphonation with 4 times its weight of 20 p.c. anhydro-acid at 20°, it yields a mixture of *β-naphthylamine-1* : 6-*disulphonic acid* with about 20 p.c. of *β-naphthylamine-6* : 8-*disulphonic acid* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 130; *cf.* Forsling, Ber. 1888, 21, 3495).

(v.) **β-Naphthylamine-7-sulphonic acid** ([δ-] acid; F-acid). This acid, mixed with about an equal quantity of β-naphthylamine-6-sulphonic acid (Schultz, Ber. 1887, 20, 3159), constitutes the product obtained when β-naphthylamine is heated with 6 times its weight of sulphuric acid at temperatures above 150° (Bayer, D. R.-P. 39925; Eng. Pat. 5846 of 1886), when β-naphthylamine sulphate is heated with 3 times its weight of sulphuric acid at 160°–170° (Bayer, D. R.-P. 41505 of 1886); or when β-naphthylamine-5- or 8-sulphonic acid is heated with 3 times its weight of sulphuric acid at 160°–170° for about 2 hours (Bayer, D. R.-P. 42272, 42273 of 1887; Weinberg, Ber. 1887, 20, 3354; Erdmann, *ibid.* 1888, 21, 637). It has been isolated (5 p.c.) from the mixture of acids formed when β-naphthylamine is heated with sulphuric acid at 100°–105° (*v.* 8-acid). It is also obtained when acet-β-naphthalide is heated with 6 times its weight of sulphuric acid at 150°–160° for 1–1½ hours, and the product deacetylated by pouring the hot melt into water (Kinzlberger & Co., D. P. Anm. K. 5732 of 1887).

Preparation.—(1) When β-naphthylamine

---

[1] The second naphthylaminesulphonic acid—characterised by its solubility in water, the solubility of its sodium salt in alcohol, and the redder shade of its azo-dyes—which is stated by the Farbfabrik vorm. Brönner (*l.c.*) to occur in the Brönner product, doubtless owed its origin to impurity in the Schaeffer acid employed (*cf.* Bayer and Duisberg, Ber. 1887, 20, 1427).

sulphate is heated with 3 times its weight of sulphuric acid at 160°–170° for about 2 hours, and the product poured on to ice, the precipitated acid consists of the 6- and 7-isomerides. From this mixture the 6-acid can be isolated with little trouble, but the separation of pure 7-acid is much more difficult. Fractional crystallisation of the mixed acids from water at about 80° (Schultz, Ber. 1887, 20, 3159), or of the mixed copper salts (Aktienges., D. R.-P. 44248; Eng. Pat. 687 of 1888), or lead salts (Aktienges., D. R.-P. 44249; Eng. Pat. *l.c.*), the 7-compound being in each case the more soluble, can be employed, but is probably not attempted on the large scale. The purity of the 7-acid obtained by direct sulphonation can be judged from the appearance of its crystals (Schultz, *l.c.*), or of those of its ammonium salt (Green, Chem. Soc. Trans. 1889, 55, 36), as they separate from solution.

(2) Pure β-naphthylamine-7-sulphonic acid is obtained without difficulty when sodium β-naphthol-7-sulphonate is heated with twice its weight of 20 p.c. ammonia at 250° for 6 hours under pressure (Cassella, D. R.-P. 43740 of 1886; Bayer and Duisberg, Ber. 1887, 20, 1432; Weinberg, *ibid.* 2908); or with 40 p.c. ammonium bisulphite solution and 20 p.c. ammonia at 100°–150°, the product finally being acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *acid* $HA+H_2O$ forms slender, voluminous needles soluble in 350 parts of boiling water. When boiled with a quantity of water insufficient to dissolve it, the crystalline acid changes into a very sparingly soluble, anhydrous, sandy powder. The *barium* salt BaA_2+5H_2O forms thin scales soluble in 400 parts of cold water; the *calcium* salt CaA_2+6H_2O, scales soluble in 270 parts of cold water; the *potassium* salt, needles soluble in 40 parts of cold water; the *ammonium* salt, small plates; the *sodium* salt $NaA+4H_2O$, small needles soluble in 70 parts of cold water, and in hot 90 p.c. alcohol (*cf.* Bayer and Duisberg, *l.c.*; Weinberg, *l.c.*; Schultz, *l.c.*). The solutions of the salts show reddish-violet fluorescence. It is convertible into *β-chloronaphthalene*-7-*sulphonyl chloride*, m.p. 86° (Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 49; Cleve, Ber. 1892, 25, 2484), and into 2 : 7-*dichloronaphthalene* (Erdmann, Ber. 1888, 21, 638; Armstrong and Wynne, *l.c.*).

Reactions.—(1) From its orange-red *diazo*-compound, *β-naphthol*-7-*sulphonic acid* (Bayer and Duisberg, *l.c.*; Schultz, *l.c.*); and *azo-* dyes (*cf.* Cassella, D. R.-P. 43740 of 1886) have been obtained.

(2) When heated with 20 p.c. sodium bisulphite solution (1 mol.) at 90°–100° for 24 hours, sodium β-naphthylamine-7-sulphonate (2 mols.) is converted into sodium *ββ′-dinaphthylamine*-7 : 7′-*disulphonate* (Bayer, D. R.-P. 114974; Eng. Pat. 22804 of 1899).

(3) Fusion with 50 p.c. caustic soda solution at 260°–300° converts it into 2-*amino*-7-*naphthol* (Gesellsch., D. R.-P. 47816 of 1888).

(4) When sulphonated with 4 times its weight of 20–25 p.c. anhydro-acid at the ordinary temperature, it yields three *β-naphthylamine-disulphonic acids*, viz. the 1 : 7-, 4 : 7-, and 5 : 7-isomerides (Bayer, D. R.-P. 79243 of 1894; Dressel and Kothe, Ber. 1894, 27, 1194; Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 130).

(vi.) **β-Naphthylamine-8-sulphonic acid** ([α-] acid; Badische acid). When β-naphthylamine is heated with 3 times its weight of sulphuric acid at 100°–105° for about 6 hours, it yields a product (Badische, D. R.-P. 20760 of 1881) which contains the four heteronucleal β-naphthylaminesulphonic acids in the approximate proportion of 50 p.c. of the 8-acid, 40 p.c. of the 5- acid, 5 p.c. each of the 6- and the 7-acids (Dahl, D. R.-P. 29084; Eng. Pat. 7712 of 1884; Green, Chem. Soc. Trans. 1889, 55, 36). The proportion of the 8-acid does not exceed 45 p.c. when β-naphthylamine sulphate is sulphonated with 3 times its weight of sulphuric acid at 15°-20° (*v.* 5-acid), diminishing at higher temperatures until at 160°–170° the product contains only the 6- and 7-acids (Schultz, Ber. 1887, 20, 3159),[1] while it amounts only to 30 p.c. when β-naphthylamine is sulphonated with 3 times its weight of 20 p.c. anhydro-acid at 70°–80° (Dahl, *l.c.*; Green, *l.c.*).

Preparation.—(1) The product obtained by sulphonating β-naphthylamine with 3 times its weight of sulphuric acid at 100°–105° is converted into sodium salt, which, as a dry powder, is extracted with 90–95 p.c. alcohol to remove the isomeric salts, the residue consisting of the pure sodium β-naphthylamine-8-sulphonate (Dahl, *l.c.*; Green, *l.c.*). Fractional crystallisation of the mixed calcium salts can be used to effect a partial separation (*v.* 5-acid).

(2) The pure acid is obtained when sodium β-naphthol-8-sulphonate is heated with ammonia under pressure (Bayer, D. R.-P. 42273 of 1887; Pfitzinger and Duisberg, Ber. 1889, 22, 397), or with 40 p.c. ammonium bisulphite solution and 20 p.c. ammonia at 100°–150°, the product finally being acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *acid* forms slender needles, soluble in 200 parts of boiling or in 1700 parts of cold water. The salts crystallise well, and like the acid, show blue fluorescence in dilute solution (*cf.* Forsling, Ber. 1887, 20, 2100). The *barium* salt BaA_2+4H_2O forms prisms soluble in 23 parts of cold water; the *calcium* salt CaA_2+6H_2O, prisms soluble in 11 parts of cold water; the *potassium* salt $KA+\frac{1}{2}H_2O$, six-sided prisms; the *sodium* salt NaA (Erdmann, Annalen, 1893, 275, 281), large prisms insoluble in alcohol; the *ammonium* salt (Green, *l.c.*), large, solid prisms. It is convertible into *β-chloronaphthalene*-8-*sulphonyl chloride*, m.p. 129°, and into 1 : 7-*dichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1888, 4, 105; 1889, 5, 53; Forsling, *l.c.*; Ber. 1888, 21, 2803; 1889, 22, 619).

Reactions.—(1) From its sparingly soluble *diazo-* compound, *β-naphthol*-8-*sulphonic acid* (Dahl, *l.c.*) and *azo-* dyes (*cf.* Badische, D. R.-P. 120322; Eng. Pat. 2784 of 1900; D. R.-P.

---

[1] Forsling's statement that the sulphonation product at 140° consists almost entirely of a mixture of the 5- and 8-acids (Ber. 1887, 20, 2100), must be regarded as incorrect in view of the fact that the product at 120° compared with that at 100° contains a smaller proportion of the 8-acid and a considerably increased yield of the 6- and 7-acids (Dahl, *l.c.*; Bayer, D. R.-P. 42273 of 1887; Weinberg, Ber. 1887, 20, 3354).

176640 of 1905; Eng. Pat. 7287 of 1906) have been obtained.

(2) By interaction with diazotised bases, it forms not azo- dyes but soluble yellow *diazo-amino-* compounds (Bayer and Duisberg, Ber. 1887, 20, 1428; Witt, *ibid.* 1888, 21, 3483; Erdmann, *l.c.*).

(3) When it is boiled with a large excess of 40 p.c. sodium bisulphite solution, and the product acidified, *β-naphthol-*8-*sulphonic acid* is formed (Badische, D. R.-P. 134401 of 1899).

(4) Fusion with caustic potash at 260°–270° converts it into 2-*amino-*8-*naphthol* (Bayer, D. P. Anm. F. 7335; Eng. Pat. 5148 of 1894).

(5) When sulphonated in the cold with 20 p.c. anhydro-acid, it gives *β-naphthylamine-*6 : 8-*disulphonic acid* as chief product (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 128).

β-Naphthylaminedisulphonic Acids.

(i.) **β-Naphthylamine- 1 : 5 -disulphonic acid** is obtained when β-naphthylamine-1-sulphonic acid is sulphonated with 20 p.c. anhydro-acid in the cold (Armstrong and Wynne, Chem. Soc. Proc. 1895, 11, 238); *or* (as minor product) mixed with the 5 : 7-acid when β-naphthylamine-5-sulphonic acid is sulphonated under similar conditions (Armstrong and Wynne, *ibid.* 1890, 6, 129).

Identification.—The *normal potassium* salt is moderately soluble in water, and is convertible into *β-chloronaphthalene-*1 : 5-*disulphonyl chloride*, m.p. 158°, and into 1 : 2 : 5-*trichloronaphthalene* (Armstrong and Wynne, *l.c.*).

Reactions.—(1) Its sparingly soluble, colourless *diazo-* compound gives *azo-* dyes (*cf.* Badische, D. R.-P. 139909; Eng. Pat. 7153 of 1902), or, with excess (1–2 mols.) of sodium carbonate solution at 50°–60°, yields 2-*diazo-α-naphthol-*5-*sulphonic acid* (Badische, D. R.-P. 145906; Eng. Pat. 6615 of 1902).

(2) When fused with caustic alkali at 210°–230°, it gives 2-*amino-*5-*naphthol-*1-*sulphonic acid* (Kalle, D. R.-P. 242052 of 1909).

(3) On sulphonation with 40 p.c. anhydro-acid at 100°, it is converted into *β-naphthylamine-*1 : 5 : 7-*trisulphonic acid* (Bayer, D. R.-P. 80878; Eng. Pat. 20580 of 1893).

(ii.) **β-Naphthylamine- 1 : 6 -disulphonic acid** is obtained as chief product, with about 20 p.c. of the 6 : 8-acid, when β-naphthylamine-6-sulphonic acid is sulphonated with 20 p.c. anhydro-acid at a temperature below 20° (Armstrong and Wynne, Chem. Proc. Soc. 1890, 6, 130; *cf.* Forsling, Ber. 1888, 21, 3495); *or*, pure, by heating sodium β-naphthol-1 : 6-disulphonate with 40 p.c. ammonium sulphite solution and 20 p.c. ammonia at 100°–150°, and afterwards acidifying the product (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *normal potassium* salt K_2A+2H_2O in large crystals, the *sodium* salt in long needles, and the *ammonium* salt $(NH_4)_2A+H_2O$ in triclinic forms, are very soluble; but the *acid potassium* salt $KHA+H_2O$ and *acid sodium* salt $NaHA+2H_2O$ in long needles, are only sparingly soluble and in dilute solution show blue fluorescence (Forsling, *l.c.*). It is convertible into *naphthalene-*1 : 6-*disulphonic acid* (Armstrong and Wynne, *l.c.*); into *β-chloronaphthalene-*1 : 6-*disulphonyl chloride*, m.p. 124·5°; and into 1 : 2 : 6-*trichloronaphthalene* (Forsling, *l.c.*; Armstrong and Wynne, *l.c.*).

Reaction.—Its sparingly soluble, crystalline *diazo-* compound, when warmed with excess of sodium carbonate solution, yields 2-*diazo-α-naphthol-*6-*sulphonic acid* (Badische, D. R.-P. 148882; Eng. Pat. 6615 of 1902).

(iii.) **β-Naphthylamine-1 : 7-disulphonic acid** is formed (25 p.c.) together with the 4 : 7- and 5 : 7-disulphonic acids, when β-naphthylamine-7-sulphonic acid is sulphonated in the cold with 20–25 p.c. anhydro-acid. It is separated by converting the product into normal potassium salt, and collecting the least soluble portion by fractional crystallisation (Bayer, D. R.-P. 79243 of 1894; Dressel and Kothe, Ber. 1894, 27, 1194). It is also obtained when potassium β-naphthol-1 : 7-disulphonate is heated either with ammonium chloride and ammonia solution at 180°–200° (Bayer, D. P. Anm. F. 7274; D. R.-P. 77596 of 1893; Eng. Pat. 1063 of 1894; Dressel and Kothe, *l.c.* 1206), or with ammonium sulphite solution and ammonia at 100°–150°, the product afterwards being acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *normal barium* salt, moderately soluble needles; the *potassium* salt K_2A+3H_2O, large monosymmetric crystals; and the *acid potassium* salt, sparingly soluble slender needles, give solutions showing violet-blue fluorescence (Dressel and Kothe, *l.c.*). The acid in acetic acid solution does not couple with diazobenzene (Bayer, D. P. Anm. F. 7274 of 1893).

Reactions.—(1) From the easily soluble *diazo-* compound *naphthalene-*1 : 7-*disulphonic acid* (Bayer, D. R.-P. 77596 of 1893); *β-naphthol-*1 : 7-*disulphonic acid* (Dressel and Kothe, *l.c.*); and 2-*diazo-α-naphthol-*7-*sulphonic acid* (Badische, D. R.-P. 148882; Eng. Pat. 6615 of 1902), have been obtained.

(2) Prolonged boiling with 20 p.c. hydrochloric acid converts it into *β-naphthylamine-*7-*sulphonic acid* (Dressel and Kothe, *l.c.*).

(iv.) **β-Naphthylamine-3 : 6-disulphonic acid** (β-naphthylamine-[α-]disulphonic acid; amino-R-acid) is obtained by heating sodium β-naphthol-3 : 6-disulphonate either with ammonia under pressure (Pfitzinger and Duisberg, Ber. 1889, 22, 398; *cf.* Landshoff, D. R.-P. 27378 of 1883); or with ammonium bisulphite solution and ammonia at 100°–150°, the product afterwards being acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900). It is also formed when sodium β-naphthylamine-3 : 6 : 8-trisulphonate is boiled with zinc dust and dilute caustic soda solution (Kalle, D. R.-P. 233934 of 1909).

Reactions.—(1) Its sparingly soluble, yellow *diazo-* compound gives *azo-* dyes (*cf.* Bayer, D. R.-P. 157508 of 1903; Eng. Pat. 12512 of 1904), and from it *naphthalene-*2 : 7-*disulphonic acid* (Pfitzinger and Duisberg, *l.c.*), *β-chloronaphthalene-*3 : 6-*disulphonyl chloride*, m.p. 165°, and 2 : 3 : 6-*trichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 12), have been obtained.

It couples with diazotised bases, yielding many *monoazo-* dyes, or, if end component, *polyazo-* dyes (*cf.* Cassella, D. R.-P. 39029; Eng. Pat. 9214 of 1885).

(2) When fused with caustic soda at 230°–250° it yields 2-*amino*-3-*naphthol*-6-*sulphonic acid* (Höchst, D. R.-P. 53076; Eng. Pat. 15176 of 1889; Friedlaender and Zakrzewski, Ber. 1894, 27, 763).

(v.) **β-Naphthylamine-3 : 7-disulphonic acid** (β-naphthylamine-[δ-]disulphonic acid) is formed when sodium β-naphthol-3 : 7-disulphonate is heated either with 25 p.c. ammonia solution under pressure at 200° (Cassella, D. R.-P. 46711 of 1888); or with ammonium bisulphite solution and ammonia at 100°–150°, the product being afterwards acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900); *or* when β-naphthylamine-1 : 3 : 7-trisulphonic acid is boiled with dilute mineral acids (Dressel and Kothe, Ber. 1894, 27, 1199).

Identification.—The *acid barium* salt forms very sparingly soluble microscopic crystals; the *acid potassium* salt, sparingly soluble scales; the *acid sodium* salt dissolves in 12·5 parts of boiling water, or in 50 parts of water at 20°, the solutions showing blue fluorescence (Dressel and Kothe, *l.c.*). It is convertible into β-*chloronaphthalene*-3 : 7-*disulphonyl chloride*, m.p. 176°, and into 2 : 3 : 7-*trichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 127).

Reactions.—(1) From the sparingly soluble, yellow *diazo*- compound, *naphthalene*-2 : 6-*disulphonic acid* (Armstrong and Wynne, *l.c.*), and *azo*- dyes (Cassella, D. R.-P. 50907; Eng. Pat. 18425 of 1888) have been obtained.

(2) On sulphonation with 40 p.c. anhydro-acid at 80°–90°, it is converted into β-*naphthylamine*-1 : 3 : 7-*trisulphonic acid* (Bayer, D. P. Anm. F. 7036 of 1893; Dressel and Kothe, *l.c.*).

(vi.) **β-Naphthylamine-4 : 7-disulphonic acid** (Andresen's acid) is obtained when β-nitronaphthalene-4 : 7-disulphonic acid is reduced (Schultz, Ber. 1890, 23, 77); *or* (25 p.c.) when β-naphthylamine-7-sulphonic acid is sulphonated with 20–25 p.c. anhydro-acid in the cold, and, after removal of the 1 : 7-disulphonic acid as potassium salt, is separated as normal sodium salt from the more soluble 5 : 7-disulphonic acid (Bayer, D. R.-P. 79243 of 1894; Dressel and Kothe, Ber. 1894, 27, 1196).

Identification.—The normal *barium* and *sodium* salts form crystalline crusts; the *acid sodium* salt $NaHA+H_2O$, needles, which in solution show intense blue fluorescence (Dressel and Kothe, *l.c.*). It is convertible into β-*chloronaphthalene*-4 : 7-*disulphonyl chloride*, m.p. 147°, and into 1 : 3 : 6-*trichloronaphthalene* (Armstrong and Wynne, Chem. Soc. Proc. 1891, 7, 27).

Reactions.—(1) From its moderately soluble, yellow *diazo*- compound, *naphthalene*-1 : 6-*disulphonic acid* has been obtained (Armstrong and Wynne, *l.c.*).

(2) By digestion with 35 p.c. caustic potash solution at 180°–200° under pressure, it gives 2-*amino*-4-*naphthol*-7-*sulphonic acid* (Bayer, D. P. Anm. F. 7978; Eng. Pat. 25214 of 1894).

(3) When heated with aniline and aniline hydrochloride at 150°–170° it yields *diphenyl*-1 : 3-*diaminonaphthalene*-6-*sulphonic acid* (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893).

(vii.) **β-Naphthylamine-4 : 8-disulphonic acid** (C-acid) is obtained by the reduction of β-nitronaphthalene-4 : 8-disulphonic acid (Cassella, D. R.-P. 65997 of 1890; Fischer, *cf.* J. Soc. Chem. Ind. 1898, 17, 837).

Identification.—The *acid* forms prisms; the *acid barium* salt, minute needles; the *acid sodium* salt needles, easily soluble in hot water. The alkaline solutions show deep blue fluorescence. It does not couple with diazotised bases to form azo- dyes (Cassella, *l.c.*).

Reactions.—(1) From the moderately soluble, yellow *diazo*- compound, *naphthalene*-1 : 5-*disulphonic acid* and β-*naphthol*-4 : 8-*disulphonic acid* have been obtained (Cassella, *l.c.*).

(2) By partial hydrolysis with water or with 10 p.c. sulphuric acid at 170°–185°, it yields β-*naphthol*-4-*sulphonic acid* (Kalle, D. R.-P. 78603 of 1893).

(3) When boiled with zinc dust and 35 p.c. caustic soda solution it gives a mixture of β-*naphthylamine*-4- and 8-*sulphonic acids* (Kalle, D. R.-P. 233934 of 1909); reduced electrolytically, it gives the 8-*sulphonic acid* (Bayer, Fr. Pat. 439010 of 1912; *v.* p. 592, footnote 1); and with sodium amalgam it yields β-*naphthylamine* (Friedlaender and Lucht, Ber. 1893, 26, 3033).

(4) By digestion with 80 p.c. caustic potash solution at 215° it is converted into 2-*amino*-4-*naphthol*-8-*sulphonic acid* (Bayer, D. P. Anm. F. 8070; D. R.-P. 85241; Eng. Pat. 3580 of 1895).

(5) When heated with aniline and aniline hydrochloride at 150°–170° it yields *diphenyl*-1 : 3-*diaminonaphthalene*-5-*sulphonic acid* (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893).

(6) On sulphonation with 40 p.c. anhydro-acid at 80°–120° it forms β-*naphthylamine*-4 : 6 : 8-*trisulphonic acid* (Bayer, D. R.-P. 89242 of 1895).

(viii.) **β-Naphthylamine-5 : 7-disulphonic acid** is obtained as chief product when β-naphthylamine-5-sulphonic acid is sulphonated with 20 p.c. anhydro-acid below 20°, remaining in the mother liquor from which the 1 : 5-disulphonate has been separated as normal potassium salt (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 129). It is also the chief (50 p.c.) and most soluble product of the sulphonation of β-naphthylamine-7-sulphonic acid (*v.* 1 : 7- and 4 : 7- acids) with 20–25 p.c. anhydro-acid (Bayer, D. R.-P. 79243 of 1894; Dressel and Kothe, Ber. 1894, 27, 1197; *cf.* Armstrong and Wynne, *l.c.* 131).

Identification.—The *acid potassium* salt is easily soluble, and is convertible into *naphthalene*-1 : 3-*disulphonic acid*; β-*chloronaphthalene*-5 : 7-*disulphonyl chloride*, m.p. 156°; and 1 : 3 : 6-*trichloronaphthalene* (Armstrong and Wynne, *l.c.*).[1] From its *diazo*- compound *azo*- dyes can be obtained (*cf.* Kalle, D. R.-P. 162180 of 1904).

Reactions.—(1) When digested with 50 p.c. caustic soda solution under pressure at 180°–195° it yields 2-*amino*-5-*naphthol*-7-*sulphonic acid* (Badische, D. P. Anm. B. 14154; D. R.-P. 75469; Eng. Pat. 2614 of 1893).

(2) On sulphonation with 40 p.c. anhydro-acid at 100° it is converted into β-*naphthylamine*-1 : 5 : 7-*trisulphonic acid* (Bayer, D. R.-P. 80878; Eng. Pat. 20580 of 1893).

(ix.) **β-Naphthylamine-6 : 8-disulphonic acid** (β-naphthylamine-[γ-]disulphonic acid; amino-G-acid) is formed as chief product when β-naphthylamine sulphate is heated with 20–30 p.c. anhydro-acid at 110°–140°, *or* when crude β-naphthylamine-8-sulphonic acid is heated

---

[1] For reduction product, *v.* p. 592, footnote 1.

with 10 p.c. anhydro-acid at 100° (Gans & Co., D. R.-P. 35019; Eng. Pat. 816 of 1884); also as chief product when β-naphthylamine-8-sulphonic acid is sulphonated with 20 p.c. anhydro-acid below 20° (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 128), *or* as minor product (20 p.c.) when the 6-acid is sulphonated with 20 p.c. anhydro-acid below 20° (Armstrong and Wynne, *ibid.* 130).

Preparation.—The pure acid is obtained by heating sodium β-naphthol-6 : 8-disulphonate either with ammonia solution under pressure (*cf.* Landshoff, D. R.-P. 27378 of 1883); or with ammonium bisulphite solution and ammonia at 100°–150°, the product afterwards being acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900; Bucherer, J. pr. Chem. 1904, [2] 70, 358).

Identification.—The acid and salts are easily soluble. It is convertible into *β-chloronaphthalene*-6 : 8-*disulphonyl chloride*, m.p. 170°, and into 1 : 3 : 7-*trichloronaphthalene* (Armstrong and Wynne, *ibid.* 13). It does not couple with diazotised bases (Schultz, Ber. 1888, 21, 3487).

Reactions.—(1) From its easily soluble, yellow *diazo-* compound, *naphthalene*-1 : 3-*disulphonic acid* (Armstrong and Wynne, *l.c.*); *β-naphthol*-6 : 8-*disulphonic acid* (Gans & Co., *l.c.*); and *azo-* dyes (*cf.* Bayer, D. R.-P. 160172 of 1903; Badische, D. R.-P. 176640 of 1905; Eng. Pat. 7287 of 1906) have been obtained.

(2) When fused with caustic soda at 200°–230° it is converted into 2-*amino*-8-*naphthol*-6-*sulphonic acid* (Höchst, D. R.-P. 53076; Eng. Pat. 15176 of 1889; Cassella, D. P. Anm. C. 3063; Eng. Pat. 16699 of 1889), but at 270°–280° into *hydroxytoluic acid* (Höchst, D. R.-P. 81281 of 1893).

(3) On sulphonation with 40 p.c. anhydro-acid at 80°–90°, it yields *β-naphthylsulphamino*-6 : 8-*disulphonic acid*, but at 120°–130°, *β-naphthylamine*-3 : 6 : 8-*trisulphonic acid* (Dressel and Kothe, Ber. 1894, 27, 2152).

β-NAPHTHYLAMINETRISULPHONIC ACIDS.

(i.) **β-Naphthylamine-1 : 3 : 7-trisulphonic acid** is formed when β-naphthylamine-3 : 7-disulphonic acid is sulphonated with 40 p.c. anhydro-acid at 80°–90° (Bayer, D. P. Anm. F. 7036 of 1893; Dressel and Kothe, Ber. 1894, 27, 1199); also when β-naphthol-1 : 3 : 7-trisulphonic acid is heated with 25 p.c. ammonia solution under pressure at 190° (Bayer, D. P. Anm. F. 7003; Eng. Pat. 17141 of 1893; Dressel and Kothe, *l.c.*).

Salts.—The *acid barium* salt and *acid sodium* salt Na_2HA+4H_2O in scales, are easily soluble, and in solution show violet-blue fluorescence.

Reactions.—(1) When boiled with dilute mineral acids it yields *β-naphthylamine*-3 : 7-*disulphonic acid* (Dressel and Kothe, *l.c.*).

(2) On sulphonation with 40 p.c. anhydro-acid at 130° it is converted into a mixture of the 3 : 5 : 7- and 3 : 6 : 7-*trisulphonic acids* with the 1 : 3 : 6 : 7-*tetrasulphonic acid* (Bayer, D. R.-P. 81762; Eng. Pat. 17141A of 1893; Dressel and Kothe, *l.c.*).

(ii.) **β-Naphthylamine-1 : 5 : 7-trisulphonic acid** is formed when β-naphthylamine-5-sulphonic, or 1 : 5-disulphonic or 5 : 7-disulphonic acid is sulphonated with 40 p.c. anhydro-acid at 100° (Bayer, D. R.-P. 80878; Eng. Pat. 20580 of 1893).

Salts.—The *barium*, *acid potassium*, and *acid sodium* salts dissolve easily, giving solutions which show blue fluorescence.

Reactions.—(1) From its easily soluble *diazo-* compound, with excess of sodium carbonate, 2-*diazo-α-naphthol*-5 : 7-*disulphonic acid* has been obtained (Höchst, D. P. Anm. F. 16863; Eng. Pat. 23993 of 1902). It does not couple with diazotised bases.

(2) When boiled with dilute mineral acids it is partially hydrolysed, forming *β-naphthylamine*-5 : 7-*disulphonic acid* (Bayer, *l.c.*)

(3) By digestion with 65 p.c. caustic soda solution under pressure at 160°–220° it is converted into 2-*amino*-5-*naphthol*-1 : 7-*disulphonic acid* (Bayer, D. R.-P. 80878; Eng. Pat. 20580 of 1893).

(4) When heated with 30 p.c. anhydro-acid at 140°–160° it undergoes change into the isomeric *β-naphthylamine*-3 : 5 : 7-*trisulphonic acid* (Bayer, D. R.-P. 90849 of 1895).

(iii.) **β-Naphthylamine-3 : 5 : 7-trisulphonic acid** is formed, together with the 3 : 6 : 7-trisulphonic, and the 1 : 3 : 6 : 7-tetrasulphonic acids, when β-naphthylamine-3 : 7-disulphonic acid is heated with 40 p.c. anhydro-acid at 130°. By boiling the product with water, the tetrasulphonic acid is hydrolysed to 3 : 6 : 7-trisulphonic acid, which is then converted into sodium salt, and, after acidification, separated as the sparingly soluble acid sodium salt. From the concentrated mother liquor the easily soluble acid sodium salt of the 3 : 5 : 7-isomeride can be separated (Bayer, D. R.-P. 81762; Eng. Pat. 17141A of 1893; Dressel and Kothe, Ber. 1894, 27, 1201). It is the sole product of the change which occurs when β-naphthylamine-1 : 5 : 7-trisulphonic acid is heated with 30 p.c. anhydro-acid at 140°–160° (Bayer, D. R.-P. 90849 of 1895).

Salts. — The *sodium* salt $Na_3A+5\frac{1}{2}H_2O$ from dilute alcohol, the *acid sodium* salt Na_2HA, and the *acid barium* salt are very soluble, and in solution show intense green fluorescence.

Reactions.—From the very soluble *diazo-* compound, *naphthalene*-1 : 3 : 7-*trisulphonic acid*, *β-naphthol*-3 : 5 : 7-*trisulphonic acid*, and, with R-salt, an easily soluble red *azo-* dye, have been obtained (Bayer, D. R.-P. 81762; Eng. Pat. 17141A of 1893; Dressel and Kothe, *l.c.*).

(iv.) **β-Naphthylamine-3 : 6 : 7-trisulphonic acid** is formed when β-naphthylamine-3 : 7-disulphonic acid is sulphonated with 40 p.c. anhydro-acid at 130°, being separated by means of its sparingly soluble acid sodium salt from the 3 : 5 : 7-trisulphonic acid, also produced; *or* when β-naphthylamine-1 : 3 : 6 : 7-tetrasulphonic acid is boiled with dilute mineral acids (Bayer, D. R.-P. 81762; Eng. Pat. 17141A of 1893); *or* when β-naphthol-3 : 6 : 7-trisulphonic acid is heated with 25 p.c. ammonia solution under pressure at 190° (Bayer, D. P. Anm. F. 7019; Eng. Pat. 17141 of 1893; Dressel and Kothe, Ber. 1894, 27, 1209).

Salts.—The *sodium* salt is easily, the *barium* salt and *acid sodium* salt Na_2HA+3H_2O in long silky needles are sparingly soluble in cold water, the solutions showing intense blue fluorescence.

Reactions.—(1) From the sparingly soluble, yellow, crystalline *diazo-* compound, *naphthalene*-2 : 3 : 6-*trisulphonic acid*, β-*naphthol*-3 : 6 : 7-*trisulphonic acid*, and, with R-salt, a sparingly soluble red *azo-* dye, have been obtained (Dressel and Kothe, *l.c.*).

(2) When heated with 65 p.c. caustic soda solution under pressure at 180°–240°, it is converted into 2-*amino*-7-*naphthol*-3 : 6-*disulphonic acid* (Bayer, D. P. Anm. F. 7019; D. R.-P. 80878; Eng. Pats. 17141, 20580 of 1893.

(3) On sulphonation with 40 p.c. anhydro-acid at 100°–130°, it yields β-*naphthylamine*-1 : 3 : 6 : 7-*tetrasulphonic acid* (Dressel and Kothe, *l.c.*).

(v.) **β-Naphthylamine - 3 : 6 : 8 - trisulphonic acid** is obtained when β-naphthol-3 : 6 : 8-trisulphonic acid is heated with ammonia at 200°–250° (Landshoff, D. R.-P. 27378 of 1883); *or* when β-naphthylamine-6 : 8-disulphonic acid is heated with 40 p.c. anhydro-acid at 120°–130° (Dressel and Kothe, Ber. 1894, 27, 2153); *or* when sodium α-nitronaphthalene-3 : 6 : 8-trisulphonate is heated with ammonia solution under pressure at 150°–170°, nitrogen being eliminated (Kalle, D. R.-P. 176621 of 1905).

Salts.—The *acid potassium* $K_2HA+1\frac{1}{2}H_2O$ salt forms needles, soluble in 40 parts of water at 20°; the *acid sodium* salt, easily soluble needles; the solutions show intense sky-blue fluorescence.

Reactions.—(1) From its yellow *diazo-* compound *azo-* dyes (*cf.* Kalle, D. R.-P. 162180 of 1904) and *naphthalene*-1 : 3 : 6-*trisulphonic acid* (Dressel and Kothe, *l.c.*) have been obtained.

(2) When boiled with zinc dust and dilute caustic soda solution, it yields α-*naphthylamine*-3 : 6-*disulphonic acid* (Kalle, D. R.-P. 233934 of 1909).

(3) By fusion with caustic soda at 230°, it is converted into 2-*amino*-8-*naphthol*-3 : 6-*disulphonic acid* (Höchst, D. R.-P. 53023; Eng. Pat. 15175 of 1889).

(vi.) **β-Naphthylamine - 4 : 6 : 8 - trisulphonic acid** is obtained when sodium β-naphthylamine-4 : 8-disulphonate is heated with 40 p.c. anhydro-acid at 80°–90°, and finally at 120° (Bayer, D. P. Anm. F. 8154; D. R.-P. 89242 of 1895).

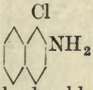
Reaction.—When heated with 60 p.c. caustic soda solution under pressure at 170°–180°, it is converted into 2-*amino*-4-*naphthol*-6 : 8-*disulphonic acid* (Bayer, *l.c.*).

β-NAPHTHYLAMINETETRASULPHONIC ACID.

β-Naphthylamine-1 : 3 : 6 : 7-tetrasulphonic acid occurs in the product formed when β-naphthylamine-3 : 7-disulphonic acid is heated with 40 p.c. anhydro-acid at 130°. It is obtained when β-naphthylamine-3 : 6 : 7-trisulphonic acid is heated with 40 p.c. anhydro-acid at 100°–130° (Dressel and Kothe, Ber. 1894, 27, 1203), *or* when sodium β-naphthol-1 : 3 : 6 : 7-tetrasulphonate is heated with 25 p.c. ammonia solution under pressure (Bayer, D. P. Anm. F. 7003; Eng. Pat. 17141 of 1893).

Salts.—The *barium* salt Ba_2A+6H_2O, in sparingly soluble, microscopic crystals, and the easily soluble *sodium* salt show, in dilute solution, violet-blue fluorescence. Acid salts have not been obtained, and acid solutions when boiled undergo partial hydrolysis giving rise to β-*naphthylamine*-3 : 6 : 7-*trisulphonic acid* (Dressel and Kothe, *l.c.*).

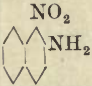
CHLORO-β-NAPHTHYLAMINE.



1 - Chloro - β - naphthylamine, obtained by chlorinating acet-β-naphthalide in acetic acid solution, and hydrolysing the product with hot hydrochloric acid, forms needles, m.p. 59°, and is convertible into 1 : 2-*dichloronaphthalene*. The *hydrochloride* $B\cdot HCl+H_2O$ forms needles; the *acetyl* derivative, needles, m.p. 147° (Cleve, Ber. 1887, 20, 1989).

1-Chloro-β-naphthylaminesulphonic acids.—When sulphonated with 2 p.c. anhydro-acid at 70°, 100°, and 160°, it yields as chief products successively the 1-*chloro*-β-*naphthylamine*-5-, 6-, and 7-*sulphonic acids* (Armstrong and Wynne, Chem. Soc. Proc. 1889, 5, 36, 48). These acids when diazotised and heated in solution with excess (2 mols.) of sodium carbonate at 50°–60°, exchange chlorine for hydroxyl, being converted into the corresponding 2-*diazo*-α-*naphtholsulphonic acids* (Badische, D. R.-P. 145906, 148882; Eng. Pat. 6615 of 1902).

NITRO-β-NAPHTHYLAMINES.



(i.) **1 - Nitro - β - naphthylamine** is obtained when acet-β-naphthalide is nitrated in acetic acid solution, and the resulting nitroacet-β-naphthalide deacetylated by heating it with alcoholic caustic potash. It forms orange-yellow needles, m.p. 126°–127°, and dissolves moderately in hot water, readily in alcohol (Jacobson, Ber. 1881, 14, 1792; Liebermann and Jacobson, Annalen, 1882, 211, 64). The *acetyl* derivative, m.p. 123·5°, is converted into 2-*amino*-1-*naphthol* when boiled with aqueous caustic soda (Jacobson, *ibid.* 806).

(ii.) **5-Nitro-β-naphthylamine** is formed as chief product, together with the 8-isomeride, when β-naphthylamine nitrate is stirred into ten times its weight of sulphuric acid below 5°, and 20 p.c. anhydro-acid is added gradually. Poured into water, the nitration product yields the less soluble 5-nitro- derivative as sulphate, the more soluble sulphate of the 8-isomeride being present in the mother liquor (Hirsch, D. R.-P. 57491; Eng. Pat. 9768 of 1890; Friedlaender and Szymanski, Ber. 1892, 25, 2076). It forms red needles, m.p. 143·5°; its *acetyl* derivative yellow needles, m.p. 185·5°.

Reactions.—From its *diazo-* compound 5-*nitro*-β-*naphthol*, yellow needles, m.p. 147°, has been obtained; by reduction it yields 1 : 6-*diaminonaphthalene*, needles, m.p. 77·5° (Friedlaender and Szymanski, *l.c.*); and when boiled with sodium sulphite or bisulphite solution it is converted into a 1 : 6-*diaminonaphthalenesulphonic acid* (Read, Holliday & Sons, Eng. Pat. 26020 of 1896).

(iii.) **8-Nitro-β-naphthylamine** (*v.* 5-nitro-β-naphthylamine) forms red needles, m.p. 103·5°, and its *acetyl* derivative, yellow needles, m.p. 195·5°. From its *diazo-* compound 8-*nitro*-β-*naphthol*, yellow needles, m.p. 142°, can be obtained, and it gives 1 : 7-*diaminonaphthalene*, scales, m.p. 117·5°, on reduction (Friedlaender and Szymanski, Ber. 1892, 25, 2081).

(iv.) **6-Nitro - β - naphthylamine - 8 - sulphonic**

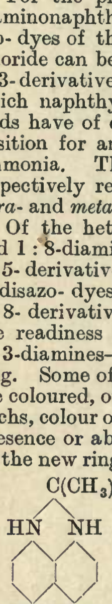
acid, obtained by nitrating β-naphthylamine-8-sulphonic acid dissolved in sulphuric acid (Immerheiser, D. R.-P. 57023 of 1890), gives a *barium* salt $BaA_2+4\frac{1}{2}H_2O$, and *ammonium* salt NH_4A, in red crystals (Jacchia, Annalen, 1902, 323, 119), and yields 2 : 6-*diaminonaphthalene* on reduction with sodium amalgam (Friedlander and Lucht, Ber. 1893, 26, 3033).

V. DIAMINO- DERIVATIVES.

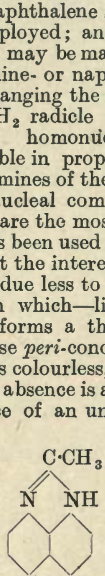
Introductory.—The existence of ten diaminonaphthalenes is to be expected on theoretical grounds, and all ten are known, having been made by methods which involve either replacement of OH by NH_2 in aminonaphthols or dihydroxynaphthalenes, or reduction of dinitronaphthalenes or nitronaphthylamines.

For the preparation of the 1 : 2- or 1 : 4-diaminonaphthalene, reduction of the *o*- or *p*-azo- dyes of the naphthalene series by stannous chloride can be employed; and for that of the 1 : 3-derivative use may be made of the property which naphthylamine- or naphthol-*m*-sulphonic acids have of exchanging the SO_3H in the *meta*-position for an NH_2 radicle when heated with ammonia. These homonucleal compounds respectively resemble in properties, the *ortho*-, *para*- and *meta*-diamines of the benzene series.

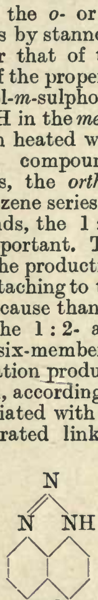
Of the heteronucleal compounds, the 1 : 5- and 1 : 8-diamines are the most important. The 1 : 5- derivative has been used for the production of disazo- dyes, but the interest attaching to the 1 : 8- derivative is due less to this cause than to the readiness with which—like the 1 : 2- and 2 : 3-diamines—it forms a third six-membered ring. Some of these *peri*-condensation products are coloured, others colourless, and, according to Sachs, colour or its absence is associated with the presence or absence of an unsaturated linking in the new ring:



Colourless.



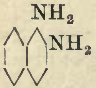
Green.



Red.

The diaminonaphthalenes crystallise well, but, as a rule, are less stable, and therefore less suitable for the production of dye-stuffs, than the respective diaminonaphthalenesulphonic acids. With nitrous acid, the 2 : 3- and 1 : 8- diamines furnish azimides, but the other bases if homonucleal are not diazotised, and if heteronucleal give tetrazo- derivatives.

DIAMINONAPHTHALENES.



(i.) 1 : 2-**Diaminonaphthalene** is obtained by reducing azo- compounds, formed by coupling diazotised bases with β-naphthylamine (Griess, Ber. 1882, 15, 2193; Lawson, *ibid.* 1885, 18, 800, 2423; Sachs, *ibid.* 3128; Witt, *ibid.* 1886, 19, 2795; 1888, 21, 3482); *or* [β-]naphthaquinonedioxime (Koreff, *ibid.* 1886, 19, 179); *or* 2-nitro-α-naphthylamine (Lellmann and Remy, *ibid.* 803); *or* 1-nitro-β-naphthylamine (Lawson, *l.c.*; Lellmann and Remy, *l.c.*) with stannous chloride in hydrochloric acid solution. It can also be obtained from 1 : 2-diaminonaphthalene-4-sulphonic acid (Friedlaender and Kielbasinski, Ber. 1896, 29, 1978) or 3- or 5-sulphonic acid (Gattermann and Schulze, *ibid.* 1897, 30, 53, 55) by interaction with sodium amalgam.

Preparation.—On the laboratory scale, 10 grams of benzeneazo-β-naphthylamine, dissolved in 300 grams of boiling acetic acid (1 : 5), are reduced by adding zinc-dust in small quantities until the colour of the solution changes to bright yellow. The sulphate, obtained by filtering the boiling solution into dilute sulphuric acid, is then boiled with sodium carbonate solution until dissolved (Bamberger and Schieffelin, Ber. 1889, 22, 1376).

Identification.—It separates from hot water in silvery rhombic scales, m.p. 95°–96°, and is oxidised rapidly, becoming brown on exposure to the air.[1] The *hydrochloride*, $B\cdot 2HCl$ forms short prisms easily soluble in water, and with ferric chloride gives an olive-green colouration, changing to brown and yellow; the *sulphate* $B_2\cdot H_2SO_4$, scales; the *diacetyl* compound, needles, m.p. 234° (Lawson, *l.c.*). With benzil, [β-]naphthaquinone, phenanthraquinone (Lawson, *l.c.*; Witt, *l.c.*), or glyoxal (Hinsberg, Ber. 1890, 23, 1394) it yields *quinoxalines.*

The 1-*acetyl* derivative has been obtained, not by acetylation but mixed with the 1 : 4-compound, by nitration and reduction of acet-α-naphthalide (Dahl, D. P. Anm. D. 6503 of 1894).

Aryl derivatives.—The 2-phenyl derivative, broad needles or scales, m.p. 138°–140°, forming sparingly soluble salts (Witt, Ber. 1887, 20, 573, 1184; Zincke and Lawson, *ibid.* 1170); and the 2-*p*-tolyl derivative, needles, m.p. 146°–147° (Fischer, *ibid.* 1892, 25, 2846), have been obtained by reduction of azo- derivatives of phenyl- and *p*-tolyl-β-naphthylamine.

(ii.) 1 : 3-**Diaminonaphthalene** is formed when 1 : 3-dinitronaphthalene is reduced with tin and hydrochloric acid (Urban, Ber. 1887, 20, 973). It is also produced when sodium α-naphthylamine- or α-naphthol-3-sulphonate is heated with ammonium chloride and 22 p.c. ammonia under pressure at 160°–180° (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895); *or* when 1-amino-3-naphthol (Friedlaender, Ber. 1895, 28, 1953), or 1 : 3-dihydroxynaphthalene (Friedlaender and Rüdt, *ibid.* 1896, 29, 1612), is heated with concentrated aqueous ammonia under pressure at 150°; *or* when 1 : 3-diaminonaphthalene-2-carboxylic acid is heated at 100° (Atkinson and Thorpe, Chem. Soc. Trans. 1906, 89, 1922).

Identification.—It crystallises from water in scales, m.p. 96°; its *hydrochloride* $B\cdot 2HCl$ and *sulphate* in easily soluble needles, which in solution give a dark brown colouration with ferric chloride; the *diacetyl* compound in sparingly soluble needles, m.p. 263°. With diazotised bases it gives chrysoïdines (Friedlaender, *l.c.*), and with nitrous acid a deep yellow colouration (Urban, Ber. 1887, 20, 974).

Aryl derivatives.—Diphenyl-1:3-diaminonaphthalene is obtained when α-naphthylamine-3-sulphonic acid (Bayer, D. R.-P. 75296; Eng Pat. 8898 of 1893), phenyl-α-naphthylamine-3-sulphonic acid (Bayer, D. R.-P. 78854; Eng. Pat. 19623 of 1893), or α-naphthol-3-sulphonic

---

[1] Coupled with an oxidising agent, it has been used as a hair dye (Aktienges., D. R.-P. 154652 of 1903).

acid (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893) is heated with aniline and aniline hydrochloride at 150°–170°. It is insoluble in, and its *hydrochloride* is decomposed by water. The corresponding ditolyl, dixylyl and phenyl tolyl derivatives have been prepared (*l.c.*). By condensation of these aryl derivatives with nitrosodimethylaniline hydrochloride, basic blue dyes of the *azine* class are formed (Bayer, D. R.-P. 78497; Eng. Pat. 8898 of 1893).

(iii.) 1 : 4-**Diaminonaphthalene** is formed by reducing azo- derivatives of *α*-naphthylamine (Perkin, Chem. Soc. Journ. 1865, 18, 173; Griess, Ber. 1882, 15, 2192; Friedlaender, *ibid.* 1889, 22, 590) with stannous chloride dissolved in hydrochloric acid, or with sodium hyposulphite (Grandmougin, *ibid.* 1906, 39, 3561); *or* by reducing 4-nitro-*α*-naphthylamine with tin and hydrochloric acid (Liebermann and Dittler, Annalen, 1876, 183, 238). It is also formed by hydrolysing 1 : 4-diaminonaphthalene-6-sulphonic acid (Cassella, D. R.-P. 74177; Eng. Pat. 15444 of 1893).

Preparation.—On the laboratory scale, benzeneazo-*α*-naphthylamine is boiled with zinc dust and water, the colourless solution filtered into dilute sulphuric acid, and the crystalline sulphate warmed with aqueous sodium carbonate for about 5 minutes (Bamberger and Schieffelin, Ber. 1889, 22, 1381).

Identification.—It crystallises from water in needles or small prisms, m.p. 120°, which when moist rapidly become coloured green, and decompose. The *hydrochloride* $B\cdot 2HCl$ forms readily soluble scales, and in neutral solution with ferric chloride gives a green colouration, changing to a brown precipitate of impure [*α*-]naphthaquinone (Griess, *l.c.*); the *sulphate* $B\cdot H_2SO_4$, sparingly soluble needles; the *diacetyl* derivative, needles, m.p. 305° (Kleemann, Ber. 1886, 19, 334; Bamberger and Schieffelin, *l.c.*).

Reactions.—(1) By nitrous acid (Dahl, *l.c.*; Grandmougin and Michel, Ber. 1892, 25, 977), or by dilute chromic acid solution, or ferric chloride, it is oxidised to [*α*-] *naphthaquinone*.

(2) When its hydrochloride is heated with *α*-naphthylamine and *α*-aminoazonaphthalene at 130°–140°, *Magdala red* is obtained (Witt, D. R.-P. 40868 of 1886, *v.* Azines).

(3) On reduction in boiling amyl alcohol solution with sodium it yields, as sole product, ar.-*tetrahydro*-1 : 4-*diaminonaphthalene* (Bamberger and Schieffelin, *l.c.*).

Monoacetyl-1:4-diaminonaphthalene, with its *hydrochloride* (Liebermann and Dittler, *l.c.*) and *sulphate* (Dahl, D. P. Anm. D. 6503 of 1894), has been prepared, and, as the one amino- group can be diazotised and coupled before the other is deacetylated, it is of importance in the production of *disazo-* dyes (*cf.* Höchst, D. R.-P. 67426, 79952; Eng. Pat. 18783 of 1891; Bayer, D. R.-P. 117972 of 1897; Eng. Pat. 18572 of 1898; Leonhardt, D. R.-P. 121667; Eng. Pat. 23615 of 1898), owing to the fact that the diamine itself cannot easily be diazotised (*cf.* Dahl, D. R.-P. 65273 of 1891; Eng. Pat. 4109 of 1892).

Alkyl and Aryl derivatives.—*unsymm.*-Dimethyl-1 : 4-diaminonaphthalene, an oil (Friedlaender and Welmans, Ber. 1888, 21, 3124); and the ethyl-, m.p. 152° (Kock, Annalen, 1888, 243, 312; Bamberger and Goldschmidt, Ber. 1891, 24, 2471); phenyl-, m.p. 148° (Wacker, Annalen, 1888, 243, 302; Fischer, *ibid.* 1895, 286, 183); and *α*-naphthyl-diamino- derivatives (Wacker, *l.c.*) have been described.

(iv.) 1 : 5-**Diaminonaphthalene** ([*α*-]diaminonaphthalene; semi-naphthalidam) is obtained from 1 : 5-dinitronaphthalene by reduction with ammonium sulphide (Zinin, Annalen, 1844, 52, 361; 1853, 85, 329), with tin and hydrochloric acid (Hollemann, Zeitsch. Chem. 1865, [2] 1, 556; Ladenburg, Ber. 1878, 11, 1651; Erdmann, Annalen, 1888, 247, 360), with stannous chloride and alcoholic hydrochloric acid (Meyer and Müller, Ber. 1897, 30, 773), or with phosphorus iodide and water (Aguiar, *ibid.* 1870, 3, 32; 1874, 7, 306). It is also formed when 1 : 4-dihydroxynaphthalene is heated either with ammonia under pressure at 250°–300° (Ewer and Pick, D. R.-P. 45549 of 1887), or with ammonium bisulphite solution and ammonia at 125° (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900); *or* when 1 : 5-diaminonaphthalene-2-sulphonic acid is heated with dilute mineral acid (Friedlaender and Kielbasinski, Ber. 1896, 29, 1983); *or* when *α*-naphthylamine is heated with naphthalene and sodamide at 230° (Sachs, Ber. 1906, 39, 3021).

Identification.—It crystallises in needles, m.p. 189·5°, sublimes without decomposition, and with ferric chloride gives an intense bluish-violet colouration. The *hydrochloride* $B\cdot 2HCl$ and the *sulphate* $B\cdot H_2SO_4$ form moderately soluble needles; the *tetrazo-* compound is convertible into 1 : 5-*dichloronaphthalene* (Erdmann, *l.c.*).

Reactions.—(1) When reduced in boiling amyl alcohol solution with sodium, it is converted into *tetrahydro*-1 : 5-*diaminonaphthalene*, which is both an *ac-* and an *ar-* base (Bamberger, Abrahall and Bammann, Ber. 1889, 22, 943, 951).

(2) When boiled with 27 p.c. sodium bisulphite solution it yields as chief product 1-*amino*-5-*naphthyl sulphite*, or, if subsequently heated with alkali, 1-*amino*-5-*naphthol* (Bucherer, J. pr. Chem. 1904, [2] 69, 57, 84).

(3) *Disazo-* dyes have been obtained from its tetrazo- compound (Badische, D. R.-P. 39954; Eng. Pat. 14625 of 1886; D. R.-P. 130475; Eng. Pat. 9287 of 1900), and *azo-* or *disazo-* dyes by coupling it with diazotised primuline (Badische, D. R.-P. 93304 of 1896; Eng. Pat. 2874 of 1897), oxamine dyes (Badische, D. R.-P. 140955 of 1902), or other bases (*cf.* Cassella, D. R.-P. 71329 of 1891; Badische, D. R.-P. 75743; Eng. Pat. 18317 of 1893).

(v.) 1 : 6-**Diaminonaphthalene**, prepared by heating 1 : 6-dihydroxynaphthalene with ammonia under pressure at 150°–300° (Ewer and Pick, D. R.-P. 45788 of 1887), *or* *β*-naphthylamine with sodamide and naphthalene at 230° (Sachs, Ber. 1906, 39, 3022), can be obtained pure by reducing either 5-nitro-*β*-naphthylamine with iron and acetic acid (Friedlaender and Szymanski, Ber. 1892, 25, 2080; *cf.* Hirsch, D. R.-P. 57491 of 1890; Dawson and Hirsch, Eng. Pat. 9768 of 1890), *or* 1 : 6-dinitronaphthalene with tin and hydrochloric acid (Kehrmann and Matis, Ber. 1898, 31, 2149). It is also formed by acting on 1 : 6-diaminonaphthalene-4-sulphonic acid with sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3034).

Identification.—It crystallises from water in short needles, m.p. 77·5°, darkens on exposure to the air, shows blue fluorescence in solution, and gives with ferric chloride a dark brownish-violet colouration. The *hydrochloride*, needles, is easily, but the *sulphate*, $B\cdot H_2SO_4$, needles, only sparingly soluble in water; the *diacetyl* derivative, needles, m.p. 257°, dissolves sparingly in alcohol; the *tetrazo-* compound is convertible into 1 : 6-*dichloronaphthalene* (Friedlaender and Szymanski, *l.c.*).

(vi.) **1 : 7-Diaminonaphthalene** is prepared by reducing 8-nitro-β-naphthylamine in alcoholic solution with tin and hydrochloric acid (Friedlaender and Szymanski, Ber. 1892, 25, 2082), *or* by heating 1 : 7-dihydroxy-β-naphthoic acid with ammonia under pressure at 200°–210° (Friedlaender and Zinberg, Ber. 1896, 29, 40).

Identification.—It crystallises from water in needles, m.p. 117·5°, gives with ferric chloride a violet colouration, and forms a *diacetyl* derivative, rhombohedra, m.p. 213°. The *tetrazo-* compound is convertible into 1 : 7-*dichloronaphthalene* (Friedlaender and Szymanski, *l.c.*).

(vii.) **1 : 8-Diaminonaphthalene** ([β-]diaminonaphthalene) can be obtained by reducing 1 : 8-dinitronaphthalene either with phosphorus iodide and water (Aguiar, Ber. 1874, 7, 306; Meyer and Müller, *ibid.* 1897, 30, 775), or with tin and hydrochloric acid (Ladenburg, *ibid.* 1878, 11, 1651; Erdmann, Annalen, 1888, 247, 363); *or* by reducing 4 : 5-dinitro-α-naphthoic acid (m.p. 265°) with tin and hydrochloric acid (Ekstrand, Ber. 1887, 20, 1353). It is also formed when 1 : 8-dihydroxynaphthalene is heated with ammonia under pressure at 250°–300° (Erdmann, *l.c.*).

Identification.—It crystallises from aqueous alcohol in needles, m.p. 67°, and in aqueous solution gives with ferric chloride a dark chestnut-brown colouration. The *hydrochloride* $B\cdot 2HCl$ forms very soluble scales, m.p. 280° (Ekstrand, *l.c.*); the *sulphate* $B\cdot H_2SO_4$, sparingly soluble needles; the *dibenzoyl* derivative, needles, m.p. 311°–312° (Sachs, Ber. 1906, 39, 3027); and the *oxalate*, either needles, m.p. 271° (Meyer and Müller, *l.c.*); or $BA+2H_2O$, decomp. 270°; B_2A, m.p. 205° (Sachs, Annalen, 1909, 365, 101).

Reactions.—(1) Many condensation products can be obtained from this diamine. For example, with acetic anhydride it forms a green *anhydro-* compound, m.p. 210° (Sachs, Ber. 1906, 39, 3027); with ethyl oxalate, a red crystalline *perimidine-* derivative (Aguiar, *ibid.* 1874, 7, 306; Meyer and Müller, *l.c.*; Sachs, Annalen 1909, 365, 69, 96); with phthalic anhydride a yellow *perimidylbenzoic acid* or red *phthaloperinone*, needles, m.p. 227°–228° (Sachs, *ibid.* 117; Bayer, D. R.-P. 202354 of 1906; Eng. Pat. 7575 of 1908); with nitrous acid a red *azimide* (Aguiar, *l.c.* Erdmann, *l.c.*); with acetone a colourless *dimethyldihydroperimidine* (Badische, D. R.-P. 122475 of 1900; *cf.* Sachs, *l.c.* 151); with phosgene or alkyl carbonates, colourless *perimidones* (Sachs, *l.c.* 135).

(2) When heated with dilute hydrochloric acid under pressure at 180°, it is converted into 1 : 8-*dihydroxynaphthalene* (Aktienges., D. P. Anm. A. 4028 of 1894).

(3) When boiled with sodium bisulphite solution it yields as chief product 1-*amino*-8-*naphthyl sulphite*, convertible by heating with alkali into 1-*amino*-8-*naphthol* (Badische, D. R.-P. 115335 of 1899; Eng. Pat. 1387 of 1900; Bucherer, J. pr. Chem. 1904, [ii.] 69, 58).

(4) *Azo-* dyes are produced by coupling it with diazotised primuline (Badische, D. R.-P. 94074; Eng. Pat. 2874 of 1897), oxamine dyes (Badische, D. R.-P. 140955 of 1902), and other bases (*cf.* Cassella, D. R.-P. 71329 of 1891; Badische, D. P. Anm. B. 31919; Eng. Pat. 20000 of 1902).

(viii.) **2 : 3-Diaminonaphthalene** is obtained by heating 2 : 3-dihydroxynaphthalene either with 30 p.c. ammonia solution under pressure at 250° (Höchst, D. R.-P. 73076 of 1893; Friedlaender and Zakrzewski, Ber. 1894, 27, 764), or with 30 p.c. ammonium sulphite solution and 20 p.c. ammonia at 80°, the product afterwards being acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

Identification.—It crystallises from water in scales, m.p. 191°, and gives no colouration with ferric chloride. The *hydrochloride* is easily, but the *sulphate* only sparingly, soluble. The *diacetyl* derivative forms needles, m.p. 247°, convertible by prolonged boiling with acetic acid into an *anhydride*, m.p. 168°.

Reactions.—(1) With nitrous acid it yields an *azimide*, yellow needles, m.p. 187°, and with diazotised bases (1 mol.) it couples giving red *azo-* dyes (Friedlaender and Zakrzewski, *l.c.*).

(2) It condenses with α- or *o*-diketones, forming *quinoxalines*, behaving, therefore, as an *o*-diamine (Friedlaender and Zakrzewski, *l.c.*).

(ix.) **2 : 6-Diaminonaphthalene** is obtained when 2 : 6-dihydroxynaphthalene is heated with ammonia under pressure at 150°–300° (Ewer & Pick, D. R.-P. 45788 of 1887), or with ammonia and ammonium chloride at 200°–250° (Lange, Chem. Zeit. 1888, 12, 856); or with ammonia-calcium chloride at 270° (Jacchia, Annalen, 1902, 323, 132). It is also formed by the interaction of 2 : 6-diaminonaphthalene-8-sulphonic acid with sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3033).

Identification.—It crystallises in scales, m.p. 216°, darkens on exposure to the air, and with ferric chloride gives a green colouration, which changes to blue when the solution is warmed. The *sulphate* is sparingly soluble; the *diacetyl* derivative forms needles.

Aryl derivative.—The diphenyl derivative, m.p. 210°, obtained by heating 2 : 6-dihydroxynaphthalene with aniline and aniline hydrochloride at 170°, yields green *azine-* dyes by interaction with nitrosodimethylaniline hydrochloride (Leonhardt, D. R.-P. 54087 of 1889; Eng. Pat. 3098 of 1890), or with quinonedichlorodiimide (Leonhardt, D. R.-P. 56990. 58576 of 1890).

(x.) **2 : 7-Diaminonaphthalene** is obtained when 2 : 7-dihydroxynaphthalene is heated with ammonia under pressure at 150°–300° (Ewer & Pick, D. R.-P. 45788 of 1887), or with ammonia and ammonium chloride at 200°–250° (Lange, Chem. Zeit. 1888, 12, 856), or with ammonia-calcium chloride at 260°–270° (Bamberger and Schieffelin, Ber. 1889, 22, 1384); *or* boiled with ammonium sulphite solution and ammonia (Franzen and Deibel, J. pr. Chem. 1908, [ii.] 78, 155). It is also formed when 2-amino-7-naphthol is heated with 40 p.c. ammonium sulphite solution and 20 p.c.

ammonia under pressure at 130°–140°, the product afterwards being acidified (Bucherer, J. pr. Chem. 1904, [ii.] 69, 89).

Identification.—It crystallises from water in scales, m.p. 161°, and gives no colouration with ferric chloride. Its salts and *tetrazo-* compound are easily soluble.

Aryl derivatives.—Diphenyl-2 : 7-diaminonaphthalene, formed when 2 : 7-dihydroxynaphthalene is heated with aniline and aniline hydrochloride at 140°–180° (Durand & Huguenin, D. R.-P. 40886 of 1886; Annaheim, Eng. Pat. 14283 of 1886; Ber. 1887, 20, 1372), forms scales m.p. 163°-164°; its *diacetyl* derivative, small crystals, m.p. 197·5° (Clausius, *ibid.* 1890, 23, 528); and its *tetramethyl*-p-*diamino-* compound, obtained by interaction of *p*-aminodimethylaniline and 2 : 7-dihydroxynaphthalene at 200°–220°, ill-defined crystals, m.p. 180° (Aktienges., D. R.-P. 75044 of 1893). From the diphenyl-derivative blue or violet *azine-* dyes are obtained by interaction with nitrosodimethylaniline or with quinonedichlorodiimide (Durand, Huguenin & Co., *l.c.*; D. R.-P. 58371 of 1891).

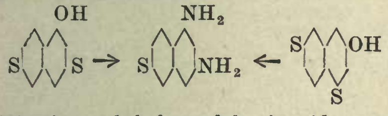
The *o*-tolyl, m.p. 106°; *p*-tolyl, m.p. 236°–237°; and *m*-xylyl, m.p. 130°, derivatives have been prepared (Durand & Huguenin, *l.c.*).

DIAMINONAPHTHALENESULPHONIC ACIDS.

The methods by which sulphonic acids of the heteronucleal diaminonaphthalenes can be obtained do not lend themselves to generalisation; those for homonucleal diaminonaphthalenesulphonic acids can be summarised—

(i.) For 1 : 2- or 1 : 4-diaminosulphonic acids: Reduction of azo- dyes formed by coupling diazotised bases with the appropriate *β*- or *α*-naphthylaminesulphonic acids (*cf.* Witt, Ber. 1888, 21, 3485; Reverdin and de la Harpe, *ibid.* 1892, 25, 1403; 1893, 26, 1281).

(ii.) For 1 : 3-diaminosulphonic acids Interaction of *α*- or *β*-naphthylamine-, or naphthol-*m*-sulphonic acids with ammonia at high temperatures (*cf.* Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895; Bayer, D. R.-P. 78854; Eng. Pat. 19623 of 1893).



Diaminonaphthalenesulphonic acids are used technically for two purposes—the production of azo- dyes and azine dyes.

For azo- dyes.—In addition to furnishing tetrazo- derivatives, diaminonaphthalenesulphonic acids, if derived from the—

1 : 3- diamine (*cf.* Kalle, D. R.-P. 90905, 90906, 92654, 93595; Eng. Pat. 9103 of 1895);

1 : 5- diamine (*cf.* Cassella, D. R.-P. 61174; Eng. Pat. 15346 of 1890);

1 : 8- diamine (*cf.* Cassella, D. R.-P. 77425; Eng. Pat. 24714 of 1893); or the

2 : 7- diamine (*cf.* Aktienges., D. R.-P. 79780, 80070, 82724; Eng. Pat. 3844 of 1894); can be coupled with diazotised bases.

Sulphonic acids derived from the 1 : 4-diamine do not couple. With nitrous acid, they are usually oxidised, but azo- dyes can be made from them by diazotising one amino-group at a time. Except for the 2-sulphonic acid (*cf.* Levinstein, D. R.-P. 102160; Eng. Pat. 17064 of 1896), this is achieved by employing sulphonic acids of 4-aminoacet-*α*-naphthalide in which the one amino- group can be diazotised and coupled before the other is deacetylated (*cf.* Dahl, D. R.-P. 66354 of 1891; Cassella, D. R.-P. 74177, 78831, 79910; Eng. Pat. 15444 of 1893; D. R.-P. 127362; Eng. Pat. 23615 of 1898).

1 : 8 -Diaminonaphthalenesulphonic acids, like the 2 : 3- derivatives, form azimides with nitrous acid. They couple with diazotised bases forming *azo-* dyes, but a marked increase in the purity of shade, and fastness is obtained if the acetone condensation products (dimethyldihydroperimidines) of these acids are used for coupling (Badische, D. R.-P. 121228, 122475; Eng. Pat. 12819 of 1900), or if the azo- dyes, formed by coupling 1 : 8- diaminosulphonic acids with diazotised bases, are converted into azimides (Cassella, D. R.-P. 77425; Eng. Pat. 24714 of 1893; D. R.-P. 139908; Eng. Pat. 26147 of 1901; Bayer, D. R.-P. 222928 of 1909; *cf.* Höchst, D. R.-P. 143387 of 1902; Eng. Pat. 953 of 1903).

For azines.—The sulphonic acids employed in the production of azine dyes have been those derived from the diaryl- 1 : 3- diaminonaphthalenes (Bayer, D. R.-P. 78497, 79189, 80778, 86223, 86224; Eng. Pats. 8898, 11892 of 1893), and from the diaryl-2 : 6- and diaryl- 2 : 7-diaminonaphthalenes (Leonhardt, D. R.-P. 54087 of 1889; Eng. Pat. 3098 of 1890).

The sources and general characters of the diaminonaphthalenesulphonic acids are summarised in the following tables, references to fluorescence, usually green in colour, or non-fluorescence of solutions of the alkali salts being omitted, for want of room :—

Diaminonaphthalenemonosulphonic Acids.

Constitution.	Preparation.	Acids, Salts and Reactions.
N : N : S		
1 : 2 : 3	Reduction of azo-derivatives of *α*-naphthylamine-3-sulphonic acid (Gattermann and Schulze, Ber. 1897, 30, 54).	*Acid* HA, broad needles. Gives intense emerald-green colouration with ferric chloride.
1 : 2 : 4	Reduction of azo-derivatives of naphthionic acid (Witt, Ber. 1886, 19, 1720); *or* of congo-red (Friedlaender and Kielbasinski, Ber. 1896, 29, 1978).	*Acid* sp. soluble needles. Is decomposed by nitrous acid and does not couple. *Acetyl* derivative converted into ethenyl compound by mineral acids or heat (Lange, D. R.-P. 57942 of 1890).
1 : 2 : 5	Reduction of azo-derivatives of *α*-naphthylamine-5-sulphonic acid (Gattermann and Schulze, Ber. 1897, 30 53); *or* of *β*-naphthylamine-5-sulphonic acid (Witt, Ber. 1888, 21, 3486).	*Acid* HA, sparingly soluble leaflets. Is decomposed by nitrous acid and does not couple with diazotised bases.

Constitution.	Preparation.	Acids, Salts and Reactions.
N : N : S		
1 : 2 : 6	Reduction of azo-derivatives of β-naphthylamine-6-sulphonic acid (Witt, Ber. 1888, 21, 3484).	*Acid* sparingly soluble needles; *sodium* salt, scales. Is decomposed by nitrous acid and does not couple with diazotised bases.
1 : 2 : 7	Reduction of azo-derivatives of β-naphthylamine-7-sulphonic acid (Witt, Ber. 1888, 21, 3485).	*Acid* grey powder. Is decomposed by nitrous acid and does not couple with diazotised bases.
1 : 3 : 5	(1) α-Naphthol-3 : 5-disulphonic acid heated with ammonia under pressure at 175° (Kalle, D. R.-P. 94075 of 1895). (2) β-Naphthylamine-4 : 8-disulphonic acid heated with 30 p.c. ammonia under pressure at 215° (Bayer, D. P. Anm. F. 8845 of 1896; but *cf.* Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895).	*Acid* readily soluble. Gives no colouration with ferric chloride, but faintly yellow solution with nitrous acid. Couples with diazotised bases. For *diaryl* derivatives, *cf.* Bayer, D. R.-P. 77866, 78854; Eng. Pats. 16780, 19623 of 1893.
1 : 3 : 6	α-Naphthylamine- or α-naphthol-3 : 6-disulphonic acid heated with ammonia under pressure at 160°–180° (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895; Friedlaender and Taussig, Ber. 1897, 30, 1462).	*Acid* sparingly; *sodium* salt, readily soluble. Forms yellow *diazo*-compound. Couples with diazotised bases (*cf.* Kalle, D. R.-P. 92654. 93595; Eng. Pat. 9103 of 1895. For *diaryl* derivatives, *cf.* Bayer, D. R.-P. 76414, 77866; Eng. Pats. 8898, 16780 of 1893.
1 : 3 : 7	α-Naphthylamine- or α-naphthol-3 : 7-disulphonic acid heated with ammonia under pressure at 160°–180° (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895).	*Acid* very sparingly soluble needles. Gives reddish-brown colouration with ferric chloride. For *diaryl* derivatives, *cf.* Bayer, D. R.-P. *l.c.*, 78854; Eng. Pats. *l.c.*, 19623 of 1893.
1 : 3 : 8	α-Naphthylamine- or α-naphthol-3:8-disulphonic acid heated with ammonia under pressure at 160°–180° (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895.	*Acid* very sparingly soluble; *alkali* salts show green fluorescence in solution. Gives reddish-brown colouration with ferric chloride. For *diaryl* derivatives, *cf.* Bayer, D. R.-P. *l.c.*; Eng. Pats. *l.c.*
1 : 4 : 2	(1) Reduction of azo-derivatives of α-naphthylamine-2-sulphonic acid (Levinstein, D. P. Anm. C. 5939; Eng. Pat. 2946 of 1896). (2) Action of sodium bisulphite on [α]-naphthaquinonedichlordiimide (Friedlaender and Oesterreich; *cf.* J. Soc. Chem. Ind. 1898, 17, 836).	*Acid* very sparingly soluble. Gives dark green colouration with ferric chloride. Forms *aminodiazonaphthalenesulphonic acid* with nitrous acid (1 mol.), but second amino-group can be diazotised after first has been coupled (Levinstein, D. R.-P. 102160; Eng. Pat. 2946 of 1896).
1 : 4 : 5	Reduction of 4-nitro-α-naphthylamine-5-sulphonic acid (Bayer, D. R.-P. 133951 of 1899; Levinstein, Eng. Pat. 13178 of 1899).	*Acid* greyish needles, rapidly oxidised in alkaline solution.
1 : 4 : 6	(1) Sulphonation of acetyl-1 : 4-diaminonaphthalene with 20 p.c. anhydro-acid at 25°–50° and subsequent deacetylation (Dahl, D. R.-P. 66354 of 1891; Ammelburg, J. pr. Chem. 1893, [ii.] 48, 286). (2) Reduction of azo-derivatives (Cassella, D. R.-P. 116922 of 1898) or of nitro-derivatives (Levinstein, Eng. Pat. 12119 of 1898) of α-naphthylamine-6- *or* 7-sulphonic acid.	*Acid* very sparingly soluble needles; *potassium* salt KA, and *barium* salt BaA_2+7H_2O, easily soluble. Forms [α]-*naphthaquinone* with nitrous acid or ferric chloride. For *monacetyl* derivatives, *cf.* Cassella, D. R.-P. 74177; Eng. Pat. 15444 of 1893; Bayer, D. R.-P 109609 of 1898.
1 : 5 : 2	(1) Nitration and reduction of α-naphthylamine-2-sulphonic acid (Cassella, D. R.-P. 70890 of 1892; Friedlaender and Kielbasinski, Ber. 1896, 29, 1983). (2) Sulphonation of 1 : 5-diaminonaphthalene sulphate with 5 p.c. anhydro-acid at 100° (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 213).	*Acid* sparingly soluble small needles; *sodium* salt readily; *barium* salt, BaA_2, sparingly soluble. Forms an easily soluble yellow *tetrazo*-compound. Couples with 1 or 2 mols. of a diazotised base.
1 : 5 : 3	Nitration and reduction of α-nitronaphthalene-7-sulphonic acid (Cassella, D. R.-P. 85058 of 1894), *or*, mixed with 1 : 8 : 3-acid, of naphthalene-β-sulphonic acid (Cassella, D. R.-P. 67017, Eng. Pat. 6972 of 1891).	*Acid* sparingly, salts readily soluble; *hydrochloride* prisms. Forms a *tetrazo*-compound.
1 : 5 : 4	(1) Nitration, reduction, and deacetylation of acetylnaphthionic acid (Nietzki and Zübelen, Ber. 1889, 22, 451; Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 255). (2) 1 : 5-Dihydroxynaphthalene-4-sulphonic acid heated with ammonium sulphite solution and ammonia (Bucherer and Uhlmann, *l.c.*).	*Acid* very sparingly soluble. Forms a *tetrazo*-compound. Couples with diazotised bases.

Constitution.	Preparation.	Acids, Salts and Reactions.
N : N : S		
1 : 6 : 4	1-Amino-6-naphthol-4-sulphonic acid heated with ammonia under pressure at 170°–180° (Dahl, D. R.-P. 65834, 71157 of 1892; Friedlaender and Kielbasinski, Ber. 1896, 29, 1979).	*Acid* very sparingly soluble needles; *sodium* and *barium* salts easily soluble. Forms a *tetrazo*-compound which decomposes at 0° into a *diazonaphtholsulphonic acid.* Couples with diazotised bases.
1 : 8 : 3	Nitration and reduction of α-nitronaphthalene-6-sulphonic acid (Cassella, D. R.-P. 85058 of 1894), *or*, mixed with 1 : 5 : 3-acid, of naphthalene-β-sulphonic acid (*ibid.*, D. R.-P. 67017; E. P. 6972 of 1891).	*Acid* sparingly soluble needles; *alkali* salts readily soluble; *hydrochloride* needles. Forms an *azimide.* Couples with 1 or 2 mols. of diazotised bases.
1 : 8 : 4	(1) Nitration and reduction of α-nitronaphthalene-5-sulphonic acid (Cassella, D. R.-P. 70019 of 1892; E. P. 4613 of 1893). (2) Acid sulphate of 1 : 8-diaminonaphthalene 'baked' above 100° in a vacuum (Bayer, D. R.-P. 216075 of 1908).	*Acid* almost insoluble; *sodium* salt readily sol.; *hydrochloride* and *sulphate* crystallise well. Forms an *azimide* (*cf.* Cassella D. R.-P. 77425; Eng. Pat. 24714 of 1893). Couples with 1 or 2 mols. of diazotised bases.
2 : 3 : 6	2-3-Dihydroxynaphthalene-6-sulphonic acid *or* 2-amino-3-naphthol-6-sulphonic acid, heated with ammonia under pressure at 150°–220° (Aktienges., D. P. Anm. A. 3676 of 1893; Eng. Pat. 8381 of 1894; Friedlaender and Oesterreich; *cf.* J. Soc. Chem. Ind. 1898, 17, 836).	*Acid* sparingly soluble; *sodium* salt leaflets, showing blue fluorescence in solution; *barium* salt, BaA_2. Gives dark yellow colouration with ferric chloride. Forms an *azimide* (Aktienges., *l.c.*). Couples with 2 mols. of diazotised bases (*cf.* Aktienges., D. R.-P. 84461 of 1894).
2 : 6 : 4	Nitration and reduction of β-naphthylamine-8-sulphonic acid (Friedlaender and Lucht, Ber. 1893, 26, 3033).	*Acid* sparingly soluble flat prisms. Gives emerald-green colouration with ferric chloride (Jacchia, Annalen, 1902, 323, 130).

Diaminonaphthalenedisulphonic Acids.

Constitution.	Preparation.	Acids, Salts and Reactions.
N : N : S : S		
1 : 2 : 3 : 6	Reduction of azo-derivatives of β-naphthylamine-3 : 6-disulphonic acid (Witt, Ber. 1888, 21, 3487).	*Acid* sp. sol.; *acid sodium* salt NaHA, needles. Gives emerald-green coln. with ferric chloride. Decomposed by nitrous acid. Does not couple in acid solution (Cassella, D. R.-P. 72584 of 1892).
1 : 2 : 3 : 8	Reduction of azo-derivatives of α-naphthylamine-3 : 8-disulphonic acid (Bernthsen, Ber. 1890, 23, 3094).	*Acid sodium* salt $NaHA+3H_2O$, needles. *Anhydride* (sultam) ($+2H_2O$), sparingly soluble long needles.
1 : 3 : (5) : 7	α-Naphthol-3 : 5 : 7-trisulphonic acid heated with ammonia and ammonium chloride under pressure at 160°–180° (Kalle, D. R.-P. 90906; Eng. Pat. 9103 of 1895).	*Acid* very sparingly soluble needles. Gives yellowish-red colouration with ferric chloride, and brown with nitrous acid. Couples with diazotised bases.
1 : 3 : 6 : 8	α-Naphthol- or α-naphthylamine-3 : 6 : 8-trisulphonic acid heated with ammonia and ammonium chloride at 160°–180° (Kalle, D. R.-P. 90905, E. P. 9103 of 1895).	*Acid* sparingly soluble leaflets. Gives intense green colouration with ferric chloride and brown with nitrous acid. Couples with diazotised bases. For 1-3-*diaryl* derivatives, *v.* 8-monosulphonic acid.
1 : 5 : 3 : 7	Dinitration and reduction of naphthalene-2 : 6-disulphonic acid (Cassella, D. R.-P. 61174, Eng. Pat. 15346 of 1890; *cf.* Oehler, D. P. Anm. O. 1430 of 1890; Bayer, D. R.-P. 126198 of 1900).	*Acid* very sparingly soluble leaflets; *sodium* and *barium* salts sparingly soluble. Forms an insol. *tetrazo*-compound (*cf.* Cassella, D. R.-P. 62075; Eng. Pat. 15346 of 1890). Couples with diazotised bases.
1 : 5 : 4 : (8)	1 : 5-Dinitronaphthalene heated with sodium bisulphite solution in reflux apparatus or under pressure (Fischesser & Co., D. R.-P. 79577; Eng. Pat. 13156 of 1894).	*Acid* readily soluble; *acid barium* salt $Ba(HA)_2+10H_2O$, moderately soluble. Gives a reddish-blue colouration with ferric chloride. Forms a *tetrazo*-compound, and couples.
1 : 6 : 3 : 8	Nitration and reduction of α-nitronaphthalene-3:8-disulphonic acid (Friedlaender and Kielbasinski, Ber. 1896, 29, 1982; *cf.* 2574).	*Acid* sparingly soluble, showing green fluorescence in solution.
1 : 6 : 4 : 8	Dinitration and reduction of naphthalene-1 : 5-disulphonic acid (Kalle, D. R.-P. 72665 of 1893; Friedlaender and Kielbasinski, Ber. 1896, 29, 1980; *cf.* 2574).	*Acid* sp. sol.; *sodium* salt, Na_2A, easily sol. needles Gives cherry-red coln. with ferric chloride. Forms a sparingly soluble *tetrazo*-compound. Couples with diazotised bases.
1 : 8 : (2) : 5	1 : 8-Diaminonaphthalene-4-sulphonic acid sulphonated with 8 p.c. anhydro-acid at 80° (Cassella, D. R.-P 72584 of 1892).	*Acid* and *sodium* salt readily soluble. Forms an *azimide.* Couples readily with 1 mol., less readily with 2 mols., of diazotised bases.
1 : 8 : 3 : 6	Dinitration and reduction of naphthalene-2 : 7-disulphonic acid (Cassella, D. R.-P. 61174; Eng. Pat. 13346 of 1890; Oehler, D. P. Anm. O. 1430 of 1890; *cf.* Alén, Förhandl. 1883, 3, 17).	*Acid potassium* salt $KHA+3H\ O$, needles; *acid barium* salt $Ba(HA)_2+6H_2O$, sp. sol. needles. Gives reddish-brown coln. with ferric chloride. Forms an *azimide* (Cassella, D. R.-P. 69963 of 1891). Couples with diazotised bases.

Constitution.	Preparation.	Acids, Salts and Reactions.
N:N:S:S 2:3:6:8	2-Amino-3-naphthol-6:8-disulphonic acid heated with 30 p.c. ammonia under pressure at 185°–190° (Aktienges., D. R.-P. 86448; Eng. Pat. 8645 of 1895).	*Acid* sparingly soluble needles; *sodium* salt readily soluble.
2:6:?:?	2:6-Dihydroxynaphthalenedisulphonic acid heated with ammonia and ammonium chloride under pressure at 200° (Jacchia, Annalen, 1902, 323, 131).	*Acid*, $H_2A + 4\frac{1}{2}H_2O$, leaflets.
2:7:3:6	2:7-Dihydroxynaphthalene-3:6-disulphonic acid heated with ammonia under pressure at 200°–220° (Aktienges., D. P. Anm. A. 3686 of 1893; Eng. Pat. 3844 of 1894).	*Acid*, sparingly, *sodium* salt, readily soluble. Gives faint brown colouration with ferric chloride. Forms a sparingly soluble *tetrazo*-compound. Couples with diazotised bases.

1:8-Diaminonaphthalene-2:4:(7 or 6)-trisulphonic acid, obtained when 1·8-dinitronaphthalene is heated with sodium bisulphite solution (Fischesser & Co., D. R.-P. 79577, Eng. Pat. 13156 of 1894), gives *acid sodium* salt $Na_2HA + 2H_2O$, readily, but *acid barium* salt $BaHA + 2H_2O$ only sparingly soluble. The colouration with ferric chloride is yellowish-brown. It forms an *azimide*, and couples with 1 mol. of a diazotised base.

TRIAMINONAPHTHALENES.

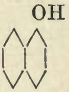
1:2:6-Triaminonaphthalene, obtained by reduction of 1:6-dinitro-β-naphthylamine (*cf.* Kehrmann and Matis, Ber. 1898, 31, 2419), forms a *triacetyl* derivative, needles, m.p. 280°, and gives the reactions of an *o*-diamine (Loewe, Ber. 1890, 23, 2544). 1:3:6-Triaminonaphthalene, obtained by heating 1:6-dihydroxynaphthalene-3-sulphonic acid with ammonia under pressure at 160°–180° (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895); and 1:3:7-triaminonaphthalene, prepared similarly from 1:7-dihydroxy-3-sulphonic or 2-amino-6-naphthol-8-sulphonic acid (Kalle, D. R.-P. 90905; Eng. Pat. 9103 of 1895) form sparingly soluble *sulphates* and give brown solutions with nitrous acid.

VI. HYDROXY- DERIVATIVES.

Introductory.—α-Naphthol, β-naphthol, several of the α- and β-naphtholsulphonic acids, and the greater number of the dihydroxynaphthalenes, are obtained on the large scale from the appropriate naphthalenesulphonic acids by fusion with caustic potash or soda. An alternative method, also of wide application, for the production of hydroxy-derivatives is that in which naphthylaminesulphonic acids are used, the exchange of the amino- group for hydroxyl being effected by the diazo- reaction, by the bisulphite method, or by water at a high temperature.

In general, the hydroxynaphthalenes resemble the hydroxybenzenes in chemical behaviour and properties, and the resemblance is complete when, by hydrogenation of the non-substituted ring, *ar.*- derivatives are formed from them (*cf.* Bamberger, Annalen, 1890, 257, 10). Nevertheless, in certain directions, differences—one of them of much technical importance—exist between the two series, as may be illustrated by reference to the two naphthols. These compounds, and β-naphthol more readily than α-naphthol, are converted into naphthylamines when heated with ammonia under pressure (Badische, D. R.-P. 14612; Eng. Pat. 2516 of 1880), into alkyl ethers when heated with alcohol and hydrochloric acid at 150° (Liebermann and Hagen, Ber. 1882, 15, 1427), and into naphthyl ethers when boiled with dilute sulphuric acid (Graebe, *ibid* 1880, 13, 1850), whereas phenol under similar conditions yields, at most, only traces of the corresponding products. Similar differences can be recognised when the dihydroxynaphthalenes are compared with the dihydroxybenzenes.

HYDROXYNAPHTHALENES.



(i.) α-**Naphthol** occurs in very small amount in coal tar fractions of high boiling-point (Schulze, Annalen, 1885, 227, 150). It was first obtained from α-naphthylamine by the diazo- reaction (Griess, Proc. Roy. Soc. 1867, 12, 419), but on the large scale is prepared either by fusing sodium naphthalene-α-sulphonate with caustic soda or potash (*cf.* Schaeffer, Annalen, 1869, 152, 281); or, free even from traces of β-naphthol, by heating α-naphthylamine with water under pressure.

Preparation.—The process adopted in the manufacture of α-naphthol from sodium naphthalene-α-sulphonate is practically identical with that described under β-naphthol (*q.v.*; *cf.* Levinstein, Eng. Pat. 2300 of 1883). Alternatively, α-naphthylamine hydrochloride or sulphate is heated with 5 times its weight of water under pressure at 200° for 1–4 hours, and the product distilled to remove small quantities of impurities of high boiling point (Höchst, D. R.-P. 74879; Eng. Pat. 14301 of 1892); *or* α-naphthylamine is heated with sodium bisulphate, phosphoric acid, or zinc chloride and water at 210° (Höchst, D. R.-P. 76595 of 1892).

Properties.—α-Naphthol crystallises in lustrous monoclinic needles (*cf.* Groth, Annalen, 1869, 152, 284), m.p. 94°, b.p. 278°–280° (Schaeffer, *l.c.*), sp.gr. 1·224 at 4° (Schröder, Ber. 1879, 12, 1613), and dissolves readily in alcohol, organic solvents, or in solutions of caustic alkalis, but only very sparingly in hot water. Its odour is phenolic and it volatilises readily with steam.

Reactions.—(1) It is converted into *α-dinaphthylene oxide* $(C_{10}H_6)_2O$ when boiled for some time in the air, when distilled with litharge, or, mixed with naphthalene and other products, when heated in a tube at 350°–400° (Graebe, Knecht, and Unzeitig, Annalen, 1881, 209, 134; Merz and Weith, Ber. 1881, 14, 195).

(2) With nitrous acid it forms a mixture of 2-*nitroso*- and 4-*nitroso-α-naphthol* (*v. Naphtha-*

quinoneoximes), the former as chief product (Fuchs, Ber. 1875, 8, 626), or, in ethereal solution, 2 : 4-*dinitro-α-naphthol* (Schmidt, *ibid.* 1900, 33, 3245).

(3) By nitration 2 : 4-*dinitro-α-naphthol* (Martius, J. pr. Chem. 1867, 102, 442), but by oxidation with nitric acid *phthalic acid* can be obtained from it. With potassium permanganate it is oxidised in acid solution to *phthalic acid*, and in alkaline solution to *phthalonic acid* (Henriques, Ber. 1888, 21, 1608).

(4) The action of ammonia, acetamide, and aniline on α-naphthol is described in connection with α-naphthylamine (*q.v.*).

(5) On reduction with sodium in amyl alcohol solution it is converted into ar.- *tetrahydro-α-naphthol*, as sole product (Bamberger and Bordt, Ber. 1890, 23, 215).

(6) By interaction of its dry sodium compound[1] with carbon dioxide 2-*hydroxy-α-naphthoic acid* is obtained (Schmitt and Burkard, Ber. 1887, 20, 2699).

Colour reactions.—Bleaching-powder solution added to an aqueous solution of α-naphthol gives first a dark-violet colouration and then a flocculent precipitate of the same colour. Ferric chloride added to an aqueous solution produces a milky opalescence, which changes to a violet flocculent precipitate of *αα′-dinaphthol* (Schaeffer, *l.c.*; Dianin, Ber. 1873, 6, 1252; 1874, 7, 487). Like β-naphthol (*q.v.*), it develops a Prussian-blue colouration with chloroform and caustic potash solution, but, unlike β-naphthol, it gives a deep violet turbid liquid when mixed in aqueous solution with sodium hypoiodite (Jorissen, Ann. Chim. anal. 1901, 7, 217).

Tests.—Commercial α-naphthol should be colourless, have a melting-point very nearly that of the pure compound, and leave only a small residue on extraction with caustic alkali solution.

Estimation.—The *picrate*, m.p. 189°–190°, which is almost insoluble in water (Marchetti, Gazz. chim. ital. 1882, 12, 503), can be employed in the quantitative estimation of α-naphthol. The sample is heated with N/20 picric acid solution in a closed vessel, and the excess of picric acid afterwards determined by titration with N/10 baryta, lacmoid being the indicator (Küster, Ber. 1894, 27, 1104).

α-Naphthyl methyl ether (α-methoxynaphthalene) is formed by heating sodium α-naphtholate with methyl chloride and methyl alcohol under pressure at 100° (Bayer, Eng. Pat. 1168 of 1879); *or* by passing methyl chloride through sodium α-naphtholate at 280° (Vincent, Bull. Soc. chim. 1883, [2] 40, 107); *or* by leading a solution of α-naphthol in methyl alcohol into naphthalene-β-sulphonic acid at 140°–145° (Krafft & Roos, D. R.-P. 76574 of 1893; Eng. Pat. 6190 of 1894); *or* by heating α-naphthylamine with methyl alcohol and zinc chloride at 180°–200° (Hantzsch, Ber. 1880, 13, 1347). It is conveniently prepared by heating α-naphthol (5 pts.) with absolute methyl alcohol (5 pts.) and sulphuric acid (2 pts.) at 140° in a reflux apparatus provided with a small mercury column (Gattermann, Annalen, 1888, 244, 72). It is an oil with an orange-like odour, b.p. 269°, sp.gr. 1·0974 at 15°, and is volatile with steam.

α-Naphthyl ethyl ether, obtained by methods similar to those described for the methyl ether (*cf.* Schaeffer, *l.c.*; Liebermann and Hagen, Ber. 1882, 15, 1427; Gattermann, *l.c.*), can be prepared by heating α-naphthol (72 grms.) with 36 p.c. caustic potash (85 c.c.) and potassium ethyl sulphate (90 grms.) for 6 hours under pressure at 150°, any unchanged α-naphthol being removed by coupling with diazotised sulphanilic acid (Witt and Schneider, Ber. 1901, 34, 3173). It is an oil of peculiar odour, m.p. 5·5°, b.p. 276°, and is volatile with steam.

Reactions.—On sulphonation it yields *ethoxy-α-naphthol-4-sulphonic acid*, from which by nitration 2 : 4-*dinitro-α-naphthol*, 4-*nitro-α-naphthyl ethyl ether*, and 2-*nitroethoxy-α-naphthol*-4-*sulphonic acid* are formed (Witt and Schneider, *l.c.*).

α-Naphthyl carbonate, formed by the interaction of phosgene and sodium α-naphtholate, is a crystalline powder, m.p. 129°–130° (Höchst, D. R.-P. 80888, 80889; Eng. Pat. 14134 of 1894).

α-Naphthyl acetate, prepared by heating α-naphthol with acetic acid at 200° (Graebe, Annalen, 1889, 209, 151), forms broad needles or tables, m.p. 49° (Miller, Annalen, 1881, 208, 248), and is hydrolysed by boiling with water.

α-NAPHTHOLSULPHONIC ACIDS.

Introductory.—The general methods employed in the preparation of α-naphtholsulphonic acids are :—

(1) Sulphonation of α-naphthol;

(2) Exchange of the amino- group in α-naphthylaminesulphonic acids for hydroxyl by the diazo- reaction, or by the bisulphite reaction, or by interaction with water at a high temperature;

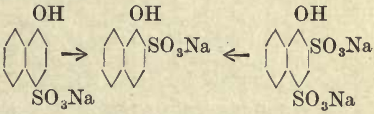
(3) Exchange of chlorine in α-chloronaphthalenesulphonic acids for hydroxyl by fusion with caustic alkali;

(4) Exchange of one sulphonic group in naphthalenepolysulphonic acids for hydroxyl by fusion with caustic alkali.

In addition to these processes, which are of technical importance, others of more limited application or value are known, such as—

(*a*) The partial hydrolysis of α-naphtholpolysulphonic acids by interaction either with dilute acids at a high temperature or with sodium amalgam;

(*b*) The change (*cf.* α-naphthylamine-4-sulphonic acid) which sodium α-naphthol-4-sulphonate and 2 : 4-disulphonate undergo when heated at 170° :—



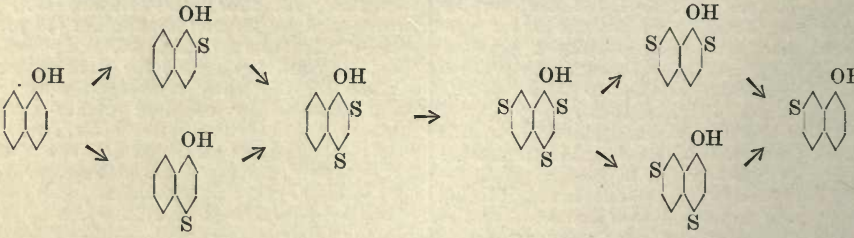
The α-naphtholsulphonic acids and their salts are more soluble and less well-defined than the related α-naphthylaminesulphonic derivatives; they are less easy, therefore, to recognise in or to isolate from mixtures containing them. The zinc salt, although easily soluble, has been used for the purpose of identifying monosulphonic acids, and it has been found that the qualitative

---

[1] Crystalline sodium α-(or β-)naphtholate can be obtained by dissolving the naphthol (1 pt.) in boiling 7·5 p.c. caustic soda solution to which, afterwards, common salt (1 pt.) is added (König, D. R.-P. 216596 of 1908).

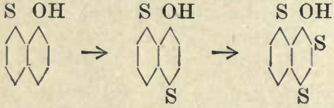
composition of a sulphonation product can be determined largely by means of nitrous acid (giving rise to *o*- or *p*-nitroso- derivatives), nitric acid (producing naphthol yellows), or diazotised bases (leading to the formation of *o*- or *p*-azo-dyes): reagents which interact with some isomerides but not with others.

The course of the sulphonation of α-naphthol, as traced by the application of these analytical methods, is shown in the scheme—



from which it will be seen that three of the acids owe their formation to partial hydrolysis of the trisulphonic acid—effected by relatively dilute sulphuric acid at the highest temperature employed in these sulphonations.

The scheme also shows that acids containing the SO_3H radicle in the 3-, 5-, or 8- position are not formed by the action of sulphuric acid on α-naphthol. Neither are they formed by the sulphonation of α-naphtholsulphonic acids obtained in other ways, for example—



and to obtain them recourse must be had to the second general method with α-naphthylaminesulphonic acids of the desired orientation.

As in the case of the corresponding α-naphthylaminesulphonic acids, it is found that α-naphtholsulphonic acids with a sulphonic group in the 3- position give 1 : 3-diaminonaphthalene derivatives with ammonia; those containing it in the 8- position give *peri*-anhydrides (*sultones*); and those in which it occurs in the 3-, 4-, or 5- position give *ortho*-azo-dyes.

α-Naphtholmonosulphonic Acids.[1]

(i.) **α-Naphthol-2-sulphonic acid** (Schaeffer's acid) has not been obtained pure by the sulphonation of α-naphthol. The earliest process for its preparation, by heating α-naphthol with twice its weight of sulphuric acid on a water-bath until sulphonation is complete (Schaeffer, Annalen, 1869, 152, 293; Darmstaedter and Wichelhaus, Eng. Pat. 89 of 1869), has been shown by Conrad and Fischer (Annalen, 1893, 273, 109), and by Bender (Ber. 1889, 22, 999), to give rise to a product containing much 4-mono- and 2 : 4-di-sulphonic acids.[2] If α-naphthol be heated only for a short time with an equal weight of sulphuric acid at 60°–70°, so that sulphonation is incomplete, the yield is increased from 23 p.c. under Schaeffer's conditions to 50 p.c., and the product can be separated as potassium salt by the addition of potassium chloride to the melt diluted slightly with water (Friedlaender and Taussig, Ber. 1897, 30, 1457).

Preparation.—It can be prepared either from α-naphthol by Friedlaender and Taussig's method (*l.c.*), or from α-naphthylamine-2-sulphonic acid by the diazo- reaction (Cleve, Ber. 1881, 24, 3476); or the sodium salt, in 70–80 p.c. yield, by heating sodium α-naphthol-4-sulphonate or 2 : 4-disulphonate, mixed with twice its weight of naphthalene or paraffin, during 3–4 hours at 160°–170° (Bayer, D. R.-P. 237396; Eng. Pat. 2355 of 1911).

Salts.—The *acid* forms small rhombic prisms and differs from its isomerides in being sparingly soluble in dilute mineral acids. The *lead* salt PbA_2+H_2O in scales; *barium* salt $BaA_2+1\frac{1}{2}H_2O$ in needles; and *calcium* salt CaA_2+H_2O(?) in scales, are sparingly soluble (Cleve, *l.c.*): the *potassium* salt $KA+\frac{1}{2}H_2O$, in prisms, is soluble in 37 parts of water at 18°, but almost insoluble in saturated potassium chloride solution (Conrad and Fischer, *l.c.*).

Reactions.—(1) Nitrous acid reacts with it in the cold forming 4-*nitroso-α-naphthol-2-sulphonic acid*, which does not give a naphthol green with iron salts,[3] but like α-naphthol-2-sulphonic acid yields 2 : 4-*dinitro-α-naphthol* when warmed with dilute nitric acid (*cf.* Bender, *l.c.*; Conrad and Fischer, *l.c.*).

(2) By further sulphonation it is converted successively into α-*naphthol*-2 : 4-*disulphonic* and 2 : 4 : 7-*trisulphonic acids* (*cf.* Bender, *l.c.*).

(ii.) **α-Naphthol-3-sulphonic acid** is obtained when naphthalene-1 : 3-disulphonic acid is fused with caustic alkalis at 200°–300° (Badische, D. R.-P. 57910; Eng. Pat. 9537 of 1890); *or* when diazotised α-naphthylamine-3-sulphonic acid is boiled with 10 p.c. sulphuric acid (Friedlaender, Ber. 1895, 28, 1952) or water (Gattermann and Schulze, *ibid.* 1897, 30, 54); *or* when diazotised 2-amino-8-naphthol-6-sulphonic acid is boiled with alcohol (Badische, *l.c.*; Friedlaender and Taussig, Ber. 1897, 30, 1458); *or* when α-naphthol-3 : 8-disulphonic acid is reduced electrolytically (Bayer, Fr. Pat. 439010 of 1912, *v.* p. 592, footnote 1).

Salts.—The *zinc* salt $ZnA_2+8\frac{1}{2}H_2O$ forms long needles and, like the *barium* salt, is easily soluble (Friedlaender and Taussig, *l.c.*).

---

[1] In every case where the constitution of an α-naphtholsulphonic acid is given, the OH radicle is supposed to be in the position '1.'

[2] Mixed products also are formed by the methods employed by Claus and Oehler (Ber, 1882, 15, 312; *cf.* Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 80), by Claus and Knyrim (Ber. 1885, 18, 2924), and by Baum (D. P. Anm. B. 4197; Eng. Pat. 3498 (prov.) of 1883), in which sulphuric acid, chlorosulphonic acid, or anhydro-acid is employed, the methods themselves being valueless (*cf.* Conrad and Fischer, *l.c.*).

[3] The production of a naphthol green with iron salts serves to distinguish *ortho*- from *para*-nitroso-derivatives.

Reactions.—(1) When coupled with diazotised bases it yields *ortho*-azo- dyes (Gattermann and Schulze, *l.c.*).

(2) When heated with ammonia under pressure at 160°–180° it is converted into 1 : 3-*diaminonaphthalene* (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895); and with aniline and its hydrochloride at 150°–170° into *diphenyl*-1 : 3-*diaminonaphthalene* (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893).

(3) Digestion with 60 p.c. caustic soda under pressure at 180° converts it into o-*toluic acid* (Kalle, D. R.-P. 79028 of 1894).

(iii.) α-**Naphthol-4-sulphonic acid** (Nevile and Winther's acid). This acid is found in the sulphonation product obtained from α-naphthol by Schaeffer's method (*v.* 2-acid), and can be separated from the 2-acid either by converting the product into sodium salt, from which it is extracted by boiling 90 p.c. alcohol (Verein, D. R.-P. 26012; Eng. Pat. 2237 of 1883), or by precipitation as zinc salt (Friedlaender and Taussig, Ber. 1897, 30, 1458).

Preparation.—From naphthionic acid: By boiling the diazo- compound with 10 p.c. sulphuric acid (Nevile and Winther, Chem. Soc. Trans. 1880, 37, 632; Dahl, Eng. Pat. 2296 of 1883; Erdmann, Annalen, 1888, 247, 341); *or* by heating the sodium salt with 50 p.c. caustic soda solution under pressure at 240°–260°, and boiling the solution of the product in water to expel ammonia (Aktienges., D. R.-P. 46307 of 1888); *or*, pure and in almost quantitative yield, by digesting the sodium salt with 40 p.c. sodium bisulphite solution at 80°–90°, boiling the product with alkali to expel ammonia, and then acidifying it to remove sulphurous acid (Bayer, D. R.-P. 109102; Eng. Pat. 16807 of 1899).

It can also be obtained by digesting α-chloronaphthalene-4-sulphonic acid with 25 p.c. caustic soda solution under pressure at 200°–220° (Oehler, D. R.-P. 77446 of 1893); *or* by heating α-methoxynaphthalene-4-sulphonic acid with 50 p.c. caustic soda solution under pressure at 240° (Dahl, D. R.-P. 88843 of 1896); *or* by stirring α-naphthyl carbonate into monohydrate at 10°–20°, pouring the solution on to ice, salting out the disulpho-α-naphthyl carbonate, and boiling this product with water at 60°–70° (Höchst, D. R.-P. 80889; Eng. Pat. 14135 of 1894; Reverdin, Ber. 1894, 27, 3460).

Salts.—The *acid* and salts are easily soluble. The *zinc* salt ZnA_2+8H_2O forms prisms; the *sodium* salt, which can be salted out from solution, forms columnar crystals (Friedlaender and Taussig, *l.c.*), is soluble in 90 p.c. alcohol, and gives with ferric chloride a blue or bluish-green colouration (Dahl, *l.c.*; Erdmann, *l.c.*).

Reactions.—(1) The ortho-*azo*- dyes which it yields by coupling with diazotised bases are of much technical importance on account of the purity of their shades (*cf.* Verein, *l.c.*; Bayer, D. R.-P. 35341; Eng. Pat. 9510 of 1885; Gesellsch., D. R.-P. 66838 of 1892).

(2) Nitrous acid reacts with it in the cold forming 2-*nitroso-α-naphthol*-4-*sulphonic acid* (Witt and Kaufmann, Ber. 1891, 24, 3160), which gives a *naphthol green* with iron salts (Gans & Co. D. R.-P. 28065; Eng. Pat. 2269 of 1884; Hoffmann, Ber. 1885, 18, 46), and, like α-naphthol-2 : 4-sulphonic acid, yields 2 : 4-*dinitro-α-naphthol* when warmed with dilute nitric acid (*cf.* Bender, Ber. 1889, 22, 997).

(3) When heated at 160°–170°, the sodium salt is converted into *sodium α-naphthol*-2-*sulphonate* (Bayer, D. R.-P. 237396; Eng. Pat. 2355 of 1911).

(4) By digestion with ammonium sulphite solution and ammonia at 100°–150°, it is converted into *naphthionic acid* (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

(5) On further sulphonation it yields successively *α-naphthol*-2 : 4-*disulphonic acid* (Armstrong, *priv. comm.*), and *α-naphthol*-2 : 4 : 7-*trisulphonic acid* (*cf.* Friedlaender and Taussig, *l.c.* 1463).

(iv.) α-**Naphthol-5-sulphonic acid** (Cleve's acid; L- acid) is obtained by boiling diazotised α-naphthylamine-5-sulphonic acid with 10 p.c. sulphuric acid (Verein, D. R.-P. 26012; Eng. Pat. 2237 of 1883; *cf.* Gaess, D. P. Anm. G. 2393 of 1883; Schöllkopf, Eng. Pat. 15781 of 1885). It is also formed when sodium naphthalene-1 : 5-disulphonate is fused with caustic soda at 160°–190°; the sparingly soluble sodium α-naphthol-5-sulphonate being obtained by acidifying the aqueous solution of the melt with hydrochloric acid (Ewer & Pick, D. R.-P. 41934 of 1887); *or* when α-chloronaphthalene-5-sulphonic acid is heated with 8 p.c. caustic soda solution under pressure at 240°–250° (Oehler, D. R.-P. 77446 of 1893).

Identification.—The *acid* forms a semi- crystalline deliquescent mass (Erdmann, Annalen, 1888, 247, 343); the *zinc* salt $ZnA_2+8\frac{1}{2}H_2O$, easily soluble long needles (Friedlaender and Taussig, Ber. 1897, 30, 1460); the *sodium* salt dissolves readily in warm alcohol, and gives with ferric chloride a violet-red colouration (Gaess, *l.c.*).

Reactions.—(1) Diazotised bases couple with it forming ortho-*azo*- dyes, but these are of little value (*cf.* Gesellsch., D. R.-P. 66838 of 1892).

(2) Nitrous acid reacts with it in the cold forming 2-*nitroso-α-naphthol*-5-*sulphonic acid*, which crystallises well, and gives a *naphthol green* with iron salts (Friedlaender and Taussig, *l.c.*).

(3) Fusion with caustic soda at 220°–260° converts it into 1 : 5-*dihydroxynaphthalene* (Ewer and Pick, *l.c.*; Schultz, Ber. 1887, 20, 3161).

(v.) α-**Naphthol-6-sulphonic acid** is obtained from α-naphthylamine-6-sulphonic acid either by the diazo- reaction (*cf.* Erdmann and Süvern, Annalen, 1893, 275, 304); or by digestion with 40 p.c. sodium bisulphite solution at 120°–150°, the product being boiled to expel ammonia and then acidified to remove sulphurous acid (Bayer, D. R.-P. 109102; Eng. Pat. 16807 of 1899). It is also formed when sodium naphthalene-1 : 6-disulphonate is fused with caustic soda (*cf.* Bucherer, J. pr. Chem. 1904, [ii.] 70, 346).

This acid is technically unimportant, and of its properties little is known.

(vi.) α-**Naphthol-7-sulphonic acid** is probably the chief product when the mixed barium salt from the acids (mainly α-naphthol-2 : 7-, and 4 : 7-disulphonic, and 2 : 4 : 7-trisulphonic acids) obtained by heating α-naphthol with 4 times its weight of sulphuric acid at 130° for an hour, is boiled with hydrochloric or diluted sulphuric acid (Liebmann and Studer, D. P. Anm. L. 4327; Eng. Pat. 7812 of 1887).

In the pure form it can be obtained either from α-naphthylamine-7-sulphonic acid by the bisulphite method (*cf.* Bucherer, J. pr. Chem. 1904, [ii.] 70, 347); *or*, from 2-carboxy-α-naphthol-7-sulphonic acid by heating it with a small quantity of water at 120° (Friedlaender and Taussig, Ber. 1897, 30, 1461).

Identification.—The *acid*, a crystalline mass, gives with ferric chloride a brownish-violet colouration, and like the salts is easily soluble. The *zinc* salt ZnA_2+8H_2O forms radiate groups of needles; the *barium* salt needles (Friedlaender and Taussig, *l.c.*).

Reactions.—(1) Coupled with diazotised bases in acetic acid solution it gives *monoazo-* and in alkaline solution *disazo-* dyes (Bender, *l.c.*; Friedlaender and Taussig, *l.c.*).

(2) Nitrous acid reacts with it forming a *nitroso-α-naphthol*-7-*sulphonic acid*, which is converted into *naphthol yellow S* when warmed with dilute nitric acid (Bender, Ber. 1889, 22, 996).

(3) By digestion with sodium bisulphite solution and ammonia at 100°–110°, followed by acidification, it is converted into α-naphthylamine-7-sulphonic acid (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

(vii.) **α-Naphthol-8-sulphonic acid** (S-acid). Unlike its isomerides, diazotised α-naphthylamine-8-sulphonic acid when boiled with water or dilute sulphuric acid is not converted into α-naphthol-8-sulphonic acid but into *naphthasultone*, the *peri*-anhydride of this acid (Schultz, Ber. 1887, 20, 3162; Erdmann, Annalen, 1888, 247, 344). The acid can be obtained from the sultone by heating it with alcoholic ammonia at 130°, adding lead acetate, and decomposing the precipitated lead salt with hydrogen sulphide (Erdmann, *l.c.*); *or* from α-naphthylamine-8-sulphonic acid either by heating it with water under pressure at 180°–220° (Höchst, D. R.-P. 74644; Eng. Pat. 14301 of 1892), or by the bisulphite method (*cf.* Bucherer, J. pr. Chem. 1904, [ii.] 70, 347).

Salts.—The *acid* $HA+H_2O$ is crystalline, m.p. 106°–107°, and very soluble. It does not lose the water of crystallisation below 180°, and shows little tendency to pass into the anhydride even in the presence of dehydrating agents. The *potassium* salt KA in scales; the *basic sodium* salt $Na_2A+1\frac{1}{2}H_2O$ in small needles; and the *ammonium* salt NH_4A in scales, are easily soluble, and like the acid give with ferric chloride a dark green colouration, changing rapidly to red (Erdmann, *l.c.*).

Reactions.—(1) With nitrous acid a sparingly soluble *nitroso-* compound is obtained, which yields 2:4-*dinitro-α-naphthol*-8-*sulphonic acid* (*brilliant yellow*) when warmed with nitric acid (Schöllkopf, D. R.-P. 42304 of 1886).

(2) When fused with caustic potash at 220° it is converted into 1:8-*dihydroxynaphthalene* (Erdmann, Annalen. 1888, 247, 356).

Naphthasultone  $C_{10}H_6<\substack{SO_2\\O}>$, first described as naphtholsulphonic acid S (Schöllkopf, D. R.-P. 40571; Eng. Pat. 15775 of 1885; *v.* S-acid), is obtained almost quantitatively by boiling diazotised α-naphthylamine-8-sulphonic acid with alcohol, water, or dilute sulphuric acid (Karpeles, *cf.* J. Soc. Chem. Ind. 1898, 17, 837). It crystallises from alcohol in large prisms, m.p. 154°, distils above 360° with only slight decomposition, and is almost insoluble in water.

Reactions.—(1) It yields salts of α-naphthol-8-sulphonic acid when boiled with aqueous caustic alkalis or alcoholic ammonia, but does not react with these in the cold (Schultz, Ber. 1887, 20, 3162; Erdmann, Annalen, 1888, 247, 345).

(2) When heated with sulphuric acid at 80°–90° it is converted into *α-naphthol*-4:8-*disulphonic acid* (Schöllkopf, *l.c.*; Bernthsen, Ber. 1890, 23, 3090), and with 25 p.c. anhydro- acid at temperatures below 100° into *α-naphthol*-2:4:8-*trisulphonic acid* (Bayer, D. P. Anm. F. 4569; Eng. Pat. 3397 of 1890; Dressel and Kothe, Ber. 1894, 27, 2143).

α-NAPHTHOLDISULPHONIC ACIDS.

(i.) **α-Naphthol-2:4-disulphonic acid** is formed by the sulphonation of α-naphthol or of α-naphthol-2- or 4-sulphonic acid at temperatures below 100°,[1] and is separated from mono- or disulphonic acids in the product by removing these either with nitrous acid as sparingly soluble nitroso- compounds, or with diazotised bases as insoluble azo- dyes. When α-naphthol (5 pts.) is heated with sulphuric acid (9 pts.) for 2 hours at 50°, the product consists of the 2:4-disulphonic acid mixed with about 5 p.c. (Conrad and Fischer, Annalen, 1893, 273, 105), or about 30 p.c. (Friedlaender and Taussig, Ber. 1897, 30, 1457), of α-naphthol-2-sulphonic acid.

Identification.—The *potassium* salt K_2A in solution gives with ferric chloride a deep blue colouration, but is not precipitated by lead acetate or barium chloride, and yields neither azo- dyes nor a nitroso- compound (Conrad and Fischer, *l.c.*).

Reactions.—(1) When warmed with nitric acid, pure 2:4-*dinitro-α-naphthol* (*Martius yellow*) is obtained (Bender, *l.c.*).

(2) When the potassium salt is heated at 170°–180° (Conrad and Fischer, *l.c.* 111), or the sodium salt, suspended in naphthalene, is heated at 150°–160° (Bayer, D. R.-P. 237396; Eng. Pat. 2355 of 1911) it is converted into potassium *α-naphthol*-2-*sulphonate.*

(3) By further sulphonation it is converted into *α-naphthol*-2:4:7-*trisulphonic acid* (*cf.* Friedlaender and Taussig, *l.c.* 1463).

(ii.) **α-Naphthol-2:5-disulphonic acid** is prepared by heating α-naphthol-5-sulphonic acid with sulphuric acid or with 20 p.c. anhydro-acid below 100° (Bayer, D. R.-P. 68344 of 1889; Eng. Pat. 3397 of 1890).

Identification.—The *sodium* salt which crystallises in prisms, does not form a nitroso- derivative (Bayer, *l.c.*) or couple with diazotised bases (Gattermann and Schulze, Ber. 1897, 30, 55).

Reaction.—By digestion with 60 p.c. caustic soda solution at 250° it gives 1:5-*dihydroxynaphthalene*-2-*sulphonic acid* (Bayer, *l.c.*).

(iii.) **α-Naphthol-2:7-disulphonic acid** occurs among the products formed when α-naphthol is heated with sulphuric acid at temperatures above 100° for several hours, and is probably the

---

[1] According to Bender (Ber. 1889, 22, 998), the product obtained by heating α-naphthol with 2½ times its weight of sulphuric acid at 100°–105° for three hours, contains in addition to the 2:4-acid about 45 p.c. of a second disulphonic acid, having a sulphonic group in each nucleus, and some trisulphonic acid, its composition being estimated from the results obtained (*a*) by nitration, (*b*) by precipitation with diazotised xylidine.

chief constituent of the mixture of acids obtained by sulphonating α-naphthol with 2–3 times its weight of 'about 93 p.c.' sulphuric acid ('65°–66°B.') at 125°–130° for about 2 hours (Leonhardt, Eng. Pat. 11318 of 1887; *cf.* Friedlaender and Taussig, Ber. 1897, 30, 1463).[1] A method for isolating the constituents of the mixture has not been described.

It can be obtained from α-naphthylamine-2 : 7-disulphonic acid by the diazo- reaction (*cf.* Reverdin and de la Harpe, Ber. 1892, 25, 1405); *or* from α-chloronaphthalene-2 : 7-disulphonic acid by digestion with 30 p.c. caustic soda solution at 200°–210° (Oehler, D. R.-P. 74744 of 1893); *or* from α-naphthol-2 : 4 : 7-trisulphonic acid by interaction with sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3031).

Identification.—Little is known of the properties of the pure acid. It forms a soluble *zinc* salt ZnA (Friedlaender and Lucht, *l.c.*), and gives a blue colouration with ferric chloride; para-*azo*-dyes by coupling with diazotised bases (Oehler, *l.c.*); and a *nitroso*- derivative which does not form a naphthol green with iron salts (Friedlaender and Taussig, *l.c.*).

(iv.) α-**Naphthol-3 : 6-disulphonic acid** obtained when sodium naphthalene-1 : 3 : 6-trisulphonate is heated with 50 p.c. caustic soda solution at 170°–180° (Gürke and Rudolph, D. R.-P. 38281; Eng. Pat. 15716 of 1885), can be prepared from α-naphthylamine-3 : 6-disulphonic acid either by the diazo-reaction (Freund, D. R.-P. 27346; Eng. Pat. 1069 of 1883)[2] or by heating its acid sodium salt with water under pressure at 180° (Cassella, D. P. Anm. C. 4375 of 1892).

Identification.—The *acid barium* salt BaH_2A_2 is sparingly soluble; the *acid sodium* salt NaHA dissolves readily in water or alcohol, gives with ferric chloride a blue colouration, and with diazotised bases ortho-*azo-* dyes (Freund, *l.c.*; *cf.* Friedlaender and Taussig, Ber. 1897, 30, 1462).

Reactions.—When heated with ammonia under pressure at 160°–180° it is converted into 1 : 3-*diaminonaphthalene-6-sulphonic acid* (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895), or with aniline and aniline hydrochloride at 150°–170° into the *diphenyl*-derivative of this acid (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893).

(v.) α-**Naphthol-3 : 7-disulphonic acid** can be prepared from α-naphthylamine-3 : 7-disulphonic acid, either by the diazo- reaction (Freund, D. R.-P. 27346; Eng. Pat. 1069 of 1883)[2] or by heating its acid sodium salt with water under pressure at 180° (Cassella, D. P. Anm. C. 5069 of 1892).

Reactions.—Of its properties or salts little is known, but it resembles the 3 : 6-acid (*q.v.*) in its behaviour towards ferric chloride, diazotised bases (Freund, *l.c.*) ammonia (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895), and aniline (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893).

(vi.) α-**Naphthol-3 : 8-disulphonic acid** (α-naphthol-[ε-]disulphonic acid) is prepared from α-naphthylamine-3 : 8-disulphonic acid either by heating its acid sodium salt with water under pressure at 180° (Höchst, D. R.-P. 71494; Eng. Pat. 14301 of 1892), or by boiling its diazo- compound with dilute sulphuric acid[3] (Aktienges., D. R.-P. 45776; Eng. Pat. 4625 of 1888; Bernthsen, Ber. 1889, 22, 3330).

Identification.—The *sodium* salt Na_2A+6H_2O forms long prisms soluble in about 5·5 parts of cold water, gives with ferric chloride a deep blue colouration and yields, not a naphthol yellow, but oxidation products with nitric acid (Aktienges., *l.c.*; Bernthsen, *l.c.*).

Reactions.—(1) It couples with diazotised bases forming ortho-*azo-* dyes (Aktienges., D. R.-P. 57444; Eng. Pat. 6932 of 1890; D. R.-P. 63951; Eng. Pat. 17333 of 1888).

(2) By digestion with 50 p.c. caustic soda solution at 170°–210° it forms 1 : 8-*dihydroxynaphthalene-3-sulphonic acid* (Kalle, D. R.-P. 82422 of 1894). Electrolytically, it is reduced to the 3-*sulphonic acid* (*v.* p. 592, footnote 1).

(3) When heated with ammonia under pressure at 160°–180° it is converted into 1 : 3-*diaminonaphthalene - 8 - sulphonic acid* (Kalle, D. R.-P. 89061 of 1894; Eng. Pat. 9103 of 1895), or with aniline and aniline hydrochloride at 150°–170° into the *diphenyl-* derivative of this acid (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893).

(4) Dehydrating agents, *ex. gr.* sulphuric acid at 100°, or phosphoric oxide, or phosphoric chloride, convert it into *naphthasultone-3-sulphonic acid* (Badische, D. R.-P. 55094 of 1889).

The *peri*-anhydride, naphthasultone-3-sulphonic acid (naphthasultonesulphonic acid-ε; ζ-naphtholdisulphonic acid), forms readily soluble silky needles; the *barium* salt sparingly soluble long needles; the *sodium* salt $NaA+3H_2O$ long needles soluble in about 93 parts of cold water. It gives no colouration with ferric chloride, and is readily convertible into α-naphthol-3 : 8-disulphonic acid by mineral acids or by alkalis (Ewer and Pick, D. R.-P. 52724 of 1888; Badische, *l.c.*; Bernthsen, *l.c.*). Ammonia reacts with it forming the half amide: α-Naphthol-8-sulphonamide-3-sulphonic acid (ε- or ζ-naphtholsulphamidesulphonic acid), $OH{\cdot}C_{10}H_5(SO_2NH_2){\cdot}SO_3H$, which crystallises in moderately soluble needles. Its *barium* salt BaA_2+5H_2O and *sodium* salt $NaA+H_2O$, needles, are moderately soluble; its *sodium ammonium* salt NaA,NH_3+H_2O ($3H_2O$ in D. R.-P. 53934) forms very soluble small prisms, and from each salt when boiled with dilute acids α-naphthol-3 : 8-disulphonic acid is obtained

---

[1] Bearing in mind the conclusions reached by Bender (Ber. 1889, 22, 998; *cf.* Aktienges., D. R.-P. 45776; Eng. Pat. 4625 of 1888), and by Friedlaender and Taussig (Ber. 1897, 30, 1463), it is probable that the Patents dealing with the prolonged sulphonation of α-naphthol may be divided into two groups:

(*a*) Those in which anhydro-acid or a relatively large proportion of sulphuric acid is used at 100°, or at temperatures below 100°, leading mainly to the production of α-naphthol-2 : 4-di- and 2 : 4 : 7-tri-sulphonic acids (*cf.* Seltzer, D. R.-P. 20716 of 1882; Durand and Huguenin, Eng. Pat. 2591 (prov. spec.) of 1883; Vignon & Co., Eng. Pat. 9808 (prov. spec.) of 1884).

(*b*) Those in which a relatively small proportion of sulphuric acid at 100°–130° is used leading to the production of α-naphthol-2 : 7-disulphonic acid mixed with varying proportions of the 4 : 7-di-, and 2 : 4 : 7-trisulphonic acids (*cf.* Badische, D. R.-P. 10785; Eng. Pat. 5305 of 1879; Levinstein, Eng. Pat. 5692 of 1882; Vignon, D. R.-P. 32291; Eng. Pat. 6872 of 1884; Leonhardt, Eng. Pat. 11318 of 1887; Read, Holliday and Sons, Eng. Pat. 5103 of 1891).

[2] In this Patent the product is considered to be a β-naphtholdisulphonic acid on account of the fastness to acids shown by the derived azo-dyes, but these are now known to be *ortho*-azo-dyes (Cassella, *l.c.*).

[3] If the boiling be stopped directly nitrogen ceases to be evolved, the solution will contain the *peri*-anhydride, which by continued boiling furnishes the naphtholdisulphonic acid (Bernthsen, *l.c.*).

(Badische, D. R.-P. 53934 of 1889; Bernthsen, *l.c.*). It couples with diazotised bases, forming ortho-*azo*- dyes (*cf.* Badische, D. R.-P. 57484, 57907 of 1889; Geigy, D. R.-P. 139287 of 1902), which when boiled for a short time with alkali hydroxides or carbonates are converted into *peri*-anhydrides  $<\genfrac{}{}{0pt}{}{NH}{SO_2}>C_{10}H_4(SO_3H){\cdot}N_2{\cdot}R$, the colour changing from bluish-red to yellow (Bernthsen, Ber. 1890, 23, 3094).

(vii.) α-**Naphthol-4 : 6-disulphonic acid** can be prepared from α-naphthylamine-4 : 6-disulphonic acid either by the diazo- reaction (Dahl, D. R.-P. 41957 of 1886), or by the bisulphite method (Bucherer, J. pr. Chem. 1904, [ii.] 70, 347); *or*, mixed with the 4 : 7- acid, from tetrasulpho-αα′-dinaphthyl carbonate, by heating the product of the sulphonation of αα′-dinaphthyl carbonate with dilute acid at 60°–70° to eliminate carbon dioxide, the 4 : 7-disulphonic acid being removed by salting out (Höchst, D. R.-P. 80888; Eng. Pat. 14134 of 1894).

Reactions.—It yields *azo*- dyes when coupled with diazotised bases, and a *naphthol yellow* when boiled with nitric acid (Dahl, *l.c.*).

(viii.) α-**Naphthol-4 : 7-disulphonic acid** occurs in varying amounts in the products obtained by the sulphonation of α-naphthol under conditions which lead also to the formation of the 2 : 7- acid (*q.v.*; *cf.* Friedlaender and Taussig, Ber. 1897, 30, 1463).

It can be prepared from α-naphthylamine-4 : 7-disulphonic acid either by the diazo-reaction (Dahl, D. R.-P. 41957 of 1886), or by the bisulphite method (Bucherer, J. pr. Chem. 1904, [2] 70, 347); *or* from α-chloronaphthalene-4 : 7-disulphonic acid by digestion with 30 p.c. caustic soda solution at 200°–210° (Oehler, D. R.-P. 74744 of 1893); *or* by boiling with dilute acid either tetrasulpho-αα′-dinaphthyl carbonate (*v.* 4 : 6-acid; Höchst, D. R.-P. 80888; Eng. Pat. 14134 of 1894), or 2-carboxy-α-naphthol-4 : 7-disulphonic acid (Friedlaender and Taussig, *l.c.*; *cf.* Seidler, D. R.-P. 56328 of 1889).

Identification.—The *barium* salt $BaA+4H_2O$ and *sodium* salt Na_2A+4H_2O are crystalline. The sodium salt in solution gives with ferric chloride a blue colouration (Oehler, *l.c.*).

Reactions.—(1) Ortho-*azo* dyes are obtained by coupling it with diazotised bases (*cf.* Dahl, *l.c.*; Oehler, *l.c.*).

(2) Nitrous acid reacts with it forming a very soluble *nitroso*- compound which, like the acid, yields 2 : 4-*dinitro-α-naphthol*-7-*sulphonic acid* (naphthol yellow S) when warmed with nitric acid (Armstrong and Wynne, Chem. Soc. Proc. 1890, 6, 17; Dahl, *l.c.*).

(3) When boiled with 65 p.c. sulphuric acid or with hydrochloric acid it is hydrolysed not to α-naphthol, but only to α-*naphthol*-7-*sulphonic acid* (Liebmann and Studer, D. P. Anm. L. 4327; Eng. Pat. 7812 of 1887; *cf.* Friedlaender and Taussig, *l. c.*).

(ix.) α-**Naphthol-4 : 8-disulphonic acid** (α-naphtholdisulphonic acid S; α-naphthol-[δ]-disulphonic acid) is obtained when naphthasultone (so-called α-naphtholsulphonic acid S of D. R.-P. 40571) is heated with sulphuric acid at 80°–90° until soluble in water (Schöllkopf, D. R.-P. 40571; Eng. Pat. 15775 of 1885; Bernthsen, Ber. 1890, 23, 3090). It is also formed from α-naphthylamine-4 : 8-disulphonic acid either by the diazo- reaction (Schöllkopf, *l.c*), or by the bisulphite method (Bucherer, J. pr. Chem. 1904, [ii.] 69, 80; *cf.* Badische, D. R.-P. 115335 of 1899; Eng. Pat. 1387 of 1900).

Identification.—The *barium* salt is sparingly soluble, the *sodium* salt Na_2A+H_2O forms very soluble scales (Aktienges., D. R.-P. 45776; Eng. Pat. 4625 of 1888), and with ferric chloride gives a deep blue colouration (Bernthsen, *l.c.*).

Reactions.—(1) It couples with diazotised bases forming ortho-*azo*- dyes (Schöllkopf, *l.c.*; Aktienges., D. R.-P. 57444; Eng. Pat. 6932 of 1890; D. R.-P. 60921 of 1891).

(2) Nitrous acid converts it into the 2-*nitroso*-derivative (Dressel and Kothe, Ber. 1894, 27, 2145) which, when warmed with nitric acid, forms 2 : 4-*dinitro-α-naphthol*-8-*sulphonic acid* (the *brilliant yellow* of D. R.-P. 40571).

(3) When fused with caustic soda at 250° it yields 1 : 8-*dihydroxynaphthalene*-4-*sulphonic acid* (Bayer, D. R.-P. 54116, 67829; Eng. Pat. 13655, 18517 of 1889).

(4) By the bisulphite reaction, it can be converted into α-*naphthylamine*-4 : 8-*disulphonic acid* (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

(5) With 5 p.c. anhydro- acid in the cold, it yields the anhydride, *naphthasultone*-4-*sulphonic acid* (Badische, D. R.-P. 57388 of 1889; Bernthsen, *l.c.*), but with 25 p.c. anhydro- acid below 100° it gives α-*naphthol*-2 : 4 : 8-*trisulphonic acid* (Bayer, D. P. Anm. F. 4569; Eng. Pat. 3397 of 1890; Dressel and Kothe, *l.c.*).

The *peri*-anhydride, naphthasultone-4-sulphonic acid (naphthasultonesulphonic acid-δ) forms an easily soluble *barium* salt. The *sodium* salt $NaA+3H_2O$, in moderately soluble scales, is converted readily into sodium α-naphthol-4 : 8-disulphonate by alkalis, boiling with 5 p.c. sulphuric acid, or prolonged boiling with water, and gives neither a colouration with ferric chloride nor azo- dyes with diazotised bases (Bernthsen, *l.c.*; *cf.* Badische, D. R.-P. 57388 of 1889). Dissolved in concentrated ammonia it gives with hydrochloric acid a precipitate of α-Naphthol-8-sulphonamide-4-sulphonic acid (δ-acid), the half amide, as *sodium* salt $OH{\cdot}C_{10}H_5(SO_2NH_2){\cdot}SO_3Na+2H_2O$, which crystallises in rhomb-like scales, regenerates the sultone or α-naphthol-4 : 8-disulphonic acid when boiled with dilute acids (Badische, D. R.-P. 57856 of 1889; Bernthsen, *l.c.*), and couples with diazotised bases forming ortho-*azo*- dyes which closely resemble those obtained from the 8-sulphonamide-3-sulphonic-acid (*cf.* Badische, D. R.-P. 60777, 64065 of 1889; Geigy, D. R.-P. 139287 of 1902).

(x.) α-**Naphthol-5 : 7-disulphonic acid** has not been described, but is mentioned in connection with the bisulphite reaction as producible from and convertible into α-*naphthylamine*-5 : 7-*disulphonic acid* (Badische, D. R.-P. 115335, 117471 of 1899; Eng. Pat. 1387 of 1900).

(xi.) α-**Naphthol-5 : 8-disulphonic acid** is obtained from α-naphthylamine-5 : 8-disulphonic acid by the diazo- reaction, the sultone first formed being converted by alkali into the naphtholdisulphonic acid (Bayer, D. R.-P. 70857 of 1892).

The *peri*-anhydride, naphthasultone-5-sulphonic acid, forms a *sodium* salt $NaA+\frac{1}{2}H_2O$ in moderately soluble long needles (Gattermann, Ber. 1899, 32, 1158), and, like the disulphonic acid, when heated with 40 p.c. caustic soda solution under pressure at 170°–200°, yields 1 : 8-*dihydroxynaphthalene*-4-*sulphonic acid* (Bayer, D. R.-P. 80667 of 1892 ; Eng. Pat. 1227 of 1894).

(xii.) α-**Naphthol-6 : 8-disulphonic acid** has been prepared from α-naphthylamine-6 : 8-disulphonic acid either by the diazo- reaction, the sultone first formed being converted into the naphtholdisulphonic acid by alkali (Bayer, D. R.-P. 75084 of 1893) or by the bisulphite reaction (Bucherer, J. pr. Chem. 1904, [ii.] 70, 347). It is also formed when α-naphthylamine-4 : 6 : 8-trisulphonic acid (Kalle, D. R.-P. 82563 of 1893), or α-naphthol-4 : 6 : 8-trisulphonic acid (Kalle, D. P. Anm. K. 11397 of 1894) is heated with dilute (2 p.c.) acid at 180°–200°.

Identification.—The *acid sodium* salt forms easily soluble short needles, which with ferric chloride gives a fleeting green colouration, and with nitrous acid a *nitroso-* derivative not convertible into a naphthol yellow by nitric acid (Kalle, *l.c.*). The naphthasultone-6-sulphonic acid and α-naphthol-8-sulphonamide-6-sulphonic acid have not been fully characterised (Bayer, *l.c.*).

Reaction.—When heated with 50 p.c. caustic soda solution at 170°–210°, it is converted into 1:8-*dihydroxynaphthalene*-6-*sulphonic acid* (Kalle, D. R.-P. 82422 of 1894).

α-NAPHTHOLTRISULPHONIC ACIDS.

(i.) α-**Naphthol-2 : 4 : 7-trisulphonic acid** is the chief product of the sulphonation of α-naphthol either with 25 p.c. anhydro- acid at 100°–110° or with 45 p.c. anhydro- acid at 40°–50° (Badische, D. R.-P. 10785 ; Eng. Pat. 5305 of 1879),[1] and can be isolated by means of the characteristic barium salt (Friedlaender and Taussig, Ber. 1897, 30, 1463). It is also obtained when diazotised α-naphthylamine-2 : 4 : 7-trisulphonic acid is boiled with acidified water (*cf.* Höchst, D. R.-P. 22545 ; Eng. Pat. 2178 of 1882), *or* when α-chloronaphthalene-2 : 4 : 7-trisulphonic acid is heated with 12 p.c. caustic soda solution at 150° (Oehler, D. R.-P. 77996 of 1893).

Identification.—The *barium* salt $Ba_3A_2+3H_2O$ in glistening minute crystals, is almost insoluble when once separated from water ; the other salts are easily soluble (Friedlaender and Taussig, *l.c.*). The *sodium* salt gives a blue colouration with ferric chloride, but yields neither azo- dyes nor a nitroso- compound.

Reactions.—(1) When warmed with nitric acid it yields 2 : 4-*dinitro-α-naphthol*-7-*sulphonic acid* (naphthol yellow S; *cf.* Badische, *l.c.* ; Höchst, *l.c.* ; Lauterbach, Ber. 1881, 14, 2028).

(2) When heated with hydrochloric acid or 65 p.c. sulphuric acid it is partially hydrolysed, forming *α-naphthol*-7-*sulphonic acid* (*cf.* Liebmann and Studer, D. P. Anm. L. 4327 ; Eng. Pat. 7812 of 1887). With sodium amalgam it furnishes *α-naphthol*-2 : 7-*disulphonic acid* (Friedlaender and Taussig, *l.c.*).

(ii.) α-**Naphthol-2 : 4 : 8-trisulphonic acid** has been prepared by sulphonating α-naphthol-4 : 8-disulphonic acid or its sultone with 25 p.c. anhydro- acid below 100° (Bayer, D. P. Anm. F. 4569 ; Eng. Pat. 3397 of 1890 ; Dressel and Kothe, Ber. 1894, 27, 2143).

Identification.—The *sodium* salt $Na_3A+1\frac{1}{2}H_2O$ is a readily soluble crystalline powder, shows green fluorescence in solution, gives with ferric chloride a blue colouration, and does not couple with diazotised bases (Dressel and Kothe, *l.c.*).

Reactions.—(1) With nitro-sulphuric acid at 20° it gives 2 : 4-*dinitro-α-naphthol*-8-*sulphonic acid* (brilliant yellow ; Dressel and Kothe, *l.c.*).

(2) By fusion with caustic soda at 210°, it is converted into 1 : 8-*dihydroxynaphthalene*-2 : 4-*disulphonic acid* (*ibid.* ; *cf.* Bayer, D. R.-P. 57021 ; Eng. Pat. 3397 of 1890).

(iii.) α-**Naphthol-3 : 5 : 7-trisulphonic acid** can be obtained either from naphthalene-1 : 3 : 5 : 7-tetrasulphonic acid by digestion with 15 p.c. caustic soda solution under pressure at 180° (Bayer, D. R.-P. 79054 ; Eng. Pat. 25074 of 1893), or from α-naphthylamine-3 : 5 : 7-trisulphonic acid by the diazo- reaction (Kalle, D. P. Anm. K. 12732 of 1895).

Reactions.—(1) When heated with ammonia under pressure at 160°–180° it is converted into 1 : 3-*diaminonaphthalene*-5 : 7-*disulphonic acid* (Kalle, D. R.-P. 90906 ; Eng. Pat. 9103 of 1895).

(2) On digestion with 50 p.c. caustic soda solution at 150°–160°, it yields 1 : 5-*dihydroxynaphthalene*-3 : 7-*disulphonic acid* (Kalle, D. P. Anm. K. 12732 of 1895), or with 60 p.c. solution at 200°, a mixture of this acid with 1 : 3-*dihydroxynaphthalene*-5 : 7-*disulphonic acid* (Bayer, D. R.-P. 79054 ; Eng. Pat. 25074 of 1893).

(iv.) α-**Naphthol-3 : 6 : 8-trisulphonic acid** is formed from α-naphthylamine-3 : 6 : 8-trisulphonic acid either by the diazo- reaction, the sultone being an intermediate product (Koch, D. R.-P. 56058 ; Eng. Pat. 9258 of 1890), *or* by heating it with water under pressure at 180°–250° (Höchst, D. R.-P. 71495 ; Eng. Pat. 14301 of 1892).

Reactions.—(1) By digestion with 60 p.c. caustic soda solution at 170°–220° it yields 1 : 8-*dihydroxynaphthalene* - 3 : 6 - *disulphonic acid* (Höchst, D. R.-P. 67563 of 1890).

(2) When heated with ammonia under pressure at 160°–180° it is converted into 1 : 3-*diaminonaphthalene*-6 : 8-*disulphonic acid* (Kalle, D. R.-P. 90905 ; Eng. Pat. 9103 of 1895), or with aniline and aniline hydrochloride at 150°–170° into the *diphenyl-* derivative of this acid (Bayer, D. R.-P. 77866 ; Eng. Pat. 16780 of 1893).

Its sultone gives yellow solutions with alkalis. When dissolved in ammonia the sodium salt of the sultone with hydrochloric acid yields sodium α-naphthol-8-sulphonamide-3 : 6-disulphonate (Koch, *l.c.* ; Höchst, D. R.-P. 69518 of 1890), which couples with diazotised bases forming *azo-* dyes (*cf.* Koch, D. R.-P. 58076 ; Höchst, D. R.-P. 65143 ; Eng. Pat. 9258 of 1890 ; Geigy, D. R.-P. 139287 of 1902).

(v.) α-**Naphthol-4 : 6 : 8-trisulphonic acid** has been obtained from α-naphthylamine-4 : 6 : 8-trisulphonic acid either by the diazo- reaction,

---

[1] The acid formed by heating α-naphthol with three times its weight of sulphuric acid at 110°–115° for twelve to fifteen hours (Badische, *l.c.*), and serving as a source of naphthol yellow S, would probably contain a large proportion of the 2 : 7- and 4 : 7-disulphonic acids (*cf.* p. 619, footnote 1).

the sultone formed being dissolved in alkali (Bayer, D. P. Anm. F. 7006; *cf.* D. R.-P. 80741; Eng. Pat. 17141c of 1893), or by the bisulphite reaction (Bucherer, J. pr. Chem. 1904, [ii.] 70, 347).

Reactions.—(1) By digestion with 70 p.c. caustic soda solution under pressure at 170°–190°, it yields 1 : 8-*dihydroxynaphthalene*-3 : 5-*disulphonic acid* (Bayer, D. P. Anm. 7004; Eng. Pat. 17141c of 1893).

(2) When heated with 2 p.c. hydrochloric acid under pressure at 160°–200° it is partially hydrolysed, forming *α-naphthol*-6 : 8-*disulphonic acid* (Kalle, D. P. Anm. K. 11397 of 1894).

Its sultone is easily soluble, forming colourless non-fluorescent solutions which with alkalis become deep yellow; the corresponding α-naphthol-8-sulphonamide-4 : 6-disulphonic acid couples with diazotised bases giving ortho-*azo-* dyes (*cf.* Geigy, D. R.-P. 139287 of 1902).

(ii.) β-**Naphthol** occurs in very small amount in the coal tar fractions of high boiling-point (Schulze, Annalen, 1885, 227, 150). On the large scale it is formed by mixing sodium naphthalene-β-sulphonate with 40 p.c. caustic soda solution (2–2·5 mols.), heating the paste with constant stirring until quite thick, and afterwards fusing it at 300° for about 12 hours. The product, dissolved in water, is decomposed by hydrochloric or 50 p.c. sulphuric acid, and the separated β-naphthol purified by distillation in a vacuum (*cf.* Wallach and Wichelhaus, Ber. 1870, 3, 846 (footnote); Levinstein, Eng. Pat. 2300 of 1883).

Properties.—β-Naphthol crystallises in odourless scales or rhombic tables (*cf.* Groth, Annalen, 1869, 152, 285), m.p. 122° (Schaeffer, *ibid.*), b.p. 285°–286° (Ebert and Merz, Ber. 1876, 9, 611), sp.gr. 1·217 at 4° (Schroeder, *ibid.* 1879, 12, 1613), and is readily soluble in alcohol, organic solvents, or caustic alkali solutions, but only sparingly in hot water. It is only slightly volatile with steam at 100°, but can be distilled with superheated steam. It has marked antiseptic properties. The *sodium* compound $C_{10}H_7{\cdot}ONa$ can be obtained crystalline (*v.* p. 615, footnote).

Reactions.—(1) It is converted by prolonged boiling in the air, more readily by distillation with phosphoric oxide or by heating with litharge, into *ββ'-dinaphthylene oxide* (Dianin, Ber. 1875, 8, 166; Graebe, Knecht, and Unzeitig, Annalen, 1881, 209, 138).

(2) Nitrous acid reacts with it, forming 1-*nitroso-β-naphthol* (Fuchs, Ber. 1875, 8, 1026; *v.* Naphthaquinoneoximes); or, in ethereal solution, 1 : 6-*dinitro-β-naphthol* (Schmidt, Ber. 1900, 33, 3246).

(3) On oxidation in alkaline solution with potassium permanganate it yields either ortho-*carboxycinnamic acid* (Ehrlich and Benedikt, Monatsh. 1888, 9, 527), or *phthalonic acid* (Henriques, Ber. 1888, 21, 1618), but on fusion with caustic alkali and copper oxide or hydrated manganese peroxide, it is converted, like α-naphthol, into *phthalic acid* and *benzoic acid* (Bindschedler, D. R.-P. 138790 of 1900; 139956; Eng. Pat. 15527 of 1901).

(4) The action of ammonia, acetamide, and aniline on β-naphthol is described in connection with β-naphthylamine (*q.v.*).

(5) When heated with 40 p.c. ammonium sulphite solution and 20 p.c. ammonia at 100°–150°, it is converted almost quantitatively into *β-naphthylamine* (Bucherer, J. pr. Chem. 1904, [ii.] 69, 88; Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

(6) On reduction with sodium in amyl alcohol solution it is converted into a mixture of ac.-*tetrahydro-β-naphthol* as chief product, with ar.-*tetrahydro-β-naphthol* (Bamberger and Lodter, Ber. 1890, 23, 197).

(7) With nitrosodimethylaniline hydrochloride it yields the hydrochloride of *β-naphthol-violet* (Meldola, Ber. 1879, 12, 2066).

(8) Iodine solution added to a solution of β-naphthol in aqueous caustic soda gives a yellowish-green precipitate of so-called *β-naphthol iodide* (Messinger and Vortmann, Ber. 1889, 22, 2322; Bayer, D. R.-P. 49739; Eng. Pat. 5079 of 1889).

Colour reactions.—Bleaching-powder solution gives to an aqueous solution of β-naphthol a pale yellow colouration which disappears on addition of an excess. Ferric chloride added to an aqueous solution (Dianin, Ber. 1873, 6, 1252; 7, 125; *cf.* Walder, *ibid.* 1882, 15, 2166) gives a pale green colouration and afterwards a white flocculent precipitate of *ββ'-dinaphthol.* When warmed with strong caustic potash solution and chloroform at 50°, it gives (like α-naphthol) a Prussian-blue colouration which gradually changes through green into brown (Lustgarten, Monatsh. 1883, 3, 720; *cf.* Rousseau, Ann. Chim. Phys. 1883, [v.] 28, 148).

Tests.—Commercial β-naphthol should be almost colourless, have approximately the right melting-point, and dissolve completely in caustic alkali forming an almost colourless solution. According to Jorissen (Ann. chim. anal. 1902, 7, 217), a solution of iodine in potassium iodide with excess of caustic soda solution gives with β-naphthol a clear colourless solution, but, if α-naphthol be present, a turbid coloured liquid, the reaction being one which can be used colorimetrically to determine the proportion.

Estimation.—A 1 p.c. solution of the sample in aqueous caustic soda (4 mols.) is titrated at 60° with excess of N/10 iodine (the equation is

$$C_{10}H_8O+3I_2+3NaOH=C_{10}H_5I_3O+3NaI+3H_2O),$$

cooled, acidified with dilute sulphuric acid and the filtrate titrated back with N/10 sodium thiosulphate (Messinger and Vortmann, *l.c.*; *cf.* Küster, Ber. 1894, 27, 1907).

β-Naphthyl methyl ether, prepared by heating β-naphthol (5 pts.), with absolute methyl alcohol (5 pts.) and sulphuric acid (2 pts.) in a reflux apparatus under slight pressure at 125° (Gattermann, Annalen, 1888, 244, 72), forms scales, m.p. 72°, b.p. 274° (Marchetti, Jahresb. Chem. 1879, 543), dissolves sparingly in alcohol and has the odour of orange flowers (neroli).

β-Naphthyl ethyl ether, prepared like the methyl ether (Gattermann, *l.c.*; *cf.* Davis, Chem. Soc. Trans. 1900, 77, 33), m.p. 37°, b.p. 282°, dissolves readily in alcohol, and has the odour of pineapple. On nitration it yields 1-*nitro-β-ethoxynaphthalene*, m.p. 104° (Wittkampf, Ber. 1884, 17, 394; Cassella, D. P. Anm. C. 2883 of 1889); and, as minor product, 6-*nitro-β-ethoxynaphthalene*, m.p. 114° (Gaess, J. pr. Chem. 1891, [ii.] 43, 22).

ββ'-Dinaphthyl ether $(C_{10}H_7)_2O$, obtained by boiling β-naphthol for some hours with 50 p.c. sulphuric acid (Graebe, Ber. 1880, 13, 1850); *or* by heating sodium 'β-naphthylsulphate' with β-naphthol at 180°–200° (Nietzki, *ibid.* 1882, 15, 305); *or* β-naphthol with phosphoric chloride (1 mol.) at 100° for two hours (Berger, Compt. rend. 1905, 141, 1027), forms scales, m.p. 105°, b.p. above 360°, and yields *β-naphtholmono-, di-,* and *tri-sulphonic acids* when heated with sulphonating agents (Brönner, D. R.-P. 26938; Eng. Pat. 3606 of 1883).

β-Naphthylsulphuric acid (*v.* β-naphthol-1-sulphonic acid).

β-Naphthyl carbonate $CO(O{\cdot}C_{10}H_7)_2$, obtained by the interaction of phosgene and β-naphthol (Schering, D. P. Anm. C. 4197 of 1892), forms needles, m.p. 176°–177°, sparingly soluble in alcohol, and on sulphonation yields a mixture of the *β-naphthol*-6-, 7-, and 8-*sulphonic acids* (Reverdin and Kauffmann, Ber. 1895, 28, 3057).

β-Naphthyl acetate, obtained by heating β-naphthol with acetyl chloride (Schaeffer, *l.c.*), or with acetic acid at 240° (Graebe, Annalen, 1881, 209, 150), forms needles, m.p. 70° (Miller, Ber. 1881, 14, 1602, footnote), dissolves sparingly in water, and is hydrolysed by distillation with steam.

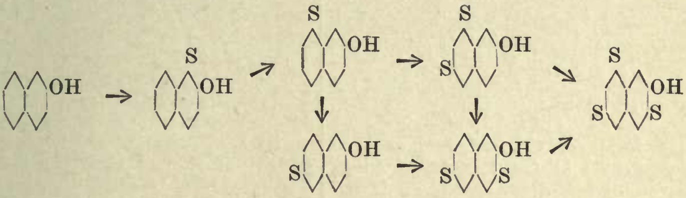
β-NAPHTHOLSULPHONIC ACIDS.

Introductory.—The greater number of the β-naphtholsulphonic acids are obtained by the sulphonation of β-naphthol, whereas in the α-series, for the production of α-naphtholsulphonic acids, direct sulphonation finds only a limited use. But this is only one of many differences between the two series. Another arises from the operation of the laws of (*a*) preferential sulphonation in α- rather than in β- positions, (*b*) preferential replacement of α- rather than of β-sulphonic groups by other radicles, which renders the methods most widely used in the α-series (*v.* p. 615) comparatively valueless for the production of β-naphtholsulphonic acids. For example:—

(1) Fusion of naphthalenesulphonic acids with caustic alkali can be applied in the β-series only to naphthalene-2 : 6- and 2 : 7 disulphonic acids, as these are the only two naphthalenepolysulphonic acids containing SO_3H radicles exclusively in β- positions;

(2) Exchange of the amino- group for hydroxyl in naphthylaminesulphonic acids, either by the diazo- reaction or by the bisulphite method, is limited in the β-series by the fact that the most convenient source of β-naphthylaminesulphonic acids is found in the β-naphtholsulphonic acids themselves.

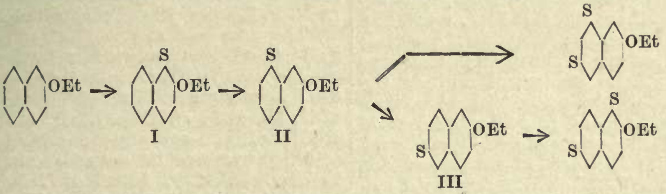
The first product of the action of sulphuric acid on β-naphthol is β-naphthol-1-sulphonic acid, regarded by its discoverers as β-naphthylsulphuric acid. Without alteration in the concentration of the sulphuric acid, but with rise of temperature, there are obtained successively at 50°–60° β-naphthol-8-sulphonic acid, and at 90°–100° the 6-sulphonic acid. When the weight of sulphuric acid is doubled there are obtained, similarly, at 60° β-naphthol-6 : 8-disulphonic acid, and at 120°–130° the 3 : 6-disulphonic acid. With anhydro- acid, sulphonation of β-naphthol reaches its limit in the formation of the 3 : 6 : 8-trisulphonic acid. The relationship between these products is shown in the scheme[1]—



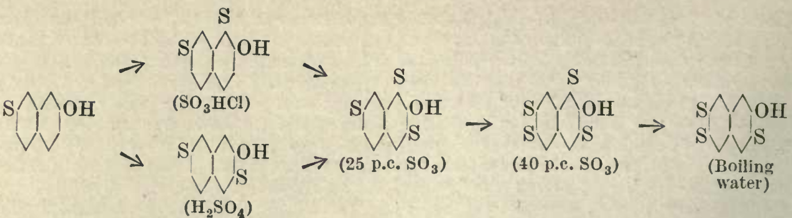
Another source of β-naphtholpolysulphonic acids is the 7-sulphonic acid, which, although known to occur in the sulphonation product of β-naphthol at 100°–130°, does not seem to have been isolated from this source, but is obtained from naphthalene-2 : 7-disulphonic acid by fusion with caustic alkali. The acids formed from it by sulphonation are shown on the next page, the agent used in the production of each being indicated under the symbol showing its constitution.

---

[1] This scheme is not to be regarded as complete. It leaves out of account the formation of β-naphthol-7-sulphonic acid (*q.v.*) recorded by Green, and should be compared with another, compiled from data furnished by Lapworth (Chem. Soc. Proc. 1895, 11, 49), in which the products formed in the sulphonation of β-ethoxynaphthalene by chlorosulphonic acid, under conditions excluding the presence of water, are displayed.



The change of acid I into acid II was found to take place at the ordinary temperature, and of acid II into acid III at the temperature of a water bath; moreover, acid III on sulphonation gave, not the 3 : 6-disulphonic acid as might be expected from the behaviour of β-naphthol-6-sulphonic acid, but the 1 : 6-disulphonic acid, not yet recognised among the sulphonation products of β-naphthol.



Bearing in mind the rule of preferential substitution in α- positions, it is noteworthy that the SO_3H radicle is not found in either the 4- or the 5- position in any of the products of the sulphonation of β-naphthol under the most varied conditions. And with reference to the 1-position, it is evident that, of the five acids obtained from β-naphthol-7-sulphonic acid by sulphonation, the three containing a SO_3H radicle in this position are formed under conditions which exclude the presence of water; whereas the two from which it is absent are obtained respectively by the use of ordinary sulphuric acid, and by desulphonation with boiling water.

The β-naphtholsulphonates are better defined, and more easily separated from mixtures than are the α-naphtholsulphonates. They can therefore be used for the production of pure β-naphthylaminesulphonic acids. Their chief use is in connection with the manufacture of *ortho*-azo- dyes, but they are not equally valuable for this purpose. For example: Of the numerous isomeric acids, those are most valuable which contain a sulphonic group in the 8- position, the shades obtained with them being orange rather than red: these acids are characterised by coupling only slowly with diazotised bases.

β-Naphtholmonosulphonic Acids.[1]

(i) **β-Naphthol-1-sulphonic acid** (β-naphthylsulphuric acid). When a solution of β-naphthol in 2–2·5 times its weight of 90–92 p.c. sulphuric acid at 35°–45° is kept for a short time until it solidifies to a crystalline mass (Tobias, D. R.-P. 74688; Eng. Pat. 15404 of 1893; *cf.* Armstrong, Ber. 1882, 15, 202; Nietzki, *ibid.* 305), *or* when chlorosulphonic acid (1 mol.) is added to β-naphthol dissolved in carbon disulphide (Armstrong, *l.c.*), a product is obtained which—at first considered to be β-naphthylsulphuric acid—was identified by Tobias as β-naphthol-1-sulphonic acid. It is separated from the 8- acid, which is also present in small quantity, by precipitation as the very sparingly soluble basic barium salt (Tobias, *l.c.*).

Identification.—Both normal and basic salts are known, which with the exception of the *basic barium* salt are easily soluble in water. The normal *barium* salt $BaA_2+2C_2H_6O$, *potassium* salt KA, and sodium salt NaA, crystallise from alcohol in scales; the *disodium* salt $Na_2A+2C_2H_6O$, in scales, shows no fluorescence in aqueous solution. In neutral solution the salts give an indigo-blue colouration with ferric chloride (Tobias, *l.c.*), and in acid solution yield β-naphthol and sulphuric acid on evaporation.

Reactions.—(1) Dissolved in sulphuric acid it is converted at 50°–60° into *β-naphthol-8-sulphonic*, *6-sulphonic*, and *6 : 8-disulphonic acids* (Höchst, D. R.-P. 36491; Eng. Pat. 816 of 1884; *cf.* Armstrong, *l.c.*).

(2) When heated with 20 p.c. ammonia under pressure at 220°-230° (Tobias, *l.c.*) or with ammonium sulphite solution and ammonia at 100°–150° (Bucherer, J. pr. Chem. 1904, [ii.] 70, 357; *cf.* Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900) it yields *β-naphthylamine-1-sulphonic acid.*

(3) With diazotised bases coupling takes place in alkaline solution, but the *azo*-dyes are derivatives of β-naphthol, not of the acid, owing to elimination of the SO_3H radicle (Tobias, *l.c.*). In neutral or acid solution, *salts* formed by combination with diazo- or tetrazo-compounds are produced (Bayer, D. R.-P. 93305; Eng. Pat. 11757 of 1895).

(ii.) **β-Naphthol-4-sulphonic acid** is obtained from β-naphthylamine-4 : 8-disulphonic acid by digestion with water or 10 p.c. sulphuric acid under pressure at 170°–185° (Kalle, D. R.-P. 78603 of 1893). Its *sodium* salt is easily soluble.

Reactions.—(1) When heated with ammonia under pressure it is converted into *β-naphthylamine-4-sulphonic acid* (Kalle, *l.c.*).

(2) By digestion with 60 p.c. caustic soda solution at 230°–280° it yields *o-toluic acid* (Kalle, D. R.-P. 79028 of 1893).

(iii.) **β-Naphthol-5-sulphonic acid** has been prepared from β-naphthylamine-5-sulphonic acid by the diazo- reaction (Dahl, D. R.-P. 29084; Eng. Pat. 7712 of 1884; Claus, J. pr. Chem. 1889, [ii.] 39, 315). On fusion with caustic alkali, it gives 1 : 6-*dihydroxynaphthalene* (Claus, *l.c.*). The *azo*-dyes obtained from it are worthless (Dahl, *l.c.*).

(iv.) **β-Naphthol-6-sulphonic acid** ([α-]acid of Armstrong and of Schultz; Schaeffer acid) is formed as chief product, mixed with about 15–20 p.c. of the 8-acid, when β-naphthol is heated on a water-bath with twice its weight of sulphuric acid until completely sulphonated (Schaeffer, Annalen, 1869, 152, 296); *or*, mixed with some 7-acid, disulphonic acid and unattacked β-naphthol, when it is heated with monohydrate (1 mol.) at 100°–105° for 2–3 hours (Armstrong, Ber. 1882, 15, 201; *cf.* Green, Chem. Soc. Trans. 1889, 55, 37); *or*, as chief product, when ββ′-dinaphthyl ether is sulphonated with 2–3 parts of sulphuric acid at 90°–100° (Brönner, D. R.-P. 26938; Eng. Pat. 3606 of 1883).

The pure acid can be obtained from sodium 2 : 6-naphthalenedisulphonate by fusing it with caustic alkali (Ebert and Merz, Ber. 1876, 9, 610; Armstrong and Graham, Chem. Soc. Trans. 1881, 39, 136; *cf.* Cassella, D. R.-P. 45221 of 1887); *or* from 1-carboxy-β-naphthol-6-sulphonic acid by warming its aqueous solution at 60° (Seidler, D. R.-P. 53343 of 1889); *or* from β-naphthylamine-6-sulphonic acid, either by the diazo- reaction, or by boiling it with 40 p.c. sodium bisulphite solution, and then acidifying the product (Badische, D. R.-P. 134401 of 1899).

---

[1] In every case where the constitution of a β-naphtholsulphonic acid is given the OH radicle is supposed to be in the position '2.'

On the laboratory scale, when prepared from β-naphthol, the acid is purified by conversion into its moderately soluble barium or calcium salt (*v.* 8-acid), which, when suspended in boiling water, becomes anhydrous and almost insoluble.

Identification.—The *acid* forms easily soluble non-deliquescent scales, m.p. 125°; the *lead* salt PbA_2+6H_2O, scales; the *barium* salt BaA_2+6H_2O, long prisms; the *calcium* salt CaA_2+5H_2O, scales, readily soluble in alcohol or in 30 parts of water at 18°; the *potassium* salt KA, prisms, soluble in about 50 parts of water at 15°; the *sodium* salt $NaA+2H_2O$, scales, soluble in about 3·3 parts of water at 80°, in 57·8 parts at 14°, and in 69 parts at 11·5° (Schaeffer, *l.c.*; Armstrong and Graham, *l.c.*); the *ammonium* salt NH_4A, long flat prisms soluble in about 34 parts of water at 24° (Meldola, Chem. Soc. Trans. 1881, 39, 41). In aqueous solution the salts show a pale blue fluorescence and give a pale green colouration with ferric chloride. With nitric acid, solutions of these salts become carmine-red when warmed (Schaeffer, *l.c.*; Armstrong and Graham, *l.c.*), the colouration being due to the formation of an *indophenol* derivative of [β-]naphthaquinone, which can be isolated in red crystals (Nietzki and Knapp, Ber. 1897, 30, 187).

Reactions.—(1) By sulphonation with anhydro- acid at 150°–160° it is converted into *β-naphthol*-3 : 6-*disulphonic acid* (Baum, D. P. Anm. B. 4199; Eng. Pat. 3523 (prov. spec.) of 1883).

(2) With nitrous acid it forms 1-*nitroso-β-naphthol*-6-*sulphonic acid* (Meldola, *l.c.*), convertible into *naphthol green-β* by interaction with iron salts (Gans & Co. D. R.-P. 28065; Eng. Pat. 2269 of 1884).

(3) When heated with ammonia under pressure at 180° (Brönner, D. R.-P. 22547; Eng. Pat. 3724 of 1882), or with 40 p.c. ammonium sulphite solution and ammonia at 100°–150° (Bucherer, J. pr. Chem. 1904, [ii.] 70, 357; *cf.* Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900), it yields *β-naphthylamine*-6-*sulphonic acid.*

(4) With 10 p.c. methylamine sulphite solution and methylamine under pressure at 125°, it gives *methyl-β-naphthylamine*-6-*sulphonic acid* (Badische, D. R.-P. 121683; Eng. Pat. 18726 of 1900); with 40 p.c. sodium bisulphite solution and aniline at the boiling point, it forms *phenyl-β-naphthylamine*-6-*sulphonic acid* (Badische, D. R.-P. 122570; Eng. Pat. 18726 of 1900); and with 40 p.c. sodium bisulphite solution and fuchsin at 90°–100°, it gives the corresponding *fuchsin*-derivative (Badische, D. R.-P. 125589; Eng. Pat. 18726 of 1900).

(5) When fused with caustic alkali, it yields 2 : 6-*dihydroxynaphthalene* (Emmert, Annalen, 1887, 241, 369).

(6) With sulphur and caustic alkali solution under pressure at 200° it forms two 'thio-β-naphtholsulphonic acids' (Aktienges., D. R.-P. 50077 of 1889).

(7) It couples with diazotised bases forming *azo*-dyes (*cf.* Bayer, D. R.-P. 26231; Eng. Pat. 2411 of 1883; Höchst, D. R.-P. 86937 of 1894).

(v.) **β-Naphthol-7-sulphonic acid** ([δ-] acid; F-acid) is obtained technically from sodium naphthalene-2 : 7-disulphonate by digestion with concentrated (50–90 p.c.) caustic soda solution at 250°, until an acidified test gives traces of dihydroxynaphthalene when extracted by ether, or until a test freed from sulphur dioxide gives with diazoxylene an amount of azo-dye equivalent to the quantity of sodium salt employed (Weinberg, Ber. 1887, 20. 2907; Cassella D. R.-P. 42112; Eng. Pat. 12908 of 1886; *cf.* D. R.-P. 45221 of 1887).

Mixed with the 6-acid it is formed when β-naphthol is heated with monohydrate (1 mol.) at 100°–130° for 2–3 hours, but does not seem to have been isolated from the product (Green, Eng. Pat. 15849 of 1888; Chem. Soc. Trans. 1889, 55, 37). From β-naphthylamine-7-sulphonic acid it can be obtained either by the diazo- reaction (Bayer and Duisberg, Ber. 1887, 20, 431; *cf.* Schultz, *ibid.* 3158) or by the bisulphite method (Bucherer, J. pr. Chem 1904, [2] 69, 73).

Identification.—The *acid* forms hydrated needles, m.p. 89°, readily soluble in water or alcohol; the *barium* salt sparingly soluble prisms; the *magnesium* salt $MgA_2+5\frac{1}{2}H_2O$, scales; the *potassium* salt $KA+H_2O$, readily soluble rhombs; the *sodium* salt $NaA+2\frac{1}{2}H_2O$, large scales soluble in 12·5 parts of water at 15° (Weinberg, *l.c.*). In alkaline solution the salts show a pure blue fluorescence, and in neutral solution give a dark-blue colouration with ferric chloride (Cassella, *l.c.*). When heated with phosphorus pentachloride the sodium salt yields 2 : 7-*dichloronaphthalene* (Weinberg, *l.c.*; Bayer and Duisberg, *l.c.*).

Reactions.—(1) By sulphonation with chlorosulphonic acid it is converted into *β-naphthol*-1 : 7-*disulphonic acid* (Bayer, D. R.-P. 77596 of 1893; Eng. Pat. 1063 of 1894); with sulphuric acid at 120° into the 3 : 7-*disulphonic acid* (Cassella, D. R.-P. 44079; Eng. Pat. 8265 of 1887; Weinberg, *l.c.*), and with 30 p.c. anhydro-acid at 100° into the 1 : 3 : 7-*trisulphonic acid* (Bayer, D. R.-P. 78569; Eng. Pat. 17141 of 1893; Dressel and Kothe, Ber. 1894, 27, 1207).

(2) With nitrous acid it forms 1-*nitroso-β-naphthol*-7-*sulphonic acid*, convertible into a *naphthol green* by iron salts (Cassella, D. R.-P. 42112; Eng. Pat. 12908 of 1886).

(3) When heated with 20 p.c. ammonia solution under pressure at 250° (Cassella, D. R.-P. 43740 of 1886), or with 40 p.c. ammonium sulphite solution and ammonia at 100°–150° (Bucherer, J. pr. Chem. 1904, [ii.] 70, 357) it yields *β-naphthylamine*-7-*sulphonic acid.* With dimethylamine under pressure at 220°, it gives *dimethyl-β-naphthylamine*-7-*sulphonic acid* (Geigy, D. R.-P. 90310 of 1896).

(4) When fused with caustic alkali, it yields 2 : 7-*dihydroxynaphthalene* (Armstrong, Chem. Soc. Trans. 1881, 39, 139; Pfitzinger and Duisberg, Ber. 1889, 22, 398).

(5) It couples with diazotised bases forming *azo*-dyes (*cf.* Cassella, *l.c.*; Höchst, D. R.-P. 86937 of 1894).

(vi.) **β-Naphthol-8-sulphonic acid** ([α-] acid of Bayer & Co.'s patents, [β-]acid of Schultz, and *o*-acid of Claus and Volz [1]; croceïc acid; Bayer or Rumpff acid) is formed as chief product (80 p.c.) together with the 2 : 6-acid, when β-naphthol is rapidly sulphonated with twice its

---

[1] Claus and Volz assign the constitution [2 : 3] to this acid, but the method employed by them has been shown to be untrustworthy (*cf.* Armstrong, Chem. Soc. Proc., 1889, 5, 9; Pfitzinger and Duisberg, Ber. 1889, 22, 397; Nietzki and Zübelen, *ibid.*, 454).

weight of sulphuric acid either at 50° or 60° (Bayer, D. R.-P. 18027; Eng. Pat. 1225 of 1881; D. R.-P. 20397 of 1882; D. R.-P. 26231[1]; Eng. Pat. 2411 of 1883) or during several days at a temperature not exceeding 20° (Leonhardt and Schulz, D. R.-P. 33857 of 1884; *cf.* Bang and Roussin, D. P. Anm. B. 13709 of 1892). It occurs (15–20 p.c.) in the product formed when β-naphthol is heated with twice its weight of sulphuric acid on a water-bath until dissolved (Schaeffer, Annalen, 1869, 152, 296), and in the so-called Armstrong acid produced when β-naphthol is heated with monohydrate (1 mol.) at 100° (Beyer and Kegel, D. R.-P. 32964; Eng. Pat. 7098 of 1884).

It is obtained pure from β-naphthylamine-8-sulphonic acid either by boiling it with 40 p.c. sodium bisulphite solution, adding alkali, and then acidifying (Badische, D. R.-P. 134401 of 1899), or by boiling its diazo- compound with 2 p.c. sulphuric acid (Dahl, D. R.-P. 29084; Eng. Pat. 7712 of 1884).

On the laboratory scale, when prepared from β-naphthol, the 8-acid is freed from the 6-acid by converting the sulphonation product into calcium salt, filtering the solution while hot, and concentrating the filtrate until the 6-salt separates out as a precipitate. About four-fifths of the 6-acid being removed as calcium salt, the remainder can be separated from the mother liquor by conversion into neutral (basic) sodium salt, which is either coupled with the requisite quantity of a diazotised base (as determined by a preliminary test) and the dye salted out, or dried and extracted with 90 p.c. alcohol in which the 6- sodium salt is practically insoluble. The filtrate in either case contains pure sodium β-naphthol-8-sulphonate (*cf.* Bayer, *l.c.*).

Identification.—The *acid* decomposes into β-naphthol and sulphuric acid when its solution is evaporated; it forms both normal (acid) and basic (neutral) salts, which are much more soluble in water than the salts of the 6-acid. The *barium* and *calcium* salts are insoluble in absolute alcohol; the *lead* salt $PbA_2+2\frac{1}{2}H_2O$, forms rhombohedra; the *zinc* salt $ZnA+2H_2O$, needles; the *sodium* salt NaA, six-sided scales; the basic *disodium* salt $Na_2A+2C_2H_6O$, deliquescent needles from 95 p.c. alcohol in which it dissolves very easily at the boiling-point, but only sparingly (1 in 100) at 15° (Badische, D. R.-P. 20760 of 1881; Claus and Volz, Ber. 1885, 18, 3155). Unlike its isomerides, it does not give a nitroso- compound (Gans & Co., D. R.-P. 28065; Eng. Pat. 2269 of 1884).

Reactions.—(1) By sulphonation with sulphuric acid below 50° it is converted into *β-naphthol-*6 : 8-*disulphonic acid* (Gans and Hoffmann, Eng. Pat. 816 of 1884).

(2) When warmed with dilute nitric acid it yields 1 : 6-*dinitro-β-naphthol-*8-*sulphonic acid* (croceïn yellow; Bayer, D. R.-P. 18027; Eng. Pat. 1225 of 1881; Nietzki and Zübelen, Ber. 1889, 22, 454).

(3) When heated with ammonia under pressure (Bayer, D. R.-P. 42273 of 1887 Pfitzinger and Duisberg, Ber. 1889, 22, 397), or with ammonium bisulphite solution and ammonia (Bucherer, J. pr. Chem. 1904, [ii.] 70, 358), it forms *β-naphthylamine-*8-*sulphonic acid.*

(4) When fused with caustic alkali it gives 1 : 7-*dihydroxynaphthalene* (Emmert, Annalen, 1887, 241, 371; Bayer, D. R.-P. 53915; Eng. Pat. 14230 of 1889).

(5) It couples only slowly with diazotised bases, forming many valuable *azo-*dyes (Schultz, Ber. 1884, 17, 461; *cf.* Bayer, D. R.-P. 26231; Eng. Pat. 2411 of 1883; Aktienges., D. R.-P. 62659 of 1891).

β-Naphtholdisulphonic Acids.

(i.) **β-Naphthol-1 : 6-disulphonic acid** is mentioned by Bucherer (J. pr. Chem. 1904, [ii.] 69, 73; *cf.* Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900) as furnishing the corresponding naphthylamine derivative by the bisulphite method, but no description of it seems to have been published.

(ii.) **β-Naphthol-1 : 7-disulphonic acid** is obtained either from sodium β-naphthol-7-sulphonate by sulphonation in the cold with chlorosulphonic acid (Bayer, D. R.-P. 77596 of 1893; Eng. Pat. 1063 of 1894; Dressel and Kothe, Ber. 1894, 27, 1206), or from β-naphthylamine-1 : 7-disulphonic acid by the diazo- reaction (Dressel and Kothe, *ibid.* 1207).

Identification.—The *barium* salt forms sparingly soluble needles; the *potassium* salt $K_2A+1\frac{1}{2}H_2O$, moderately soluble prisms; the *sodium* salt, very soluble needles. In alkaline solution the salts give a pale blue fluorescence. It does not couple with diazotised bases.

Reactions.—(1) When heated either with 25 p.c. ammonia solution under pressure at 180°–200° (Bayer, *l.c.*; D. P. Anm. F. 7274 of 1893), or with ammonium sulphite solution and ammonia at 100°–150° (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900), it yields *β-naphthylamine-*1 : 7-*disulphonic acid.*

(2) When boiled with 10 p.c. hydrochloric acid, it reverts to *β-naphthol-*7-*sulphonic acid* (Dressel and Kothe, *l.c.*).

(iii.) **β-Naphthol-3 : 6-disulphonic acid** ([α-] disulphonic acid; R-acid) is formed as chief product, mixed with some 6 : 8-acid, when β-naphthol is heated with 3–4 times its weight of sulphuric acid at 100°–110° for 12 hours (Höchst, D. R.-P. 3239; Eng. Pat. 1715 of 1878; Griess, Ber. 1880, 13, 1956), or at 125°–150° for 5–6 hours (Beyer and Kegel, D. R.-P. 33916; Eng. Pat. 7097 of 1884). It is said to be the only product when equal weights of potassium β-naphthol-6-sulphonate, potassium pyrosulphate, and sulphuric acid are heated for 5–6 hours at 160° (Baum, D. P. Anm. B. 4199; Eng. Pat. 3523 (prov. spec.) of 1883).

On the laboratory scale, the product from any of these sources is freed from 6 : 8- salt and any other impurities by conversion through the calcium salt into the sodium salt, which when dry is extracted with 80–90 p.c. alcohol, the impurities passing into solution, leaving pure R-salt (*cf.* Höchst, *l.c.*). Or the greater part of the R-acid in the product can be separated as the crystalline sodium salt by pouring the sulphonation melt into brine, the mother

---

[1] In this Patent reference is made to the presence of a third acid in the sulphonation product, and it is suggested that this acid may have been derived from impurity (doubtless α-naphthol) in the β-naphthol used (*cf.* however, Bayer, D. R.-P. 30077; Eng. Pat. 8495 of 1884). There is no reason to suppose that more than two β-naphtholsulphonic acids are formed under these conditions.

liquor containing 6 : 8-salt with the remainder of the R-salt (*cf.* Beyer and Kegel, *l.c.*).

Identification.—The *acid* forms silky, deliquescent needles very soluble in water or alcohol, the *barium* salt $BaA+6H_2O$, needles soluble in 12 parts of boiling water, but insoluble in alcohol, the *sodium* salt aggregates of minute needles readily soluble in cold water, but only sparingly soluble in alcohol or in brine. In aqueous solution the salts show a bluish-green fluorescence (Griess, *l.c.*).

The readily soluble *aluminium* salt has been introduced as an antiseptic and astringent under the name 'Alumnol' (Höchst, D. R.-P. 74209; Eng. Pat. 10668 of 1892). By warming a solution of the sodium salt with mercuric chloride a *compound* is obtained in which the mercury present (32 p.c.) cannot be detected by the ordinary reagents (Aktienges., D. R.-P. 143448 of 1901).

Reactions.—(1) By sulphonation with 20 p.c. anhydro- acid, it is converted into *β-naphthol*-3 : 6 : 8-*trisulphonic acid* (*cf.* Höchst, D. R.-P. 22038; Eng. Pat. 2544 of 1882).

(2) When heated either with ammonia under pressure (Pfitzinger and Duisberg, Ber. 1889, 22, 398; *cf.* Landshoff, D. R.-P. 27378 of 1883), or with ammonium sulphite solution and ammonia (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900) it yields *β-naphthylamine*-3 : 6-*disulphonic acid.*

(3) When fused with caustic soda at 220°–240° it gives 2 : 3-*dihydroxynaphthalene*-6-*sulphonic acid* (Höchst, D. P. Anm. F. 4153; Eng. Pat. 9642 of 1889; Badische, D. R.-P. 57525; Eng. Pat. 15803 of 1890: Friedlaender and Zakrzewski, Ber. 1894, 27, 762).

(4) It is not hydrolysed by dilute (20 p.c.) mineral acids at the boiling-point (*cf.* Bayer, D. R.-P. 77596 of 1893), but at higher temperatures, or by means of sodium amalgam, it reverts to *β-naphthol*-6-*sulphonic acid* (Friedlaender and Lucht, Ber. 1893, 26, 3029, 3032).

(5) It couples readily with diazotised bases and is an important source of *azo*- dyes (*cf.* Höchst, D. R.-P. 3229, 7217; Eng. Pats. 1715, 4914 of 1878; Aktienges., D. R.-P. 94082; Eng. Pat. 16569 of 1892; Badische, D. R.-P. 160788; Eng. Pat. 19165 of 1904).

(iv.) **β-Naphthol-3 : 7-disulphonic acid** ([δ-] disulphonic acid; disulphonic acid F) is the product formed when sodium β-naphthol-7-sulphonate is heated with twice its weight of sulphuric acid at 120° for about 12 hours (Cassella, D. R.-P. 44079; Eng. Pat. 8265 of 1887), or with 3–4 times its weight of the acid on a water-bath (Dressel and Kothe, Ber. 1894, 27, 1206). It can be obtained by partial hydrolysis of β-naphthol-1 : 3 : 7-trisulphonic acid with 10 p.c. hydrochloric acid (Bayer, D. R.-P. 78569; Eng. Pat. 17141 of 1893; Dressel and Kothe, *l.c.*).

Identification.—The *barium* salt $BaA+2\frac{1}{2}H_2O$, forms small prisms soluble in 185 parts of boiling water; the *sodium* salt Na_2A is soluble in 100 parts of 80 p.c. alcohol and very soluble in water, the solution showing green fluorescence (Cassella, *l.c.*; Weinberg, Ber. 1887, 20, 2911).

Reactions.—(1) By sulphonation with 25 p.c. anhydro- acid at 80°–90° it is converted into *β-naphthol*-1 : 3 : 7-*trisulphonic acid* (Bayer, *l.c.*; Dressel and Kothe, *l.c.*).

(2) When heated either with 25 p.c. ammonia solution under pressure at 200° (Cassella, D. R.-P. 46711 of 1888), or with ammonium sulphite solution and ammonia (Badische D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900), it yields *β-naphthylamine*-3 : 7-*disulphonic acid.*

(3) Fusion with caustic alkali converts it into 2 : 7-*dihydroxynaphthalene*-3-*sulphonic acid* (*cf.* Bayer, D. R.-P. 57166; Eng. Pat. 13665 of 1889: D. R.-P. 85241; Eng. Pat. 3580 of 1895).

(4) Boiling it with dilute (20 p.c.) mineral acids does not effect hydrolysis (*cf.* Bayer, D. R.-P. 77596 of 1893), but at higher temperatures it yields *β-naphthol*-7-*sulphonic acid* (*cf.* Friedlaender and Lucht, Ber. 1893, 26, 3029).

(v.) **β-Naphthol-4 : 7-disulphonic acid** has been prepared from β-naphthylamine-4 : 7-disulphonic acid by the diazo- reaction (Bayer, D. R.-P. 77866: Eng. Pat. 16780 of 1893), but its salts have not been described. When heated with aniline and aniline hydrochloride at 150°–170° it is converted into *diphenyl*-1 : 3-*diaminonaphthalene*-6-*sulphonic acid* (Bayer, *l.c.*).

(vi.) **β-Naphthol-4 : 8-disulphonic acid** (C-acid) is obtained from β-naphthylamine-4 : 8-disulphonic acid by the diazo- reaction (Cassella, D. R.-P. 65997 of 1890). The *calcium* salt forms prisms; the solution of the *sodium* salt shows blue fluorescence.

Reactions.—(1) When heated with aniline and aniline hydrochloride at 150°–170° it yields *diphenyl* - 1 : 3-*diaminonaphthalene* - 5 - *sulphonic acid* (Bayer, D. R.-P. 77866; Eng. Pat. 16780 of 1893).

(2) In concentrated solution it couples with diazotised bases forming *azo*-dyes (Cassella, *l.c.*).

(vii.) **β-Naphthol-5 : 7-disulphonic acid** has been prepared from β-naphthylamine-5 : 7-disulphonic acid by heating its acid sodium salt with 30 p.c. sodium bisulphite solution, decomposing the sulphite with alkali, and afterwards acidifying to remove sulphurous acid (Badische, D. R.-P. 134401 of 1899; Bucherer, J. pr. Chem. 1904, [ii.] 70, 347). No description of the acid has been published.

(viii.) **β-Naphthol-6 : 8-disulphonic acid** ([γ-] disulphonic acid; G-acid (Y-acid of some English Patents); also known as [β-]disulphonic acid when mixed with some R-acid (*cf.* Griess, Ber. 1880, 13, 1956), is formed as chief product when a mixture of β-naphthol either with 5 parts of sulphuric acid at 0° is gradually heated to 60° in the course of 36 hours, or with 4 parts of acid is maintained at 60° during 48 hours or at 20° during 8–10 days (Höchst, D. R.-P. 36491; Gans and Hoffmann, Eng. Pat. 816 of 1884); *or* when β-naphthol-8-sulphonic acid, mixed with 3 times its weight of sulphuric acid, is either heated at 40°–50° during 5–6 hours or left at 25° for 8–10 days (Gans and Hoffmann, *l.c.*). It has been prepared from β-naphthylamine-6 : 8-disulphonic acid by the diazo- reaction (Gans & Co. D. R.-P. 35019; Eng. Pat. 816 of 1884).

To purify the sulphonation product advantage is taken of the fact that G-acid, like the 8- or Bayer acid, couples less readily with diazo-compounds than the accompanying Schaeffer and R-acids. The process consists in adding to an alkaline solution of the sodium salt the quantity of diazo- compound calculated from a test, and salting out the azo-dye; the filtrate contains the sodium salt of technically pure G-acid (Hochst, *l.c.*).

Identification.—With the exception of the *potassium* salt which dissolves in 2·5 parts of boiling water, the salts of pure G-acid have not been described. They are much more soluble in water than the corresponding R- or Schaeffer salts and the first (incomplete) separation of G- from R-acid was achieved by means of the different solubilities of the respective barium salts (Griess, *l.c.*). The *barium* salt $BaA+8H_2O$, and *sodium* salt Na_2A of the so-called [β-] acid form prisms, and in solution give a bluish-green fluorescence (Griess, *l.c.*).

Reactions.—(1) By sulphonation with 20 p.c. anhydro- acid it is converted into *β-naphthol*-3 : 6 : 8-*trisulphonic acid* (*cf.* Höchst, D. R.-P. 22038; Eng. Pat. 2544 of 1882).

(2) When heated with ammonia under pressure (*cf.* Landshoff, D. R.-P. 27378 of 1883) or with ammonium sulphite and ammonia at 100°–150° (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900; Bucherer, J. pr. Chem. 1904, [ii.] 70, 358) it yields *β-naphthylamine*-6 : 8-*disulphonic acid.*

(3) When fused with caustic soda at 220°–230° it gives 2 : 8-*dihydroxynaphthalene*-6-*sulphonic acid* (Höchst, D. P. Anm. F. 4153; Eng. Pat. 9642 of 1889), but at 260°–320° *hydroxytoluic acid* (Höchst, D. R.-P. 81333 of 1893).

(4) It is not hydrolysed when boiled with dilute (20 p.c.) acids (*cf.* Bayer, D. R.-P. 77596 of 1893), but at higher temperatures, or by means of sodium amalgam, it is converted into *β-naphthol*-6-*sulphonic acid* (Friedlaender and Lucht, Ber. 1893, 26, 3032).

(5) It couples only slowly and in concentrated solutions with diazotised bases, but is an important source of *azo*- dyes (*cf.* Cassella, D. R.-P. 54084; Eng. Pat. 12560 of 1889; Bayer, D. P. Anm. F. 6114; Eng. Pat. 14927 of 1892.

β-NAPHTHOLTRISULPHONIC ACIDS.

(i.) **β-Naphthol-1 : 3 : 7-trisulphonic acid** is prepared by sulphonating either β-naphthol-7-sulphonic acid or β-naphthol-3 : 7-disulphonic acid with 25 p.c. anhydro- acid at 80°–90° (Bayer, D. R.-P. 78569; Eng. Pat. 17141 of 1893; Dressel and Kothe, Ber. 1894, 27, 1207).

Identification.—The *barium* salt is easily soluble; the *sodium* salt Na_3A is very soluble in water, but only sparingly in alcohol, and gives with ferric chloride a violet colouration. In alkaline solution it shows a bluish-green fluorescence and does not couple with diazotised bases (Dressel and Kothe, *l.c.*).

Reactions.—(1) By sulphonation with 40 p.c. anhydro-acid at 120°–130° it is converted into *β-naphthol*-1 : 3 : 6 : 7-*tetrasulphonic acid* (Bayer, D. P. Anm. F. 6991; Eng. Pat. 17141 of 1893; Dressel and Kothe, *l.c.*).

(2) When heated with 25 p.c. ammonia solution under pressure at 190°, it yields *β-naphthylamine*-1 : 3 : 7-*trisulphonic acid* (Bayer, D. P. Anm. F. 7003; Eng. Pat. 17141 of 1893; Dressel and Kothe, *l.c.*).

(3) When boiled with dilute mineral acids it reverts to *β-naphthol*-3 : 7-*disulphonic acid* (Bayer, *l.c.*; Dressel and Kothe, *l.c.*).

(ii.) **β-Naphthol-3 : 5 : 7-trisulphonic acid**, obtained from β-naphthylamine-3 : 5 : 7-trisulphonic acid by the diazo-reaction, couples with diazotised bases forming *azo*-dyes (Dressel and Kothe, Ber. 1894, 27, 1203).

(iii.) **β-Naphthol-3 : 6 : 7-trisulphonic acid** is formed either from β-naphthol-1 : 3 : 6 : 7-tetrasulphonic acid by boiling it with water or dilute acids (Bayer, D. R.-P. 78569; Eng. Pat. 17141 of 1893; Dressel and Kothe, Ber. 1894, 27, 1209), or from β-naphthylamine-3 : 6 : 7-trisulphonic acid by the diazo- reaction (Dressel and Kothe, *l.c.*).

Identification.—The *barium* salt is gelatinous; the *sodium* salt Na_3A, in needles, is less soluble than its isomerides in water, brine, or alcohol, gives a violet colouration with ferric chloride, and shows in alkaline solution a bluish-green fluorescence. It is not hydrolysed by dilute acids.

Reactions.—(1) When heated with 25 p.c. ammonia solution under pressure it yields *β-naphthylamine*-3 : 6 : 7-*trisulphonic acid* (Bayer, D. P. Anm. F. 7019; Eng. Pat. 17141 of 1893; Dressel and Kothe, *l.c.*).

(2) By digestion with 65 p.c. caustic soda at 220°–300° it gives 2 : 7-*dihydroxynaphthalene*-3 : 6-*disulphonic acid* (Bayer, D. P. Anm. F. 7243; Eng. Pat. 25074A of 1893).

(3) It couples with diazotised bases forming sparingly soluble *azo*-dyes (Dressel and Kothe, *l.c.*).

(iv.) **β-Naphthol-3 : 6 : 8-trisulphonic acid** has been prepared by sulphonating β-naphthol either with 4–5 p.c. times its weight of 20 p.c. anhydro-acid at 140°–160° (Höchst, D. R.-P. 22038; Eng. Pat. 2544 of 1882), or with 40 p.c. anhydro- acid at 90°–120° (Nietzki, Chem. Zeit. 1891, 15, 296). Instead of β-naphthol, β-naphthol-6- or 8-sulphonic acid, *or* β-naphthol-3 : 6- or 6 : 8-disulphonic acid may be used (*cf.* Levinstein, Eng. Pat. 706 of 1883; Ber. 1883, 16, 462; Limpach, *ibid.* 726).

By Nietzki's process a crystalline powder is obtained when the melt is mixed with 3 times its weight of ice. This is considered to be a 2 : 3-anhydride or sultone. In solution it is non-fluorescent, and does not give a colouration with ferric chloride. Alkalis convert it into salts of the trisulphonic acid, which with ferric chloride give a violet colouration, and in alkaline solution show a yellowish-green fluorescence (Nietzki, *l.c.*).

Reactions.—(1) When heated with ammonia under pressure it yields *β-naphthylamine*-3 : 6 : 8-*trisulphonic acid* (Landshoff, D. R.-P. 27378 of 1883; *cf.* Dressel and Kothe, Ber. 1894, 27, 2154).

(2) By fusion with caustic alkali at 220°–280° it gives a mixture of 1 : 7-*dihydroxy*-3 : 6-*disulphonic* and 2 : 3-*dihydroxy*-6 : 8-*disulphonic acids* (Höchst, D. P. Anm. F. 4154; Eng. Pat. 9642 of 1889; D. R.-P. 67563 of 1890; *cf.* Friedlaender and Silberstern, Monatsh. 1902, 23, 527).

(3) It couples with diazotised bases, forming *azo*-dyes (*cf.* Bayer, D. P. Anm. F. 17644 of 1903; F. 18438 of 1904).

β-NAPHTHOLTETRASULPHONIC ACID.

β-Naphthol-1 : 3 : 6 : 7-tetrasulphonic acid is obtained by the sulphonation of β-naphthol-7-sulphonic, or 3 : 7-disulphonic, or 1 : 3 : 7-trisulphonic acid with 40 p.c. anhydro- acid at 120°–130°, provided care be taken to prevent the solution of the product, so long as it is acid, becoming warm (Bayer, D. P. Anm. F. 6991; Eng. Pat. 17141 of 1893; Dressel and Kothe, Ber. 1894, 27, 1208).

Identification.—The *barium* salt is a very sparingly soluble sandy powder; the sodium salt Na_4A is easily soluble in water but insoluble in alcohol, and in alkaline solution shows a bluish-green fluorescence. It does not couple with diazotised bases.

Reactions.—(1) When heated with 25 p.c. ammonia solution under pressure at 190° it gives *β-naphthylamine*-1 : 3 : 6 : 7-*tetrasulphonic acid* (Bayer, D. P. Anm. F. 7003; Eng. Pat. 17141 of 1893; Dressel and Kothe, *l.c.*).

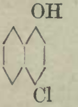
(2) When boiled with dilute mineral acids it yields *β-naphthol*-3 : 6 : 8-*trisulphonic acid* (Bayer, D. R.-P. 78569; Eng. Pat. 17141 of 1893; Dressel and Kothe, *l.c.*).

CHLORONAPHTHOLS.

Introductory.—By chlorination both α- and β-naphthol give rise only to homonucleal derivatives. When the operation is carried out by passing chlorine into a cooled acetic acid solution of the naphthol, the substitution product is:

From α-naphthol, 2 : 4-*dichloro-α-naphthol*; then the additive compounds trichloro-α-keto- and pentachloro-α-keto-naphthalene are formed (Zincke and Kegel, Ber. 1888, 21, 1030).

From β-naphthol, 1-*chloro-β-naphthol*; then dichloro-β-keto- and tetrachloro-β-keto-naphthalene (Zincke and Kegel, *ibid.* 3378).



4-Chloro-α-naphthol (m.p. 117°–118°) can be obtained by chlorinating either α-naphthyl carbonate (Reverdin and Kauffmann, Ber. 1895, 28, 3051), or α-naphthyl toluene-*p*-sulphonate in carbon tetrachloride solution (Aktienges., D. R.-P. 240038 of 1910). It is also formed from α-naphthol by employing sulphuryl chloride as the chlorinating agent (Kast, Ber. 1911, 44, 1337); but when the naphthol dissolved in alkali is chlorinated by hypochlorous acid (Kalle, D. R.-P. 167458 of 1904), a pure product is not formed (*cf.* King, Proc. Chem. Soc. 1911, 27, 266), although pure 1-*chloro-β-naphthol* (m.p. 70°) is the product from β-naphthol under similar conditions (Kalle, D. R.-P. 168824 of 1904).

Four chloro-α-naphtholsulphonic acids have been used for coupling with diazotised dehydrothiotoluidine in the production of *o*-azo- dyes. They are respectively the 6- and 7-*chloro-α-naphthol*-3-*sulphonic acids*, the 6-*chloro-α-naphthol*-3 : 5- and the 8-*chloro-α-naphthol*-3 : 6-*disulphonic acids*, formed from the corresponding aminonaphtholmono- and di-sulphonic acids by the Sandmeyer reaction (Bayer, D. R.-P. 96768; Eng. Pat. 9441 of 1894).

8-Chloro-α-naphthol-3 : 6-disulphonic acid, a crystalline, deliquescent substance, forms an *acid barium* salt, BaA_2+6H_2O, in needles; *acid potassium* salt, in scales, and *acid sodium* salt in needles. The normal salts dissolve easily, yielding non-fluorescent solutions, which with ferric chloride give a dark green colouration (Cassella, D. R.-P. 79055 of 1893; Eng. Pat. 1920 of 1894). Compared with the azo- dyes from α-naphthol-3 : 6-disulphonic acid, those from this *peri*-chloro- acid are much bluer in shade and of enhanced fastness (Cassella, *l.c.*; D. R.-P. 82285 of 1893; 99227 of 1894).

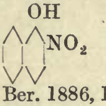
NITROSONAPHTHOLS.

(*v. Naphthaquinoneoximes*).

NITRONAPHTHOLS.

Introductory.—Nitronaphthols are obtained usually from naphtholsulphonic acids, nitrosonaphthols, or nitrosonaphtholsulphonic acids, containing the nitroso- group or at least one sulphonic group in the same nucleus as the hydroxyl radicle, as when produced by direct nitration of the naphthols, the yields are unsatisfactory owing to the formation of tars. Only in one instance has the preparation from a chloronitronaphthalene been achieved, the 1 : 4-derivative yielding 4-nitro-α-naphthol when digested with sodium carbonate solution.

The nitro-α-naphthols containing a nitro-group in the *ortho-* position relatively to the hydroxyl radicle dye wool and silk in various shades of yellow.



(i.) **2-Nitro-α-naphthol** is obtained by boiling 2-nitroacet-α-naphthalide (Liebermann and Dittler, Annalen, 1876, 183, 246; Lellmann and Remy, Ber. 1886, 19, 802) with aqueous caustic soda; by hydrolysing 2-nitro-α-ethoxynaphthalene-4-sulphonic acid (Witt and Schneider, *ibid.* 1901, 34, 3189); *or*, together with 2 : 4-dinitro-α-naphthol, by boiling α-diazonaphthalene sulphate with nitric acid in mol. prop. (Noelting and Wild, *ibid.* 1885, 18, 1339); *or*, better, by suspending 2-nitroso-α-naphthol (5 grms.) in water (60 c.c.), adding nitric acid of sp.gr. 1·3 (45 c.c.) in the cold, and, after 15 hours, distilling the product with steam (Grandmougin and Michel, *ibid.* 1892, 25, 973).

Properties.—It crystallises in greenish-yellow scales, m.p. 128°, dissolves sparingly in dilute alcohol, but less readily in water, and resembles *o*-nitrophenol in being volatile with steam and in forming dark red salts. Its *acetate* forms bright-yellow needles, m.p. 118° (Grandmougin and Michel, *l.c.*), and *ethyl ether*, bright yellow needles, m.p. 84° (Heermann, J. pr. Chem. 1891, [ii.] 44, 240).

(ii.) **4-Nitro-α-naphthol** (*French yellow*; *Campobello yellow*; *Chryseïc acid*) can be prepared by boiling 4-nitroacet-α-naphthalide with aqueous caustic soda (Andreoni and Biedermann, Ber. 1873, 6, 343; *cf.* Lellmann and Remy, *ibid.* 1886, 19, 796); and is formed when bis-4-nitro-α-naphthyl carbonate, m.p. 212°, is heated with alcoholic potash (Reverdin and Kauffmann, *ibid.* 1895, 28, 3050); *or* when 4-nitro-α-chloronaphthalene is heated with aqueous sodium carbonate under pressure at 150°–155° (Griesheim, D. R.-P. 117731; Eng. Pat. 7692 of 1900).

Properties.—It crystallises from hot water in golden-yellow needles, m.p. 164°, is readily soluble in alcohol or acetic acid, and, like *p*-nitrophenol, does not volatilise with steam. The salts (Biedermann, Ber. 1873, 6, 1118) are orange-red to dark red in colour, and dissolve readily in water; the *sodium* salt, $NaA + 2H_2O$, carmine-red needles, was formerly used as a yellow dye for silk or wool. The *methyl ether*, m.p. 85°–86 (Griesheim, *l.c.*), and *ethyl ether*, needles, m.p. 116°–117° (Heermann, *l.c.*; Witt and Schneider, *l.c.*) have been described.

Reactions.—(1) On nitration, it is converted into 2 : 4-*dinitro-α-naphthol* (Liebermann and Dittler, Annalen, 1876, 183, 249).

(2) When heated with 20 p.c. caustic soda solution under pressure at 170°–250°, it yields a mixture of *phthalic* and *benzoic acids* (Bindschedler, D. R.-P. 136410; Eng. Pat. 15527 of 1901).

(iii.) 5-**Nitro-α-naphthol**, obtained from 5-nitro-α-naphthylamine sulphate by the diazo-reaction, separates from hot water in dark yellow crystals, m.p. 165°; gives an *acetate*, needles, m.p. 114°; and *benzoate*, needles, m.p. 109°; couples with diazotised bases; and with nitrous acid yields 5-*nitro*-4-*nitroso-α-naphthol* (Kaufler and Bräuer, Ber. 1907, 40, 3271).

(iv.) 1-**Nitro-β-naphthol** is produced when 1-nitroso-β-naphthol is oxidised by dilute nitric acid (Stenhouse and Groves, Chem. Soc. Trans. 1877, 32, 51; *cf.* Hewitt and Mitchell, *ibid.* 1906, 89, 1172); *or* when 1-nitroacet-β-naphthalide is boiled with 6 p.c. caustic soda solution (Liebermann and Jacobson, Annalen, 1882, 211, 46); *or* when α-nitronaphthalene is heated at 50°–60° with 20 times its weight of pulverised caustic soda (Wohl, D. R.-P. 116790 of 1899; *cf.* Wohl and Aue, Ber. 1901, 34, 2444). It forms yellow needles, m.p. 103°; its *sodium* salt, red needles; *ethyl ether*, yellow needles, m.p. 103°–104° (Wittkampf, Ber. 1884, 17, 394), and *acetate*, colourless needles, m.p. 61° (Böttcher, *ibid.* 1883, 16, 1938).

(v.) 5-**Nitro-β-naphthol**, prepared from 5-nitro-β-naphthylamine by the diazo- reaction, crystallises from water in yellow needles, m.p. 147°. The salts are reddish-yellow and easily soluble; the *ethyl ether* forms yellow needles, m.p. 115° (Friedlaender and Szymanski, Ber. 1892, 25, 2079).

(vi.) 8-**Nitro-β-naphthol**, obtained from the ethyl ether by hydrolysis with hydrochloric acid at 160° (Gaess, J. pr. Chem. 1891, [ii.] 44, 614), *or* from 8-nitro-β-naphthylamine by the diazo-reaction (Friedlaender and Szymanski, Ber. 1892, 25, 2028), forms deep yellow needles, m.p. 144°–145°. The *ethyl ether*, prepared by nitration of β-ethoxynaphthalene, forms long golden-yellow needles, m.p. 72°–73° (Gaess, J. pr. Chem. 1891, [ii.] 43, 25), and the *acetate*, needles, m.p. 101°–102° (Gaess, *ibid.* 45, 615).

DINITRONAPTHOLS.

(i.) 2 : 4-**Dinitro-α-naphthol** (*Martius yellow, Manchester yellow, Naphthalene yellow, Naphthol yellow*) is obtained by the action of nitric acid on α-naphthol (Dale, Caro and Martius, Eng. Pat. 2785 of 1864; Martius, J. pr. Chem. 1867, 102, 442), 2-nitroso- or 4-nitroso-α-naphthol (Fuchs, Ber. 1875, 8, 629), 4-nitro-α-naphthol, 1-nitro-β-naphthol (Liebermann and Dittler, Annalen, 1876, 183, 249), α-naphthol-2-sulphonic acid (Darmstaedter and Wichelhaus, Eng. Pat. 89 of 1869; Annalen, 1869, 152, 299), α-naphthol-4-sulphonic acid (Cleve, Förhandl. 1876, 7, 40), α-naphthol-2 : 4-disulphonic acid (Bender, Ber. 1889, 22, 996), or (mixed with 2-nitro- and 4-nitro-α-naphthol) on α-ethoxynaphthalene-4-sulphonic acid (Witt and Schneider, Ber. 1901, 34, 3186). It is also formed when α-naphthylamine is heated with concentrated nitric acid (Balló, Ber. 1870, 3, 288); *or* when 2 : 4-dinitroacet-α-naphthalide is boiled with aqueous caustic soda (Liebermann and Hammerschlag, Annalen, 1876, 183, 273); *or* when nitrous fumes are led into an ethereal solution of α-naphthol at 0° (Schmidt, Ber. 1900, 33, 3245).

Preparation.—Direct nitration of α-naphthol, or of any of its derivatives except α-naphthol-2 : 4-disulphonic acid, results in the production of much resinous matter. In practice, either α-naphthol-2 : 4-disulphonic acid, made by dissolving α-naphthol in its own weight of sulphuric acid, is heated with dilute nitric acid at 100°, or the two α-naphtholsulphonic acids, formed when α-naphthol is sulphonated under Schaeffer's conditions (*v.* α-naphthol-2-sulphonic acid), are converted into their nitroso- derivatives by interaction with sodium nitrite and sulphuric acid in the cold, and the mixed product is then warmed with nitric acid (*cf.* Bender, *l.c.* footnote).

Properties.—It crystallises from alcohol in citron-yellow needles, m.p. 138°, does not volatilise with steam, is almost insoluble in water, and dissolves only sparingly in alcohol, ether, or benzene. It is sufficiently acidic to expel carbon dioxide from carbonates, and it forms soluble, orange-coloured salts (Martius, *l.c.*; for salts with organic bases *cf.* Norton and Lowenstein, J. Amer. Chem. Soc. 1897, 19, 923; Korczyński, Ber. 1909, 42, 174). The *sodium* salt $NaA+H_2O$, *ammonium* salt NH_4A+H_2O, and *calcium* salt CaA_2+6H_2O, crystallise in needles (Martius, *l.c.*), and were used formerly as golden-yellow dyes for silk and wool. Dinitro-α-naphthol, however, has little affinity for the fibre, being removed from it either by volatilisation or by washing.

Reactions.—(1) Nitration in the presence of much sulphuric acid at temperatures below 50° converts it into a mixture of 2 : 4 : 5-*trinitro-* (Ekstrand, Ber. 1878, 11, 162; Diehl and Merz, *ibid.* 1661) with 2 : 4 : 7-*trinitro-α-naphthol* (Kehrmann and Haberkant, *ibid.* 1898, 31, 2420). Prolonged boiling with concentrated nitric acid oxidises it to *phthalic* and *oxalic acids* (Martius, *l.c.*).

(2) When heated with alcoholic ammonia at 190°–200° it yields 2 : 4-*dinitro-α-naphthylamine* (Witt, Ber. 1886, 19, 2033).

(3) With potassium cyanide in hot alcoholic solution it yields *naphthylpurpuric acid*, or, in hot aqueous solution of its ammonium salt, a mixture of this substance with *indophan* (Sommaruga, Annalen, 1871, 157, 328).

(ii.) 4 : 5-**Dinitro-α-naphthol**, formed when 5-nitro-4-nitroso-α-naphthol is oxidised by alkaline potassium ferricyanide solution, crystallises in yellow needles, m.p. 230°, dissolves only sparingly in water, and has only feeble dyeing properties (Friedlaender, Ber. 1899, 32, 3529). The *methyl* ether, m.p. 216°, and *ethyl* ether, scales, m.p. 182°, have been described (Ullmann and Consonno, Ber. 1902, 35, 2808).

(iii.) 4 : 8-**Dinitro-α-naphthol**, obtained similarly from 8-nitro-4-nitroso-α-naphthol, has m.p. 235°, but otherwise resembles the 4 : 5- derivative in properties (Graebe and Oeser, Annalen, 1904, 335, 154).

(iv.) 1 : 6-**Dinitro-β-naphthol** is formed from β-naphthol by nitration in alcoholic solution (Wallach and Wichelhaus, Ber. 1870, 3, 846), or by means of nitrous fumes in cold ethereal solution (Schmidt, *ibid.* 1900, 33, 3246); *or* by boiling diazotised β-naphthylamine with dilute nitric acid (Graebe and Drews, *ibid.* 1884, 17, 1170).

Properties.—It crystallises in yellow needles, m.p. 195°; the *potassium* salt $KA+2H_2O$, in sparingly soluble needles; and the *ethyl ether* in yellow needles, m.p. 144° (Gaess, J. pr. Chem. 1891, [ii.] 43, 29). It dyes wool and silk yellow. When heated with alcoholic ammonia at 150°–160°, it yields 1 : 6-*dinitro-β-naphthylamine* (Kehrmann and Matis, Ber. 1898, 31, 2419).

1:8-Dinitro- and 5:8-dinitro-β-naphthol have not been isolated, but their *ethyl ethers* are known (*cf.* Gaess, *l.c.* and Onufrowicz, Ber. 1890, 23, 3360, respectively).

TRINITRONAPHTHOLS.

(i.) 2:4:5-**Trinitro-α-naphthol** (*Naphthopicric acid*) is formed when 5-nitro-4-nitroso-α-naphthol is warmed with dilute nitric acid (Graebe, Ber. 1899, 32, 2878; Graebe and Oeser, Annalen, 1904, 335, 147; Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339); *or*, mixed with the 2 : 4 : 7-trinitro- derivative, when 2 : 4-dinitro-α-naphthol is nitrated in the cold with nitrosulphuric acid (Kehrmann and Haberkant, Ber. 1898, 31, 2421; *cf.* Diehl and Merz, *ibid.* 1878, 11, 1662).

Properties.—It forms needles, m.p. 190°, and its *potassium* salt $KA+H_2O$, needles, easily soluble in hot, but only sparingly soluble in cold water (Kehrmann and Steiner, *ibid.* 1900, 33, 3281), It is a strong acid, dyes wool yellow, and on oxidation yields 3-*nitrophthalic acid*.

(ii.) 2 : 4 : 7-**Trinitro-α-naphthol** is the more soluble product obtained when 2 : 4-dinitro-α-naphthol is nitrated in the cold with nitrosulphuric acid (Kehrmann and Haberkant, Ber. 1898, 31, 2421), and is freed from the 2 : 4 : 5- compound by conversion into the sparingly soluble sodium salt (Kehrmann and Steiner, Ber. 1900, 33, 3286).

Properties.—It forms yellow needles, m.p. 145°, but, from benzene or acetic acid, prisms containing solvent which effloresce in the air. On oxidation it yields 4-*nitrophthalic acid* (Kehrmann and Haberkant, *l.c.*). The *potassium* salt is easily, but the *sodium* salt, yellow needles, only sparingly soluble in water.

(iii.) 2 : 4 : 8-**Trinitro-α-naphthol,** obtained by mixing 8-nitro-4-nitroso-α-naphthol with 50 p.c. nitric acid in the cold (Graebe and Oeser, Annalen, 1904, 335, 156; Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339), forms yellow prisms, m.p. 175°, and dyes wool yellow. The *potassium* salt KA, crystallises well (Friedlaender, Ber. 1899, 32, 3530).

(iv.) 4 : 5 : 7- (or 4 : 6 : 8-) Trinitro-α-naphthol has not been isolated, but its *methyl ether* is formed by the interaction of 1 : 3 : 5 : 8-tetranitronaphthalene and sodium methoxide. This ether crystallises in yellow needles, m.p. 186°, and on oxidation yields 3 : 5-*dinitrophthalic acid* (Will, Ber. 1895, 28, 372).

TETRANITRONAPHTHOL.

2 : 4 : 5 : 7-**Tetranitro - α - naphthol** (*Heliochrysin*) is obtained by digesting tetranitro-α-bromonaphthalene (m.p. 170·5°) with warm, concentrated sodium carbonate solution (Höchst, D. R.-P. 14954; Eng. Pat. 5327 of 1880; Merz and Weith. Ber. 1882, 15. 2714). It crystallises in yellow scales, m.p. 180°, and forms reddish-yellow salts, which dissolve only sparingly in water. The *potassium* salt $KA+1\frac{1}{2}H_2O$, prisms, is soluble in 340 parts, and the *sodium* salt $NaA+2H_2O$, scales, in about 94 parts of water at 19°. It dyes silk and wool golden-yellow, but has no technical value.

NITRONAPHTHOLSULPHONIC ACIDS.

(i.) 2-**Nitro-α-naphthol-4-sulphonic acid** can be obtained from the corresponding ethyl ether by hydrolysis with caustic potash solution. The *basic barium* salt $BaA+H_2O$ is very sparingly soluble; the yellow *potassium* and orange *basic potassium* salts form needles easily soluble in water. When its salts are heated with hydrochloric acid under pressure at 150°–160° 2-*nitro-α-naphthol* is obtained (Witt and Schneider, Ber. 1901, 34, 3189).

(ii.) 2 - **Nitro-α - naphthol - 7 - sulphonic acid,** formed from diazotised 2-nitro-4-amino-α-naphthol-7-sulphonic acid (*v.* 2 : 4-dinitro- acid) by means of copper powder, crystallises with 1 mol. H_2O in yellow needles, and its *copper* salt CuA_2+5H_2O in greenish-yellow needles. On reduction it yields 2-*amino-α-naphthol*-7-*sulphonic acid* (Finger, J. pr. Chem. 1909, [ii.] 79, 441).

(iii.) 6 - **Nitro - β - naphthol - 8 - sulphonic acid,** obtained from 6-nitro-β-naphthylamine-8-sulphonic acid by the diazo- reaction, forms long yellow prisms, with 4 mols. H_2O; the *barium* salt $BaA_2+6\frac{1}{2}H_2O$, dark-yellow prisms; *potassium* salt KA, orange prisms; *sodium* salt $NaA+5H_2O$ (?), orange-red needles (Jacchia, Annalen, 1902, 323, 122).

(iv.) 2 : 4-**Dinitro - α -naphthol - 7 - sulphonic acid** (*Naphthol yellow S; acid yellow S*) is formed by nitration of α-naphthol-7-sulphonic acid (Liebmann and Studer, Eng. Pat. 7812 of 1887; *cf.* Bender, Ber. 1889, 22, 996), *or* of α-naphthol-4 : 7-disulphonic acid (Dahl, D. R.-P. 41957 of 1886), *or* of a mixture of α-naphthol-2 : 7- and 4 : 7-disulphonic acids (Seltzer, D. R.-P. 20716 of 1882; Levinstein, Eng. Pat. 5692 of 1882; L. Vignon & Co., Eng. Pat. 9808 (prov.) of 1884; Leonhardt, Eng. Pat. 11318 of 1887), *or* of α-naphthol-2 : 4 : 7-trisulphonic acid (Badische, D. R.-P. 10785; Eng. Pat. 5305 of 1879; *cf.* Lauterbach, Ber. 1881, 14, 2028; Höchst, D. R.-P. 22545; Eng. Pat. 2178 of 1882), *or* of α-methoxynaphthalenedisulphonic acid (Dahl, Eng. Pat. 1964 of 1883).

Preparation.—(1) The melt obtained by the trisulphonation of α-naphthol (10 kilos.), after being diluted with water, is mixed gradually with nitric acid of sp.gr. 1·38 (25 kilos.) below 50°, and the reaction completed either at 50° or by allowing the mixture to remain in the cold for 12 hours. From the solution dinitro-α-naphtholsulphonic acid separates in needles, the mother liquors containing other nitration products, of which nothing definite is known (Badische, *l.c.*).

(2) The mixed α-naphtholdisulphonic acids of Leonhardt & Co.'s Eng. Pat. 11318, after conversion into nitroso- compounds by means of sodium nitrite, are nitrated at 50° with nitric acid, also in the proportion of 25 kilos. to every 10 kilos. of α-naphthol sulphonated (Leonhardt, *l.c.*).

Salts.—The *acid* crystallises from hydrochloric acid in yellow needles. The *barium* and *basic potassium* K_2A salts are very sparingly soluble; the *acid potassium* KA, *basic sodium* Na_2A, and *ammonium* salts are readily soluble in water and are orange-yellow (Lauterbach, *l.c.*).

It is a strong acid, has considerable tinctorial power, is used as a yellow dye for wool, and, unlike 2:4-dinitro-α-naphthol, does not volatilise from the fibre, and is not poisonous.

Reactions.—(1) On oxidation with nitric acid of sp.gr. 1·33 it is converted into *β-sulphophthalic acid* (Graebe, Ber. 1885, 18, 510; Rée, Chem. Soc. Trans. 1886, 49, 511).

(2) On reduction with stannous chloride and hydrochloric acid it yields 2-*nitro*-4-*amino-α-naphthol*-7-*sulphonic acid* (Lauterbach, *l.c.*; Finger, J. pr. Chem. 1909, [2] 79, 441); but in ammoniacal solution with sodium sulphide, the isomeric 4-*nitro*-2-*amino-α-naphthol*-7-*sulphonic acid* is the product (Gesellsch., D. R.-P. 189513 of 1905; Eng. Pat. 7535 of 1906).

(v.) **2:4-Dinitro-α-naphthol-8-sulphonic acid** (*brilliant yellow*) is formed when sodium nitroso-α-naphthol-8-sulphonate in dilute sulphuric acid solution, is mixed with nitre in the cold, the reaction being completed on a water-bath (Schöllkopf, D. R.-P. 42304 of 1886); *or* when sodium α-naphthol-4:8-disulphonate in aqueous solution is heated with dilute nitric acid at 60°–70° (Schöllkopf, D. R.-P. 40571; Eng. Pat. 15775 of 1885); or its nitroso- derivative is boiled with nitric acid (Karpeles, *cf.* J. Soc. Chem. Ind. 1898, 17, 837); *or* when sodium α-naphthol-2:4:8-trisulphonate dissolved in sulphuric acid is mixed with nitrosulphuric acid at 20° (Dressel and Kothe, Ber. 1894, 27, 2145).

Properties.—The *potassium* salt $KA+H_2O$ (Karpeles, *l.c.*), and the *sodium* salt NaA (Dressel and Kothe, *l.c.*) form sparingly soluble yellow needles, and in an acid bath dye silk and wool a more orange shade than that produced with naphthol yellow S. As a dyestuff it has no technical value.

(vi.) **1:6-Dinitro-β-naphthol-8-sulphonic acid** (*croceïn yellow*) is produced by warming sodium β-naphthol-8-sulphonate with dilute nitric acid at 30°–40° until nitration is complete (Bayer, D. R.-P. 18027; Eng. Pat. 1225 of 1881; Nietzki and Zübelen, Ber. 1889, 22, 454). The *potassium* salt, KA, forms yellow needles, but the *basic potassium* salt K_2A, sparingly soluble, yellow scales. It dyes wool yellow, but has little tinctorial power.

VII.—AMINOHYDROXY-DERIVATIVES.

Introductory.—All the fourteen isomeric aminonaphthols theoretically possible have been prepared, and are obtained by methods which usually afford evidence of their structure. Summarised, these methods are—

(1) Reduction of the corresponding nitronaphthols;

(2) Reduction of nitroso- or azo- derivatives of α- or β-naphthol;

(3) Fusion of α- or β-naphthylaminemonosulphonic acids with caustic alkali, α-naphthylamine-4-sulphonic acid being an exception, as it furnishes α-naphthol-4-sulphonic acid under these conditions (*cf.* Aktienges., D. R.-P. 46307 of 1888);

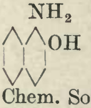
(4) Fusion of naphtholmonosulphonic acids with sodamide;

(5) Interaction of dihydroxynaphthalenes with ammonia, or with ammonium bisulphite and ammonia.

The only instances of change in structure observed in any of these reactions occur with the β-naphthol-6-, 7-, and 8-sulphonic acids, all of which yield 5-amino-β-naphthol on fusion with sodamide.

The aminonaphthols are basic compounds forming salts with acids; but, nevertheless, dissolve readily in alkalis. In solution, or in the moist state, they are readily oxidised in the air, and those which contain the radicles relatively in 1:2- or 1:4- positions form naphthaquinones on oxidation with ferric chloride, chromic acid, or nitrous acid in acid solution.

AMINONAPHTHOLS.[1]



(i.) **1-Amino-2-naphthol** (1-*amino-β-naphthol*) is formed when 1-nitroso-β-naphthol is reduced by ammonium sulphide (Stenhouse and Groves, Chem. Soc. Trans. 1877, 32, 52), or by stannous chloride (Groves, *ibid.* 1884, 45, 296; Paul, *cf.* J. Soc. Chem. Ind. 1897, 16, 733); *or* when 1-nitro-β-naphthol is reduced by tin and hydrochloric acid (Jacobson, Ber. 1881, 14, 806; Zincke, Annalen, 1892, 268, 273).

Preferably, it is obtained when benzeneazo-β-naphthol (Liebermann, Ber. 1883, 16, 286; Groves, *l.c.*), orange II (Liebermann, Ber. 1881, 14, 1311; Witt, *ibid.* 1888, 21, 3472; Grandmougin and Michel, *ibid.* 1892, 25, 981; Russig, J. pr. Chem. 1900, [ii.] 62, 55; Paul, *l.c.*), or other azo- derivatives of β-naphthol are reduced either by stannous chloride and hydrochloric acid or (Grandmougin, Ber. 1906, 39, 2495) by sodium hyposulphite. Its production electrolytically from orange II has been described (Boehringer, D. R.-P. 121835; Eng. Pat. 13542 of 1900), and it can be obtained from the 4-sulphonic acid by means of sodium amalgam (Friedlaender and Reinhardt, Ber. 1894, 27, 241).

Properties.—It forms scales, sparingly soluble in boiling water, and in alkaline or ammoniacal solution rapidly becomes brown on exposure to air. Ferric chloride and acid oxidising agents convert it into [β-]*naphthaquinone* (for references *cf.* Grandmougin and Michel, *l.c.*). The *hydrochloride* B·HCl forms needles (Jacobson, *l.c.*); N-*acetyl* derivative, scales, m.p. 235° (Michel and Grandmougin, Ber. 1892, 25, 3433); *diacetyl* derivative, m.p. 116° (Grandmougin, *l.c.*); *dibenzoyl* derivative, silky needles, m.p. 235·5° (Sachs, Ber. 1906, 39, 3024); and *ethyl ether*, prisms, m.p. 51°, b.p. 300°–302° (Cassella, D. P. Anm. C. 2883 of 1889; Gaess, J. pr. Chem. 1891, [ii.] 43, 27). It has been used in the production of *oxazine* dyes (Bayer, D. R.-P. 77120; Eng. Pat. 8093 of 1893).

Reactions.—It couples in acetic acid solution with diazotised bases forming *azo-* dyes (Aktienges., D. R.-P. 77256, 79103; Eng. Pat. 13833 of 1893), but with nitrous acid in the presence

---

[1] In this section, which includes the aminonaphthols, aminonaphtholsulphonic acids and diaminonaphthols, a departure is made from the rule that the numbering indicates the position occupied by the substituted group (NH_2) relatively to the characteristic radicle (OH) of the substance (naphthol) in which substitution is supposed by the name (aminonaphthol) to have occurred. This departure has been made to avoid confusion when German Patents, in which the numbering is given with reference to the amino-group, are consulted. The alternative numbering, based on the rule, is given in brackets.

of mineral acids diazotisation does not occur, although in neutral solution with copper salts present, *naphthalene*-1-*diazo*-2-*oxide* is obtained (Geigy, D. R.-P. 172446; Eng. Pat. 10235 of 1904).

(ii.) **1-Amino-3-naphthol**[1] (4-*amino-β-naphthol*) is formed when α-naphthylamine-3-sulphonic acid is fused with caustic potash at 250°–260° (Friedlaender, Ber. 1895, 28, 1952). It crystallises in needles, decomp. at 185°, is sparingly soluble in water, gives a violet-brown colouration with ferric chloride, forms easily soluble salts, couples readily, and yields an unstable *diazo*- compound. The N-*acetyl* derivative forms needles, m.p. 179° (Friedlaender, *l.c.*), and has been used in the production of *oxazine* dyes (Bayer, D. R.-P. 77802; Eng. Pat. 15045 of 1893); the *dibenzoyl* derivative, scales, m.p. 309°–310° (Sachs, Ber. 1906, 39, 3024).

Reactions.—(1) By prolonged boiling with acidified water, its amino- group is eliminated as ammonia, and 1 : 3-*dihydroxynaphthalene* is formed (Friedlaender, *l.c.*; Friedlaender and Rüdt, Ber. 1896, 29, 1609).

(2) When heated with aqueous ammonia under pressure, it is converted into 1 : 3-*diaminonaphthalene* (Friedlaender, *l.c.*).

(3) On sulphonation with monohydrate at the ordinary temperature, it yields 1-*amino*-3-*naphthol*-4-*sulphonic acid* (Friedlaender and Rüdt, *l.c.*).

(iii.) **1-Amino-4-naphthol** (4-*amino-α-naphthol*) can be prepared from 4-nitroso-α-naphthol (Grandmougin and Michel, Ber. 1892, 25, 976); *or* from 4-nitro-α-naphthol (Liebermann and Dittler, Annalen, 1876, 183, 247); *or* from α-naphthol-orange (Liebermann and Jacobson, *ibid.* 1882, 211, 61; Seidel, Ber. 1892, 25, 423; Russig, J. pr. Chem. 1900, [ii.] 62, 30) or other *p*-azo- derivatives of α-naphthol, by reduction with stannous chloride and hydrochloric acid. It is also formed when 4-amino-α-naphthol-2-carboxylic acid is heated at 230°, carbon dioxide being eliminated (Nietzki and Guitermann, Ber. 1887, 20, 1276).

Properties.—It crystallises in very soluble needles, which, when moist, rapidly become blue on exposure to the air, forms easily soluble salts, does not couple, and has not been diazotised. The N-*formyl* derivative forms rosettes, m.p. 168° (Gaess, D. R.-P. 149022 of 1902); the *diacetyl* derivative, prisms, m.p. 158° (Grandmougin and Michel, *l.c.*); the *dibenzoyl* derivative, rhombic crystals, m.p. 215° (Sachs, Ber. 1906, 39, 3026); the N-*dimethyl* derivative, prisms, m.p. 113° (Friedlaender and Lagodzinski (*cf.* J. Soc. Chem. Ind. 1897, 16, 793); and the *ethyl ether*, needles, m.p. 96° (Heermann, J. pr. Chem. 1892, [ii.] 45, 545; *cf.* Cassella, D. P. Anm. C. 2883 of 1889).

Reactions.—(1) It is converted into [α-]*naphthaquinone* by oxidising agents (*cf.* Liebermann, Ber. 1881, 14, 1796), including nitrous acid (*cf.* Badische, D. R.-P. 55404 of 1889).

(2) When its hydrochloride is heated with methyl or ethyl alcohol under pressure at 170°–180°, the corresponding *monoalkyl ether* of 1 : 4-*dihydroxynaphthalene* is obtained (Höchst, D. R.-P. 234411 of 1910).

(3) On sulphonation with 10 p.c. anhydro-acid at 30°–40°, it gives 1-*amino*-4-*naphthol*-3-*sulphonic acid* (Seidel, *l.c.*; *cf.* Conrad and Fischer, Annalen, 1893, 273, 114).

1-Acetylamino-4-naphthol (*naphthacetol*), obtained by acetylating the hydrochloride in presence of sodium acetate (Witt, D. R.-P. 90596; Eng. Pat. 20676 of 1896; Witt and Dedichen, Ber. 1896, 29, 2948), forms needles, m.p. 187°, moderately soluble in warm water, and couples in alkaline solution with diazotised bases, giving ortho-*azo*- dyes (Witt, *l.c.*; D. R.-P. 93312; Eng. Pat. 20676 of 1896). The *ethyl ether* (naphthacetin) forms needles, m.p. 189°, soluble in 7·4 parts of boiling alcohol (Henriques, Ber. 1892, 25, 3060; Heermann, *l.c.*).

(iv.) **1-Amino-5-naphthol** (5-*amino-α-naphthol*) can be obtained from α-naphthylamine-5-sulphonic acid by digestion with 60 p.c. caustic soda solution at 240°–250° (Aktienges., D. R.-P. 49448 of 1889; *cf.* Friedlaender and Lagodzinski, J. Soc. Chem. Ind. 1897, 16, 793); *or* from 1 : 5-diaminonaphthalene either by digestion with dilute mineral acids under pressure (*cf.* Aktienges., D. P. Anm. A. 4029 of 1894), or, in 80 p.c. yield, by the bisulphite method (Bucherer, J. pr. Chem. 1904, [ii.] 69, 84). It is also formed from α-naphthol, *or* from α-naphthol-5-sulphonic acid by fusion with sodamide and naphthalene at 190° or 230° respectively (Sachs, D. R.-P. 173522 of 1904; 181333; Eng. Pat. 22412 of 1905; Ber. 1906, 39, 3018).

Properties.—In alkaline solution it undergoes little change on exposure to the air. The *hydrochloride* is crystalline, and the *dibenzoyl* derivative forms rhombic scales, m.p. 276°. The *azo*-dye obtained by coupling it with diazotised naphthionic acid is not red as is the case with its isomerides, but cornflower-blue in colour (Sachs, *l.c.*).

Reactions.—(1) It yields 1 : 5-*dihydroxynaphthalene* by prolonged heating with dilute hydrochloric acid at 180° (*cf.* Aktienges., D. P. Anm. A. 4029 of 1894), or by the bisulphite reaction (*cf.* Bucherer, J. pr. Chem. 1904, [ii.] 69, 84).

(2) When heated with ammonium sulphite solution and ammonia at 125°, it is converted into 1 : 5-*diaminonaphthalene* (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

(3) With sulphuric acid in the cold it gives 1-*amino*-5-*naphthol*-6-*sulphonic acid* (Aktienges., D. R.-P. 68564 of 1891); but with 23 p.c. anhydro- acid at 100° a *disulphonic acid* is formed (*ibid.*, D. P. Anm. A. 3767 of 1894).

(4) It can be diazotised (*cf.* Bayer, D. R.-P. 79166 of 1891), and it couples in acid or alkaline solution with diazotised bases forming *monoazo*-dyes (*cf.* Bayer, D. R.-P. 66688; Eng. Pat. 5984 of 1891; Cassella, D. R.-P. 78875; Eng. Pat. 24715 of 1893; D. R.-P. 95190; Eng. Pat. 24134 of 1896; Bayer, D. R.-P. 174557 of 1902; 180481; Eng. Pat. 26132 of 1903).

(v.) **1-Amino-6-naphthol** (5-*amino-β-naphthol*) is formed when 5-nitro-β-naphthol is reduced by stannous chloride and hydrochloric acid (Friedlaender and Szymanski, Ber. 1892, 25, 2079); *or* when α-naphthylamine-6-sulphonic acid is fused with caustic alkalis (Bayer, D. R.-P. 74060; Eng. Pat. 11533 of 1892); *or* when 1-amino-6-naphthol-4-sulphonic acid interacts with sodium amalgam (Friedlaender and Kielbasinski, Ber. 1896, 29, 1979). It is also formed

---

[1] The substance described as αγ-aminonaphthol (Gesellsch., D. R.-P. 55059 of 1889), is probably a mixture of 1-amino-6- and 1-amino-7-naphthol (Friedlaender and Szymanski, Ber. 1892, 25, 2076).

when β-naphthol, or β-naphthol-6-, or 7-, or 8-sulphonic acid is heated with sodamide and naphthalene at 230° (Sachs, D. R.-P. 173522 of 1904; 181333; Eng. Pat. 22412 of 1905; Ber. 1906, 39, 3016).

Properties.—It crystallises in scales, m.p. 186°, shows blue fluorescence in ammoniacal solution, rapidly darkens when moist on exposure to the air, and with ferric chloride gives a dark violet colouration. The following derivatives have been described: N-*acetyl*, needles, m.p. 215°–216° (Kehrmann and Deuk, Ber. 1900, 33, 3296; Sachs, Ber. 1906, 39, 3025); *diacetyl*, m.p. 187°; N-*benzoyl*, needles, m.p. 152°; *dibenzoyl*, needles, m.p. 223°; *picrate*, yellow needles, m.p. 183° (Sachs, *l.c.*).

Reactions.—It can be diazotised (Sachs, *l.c.*), and it couples in alkaline solution with diazotised bases (1 or 2 mols). forming *azo-* dyes (*cf.* Cassella, D. R.-P. 78875; Eng. Pat. 24715 of 1893; D. R.-P. 86848 of 1894).

(vi.) **1-Amino-7-naphthol** (8-*amino-β-naphthol*) is obtained from 8-nitro-β-naphthol by reduction with stannous chloride and hydrochloric acid (Friedlaender and Syzmanski, Ber. 1892, 25, 2082); *or* from α-naphthylamine-7-sulphonic acid by digestion with 60 p.c. caustic soda solution at 250° (Cassella, D. R.-P. 69458 of 1891; Friedlaender and Zinberg, Ber. 1896, 29, 41).

Properties.—It crystallises from water in needles, decomp. 212°–218° (m.p. 206°, Cassella, *l.c.*), gives with ferric chloride a greenish-blue colouration, and in acid or alkaline solution shows blue fluorescence. The N-*acetyl* derivative forms tablets, m.p. 165° (Friedlaender and Zinberg, *l.c.*); the *dibenzoyl* derivative, needles, m.p. 208° (Sachs, Ber. 1906, 39, 3026); and the *ethyl ether*, prisms, m.p. 67°, b.p. 315° (Gaess, J. pr. Chem. 1891, [ii.] 43, 28).

Reactions.—(1) With sulphuric acid at 20°–30°, it yields 1-*amino*-7-*naphthol*-(4)-*sulphonic acid* (Cassella, D. R.-P. 75066 of 1891), and at 100°, or with anhydro- acid, a *disulphonic acid* (Cassella, D. R.-P. 69458 of 1891).

(2) It can be diazotised, and it couples in acid or in alkaline solution with diazotised bases (1 or 2 mols.) forming *azo-* dyes (*cf.* Cassella, D. R.-P. 78875; Eng. Pat. 24715 of 1893; D. R.-P. 84610, 86848; Eng. Pat. 22273 of 1894; Bayer, D. R.-P. 164319; Eng. Pat. 18569 of 1902; D. R.-P. 197034, 198137; Eng. Pat. 18698 of 1907; Friedlaender and Zinberg, *l.c.*).

(vii.) **1-Amino-8-naphthol** (8-*amino-α-naphthol*) can be prepared by fusing α-naphthylamine-8-sulphonic acid with caustic alkali at 230°–240° (Badische, D. R.-P. 55404; 62289 of 1889; Eng. Pat. 9676 of 1890; Fichter and Gaguer, Ber. 1906, 39, 3331); *or* by heating 1:8-diaminonaphthalene either with dilute mineral acids under pressure (*cf.* Aktienges., D. P. Anm. A. 4029 of 1894), or with sodium bisulphite solution (Bucherer, J. pr. Chem. 1904 [ii.] 69, 58); *or* by digesting 1:8-diaminonaphthalene-4-sulphonic acid with 25 p.c. sulphuric acid, or 1-amino-8-naphthol-5-sulphonic acid with 20 p.c. sulphuric acid under pressure at 135°–140° (Cassella, D. R.-P. 73381 of 1893). It is also formed by heating α-naphthol-8-sulphonic acid with sodamide and naphthalene at 230° (Sachs, D. R.-P. 173522 of 1904; Eng. Pat. 22412 of 1905; Ber. 1906, 39, 3018).

Properties.—It crystallises in needles, m.p. 95°–97°, is sparingly soluble in cold, and its *sulphate* in hot, water (Badische, *l.c.*; *cf.* Friedlaender and Silberstern, Monatsh. 1902, 23, 516). The N-*acetyl* derivative, forms needles, m.p. 168°–169°; the *diacetyl* derivative, needles, m.p. 118·5°; the *nitroso-* derivative, brown needles, decomp. 175°–180° (Fichter and Gaguer, *l.c.*); and the N-*dimethyl* derivative, hexagonal tablets, m.p. 112° (Gesellsch., D. R.-P. 50142 of 1889).

Reactions.—(1) With 75 p.c. sulphuric acid at 130°–160°, it gives 1-*amino*-8-*naphthol*-7-*sulphonic acid* (Badische, D. R.-P. 82900 of 1894), but with sulphuric acid at 15°–20° it yields a mixture of this acid with the 5-*sulphonic acid* as chief product (Badische, D. R.-P. 62289 of 1889; 77937, 82900, 84951 of 1894), and at 100° the 5 : 7-*disulphonic acid* (Badische, D. R.-P. 62289, 82900).

(2) It can be diazotised (Badische, D. R.-P. 62289; *cf.* Fichter and Gaguer, *l.c.*) and it couples in alkaline solution with diazotised bases forming *azo-* dyes (*cf.* Cassella, D. R.-P. 78875; Eng. Pat. 24715 of 1893; Friedlaender and Silberstern, *l.c.*).

Its sulphite, when diazotised, has been used for the production of *azo*-dyes (Bayer, D. R.-P. 211381; Eng. Pat. 11878 of 1908).

(viii.) **2-Amino-1-naphthol** (2-*amino-α-naphthol*) is obtained by reducing 2-nitroso-α-naphthol with stannous chloride (Liebermann and Jacobson, Annalen, 1882, 211, 55; Grandmougin and Michel, Ber. 1892, 25, 974); *or* 2-nitro-α-naphthol with tin and hydrochloric acid (Liebermann and Dittler, Annalen, 1876, 183, 248); *or* [β-]naphthaquinonephenylhydrazone with sodium hyposulphite (Grandmougin, Ber. 1906, 39, 2496; *cf.* Zincke and Rathgen, *ibid.* 1886, 19, 2483). It is also formed from 2-amino-1-naphtholsulphonic acids by interaction with sodium amalgam (Gattermann and Schulze, Ber. 1897, 30, 51).

Properties.—It crystallises in needles, and is only sparingly soluble in cold water. When dissolved in ammonia and shaken with air it gives a green solution, on the surface of which a characteristic violet skin forms (Liebermann and Jacobson, *l.c.*). The N-*acetyl* derivative, needles, m.p. 128°–129°, which couples with diazotised bases; *diacetyl* derivative, needles, m.p. 116° (Grandmougin, *l.c.*); and N-*dialkyl* derivatives, which can be diazotised (Grandmougin and Michel, Ber. 1892, 25, 975), have been described. It has been used in the production of *oxazine* dyes (Bayer, D. R.-P. 77120; Eng. Pat. 8093 of 1893).

Reactions.—(1) Nitrous acid oxidises it to [β-]*naphthaquinone* (Michel and Grandmougin, Ber. 1892, 25, 3430), but in presence of copper salts converts it in neutral solution into *naphthalene-2-diazo-1-oxide* (Geigy, D. R.-P. 172446; Eng. Pat. 10235 of 1904).

(2) When boiled with sodium bisulphite solution it gives 1-*amino*-8-*naphthyl sulphite* with only a very small proportion of the *ester* of 1 : 8-*dihydroxynaphthalene* (Bucherer, J. pr. Chem. 1904, [ii.] 69, 61).

(3) On sulphonation with 10 p.c. anhydro-acid at 40°–50° it furnishes a *monosulphonic acid* (Sandoz, D. R.-P. 69228 of 1892; Reverdin and de la Harpe, Ber. 1893, 26, 1281).

(ix.) **2-Amino-3-naphthol** (3-*amino-β-naphthol*) is formed when 2 : 3-dihydroxynaphthalene is heated with 30 p.c. ammonia solution at 140°–150° (Höchst, D. R.-P. 73076 of 1893; Friedlaender and Zakrzewski, Ber. 1894, 27, 763), or with ammonium sulphite solution and ammonia at 80°, the product afterwards being acidified (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900). It crystallises in needles, m.p. 234°, sparingly soluble in cold water, and its N-*benzoyl* derivative in hexagonal scales, m.p. 233·5° (Sachs, Ber. 1906, 39, 3024). By coupling it in alkaline solution with diazotised bases, *disazo-* dyes have been obtained (*cf.* Bayer, D. R.-P. 99468; Eng. Pat. 28090 of 1897).

(x.) **2-Amino-4-naphthol** (3-*amino-α-naphthol*) has been prepared by heating 1 : 3-dihydroxynaphthalene with ammonia at 130°–140°. Its *hydrochloride* is sparingly soluble; its N-*phenyl* derivative forms needles, and is rapidly oxidised in alkaline solution to [*α*-]*naphthaquinoneanil*. The *azo-* dyes derived from it resemble closely those from 1-amino-3-naphthol (Friedlaender and Rüdt, Ber. 1896, 29, 1612).

(xi.) **2-Amino-5-naphthol** (6-*amino-α-naphthol*) can be obtained from *β*-naphthylamine-5-sulphonic acid by fusion with caustic potash at 260°–270° (Bayer, D. P. Anm. F. 7372; Eng. Pat. 5267 of 1894); *or* from 2-amino-5-naphthol-8-sulphonic acid by means of sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3034), but no description of it has been published. On sulphonation it yields a mixture of two *monosulphonic acids*, of which the less soluble constitutes 30 p.c. of the product (Bayer, *l.c.*).

(xii.) **2-Amino-6-naphthol** (6-*amino-β-naphthol*), obtained from 2-amino-6-naphthol-4-sulphonic acid by means of sodium amalgam, crystallises in scales, m.p. 190°–195° (Jacchia, Annalen, 1902, 323, 127); its *dibenzoyl* derivative, in needles, m.p. 233·5° (Sachs, Ber. 1906, 39, 3025); and its *ethyl ether* in pyramids, m.p. 90°–91°, b.p. 330° (Gaess, J. pr. Chem. 1891, [ii.] 43, 28). It couples in alkaline solution with diazotised *o*-aminophenolsulphonic acids forming *monoazo-* dyes (Bayer, D. R.-P. 164516; Eng. Pat. 18569 of 1902).

(xiii.) **2-Amino-7-naphthol** (7-*amino-β-naphthol*) is formed when *β*-naphthylamine-7-sulphonic acid is digested with 50 p.c. caustic soda solution at 260°–300° (Gesellsch., D. R.-P. 47816 of 1888); *or* when 2 : 7-diaminonaphthalene is boiled with sodium bisulphite solution, and the product made alkaline with caustic soda (Badische, D. R.-P. 134401 of 1899); *or* when 2 : 7-dihydroxynaphthalene is heated either with ammonia under pressure (Gesellsch., D. R.-P. 55059 of 1889), or with ammonium sulphite solution and ammonia in a reflux apparatus (Franzen and Deibel, J. pr. Chem. 1908, [ii.] 78, 155). It is also obtained, mixed with 1-amino-6-naphthol (Sachs, Ber. 1906, 39, 3017), when *β*-naphthol-7-sulphonic acid is heated with sodamide and naphthalene at 230° (Sachs, D. R.-P. 173522 of 1904; Eng. Pat. 22412 of 1905).

Properties.—It crystallises in needles, m.p. 201° (Franzen and Deibel, *l.c.*; *cf.* Gesellsch., *l.c.*), and is sparingly soluble in water. The N-*acetyl* derivative forms scales, m.p. 220° (Kehrmann and Wolff, Ber. 1900, 33, 1538); the *dibenzoyl* derivative, needles, m.p. 187·5° (Sachs, *l.c.*); and N-*phenyl* derivative, needles, m.p. 160° (Kalle, D. R.-P. 60103 of 1891; Fischer and Schütte, Ber. 1893, 26, 3087).

Reactions.—(1) When heated with 40 p.c. ammonium sulphite solution and 20 p.c. ammonia at 130°–140°, it yields 2 : 7-*diaminonaphthalene* (Bucherer, J. pr. Chem. 1904, [ii.] 69, 89).

(2) It can be diazotised (*cf.* Bayer, D. R.-P. 79166 of 1891), and it couples in acid or in alkaline solution with diazotised bases forming *azo-* dyes (*cf.* Cassella, D. R.-P. 71329 of 1891; 78875; Eng. Pat. 24715 of 1893; D. R.-P. 117298; Eng. Pat. 16149 of 1899).

The trimethylammonium chloride, obtained by heating the aminonaphthol in alkaline alcoholic solution with methyl chloride under pressure at 110° (Geigy, D. R.-P. 90310 of 1896), couples with diazotised bases forming *azo-* dyes (Geigy, *l.c.*; Höchst, D. R.-P. 97244; Eng. Pat. 27896 of 1896).

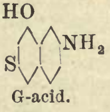
(xiv.) **2-Amino-8-naphthol** (7-*amino-α-naphthol*), obtained either by fusing *β*-naphthylamine-8-sulphonic acid with caustic alkali at 260°–270° (Bayer, D. P. Anm. F. 7335; Eng. Pat. 5148 of 1894), *or* by heating 1 : 7-dihydroxy-*β*-naphthoic acid with ammonia at 170°–180° (Friedlaender and Zinberg, Ber. 1896, 29, 40), crystallises in scales, m.p. 158° (Bayer, *l.c.*), and its N-*acetyl* derivative in needles, m.p. 210°–211° (Friedlaender and Zinberg, *l.c.*).

Reactions.—(1) With sulphuric acid at 20°–30°, it yields a mixture of the 'V' and 'Sch.' 2-*amino*-8-*naphtholmonosulphonic acids* in about equal amount (Bayer, *l.c.*).

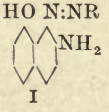
(2) It couples in acetic acid or in alkaline solution with diazotised bases forming *azo-* dyes (Bayer, D. P. Anm. F. 25069 of 1908; Friedlaender and Zinberg, *l.c.* 42).

AMINONAPHTHOLSULPHONIC ACIDS.

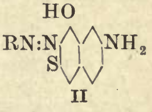
Introductory.—Aminonaphtholsulphonic acids came into use as components of azo- dyes about the year 1889 (*cf.* Cassella, D. R.-P. 55024, 55648; Eng. Pat. 16699 of 1889), when the discovery was made that certain of them have the property of forming two series of these dyes, tinctorially as well as chemically different in character. Provided the NH$_2$ and OH radicles be contained in different nuclei, and the position of the sulphonic group or groups be such[1] as to determine the entry of the diazo-complex only into *ortho-* positions relatively to these radicles, coupling in weak acid solution will lead to the production of an azo-dye of type I, and in alkaline solution to one of type II:—



G-acid.



I



II

The compounds of type I do not couple further in *acid* solution and cannot be diazotised; those of type II, on the other hand, are diazotisable. In many cases monoazo- dyes of either type will couple in *alkaline* solution, to form disazo- dyes, containing the aminonaphtholsulphonic acid as the middle component, but there are exceptions. For example, of the

---

[1] Compare pp. 570, 589, 601, 616.

two monoazo- dyes obtained from G-acid (I and II, p. 635), only that numbered I can be coupled further under any conditions. This capacity for further coupling cannot be foreseen, and the reasons which promote or inhibit it are unknown.

The importance of the aminonaphtholsulphonic acids for the production of azo- dyes, and the extent to which this group of naphthalene derivatives has been explored, can be gauged from the tables which follow (see also p. 567).

The chief methods employed for the preparation of acids of this series are—

(1) Reduction of nitroso- or azo- derivatives of naphtholsulphonic acids with tin or stannous chloride and hydrochloric acid, or with sodium hyposulphite. By these methods the 1 : 2-, 1 : 4-, and 2 : 1-aminonaphtholsulphonic acids are produced;

(2) Digestion of naphthylaminedi- or trisulphonic acids with concentrated caustic alkali solution at 180°–200°. With sulphonic acids from *α-naphthylamine*, the SO_3H group in position 8 is the most easily displaced, then that in 5, the group in 2 or 4 resisting displacement; with acids from *β-naphthylamine*, the SO_3H group in position 4, 5, or 8 is easily displaced, but that in 1 or 6 resists displacement.

If the temperature be too high, the amino-group also may be eliminated, and a dihydroxynaphthalenesulphonic acid result from the fusion.

(3) Heating diaminonaphthalenesulphonic acids with dilute mineral acids or water under pressure, or with sodium bisulphite solution at the boiling-point, the ester formed in the latter case being afterwards decomposed with alkali.

(4) Heating dihydroxynaphthalenesulphonic acids with aqueous ammonia under pressure, the replacement by NH_2 being effected more easily when the OH radicle is in a *β*- position.

(5) Sulphonation of certain aminonaphthols with sulphuric acid or anhydro-acid.

Reference to the tables will show that the constitution of most of the acids is known. This has been determined chiefly by a knowledge of the structure of the naphthylaminesulphonic acid employed in the second method, or of the naphtholsulphonic acid, the nitroso- or azo-derivative of which is reduced when the first method is used. Confirmatory evidence can be obtained in many cases by a study of the interaction of the acid with sodium amalgam, as SO_3H groups in *α*- positions are more readily eliminated than those in *β*- positions (Friedlaender and Lucht, Ber. 1893, 26, 3028); or of the hydrolytic action of 20 p.c. hydrochloric acid at the boiling point, which occurs only when the OH and SO_3H radicles occupy relatively the 1 : 4- position (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 204).

Only scanty information is given in the Patent literature about the properties of the aminonaphtholsulphonic acids and their salts. Apart from their behaviour towards nitrous acid, and towards diazotised bases (*cf.* Cassella, D. R.-P. 82676 of 1894), these compounds are usually distinguished by the fluorescence or non-fluorescence of solutions of their alkali salts and by the colourations given with ferric chloride or bleaching powder solutions (*cf.* Aktienges., D. R.-P. 68564 of 1891; Bayer, D. R.-P. 75317 of 1891). They reduce ammoniacal silver nitrate solution in the cold, and in some cases separate silver from an acid solution of the salt (*cf.* Bayer, D. R.-P. 81621 of 1893). In the tables which follow, references to fluorescence and to the colourations with bleaching powder solution are usually omitted for want of room.

Allusion has been made to the fact that many of the aminonaphtholsulphonic acids furnish two series of monoazo- dyes, according as coupling takes place in an acid or in an alkaline bath. Among acids of this type are included all that are most valuable for the production of disazo- dyes, as, for example, the G-, J-, and S-monosulphonic, and the B-, H-, and K-disulphonic acids.

The acids derived from 1-amino-8-naphthol, of which all the possible monosulphonic, and many disulphonic acids have been prepared, divide themselves into two groups: (*a*) those which furnish *ortho*-azo- dyes by coupling with diazotised bases, viz. the 4- and 5- (or S-) monosulphonic, and the 3 : 5- (or B-), 3 : 6- (or H-) and 4 : 6- (or K-) disulphonic acids, and are of much importance; (*b*) those, comprising the remainder, which form *para*-azo- dyes and have no industrial value.

Among the aminonaphtholsulphonic acids derived from *β*-naphthylamine, two, *viz.* the G- and J-acids, are largely used. They, too, give *ortho*-azo- dyes when coupled with diazotised bases, and J-acid is remarkable as it endows azo- derivatives, of which it is a component, with the property of dyeing unmordanted cotton (*v.* p. 567).

Of the other aminonaphtholsulphonic acids, mention may be made of the 2 : 1- and 1 : 2-derivatives, which are oxidised by nitrous acid, but when diazotised in the absence of free acid (*v.* p. 571), furnish valuable *ortho*-hydroxyazo-dyes.

By substitution of alkyl, acyl, or aryl radicles in the NH_2 group, a series of derivatives, chiefly from 1-amino-8-naphthol-, 2-amino-5-naphthol-, and 2-amino-8-naphthol-sulphonic acids, has been obtained. For an account of some of these, reference may be made to the following Patents:—

Alkyl (Cassella, D. R.-P. 73128 of 1892; Eng. Pat. 5407 of 1893; Geigy, D. R.-P. 91506 of 1895; Eng. Pat. 2771 of 1896);

Acetyl (Höchst, D. R.-P. 129000 of 1899; Eng. Pat. 17366 of 1898; Bayer, D. R.-P. 206455 of 1907).

Aryl monosulphonic acids (Cassella, D. R.-P. 79014; Eng. Pat. 11157 of 1894; D. R.-P. 80417 of 1894; Leonhardt, D. R.-P. 114248 of 1896; Badische, D. R.-P. 122570; Eng. Pat. 18726 of 1900); disulphonic acids (Bayer, D. R.-P. 181929, 179829 of 1905; Eng. Pat. 5749 of 1906);

Nitroacyl, *nitroaryl*, etc. (Gesellsch., D. R.-P. 101286 of 1897; 170045 of 1902).

These substituted acids, or their nitroso-derivatives, by coupling with diazotised bases, furnish monoazo- dyes which differ in shade and degree of fastness from those obtained with the respective aminonaphtholsulphonic acids, and belong exclusively to the type numbered II on the preceding page.

Aminonaphtholmonosulphonic Acids.

Constitution.	Preparation.	Acids, Salts and Reactions.
N:O:S		
1:2:4	(1) Reduction of nitroso-β-naphthol with sulphurous acid (Böniger, Ber. 1894, 27, 23). (2) Action of sodium bisulphite on [β]-naphthaquinone-α-chlorimide (Friedlaender and Reinhardt, Ber. 1894, 27, 241).	*Acid*, $HA+\frac{1}{2}H_2O$, very sparingly soluble needles; *sodium* salt, NaA, needles. Diazotised, in absence of mineral acids, giving *diazo-oxide* (*cf.* Geigy, D. R.-P. 171024; Eng. Pat. 10235 of 1904; *v.* p. 571).
1:2:5	Reduction of azo-derivatives of β-naphthol-5-sulphonic acid (Witt, Ber. 1888, 21, 3478).	*Acid*, very sparingly soluble. Gives brown colouration with ferric chloride.
1:2:6	(1) Reduction of nitroso-β-naphthol-6-sulphonic acid (Meldola, Chem. Soc. Trans. 1881, 39, 47). (2) Reduction of azo-derivatives of β-naphthol-6-sulphonic acid (Witt, Ber. 1888, 21, 3475).	*Acid*, HA, sparingly soluble needles; *sodium* salt (*Eikonogen*), $NaA+2\frac{1}{2}H_2O$. Solutions, especially if alkaline, are very sensitive to air. Gives brown colouration with ferric chloride. For *diazo-oxide*, *cf.* Geigy, *l.c.*; *v.* p. 571. Couples with diazotised bases (*cf.* Aktienges., D. R.-P. 79103; Eng. Pat. 13833 of 1893).
1:2:7	Reduction of azo-derivatives of β-naphthol-7-sulphonic acid (Witt, Ber. 1888, 21, 3477).	*Acid*, very sparingly soluble needles. Gives brown colouration with ferric chloride. For *diazo-oxide*, *cf.* Geigy, *l.c.*; *v.* p. 571. Couples with diazotised bases (*cf.* Aktienges., *l.c.*).
1:2:8	Reduction of azo-derivatives of β-naphthol-8-sulphonic acid (Witt, Ber. 1888, 21, 3474).	*Acid*, very sparingly soluble leaflets. Gives brown colouration with ferric chloride. For *diazo-oxide*, *cf.* Geigy, *l.c.*; *v.* p. 571.
1:3:4 [4:2:1]	1-Amino-3-naphthol sulphonated with monohydrate (Friedlaender and Rüdt, Ber. 1896, 29, 1609).	*Acid*, very sparingly soluble needles. Hydrolysed by water at 120° to 1:3-*dihydroxynaphthalene*.
1:3:6 [4:2:7]	Mixed with 1:6:3-acid, by boiling α-naphthylamine-3:6-disulphonic acid with 75 p.c. caustic potash solution (Cassella, D. R.-P. 82676 of 1894).	*Acid*, very sparingly soluble; *sodium salt* salted out to separate from 1:6:3-acid. Forms a readily soluble *diazo*-compound.
1:3:7 [4:2:6]	Mixed with 1:7:3-acid, by heating α-naphthylamine-3:7-disulphonic acid with 40 p.c. caustic soda solution under pressure at 200° (Cassella, D. R.-P. 57007, 58352 of 1890).	*Acid*, readily soluble.
1:4:2 [4:1:3]	Reduction of nitroso- or azo-derivatives of α-naphthol-3-sulphonic acid (Reverdin and de la Harpe, Ber. 1893, 26, 1281).	No description published.
1:4:3 [4:1:2]	(1) 1-Amino-4-naphthol sulphonated with 10 p.c. anhydro- acid at 30°-40° (Seidel, Ber. 1892, 25, 424; *cf.* Friedlaender and Reinhardt, Ber. 1894, 27, 239). (2) Reduction of nitroso- (Conrad and Fischer, Annalen, 1893, 273, 114), or of azo-derivatives (Reverdin and de la Harpe, Ber. 1892, 25, 1403), of α-naphthol-2-sulphonic acid.	*Acid*, very sparingly soluble needles, which give a grass-green solution in caustic soda. Oxidised by nitric acid to [α-]*naphthaquinone*-3-*sulphonic acid*.
1:4:5 [4:1:8]	(1) Reduction of azo-derivatives of α-naphthol-8-sulphonic acid (Reverdin and de la Harpe, Ber. 1892, 25, 1404). (2) Electrolytic reduction of α-nitronaphthalene-5-sulphonic acid in sulphuric acid solution (Gattermann, Ber. 1893, 26, 1852; Bayer, D. R.-P. 81621 of 1893).	*Acid*, leaflets soluble in water but insoluble in cold alcohol, solution in ammonia yellow; *lead* and *barium* salts, sparingly soluble in water (Bayer, *l.c.*).
1:4:6 [4:1:7]	Electrolytic reduction of α-nitronaphthalene-6-sulphonic acid in sulphuric acid solution (Bayer, D. R.-P. 81621 of 1893).	*Acid*, needles soluble in water or cold alcohol, solution in ammonia yellow; *lead* and *barium* salts soluble in water (Bayer, *l.c.*).
1:4:7 [4:1:6]	Electrolytic reduction of α-nitronaphthalene-7-sulphonic acid in sulphuric acid solution (Bayer, D. R.-P. 81621 of 1893).	*Acid*, needles soluble in water or cold alcohol, solution in ammonia yellow; *lead* and *barium* salts soluble in water (Bayer, *l.c.*).
1:5:2 [5:1:6]	(1) α-Naphthylamine-2:5-disulphonic acid heated with 50 p.c. caustic soda solution at 250° (Landshoff, Eng. Pat. 6195 of 1890; D. P. Anm. C. 4479 of 1892). (2) 1:5-Diaminonaphthalene-2-sulphonic acid boiled with sodium bisulphite solution and product decomposed by alkali (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 213).	*Acid*, sparingly soluble needles. Gives green colouration with ferric chloride (*cf.* Bayer, D. R.-P. 75317 of 1891). Forms sparingly soluble *diazo*-compound. Couples with diazotised bases (*cf.* Cassella, D. R.-P. 82676 of 1894).

Constitution.	Preparation.	Acids, Salts and Reactions.
N : O : S		
1 : 5 : 4 [5 : 1 : 8]	(1) 1-Acetylamino-5-aminonaphthalene-4-sulphonic acid boiled with sodium bisulphite solution and product decomposed by alkali (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 229). (2) 1 : 5-Dihydroxynaphthalene-4-sulphonic acid heated with sodium bisulphite solution and ammonia (*ibid.* 223).	*Acid*, HA, crystallises in needles. Couples with diazotised bases forming *azo*-dyes.
1 : 5 : 6 [5 : 1 : 2]	1-Amino-5-naphthol sulphonated with sulphuric acid below 100° (Aktiengcs., D. R.-P. 68564 of 1891).	*Acid*, very sparingly soluble needles. Gives blue colouration with ferric chloride. Forms greenish-yellow solution with nitrous acid. Couples with diazotised bases.
1 : 5 : 7 [5 : 1 : 3] **M-acid.**	(1) α-Naphthylamine-5 : 7-disulphonic acid heated with 75 p.c. caustic soda solution at 170° (Badische, D. R.-P. 73276, Eng. Pat. 2370 of 1893). (2) 1 : 5-Diaminonaphthalene-7-sulphonic acid heated with water under pressure at 160° (Cassella, D.R.-P. 85058 of 1894). (3) 1 : 5-Dihydroxynaphthalene-7-sulphonic acid heated with ammonium sulphite and ammonia (Badische, D. R.-P. 117471 of 1899 ; Eng. Pat. 1387 of 1900) (4) 1-Amino-5-naphthol-2 : 7-disulphonic acid heated with 10 p.c. sulphuric acid under pressure at 135° (Cassella, D. R.-P. 188505 of 1905).	*Acid* and *sodium* salt, sparingly soluble leaflets. Gives black colouration with ferric chloride. Forms a deep orange-yellow sparingly soluble *diazo*-compound (*cf.* Cassella, D. R.-P. 82676 of 1894). Couples in alkaline solution with diazotised bases forming *azo*-dyes (*cf.* Badische, D. R.-P. 75327, 82572 ; Eng. Pat. 2370 of 1893).
1 : 5 : 8 [5 : 1 : 4]	1 : 5-Diaminonaphthalene-4-sulphonic acid boiled with sodium bisulphite solution and product decomposed by alkali (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 226).	*Acid*, $HA + 3\frac{1}{2}H_2O$. Couples with diazotised bases forming *azo*-dyes.
1 : 6 : 3 [5 : 2 : 7]	(1) Mixed with 1 : 3 : 6-acid, by boiling α-naphthylamine-3 : 6-disulphonic acid with 75 p.c. caustic potash solution (Cassella, D. R.-P. 82676 of 1894). (2) 1-Amino-6-naphthol-3 : 5-disulphonic acid boiled with dilute acids (Cassella, D. P. Anm. C. 5163 of 1894).	*Acid*, sparingly soluble ; *sodium* salt readily soluble. Forms a yellow sparingly soluble *diazo*-compound. Couples with diazotised bases (Cassella, D. R.-P. 82676 of 1894).
1 : 6 : 4 [5 : 2 : 8]	α-Naphthylamine-4:6-disulphonic acid fused with caustic soda at 180°–200° (Dahl, D. R.-P. 68232 of 1891 ; Friedlaender and Kielbasinski, Ber. 1896, 29, 1979).	*Acid*, sp. sol. needles ; *sodium* salt, NaA, needles, *barium* salt, prisms, readily soluble. Gives brownish colouration with ferric chloride. Forms sp. sol. *diazo*-compound. Couples with diazotised bases (*cf.* Cassella, D. R.-P. 82676 of 1894).
1 : 7 : 3 [8 : 2 : 6] **B-acid.**	Mixed with 1 : 3 : 7-acid by heating α-naphthylamine-3 : 7-disulphonic acid with 40 p.c. caustic soda under pressure at 200° (Cassella, D. R.-P. 57007, 58352 of 1890).	*Acid*, very sparingly soluble needles ; *sodium* salt readily soluble leaflets. Forms a very sparingly soluble *diazo*-compound. Couples with diazotised bases, giving two series of *monoazo*-dyes (Cassella, *l.c.*).
1 : 7 : (4) [8 : 2 : (5)]	1-Amino-7-naphthol sulphonated with sulphuric acid below 30° (Cassella, D. R.-P. 75066 of 1891).	*Acid*, sp. sol. ; *alkali* salts readily soluble. Forms a sp. sol. *diazo*-compound. Couples in alkaline solution with diazotised bases (Cassella, *l.c.* ; Bayer, D. R.-P. 198138 of 1907).
1 : 8 : 2 [8 : 1 : 7]	(1) α-Naphthylamine-2 : 8-disulphonic acid fused with caustic soda at 170°–220° (Cassella, D. R.-P. 75710 of 1893). (2) 1-Amino-8-naphthol-2 : 4-disulphonic acid boiled with 50 p.c. sulphuric acid (*ibid.*).	*Acid*, sparingly soluble radiate prisms. Forms a dark brown sparingly soluble *diazo*-compound. Couples with diazotised bases (*cf.* Cassella, D. R.-P. 82676 of 1894).
1 : 8 : 3 [8 : 1 : 6]	(1) α-Naphthylamine-3 : 8-disulphonic acid fused with caustic alkali below 210° (Bayer, D.P.Anm.F.4723 ; Eng.Pat.13443 of 1890). (2) 1-Amino-8-naphthol-3 : 5-disulphonic acid boiled with dilute sulphuric acid at 140° (Leonhardt, D. P. Anm. F. 8626 ; Eng. Pat. 19253 of 1895).	*Acid*, sparingly soluble prisms or needles ; *sodium* salt readily soluble. Forms an orange-yellow sparingly soluble *diazo*-compound. Couples with diazotised bases (*cf.* Cassella, D. R.-P. 82676 of 1894).
1 : 8 : 4 [8 : 1 : 5] **S-acid.**	(1) α-Naphthylamine-4 : 8-disulphonic acid fused with caustic alkali at 210° (Badische, D. R.-P. 63074 ; Eng. Pat. 20275 of 1891 ; Bayer, D. R.-P. 75317 of 1891). (2) 1 : 8-Diaminonaphthalene-4-sulphonic acid, heated with 40 p.c. sodium bisulphite solution at 95° in presence of acetone, and product decomposed by alkali (Badische, D. R.-P. 120016 ; Eng. Pat. 16921 of 1900 ; Bucherer, J. pr. Chem. 1904, [ii.] 70, 349).	*Acid*, sparingly soluble needles ; *alkali* salts readily soluble, showing bluish-green fluorescence in solution (Bayer, *l.c.*). Gives emerald-green colouration with ferric chloride (*ibid.*). Forms an orange sp. sol. *diazo*-compound (*cf.* Cassella, D. R.-P. 82676 of 1894). Couples in acid or in alkaline solution with diazotised bases, being used as middle component for *disazo*-dyes (*cf.* Badische, D. R.-P. 91855 of 1891 ; Eng. Pat. 9894 of 1893 ; D. R.-P. 114976 of 1899). For *acetyl*, *aryl*, and *nitroaryl* derivatives, see p. 636.

Constitution.	Preparation.	Acids, Salts and Reactions.
N:O:S		
1:8:5 [8:1:4]	(1) 1:8-Diaminonaphthalene-5-sulphonic acid boiled with 20 p.c. sulphuric acid (Cassella, D.R.-P. 73607 of 1892; Eng. Pat. 4613 of 1893); or heated with 40 p.c. sodium bisulphite solution, and product decomposed with alkali (Bayer, D. R.-P. 109102, Eng. Pat. 16807 of 1899). (2) α-Naphthylamine-5:8-disulphonic acid heated with 75 p.c. caustic potash solution at 150° (Bayer, D. R.-P. 75055, Eng. Pat. 15269 of 1893). (3) 8-Chloro-α-naphthylamine-5-sulphonic acid heated with 50 p.c. caustic soda solution under pressure at 190° (Badische, D. R.-P. 112778 of 1899). (4) Mixed with 1:8:7 acid, when 1-amino-8-naphthol is sulphonated with sulphuric acid at 15°–20° (Badische, D. R.-P. 62289 of 1889; Eng. Pat. 9676 of 1890; D. R.-P. 77937, 84951 of 1894).	*Acid*, very sparingly soluble needles; *sodium* and *potassium* salts readily soluble, showing violet fluorescence in solution (Cassella, *l.c.*). The *calcium* salt is easily soluble (Badische, D. R.-P. 77937 of 1894). Gives dirty green colouration with ferric chloride (Bayer, D. R.-P. 75055 of 1893). Forms a readily soluble yellow *diazo*-compound (Cassella, *l.c.*). Couples in acid or in alkaline solution with diazotised bases, being used as a middle component for *disazo*-dyes (*cf.* Badische, D. R.-P. 81241 of 1891; 114906 of 1896). For *benzoyl* derivative and *azo*-dyes therefrom, *cf.* Badische, D. R.-P. 54662; Eng. Pat. 9676 of 1890.
1:8:6 [8:1:3] H-acid.	(1) 1:8-Diaminonaphthalene-3-sulphonic acid heated with 15 p.c. sulphuric acid at 120° (Cassella, D. R.-P. 70780; E. P. 6972 of 1891; *cf.* Cassella, D. R.-P. 73607 of 1892). (2) α-Naphthylamine-6:8-disulphonic acid heated with 50 p.c. caustic potash solution under pressure at 200° (Bayer, D. R.-P. 80853; Eng. Pat. 15269 of 1893).	*Acid*, sp. sol. needles; *sodium* and *potassium* salts readily soluble; *barium* salt, needles (Bayer, *l.c.*). Gives green colouration with ferric chloride (Bayer, *l.c.*). Forms a yellow sparingly soluble *diazo*-compound (Bayer, *l.c.*). Couples in alkaline solution with diazotised bases (*cf.* Bayer, D. R.-P. 82074, 85389; Eng. Pat. 15269 of 1893).
1:8:7 [8:1:2]	1-Amino-8-naphthol sulphonated with 75 p.c. sulphuric acid at 130°–160° (Badische, D. R.-P. 82900 of 1894), *or* (mixed with 1:8:5 acid) with sulphuric acid at 15°–20° (*ibid.* D. R.-P. 62289 of 1889; 84951 of 1894.	*Acid*, sparingly soluble; *acid calcium* salt almost insoluble. Forms a readily soluble *diazo*-compound. Couples with diazotised bases.
2:1:3	Reduction of azo-derivatives of α-naphthol-3-sulphonic acid (Gattermann and Schulze, Ber. 1897, 30, 54).	*Acid*, HA, broad needles.
2:1:4[1]	(1) Reduction of azo- (König, Ber. 1890, 23, 808) *or* nitroso-derivatives of α-naphthol-4-sulphonic acid (Witt and Kaufmann, Ber. 1891, 24, 3162). (2) 2-Nitroso-α-naphthol boiled with 35 p.c. sodium bisulphite solution (Schmidt, J. pr. Chem. 1891, [ii.] 44, 531; *cf.* Böniger, Ber. 1894, 27, 29).	*Acid*, HA (Friedlaender and Reinhardt, Ber. 1894, 27, 242), sparingly soluble needles. Forms a violet-black dyestuff by oxidation (Reverdin and de la Harpe, D. R.-P. 63043; Eng. Pat. 16377 of 1891). Not diazotisable in acid solution (*cf.* Cassella, D. R.-P. 82676 of 1894), but if not acid, gives *diazo-oxide* (*cf.* Geigy, D. R.-P. 171024; *v.* p. 571).
2:1:5[1]	Reduction of azo-derivatives of α-naphthol-5-sulphonic acid (Gattermann and Schulze, Ber. 1897, 30, 51; *cf.* Reverdin and de la Harpe, Ber. 1893, 26, 1280).	*Acid*, HA, sparingly soluble scales or needles. Diazotised in absence of free mineral acid giving *diazo-oxide* (*cf.* Geigy, D. R.-P. 171024; Eng. Pat. 10235 of 1904; *v.* p. 571).
2:1:7	Reduction of 2-nitro-α-naphthol-7-sulphonic acid (Finger, J. pr. Chem. 1909, [ii.] 79, 444).	*Acid*, $HA + 2H_2O$, needles; alkaline solution becomes dark green on exposure to the air.
2:3:6 [3:2:7] R-acid.	β-Naphthylamine-3:6-disulphonic acid heated with 75 p.c. caustic soda at 230°–250° (Höchst, D. R.-P. 53076; Eng. Pat. 15176 of 1889; Friedlaender and Zakrzewski, Ber. 1894, 27, 763).	*Acid*, very sp. sol. needles; *sodium* salt, leaflets; *barium* salt BaA_2, sparingly soluble. Gives dark blue col. with ferric chloride (Höchst, *l.c.*). Forms an orange *diazo*-compound (*cf.* Höchst, *l.c.*; Cassella, D. R.-P. 109932; Eng. Pat. 28107 of 1897). Couples in alkaline solution with diazotised bases (*cf.* Aktienges., D. R.-P. 84145 of 1894).
2:4:6 [3:1:7]	α-Naphthol-3:7-disulphonic acid heated with ammonia under pressure at 180° (Kalle, D. R.-P. 94079 of 1896).	*Acid*, sp. sol. leaflets; *alkali* salts readily soluble. Forms a yellow *diazo*-compound. Couples with diazotised bases.
2:4:7 [3:1:6]	(1) β-Naphthylamine-4:7-disulphonic acid fused with caustic alkali at 215° (Bayer, D.P.Anm.F.7978; Eng.Pat.25214 of 1894). (2) α-Naphthol-3:6-disulphonic acid heated with ammonia under pressure at 180° (Kalle, D. R.-P. 94079 of 1896).	*Acid*, moderately soluble leaflets; *alkali* salts readily soluble. Forms a yellow *diazo*-compound. Couples in alkaline solution with diazotised bases (*cf.* Bayer, *l.c.*).
2:4:8 [3:1:5]	β-Naphthylamine-4:8-disulphonic acid fused with caustic alkali at 215° (Bayer, D. R.-P. 85241; D. P. Anm. F. 8070; Eng. Pat. 3580 of 1895).	*Acid*, sp. sol. needles; *alkali* salts easily soluble. Gives no colouration with ferric chloride. Forms a yellow sp. sol. *diazo*-compound. Couples in alkaline solution with diazotised bases.
2:5:(6) [6:1:(2)] and 2:5:(8) [3:1:(4)]	2-Amino-5-naphthol sulphonated with sulphuric acid at 20°–30° (Bayer, D. P. Anm. F. 7372; Eng. Pat. 5267 of 1894) forms two acids, about which little is known, the yield of the less soluble being 30 p.c.	One of the acids gives a dirty precipitate, the other a bluish-grey precipitate with ferric chloride. Each acid forms a yellow *diazo*-compound and couples with diazotised bases.

[1] An acid containing the sulphonic group in either the 4- or the 5- position is produced when 2-amino-1-naphthol is sulphonated with 10 p.c. anhydro-acid at 40°. It is sparingly soluble and gives a brown colouration with ferric chloride (Reverdin and de la Harpe, Ber. 1893, 26, 1280; Kern and Sandoz, D. R.-P. 69228 of 1891).

Constitution.	Preparation.	Acids, Salts and Reactions.
N:O:S		
2:5:1 [6:1:5]	β-Naphthylamine-1:5-disulphonic acid fused with caustic alkali (Kalle, D. R.-P. 242052 of 1909).	Forms a *diazo*-compound. Couples in alkaline solution with diazotised bases, but in acid solution loses SO_3H in coupling.
2:5:7 [6:1:3] **J-acid.**	(1) β-Naphthylamine-5 : 7-disulphonic acid fused with caustic alkali at 180°, or under pressure with 50 p.c. caustic soda solution at 190° (Badische, D. P. Anm. B. 14154; D. R.-P. 75469; Eng. Pat. 2614 of 1893. (2) 1 : 6-Dihydroxynaphthalene-3-sulphonic acid heated with ammonium sulphite solution and ammonia at 150° (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).	*Acid*, sparingly soluble; *alkali* salts readily sol. Gives no colouration with cold, but brownish-black precipitate with hot ferric chloride (*cf.* Badische, D. R.-P. 73276) of 1893. Forms a yellow *diazo*-compound giving violet product with sodium carbonate solution. Couples in acid or in alkaline solution with diazotised bases, forming two series of *monoazo*-dyes (*cf.* Gesellsch., D. R.-P. 126802 of 1901). Extensively used as a source of direct cotton dyes. For *alkyl*, *aryl*, and other derivatives, *v.* p. 568.
2:5:8 [6:1:4]	1:6-Dihydroxynaphthalene-4-sulphonic acid heated with 28 p.c. ammonia under pressure at 140°–180° (Dahl, D. R.-P., 70285 of 1891; Eng. Pat. 4110 of 1892).	*Acid*, sparingly soluble; *alkali* salts readily soluble. Gives brown colouration with ferric chloride. Forms a yellow sp. sol. *diazo*-compound. Couples in acid or in alkaline solution with diazotised bases (Dahl, *l.c.*; D. R.-P. 67258 of 1891).
2:6:4 [6:2:8]	Reduction of 6-nitro-β-naphthol-8-sulphonic acid (Jacchia, Annalen, 1902, 323, 124).	*Acid*, $HA + H_2O$, sparingly soluble needles. Forms a yellow sp. sol. *diazo*-compound.
2:7:(3) [7:2:(6)] **F-acid.**	2 : 7-Dihydroxynaphthalenesulphonic acid heated with 30 p.c. ammonia under pressure at 120°–150° (Aktienges., D. R.-P. 63956 of 1891).	*Acid*, very sp. sol.; *alkali* salts easily soluble. Gives greenish-black col. with ferric chloride. Forms a yellow sp. sol. *diazo*-compound. Couples in acid or in alkaline solution with diazotised bases.
2:7:? [7:2:?]	Partial hydrolysis of the disulphonic acid formed from 2-amino-7-naphthol by sulphonation with sulphuric acid at 30° (Cassella, D. R.-P. 131526 of 1901).	*Acid*, needles; *sodium* salt, $NaA + H_2O$, sp. soluble. Gives violet precipitate with ferric chloride. Forms a yellow sp. sol. *diazo*-compound. Couples in acid or in alkaline solution with diazotised bases, giving two series of *azo*-dyes.
2:8:(5) [7:1:(4)] 2:8:(7) [7:1:(2)]	2-Amino-8-naphthol sulphonated with sulphuric acid at 30° forms two acids in about equal proportion (Bayer, D. P. Anm. F. 7335; Eng. Pat. 5148 of 1894).	"*Sch.*" *acid*, readily, "*V*" *acid*, sp. sol.; separated by adding acid to soln. of mixed calcium salts. Each acid forms a yellow soluble *diazo*-compound and couples with diazotised bases.
2:8:6 [7:1:3] **G-acid.**	(1) β-Naphthylamine-6 : 8-disulphonic acid heated with 75 p.c. caustic soda solution at 230°–250° (Höchst, D. R.-P. 53076; Eng. Pat. 15176 of 1889; *cf.* Cassella, D. P. Anm. C. 3063; Eng. Pat. 16699 of 1889). (2) 2 : 8-Dihydroxynaphthalene-6-sulphonic acid heated with 30 p.c. ammonia under pressure at 120°–150° (Aktienges., D. R.-P. 62964 of 1890). (3) 2 : 8-Dihydroxynaphthalene-6-sulphonic acid heated with ammonium sulphite solution and ammonia at 150° (Bucherer, J. pr. Chem. 1904, [ii.] 69, 89).	*Acid*, very sparingly soluble needles; *alkali* and *alkaline earth* salts, readily soluble; *lead* salt sparingly soluble needles (Täuber and Walder, Ber. 1896, 29, 2268). Gives dirty claret colouration with ferric chloride. Forms a yellow sparingly soluble *diazo*-compound which gives a blue dye with sodium carbonate solution (Täuber and Walder, *l.c.*). Couples in acid or in alkaline solution forming two series of *monoazo*-dyes (*cf.* Cassella, D. R.-P. 55024, 55648; Eng. Pat. 16669 of 1889; *v.* p. 635). Is largely used for production of *polyazo*-dyes. For *alkyl*, *acetyl*, *aryl*, etc., derivatives, see p. 636.

Aminonaphtholdisulphonic Acids.

Constitution.	Preparation.	Acids, Salts and Reactions.
N:O:S:S		
1:2:3:6	Reduction of azo-derivatives of β-naphthol-3 : 6-disulphonic acid (Witt, D. R.-P. 49857 of 1889; Ber. 1888, 21, 3479).	*Acid sodium* salt, NaHA, readily soluble needles. Gives dark brown colouration with ferric chloride. In absence of mineral acid gives *diazo-oxide* (*cf.* Geigy, D. R.-P. 171024 of 1904; *v.* p. 571). Does not couple with diazotised bases.
1:2:3:7	Reduction of nitroso-β-naphthol-3 : 7-disulphonic acid (Geigy, D. R.-P. 171024; Eng. Pat. 10235 of 1904).	*Acid*, sp. sol.; *alkaline* solutions greenish yellow. Diazotised in absence of mineral acid giving *diazo-oxide* (*cf.* Geigy, *l.c.*; *v.* p. 571).
1:2:4:6	Interaction of nitroso-β-naphthol-6-sulphonic acid and sulphurous acid (Böniger, Ber. 1894, 27, 3052).	*Acid sodium* salt, NaHA, readily soluble needles. Diazotised in absence of mineral acid giving *diazo-oxide* (*cf.* Geigy, *l.c.*; *v.* p. 571).
1:2:4:?	Sulphonation of 1-amino-2-naphthol-4-sulphonic acid with monohydrate below 100° (Griesheim, D. P. Anm. C. 15414 of 1907; Eng. Pat. 3655 of 1908; D. P. Anm. C. 15820 of 1907).	*Acid sodium* salt, NaHA, very soluble, shows in solution bluish-green fluorescence like the acid sodium salt of the 4 : 6-disulphonic acid, with which it may be identical.
1:2:4:7	Interaction of nitroso-β-naphthol-7-sulphonic acid and sulphurous acid (Böniger, Ber. 1894, 27, 3052).	*Acid sodium* salt, NaHA, sp. sol. needles. Diazotised in absence of mineral acid giving *diazo-oxide* (*cf.* Geigy. *l.c.*; *v.* p. 571).

Constitution.	Preparation.	Acids, Salts and Reactions.
N:O:S:S		
1:2:6:8	Reduction of azo-derivatives of β-naphthol-6:8-disulphonic acid (Witt, D. R.-P. 49857 of 1889; Ber. 1888, 21, 3981).	*Acid sodium* salt, NaHA, easily soluble prisms. Gives dark brown colouration with ferric chloride. For *diazo-oxide, cf.* Geigy, *l.c.*; *v.* p. 571.
1:4:3:6 [4:1:2:7]	(1) Reduction of azo-derivatives of α-naphthol-2:7-disulphonic acid (Reverdin and de la Harpe, Ber. 1892, 25, 1405. (2) Electrolytic reduction of α-nitronaphthalene-3:6-disulphonic acid (Bayer, D. R.-P. 81621 of 1893).	*Acid* sp. soluble needles; *sodium* salt readily soluble. Gives a dark red colouration with ferric chloride (Bayer, *l.c.*). Is not diazotisable (*cf.* Reverdin and de la Harpe, Ber. 1893, 26, 1284).
1:4:3:7 [4:1:2:6]	Electrolytic reduction of α-nitronaphthalene-3:7-disulphonic acid (Bayer, D. R.-P. 81621 of 1893).	*Barium* salt sparingly soluble. Gives a rose-red colouration with ferric chloride.
1:4:3:8 [4:1:2:5]	Reduction of 4-nitroso-α-naphthol-3:8-disulphonic acid (Friedlaender, Ber. 1895, 28, 1536).	*Acid*, readily soluble needles. Is not diazotisable, and does not couple with diazotised bases.
1:5:2:7 [5:1:3:6]	α-Naphthylamine-2:5:7-trisulphonic acid heated with 50 p.c. caustic potash at 180°–200° (Bayer, D. P. Anm. F. 7001; Eng. Pat. 17141B of 1893; Cassella, D. R.-P. 188505 of 1905).	*Acid sodium* salt, moderately soluble needles. Gives wine-red colouration with ferric chloride. Forms an orange-red soluble *diazo*-compound, which with sodium carbonate solution becomes sky-blue and then orange.
1:5:3:7 [5:1:3:7]	Fusion of α-naphthylamine-3:5:7-trisulphonic acid with caustic soda at 160°–170° (Cassella, D. R.-P. 75432 of 1891).	*Acid* and *acid sodium* salt readily soluble (Cassella, D. R.-P. 84952 of 1894). Gives dark-green col. with ferric chloride (*ibid.*). Forms an orange *diazo*-compound. Couples in alkaline solution with diazotised bases (*cf.* Cassella, *l.c.*; D. R.-P. 83011 of 1892).
1:5:(4):(6) 5:1:(2):(8)	1-Amino-5-naphthol sulphonated with 23 p.c. anhydro-acid at 100° (Aktienges., D.P. Anm. A. 3767 of 1894).	*Acid* and *sodium* salt readily soluble. Forms a yellow *diazo*-compound. Couples with diazotised bases.
1:6:3:5 [5:2:1:7]	1-Amino-6-naphthol-3-sulphonic acid sulphonated with 12 p.c. anhydro-acid below 20° (Cassella, D. P. Anm. C. 5163 of 1894; *cf.* Cassella, D. R.-P. 84952 of 1894).	*Acid sodium* salt readily, *calcium* salt sparingly sol. Gives violet-black col. with ferric chloride. Forms a yellow soluble *diazo*-compound. Couples in acid or alkaline solution with diazotised bases, but gives only one series of *monoazo*-dyes.
1:6:3:7 [5:2:3:7]	1-Amino-6-naphthol-3-sulphonic acid heated with sulphuric acid at 140°–150°, *or* the 3:5-disulphonic acid heated with sulphuric acid at 150° (Cassella, D. R.-P. 84952 of 1894).	*Acid sodium* salt, sparingly soluble needles. Gives greenish-black col. with ferric chloride. Forms a soluble *diazo*-compound. Couples in alkaline solution with diazotised bases (*cf.* Cassella, *l.c.*; D. R.-P. 95988 of 1894).
1:7:(4):? [8:2:(5):?]	1-Amino-7-naphthol sulphonated with sulphuric acid above 100° (Cassella, D. R.-P. 69458; *cf. ibid.*, D. R.-P. 75066 of 1891).	*Acid* readily soluble.
1:8:2:4 [8:1:5:7] **S-acid**	(1) Fusion of α-naphthylamine-2:4:8-trisulphonic acid with caustic alkali (Cassella, D. R.-P. 75710 of 1893; Aktienges., D.P.Anm.A.3346; Eng.Pat.2984 of 1893). (2) Fusion of naphthasultam-2:4-disulphonic acid S with 90 p.c. caustic soda at 170° (Bayer, D. R.-P. 79566, 80668; Eng. Pat. 4979 of 1893; Dressel and Kothe, Ber. 1894, 27, 2141).	*Acid* readily sol.; *acid sodium* salt, NaHA + H_2O, easily sol. needles; *calcium* salt moderately sol. Gives greenish-black col. with ferric chloride. Forms a reddish-yellow soluble *diazo*-compound. Couples in acetic acid or in alkaline solution with diazotised bases giving only one series of *monoazo*-dyes; but in HCl solution, *disazo*-dyes of the 4-monosulphonic acid may be formed (*cf.* Bayer D. R.-P. 77703; Eng. Pat. 4979 of 1893).
1:8:(2):(5) 8:1:(4):(7) **L-acid**	1:8-Diaminonaphthalene-(2):5-disulphonic acid boiled with 20 p.c. sulphuric acid (Cassella, D. R.-P. 73048 of 1893).	*Acid* moderately, *acid sodium* salt readily soluble. Gives brown colouration with ferric chloride. Forms yellow *diazo*-compound. Couples with diazotised bases (*cf.* Cassella, D. R.-P. 84952 of 1894).
1:8:2:? [8:1:?:7]	1:8-Diaminonaphthalenetrisulphonic acid boiled with water or 10 p.c. sulphuric acid (Fischesser & Co., D. P. Anm. F. 7595; Eng. Pat. 13203 of 1894).	*Acid sodium* salt, NaHA, moderately soluble. Gives green colouration with ferric chloride. Forms a yellow soluble *diazo*-compound. Couples in acid solution with diazotised bases.
1:8:3:5 [8:1:4:6] **B-acid**	1-Amino-8-naphthol-3-sulphonic acid sulphonated with monohydrate at the ordinary temperature (Leonhardt, D. P. Anm. F. 8626; Eng. Pat. 19253 of 1895; Cassella, D. R.-P. 108848 of 1895).	*Acid* and *acid sodium* salt sparingly soluble. Forms a yellow sparingly soluble *diazo*-compound. Couples in acid or alkaline solution with diazotised bases, forming two series of *monoazo*-dyes (*cf.* Cassella, *l.c.*). For *aryl* derivatives, see p. 636.
1:8:3:6 [8:1:3:6] **H-acid**	(1) 1:8-Diaminonaphthalene-3:6-disulphonic acid heated with 10 p.c. sulphuric acid at 100°–120°, or with 40 p.c. caustic soda at 200° (Cassella, D. R.-P. 67062 of 1890; Eng. Pat. 1742 of 1891), *or* its azimido- derivative heated with 80 p.c. sulphuric acid at 170° (*ibid.* D. R.-P. 69963 of 1891).	*Acid* sparingly soluble in cold water; *acid sodium* salt, NaHA + $1\frac{1}{2}H_2O$, and *acid barium* salt, $BaH_2A_2 + 4\frac{1}{2}H_2O$, sparingly soluble needles (Dressel and Kothe, Ber. 1894, 27, 2150). Gives brownish-red colouration with ferric chloride. Forms a yellow soluble *diazo*-compound. Couples in acid or alkaline solution with diazotised bases, forming two series of *monoazo*-dyes

Constitution.	Preparation.	Acids, Salts and Reactions.
N:O:S:S 1:8:3:6 (*contd.*)	(2) Naphthasultam-3 : 6-disulphonic acid fused with 90 p.c. caustic soda at 170° (Bayer, D. R.-P. 80668 ; Eng. Pat. 4979 of 1893 ; Dressel and Kothe, Ber. 1894, 27, 2150), *or* α-naphthylamine-3 : 6 : 8-trisulphonic acid with caustic soda at 180°–190° (Bayer, D. R.-P. 69722 ; Eng. Pat. 13443 of 1890), *or* 8-chloro-α-naphthylamine-3 : 6-disulphonic acid with caustic alkali (Badische, D. R.-P. 147852 of 1903). (3) 1 : 8-Dinitronaphthalene-3:6-disulphonic acid heated with sodium bisulphite solution at 90°–100° (Bayer, D. R.-P. 113944 ; Eng. Pat. 21138 of 1899).	(*cf.* Bayer, D. R.-P. 62368 ; Eng. Pat. 13443 of 1890 ; Cassella, D. R.-P. 65651 ; Eng. Pat. 1742, 6972 of 1891). Largely used in the production of *azo*-dyes. For *alkyl, acetyl, aryl, nitrobenzoyl* derivatives, see p. 636.
1:8:3:? [8:1:6:?]	Fusion of naphthasultamdisulphonic acid ε with caustic alkali (Bayer, D. R.-P. 79566 ; Eng. Pat. 4979 of 1893).	No description published.
1:8:4:6 [8:1:3:5] K-acid	Fusion of α-naphthylamine-4 : 6 : 8-trisulphonic acid with 70 p.c. caustic soda under pressure at 175° (Bayer, D. R.-P. 80741 ; Eng. Pat. 17141c of 1893 ; Kalle, D. R.-P. 99164 of 1893 ; Eng. Pat. 515 of 1894).	*Acid sodium* salt readily soluble needles (Bayer, *l.c.*). Gives yellowish-green col. with ferric chloride. Forms a yellow readily soluble *diazo*-compound. Couples in acid or alkaline solution with diazotised bases forming two series of *monoazo*-dyes (*cf.* Kalle, *l.c.* ; D. R.-P. 108266 of 1896).[1] For *acetyl, aryl, nitroaryl* derivatives, see p. 636.
1 : 8 : 4 : (7) [8 : 1 : (2) : 5]	1 - Amino - 8 - naphthol - 4 - sulphonic acid sulphonated with 23 p.c. anhydro-acid at the ordinary temperature (Aktienges., D. P. Anm. A. 3918 of 1894 ; Badische, D. R.-P. 125696 ; Eng. Pat. 18366 of 1900).	*Acid sodium* salt sparingly soluble needles. Gives brownish-black col. with ferric chloride. Forms a yellowish-brown *diazo*-compound. Couples with diazotised bases (*cf.* Aktienges., *l.c.*).
1:8:5:7 [8:1:2:4]	1-Amino-8-naphthol-5-sulphonic or 7-sulphonic acid sulphonated with monohydrate at 100° (Badische, D. R.-P. 62289 of 1889 ; Eng. Pat. 9676 of 1890 ; *cf.* Badische, D. R.-P. 82900 of 1894).	*Acid* readily soluble leaflets ; *acid sodium* salt readily soluble. Gives blue colouration with ferric chloride. Forms a yellow sparingly soluble *diazo*-compound and couples with diazotised bases (*cf.* Cassella, D. R.-P. 84952 of 1894).
1:8:(5):? [8:1:(4):?] D-acid	Fusion of naphthasultamdisulphonic acid D with 90 p.c. caustic soda at 170° (Bayer, D. R.-P. 80668 ; Eng. Pat. 4979 of 1893).	*Acid sodium* salt moderately soluble needles. Gives green colouration with ferric chloride. Couples with diazotised bases.
2:1:3:6	Reduction of 2-nitroso-α-naphthol-3 : 6-disulphonic acid (Geigy, D. R.-P. 171024 ; Eng. Pat. 10235 of 1904).	*Acid sodium* salt easily soluble needles. Forms a *diazo-oxide* in absence of mineral acid (*cf.* Geigy, *l.c.* ; *v.* p. 571).
2:1:3:8	Reduction of azo-derivatives of α-naphthol-3 : 8-disulphonic acid (Bernthsen, Ber. 1890, 23, 3093).	Forms a *diazo-oxide* in absence of mineral acid (*cf.* Geigy, D. R.-P. 171024 ; Eng. Pat. 10235 of 1904 ; *v.* p. 571).
2:1:4:6	Reduction of azo-derivatives of α-naphthol-4 : 6-disulphonic acid (Reverdin and de la Harpe, Ber. 1893, 26, 1282 ; *cf.* Böniger, Ber. 1894, 27, 3052).	*Acid* readily soluble ; *acid sodium* salt sparingly soluble needles.
2:1:4:7	Reduction of azo- or nitroso-derivatives of α-naphthol-4 : 7-disulphonic acid (Reverdin and de la Harpe, Ber. 1893, 26, 1282 ; *cf.* Böniger, Ber. 1894, 27, 3054).	*Acid* moderately soluble needles ; *sodium* salt readily soluble. Forms a *diazo-oxide* in absence of mineral acid (*cf.* Geigy, *l.c.*).
2:1:4:8	Reduction of azo-derivatives of α-naphthol-4 : 8-disulphonic acid (Reverdin and de la Harpe, Ber. 1893, 26, 1283).	*Acid* and *acid sodium* salt moderately soluble. Forms a *diazo-oxide* in absence of mineral acid (*cf.* Geigy, D. R.-P. 171024 ; Eng. Pat. 10235 of 1904 ; *v.* p. 571).
2:3:6:8 [3:2:5:7]	Sulphonation of 2-amino-3-naphthol-6-sulphonic acid (Aktienges., D. R.-P. 86448 ; Eng. Pat. 8645 of 1895).	No description published.
2:4:6:8 [3:1:5:7]	Fusion of β-naphthylamine-4 : 6 : 8 -trisulphonic acid with 60 p.c. caustic soda at 170°–180° (Bayer, D. P. Anm. F. 8154 ; D. R.-P. 89242 of 1895.	*Acid sodium* salt, moderately soluble. Gives bluish-green colouration with ferric chloride. Forms a pale yellow *diazo*-compound. Couples with diazotised bases.
2:5:1:7 [6:1:3:5]	Fusion of β-naphthylamine-1 : 5 : 7-trisulphonic acid with 66 p.c. caustic soda at 160°–220° (Bayer, D. R.-P. 80878 ; Eng. Pat. 20580 of 1893).	*Acid sodium* salt readily soluble needles. Gives green colouration with ferric chloride. Forms an orange-yellow soluble *diazo*-compound. Couples in alkaline solution with diazotised bases (*cf.* Bayer, D. R.-P. 92708 ; Eng. Pat. 1062 of 1894).
2:5:3:7 [6:1:3:7]	β-Naphthylamine-3 : 5 : 7-trisulphonic acid heated with 30 p.c. caustic soda at 190° (Oehler, D. R.-P. 158147 of 1903 ; Eng. Pat. 1581 of 1904).	*Acid sodium* salt easily soluble. Gives yellowish-brown col. with ferric chloride. Forms an easily soluble orange *diazo*-compound. Couples in alkaline solution with diazotised bases.

---

[1] The colouration produced by the interaction of this acid with sulphanilic acid in the presence of nitrous acid forms a delicate test for minute quantities of nitrites in water (Erdmann, Ber. 1900, 33, 213).

Constitution.	Preparation.	Acids, Salts and Reactions.
N:O:S:S 2:7:3:6 [7:2:3:6]	(1) β-Naphthylamine-3 : 6 : 7-trisulphonic acid heated with 55 p.c. caustic soda at 180°–240° (Bayer, D. P. Anm. F. 7019; Eng. Pat. 17141 of 1893; *cf. ibid.*, D. R.-P. 80878 of 1893). (2) 2 : 7-Dihydroxynaphthalene-3 : 6-disulphonic acid heated with 23 p.c. ammonia at 180°–220° (Aktienges., D. R.-P. 75142; Eng. Pat. 16199 of 1893). (3) 2-Amino-7-naphthol sulphonated with sulphuric acid at 30° (Cassella, D. R.-P. 131526 of 1901).	*Acid* sparingly soluble; *acid sodium* salt sparingly soluble needles. Gives deep violet colouration with ferric chloride (Bayer, *l.c.*; Aktienges., *l.c.*). Forms a sparingly soluble yellow *diazo*-compound (Cassella, *l.c.*). Couples only slowly or not at all with diazotised bases (Cassella, *l.c.*).
2:8:3:6 [7:1:3:6] 2 R-acid	Fusion of β-naphthylamine-3 : 6 : 8-trisulphonic acid with 80 p.c. caustic soda at 200°–260° (Höchst, D. R.-P. 53023; Eng. Pat. 15175 of 1889).	*Acid* and *salts* readily soluble. Gives dark green colouration with ferric chloride. Forms a yellow sparingly soluble *diazo*-compound. Couples in alkaline solution with diazotised bases (*cf.* Aktienges., D. R.-P. 108215; Eng. Pat. 14895 of 1893).

Aminonaphtholtrisulphonic Acids.

1-Amino-2-naphthol- and 2-amino-1-naphthol-3:6:8-trisulphonic acids are obtained by reduction of azo-derivatives of the corresponding β-naphthol- and α-naphthol-3 : 6 : 8-trisulphonic acids. They give *diazo-oxides* on diazotisation in absence of mineral acid (Geigy, D. R.-P. 171024; Eng. Pat. 10235 of 1904).

1-Amino-8-naphthol-2:4:6-trisulphonic acid, obtained by fusing naphthasultam-2 : 4 : 6-trisulphonic acid with 85 p.c. caustic potash at 150°–160°, forms a sparingly soluble *acid potassium* salt, gives a green colouration with ferric chloride, also a readily soluble orange *diazo*-compound, and couples with diazotised bases (Bayer, D. R.-P. 84597 of 1894).

NITROAMINONAPHTHOLSULPHONIC ACIDS.

Nitroamino-1-naphthol, obtained from 2 : 4-dinitro-α-naphthol by reduction with ammonium sulphide, forms yellow needles, m.p. 130° (Ebell, Ber. 1875, 8, 564).

(i.) **3-Nitro-1-amino-4-naphthol-6-sulphonic acid**, obtained from naphthol yellow S by reduction with stannous chloride and hydrochloric acid (Lauterbach, Ber. 1881, 14, 2029; Finger, J. pr. Chem. 1909, [ii.] 79, 442) forms sparingly soluble golden-yellow scales. Its *diazo-* compound couples with β-naphthol, &c., but the *azo-* dyes are valueless (Gesellsch., D. R.-P. 189513 of 1905; Eng. Pat. 7535 of 1906); when boiled with alcohol and copper powder, it is converted into *copper 2-nitro-α-naphthol-7-sulphonate* (Finger, *l.c.*).

(ii.) **4-Nitro-2-amino-1-naphthol-7-sulphonic acid**, obtained when naphthol yellow S in ammoniacal solution is reduced by sodium sulphide at 90°–95°, forms yellow crystals, sparingly soluble in cold water. Its *diazo-* compound couples with β-naphthol, &c., giving *azo-* dyes (Gesellsch., D. R.-P. 189513 of 1905; Eng. Pat. 7535 of 1906).

(iii.) **(8)-Nitro-2-amino-3-naphthol-6-sulphonic acid** can be prepared by adding nitre to a solution of 2-amino-3-naphthol-6-sulphonic acid in sulphuric acid at 5°. It forms yellow needles, and its *potassium* and *sodium* salts are easily soluble (Cassella, D. R.-P. 110369 of 1899). The *diazo-* compound couples with phenols and amines giving *azo-* dyes (*ibid.* D. R.-P. 111933 of 1899).

Although the corresponding nitro-amino-2-naphthol-(or 2-amino-1-naphthol-)sulphonic acids have not been described, the diazo- compounds, to which they would give rise, can be obtained by nitrating *o*-diazonaphtholsulphonic acids. Nitro-1-diazo-2-naphthol-4-sulphonic acid (Geigy, D. R.-P. 171024; Eng. Pat. 10235 of 1904; D. R.-P. 164655; Eng. Pat. 15418 of 1904) forms pale yellow crystals, and couples with phenols and amines forming *azo-* dyes (*ibid.* D. R.-P. 169683; Eng. Pat. 15982 of 1904). Nitro-1-diazo-2-naphthol-6-sulphonic and nitro-2-diazo-1-naphthol-5-sulphonic acids give *azo-* dyes, in which, with alkaline reducing agents, the NO_2 radicle can be converted into a diazotisable NH_2 group (Kalle, D. R.-P. 176619 of 1905).

DIAMINONAPHTHOLS.

Introductory.—The diaminonaphthols have been isolated only in three cases, being very rapidly oxidised on exposure of their solutions to the air. In the table a summary is given of the hydrochlorides, obtained chiefly by reduction processes; the acetyl derivatives, by which the diaminonaphthols have been characterised; and the sulphonic acids belonging to this group of compounds:

NH_2 : NH_2 : OH	
1 : 2 : 3 [3 : 4 : 2]	Unknown. 6-Sulphonic acid obtained by reduction of azo-dye from 2-amino-3-naphthol-6-sulphonic acid (Cassella, D. P. Anm. C. 19212 of 1910).
1 : 2 : 4 [3 : 4 : 1]	Unknown. *Diacetyl methyl ether*, m.p. 254° (Henriques, Ber. 1892, 25, 3067); *ethenyl* derivative, needles, m.p. 179° (Heermann, J. pr. Chem. 1892, [ii.] 45, 552).
1 : 2 : 7 [7 : 8 : 2]	Not described. Obtained by reduction of 7-hydroxy-[β-]naphthaquinonedioxime. *Hydrochloride*, B·2HCl; *triacetyl* derivative, m.p. 244°–245° (Nietzki and Knapp, Ber. 1897, 30, 1124).
1 : 2 : 8 [7 : 8 : 1]	Not isolated. Obtained by reduction of sulphonanilazo-2-amino-8-naphthol (Badische, D. R.-P. 90212; Eng. Pat. 15953 of 1896). The 4-, 5-, 6-mono-, and 3 : 6- and 5 : 7-disulphonic acids have been obtained from the corresponding 2-amino-8-naphtholsulphonic acids (*cf.* Badische, *l.c.*).

NH_2:NH_2:OH	
1 : 3 : 4 [2 : 4 : 1]	Not isolated. Obtained by reduction of 2 : 4-dinitro-α-naphthol. *Hydrochloride*, B·2HCl, scales, and *sulphate*, $B{\cdot}H_2SO_4+2H_2O$, needles, are both rapidly oxidised in air to diimino-α-naphthol (Graebe and Ludwig, Annalen, 1870, 154, 307); *triacetyl* derivative, needles, m.p. 280°, decomp. (Meerson, Ber. 1888, 21, 1196). The 7-sulphonic acid, obtained by reduction of naphthol yellow S, gives *hydrochloride* B·HCl, in needles (Gaess, Ber. 1899, 32, 232; *cf.* Lauterbach, Ber. 1881, 14, 2028), is not diazotisable, does not couple (*cf.* Aktienges., D. R.-P. 86448; Eng. Pat. 8645 of 1895), and is readily oxidised to the diimino- compound (Lauterbach, *l.c.*; Gaess, *l.c.*).
1 : 3 : 5 [5 : 7 : 1]	Unknown. The 7-sulphonic acid, obtained by digesting 1 : 3-diaminonaphthalene-5 : 7-disulphonic acid with 60 p.c. caustic soda solution at 210°, couples with diazotised bases (Kalle, D. R.-P. 92239 of 1896).
1 : 3 : 8 [5 : 8 : 1]	Unknown. The 6-sulphonic acid, obtained similarly from 1 : 3-diaminonaphthalene-6 : 8-disulphonic acid, couples with diazotised bases (Kalle, D. R.-P. 92239 of 1896).
1 : 4 : 2	Not isolated. Obtained by reduction of 4-nitrodiacetyl-1-amino-2-naphthol, *or* of azo- derivative of 1-amino-2-naphthol (Nietzki and Becker, Ber. 1907, 40, 3397; Kalle, D. R.-P. 195901 of 1906); rapidly oxidised to blue *oxazine* in the air (*ibid.*). *Hydrochloride*, B·2HCl, needles; N-*diacetyl* derivative, m.p. 250°–260°, decomp. (Kehrmann and Hertz, Ber. 1896, 29, 1417). The 6-sulphonic acid, obtained by reduction of azo- derivative of 1-amino-2-naphthol-6-sulphonic acid, forms *hydrochloride*, B·HCl, (Nietzki and Becker, *l.c.*; Kalle, *l.c.*). The 8-sulphonic acid, obtained by reduction of croceïn yellow, forms *hydrochloride*, B·HCl, needles, readily oxidised to the diimide, and is diazotisable (Nietzki and Zübelen, Ber. 1889, 22, 455).
1 : 4 : 8 [5 : 8 : 1]	Not described. Obtained by reduction of 4-nitroacet-1-amino-8-naphthol (Fichter and Gaguer, Ber. 1906, 39, 3336).
1 : 5 : 3 [4 : 8 : 2]	Unknown. The 7-sulphonic acid, obtained by fusing 1 : 5-diaminonaphthalene-3 : 7-disulphonic acid with 90 p.c. caustic soda solution at 200°–240°, forms needles sparingly soluble in hot water, and couples with diazotised bases (Cassella, D. R.-P. 91000 of 1896).
1 : 5 : 8 [4 : 8 : 1]	Not isolated. Obtained by reduction of 1-nitro-5-nitroso-8-naphthol (Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339; Graebe and Oeser, Annalen, 1904, 335, 155); *or* of azo- derivatives of 1-amino-8-naphthol (Fichter and Gaguer, Ber. 1906, 39, 3333). *Hydrochloride*, B·2HCl; N-*diacetyl* derivative, needles, m.p. 247°; *triacetyl* derivative, m.p. 258° (Fichter and Gaguer, *l.c.*).
1 : 6 : 2	M.p. 194° (*cf.* Cassella, D. R.-P. 117298; Eng. Pat. 16149 of 1899). Obtained by reduction of 1 : 6-dinitro-β-naphthol (Loewe, Ber. 1890, 23, 2543; Kehrmann and Matis, Ber. 1898, 31, 2413). *Hydrochloride*, B·2HCl, needles; N-*diacetyl* derivative, needles, m.p. 235°; *triacetyl* derivative, needles, m.p. 203° (Loewe, *l.c.*).
1 : 7 : 2	Scales, m.p. 220° (decomp.). Obtained by reduction of azo-derivative of 7-amino-2-naphthol (Cassella, D. R.-P. 117298; Eng. Pat. 16149 of 1899). *Sulphate*, sparingly soluble (*ibid.*); N-*diacetyl* derivative, needles, m.p. 226°; *triacetyl* derivative, needles (Kehrmann and Wolff, Ber. 1900, 33, 1540).
1 : 7 : 8 [2 : 8 : 1]	Not isolated. Obtained by reduction of 1-amino-7-nitroso-8-naphthol. *Hydrochloride*, B·2HCl, needles; *triacetyl* derivative, needles, m.p. 234° (Fichter and Gaguer, Ber. 1906, 39, 3338). The 3 : 6-disulphonic acid, obtained by reduction of azo- derivative of 1-amino-8-naphthol-3 : 6-disulphonic acid (H-acid), is not diazotisable in acid solution (Höchst, D. R.-P. 92012 of 1896). The 4-mono- and 4 : 6-disulphonic acids, obtained similarly from S-monosulpho- and K- acids, have been introduced, like the 3 : 6-acid, as photographic developers (Schultz, D. R.-P. 101953 of 1897).
1 : 8 : 4 [4 : 5 : 1]	Not isolated. Obtained by reduction of 8-nitro-1-nitroso-4-naphthol (Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339; Graebe and Oeser, Annalen, 1904, 335, 152). *Hydrochloride*, B·2HCl.
2 : 3 : 8 [6 : 7 : 1]	Unknown. The 6-sulphonic acid, obtained by fusing 2 : 3-diaminonaphthalene-6 : 8-disulphonic acid with 90 p.c. caustic potash solution at 190°–200°, forms an *azimide* with nitrous acid, and couples with diazotised bases (Aktienges., D. R.-P. 86448; Eng. Pat. 8645 of 1895).
2 : 6 : 1	Not isolated. Obtained by reduction of 6-nitronaphthalene-2-diazo-1-oxide. *Hydrochloride*, not described; *triacetyl* derivative, needles, m.p. 261°, decomp. (Gaess and Ammelburg, Ber. 1894, 27, 2213).
2 : 7 : 8 [2 : 7 : 1]	Unknown. The 6-sulphonic acid, obtained by reduction of azo- derivative of β-naphthylamine-6 : 8-disulphonic acid, is not diazotisable in acid solution (Höchst, D. R.-P. 92012 of 1896).

VIII. DIHYDROXY-DERIVATIVES.

Introductory.—The dihydroxynaphthalenes, like the naphthols, can be obtained from sulphonic acids by fusion with caustic alkali. For this purpose the four disulphonic acids producible from naphthalene by sulphonation, six of the naphtholsulphonic acids, β-naphthol-3 : 6-disulphonic acid, and α-naphthylamine-8-sulphonic acid have been employed. It has not been possible to prepare 1 : 2-, 1 : 3-, or 1 : 4-dihydroxynaphthalene by this method.

Another process, although less general, in which diaminonaphthalenes, aminonaphthols, aminonaphtholsulphonic acids, or dihydroxynaphthalenesulphonic acids are heated with dilute mineral acid under pressure, leads to the formation of dihydroxynaphthalenes from the amino- derivatives by exchange of NH_2 for OH, and—when a sulphonic acid is employed—elimination of the SO_3H group by hydrolysis.

For the preparation of the 1 : 2- and 1 : 4-dihydroxynaphthalenes (naphthaquinols), reduction of the respective naphthaquinones is the only practicable method.

The dihydroxynaphthalenes, of which the complete series of ten is known, are easily soluble in caustic alkali solutions, but only sparingly in cold water; the alkaline solutions rapidly become dark brown or black on exposure to the air.

When heated with ammonia under pressure, the four *αβ*-dihydroxynaphthalenes yield *β*-amino-*α*-naphthols as intermediate products, thus resembling *β*- rather than *α*-naphthol.

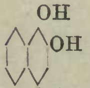
With nitrous acid the dihydroxynaphthalenes yield mononitroso-, and in some cases dinitroso-compounds, of which the *ortho*-mononitroso-compounds form lakes with chromium or iron salts. The nitroso- derivatives formed from the monoalkyl ethers of 1 : 8-, 2 : 6-, and 2 : 7-dihydroxynaphthalenes closely resemble 2-nitroso-*α*-naphthol and nitroso-*β*-naphthol, respectively, in properties, and like these can be employed in the production of thiazines (Bayer, D. R.-P. 91234; Eng. Pat. 6035A of 1893).

The azo- dyes obtained by coupling the following dihydroxynaphthalenes with diazotised bases:

1 : 2- (Witt, D. R.-P. 49979; Eng. Pat. 2499 of 1889);
2 : 3- (Badische, D. R.-P. 62947 of 1891);
1 : 8- (Badische, D. R.-P. 51559, 52958 of 1889);

form lakes, a property associated in dyestuffs of various types with the presence of hydroxyl groups in relatively *ortho*- positions. Those obtained by coupling 1 : 3 - dihydroxynaphthalene have a characteristic yellow shade.

DIHYDROXYNAPHTHALENES.



(i.) **1:2-Dihydroxynaphthalene** ([*β*-]naphthaquinol, [*β*-]naphthahydroquinone) is obtained by reducing [*β*-]naphthaquinone with sulphurous acid in the cold (Liebermann and Jacobson, Annalen, 1882, 211, 58; Paul, *cf.* J. Soc. Chem. Ind. 1897, 16, 733); *or* by heating 1-amino-2-naphthol-6 : 8-disulphonic acid with water under pressure above 200° (Bayer, D. R.-P. 89242 of 1895).

Identification.—It forms scales, m.p. 60°, dissolves in alkalis forming yellow solutions which become green on exposure to the air, and in aqueous solution exerts a severe caustic action on the skin (Liebermann and Jacobson, *l.c.*). The *diacetate* forms scales, m.p. 110° (Crépieux, Bull. Soc. chim. 1891, [3] 5, 158); the 1-*methyl ether*, monoclinic plates, m.p. 90·5°; the *dimethyl ether*, m.p. 31°, b.p. 278°–280° (Bezdzik and Friedlaender, Monatsh. 1909, 30, 280).

Reactions.—(1) In aqueous solution with ferric chloride, it yields [*β*-]*naphthaquinone* (Zincke, Annalen, 1892, 268, 275).

(2) By nitric acid of sp.gr. 1·48 it is converted into 3-*nitro*-[*β*-]*naphthaquinone* (Korn, Ber. 1884, 17, 3024; *cf.* Zincke, *l.c.*).

(3) With diazotised bases it couples, forming *azo*- dyes which give red to bluish-violet lakes with aluminium or chromium salts (Witt, D. R.-P. 49979; Eng. Pat. 2499 of 1889).

(4) It has been used for the production of *oxazines* (Bayer, D. R.-P. 77120; Eng. Pat. 8093 of 1893), and *thiazines* (Badische, D. R.-P. 96690; Eng. Pat. 19962 of 1893).

(ii.) **1 : 3-Dihydroxynaphthalene** is obtained when 1-amino-3-naphthol is boiled with dilute acid (Friedlaender, Ber. 1895, 28, 1952); *or* when 1-amino-3-naphthol-4-sulphonic acid is heated with water or dilute acid at 120° (Friedlaender and Rüdt, Ber. 1896, 29, 1609); *or* when 2-amino-4-naphthol-8-sulphonic acid (Bayer, D. R.-P. 87429; Eng. Pat. 3580 of 1895), or 1 : 3-dihydroxynaphthalene-7-mono- or 5 : 7-disulphonic acid (*ibid.* D. R.-P. 90096; Eng. Pat. 4962 of 1895) is heated with 5 p.c. sulphuric acid at 235°; *or* when 1 : 3-dihydroxy-*β*-naphthoic acid is heated with water under pressure at 100° (Metzner, Annalen, 1897, 298, 388).

Identification.—It crystallises from water in scales, m.p. 124°, is almost insoluble in benzene, becomes rapidly brown in alkaline solution on exposure to the air, and gives with ferric chloride a yellowish-brown precipitate (Friedlaender and Rüdt, *l.c.*). The *diacetate* forms prisms, m.p. 56° (*ibid.*).

Reactions.—(1) On digestion with 60 p.c. caustic soda solution at 180°–190°, it is converted into o-*toluic* acid (Friedlaender and Rüdt, *l.c.*; Kalle, D. R.-P. 79028 of 1893).

(2) When heated with aqueous ammonia at 130°–140°, it yields 2-*amino*-4-*naphthol* and 1 : 3-*diaminonaphthalene*, but with aniline *phenyl*-2-*amino*-4-*naphthol* (Friedlaender and Rüdt, *l.c.*).

(3) With nitrosodimethylaniline in acetic acid solution it gives a violet dyestuff (*ibid.*).

(4) When heated with phthalic anhydride and either phosphoric oxide at 130°, or zinc chloride at 200°, it furnishes *naphthafluoresceïn* (Friedlaender and Rüdt, *l.c.*; Bayer, D. R.-P. 84990; Eng. Pat. 3497 of 1895).

(5) With diazotised bases it couples in alkaline or weak acid solution, giving *azo*- dyes characterised by their yellow colour (Friedlaender and Rüdt, *l.c.*).

(iii.) **1 : 4-Dihydroxynaphthalene** ([*α*-]naphthaquinol, [*α*-]naphthahydroquinone) is formed when [*α*-]naphthaquinone is reduced with hydriodic acid and phosphorus (Groves, Chem. Soc. Trans. 1873, 26, 210); with tin and hydrochloric acid, or at 140°–150° with sulphurous acid (Plimpton, *ibid.* 1880, 37, 635); or with stannous chloride and very dilute hydrochloric acid (Russig, J. pr. Chem. 1900, [ii.] 62, 32). It is best prepared by adding powdered [*α*-]naphthaquinone to a boiling mixture of tin and hydrochloric acid.

Identification.—It crystallises in needles, m.p. 176°, and is readily soluble in alcohol, ether or boiling water, but only sparingly in benzene. By chromic acid or other oxidising agents, it is converted into [*α*-]*naphthaquinone.* The *diacetate* forms tablets, m.p. 128°–130° (Korn, Ber. 1884, 17, 3025).

Alkyl derivatives. The *monomethyl ether*, obtained by etherification at the ordinary temperature with 18 p.c. methyl alcoholic hydrogen chloride, forms needles, m.p. 131°; the *monoethyl ether*, obtained by boiling the dihydroxynaphthalene with 3 p.c. ethyl alcoholic hydrogen chloride, forms needles, m.p. 105° (Badische, D. R.-P. 173730 of 1905; Eng. Pat. 7287A of 1906; *cf.* Russig, J. pr. Chem. 1900, [ii.] 62, 50). These ethers, which can also be obtained by heating 1-amino-4-naphthol hydrochloride with the corresponding alcohol under pressure at 170°–180° (Höchst, D. R.-P. 234411 of 1910), when coupled with diazotised aminosulphonic acids, furnish *ortho*-azo- dyes

(Badische, D. R.-P. 176640 of 1905; Eng. Pat. 7287 of 1906). The *dimethyl* ether forms needles, m.p. 85° (Russig, *l.c.*).

(iv.) 1 : 5-**Dihydroxynaphthalene** is formed when potassium *α*-naphthol-5-sulphonate is fused with caustic potash at 200°–250° (Cleve, Förhandl., 1875, 9, 28; Bull. Soc. chim. 1875, [ii.] 24, 513; Erdmann, Annalen, 1888, 247, 356; *cf.* Ewer and Pick, D. R.-P. 41934 of 1887); *or* when sodium naphthalene-1 : 5-disulphonate is fused with caustic soda at 220°–260° (Ewer and Pick, *l.c.*; Armstrong and Wynne, Chem. Soc. Proc. 1887, 3, 43; Bernthsen and Semper, Ber. 1887, 20, 938; Schultz, *ibid.* 3161); *or* when 1 : 5-diaminonaphthalene is either heated with 4 p.c. hydrochloric acid under pressure at 180° (Aktienges., D. P. Anm. A. 4029 of 1894), or boiled with sodium bisulphite solution and the product decomposed by alkali (Bucherer, J. pr. Chem. 1904, [ii.] 69, 84; *cf.* 70, 352).

Identification.—It crystallises from water in scales, m.p. 265° (Bentley, Robinson and Weizmann, Chem. Soc. Trans. 1907, 91, 106), sublimes in needles, is almost insoluble in benzene, reduces silver solution, and in alkaline solution becomes dark-brown on exposure to the air—a property which has suggested its use as a hair-dye (Erdmann, D. R.-P. 51073 of 1889). The *diacetate* forms feathery crystals, m.p. 159°–160° (Bernthsen and Semper, *l.c.*); the *monomethyl ether*, leaflets, m.p. 140°; and the *dimethyl ether*, needles, m.p. 183°–184° (Bentley, Robinson and Weizmann, *l.c.*).

Reactions.—(1) On oxidation with chromic acid mixture, it is converted into *juglone* (5-hydroxy-[*α*-]naphthaquinone, *cf.* Bernthsen and Semper, *l.c.*).

(2) With nitrous acid, it gives a *mono-* and a *di-nitroso-* derivative (Read, Holliday & Co., D. R.-P. 68809; Eng. Pat. 1812 of 1890).

(3) When warmed with sulphuric acid at 50°–60°, it yields a mixture of the 2- and 4-*monosulphonic acids* (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 235), but at 100°–160° a *disulphonic acid* (*cf.* Ewer and Pick, *l.c.*; Majert, Eng. Pat. 4243 of 1887).

(4) By interaction with ammonia under pressure at 250°–300° (Ewer and Pick, D. R.-P. 45549 of 1887), or with ammonium bisulphite solution and ammonia at 125°, it gives 1 : 5-*diaminonaphthalene* (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

(5) It couples with diazotised naphthionic acid, forming an *azo-* dye which closely resembles litmus in the colours given with acids, alkalis, and carbon dioxide (Erdmann, Annalen, 1888, 247, 356), or a *disazo-* dye if the coupling be effected in alkaline solution (Badische, D. P. Anm. B. 33987; Eng. Pat. 10536 of 1903); also with diazotised *o*-aminophenolsulphonic acids in alkaline solution giving *monoazo-* dyes, distinguished by their fastness on wool after chroming (Bayer, D. R.-P. 157786; Eng. Pat. 18569 of 1902).

(v.) 1 : 6-**Dihydroxynaphthalene** is formed when sodium naphthalene-1 : 6-disulphonate is fused with caustic soda at 230°–250° (Ewer and Pick, D. R.-P. 45229 of 1887); *or* when *β*-naphthol-5-sulphonic acid is fused with caustic potash and a little water at 260° (Claus, J. pr. Chem. 1889, [ii.] 39, 316); *or* when 1 : 6-dihydroxynaphthalene-4-sulphonic acid is desulphonated by sodium amalgam (Friedlaender and Lucht, Ber. 1893, 26, 3034).

Identification.—It crystallises from benzene in small prisms or serrated scales, m.p. 135°, sublimes in scales, is only sparingly soluble in water, and with ferric chloride gives a transient blue colouration. The *diacetate* forms prisms, m.p. 73° (Claus, *l.c.*).

Reactions.—(1) With nitrous acid, it yields a *mono-* and a *di-nitroso-* derivative (Read, Holliday & Co., D. R.-P. 68809; Eng. Pat. 1812 of 1890).

(2) When heated with ammonia under pressure at 150°–300°, it is converted into 1 : 6-*diaminonaphthalene* (Ewer and Pick, D. R.-P. 45788 of 1887).

(3) It couples in alkaline solution with diazotised *o*-aminophenolsulphonic acids, forming *monoazo-* dyes, which are fast on wool after chroming (Bayer, D. R.-P. 164318; Eng. Pat. 18569 of 1902).

(vi.) 1 : 7-**Dihydroxynaphthalene** is obtained by fusing *β*-naphthol-8-sulphonic acid with caustic potash (Emmert, Annalen, 1887, 241, 371); *or* by boiling 1 : 7-dihydroxy-*β*-naphthoic acid with aniline to eliminate carbon dioxide (Friedlaender and Zinberg, Ber. 1896, 29, 40).

Identification.—It crystallises in needles, m.p. 178°, is moderately soluble in water, but readily in benzene, rapidly becomes black on exposure in alkaline solution to the air, and with ferric chloride gives at first (like *α*-naphthol) a white turbidity which with more of the reagent becomes blue (Friedlaender and Zinberg, *l.c.*). The *diacetate* forms rhombic tables, m.p. 108° (Emmert, *l.c.*).

Reactions.—(1) With nitrous acid it yields a *mononitroso-* derivative (Bayer, D. R.-P. 53915; Eng. Pat. 14230 of 1889).

(2) By interaction of its sodium derivative with carbon dioxide under pressure at 140°, it gives 1 : 7-*dihydroxy-β-naphthoic acid* (Heyden, D. R.-P. 55414 of 1890).

(3) It couples in alkaline solution with diazotised *o*-aminophenolsulphonic acids furnishing *monoazo-* dyes, which are fast on wool after chroming (Bayer, D. R.-P. 164318; Eng. Pat. 18569 of 1902).

(vii.) 1 : 8-**Dihydroxynaphthalene** is obtained when either naphthasultone or *α*-naphthol-8-sulphonic acid is fused with 75 p.c. caustic potash solution at 220°–230° (Erdmann, Annalen, 1888, 247, 356); *or* when *α*-naphthylamine-8-sulphonic acid is heated with 9 p.c. caustic soda solution under pressure at 220°–260° (Höchst, D. P. Anm. F. 6311 of 1892). It is also formed when 1 : 8-dihydroxynaphthalene-4-sulphonic acid (Bayer, D. R.-P. 67829; Eng. Pat. 13665 of 1889), *or* 1 : 8-dihydroxynaphthalene-2 : 4-disulphonic acid (Dressel and Kothe, Ber. 1894, 27, 2143), *or* naphthasultamdisulphonic acid D (Bayer, D. R.-P. 80668; Eng. Pat. 4979 of 1893) is heated with 20 p.c. sulphuric acid at 160°–200°; *or* when 1 : 8-diaminonaphthalene is heated with 17 p.c. hydrochloric acid under pressure at 180° (Aktienges., D. P. Anm. A. 4028 of 1894).

Identification.—It crystallises in long needles, m.p. 140°, or with 1 mol. H_2O in scales, oxidises rapidly when moist on exposure to the air, is only sparingly soluble in water but readily in benzene, and gives with ferric chloride a white flocculent precipitate, which rapidly becomes green. The *diacetate* forms scales, m.p. 147°–148° (Erdmann, *l.c.*).

Reactions.—(1) On oxidation with chromic acid mixture, it gives *juglone* (5-hydroxy-[α-] naphthaquinone) in small quantity (Erdmann, *l.c.*).

(2) When warmed with sulphuric acid at 50°, it is converted into a mixture of the I-, G-, and R-*disulphonic acids* (Badische, D. R.-P. 79029, 79030; *cf.* Eng. Pat. 14294 of 1891).

(3) With nitrous acid it furnishes a *mono*- and a *di-nitroso*- derivative (Bayer, D. R.-P. 51478; Eng. Pat. 14230 of 1889).

(4) By interaction of its sodium derivative with carbon dioxide under pressure at 140°, it yields 1 : 8-*dihydroxy-β-naphthoic acid* (Heyden, D. R.-P. 55414 of 1890).

(5) When boiled with 40 p.c. sodium bisulphite solution, it furnishes the corresponding *sulphite* (Badische, D. R.-P. 115335 of 1899; Eng. Pat. 1387 of 1900; Bucherer, J. pr. Chem. 1904, [ii.] 69, 87).

(6) By condensation with acyl chlorides or anhydrides in presence of zinc chloride at 140°–150°, it yields yellow or orange dihydroxyketones (*e.g.* 1 : 8-*dihydroxy*-2-*acetonaphthone*, needles, m.p. 100°–101°, and *benzonaphthone*, needles, m.p. 121°–122°) which form lakes with alumina, &c. (Lange, D. R.-P. 126199; Eng. Pat. 21970 of 1900; *cf. ibid.*, D. R.-P. 129035, 129036 of 1900).

(7) It couples in alkaline solution with diazotised bases giving 4-*monoazo*- (*cf.* Badische, D. R.-P. 51559; 52958 of 1889; Bayer, D. R.-P. 70659; Eng. Pat. 14478 of 1892), or 4 : 7-*disazo*- dyes (*cf.* Badische, D. R.-P. 52140, 53499; Eng. Pat. 6874 of 1890; Friedlaender and Silberstern, Monatsh. 1902, 23, 518).

(viii.) 2 : 3-**Dihydroxynaphthalene** has been prepared by fusing β-naphthol-3 : 6-disulphonic acid, or 2 : 3-dihydroxynaphthalene-6-sulphonic acid, with 90 p.c. caustic soda solution at 280°–320° (Badische, D. R.-P. 57525; Eng. Pat. 15803 of 1890); also by heating 2 : 3-dihydroxynaphthalene-6-sulphonic acid with 25 p.c. sulphuric acid at 200° (*ibid.*; Friedlaender and Zakrzewski, Ber. 1894, 27, 762); *or* 2-amino-3-naphthol-6-sulphonic acid with dilute mineral acid under pressure at 180°–200° (Höchst, D. R.-P. 73076 of 1893; *cf.* Friedlaender and Zakrzewski, *l.c.*).

Identification.—It forms monoclinic scales (Siegmund, Monatsh. 1908, 29, 1087), m.p. 160°–161°, is sparingly soluble in water, and gives with ferric chloride a dark-blue colouration or precipitate (Badische, *l.c.*). The *monomethyl ether* forms needles, m.p. 108°; *dimethyl ether*, needles, m.p. 115°–116°; *monoethyl ether*, m.p. 109°–110°; *diethyl ether*, m.p. 96°–97° (Friedlaender and Silberstern, Monatsh. 1902, 23, 519; Silberstern, D. R.-P. 133459 of 1901).

Reactions.—(1) When heated with 30 p.c. ammonia at 140°–150° it yields 2-*amino*-3-*naphthol*, but at 250°, 2 : 3-*diaminonaphthalene* (Höchst, *l.c.*; Friedlaender and Zakrzewski, *l.c.*). These products can be obtained at 80° by heating it with ammonium sulphite solution and ammonia (Badische, D. R.-P. 117471 of 1899; Eng. Pat. 1387 of 1900).

(2) It couples with diazotised bases giving in an acetic acid bath 1-*monoazo*- dyes, and in an alkaline bath 1 : 4-*disazo*- dyes (Friedlaender and Silberstern, *l.c.*; *cf.* Friedlaender and Zakrzewski, *l.c.*; Badische, D. R.-P. 62947 of 1891; Höchst, D. R.-P. 86937 of 1894; Bayer, D. R.-P. 99468; Eng. Pat. 28090 of 1897).

(ix.) 2 : 6-**Dihydroxynaphthalene** is obtained by fusing sodium naphthalene-2 : 6-disulphonate (*cf.* Dusart, Compt. rend. 1867, 64, 859; Darmstaedter and Wichelhaus, Annalen, 1869, 152, 306; Armstrong and Graham, Chem. Soc. Trans. 1881, 39, 140), *or* sodium β-naphthol-6-sulphonate (Armstrong and Graham, *l.c.*; Emmert, Annalen, 1887, 241, 369) with caustic potash.

Identification.—It forms rhomb-like scales, m.p. 218° (Willstätter and Parnas, Ber. 1907, 40, 1410), dissolves only sparingly in water (1 litre at 14° dissolves 1·08 grm.) or light petroleum, shows strong blue fluorescence in alkaline solution, gives with ferric chloride a yellowish-white precipitate, and has a strong caustic effect on the skin. The *diacetate* forms scales, m.p. 175° (Emmert, *l.c.*); the *dimethyl ether*, rhomb-like scales, m.p. 150° (Willstätter and Parnas, *l.c.*); the *diethyl ether* scales, m.p. 162° (Emmert, *l.c.*).

Reactions.—(1) In boiling benzene solution with lead peroxide, it is oxidised to 2 : 6-*naphthaquinone* (Willstätter and Parnas, *l.c.*).

(2) With nitrous acid it gives the 1-*nitroso*-derivative (Bayer, D. R.-P. 55126, 59268 of 1890; Eng. Pat. 14230 of 1889).

(3) When heated with ammonia under pressure at 150°–300°, it yields 2 : 6-*diaminonaphthalene* (Ewer and Pick, D. R.-P. 45788 of 1887), and with aniline at 170°, it forms *diphenyl*-2 : 6-*diaminonaphthalene* (Leonhardt, D. R.-P. 54087 of 1889; Eng. Pat. 3098 of 1890).

(4) With monohydrate at 5°, it is converted into an acid which Bayer & Co. consider to be the 4-monosulphonic acid (D. R.-P. 72222 of 1893), but Jacchia, the 1 : 5-disulphonic acid (Annalen, 1902, 323, 114); with sulphuric acid at 100° it gives a *disulphonic acid* (Griess, Ber. 1880, 13, 1959).

(5) It couples in acetic acid (Kehrmann, Ber. 1907, 40, 1962) or in alkaline solution (Bayer, D. R.-P. 164317; Eng. Pat. 18569 of 1902), furnishing 1-*monoazo*- dyes (*cf.* Höchst, D. R.-P. 86937 of 1894; Kaufler and Bräuer, Ber. 1907, 40, 3276).

(x.) 2 : 7-**Dihydroxynaphthalene** is formed when sodium naphthalene-2 : 7-disulphonate is fused with caustic soda at 290°–300° (Ebert and Merz, Ber. 1876, 9, 609; Weber, *ibid.* 1881, 14, 2206); *or* when β-naphthol-7-sulphonic acid is fused with caustic soda (Pfitzinger and Duisberg, *ibid.* 1889, 22, 398). It is also formed when 2 : 7-dihydroxynaphthalene-3 : 6-disulphonic acid is heated with 20 p.c. sulphuric acid at 200° (Bayer, D. P. Anm. F. 7243; Eng. Pat. 25074A of 1893).

Identification.—It forms needles, m.p. 190° (Clausius, Ber. 1890, 23, 520), dissolves readily in hot water, but only sparingly in benzene, and gives no colouration with ferric chloride, but blackens rapidly in alkaline solution. The *diacetate* forms scales, m.p. 136° (Clausius, *l.c.*); the *dimethyl ether*, scales, m.p. 134° (Weber, *l.c.*); and the *diethyl ether*, scales, m.p. 104° (Liebermann and Hagen, Ber. 1882, 15, 1428).

Reactions.—(1) With nitrous acid it yields the 1-*nitroso*- derivative (Leonhardt, D. R.-P.

55204; Eng. Pat. 17223 of 1889; Clausius, *l.c.*; Kaufler and Bräuer, Ber. 1907, 40, 3275; *cf.* Read, Holliday & Co., D. R.-P. 68809; Eng. Pat. 1812 of 1890), which with iron salts gives a *naphthol green* (Leonhardt, D. R.-P. 58611 of 1889).

(2) When heated with sulphuric acid at 100° it forms 2 : 7-*dihydroxynaphthalene*-3 : 6-*disulphonic acid* (Bayer, D. P. Anm. F. 7243; Eng. Pat. 25074A of 1893; *cf.* Weber, *l.c.*; Aktienges., D. R.-P. 75142; Eng. Pat. 16199 of 1893).

(3) It gives 2 : 7-*diaminonaphthalene* when heated with ammonia under pressure at 150°–300° (Ewer and Pick, D. R.-P. 45788 of 1887), or boiled with ammonium sulphite solution and ammonia (Franzen and Deibel, J. pr. Chem. 1908, [ii.] 78, 155); *phenyl*-7-*amino*-β-*naphthol* with aniline at 190° (Kalle, D. R.-P. 60103 of 1891); and the corresponding *diaryl*-2 : 7-*diaminonaphthalenes* with arylamines (aniline, &c.), and either their hydrochlorides at 140°–150° (Durand and Huguenin, D. R.-P. 40886; Annaheim, Eng. Pat. 14283 of 1886; Ber. 1887, 20, 1372), or calcium chloride at 280°–290° (Clausius, *l.c.*).

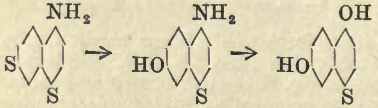
(4) It couples in alkaline solution with diazotised bases giving 1-*monoazo*- (Kaufler and Bräuer, *l.c.*; Erdmann and Borgmann, D. R.-P. 78409 of 1893; *cf.* Bayer, D. R.-P. 164318; Eng. Pat. 18569 of 1902), or 1 : 8-*disazo*- dyes (Cassella, D. R.-P. 108166; Eng. Pat. 9502 of 1899).

Dihydroxynaphthalenesulphonic Acids.

Introductory. — Dihydroxynaphthalenesulphonic acids are seldom obtained by direct sulphonation, and for their preparation recourse is had usually to α- or β-naphtholdi- or trisulphonic acids, or to α-naphthylaminedi- or trisulphonic acids. The exchange of the SO_3H, or of the NH_2 and SO_3H radicles, for OH in these acids is effected by fusion with 60–75 p.c. caustic alkali solution at high temperatures (180°–230°), with results which can be summarised thus:

(1) From *α-naphtholsulphonic acids*, the sulphonic group in the 8- position is the most easily displaced, then that in 5, but that in 2 or 4 resists displacement. From *β-naphtholsulphonic acids*, the sulphonic group in the 4-, 5-, or 8- position is easily displaced, but that in 1 or 6 resists displacement.

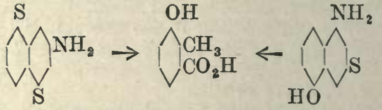
(2) With *α-naphthylaminesulphonic acids*, the order of replaceability of the SO_3H radicle by OH follows closely that observed with α-naphtholsulphonic acids. The resistance of a 4-sulphonic group to displacement by OH is displayed, for example, in the products obtained successively from α-naphthylamine-4 : 6-disulphonic acid by fusion with caustic alkali—



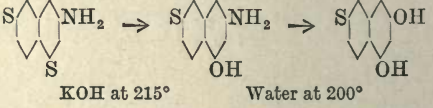
The exchange of the NH_2 radicle for OH in these acids is effected most readily when a sulphonic group is present in the 3-, 4-, or 5- position.

With β-naphthylaminesulphonic acids, the 4- or 5-sulphonic group is more easily displaced than that in the 8- position, otherwise the order of replaceability agrees with that experienced with the β-naphtholsulphonic acids. But the NH_2 radicle is not displaced by OH in the alkali fusion, and 2-aminonaphtholsulphonic acids, therefore, are the final products under ordinary conditions.

To these rules an important exception exists. Reactions which might be expected to produce 1 : 3-dihydroxynaphthalenesulphonic acids in the alkali fusion, lead almost invariably to decomposition with the formation of hydroxytoluic acids (*cf.* Kalle, D. R.-P. 91201 of 1893; Eng. Pat. 16559 of 1894; Höchst, D. R.-P. 81281; 81333 of 1893):



Turning to aminonaphtholsulphonic acids as sources of dihydroxynaphthalenesulphonic acids, those containing an α-amino- group exchange it for OH when heated with water or dilute (5 p.c.) mineral acid under pressure. With β-aminonaphtholsulphonic acids (except 2-amino-3-naphthol-6-sulphonic acid), the exchange takes place only when one of the other constituents, usually the OH radicle, is present in the 4- position.



Apart from these methods, dihydroxynaphthalenesulphonic acids have been obtained, but only in a few instances, from aminonaphtholsulphonic acids by the bisulphite method, and from [α-] or [β-]naphthaquinonesulphonic acids by reduction.

The dihydroxynaphthalenesulphonic acids and their alkali salts are easily soluble in water, the solutions when alkaline usually exhibiting fluorescence. When heated with dilute mineral acids above 200° many of them furnish the corresponding dihydroxynaphthalenes. They give colour reactions with ferric chloride and bleaching powder solutions, being characterised mainly by these and by the azo-dyes produced by coupling with certain diazotised bases. Summaries of the properties of many of the mono- and di-sulphonic acids may be found in the Patent literature (*cf.* Bayer, D. R.-P. 85241 of 1895; and 79054 of 1893 respectively).

Azo- dyes. For the production of azo- dyes, the most valuable of these products are the 1 : 8-dihydroxynaphthalene-4-monosulphonic, and the 2 : 4-, and 3 : 6-disulphonic acids, owing to the fact that the azo- dyes derived from them form lakes with chromium (aluminium or iron) mordants (*cf.* Höchst, D. R.-P. 67563 of 1890). As illustrating the resemblance between the properties of the 1 : 8- and the *ortho*- position, it may be noted that, in this series, the azo-dyes which furnish lakes are derived exclusively from the 1 : 2-, 2 : 3-, and 1 : 8- dihydroxynaphthalenesulphonic acids (*cf.* for 1 : 2-, Witt, D. R.-P. 49872 of 1889; for 2 : 3-, Bayer, D. R.-P. 82774 of 1893). The azo- dyes obtained from 1 : 3-dihydroxynaphthalenesulphonic acid are remarkable for their yellow shade (*cf.* Bayer, D. R.-P. 78877 of 1893; Eng. Pat. 3032 of 1894).

Azines. Use has been made of 1 : 2-dihydroxynaphthalenesulphonic acids for the preparation of *thiazines* (*cf.* Bayer, D. R.-P. 84232; Eng. Pat. 825 of 1893; D. R.-P. 84233; Eng. Pat. 4757 of 1893; D. R.-P. 87900; 87899; Eng. Pat. 8093 of 1893; Aktienges., D. R.-P. 83269; Eng. Pat. 23311 of 1893), and of *oxazines* (*cf.* Bayer, D. R.-P. 77120; Eng. Pat. 8093 of 1893; D. R.-P. 80744; Eng. Pat. 5056 of 1894; Dahl, D. R.-P. 84850; Eng. Pat. 5153 of 1895).

Dihydroxynaphthalenemonosulphonic Acids.

Constitution.	Preparation.	Acids, Salts and Reactions.
O : O : S		
1 : 2 : 4	(1) Reduction of [β-]-naphthaquinone-4-sulphonic acid with sulphurous acid (Witt and Kaufmann, Ber. 1891, 24, 3163) (2) Action of sodium bisulphite solution on [β-]naphthaquinone (Bayer, D. R.-P. 70867 of 1892; Eng. Pat. 825 of 1893).	*Sodium* salt, readily soluble needles; *potassium* salt sparingly soluble prisms. Does not couple with diazotised bases (*cf.* Bayer, D. R.-P. 85241 of 1895). Alkaline solution turns red on exposure to air forming 2-hydroxy-[α-]naphthaquinone.
1 : 2 : 6	Reduction of [β-]-naphthaquinone-6-sulphonic acid with sulphurous acid (Witt, Ber. 1891, 24, 3154; D. R.-P. 50506 of 1889; Paul, *cf.* J. Soc. Chem. Ind. 1897, 21, 733).	*Ammonium* salt NH_4A, readily soluble leaflets. Couples with diazotised bases, forming *azo*-dyes, which give lakes with chromium and other oxides (Witt, *l.c.*; D. R.-P. 49872 of 1889).
1 : 2 : 5 1 : 2 : 7 1 : 2 : 8	These acids obtained by reduction of the corresponding [β-]-naphthaquinonesulphonic acids (Witt, Ber. 1891, 24, 3157).	No description published.
1 : 3 : 5	2-Amino-4-naphthol-8-sulphonic acid heated with water under pressure at 180°–200° (Bayer, D. R.-P. 85241; Eng. Pat. 3580 of 1895).	*Alkali* salts form yellow solutions which show green fluorescence. Gives dirty green col. with ferric chloride. Couples with diazotised bases.
1 : 3 : 6	(1) 1-Amino-3-naphthol-6-sulphonic acid heated with water under pressure at 120° (Friedlaender and Rüdt, Ber. 1896, 29, 1613). (2) 2-Amino-4-naphthol-7-sulphonic acid heated with water under pressure at 200° (Bayer, D. P. Anm. F. 7978; Eng. Pat. 25214 of 1894.	*Alkali* salts very soluble, show green fluorescence in alkaline solution; *barium* salt, BaA_2, readily soluble needles (Friedlaender and Rüdt, *l.c.*). Couples with diazotised bases, forming *azo*-dyes (*cf.* Bayer, D. R.-P. 84991; Eng. Pat. 3580 of 1895).
1 : 3 : 7	1:3-Dihydroxynaphthalene-5:7-disulphonic acid heated with 5 p.c. sulphuric acid under pressure at 210° (Bayer, D. R.-P. 90878 of 1895).	*Alkali* salts give yellow solutions which show intense green fluorescence. Gives bluish-black col. with ferric chloride. Couples with diazotised bases, giving *azo*-dyes (*cf.* Bayer, D. R.-P. 86100; Eng. Pat. 4962 of 1895).
1 : 5 : 2 C-acid	(1) Together with the 4-acid, when 1:5-dihydroxynaphthalene is warmed with sulphuric acid at 50°–60° (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 235; *cf.* Ewer and Pick, D. R.-P. 41934 of 1887). (2) *a*-Naphthol-2 : 5-disulphonic acid heated with 60 p.c. caustic soda at 250° (Bayer, D. R.-P. 68344 of 1889; Eng. Pat. 3397 of 1890).	*Acid sodium* salt, readily soluble leaflets; the alkaline solutions show blue fluorescence. Gives bluish-green colouration with ferric chloride. Couples with diazotised bases forming *azo*-dyes (*cf.* Bayer, *l.c.*).
1 : 5 : 3	Naphthalene-1 : 3 : 5-trisulphonic acid fused with caustic alkali (Bayer, D. R.-P. 166768; Eng. Pat. 18569 of 1902).	Couples with diazotised bases forming *azo*-dyes (Bayer, *l.c.*).
1 : 5 : 4	Together with the 2-acid (*q.v.*), when 1:5-dihydroxynaphthalene is warmed with sulphuric acid at 50°–60°.	*Calcium* salt forms a sparingly soluble double salt with calcium sulphate. Couples with diazotised bases.
1 : 5 : 7	1-Amino-5-naphthol-7-sulphonic acid boiled with sodium bisulphite solution, and product decomposed by mineral acid (Bucherer and Uhlmann, J. pr. Chem. 1909, [ii.] 80, 238).	*Acid*, scales, crystallises with ½ mol. of alcohol. Couples with diazotised bases.
1 : 6 : 3	(1) Fusion of naphthalene-1:3:6-trisulphonic acid with 90 p.c. caustic soda at 250° (Aktienges., D. R.-P. 42261 of 1886; Bayer, D. R.-P. 63015 of 1891; *cf.* Kalle, D. R.-P. 89061 of 1894). (2) 1-Amino-6-naphthol-3-sulphonic acid heated with water under pressure at 200° (Cassella, D. P. Anm. C. 5020 of 1894; *cf.* Bayer, D. R.-P. 85241; Eng. Pat. 3580 of 1895). (3) 2-Amino-5-naphthol-7-sulphonic acid heated with 40 p.c. sodium bisulphite solution, and product decomposed by mineral acid (Badische, D. R.-P. 126136, 134401 of 1899; Bucherer, J. pr. Chem. 1904, [ii.] 69, 83).	*Sodium* salt, sparingly soluble, shows in alkaline solution reddish-blue fluorescence. Gives green colouration with ferric chloride. Forms a yellow easily soluble *nitroso*-compound (Cassella, *l.c.*). Couples with diazotised bases forming *azo*-dyes (Bayer, *l.c.*; Casella, *l.c.*).

Constitution.	Preparation.	Acids, Salts and Reactions.
0:0:S		
1:6:4	Fusion of α-naphthylamine-4:6-disulphonic acid (Dahl, D. R.-P. 57114 of 1889; Eng. Pat. 735 of 1890); *or* of α-chloronaphthalene-4:6-disulphonic acid with caustic soda at 210°–220° (Rudolph, D. R.-P. 104902 of 1898).	*Acid* and *acid sodium* salt, sparingly soluble leaflets; alkaline solutions show violet fluorescence. Forms a yellow sparingly soluble *nitroso*-derivative (Rudolph, *l.c.*). Gives green col. with ferric chloride (*ibid.*). Couples with diazotised bases (Dahl, *l.c.*).
1:7:3 G-acid	Fusion of β-naphthol-6:8-disulphonic acid with caustic soda at 220°–230° (Höchst, D. P. Anm. F. 4153; Eng. Pat. 9642 of 1889; *cf.* Bayer, D. R.-P. 85241 of 1895).	*Acid sodium* salt readily soluble needles; alkaline solutions show blue fluorescence. Gives green colouration with ferric chloride. Couples with diazotised bases.
1:7:4	(1) Fusion of 2-carboxy-α-naphthol-4:7-disulphonic acid with caustic alkali at 230°–290° (Bindschedler, D. R.-P. 81938 of 1893; Eng. Pat. 4629 of 1894). (2) 1:7-Dihydroxy-2-carboxynaphthalene-4-sulphonic acid heated with 30 p.c. caustic soda under pressure at 140°–160° (*ibid.*, D. R.-P. 83965 of 1895).	*Acid* and *acid salts* readily soluble; alkaline solutions show violet fluorescence. Gives green colouration with ferric chloride. Couples with diazotised bases.
1:8:2	1-Amino-8-naphthol-7-sulphonic acid heated with lime and water under pressure at 250° (Bayer, D. P. Anm. F. 7509 of 1894).	*Acid sodium* salt needles, shows reddish-violet fluorescence in solution. Gives green colouration with ferric chloride. Couples with diazotised bases.
1:8:3 ε-acid	(1) α-Naphthylamine-3:8-disulphonic acid heated with 35 p.c. caustic soda under pressure at 220°–250° (Höchst, D. P. Anm. F. 7112 of 1892). (2) Fusion of α-naphthol-3:8-disulphonic acid with caustic alkali, or, more easily, of α-naphthol-6:8-disulphonic acid with 50 p.c. caustic soda at 170°–210° (Kalle, D. R.-P. 82422 of 1894). (3) 1-Amino-8-naphthol-3:5-disulphonic acid heated with water at 200° (Leonhardt, D. P. Anm. F. 8626; Eng. Pat. 19253 of 1895; Cassella, D. R.-P. 108848 of 1895).	*Acid sodium* salt sparingly soluble needles; alkaline solutions show blue fluorescence (Kalle, *l.c.*). Gives green colouration with ferric chloride (Kalle, *l.c.*). Couples with diazotised bases (*cf.* Bayer, D. R.-P. 85241 of 1895).
1:8:4 S-acid.	(1) Fusion of the following with caustic alkali or caustic alkali solution: α-naphthol-4:8-disulphonic acid (Bayer, D. R.-P. 54116, 67829; Eng. Pat. 13665, 18517 of 1889), *or* α-naphthol-5:8-disulphonic acid, or its sultone (Bayer, D. R.-P. 80667 of 1892; Eng. Pat. 1227 of 1894); also of α-naphthylamine-4:8-disulphonic acid under pressure (Bayer, D. R.-P. 71836 of 1890), *or* α-naphthylamine-5:8-disulphonic acid (Bayer, D. R.-P. 77285 of 1892; Eng. Pat. 1227 of 1894); also of 1-amino-8-naphthol-4-sulphonic acid (Bayer, D. R.-P. 80315 of 1893), *or* 1-amino-8-naphthol-5-sulphonic acid (Bayer, D. R.-P. 75055; Eng. Pat. 15269 of 1893; Badische, D. R.-P. 80234; Eng. Pat. 18924 of 1893). (2) 1:8-Diaminonaphthalene-4-sulphonic acid heated with milk of lime under pressure at 230° (Cassella, D. R.-P. 75962 of 1893). (3) 1-Amino-8-naphthol-4-sulphonic acid (Bayer, D. R.-P. 109102 of 1899), or 5-sulphonic acid (Bucherer, J. pr. Chem. 1904, [ii.] 69, 86), heated with sodium bisulphite solution and product decomposed by caustic alkali.	*Acid* forms three series of salts, all easily soluble; *monosodium* salt, NaH_2A, silky leaflets; *disodium* salt, Na_2HA+2H_2O, leaflets; *monobarium* salt, BaH_4A_2, needles; *dibarium* salt, $BaHA+1\frac{1}{2}H_2O$ (Bayer, D. R.-P. 67829; Eng. Pat. 13665 of 1889). Basic salts (*trisodium*, etc.) show bluish-green fluorescence in solution. Gives dirty green precipitate with ferric chloride. Couples with diazotised bases, giving many valuable *azo*-dyes which have the property of forming lakes with chromium and other oxides (*cf.* Bayer, *l.c.*; D. R.-P. 61707 of 1889; 66693; Eng. Pat. 5984 of 1891). For *monoalkyl* derivatives and the *disazo*-dyes obtained by coupling them with diazotised bases, see Bayer, D. R.-P. 73741, 78937; Eng. Pat. 3495 of 1893.
2:3:6 R-acid.	Fusion of β-naphthol-3:6-disulphonic acid with caustic soda at 240°–280° (Badische, D. R.-P. 57525; Eng. Pat. 15803 of 1890; Höchst, D. P. Anm. F. 4153; Eng. Pat. 9642 of 1889; Friedlaender and Zakrzewski, Ber. 1894, 27, 762).	*Acid sodium* salt, sp. sol. leaflets, shows reddish-blue fluorescence in alkaline solution; *barium* salt, BaA_2, sp. sol. (*cf.* Bayer, D. R.-P. 85241 of 1895). Gives intense violet col. with ferric chloride (*ibid.*). Couples with diazotised bases, giving *azo*-dyes which form lakes with metallic oxides (*cf.* Bayer, D. R.-P. 82774 of 1893).
2:7:3[1] F-acid.	Fusion of β-naphthol-3:7-disulphonic acid with caustic alkali (*cf.* Aktienges., D. R.-P. 63956 of 1891; Bayer, D. R.-P. 85241 of 1895).	*Sodium* salt, sparingly soluble crystalline powder, shows bluish-violet fluorescence in solution (*cf.* Bayer, *l.c.*). Gives deep blue colouration with ferric chloride.

---

[1] The acid described as 2:6-dihydroxynaphthalene-4-sulphonic acid (Bayer, D. R.-P. 72222 of 1893) is considered by Jacchia (Annalen, 1902, 323, 131) to be a disulphonic acid.

Dihydroxynaphthalenedisulphonic Acids.

Constitution.	Preparation.	Acids, Salts and Reactions.
O:O:S:S		
1:2:3:6[1] and 1:2:6:8	(1) Acid sodium salt of 1-amino-2-naphthol-3:6-(resp. 6:8-)disulphonic acid boiled with water (Witt, Ber. 1888, 21, 3480; D. R.-P. 49857 of 1889). (2) Reduction of [β]-naphthaquinone-3:6-(resp. 6:8-)disulphonic acid with sulphurous acid (Witt, Ber. 1891, 24, 3157).	*Acid sodium* salts readily soluble leaflets; decompose very rapidly in alkaline solution (*cf.* Bayer, D. R.-P. 79054 of 1893). Do not couple with diazotised bases (Bayer, *l.c.*; *cf.* Witt, Ber. 1891, 24, 3156). Precipitate gelatin or basic aniline dyes from solution (*naphthotannins*) (*cf.* Witt, D. R.-P. 49857 of 1889).
1:3:5:7 "Yellow" acid.	(1) Mixed with 30 p.c. of "red"-acid, by heating naphthalene-1:3:5:7:tetrasulphonic acid *or* α-naphthol-3:5:7-trisulphonic acid with 60 p.c. caustic soda under pressure at 180°–200° (Bayer, D. R.-P. 79054; Eng. Pat. 25074 of 1893). (2) 2-Amino-4-naphthol-6:8-disulphonic acid heated with water under pressure at 210°–220° (Bayer, D. R.-P. 89242; D. P. Anm. F. 8154 of 1895).	*Sodium* salt, readily soluble; *potassium* salt, leaflets; alkaline solutions show green fluorescence; *barium* salt, BaA, moderately soluble needles (Friedlaender and Rüdt, Ber. 1896, 29, 1613). Gives blue colouration with ferric chloride. Couples in alkaline solution with diazotised bases, giving *azo*-dyes of yellow shade (*cf.* Bayer, D. R.-P. 78877 of 1893; Eng. Pat. 3032 of 1894).
1:5:3:7 "Red" acid.	(1) α-Naphthol-3:5:7-trisulphonic acid heated with 50 p.c. caustic soda at 150°–160° (Kalle, D. P. Anm. K. 12732 of 1895). (2) Mixed with 70 p.c. of yellow acid (*q.v.*), from naphthalene-1:3:5:7-tetrasulphonic acid.	*Potassium* and *sodium* salts readily soluble needles; in alkaline solution shows bluish-violet fluorescence (Bayer, D. R.-P. 79054 of 1893). Gives bluish-green col. with ferric chloride. Couples in acid or alkaline solution (*cf.* Bayer, *l.c.*) with 1 or 2 mols. (*cf.* Kalle, *l.c.*) of diazotised bases, giving *azo*-dyes.
1:5:(2):(4)	1:5-Dihydroxynaphthalene sulphonated with sulphuric acid at 100°–160° or with anhydro-acid in the cold (Ewer and Pick, D. R.-P. 41934 of 1887).	No description published, but acid said to couple with diazotised bases (Ewer and Pick, *l.c.*; *cf.* 2- and 4-monosulphonic acids).
1:(7):(2):(4)	Fusion of α-naphthol-2:4:7-trisulphonic acid with caustic alkali (*cf.* Höchst, D. R.-P. 67426; Eng. Pat. 18783 of 1891).	No description published.
1:7:3:6 A-acid	Mixed with 30 p.c. of the 2:3:6:8-acid (B-acid), by fusion of β-naphthol-3:6:8-trisulphonic acid with caustic alkali under pressure at 230°–240° (Höchst, D. P. Anm. F. 4154; Eng. Pat. 9642 of 1889; D. R.-P. 67563 of 1890; *cf.* Friedlaender and Silberstern, Monatsh. 1902, 23, 527).	*Sodium* salt, Na_2A, sparingly soluble needles; alkaline solutions show bluish-green fluorescence. Forms a dark blue precipitate with formaldehyde and hydrochloric acid (Friedlaender and Silberstern, *l.c.*). Gives fleeting blue col. with ferric chloride (*ibid.*). Couples with diazotised bases (Höchst, *l.c.*).
1:8:2:4 S-acid	(1) 1-Amino-8-naphthol- or naphthasultam-2:4-disulphonic acid heated with 80 p.c. caustic soda solution above 180° (Bayer, D. R.-P. 79566, 80668; Eng. Pat. 4979 of 1893; Cassella, D. R.-P. 81282; of 1893; Dressel and Kothe, Ber. 1894, 27, 2142). (2) 1-Amino-8-naphthol-5:7-disulphonic acid heated with dilute caustic soda solution above 250° (Badische, D. P. Anm. B. 16142; Eng. Pat. 18924 of 1893). (3) Fusion of α-naphthol-2:4:8-trisulphonic acid with caustic alkali at 210° (Bayer, D. R.-P. 57021; Eng. Pat. 3397 of 1890; Dressel and Kothe, Ber. 1894, 27, 2144).	*Disodium* salt readily soluble needles, showing faint blue fluorescence in solution; *trisodium* salt, $Na_3HA + 4H_2O$, readily soluble prisms, formed in alkaline solution, shows greenish fluorescence (Dressel and Kothe, *l.c.*). Forms an orange soluble *mononitroso*-compound (Cassella, *l.c.*; Dressel and Kothe, *l.c.*). Gives green colouration with ferric chloride (*cf.* Badische, *l.c.*). Couples with diazotised bases (Badische, *l.c.*). In acid solution with dichromate gives black dye on wool (Cassella, *l.c.*).
1:8:3:5 K-acid	(1) Fusion of α-naphthol-4:6:8-trisulphonic acid with 70 p.c. caustic soda solution under pressure at 170°–190° (Bayer, D. P. Anm. F. 7004; Eng. Pat. 17141c 1893; *cf.* Kalle, Eng. Pat. 1641 of 1894). (2) 1-Amino-8-naphthol-3:5-disulphonic acid heated with 7 p.c. caustic soda solution under pressure at 240° (Leonhardt, D. P. Anm. F. 8682; Eng. Pat. 21919 of 1895; Cassella, D. R.-P. 108848 of 1895). (3) 1-Amino-8-naphthol-4:6-disulphonic acid heated with 70 p.c. caustic alkali solution above 240° (Bayer, D. R.-P. 80741; Eng. Pat. 17141c of 1893).	*Disodium* salt readily soluble needles; solutions of *acid salts* show faint blue fluorescence (*cf.* Bayer, D. R.-P. 79054 of 1893). Forms a yellow readily soluble *nitroso*- derivative. Gives green colouration with ferric chloride (Bayer, *l.c.*). Couples with diazotised bases (Bayer, D. P. Anm. F. 7004; Eng. Pat. 17141c of 1803).
1:8:3:6 Chromotrope acid	(1) α-Naphthol-3:6:8-trisulphonic acid or its sultone heated with 60 p.c. caustic soda at 170°–220° (Höchst, D. R.-P. 67563 of 1890). (2) 1-Amino-8-naphthol-3:6-disulphonic acid heated with 5 p.c. caustic soda under pressure at 265° (Bayer, D. R.-P. 68721 of 1891; Eng. Pat. 11522 of 1892).	*Acid* forms four series of salts, two strongly acid, one neutral, one basic. *Disodium* salt, $Na_2H_2A + 2H_2O$, readily soluble in water, and acid towards sodium carbonate; alkaline solutions show violet-blue fluorescence. *Barium* salt, $BaH_2A + 3H_2O$, small leaflets, which in solution with sodium carbonate yields the *sodium barium* salt, $BaNaHA + 3H_2O$, in needles (Höchst, *l.c.*).

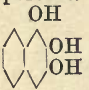
---

[1] The 1:2-dihydroxynaphthalene-3:6-disulphonic acid is also formed when 1:2-diaminonaphthalene-3:6-disulphonic acid is heated with dilute mineral acids (*cf.* Cassella, D. R.-P. 72584 of 1892).

Constitution.	Preparation.	Acids, Salts and Reactions.
O : O : S : S 1 : 8 : 3 : 6 (*contd.*)	(3) 1:8-Diaminonaphthalene-3:6-disulphonic acid heated with 5 p.c. caustic soda under pressure at 260°–280° (Bayer, D. R.-P. 69190 of 1891; Eng. Pat. 11522 of 1892), or with dilute mineral acids or water under pressure at 150°–160° (Cassella, D. R.-P. 75153 of 1892). (4) 8-Chloro-α-naphthol - 3 : 6 - disulphonic acid fused with caustic alkali (Badische, D. R.-P. 147852 of 1903).	Gives grass-green col. with ferric chloride (*ibid.*). Couples with 1 or 2 mols. of diazotised bases, forming ortho-*azo*- dyes (Hantower and Täuber, Ber. 1898, 31, 2156), and forms lakes, which give scarlet, claret, violet, or bluish-black shades (Höchst, *l.c.*). Is extensively used in the production of mordant *azo*-dyes. In acid solution with dichromate gives brown dye on wool (Höchst, D. R.-P. 77552 of 1891). For *chloro*-derivative and derived *azo*-dyes, see Höchst, D. R.-P. 153195 of 1903.
1 : 8 : ? : ? I-acid 1 : 8 : ? : ? G-acid 1 : 8 : ? : ? R-acid	1 : 8-Dihydroxynaphthalene sulphonated with sulphuric acid at 50° and the respective products separated by means of their barium salts of which that of I-acid is least and of R-acid most soluble (Badische, Eng. Pat. 14294 of 1891; *ibid.* D. R.-P. 79029, 79030 of 1891).	*Sodium* salts very readily soluble, show blue fluorescence in alkaline solution. Give green colourations with ferric chloride. Couple with diazotised bases, forming *azo*-dyes, which, if from I-acid are worthless, but from G-acid valuable (*cf.* Bayer, D. R.-P. 79054 of 1893).
2 : 3 : 6 : 8 B-acid	Mixed with the 1 : 7 : 3 : 6-acid, by fusion of β-naphthol-3 : 6 : 8-trisulphonic acid with caustic alkali (Höchst, D. R.-P. 67563 of 1890; *cf.* Friedlaender and Silberstern, Monatsh., 1902, 23 527).	*Sodium* salt, $Na_2A+3\frac{1}{2}H_2O$, easily soluble needles, shows bluish-violet fluorescence in alkaline solution; *barium* salt BaA, sp. sol. needles. Gives violet col. with ferric chloride, and does not form a precipitate with formaldehyde and hydrochloric acid (Friedlaender and Silberstern, *l.c.*). Couples with diazotised bases (*ibid.*).
2 : 7 : 3 : 6	(1) 2:7-Dihydroxynaphthalene heated with sulphuric acid at 100° (Aktienges., D. R.-P. 75142; Eng. Pat. 16199 of 1893; *cf.* Weber, Ber. 1881, 14, 2208). (2) β-Naphthol-3 : 6 : 7 : trisulphonic acid heated with 66 p.c. caustic soda solution under pressure at 220°–300° (Bayer, D. P. Anm. F. 7243; Eng. Pat. 25074A of 1893).	*Acid sodium* salt moderately soluble; *potassium* salt, large needles; *barium* salt, almost insoluble; salts show bluish-green fluorescence in alkaline solution (*cf.* Bayer, D. R.-P. 79054 of 1893). Forms a sp. soluble orange *nitroso*- compound. Gives deep-blue col. with ferric chloride. Couples in alkaline solution with 1 mol. of diazotised bases (Bayer, D. P. Anm. F. 7243 of 1893).

TRIHYDROXYNAPHTHALENES.

Introductory.—The trihydroxynaphthalenes have little technical interest. The methods available for their production are fusion of sulphonic acids with caustic alkali, and reduction of hydroxynaphthaquinones, but the number of isomerides they can give is limited by the small number of acids or quinones available. Only five of the fourteen isomeric trihydroxynaphthalenes have been isolated and characterised, but sulphonic acids of two others are known. The azo- dyes obtained from those that couple with diazotised bases are unimportant.



(i.) 1 : 2 : 3-**Trihydroxynaphthalene** (*Naphthapyrogallol*), obtained by boiling *iso*naphthazarin with zinc and dilute sulphuric acid (Zincke and Ossenbeck, Annalen, 1899, 307, 18), is crystalline, and gives a *triacetate*, in prisms, m.p. 250°–255° (Zincke and Noack, *ibid.* 1897, 295, 19).

(ii.) 1 : 2 : 4-**Trihydroxynaphthalene**, formed by reduction of hydroxy-[α-]naphthaquinone with tin and hydrochloric acid (Graebe and Ludwig, Annalen, 1870, 154, 324); *or* by hydrolysis of the triacetate with alcoholic hydrogen chloride (Thiele and Winter, *ibid.* 1900, 311, 346; Bayer, D. R.-P. 101607 of 1897; Eng. Pat. 10590 of 1898), crystallises in needles, m.p. 154°, and in alkaline solution absorbs oxygen giving *hydroxy*-[α-]*naphthaquinone*.

The *triacetate*, obtained by heating [α-] or [β-]naphthaquinone and acetic anhydride with a small quantity of sulphuric acid (Bayer, *l.c.*; Thiele and Winter, *l.c.*) or phosphoric acid (Bayer, D. R.-P. 107508 of 1898; Eng. Pat. *l.c.*) at 30°–40°, or zinc chloride at 50°–60° (Thiele and Winter, *l.c.*), crystallises in needles, m.p. 134°–135°.

(iii.) 1 : 3 : 5-Trihydroxynaphthalene, unknown. The **7-sulphonic acid** is formed when naphthalene-1 : 3 : 5 : 7-tetrasulphonic acid (*or* the α-naphthol-3 : 5 : 7-trisulphonic acid *or* the 1 : 3- or 1 : 5-dihydroxynaphthalenedisulphonic acid obtainable from it) is fused with caustic potash at 280° (Bayer, D. R.-P. 80464; Eng. Pat. 19624 of 1893). Its *potassium* salt separates in needles, and couples with 1 or 2 mols. of a diazotised base, forming *azo*- dyes (Bayer, D. R.-P. 87583 of 1893; Eng. Pat. 1229 of 1894).

(iv.) 1 : 3 : 6-**Trihydroxynaphthalene**,[1] obtained by fusing 1 : 6-dihydroxynaphthalene-3-sulphonic acid with caustic soda at 250°–270° (Kalle, D. R.-P. 112176 of 1899; Meyer and Hartmann, Ber. 1905, 38, 3950), forms doubly refracting crystals, m.p. 95°; a *hydrochloride* in yellow needles; and a *triacetate*, needles, m.p. 112°–113°. It couples with diazotised bases forming *azo*- dyes.

(v.) 1 : 3 : 8-Trihydroxynaphthalene, unknown. The **6-sulphonic acid**, obtained by fusing α-naphthol-3 : 6 : 8-trisulphonic acid, or 1 : 8 - dihydroxynaphthalene - 3 : 6 - disulphonic acid with caustic potash at 310°–320° (Bayer, D. R.-P. 78604; Eng. Pat. 17141C of 1893), forms easily soluble alkali salts, which show greenish-blue fluorescence in solution, and couple with 1 or 2 mols. of a diazotised base forming *azo*- dyes.

---

[1] A polymeride $C_{20}H_{10}(OH)_6$, possibly a dinaphthyl derivative, of which the *hexa-acetate* in scales, m.p. 200°, is formed by boiling the aqueous solution of this trihydroxynaphthalene (Kalle, *l.c.*; Meyer and Hartmann, *l.c.*).

(vi.) 1 : 4 : 5-**Trihydroxynaphthalene** ([α-]*hydrojuglone*; *cf.* Bernthsen and Semper, Ber. 1887, 20, 941), mixed with about one-fifth the amount of [β-]hydrojuglone,[1] is present in the unripe shells of the walnut (Mylius, *ibid.* 1884, 17, 2412); the same compounds also occur in the ripe shells, and in about the same proportion, but differently combined, as they cannot be extracted by ether (Mylius, *ibid.* 1885, 18, 2568, footnote). It crystallises in scales or needles, m.p. 168°–170°; with ferric chloride gives *juglone;* and with acetic anhydride yields the *triacetate* of [β-]hydrojuglone, which forms prisms, m.p. 129°–130°.

(vii.) 1 : 6 : 7-**Trihydroxynaphthalene,** obtained when 1 : 6 : 7-trihydroxynaphthalene-3-sulphonic acid is heated with water or 5 p.c. sulphuric acid under pressure at 210°–220° (Cassella, D. R.-P. 112098; Eng. Pat. 27345 of 1898; Friedlaender and Silberstern, Monatsh. 1902, 23, 530), forms needles, m.p. 175°; its *triacetate,* needles, m.p. 143°–144°; and *trimethyl ether,* prisms, m.p. 127°–128°. It couples in the 4- position with 1 mol. of a diazotised base giving *azo-* dyes which form lakes with chromium or iron salts (Cassella, D. R.-P. 110618; Eng. Pat. *l.c.*; D. R.-P. 110904 of 1899).

The 3-sulphonic acid, prepared from β-naphthol-3 : 6 : 8-trisulphonic acid by fusion with caustic alkali (*cf.* Höchst, D. R.-P. 67426; Eng. Pat. 18783 of 1891) at 240°–250° (Friedlaender and Silberstern, *l.c.* 529), gives a *sodium* salt in sparingly soluble needles, a *barium* salt BaA$_2$ in sparingly soluble leaflets, and couples with diazotised bases forming *azo-* dyes (Höchst, *l.c.*).

AMINODIHYDROXYNAPHTHALENES.

The aminodihydroxynaphthalenes are of interest chiefly in relation to hydroxynaphthaquinoneoximes (nitrosodihydroxynaphthalenes) and have no technical value. Little is known about them, the hydrochloride and triacetyl derivative being almost the only definite substances isolated in each case.

N : O : O	[$NH_2 \cdot C_{10}H_5(OH)_2$]
1 : 2 : 3	Decomp. 230° (Friedlaender and Silberstern, Monatsh. 1902, 23, 521).
1 : 2 : 4[2] [4 : 1 : 3]	Not isolated. *Triacetyl* derivative, tablets, m.p. 155°–156° (Kehrmann and Mascioni, Ber. 1895, 28, 351; Kehrmann and Hertz, *ibid.* 1896, 29, 1419).
1 : 2 : 6	Not isolated. Obtained by reduction of azo-derivative of 2 : 6-dihydroxynaphthalene (Kehrmann and Sabo, Ber. 1907, 40, 1962).
1 : 2 : 7	Not isolated. Obtained by reduction of nitroso-2 : 7-dihydroxynaphthalene. *Triacetyl* derivative, m.p. 183° (Clausius, Ber. 1890, 23, 521; Nietzki and Knapp, *ibid.* 1897, 30, 1123).
1 : 3 : 4 [4 : 1 : 2]	Not isolated. *Triacetyl* derivative, prisms, m.p. 193° (Kehrmann, Ber. 1894, 27, 3340).
1 : 5 : 8 [5 : 1 : 4]	Not isolated. *Triacetyl* derivative, needles, m.p. 165° (Graebe, Ber. 1899, 32, 2878; Graebe and Oeser, Annalen, 1904, 335, 149).
N : O : O	[$NH_2 \cdot C_{10}H_5(OH)_2$]
1 : (6) : 8 [8 : 1 : (3)]	Unknown. The (6)-sulphonic acid, obtained by fusing 1-amino-8-naphthol-3 : 6-disulphonic acid (H-acid) with 60 p.c. caustic soda solution at 210°, is diazotisable (Bayer, D. R.-P. 75097 of 1891). The alkali salts show greenish blue fluorescence in solution.
2 : 1 : 4	Not isolated. *Triacetyl* derivative, needles, m.p. 259°–260° (Kehrmann, Ber. 1894, 27, 3343).
2 : 3 : 4 [3 : 1 : 2]	Needles, m.p. 164°. *Triacetyl* derivative, needles, decomp. above 200° (Korn, Ber. 1884, 17, 907; Zincke and Noack, Annalen, 1897, 295, 13); N-*acetyl* derivative, decomp. 170° (Kehrmann and Zimmerli, Ber. 1898, 31, 2405).
2 : (3) : 8 [7 : 1 : (6)]	Unknown. The (6)-sulphonic acid, obtained by fusing 2-amino-8-naphthol-3 : 6-disulphonic acid with caustic alkali at 240°–280°, forms sparingly soluble needles, and is diazotisable, (Höchst, D. R.-P. 53023; Eng. Pat. 15175 of 1889). The alkali salts show bluish-violet fluorescence in solution.

TETRAHYDROXYNAPHTHALENES.

1 : 2 : 3 : 4-**Tetrahydroxynaphthalene** (*leuco-*iso*naphthazarin*), obtained from *iso*naphthazarin by reduction, forms easily soluble scales, and its *tetra-acetyl* derivative, needles, m.p. 220°. It is readily oxidised to *iso*naphthazarin, and reduced to 1 : 2 : 3-*trihydroxynaphthalene* (Zincke and Ossenbeck, Annalen, 1899, 307, 16).

1 : 2 : 5 : 8-**Tetrahydroxynaphthalene** (*leuco-naphthazarin*) is obtained when naphthazarin is boiled with alcohol, stannous chloride, and hydrochloric acid (Zincke and Schmidt, Annalen, 1895, 286, 37); or when a boiling aqueous solution of 'naphthazarin melt' is reduced by iron (Badische, D. R.-P. 129074; Eng. Pat. 23887 of 1900). It forms needles, m.p. 154°, and its *tetra-acetyl* derivative, minute prisms, m.p. 277°–279° (Schunck and Marchlewski, Ber. 1894, 27, 3463; Zincke and Schmidt, *l.c.*; Liebermann, Ber. 1895, 28, 1457). It is readily oxidised to naphthazarin, and is a substantive dye which when oxidised with chromic acid on the fibre gives black shades (Badische, *l.c.*).

DIAMINODIHYDROXYNAPHTHALENES.

Several diaminodihydroxynaphthalenes have been described, but only those which furnish clues to the constitution of disazo- dyes obtained from dihydroxynaphthalenes need be mentioned here.

1 : 4-Diamino-2 : 3-dihydroxynaphthalene, obtained by reduction of disazo-dye from 2 : 3-dihydroxynaphthalene, forms *sulphate,* $B \cdot H_2SO_4$, leaflets, turning blue on oxidation, and gives iso*naphthazarin* with ferric chloride (Friedlaender and Silberstern, Monatsh, 1902, 23, 524).

1 : 6-Diamino-4 : 5-dihydroxynaphthalene, obtained by reduction of disazo-dye from 1 : 8-dihydroxynaphthalene, is very rapidly oxidised to *naphthazarin* (*ibid.* 518).

1 : 8-Diamino-2 : 7-dihydroxynaphthalene, obtained by reduction of disazo-dye from 2 : 7-dihydroxynaphthalene, gives *sulphate,* needles, which forms blue solution in alkalis (Cassella, D. R.-P. 108166; Eng. Pat. 9502 of 1899).

IX. QUINONE DERIVATIVES.

Introductory.—From the formula of naphthallene the existence of three homo- and three hetero-nucleal quinones may be predicted. Two of the homonucleal naphthaquinones together with derivatives of the third (2 : 3-) are known,

---

[1] [β-]Hydrojuglone, the constitution of which is unknown, dissolves easily in chloroform, whereas [α-] hydrojuglone is insoluble in this solvent (Mylius, *l.c.*).

[2] An amino-1 : 3-dihydroxynaphthalene, m.p. 162°, which may have this constitution has been described by Zincke and Wiegand (Annalen, 1895, 286, 89); and a second, possibly the 2-amino-1 : 3- derivative, has been isolated by Friedlaender and Rüdt (Ber. 1896 29, 1611).

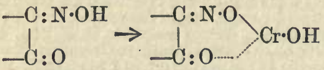
but only one of the heteronucleal compounds (2 : 6-) has been isolated.[1] A comparison shows that in physical properties 1 : 4- or [α-]naphthaquinone, but in chemical properties 2 : 6-naphthaquinone, most closely resembles ordinary *para*-benzoquinone, whereas 1 : 2- or [β-]naphthaquinone exhibits the general characters of an α- or *ortho*-diketone.

The naphthaquinones are coloured substances, and, with few exceptions, give rise to derivatives, which also are coloured, but only a small proportion of them are dyes. The 'tinctogenic' groups, which endow naphthaquinone derivatives with the property of forming coloured lakes, are associated with contiguous carbon atoms, *i.e.* are present relatively in the *ortho*-position. For quinones, these groups have been shown by Kostanecki (Ber. 1887, 20, 3147; 1889, 22, 1349) to be the following—

·C : O   ·C : N·OH   ·C : N·OH   ·C : N·OH
:C · OH   :C · OH   ·C : O   ·C : N·OH

To illustrate their effect, reference may be made to the following series of [α-]naphthaquinone derivatives in which I is not a dye, but II and III form coloured lakes with basic mordants—

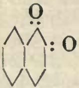
I. 
II. 
III. 
In the more recent discussion of the subject (*cf.* Tschugaeff, J. pr. Chem. 1907, [ii.] 76, 88; Werner, Ber. 1908, 41, 1062, 2383; Liebermann, *ibid.* 1436), the production of lakes by compounds of these types is referred to the formation of complex heterocyclic groups, in which the metallic base forms one component of the 5- or 6-membered ring. But cyclic structure is not of itself sufficient to develop colour with basic mordants, and in each tinctogenic complex there is present not only a salt-forming group, but a radicle, which by its 'subsidiary' valency can be linked with the metal. For example, [β-]naphthaquinoneoxime (1-nitroso-β-naphthol) is a dye, because in it, according to Tschugaeff and Werner, oxygen of the carbonyl group has residual valency, and through this residual or 'subsidiary' valency (shown in the formula by the dotted line) becomes linked to the basic radicle of the mordant:—



Oxime. Lake.

Naphthaquinonoximes, obtainable from the quinones by interaction with hydroxylamine, are usually made from the naphthols or from dihydroxynaphthalene derivatives by means of nitrous acid. As the chief interest attaching to these substances from the technical side lies in the colouring matters to which some of them give rise, they are described in this article as nitrosonaphthols, following the Patent literature, although classified as oximes.

Naphthaquinones.



(i.) 1 : 2-Naphthaquinone ([β-]naphthaquinone) is obtained by the oxidation of 1-amino-2-naphthol either with chromic acid mixture (Stenhouse and Groves, Chem. Soc. Trans. 1877, 32, 52; 1878, 33, 415; Liebermann and Jacobson, Annalen, 1882, 211, 49; Grandmougin and Michel, Ber. 1892, 25, 982; Paul, *cf.* J. Soc. Chem. Ind. 1897, 19, 733; Russig, J. pr. Chem. 1900, [ii.] 62, 56), or with ferric chloride (Groves, Chem. Soc. Trans. 1884, 45, 298; Paul, *l.c.*).

Preparation.—Freshly-prepared 1-amino-2-naphthol, obtained by reduction of Orange II (100 grms.) with sodium hyposulphite, is dissolved or suspended in sulphuric acid of sp.gr. 1·2 (200 c.c.) and oxidised in the cold by a solution of sodium dichromate (30 grms.) in water (Grandmougin, Ber. 1906, 39, 3561). Or the freshly prepared product, obtained from β-naphthol (50 grms.) by reducing its nitroso- compound with hydrogen sulphide, is dissolved in 5 p.c. sulphuric acid (1400 c.c.) and oxidised in the cold with a solution of potassium dichromate (35 grms.) in water (Lagodzinski and Hardine, Ber. 1894, 27, 3076). The yield amounts to about 25 p.c. of the weight of the Orange II (*p*-sulphobenzeneazo-β-naphthol), or to about 80 p.c. of that of the β-naphthol employed.

Identification.—It crystallises in red needles or in orange scales, decomposes with blackening at 115°–120° (Liebermann and Jacobson, *l.c.*), and resembles [α-]naphthaquinone in solubility, but differs from it by being destitute of odour and non-volatile with steam. Dilute alkalis dissolve it, forming yellow solutions, which rapidly become dark on being shaken with air.

Reactions.—(1) By sulphurous acid, or dilute hydriodic acid, it is reduced to 1 : 2-*dihydroxynaphthalene*, but stannous chloride in hydrochloric acid solution converts it into β-*dinaphthyldihydroquinone* (Stenhouse and Groves, *l.c.*: Liebermann and Jacobson, *l.c.*).

(2) With ferric chloride in 10 p.c. aqueous solution, it gives *di-β-naphthaquinone oxide* (Wichelhaus, Ber. 1897, 30, 2199); with nitric acid of sp.gr. 1·38 (Zaertling, Ber. 1890, 23, 175; *cf.* Stenhouse and Groves, *l.c.*), it yields successively 3-*nitro*-[β-]*naphthaquinone* and *phthalic acid*; but with potassium permanganate (Liebermann and Jacobson, *l.c.*) or dichromate (Boswell, J. Physical Chem. 1907, 11, 119), the product is *phthalic acid.*

(3) With phenylhydrazine it gives the *hydrazone* [O : N_2HPh=1 : 2], red needles, m.p. 138°, isomeric with benzeneazo-β-naphthol (Zincke and Bindewald, Ber. 1884, 17, 3030; Zincke and Rathgen, *ibid.* 1886, 19, 2483; Bamberger, *ibid.* 1897, 30, 514); and with hydroxylamine it forms the *monoxime*, identical with 2-nitroso-α-naphthol (Goldschmidt, *ibid.* 1884, 17, 215).

(4) When warmed in alcoholic solution with aniline it yields 2-*hydroxy*-[α-]*naphthaquinoneanil* [O : OH : NPh=1 : 2 : 4], m.p. above 240°, red needles, soluble in alkali. This anil boiled with acetic acid is converted into 2-*anilino*-[α-]*naphthaquinone*, m.p. 190°–191°, red needles, insoluble in alkali (Liebermann and Jacobson, *l.c.*; Zincke, Ber. 1881, 14, 1494), but in alcoholic solution

---

[1] The compound described as 1 : 8- or *peri*naphthaquinone by Meldola and Hughes (Chem. Soc. Trans. 1890, 57, 632) is now known to be a *dinaphthaquinone* (Liebermann and Schlossberg, Ber. 1899, 32, 546; *cf.* Meldola, *ibid.* 868).

with aniline furnishes 2-*anilino-[α-]naphthaquinoneanil* [O : NHPh : NPh = 1 : 2 : 4], red needles, m.p. 187° (Zincke, *ibid.* 1882, 15, 481). From 2-anilino-[α-]naphthaquinoneanil, by heating it with aniline and aniline hydrochloride at 130°–160°, *phenylrosinduline* has been obtained (Badische, D. R.-P. 45370; Eng. Pat. 15259 of 1888; Fischer and Hepp, Ber. 1888, 21, 2622).

(5) Acetic anhydride with sulphuric acid or zinc chloride or phosphoric acid, converts it at 40°–60° into the *triacetate* of 1 : 2 : 4-trihydroxynaphthalene (Thiele and Winter, Annalen, 1900, 311, 345; Bayer, D. R.-P. 101607 of 1897; 107508; Eng. Pat. 10590 of 1898).

(6) With sodium bisulphite solution of sp.gr. 1·4 it gives 1 : 2-*dihydroxynaphthalene*-4-*sulphonic acid* at the ordinary temperature (Bayer, D. R.-P. 70867 of 1892; Eng. Pat. 825 of 1893), and, in mol. prop. with sodium thiosulphate and acetic acid, it gives 1 : 2-*dihydroxynaphthalene*-4-*thiosulphonic acid* (Bayer, D. R.-P. 71314 of 1892; Eng. Pat. *l.c.*).

(7) When heated with sulphuric acid, with or without the presence of boric acid, at 125°–150°, it is converted into *naphthaquinone black*, which dyes wool in greenish-blue to brown, but with mordants in black, shades (Heyden, D. R.-P. 113336 of 1898; Eng. Pat. 3265 of 1900).

(ii.) 1 : 4-**Naphthaquinone** ([α-]naphthaquinone) can be obtained by the oxidation of naphthalene with chromic acid in acetic acid solution (Groves, Chem. Soc. Journ. 1873, 26, 209; Plimpton, Chem. Soc. Trans. 1880, 37, 633; Japp and Miller, *ibid.* 1881, 39, 220). It is also formed when 1 : 4-diaminonaphthalene *or* α-naphthol (Miller, Ber. 1881, 14, 1602), *or* 1-amino-4-naphthol (Liebermann and Dittler, Annalen, 1876, 183, 242, 248); *or* α-naphthylamine, *or* dimethyl-α-naphthylamine, *or* naphthylamine-4-sulphonic acid (Monnet, Reverdin, and Noelting, Ber. 1879, 12, 2306) is oxidised with chromic acid mixture.

Preparation.—It is prepared conveniently from 1-amino-4-naphthol by oxidation with potassium dichromate and dilute sulphuric acid, the yield amounting to about 40 p.c. of that calculated (Liebermann and Jacobson, Annalen, 1882, 211, 61), but can be obtained in equally good yield from naphthalene by oxidation, in concentrated glacial acetic acid solution, with four times its weight of chromium trioxide dissolved in acetic acid, the mixture being kept at 15°–20° during 3 days (Miller, Ber. 1884, 17, Ref. 355). The product can be purified either by distillation with steam or by crystallisation from light petroleum (b.p. 85°–120°).

Identification.—It crystallises in yellow triclinic needles, m.p. 125°, begins to sublime below 100°, has the odour of *p*-benzoquinone, is readily volatile with steam, and dissolves easily in most organic solvents, but only sparingly in light petroleum or water.

Reactions.—(1) It is not reduced by sulphurous acid in the cold, but when heated with hydriodic acid and phosphorus or with tin and hydrochloric acid it is converted into 1 : 4-*dihydroxynaphthalene* (Groves, *l.c.*; Plimpton, *l.c.*). Partial reduction results in the formation of *naphthaquinhydrone.*

(2) In caustic soda solution it absorbs oxygen from the air forming 2-*hydroxy-[α-]naphthaquinone* (Kowalski, Ber. 1892, 25, 1659), but on oxidation with nitric acid (Liebermann and Dittler, *l.c.*), or permanganate (Japp and Miller, *l.c.*; *cf.* Boswell, J. Physical Chem. 1907, 11, 119), *phthalic acid* is formed.

(3) In acetic acid solution with chlorine it gives the *dichloride*, m.p. 176°, and with bromine the *dibromide*, m.p. 92° (Zincke and Schmidt, Ber. 1894, 27, 2757).

(4) With phenylhydrazine hydrochloride it yields the *hydrazone*, identical with benzeneazo-α-naphthol (Zincke and Bindewald, Ber. 1884, 17, 3026); and with hydroxylamine it forms the *monoxime*, identical with 4-nitroso-α-naphthol (Goldschmidt and Schmid, *ibid.* 2064).

(5) When heated with acetic anhydride and zinc chloride or sulphuric acid at 50° it furnishes 1 : 2 : 4-*trihydroxynaphthalene triacetate* (Thiele and Winter, Annalen, 1900, 311, 345; Bayer, D. R.-P. 101607 of 1897; 107508; Eng. Pat. 10590 of 1898).

(6) When warmed in alcoholic solution with aniline, it yields 2-*anilino-[α-]naphthaquinone*, red needles, m.p. 190°–191° (Plimpton, *l.c.*).

(iii.) 2 : 6-**Naphthaquinone**, obtained from 2 : 6-dihydroxynaphthalene by oxidation in boiling benzene solution with lead peroxide, forms reddish-yellow prisms, and is odourless and non-volatile, but, unlike [β-]naphthaquinone, is an oxidising agent comparable in this respect with *p*-benzoquinone (Willstätter and Parnas, Ber. 1907, 40, 1411, 3971).

HYDROXYNAPHTHAQUINONES.

(i.) 2-**Hydroxy-[α-]naphthaquinone**[1] can be obtained by boiling amino-[α-]naphthaquinoneimide (diimino-α-naphthol, *v.* 2 : 4-diamino-α-naphthol) with dilute acids (Martius and Griess, Annalen, 1865, 134, 377; Graebe and Ludwig, *ibid.* 1870, 154, 321), or with sodium carbonate solution which afterwards is acidified (Diehl and Merz, Ber. 1878, 11, 1315); *or* by heating 2-anilino-[α-]naphthaquinone (Baltzer, Ber. 1881, 14, 1900), or 2-hydroxy-[α-]naphthaquinoneanil (Liebermann and Jacobson, Annalen, 1882, 211, 80; Böniger, Ber. 1894, 27, 257) with hydrochloric acid; *or* by dissolving [β-]naphthaquinone-4-sulphonic acid in sulphuric acid and, after some hours at 25°, pouring the solution on to ice (Aktienges., D. R.-P. 100703; Eng. Pat. 26675 of 1897). It is formed, also, when an alkaline solution of [α-]naphthaquinone (Kowalski, Ber. 1892, 25, 1659) or of 1 : 2-dihydroxynaphthalene-4-sulphonic acid (Bayer, D. R.-P. 70867 of 1892; Eng. Pat. 825 of 1893), is exposed to the air; and readily by oxidizing either [β-]naphthaquinone, suspended in caustic soda solution, with hydrogen peroxide (Teichner and Weil, Ber. 1905, 38, 3376) or 1 : 2 : 4-trihydroxynaphthalene in aqueous solution with dichromate mixture at 0° (Thiele and Winter, Annalen, 1900, 311 347).

Identification.—It crystallises or sublimes in yellow needles, m.p. 190°–191°, dissolves only sparingly in boiling water, expels carbon dioxide from carbonates, and dyes wool or silk yellow.

---

[1] By condensation with *o*-phenylenediamine, 2-hydroxy-[α-]naphthaquinone gives an *azine* (Kehrmann, Ber. 1890, 23, 2453), behaving as if it were 4-hydroxy-[β-]naphthaquinone. Many of the monosubstituted naphthaquinones of the 1 : 2 : 4-type exhibit a similar tautomerism (*cf.* Miller, Chem. Soc. Abstr. 1911, i. 465), although the formulæ usually assigned to them represent only one of the two isomeric forms.

The *acetate* forms yellow scales, m.p. 130° (Thiele and Winter, *l.c.*).

Reactions.—(1) On reduction with tin and hydrochloric acid, it yields 1 : 2 : 4-*trihydroxynaphthalene* (Graebe and Ludwig, *l.c.*).

(2) It couples with diazotised bases in presence of sodium acetate, forming *azo-* dyes which are remarkable because in them, the 1- or *α-* position not being available, the azo- group has taken up the alternative *ortho-*, namely the 3- or *β-* position to the hydroxyl radicle (Kehrmann and Goldenberg, Ber. 1897, 30, 2126).

3-Nitro-2-hydroxy-[α-]naphthaquinone is formed from [β-]naphthaquinone-4-sulphonic acid, or from 1-amino-2-naphthol-4-sulphonic acid by nitration in sulphuric acid solution below 50° (Aktienges., D. R.-P. 100611; Eng. Pat. 26675 of 1897). It is crystalline, and with phenylhydrazinesulphonic acid gives a yellow *azo-* dye for wool (*ibid.* D. R.-P. 102071; Eng. Pat. 676 of 1898).

2-Hydroxy-[α-]naphthaquinone-3-sulphonic acid, obtained by sulphonating 2-hydroxy-[α-]naphthaquinone with 25 p.c. anhydro- acid at 20°, forms a sparingly soluble *sodium* salt in pale-yellow scales (Atkienges., D. R.-P. 99759; Eng. Pat. 26675 of 1897), and with phenylhydrazinesulphonic acid (*ibid.* D. R.-P. 101918; Eng. Pat. 676 of 1898) or with the hydrazine from 1-amino-8-naphthol-3 : 6-disulphonic acid (*ibid.* D. R.-P. 102070; Eng. Pat. 676 of 1898), gives respectively an orange-yellow or reddish-yellow *azo-* dye for wool.

The 6-sulphonic acid is produced when a mixture of [β-]naphthaquinone-4 : 6-disulphonic acid and sulphuric acid is kept at 25° for some hours (Aktienges., D. R.-P. 100703; Eng. Pat. 26675 of 1897); or when 1 : 2-dihydroxynaphthalene-6-sulphonic acid is oxidised in caustic soda solution with hydrogen peroxide (Teichner and Weil, Ber. 1905, 38, 3376). The *sodium* salt forms red needles.

The 7-sulphonic acid (Gaess, Ber. 1899, 32, 237), which gives two *sodium* salts $NaA+3H_2O$, and Na_2A, and two *barium* salts BaA_2+2H_2O, and $BaA+3\frac{1}{2}H_2O$, forms an *azine* with *o*-phenylenediamine, reacting as if it were 4-hydroxy-[β-]naphthaquinone-7-sulphonic acid.[1]

(ii.) **5-Hydroxy-[α-]naphthaquinone** (*juglone*; *regianin*; *nucin*) occurs in the green parts and shells of the walnut (Brissemoret and Combes, Compt. rend. 1905, 141, 838; Combes, Bull. Soc. chim. 1907, [iv.] 1, 803), but in nuts not freshly gathered is replaced in part or wholly by hydrojuglone (*cf.* Mylius, Ber. 1885, 18, 2567). It can be extracted from the shells by ether (Combes, *l.c.*), and is obtained by oxidation of 1 : 4 : 5-trihydroxynaphthalene with ferric chloride (Mylius, *l.c.*), or chromic acid mixture (Bernthsen and Semper, Ber. 1885, 18, 204); *or* of 1 : 5-dihydroxynaphthalene with chromic acid mixture (*ibid.* 20, 939); *or* of 4 : 8-diamino-*α*-naphthol with ferric chloride (Friedlaender and Silberstern, Monatsh. 1902, 23, 517).

Identification.—It crystallises in yellowish-red or brown needles, m.p. 151°–154°, is almost insoluble in water, and in aqueous solution colours the skin yellow like walnut juice.

(iii.) **6-Hydroxy-[β-]naphthaquinone,** prepared by oxidising 1-amino-2 : 6-dihydroxynaphthalene with ferric chloride, forms brick-red scales, decomp. at 165° (Kehrmann, Ber. 1907, 40, 1962).

The 4-sulphonic acid closely resembles that from 7-hydroxy-[β-]naphthaquinone in mode of preparation and properties (Bayer, D. R.-P. 87900; Eng. Pat. 6035 of 1893).

(iv.) **7-Hydroxy-β-naphthaquinone,** obtained similarly from 1-amino-2 : 7-dihydroxynaphthalene (Clausius, Ber. 1890, 23, 522) forms brown needles, m.p. 194° (Nietzki and Knapp, *ibid.* 1897, 30, 1123).

The 4-sulphonic acid, prepared by oxidising 1-amino-2 : 7-dihydroxynaphthalene-4-sulphonic acid with nitrous acid (Böniger, Ber. 1894, 27, 3051) gives a *potassium* salt in brown needles, and has been employed in the production of *thiazines* (Bayer, D. R.-P. 87900; Eng. Pat. 6035 of 1893).

(v.) **8-Hydroxy-[β-]naphthaquinone** has not been described. The 4-sulphonic acid, obtained by oxidising 8-hydroxy-1 : 2-diaminonaphthalene-4-sulphonic acid with dichromate has been used for the production of *thiazines* (Bayer, D. R.-P. 87900; Eng. Pat. 6035 of 1893).

(vi.) **2 : 3-Dihydroxy-[α-]naphthaquinone** (*Isonaphthazarin*) is formed when 3-amino-2-hydroxy-[α-]naphthaquinone is heated with dilute hydrochloric acid at 180° (Diehl and Merz, Ber. 1878, 11, 1322); *or* when 1 : 4-diamino-2 : 3-dihydroxynaphthalene is oxidised by ferric chloride (Friedlaender and Silberstern, Monatsh. 1902, 23, 525); *or* when β-naphthaquinone is dissolved in dilute bleaching powder solution, which is then acidified with acetic acid and boiled with a few c.c. of hydrochloric acid (Zincke and Ossenbeck, Annalen, 1899, 307, 11; *cf.* Bamberger, Ber. 1892, 25, 134, 891; Zincke and Scharfenberg, *ibid.* 409).

Identification.—It crystallises in red needles, m.p. 280°; dissolves in caustic alkali solutions with a blue colour which disappears on exposure to the air, *o-carboxyphenylglyoxylic acid* being formed; yields 1 : 2 : 3 : 4-*tetrahydroxynaphthalene* on careful, but 1 : 2 : 3-*trihydroxynaphthalene* on vigorous reduction with zinc and dilute sulphuric acid; and is a dye for mordanted wool. Its *diacetate* forms colourless needles, m.p. 105° (Zincke and Ossenbeck, *l.c.*).

(vii.) **5 : 6-Dihydroxy-[α-]naphthaquinone** (**Naphthazarin.** *Alizarin black*; *v.* p. 569), was first obtained by heating 1 : 5-dinitronaphthalene with zinc and sulphuric acid at 200° (Roussin, Compt. rend. 1861, 52, 1033, 1177; *cf.* Liebermann, Annalen, 1872, 162, 330). It is produced on the large scale by stirring 1 : 5-dinitronaphthalene (2 pts.) into monohydrate (40 pts.), adding a solution of sulphur (1 pt.) in 40 p.c. anhydro-acid (10 pts.) below 40°, and, when a test gives a blue solution, pouring the 'naphthazarin melt' into water, removing sulphur by filtration, and boiling the filtrate until the colour has changed to red (Bayer, D. R.-P. 71386 of 1892). Substances which yield sulphur such as hydrogen sulphide, sulphur chloride, &c., can replace it as reducing agents (*ibid.* D. R.-P. 77330 of 1893; Eng. Pat. 17673 of 1892).

Naphthazarin melt contains a 'naphthazarin intermediate product' which is probably an impure form of 5-*amino*-6-*hydroxy*-[α-]*naphthaquinoneimide* (*cf.* Badische, D. R.-P. 129074; Eng. Pat. 23887 of 1900; *v.* p. 570). The blue

---

[1] See footnote p. 655.

solution of this product in water, when boiled, yields naphthazarin. According to Aguiar and Bayer, the melt contains in addition a trihydroxy-[α-]naphthaquinone, producible by heating naphthazarin with sulphuric acid (Ber. 1871, 4, 439).

1:8-Dinitronaphthalene (1 pt.) also furnishes naphthazarin when heated at 120°–130° with sulphuric acid (20 pts.) and reducing agents such as aniline, phenylhydrazine, or tin, provided the melt [1] is boiled with water (Badische, D. R.-P. 76922 of 1893; Eng. Pat. 3828 of 1894; *cf.* D. R.-P. 79406 of 1894); hence it is possible in the manufacturing process to substitute the dinitration product from naphthalene for the pure 1 : 5-dinitro- derivative.[2]

As naphthazarin can be formed by boiling 1 : 4 : 5 : 6-tetra-aminonaphthalene with dilute hydrochloric acid, its constitution is known with certainty (Will, Ber. 1895, 28, 2234; Friedlaender and Silberstern, Monatsh. 1902, 23, 518).

Properties.—It sublimes in brown needles showing a green lustre, is only sparingly soluble in water, but dissolves in alkalis forming a cornflower-blue, and in sulphuric acid a magenta solution. It is an important dyestuff, giving very fast violet-black lakes with chromium salts. When warmed at 50°–70° with sodium bisulphite solution, it is converted into a soluble compound used in dyeing under the names of alizarin black S and naphthazarin S (Badische, D. R.-P. 41518; Eng. Pat. 7833 of 1887), but with concentrated sodium bisulphite solution at 100°, followed by oxidation of the resulting leuco- compound, it yields *naphthazarinsulphonic acid* (Höchst, D. R.-P. 116866 of 1889). The *diacetate*, needles, m.p. 189° (Zincke and Schmidt, Annalen, 1895, 286, 36), and the *tetra-acetate* of 1:2:5:8-tetrahydroxynaphthalene (Liebermann, Ber. 1895, 28, 1457) have been prepared from it.

By condensation of naphthazarin with salts of aromatic amines or with their sulphonic acids at 25°–40° in presence of boric acid, black dyes are formed (Badische, D. R.-P. 101525, 101152; Eng. Pat. 21297 of 1897; D. R.-P. 157684; Eng. Pat. 2468 of 1904).

Naphthazarin 'Intermediate Product,' and the derived colouring matters.

The **intermediate product** can be isolated by precipitating naphthazarin melt with zinc chloride (Höchst, D. R.-P. 111683; Eng. Pat. 16295 of 1899); *or* by oxidising the leuco-compound (*v. infra*), dissolved in caustic soda, with a rapid current of air (Badische, D. R.-P. 108551 of 1899), or a solution of the melt with hypochlorite or dichromate (*ibid.* D. R.-P. 101372; Eng. Pat. 15909 of 1898), and boiling the sodium salt thus obtained (which separates as blue needles) with acetic acid (*ibid.* D. R.-P. 108552 of 1899). By oxidation with dichromate (Badische, D. R.-P. 101372; Eng. Pat. *l.c.*); by condensation either with phenols (*ibid.* D. R.-P. 103150 of 1897; Eng. Pat. 10597 of 1898), or with aromatic amines (*ibid.* D. R.-P. 118078; Eng. Pat. 20997 of 1899; Höchst, D. R.-P. 125574; Eng. Pat. 20485 of 1899); or by sulphonation with 20 p.c. anhydro- acid (Höchst, D. R.-P. 117359 of 1899), naphthazarin melt gives respectively black, bluish-grey, green, or blue mordant dyes. Further, by reduction with stannous chloride, it is converted into the **leuco-** compound, crystallising in colourless needles (Badische, D. R.-P. 101371; Eng. Pat. 15708 of 1898), which, sulphonated with 23 p.c. anhydro- acid, gives a blue dye (*ibid.* D. R.-P. 106029; Eng. Pat. 24752 of 1898), convertible into black, green, or blue mordant dyes by boiling respectively with hydrochloric acid (*ibid.* D. R.-P. 106033; Eng. Pat. *l.c.*), or with aniline and aniline hydrochloride (*ibid.* D. R.-P. 108414; Eng. Pat. *l.c.*), or with aniline hydrochloride and water (*ibid.* D. R.-P. 108415 of 1898).

(viii.) **6 : 7-Dihydroxy-[α-]naphthaquinone,** obtained from 5-amino-2 : 3 : 8-trihydroxynaphthalene by oxidation with ferric chloride, forms reddish-brown needles, gives a green solution in caustic soda, and has only feeble dyeing properties. Its *diacetate* forms yellow needles, m.p. 65°–67° (Friedlaender and Silberstern, Monatsh. 1902, 23, 532).

(ix.) **5 : 6 : 8-Trihydroxy-[α-]naphthaquinone** (naphthapurpurin), one of the products (A) of the action of sulphuric acid in presence of boric acid on 1 : 5-dinitronaphthalene at 220° (Bayer, D. R.-P. 82574 of 1894), is obtained in a pure state either by boiling naphthazarin with an equal weight of caustic soda in 1 p.c. solution until the colour has changed to magenta (Badische, D. R.-P. 167641; Eng. Pat. 9547 of 1905), or with manganese dioxide and dilute sulphuric acid (Jaubert, Compt. rend. 1899, 129, 684). It forms reddish-brown needles, is easily soluble in the ordinary solvents, dyes wool orange-red, chroming to black (Badische, *l.c.*), and condenses with aromatic amines forming dyes, which when sulphonated give blue, green, or black shades on chromed wool (Bayer, D. R.-P. 127766 of 1900).

NAPHTHAQUINONESULPHONIC ACIDS.

[β-]Naphthaquinone-4-sulphonic acid is prepared by oxidising 2-amino-1-naphthol-4-sulphonic acid (Witt and Kaufmann, Ber. 1891, 24, 3163), or 1-amino-2-naphthol-4-sulphonic acid (Böniger, *ibid.* 1894, 27, 24) with nitric acid; *or* 1 : 2-dihydroxynaphthalene-4-sulphonic acid with nitrous acid (Bayer, D. R.-P. 83046 of 1892; Eng. Pat. 825 of 1893). It forms easily soluble salts; is converted by nitrosulphuric acid into *3-nitro-2-hydroxy-*[α-]*naphthaquinone* (Aktienges., D. R.-P. 100611; Eng. Pat. 26675 of 1897), or by sulphuric acid at 25° into *2-hydroxy-*[α-] *naphthaquinone* (*ibid.* D. R.-P. 100703; Eng. Pat. *l.c.*); and gives *thiazines* by condensation with aromatic nitroso- compounds (Bayer, *l.c.*), or with thiosulphonated arylamines (Sandoz, D. R.-P. 109273 of 1893; Eng. Pat. 3886 of 1894), also *oxazines* with aminonaphtholsulphonic acids (Dahl, D. R.-P. 82740; Eng. Pat. 5153 of 1895).

The 4 : 6- and 4 : 7-disulphonic acids, obtained by oxidising 1-amino-2-naphthol-4 : 6-

---

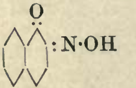
[1] The naphthazarin melt from 1:8-dinitronaphthalene contains an intermediate product different from, but probably isomeric with, that furnished by 1:5-dinitronaphthalene.

[2] When heated in sulphuric acid solution at 130° with hydrogen sulphide, 1:5-dinitronaphthalene (Badische, D. R.-P. 134705; Eng. Pat. 6053 of 1900; Höchst, D. R.-P. 138105 of 1900), and 1:8-dinitronaphthalene (Badische, D. R.-P. 114264 of 1899; Eng. Pat. 890 of 1900) give products which, unlike naphthazarin, develop blue and violet shades on wool without a mordant.

and 4 : 7-disulphonic acids respectively with nitric acid (Böniger, Ber. 1894, 27, 3052), form *thiazines* by condensation with thiosulphonated arylamines (Sandoz, D. R.-P. 116765 of 1894).

By oxidising the corresponding aminonaphtholsulphonic acids, the β-naphthaquinone-6-, 7-, and 8-mono-, and 4 : 8- and 6: 8-disulphonic acids have been obtained, which furnish *thiazines* by condensation with aromatic nitroso- compounds (Bayer, D. R.-P. 84233; Eng. Pat. 4757 of 1893).

NAPHTHAQUINONEOXIMES.



(i.) **2-Nitroso-α-naphthol** ([α-] naphthaquinone-2-oxime) can be obtained from [β-]-naphthaquinone by boiling it in alcoholic solution with hydroxylamine hydrochloride (Goldschmidt, Ber. 1884, 17, 215); *or* from 1-hydroxy-β-naphthoic acid by means of nitrous acid (Reverdin and de la Harpe, *ibid.* 1893, 26, 1280); *or,* mixed with the 4-oxime (*q.v.*), from α-naphthol by interaction with nitrous acid (Fuchs, Ber. 1875, 8, 626; Worms, *ibid.* 1882, 15, 1816; Ilinski, *ibid.* 1884, 17, 2589; Henriques and Ilinski, *ibid.* 1885, 18, 706). It crystallises in yellow needles, m.p. 152° (Goldschmidt), soluble in the ordinary organic solvents or in hot water; forms coloured salts and ethers, the *potassium* and *ammonium* salts being green, and the *methyl* (m.p. 95°) and *ethyl* (m.p. 101°) *ethers,* greenish-yellow (Fuchs, *l.c.*).

Reactions.—(1) Concentrated nitric acid in acetic acid solution converts it into 2 : 4-*dinitro-α-naphthol*; potassium ferricyanide in alkaline solution oxidises it rapidly to 2-*nitro-α-naphthol* (Fuchs, *l.c.*).

(2) With sodium bisulphite solution it yields 2-*amino*-1-*naphthol*-4-*sulphonic acid* (Böniger, Ber. 1894, 27, 29).

(3) Like nitroso-β-naphthol it gives [β-] *naphthaquinonedioxime* with hydroxylamine (Goldschmidt and Schmid, Ber. 1884, 17, 2066), forms metallic salts (Ilinski, *ibid.* 1884, 17, 2592), and is a mordant dye (*cf.* Aktienges., D. R.-P. 66786 of 1891).

2-Nitroso-1 : 8-dihydroxynaphthalene (Erdmann, Annalen, 1888, 247, 358) gives black lakes (Bayer, D. R.-P. 51478; Eng. Pat. 14230 of 1889).

2-Nitroso-α-naphthol-4-sulphonic acid gives a *naphthol-green* with ferric chloride (Gans & Co. D. R.-P. 28065; Eng. Pat. 2269 of 1884; Hoffmann, Ber. 1885, 18, 46).

(ii.) **4-Nitroso-α-naphthol** ([α-]naphthaquinone-4-oxime) is formed when [α-]naphthaquinone in alcoholic solution is boiled with hydroxylamine hydrochloride (Goldschmidt and Schmid, Ber. 1884, 17, 2064), *or,* mixed with the 2-oxime, by the interaction of α-naphthol with nitrous acid (Fuchs, *ibid.* 1875, 8, 626; Worms, *ibid.* 1882, 15, 1816). The best yield, viz. 40 grms. of the colourless 4-oxime and 50 grms. of the yellow 2-oxime from 100 grms. of α-naphthol, is obtained by boiling a solution of α-naphthol (1 pt.) and zinc chloride (1 pt.) in alcohol (6 pts.) with aqueous sodium nitrite (0·5 pt.) during 2–3 hours, the product which separates consisting of the 4-oxime mixed with the zinc salt of the 2-oxime (Henriques and Ilinski, Ber. 1885, 18, 706; *cf.* Ilinski, *ibid.* 1884, 17, 2590). It crystallises in needles, m.p. 190° (Friedlaender and Reinhardt, Ber. 1894, 27, 240), dissolves easily in alcohol or ether, gives a *methyl ether,* m.p. 98°–100° (Ilinski, *l.c.*), and is destitute of tinctorial power (Kostanecki, *ibid.* 1887, 20, 3147).

Reactions.—(1) Concentrated nitric acid in acetic acid solution converts it into 2 : 4-*dinitro-α-naphthol*; potassium ferricyanide in alkaline solution oxidises it very slowly to 4-*nitro-α-naphthol* (Fuchs, *l.c.*).

(2) Like the 4-oxime and [β-]naphthaquinone-1-oxime, it gives 2-*anilino*-[α-]*naphthaquinone-anil,* m.p. 187°, when boiled with aniline and acetic acid (Brömme, Ber. 1888, 21, 393).

4-Nitroso-α-naphthol-2-sulphonic acid does not give a naphthol-green with ferrous sulphate, but is readily converted into 2:4-dinitro-α-naphthol by dilute nitric acid (Conrad and Fischer, Annalen, 1893, 273, 110).

4-Nitroso-α-naphthol-2: 5-disulphonic acid is formed when α-nitronaphthalene-3 : 8-disulphonic acid is warmed with concentrated caustic soda solution. Its *potassium* salt $K_2A+1\frac{1}{2}H_2O$, forms yellow, and *basic potassium* salt green, needles; the *amino-* acid, obtained from it by reduction, furnishes 1-*amino*-4-*naphthol* on desulphonation with sodium amalgam (Friedlaender, Ber. 1895, 28, 1535).

5-Nitro-4-nitroso-α-naphthol (5-nitro-[α-] naphthaquinoneoxime) is produced when 1 : 8-dinitronaphthalene is heated with 12–23 p.c. anhydro- acid at 40°–50° (Badische, D. R.-P. 90414; Eng. Pat. 14955 of 1896; Graebe, Ber. 1899, 32, 2877; Friedlaender, *ibid.* 3528; Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339). It crystallises in yellow needles, and is soluble in alkalis giving yellow solutions which become red when heated with zinc dust (Badische, *l.c.*).

Reactions.—(1) By potassium ferricyanide it is oxidised to 4 : 5-*dinitro-α-naphthol* (Friedlaender, *l.c.*); by dilute nitric acid to 2 : 4 : 5-*trinitro-α-naphthol* (Friedlaender and Scherzer, *l.c.*); and by potassium permanganate to 3-*nitrophthalic acid.*

(2) On reduction with ammonium sulphide or stannous chloride, it gives 4 : 5-*diamino-α-naphthol,* but with tin and hydrochloric acid 5-*amino*-1 : 4-*dihydroxynaphthalene* (Graebe and Oeser, Annalen, 1904, 335, 152).

The 2 : 7-disulphonic acid, formed by the action of very dilute caustic soda solution [1] on 1 : 8-dinitronaphthalene-3 : 6-disulphonic acid at the ordinary temperature, gives a yellow *potassium* salt K_2A+2H_2O and a green *basic potassium* salt. With dilute nitric acid it furnishes a crystalline yellow nitro- dye with the loss of one of the SO_3H groups (Kalle, D. R.-P. 113063 of 1899).

7-Nitro-4-nitroso-α-naphthol (7-nitro-[α-] naphthaquinone-4-oxime), obtained when 1 : 6-dinitronaphthalene is heated with 15–17 p.c. anhydro- acid at 40°–50°, crystallises in yellow needles, is soluble in alkalis, and on oxidation gives 4-*nitrophthalic acid* (Graebe, Annalen, 1904, 335, 144).

8-Nitro-4-nitroso-α-naphthol (8-nitro-[α-] naphthaquinone-4-oxime), obtained by heating

---

[1] If concentrated caustic soda solution is used, the product is a 1 : 8-dinitrosodihydroxynaphthalene-3 : 6-disulphonic acid, the *sodium* salt Na_3A+3H_2O of which crystallises in needles (Kalle, *l.c.*).

1 : 5-dinitronaphthalene with 12–23 p.c. anhydro-acid at 40°–50° (Badische, D. R.-P. 91391; Eng. Pat. 14955 of 1896; *v.* 5-nitro-compound for other references) forms yellow crystals; these dissolve in alkalis giving yellow solutions which become green when boiled with zinc dust (Badische, *l.c.*).

Reactions.—(1) By potassium ferricyanide it is converted into 4 : 8-*dinitro-α-naphthol* (Friedlaender, Ber. 1899, 32, 3529), but by dilute nitric acid into 2 : 4 : 8-*trinitro-α-naphthol* (Friedlaender and Scherzer, *cf.* J. Soc. Chem. Ind. 1900, 19, 339; Graebe and Oeser, Annalen, 1904, 335, 154).

(2) On reduction with tin and hydrochloric acid, it furnishes 1 : 5-*diamino*-8-*naphthol* (Graebe and Oeser, *l.c.*).

(iii.) **1-Nitroso-β-naphthol** ([β-]naphthaquinone-1-oxime) is obtained by the action of nitrous acid on β-naphthol (Fuchs, Ber. 1875, 8, 1026; Stenhouse and Groves, Chem. Soc. Trans. 1877, 32, 47; Ilinski, Ber. 1884, 17, 2584; Groves, Chem. Soc. Trans. 1884, 45, 295; *cf.* Köhler, D. R.-P. 25469 of 1883). As the sparingly soluble reddish-brown zinc salt, it is formed when a solution of sodium nitrite (2 pts.) is added to a hot solution of β-naphthol (4 pts.) and zinc chloride (3 pts.) in alcohol (24 pts.), and the mixture boiled for a short time, the product being converted into the oxime by digestion with caustic soda solution and acidification of the filtrate (Henriques and Ilinski, Ber. 1885, 18, 705). As a greenish-yellow precipitate, it is produced when 10 p.c. sulphuric acid (700 c.c.) is added gradually to a solution of β-naphthol (50 grms.), caustic soda (14 grms.), and sodium nitrite (25 grms.) in water (1500 c.c.) containing one-third its weight of ice (Lagodzinski and Hardine, Ber. 1894, 27, 3076). It crystallises from alcohol in anhydrous orange-brown thin plates or short thick prisms, m.p. 109·5°, dissolves only very sparingly in hot water, and when pure is readily volatile with steam (Ilinski, *l.c.*).

Salts.—The *cupric* salt CuA_2 (Knorre, Ber. 1887, 20, 283), and *ferric* salt FeA_3, are insoluble in water or in 50 p.c. acetic acid (Ilinski and Knorre, *ibid.* 1885, 18, 2728); and the *cobaltic* salt CoA_3, is only very slightly soluble in boiling 50 p.c. acetic acid (*ibid.* 699). Since Hg, Pb, Cd, Al, Cr, Ni, Zn, Mn, Mg, Gl, &c., are not precipitated by it in acetic acid solution, nitroso-β-naphthol can be employed for the quantitative separation of Cu, or Fe, or Co, from any of the metals named (*cf.* Knorre, Zeitsch. angew. Chem. 1893, 6, 264). The *barium, potassium* KA, and *sodium* salts are green (Ilinski, Ber. 1884, 17, 2885).

Reactions.—(1) With dilute nitric acid (Stenhouse and Groves, *l.c.*) or potassium ferricyanide it gives 1-*nitro-β-naphthol.*

(2) By concentrated sodium bisulphite solution below 50°, it is converted into a crystalline bisulphite *compound*, which, unlike nitroso-β-naphthol, couples with diazotised bases forming *azo-* dyes (Dahl, D. R.-P. 79583 of 1893; D. R.-P. 95758 of 1897; *cf.* Ashworth and Bürger, Eng. Pat. 11556 of 1893). When decomposed by hydrochloric acid this compound furnishes 1-*amino*-2-*naphthol*-4-*sulphonic acid* (Böniger, Ber. 1894, 27, 23).

(3) Dissolved in hot methyl alcohol (Goldschmidt and Schmid, Ber. 1884, 17, 2067) or in cold caustic soda solution (Kehrmann and Messinger, *ibid.* 1890, 23, 2815), it yields [β-]*naphthaquinonedioxime*, m.p. 180°–181°, with hydroxylamine hydrochloride, but if the alkali solution be warm, the product is the *anhydride*, m.p. 78° (Kehrmann and Messinger, *l.c.*).

(4) Under the name 'Gambin R.' it has been introduced as a mordant dye for cotton (Aktienges., D. R.-P. 66786 of 1891).

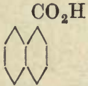
1-Nitroso-β-naphthol-6-sulphonic acid, formed by the action of nitrous acid on β-naphthol-6-sulphonic acid (Meldola, Chem. Soc. Trans. 1881, 39, 40), needles, gives a *barium* salt BaA_2+H_2O, in orange needles; a green *basic barium* salt $BaA+H_2O$; a *basic sodium* salt Na_2A+2H_2O, in green needles (Hoffmann, Ber. 1891, 24, 3471), and coloured metallic salts with Co, Ni, and Fe, from which the metal is not precipitated by alkalis or alkali carbonates. With ferric chloride and sodium carbonate it forms the *iron sodium salt* $Fe(NaA)_3$ (Gans, D. R.-P. 28065; Eng. Pat. 2269 of 1884; Hoffmann, Ber. 1885, 18, 46; *l.c.*), which, under the name *naphthol-green*, has been introduced as a green dye for wool (Gans, D. R.-P. 28901 of 1884; *cf.* Ulrich, J. Soc. Chem. Ind. 1890, 8, 1126).

1-Nitroso-2 : 6-dihydroxynaphthalene (Bayer, D. R.-P. 55126, 59268 of 1900; Eng. Pat. 14230 of 1889); 1-nitroso-2 : 7-dihydroxynaphthalene or *dioxin* (Leonhardt, D. R.-P. 55204; Eng. Pat. 17223 of 1889); and nitroso-2 : 8-dihydroxynaphthalene (Bayer, D. R.-P. 53915; Eng. Pat. 14230 of 1889) are mordant dyes, the two former giving green shades with iron salts.

X. Carboxy-Derivatives.

The naphthoic acids are technically unimportant, as are their derivatives with the exception of the hydroxynaphthoic acids.

Naphthoic Acids.



α-Naphthoic acid can be prepared by heating α-naphthonitrile with hydrochloric acid at 200° (Boessneck, Ber. 1883, 16, 639), or with 15 p.c. alcoholic soda at 160° (Bamberger and Philip, *ibid.* 1887, 20, 242), but most easily by boiling it with a mixture of sulphuric and acetic acids (Rabe, *ibid.* 1898, 31, 1898). It crystallises in needles, m.p. 160°, b.p. 300°, dissolves only sparingly in hot water, and on nitration yields both the 5- and the 8-*nitro-α-naphthoic acids* (Ekstrand, J. pr. Chem. 1888, [ii.] 38, 156). The *barium* salt BaA_2+4H_2O, and the *calcium* salt CaA_2+2H_2O, crystallise in needles; the *nitrile*, needles, m.p. 34°, b.p. 299°.

β-Naphthoic acid is obtained when β-naphthonitrile is boiled with alcoholic potash (Vieth, Annalen, 1876, 180, 305), or with a mixture of sulphuric and acetic acids (Baeyer and Besemfelder, *ibid.* 1891, 266, 187). It crystallises in silky needles, m.p. 184°, dissolves only sparingly in hot water, and yields *trimellitic acid* on oxidation with alkaline permanganate (Ekstrand, J. pr. Chem. 1891, [ii.] 43, 427). The *barium* salt BaA_2+4H_2O, and *calcium* salt CaA_2+3H_2O, crystallise in very sparingly soluble needles; the *nitrile* forms scales, m.p. 66·5°, b.p. 306·5°.

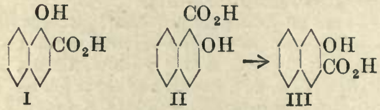
Hydroxynaphthoic Acids.

Introductory.—Two general methods have been used for the production of hydroxynaphthoic acids—

(1) Fusion of sulphonated naphthoic acids with caustic alkali;

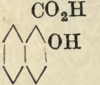
(2) Interaction of the sodium salts of the naphthols or dihydroxynaphthalenes with carbon dioxide under pressure at a suitable temperature.

The acids formed from the naphthols are—



The α- acid (II) from β-naphthol is obtained at 120°–140°, and the β- acid (III) at 200°–250°, a transformation which affords the only example in the naphthalene series of the entry of a radicle into the 3- position to produce a 2 : 3- disubstitution derivative.

The hydroxynaphthoic acids have found only a limited use in the manufacture of dye-stuffs. They give both normal and basic salts, and with ferric chloride usually a blue colouration. The order of stability of the acids and of their sulphonic derivatives may be inferred from the following facts: Acid II loses carbon dioxide more readily than acid I, and both by coupling furnish azo- dyes which do not contain the carboxyl group. Acid III and its derivatives, on the contrary, do not suffer this decomposition, although they, too, lose carbon dioxide when boiled with sodium bisulphite solution (Bucherer, *cf.* J. Soc. Chem. Ind. 1902, 21, 1272; J. pr. Chem. 1905, [ii.] 71, 445), a reaction which has thrown light on the constitution of some of the sulphonic acids of the group (Bucherer, *cf.* J. Soc. Chem. Ind. 1903, 22, 945).



(i.) **2-Hydroxy-1-naphthoic acid** is obtained by acting on dry sodium β-naphtholate with solid, liquid, or gaseous carbon dioxide under pressure in the cold, and subsequently heating the sodium β-naphthyl carbonate thus produced at 120°–140° (Schmitt, D. R.-P. 31240 of 1884; Schmitt and Burkard, Ber. 1887, 20, 2701; Heyden, D. R.-P. 38052 of 1886). The *acid* crystallises in needles, m.p. 156°–157°, but when slowly heated begins to decompose at 124°–128°, and is converted quantitatively into β-naphthol and carbon dioxide by prolonged boiling with water (Schmitt and Burkard, *l.c.*). It couples with diazotised bases, but the products are *azo-* derivatives of β-naphthol (Nietzki and Guitermann, Ber. 1887, 20, 1275).

The 6-sulphonic acid is formed by sulphonating 2-hydroxy-1-naphthoic acid with 20 p.c. anhydro- acid at 40°. It loses carbon dioxide forming *β-naphthol-6-sulphonic acid,* either when warmed in aqueous solution at 60°, or when coupled with diazotised bases (Seidler, D. R.-P. 53343 of 1889).

(ii.) **8-Hydroxy-1-naphthoic acid,** formed, together with the *anhydride* or lactone (m.p. 108)°, by boiling diazotised α-naphthylamine-8-carboxylic acid with dilute sulphuric acid, crystallises in needles, m.p. 169° (Ekstrand, Ber. 1886, 19, 1138); it does not readily reform the lactone.

(iii.) **1-Hydroxy-2-naphthoic acid** is obtained by acting on dry sodium α-naphtholate with carbon dioxide under pressure at 120°–145° (Heyden, D. R.-P. 38052 of 1886), or with solid, liquid, or gaseous carbon dioxide in the cold and subsequently heating the sodium α-naphthyl carbonate thus produced at 120°–140° (Schmitt, D. R.-P. 31240 of 1884; Schmitt and Burkard, Ber. 1887, 20, 2699). The *acid* crystallises in needles, m.p. 187°, is only very sparingly soluble in water (0·058 grm. in 100 c.c. at 17°), and gives with ferric chloride a blue colouration. The *sodium* salt $NaA+H_2O$, scales, and the *ammonium* salt NH_4A, needles, are readily soluble in hot water (Schmitt and Burkard, *l.c.*).

Reactions.—(1) Nitrous acid reacts with it, forming 2-*nitroso-α-naphthol* with the elimination of carbon dioxide (Reverdin and de la Harpe, Ber. 1893, 26, 1280); nitric acid converts it into 2 : 4-*dinitro-α-naphthol* (Nietzki and Guitermann, Ber. 1887, 20, 1275).

(2) It couples with diazotised bases forming para- *azo-* dyes (Nietzki and Guitermann, *l.c.*; Bischoff, Ber. 1890, 23, 1910; *cf.* Nietzki, D. R.-P. 44170; Eng. Pat. 17583 of 1887; D. R.-P. 46203 of 1888; Höchst, D. R.-P. 48357 of 1888).

The 4-sulphonic acid is obtained by warming 1-hydroxy-2-naphthoic acid with monohydrate at 60°–70° until sulphonation is complete (Dahl, D. R.-P. 51715 of 1889; *cf.* König, Ber. 1889, 22, 787). The *acid* H_2A+5H_2O, crystallising in small needles, shows blue fluorescence in alkaline solution.

Reactions.—(1) Nitric acid converts it successively into 4-*nitro*-1-*hydroxy*-2-*naphthoic acid* and 2 : 4-*dinitro-α-naphthol* (König, Ber. 1890, 23, 806).

(2) It couples with diazotised bases forming *azo-* dyes, which, owing to elimination of carbon dioxide, are derivatives not of β-naphthoic acid, but of α-naphthol-4-sulphonic acid (König, Ber. 1890, 23, 806; *cf.* Dahl, *l.c.*; Bayer, D. R.-P. 38802; Eng. Pat. 14424 of 1885).

The 4 : 7-disulphonic acid is the main product of the sulphonation of 1-hydroxy-β-naphthoic acid with 20 p.c. anhydro- acid at 100° (König, Ber. 1889, 22, 787; Seidler, D. R.-P. 56328 of 1889). The acid H_3A+4H_2O, needles, shows bluish-green fluorescence in alkaline solution.

Reactions.—(1) When boiled with 3 p.c. hydrochloric acid it yields *α-naphthol*-4 : 7-*disulphonic acid,* but when heated with dilute sulphuric acid (b.p. 160°) at 140° it gives 7-*sulpho*-1-*hydroxy*-2-*naphthoic acid* (Friedlaender and Taussig, Ber. 1897, 30, 1460).

(2) On fusion with caustic alkali at 220°–240°, it forms 4-sulpho-1 : 7-dihydroxy-2-naphthoic acid (Friedlaender and Zinberg, Ber. 1896, 29, 38), and at a higher temperature 1 : 7-*dihydroxynaphthalene*-4-*sulphonic acid* (Bindschedler, D. R.-P. 81938 of 1893; Eng. Pat. 4629 of 1894).

(3) It couples with diazotised bases forming *azo-* dyes of α-naphthol-4 : 7-disulphonic acid, owing to elimination of carbon dioxide (König, Ber. 1890, 23, 810; *cf.* Bindschedler, D. R.-P. 96930; Eng. Pat. 4630 of 1894).

(iv.) **2-Hydroxy-3-naphthoic acid** is obtained by allowing the calculated quantity of carbon dioxide to act on dry sodium β-naphtholate at at 200°–250° under pressure (Heyden, D. R.-P. 50341; Eng. Pat. 9612 of 1889; Schmitt and Burkard, Ber. 1887, 20. 2702). It crystallises in yellow scales, m.p. 216°, dissolves only very sparingly in hot water, and is characterised by its great stability, being decomposed, with loss of carbon dioxide, only when boiled with sodium bisulphite solution (Bucherer, J. pr. Chem. 1905, [ii.] 71, 445). Its normal salts are yellow, but the basic *sodium* salt, like the *acetyl* derivative, m.p. 176°–177° (Grädenwitz, Ber. 1894, 27, 2624), is colourless.

Reactions.—(1) On oxidation with potassium permanganate in alkaline solution it gives *o-carboxyphenylglyoxylic acid* (Schöpff, Ber. 1893, 26, 1123) and *phthalic acid* (Schmid, *ibid.* 1114).)

(2) When heated with ammonia under pressure at 260°–280° it is converted into 2-*amino*-3-*naphthoic acid* (Möhlau, Ber. 1893, 26, 3067).

(3) With nitrous acid it yields 1-*nitroso*-2-*hydroxy*-3-*naphthoic acid* (Kostanecki, Ber. 1893, 26, 2898).

(4) It couples with diazotised bases, forming *azo-* dyes, without elimination of the carboxyl group (Kostanecki, *l.c.*: *cf.* Aktienges., D. R.-P. 77286; Eng. Pat. 15789 of 1892; Griesheim, D. R.-P. 171904; Eng. Pat. 7839 of 1905; Merz, D. R.-P. 213499 of 1907; Eng. Pat. 16372 of 1908).

The 6-sulphonic acid (L- acid), and the 8-sulphonic acid (S- acid), obtained by sulphonating 2-hydroxy-3-naphthoic acid with monohydrate at 60° or above, are separated as calcium salts, that of the L-acid being the more soluble in hot water (Gesellsch., D. R.-P. 69357 of 1892; Schmid, Ber. 1893, 26, 1118; Hirsch, *ibid.* 1177), or as acid sodium salts, that of the L-acid being the less soluble (Bucherer, *cf.* J. Soc. Chem. Ind. 1903, 22, 945). The L-acid couples readily, but the S- acid only slowly with diazotised bases.

The 6 : 8-disulphonic acid is the chief product of the sulphonation of 2-hydroxy-3-naphthoic acid (Gesellsch., D. R.-P. 67000; Eng. Pat. 14161 of 1892), or of L- acid or S- acid (Schmid, *l.c.*), with 24 p.c. anhydro-acid at 125–150°.

Reactions.—(1) By fusion with caustic soda at 210°–240° it is converted into 3-*sulpho*-1 : 7-*dihydroxy*-6-*naphthoic* or *nigrotic acid* (Gesellsch., *l.c.*; *cf.* D. R.-P. 71202 of 1892; Schmid, *l.c.*).

(2) When heated with ammonia solution under pressure at 240°–280°, it gives 6-*sulpho*-2-*amino*-8-*hydroxy*-3-*naphthoic acid* (Gesellsch., D. R.-P. 69740 of 1892).

Of the remaining hydroxynaphthoic acids four have been obtained by fusing the isomeric sulphonaphthoic acids with caustic potash (Battershall, Annalen, 1873, 168, 121; Stumpf, *ibid.* 1877, 188, 1), and two from the corresponding naphthylaminecarboxylic acids (Friedlaender, Heilpern and Spielfogel, *cf.* J. Soc. Chem. Ind. 1898, 17, 836).

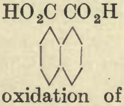
DIHYDROXYNAPHTHALENECARBOXYLIC ACIDS.

Introductory. — The dihydroxynaphthalenecarboxylic acids have little technical importance. *Five*, namely those containing the radicles OH : OH : CO_2H in the 1 : 2 : 3-, 1 : 4 : 2-, 1 : 7 : (?)-, 1 : 8 : 2-, and 2 : 7 : (3)- positions, have been obtained by interaction of the heated sodium salts of the respective dihydroxynaphthalenes with carbon dioxide under pressure (*cf.* Möhlau, Ber. 1893, 26, 3067; 1895, 28, 3093; Schmid, *ibid.* 1893, 26, 1117; Heyden, D. R.-P. 55414 of 1890), and *two*, containing these radicles respectively in the 1 : 7 : 6- (*infra*) and 2 : 6 : 3-positions, by fusion of the isomeric sulpho-2-hydroxy-3-naphthoic acids, S and L, with caustic alkali (*cf.* Schmid, *l.c.*; Gesellsch., D. R.-P. 69357 of 1892). Of these acids four, *viz.* the 1 : 7 : 6-, 1 : 8 : 2-, 2 : 6 : 3-, and 2 : 7 : (3)-derivatives, couple with diazotised bases forming *azo-* dyes.

1 : 7-*Dihydroxynaphthalene*-2-*carboxylic acid.* The 4-sulphonic acid is produced by fusing 4 : 7-disulpho-1-hydroxy-2-naphthoic acid with 80 p.c. caustic soda solution at 190° (Bindschedler, D. R.-P. 84653; Eng. Pat. 4630 of 1894), or with caustic soda at 220°–240° (Friedlaender and Zinberg, Ber. 1896, 29, 38). It couples with diazotised bases (Bindschedler, *l.c.*), and is converted into 1 : 7-*dihydroxynaphthalene*-4-*sulphonic acid* when heated with 30 p.c. caustic soda at 140°–160° (Bindschedler, D. R.-P. 83965 of 1893), but into the 2-*carboxylic acid* when either boiled with 20 p.c. hydrochloric acid (Bayer, D. R.-P. 89539 of 1894), or heated at 140° with 50 p.c. sulphuric acid (Friedlaender and Zinberg, *l.c.*).

1 : 7-*Dihydroxynaphthalene*-6-*carboxylic acid.* The 3-sulphonic acid (**nigrotic acid**, *cf.* Bucherer, J. pr. Chem. 1907, [2] 75, 287), obtained by fusing 6 : 8-disulpho-2-hydroxy-3-naphthoic acid with caustic soda at 210°–240° (Gesellsch., D. R.-P. 67000; Eng. Pat. 14161 of 1892; Schmid, Ber. 1893, 26, 1119) shows yellowish-green fluorescence in alkaline solution. It couples with diazotised bases forming black or grey *azo-* dyes (Gesellsch., D. R.-P. 71202 of 1892; D. R.-P. 75258; Eng. Pat. 14253 of 1892; D. R.-P. 80912, 84546; Eng. Pat. 4460 of 1894).

NAPHTHALENEDICARBOXYLIC ACIDS.



The naphthalenedicarboxylic acids have no technical value, but **naphthalene-1 : 8-dicarboxylic acid** (*naphthalic acid*), obtained by the oxidation of acenaphthene with chromic acid mixture (Behr and Van Dorp, Annalen, 1874, 172, 266; Anselm, Ber. 1892, 25, 652), is of interest chiefly on account of the readiness with which, like *ortho*-dicarboxylic acids, it is converted into an *anhydride* (m.p. 274°) or *imide* (m.p. 300°); and of the resemblance which this *peri*-anhydride shows to phthalic anhydride (Terisse, Annalen, 1885, 227, 135) in forming a *fluoresceïn* by condensation with resorcinol.

NARINGIN $C_{21}H_{26}O_{11}$. A glucoside obtained from the blossoms of *Citrus decumana* (Murr.). It is a white substance which dissolves in alcohol and in warm water, and crystallises with

4 mols. H_2O, sp. rotatory power in aqueous solution $[\alpha]_D=84 \cdot 5°$; in alcoholic solution $[\alpha]_D=87 \cdot 6°$. By hydrolysis is resolved into *iso*dulcit and *naringenin* $C_{15}H_{12}O_5$, a white crystalline substance, m.p. 248° with decomposition. Gives a deep-brown-coloured solution with ferric chloride, and is readily soluble in alcohol, ether, and benzene. Naringenin is readily decomposed when boiled with conc. KOH, into phloroglucinol and *naringenic acid* C_9H_8O, a white crystalline powder, m.p. 207°, soluble in water, giving a red-brown-coloured solution with ferric chloride. Its aqueous solution treated with sodium amalgam gives *hydronaringeninic acid* ($C_9H_{10}O_3$), m.p. 126° (W. Will, Ber. 20, 294) (*v.* GLUCOSIDES).

NATROLITE. One of the commonest of the several minerals belonging to the zeolite group of hydrated silicates. Its composition is $Na_2Al_2Si_3O_{10},2H_2O$, and it crystallises in the orthorhombic system, sometimes as square prisms, but more often as fine needles. It is usually found as radiating fibrous masses in the steam-cavities of volcanic rocks. Sp.gr. 2·25. Colour, usually white; lustre, vitreous. Compact, radially-fibrous material with concentric yellow bands, from Hohentwiel in Würtemberg, has occasionally been cut and polished for ornamental purposes. L. J. S.

NATRON. A mineralogical term (from the ancient νίτρον, soda) for the hydrated sodium carbonate $Na_2CO_3,10H_2O$, crystallising in the monoclinic system. Since this hydrate crystallises only at temperatures below 20°, it is only under exceptional conditions that it is likely to be found in the natron or soda lakes of desert regions; and if formed it would soon effloresce into the monohydrate Na_2CO_3,H_2O, known as thermonatrite. According to Dana it exists only in solution. The native soda met with in the regions of natron lakes consists for the most part of the salt $Na_2CO_3 \cdot NaHCO_3,2H_2O$ known as trona, together with thenardite (Na_2SO_4) and halite (NaCl) (*v.* TRONA). L. J. S.

NEAPOLITAN YELLOW *v.* ANTIMONY.

NEAT'S FOOT OIL. Neat's foot oil (*Oleum bubulum* of the B.P.) is obtained from the feet of cattle by boiling with water. In this country the preparation of neat's foot oil is chiefly carried out in small establishments, in which the by-products and waste material of the slaughter-houses are worked up ('tripe shops'). The feet are carefully scraped and washed, the hoofs are cut off, and after the hair has been removed, they are boiled with water in jacketed pans heated by steam, the water being kept simmering for 8–10 hours. The oil rises to the top, and is skimmed off from time to time by means of suitable skimmers.

On a large scale, neat's foot oil is obtained as a by-product in the centres of the meat-packing trade (Chicago, South America). There the feet are taken in their fresh state from the slaughter-houses and sawn by a circular saw into suitable sizes for further working up. The chief object of sawing off the feet is to separate the more costly shin bones from the feet proper, which latter yield the genuine neat's foot oil. The fatty matter contained in the shin bones approaches somewhat in consistence horse- or beef-marrow fat, as the case may be. When kept separate it is sold as 'bone oil.' This oil must not be confounded with neat's foot oil, nor with bone fat. It is, however, customary in America to recover the oil from the shin bones, together with the neat's foot oil, by boiling the shin bones with the feet. Therefore American oil has a higher solidifying-point than that prepared in this country. The feet are scalded by immersion in boiling water from 10 to 15 minutes in order to loosen the hoofs, which are removed.

The oil is skimmed off as it rises to the surface, filtered roughly through a fine wire screen, separated from water as far as possible, and then run into vessels provided with close steam coils. Steam is passed through the coils and the water still contained in the oil thereby driven off, whilst at the same time organic impurities (albumen) become coagulated. The dried oil is finally obtained in a perfectly limpid state by filtering.

Neat's foot oil is pale yellow and has a bland taste. For the chemical and physical characters of the oil, *see* OILS, FIXED, AND FATS, tables. Properly prepared oil contains only a very small amount of free fatty acids. On standing, the oil deposits 'stearine.' This 'stearine' is frequently removed by filtering at a low temperature; this is done especially in the preparation of neat's foot oil for the leather industries, in which oil of a low 'cold test' is required. Owing to its comparatively high price neat's foot oil is largely adulterated with vegetable oils, fish oils, and even mineral oils. For the detection of the adulterants, *see* Lewkowitsch, Chem. Techn. ii. 403.

Neat's foot oil is a valuable lubricating oil for clocks, guns, sewing machines, and other delicate machinery. It is largely used in the leather industries ('fat liquor'). J. L.

NEEDLE-ORE or **AIKINITE** $PbCuBiS_3$.

NEMALITE *v.* BRUCITE.

NEODYMIUM. Sym. Nd. At.wt. 144·3. The fractionation of the cerite earths by Mosander in 1842 led to the separation of a new oxide, to the supposed element of which the name '*Didymium*' was given on account of the constant association of this substance with the metal lanthanum.

In 1879 the didymium earths yielded another element, samarium (Lecoq de Boisbaudran, Compt. rend. 88, 323), and six years later Auer von Welsbach succeeded in resolving 'didymium' into two components *neodymium* and *praseodymium* by the systematic fractional crystallisation of the double ammonium and sodium nitrates (Monatsh. 1885, 6, 477).

Occurrence.—In the rare minerals cerite, orthite, ytterbite, aeschynite, monazite, and samarskite.

Separation. (I.) *Fractional precipitation methods* depending on differences in basic strength (*v.* LANTHANUM).

(II.) *Crystallisation methods.*—The rare earth nitrates in aqueous solution are acidified with one-tenth of their weight of nitric acid and treated with the calculated amount of ammonium nitrate, the liquid being then evaporated to the crystallising-point and left for 24 hours. The mother liquor is again concentrated to the crystallising-point and the process repeated 6–8 times. The fractions thus obtained are again systematically crystallised and the cycle of operations repeated many times until finally the lanthanum ammonium nitrate separates in the least soluble fractions, followed successively by the praseodymium and neodymium double salts. The course of the separation is to some extent indicated by the colour differences of the various fractions; those richest in lanthanum are colourless, then follow successively green fractions containing chiefly praseodymium and some colourless fractions in which the neutral tint is due to the complementary colours of praseodymium and neodymium salts. The more soluble fractions show the pink colour of neodymium salts, and finally the uncrystallisable mother liquors contain the very soluble salts of samarium and the terbium and yttrium metals. Owing to the presence of these soluble salts the neodymium fractions do not crystallise readily, and it is therefore convenient to remove the yttrium earths by a basic process and then convert the crude neodymium salt into double sodium nitrate. The crystallisation of this double salt furnishes fractions still containing praseodymium, and this component is the more readily separated from neodymium by the addition of lanthanum, with which it subsequently crystallises in the least soluble fractions.

Although the proportions of neodymium and praseodymium present in the rare earths vary within wide limits, yet ‘didymium’ solutions generally have a pink colour owing to the predominance of the former component.

Various modifications of von Welsbach's process have been introduced. After removing the main portion of the lanthanum the separation of praseodymium is accelerated by the addition of pure cerous ammonium nitrate, the cerous and praseodymium double salts crystallising together (Schéele, Ber. 1899, 32, 409; *cf.* Dennis and Chamot, J. Amer. Chem. Soc. 1897, 19, 799).

The manganous double nitrates, when crystallised from strong nitric acid give only a small amount of the middle fractions containing mixed praseodymium and neodymium salts, and bring about a sharp separation between the latter metal and samarium (Lacombe, Bull. Soc. chim. 1904, [iii.] 31, 570).

The magnesium double nitrates

$$2R(NO_3)_3,3Mg(NO_3)_2,24H_2O$$

have been employed in acid, neutral and slightly basic solutions. In this process a preliminary separation is sometimes effected by means of moderately concentrated potassium carbonate when lanthanum and praseodymium are concentrated in the precipitate whilst neodymium, samarium, and the yttrium metals accumulate in the filtrate (Demarçay, Compt. rend. 1900, 130, 1019, 1185; Drossbach, Ber., 1902, 35, 2826; Muthmann and Weiss, Annalen, 1904, 331, 1).

Fractionation of the oxalates has been used in freeing praseodymium from lanthanum, and neodymium from samarium (Schéele, *l.c.*; R. T. Meyer, Zeitsch. anorg. Chem. 1904, 41, 94).

Purification of neodymium and praseodymium. Neodymium is freed from samarium and the yttrium metals by continued crystallisation of the double nitrates and finally by fractional precipitation with ammonia.

The *m*-nitrobenzenesulphonates have been suggested as a means of obtaining pure neodymium preparations (Holmberg, Bihang. Sv. Vet. Akad. Handl. 1903, 28, II. No. 5; Chem. Centr. 1906, ii. 1595).

Fractional precipitation of neodymium chloride with hydrogen chloride serves to free neodymium from lanthanum (Baskerville and Stevenson, J. Amer. Chem. Soc. 1904, 26, 54).

Praseodymium sulphate is approximately twice as soluble in water as neodymium sulphate at temperatures ranging from 10° to 70°, and this difference has been utilised in separating the two elements (Muthmann and Rölig, Ber. 1898, 31, 1718).

It is scarcely possible to free praseodymium from last traces of lanthanum, but the following means have been recommended: crystallisation of oxalates (Feit and Przibylla, Zeitsch. anorg. Chem. 1905, 43, 202); crystallisation of citrates (Baskerville and Turrentine, J. Amer. Chem. Soc. 1904, 26, 46; Zeitsch. anorg. Chem. 1905, 45, 86; *cf.* R. J. Meyer, *ibid.* 1904, 41, 94); fusion of nitrates with potassium nitrate when praseodymium dioxide and basic lanthanum nitrate are produced, the latter being extracted with cold aqueous ammonium nitrate; oxidation with potassium permanganate and mercuric oxide followed by the gradual addition of cerous chloride when the higher oxides of praseodymium and cerium are precipitated, the lanthanum remaining in solution (Orloff, Chem. Zeit. 1907, 31, 115).

Metallic neodymium, sp.gr. 6·9563, m.p. 840°, which is obtained by electrolysing the fused chloride (Annalen, 1902, 320, 231; 1904, 331, 1), has a pale-yellow tinge; when heated at 220° in hydrogen it absorbs the gas forming the hydride NdH_3 or NdH_2.

Neodymium carbide NdC_2, yellow hexagonal plates, sp.gr. 5·15, produced by heating the oxide with sugar carbon in the electric furnace (900 ampères, 50 volts) is decomposed by water evolving approximately 66 p.c. of acetylene, 6 p.c. of olefines, and 28 p.c. of paraffins (Moissan, Compt. rend. 1900, 131, 595).

Neodymium sulphide Nd_2S_3, olive green, sp.gr. 5·179, obtained by passing hydrogen sulphide over the heated sulphate or sulphur vapour over the carbide (Ber. 1899, 32, 3413).

Neodymium fluoride NdF_3, lilac crystalline powder, precipitated by hydrofluoric acid from a warm solution of the nitrate (Ber. 1908, 41, 634).

Neodymium chloride $NdCl_3$, a crystalline pink hygroscopic mass prepared by (1) dehydrating the hydroxide in a current of hydrogen chloride; (2) heating the oxide or sulphate in chlorine and sulphur chloride (Matignon, Compt. rend. 1901, 133, 289; 1904, 138, 631); (3) decomposition of the sulphide with hydrogen chloride (Muthmann and Stützel, Ber. 1899, 32, 3413). The anhydrous salt absorbs from 2 to 12 molecular proportions of ammonia, and is slowly converted by dry air into the oxychloride NdOCl. The hexahydrate $NdCl_3,6H_2O$ separates from aqueous or aqueous-alcoholic solution in pink rhombic crystals (Ann. Chim. Phys. 1906, [vii.] 8, 243; Ber. 1902, 35, 2622).

Neodymium bromide and **iodide** are produced respectively by warming the anhydrous chloride in hydrogen bromide and iodide; the latter is a black crystalline mass (Compt. rend. 1905, 140, 1637).

Neodymium hydroxide $Nd(OH)_3$, obtained as a bluish-white precipitate from soluble neodymium salts by the action of caustic alkalis or ammonia (Zeitsch. anorg. Chem. 1905, 43, 267).

Neodymium oxide (*neodymia*) Nd_2O_3, a pale blue powder with violet tinge, prepared by heating the hydroxide, oxalate, nitrate, &c. (Monatsh. 1885, 6, 477; Amer. Chem. J. 1898, 20, 345; Compt. rend. 1898, 126, 1039; Annalen, 1904, 331, 1; J. Amer. Chem. Soc. 1904, 26, 54; Bull. Soc. chim. 1904, [iii.] 31, 570). Higher oxides have been described: NdO_2 by Brauner (Zeitsch. anorg. Chem. 1902, 32, 1) and Nd_4O_7 by Waegner (*ibid.* 1904, 42, 118).

Neodymium nitrate $Nd(NO_3)_3,6H_2O$ (for isodimorphism with bismuth nitrate, *v.* Bodman, Ber. 1898, 31, 1237) furnishes the following double nitrates—

$$2Nd(NO_3)_3,3Mg(NO_3)_2,24H_2O,$$
$$Nd(NO_3)_3,2NH_4NO_3,4H_2O,$$
$$\text{and } Nd(NO_3)_3,2RbNO_3,4H_2O$$

(Zeitsch. anorg. Chem. 1911, 69, 221).

Neodymium chromate, moss green mass (Chem. Zeit. 1907, 31, 562).

Neodymium carbonate $Nd_2(CO_3)_3$, a pale red precipitate readily soluble in excess of alkali carbonates forming double carbonates

$$Nd_2(CO_3)_3,R_2CO_3,$$

the solutions of which are blue and exhibit absorption spectra differing as to the position and intensity of the bands from those of simpler neodymium salts.

Neodymium oxalate $Nd_2(C_2O_4)_3,10H_2O$ with the exception of thorium oxalate is the least soluble in acids of any of the rare earth oxalates.

Neodymium acetylacetonate

$$Nd[CH(CO{\cdot}CH_3)_2]_3$$

violet crystalline mass, m.p. 144°–146°; its molecular weight in ethyl sulphide is double that indicated by the foregoing formula.

The *absorption spectrum* of neodymium is much more complex than that of praseodymium. A 10 p.c. neodymium chloride solution shows upwards of 17 bands, and 29 (range $\lambda742$–$\lambda328$) have been noticed on dilution (Le Radium, 1909, 6, 215; Compt. rend, 1898, 126, 1039; Proc. Amer. Phil. Soc. 1908, 47, 276).

For *spark* and *arc spectra v.* Exner and Haschek, Sitzungsber. Wien. 1899, II*a*. 108, 1088; Die Wellenlängen der Bogenspektra, 1904; Zeit. wiss. Photograph. Photophys. Photochem. 1906, 3, 411, 4, 16.

$$[Nd,Pr]{\cdot}[C_6H_4(OH){\cdot}CO_2]_3$$

a reddish-white substance, has been employed as a dusting powder having non-irritant, non-poisonous and antiseptic properties (Kopp, Therapeutische Monatsh. 1901, 2). G. T. M.

NEOGEN. An alloy resembling silver in colour, said to have the following composition (Sauvage, Dingl. poly. J. 215, 377):

Cu	Zn	Ni	Sn	Al	Bi
58·0	27·0	12·0	2·0	0·5	0·5

NEON. Sym. Ne. At.wt. 20·2 (Watson, *v. infra*). An inert gas, discovered by Ramsay and Travers in the lighter portions of gas obtained by fractionating 15 litres of crude argon (Proc. Roy. Soc. 1898, 63, 438; Phil. Trans. 1901, 47). The method employed in the separation of neon from the accompanying helium and argon is fully described in Travers’ Study of Gases, 212–218. To obtain a gas rich in neon (and helium), the gas escaping from an air liquefier is used. This gas is chiefly nitrogen; it is liquefied and a current of air blown through the liquid. The first portion of the liquid to evaporate contains nearly all the neon and helium present. After removing oxygen and nitrogen, the argon is separated by fractional evaporation at the temperature of liquid air. To separate neon from helium effectively, fractionation must be carried out at the temperature of liquid hydrogen (*cf.* Watson, Chem. Soc. Trans. 1910, 97, 810). Neon and helium may be separated from the remaining inert gases by absorbing the latter in charcoal at the temperature of liquid air (Valentiner and Schmidt, Sitzungber. K. Akad. Wiss. Berlin, 1905, 38, 816).

Neon is much more abundant in the atmosphere than krypton and xenon; 1 million volumes of air contain 15 volumes of neon (Claude, Compt. rend. 1909, 148, 1454; *cf.* Watson, Chem. Soc. Trans. 1910, 97, 810; Ramsay, Proc. Roy. Soc. 1905, 76, A, 111; 1908, 80, A, 599). It also occurs in the gases evolved from many thermal springs (Moureu and Biquard, Compt. rend. 1906, 143, 180).

Neon is a colourless, odourless, tasteless gas. Next to helium and hydrogen, it is the least easily condensable gas known. Its critical temperature is below −210°; at the temperature of liquid hydrogen it solidifies. The critical pressure is 29 atmospheres, and the triple-point pressure for the system solid-liquid-gas is 35 cm. (Onnes, Proc. K. Akad. Wetensch. Amsterdam, 1909, 12, 175). At N.T.P. 1 litre of neon weighs $0{\cdot}9002\pm0{\cdot}0003$ grams (Watson, Chem. Soc. Trans. 1910, 97, 832). The compressibility of the gas has been studied by Burt (Trans. Faraday Soc. 1910, 6, 19). The refractive index of neon at N.T.P. for the green mercury line ($\lambda=5461$) is 1·0000672 (Cuthbertson and Cuthbertson, Proc. Roy. Soc. 1910, 83, A, 149); for its viscosity, *v.* Rankine (Proc. Roy. Soc. 1910, 83, A, 516). Neon is slightly soluble in water, the absorption coefficient at 20° being 0·0147 (Antropoff, *ibid.* 1910, 83, A, 474).

When neon is shaken in a tube with mercury, a red glow is observed, which is as bright at 120–200 mm. as at 760 mm. On long shaking, the glow ceases to appear; but the property is restored by sparking the gas. Moisture must be absent; hydrogen does not seriously affect the glow, which is more pronounced in a silica tube than in one of glass (Collie, Proc. Roy. Soc. 1909, 82, A, 378). For the spectrum of neon, *v.* Baly (*ibid.* 1903, 72, 84; Phil. Trans. 1903, A, 202, 183); Liveing and Dewar (Proc. Roy. Soc. 1901, 68, 389); Purvis (Proc. Camb. Phil. Soc. 1909, 15, 45).

Neon is monatomic, since the ratio of its specific heat is 1·66 (Ramsay and Travers).

NEPHRITE *v.* JADE.

NEROL $C_{10}H_{18}O$ is a terpene alcohol, first isolated by Hesse and Zeitschel (J. pr. Chem. 1902, [ii.] 66, 481) from the neroli oil of orange blossom oil. It is also contained in petit-grain oil (Soden and Zeitschel, Ber. 1903, 36, 265); in

Bergamot, Java Cananga, and in French lavender and other ethereal oils (Elze, Chem. Zeit. 1910, 34, 538, 857, 1029; Soden and Treff, Ber. 1904, 37, 1094).

Preparation.—South American petit-grain oil is saponified and then carefully distilled with steam or under reduced pressure. The higher boiling-point fractions contain the nerol together with geraniol and terpineol; the two former are separated from the latter by converting them into their acid phthalic esters. After purifying and saponifying, the mixture is treated with powdered anhydrous calcium chloride with which geraniol gives a solid product, whereas nerol is unaffected and can be washed out with light petroleum (D. R. P. 150495; Soden and Zeitschel, *l.c.*). In a similar manner nerol can be prepared from *Helichrysum angustifolium* and other species of *Helichrysum* from which larger yields are said to be obtained (D. R. P. 209382; Chem. Zentr. 1909, i. 1785). Nerol of the same composition and properties has also been obtained by heating linalool with acetic anhydride and sodium acetate, or with formic acid, or a mixture of sulphuric and acetic acids, the nerol being separated from the resulting product as above (D. R. PP. 165894; 165895; 165896; Zeitschel, Ber. 1906, 39, 1780, 1792).

The nerol obtained by any of the above methods still contains geraniol from which it can be finally purified by treatment with diphenyl carbamide chloride in the presence of pyridine. The geranyl and neryl diphenyl urethanes thus formed are separated by fractional crystallisation from light petroleum.

Neryl diphenyl urethane, m.p. 52°–53°, when treated with an alcoholic solution of potassium hydroxide, yields pure nerol (Soden and Treff, Chem. Zeit. 1903, 27, 897; Ber. 1906, 39, 906).

Properties.—Nerol is a colourless oil, b.p. 226°–227°/755 mm., 125°/25 mm., sp.gr. 0·8813 at 15°, and having a delicate fresh rose smell (Austerweil and Cochin, Compt. rend. 1910, 151, 440) on account of which it has been employed for the manufacture of artificial perfumes (D. R. P. 155287; J. Soc. Chem. Ind. 1903, 819). Nerol has been found to have a toxic action on mice (Hildebrandt, Beitr. Chem. Physiol. Path. 1903, 4, 251). Nerol is probably a space isomeride of geraniol; when oxidised with chromic acid it yields a substance with the odour of methylheptanone, and, probably, citral *b*, mixed with a little citral *a*. Citral *b* when reduced forms nerol. On prolonged shaking nerol forms terpin hydrate (Zeitschel, Ber. 1906, 39, 1780).

Nerol tetrabromide $C_{10}H_{18}OBr_4$, obtained by adding the calculated quantity of bromine to a solution of nerol in chloroform, evaporating and recrystallising from ethyl acetate, forms long, silky needles, m.p. 118°–119° (Soden and Treff, Ber. 1906, 39, 906).

The aliphatic esters of nerol have a similar smell to nerol; the *acetate*, b.p. 93°–94°/3 mm., 134°/25 mm., sp.gr. 0·916 at 15°, saponification number 286·2, and the *formate*, b.p. 119°–121°/25 mm., sp.gr. 0·928 have been prepared (Soden and Zeitschel, *l.c.*; Soden and Treff, *l.c.*).

Nerolidol $C_{10}H_{26}O$ is probably an aliphatic sesquiterpene alcohol. It is contained in neroli, and rose oils, and is, possibly, identical with or very similar to farnesol. It forms a colourless oil possessing a faint but permanent pleasant odour, has b.p. 128°–129°/6 mm., 164°–165°/25 mm., 276°–277°/760 mm., sp.gr. 0·880; $[\alpha]_D + 13·32°$ (Hesse and Zeitschel, *l.c.*), b.p. 149°/4 mm., sp.gr. 0·894 at 15°, $\alpha \pm 0°$ (Soden and Treff, Ber. 1904, 37, 1094). It forms an addition product with 6 atoms of bromine.

NICKEL. At.wt. 58·68; sym. Ni.

History.—This metal was discovered by Cronstedt in 1751, who isolated it from an ore containing arsenide of nickel NiAs, a copper coloured mineral called by the German miners *kupfer-nickel* or false copper, because of its resemblance to the colour of certain copper ores.

Occurrence.—Nickel is always present in meteoric iron, which is composed mainly of a nickel iron alloy containing 6–7 p.c. nickel, and in addition a small quantity of a complex alloy containing a constituent with about 40 p.c. nickel (Smith, Proc. Roy. Soc. A, 1907, 79, 132). It is also a constituent of the solar atmosphere.

The ores of nickel are widely distributed and have been worked for some time in many countries, especially in Saxony, Norway, and Sweden, Austria, Spain, Russia, the United States, and to some extent in different parts of Great Britain. Nickel exists in these countries usually associated with cobalt, as *kupfer-nickel* NiAs, *nickel-glance* $Ni(AsS)_2$, *nickel-blende* or *millerite* NiS, *cobalt-speiss* $(CoNiFe)As_2$, magnetic pyrites, &c.

The ores that have been found in the above countries are generally very complex in composition, containing, besides nickel and cobalt, copper, antimony, arsenic, iron, manganese, sulphur, &c. This fact renders the extraction of metallic nickel from such ores both expensive and troublesome.

The principal sources of nickel at the present time, however, are (1) mixed silicate of nickel and magnesium named after its discoverer *Garnierite*, and (2) nickeliferous magnetic, or copper, pyrites. The former (1) occurs in New Caledonia as a green- or brown-coloured ore which is found in veins in serpentine and other rocks. Similar silicates have since been found in other localities, but only in small quantities. The ore usually contains about 10 p.c. of nickel, and the following composition may be regarded as typical: 9–17 p.c. NiO; 41–46 p.c. SiO_2; 5–14 p.c. Fe_2O_3; 1–7 p.c. Al_2O_3; 6–9 p.c. MgO; 8–16 p.c. H_2O.

The nickeliferous magnetic pyrites (*pyroholite*) are found in Norway, Sweden, Saxony, Pennyslvania, &c., but the principal deposits occur at Sudbury in Ontario, these being now the chief source of the nickel of commerce. They occur chiefly as lenticular deposits in diorite dykes in rocks of the Huronian and Laurentian formations, these deposits being occasionally over 300 feet in length and 100 feet in thickness. The average amount of nickel is about 3 p.c., but the percentage apparently increases with the depth of the deposit, some of the lower deposits giving from 8 to 10 p.c. of nickel.

Extraction.—The method of extraction of nickel varies with the nature of the ore, and differs in detail in different works, but the general principle is as under. In the case of sulphide ores containing chiefly iron sulphide with a smaller quantity of nickel sulphide, and also probably some copper sulphide, the treatment consists of the following processes: (*a*) the removal of earthy materials and excess of sulphur with the production of a matte consisting of the sulphides of the metals; (*b*) the refining of the matte, that is the removal of the iron; (*c*) the conversion of the refined nickel sulphide, or nickel-copper sulphides into nickel, or if desired into an alloy of nickel and copper.

(*a*) If the percentage of sulphur is high the ores are subjected to a preliminary roasting either in heaps, stalls, kilns, or reverberatory furnaces. When roasted in heaps, the ore is broken and piled on a bed of wood above a layer of fine ore; the whole heap is covered with fine ore, and a central chimney is left. Such a heap may contain from 600 to 3000 tons, and the roasting may take from 6 to 20 weeks. If the percentage of sulphur is low this roasting may not be necessary. The resulting mass consists chiefly of sulphides of the metals, together with oxide of iron and gangue. This is next smelted with a suitable flux in special water-jacketed blast furnaces. These usually vary from 10 to 20 feet in height, and are capable of working from 100 tons of ore daily. If oxide of iron is in excess a silicious flux is added such as an acid slag, but if the iron present is insufficient to form a slag, a basic slag is added. During the smelting the iron passes into the slag, the nickel and copper remaining in the matte as sulphides, but it is necessary still to leave a quantity of iron sulphide in the matte, as otherwise considerable loss of nickel will result. A matte thus produced from Sudbury ore may contain from 15 to 25 p.c. nickel, and from 25 to 35 p.c. of iron, together with some copper, present almost entirely as sulphides. Arsenic, if present, is partly volatilized and partly passes into the matte. The slag consists chiefly of silicate of iron, the Sudbury slag containing from 27 to 38 p.c. silica, and from 40 to 46 p.c. ferrous oxide. When poor ores are employed it may be necessary to concentrate the matte by repeating these processes.

(*b*) The removal of the iron, or the refining of the matte may be effected in reverberatory furnaces, or more speedily and effectively in Bessemer converters. When reverberatory furnaces are employed, two refining processes may be necessary. The matte is partially roasted and afterwards the temperature is raised and sand added to slag the iron. A refined matte containing about 0·5 p.c. iron is thus obtained. The converters employed resemble ordinary Bessemer converters with a quartz lining, and are capable of holding from 1 to 6 tons of matte, which is either previously melted or run in directly from the furnace in which it is produced. Fine sand is added during the blow in order to slag the iron and to preserve the converter lining. When the process is complete the blast is stopped and the slag and matte poured into separate pots. The refined matte consists almost entirely of sulphides of copper and nickel, and a very small quantity (about 0·3 p.c.) of iron. The slag, however, which is chiefly silicate of iron may contain from 2 to 10 p.c. of nickel, and is added to the ore charges.

(*c*) The refined matte is next converted into metallic nickel. If copper is absent the matte is crushed and roasted, at first at a dull red and later at a bright heat. After this roasting it is ground fine, sieved and again roasted at a bright red heat with the production of an oxide of nickel containing less than 0·005 p.c. sulphur. This is mixed with meal or sugar syrup, moulded into cubes, dried and heated with carbon in crucibles or in a muffle furnace for about 24 hours. The temperature of reduction is not sufficient to effect fusion of the nickel, and if molten nickel is required a flux is added and a higher temperature employed. When copper is present separation of the sulphides is necessary. To effect this the matte may be first fused with sodium sulphate and coal; the molten mass separates into two layers, the upper layer—'*tops*'—consisting chiefly of sulphides of sodium, iron, and copper, and the lower—'*bottoms*'—being chiefly sulphide of nickel. The 'bottoms' together with those obtained from a further treatment of the tops are again similarly smelted with sodium sulphate and coal, and the resulting concentrated 'bottoms,' consisting almost entirely of nickel sulphide treated as above. For treatment of the copper-nickel matte the Mond process (Eng. Pat. 23665, Dec. 10, 1895) is also employed. This is dependent on the formation of the volatile compound $Ni(CO)_4$ by the action of carbon monoxide on nickel, and its subsequent decomposition by increase of temperature. The matte is dead roasted in rotating reverberatory furnaces and completely converted into oxides; the resulting mass is finely ground and leached with dilute sulphuric acid in lead vats at a temperature of about 85°, and much of the copper is thus extracted. After drying the mass is reduced by heating in a current of water gas, the temperature being maintained at about 250°, whereby reduction of any oxide of iron is obviated, and the reduced nickel is obtained in a reactive condition. The nickel is then converted into nickel carbonyl in volatilising towers by the action of carbon monoxide at a temperature of about 50°. The gas is obtained partly from the later decomposition of carbonyl and partly from the unused water gas. The nickel carbonyl produced is drawn into towers heated by gas burners in an outer annular space to about 200°, and containing nickel pellets kept in motion. The gas passes up the towers depositing nickel on the pellets, and the carbon monoxide is drawn off through a cooled tube again to pass through the volatilisers. The pellets are drawn off from below, screened, and the smaller ones added with fresh charges at the top of the reduction towers, the larger ones being used for commerce. Before the reduced matte in the volatilisers is completely exhausted the action becomes very slow, and the matte is then again roasted, leached, and reduced. The nickel thus obtained is of a very high degree of purity, some specimens containing over 99·5 p.c. nickel, the chief impurity being a very small quantity of iron.

Various other methods for treatment of the refined mattes have been proposed, many dependent on the fact that by chlorinating, roasting, or by treatment with chlorides and superheated steam, the copper, cobalt, &c., are more readily converted into chloride than is the nickel, and are hence removable by lixiviation (J. Soc. Chem. Ind. 1906, 115). These methods are best adapted for ores with low copper percentage. When it is desired to produce a copper-nickel alloy direct from the matte, the latter is first dead roasted for complete elimination of sulphur. This is frequently done in two operations, the material being finely powdered after the first roasting. The resulting mixture of copper and nickel oxides is then made into cubes with syrup, &c., and heated with powdered charcoal in crucibles or is smelted with charcoal in suitable furnaces.

In the case of arsenical ores such as kupfernickel, &c., the treatment is similar to that of the sulphides, *i.e.* the ores are roasted, whereby the iron is oxidised while the nickel remains as arsenide. The coarse '*speiss*,' as this regulus is termed, is then smelted to slag the iron, the processes being repeated until the refined speiss contains little or no iron. This is then dead roasted with, if necessary, the addition of carbonaceous material and later saltpetre in order (1) to reduce arsenate, and (2) to complete the oxidation of arsenides. The oxide of nickel so obtained is treated as above.

The New Caledonian ores consist chiefly of silicate of nickel, and for its extraction these ores are first converted into sulphides by smelting in shaft furnaces with calcium sulphide (obtained from alkali waste) or with a mixture of calcium sulphate and coal. The ore, gypsum, and coal are first ground to powder and compressed into bricks; during the smelting the gypsum is reduced to sulphide, which interacts with the nickel silicate forming nickel sulphide and calcium silicate. The coarse matte thus obtained may contain 50–55 p.c. nickel, 25–30 p.c. iron, and 16–18 p.c. sulphur, and is then treated similarly to the mattes from sulphide ores (*v. supra*).

Wet methods. Wet methods are not used to any extent for the extraction of nickel direct from the ores, but are frequently used for its extraction from the speiss or matte produced as above. Very many variations of the method in general use have been proposed, but little information is forthcoming regarding the technical or commercial success of many of these. The general method involves first the dead roasting of the matte or speiss (in the case of the latter, carbonaceous material and an oxidiser may be added to effect the complete removal of the arsenic) the temperature being raised towards the end in order to obtain as much of the iron as possible in the ferric condition. The mixture of oxides thus produced is brought into solution by means of hydrochloric acid and precipitation of iron, as ferric oxide in the case of a matte and a mixture of oxide and arsenate in the case of a speiss, is effected by bleaching powder. Copper is precipitated as sulphide by hydrogen sulphide, and excess of the latter removed by boiling. The liquid is then neutralised and cobalt precipitated by bleaching powder, and finally the nickel is thrown down as hydroxide by means of milk of lime. It is afterwards dried and reduced to metal as above.

Various liquids have been used or suggested as solvents for the nickel in the roasted mattes, &c., *e.g.* sulphuric acid, ferric sulphate solution (Emmens, Min. Industry, 1894, 463), magnesium chloride solution or ammonia solution with air blast (McIvor and Fradd, J. Soc. Chem. Ind. 1906), ferric chloride (D. R. P. 100142). A method due to Herrenschmidt for the treatment of New Caledonian ores consists of treatment with concentrated ferrous sulphate solution, manganese cobalt and nickel dissolving as sulphates and the iron being precipitated as oxide. The three metals are precipitated as sulphides, by sodium sulphide, the manganese converted into calcium manganite by milk of lime and air blast and the precipitate of cobalt and nickel sulphides is converted into sulphates in a reverberatory furnace, from which, after conversion into chlorides, the cobalt is precipitated as sesquioxide. Another wet process (D. R. P. 68559) proposes precipitation of iron by copper carbonate, then copper by nickel hydroxide, and then separation of the cobalt and nickel.

Electrolytic methods for treatment of the mattes, &c., have been proposed and attempted. The methods are usually dependent on the use of the mattes or of the nickel-copper alloys produced from them as anodes in an acid electrolyte with low currents. In this case copper only is deposited, nickel passes into solution, while silver, platinum, &c. (occasionally present in Sudbury ores) pass into an anode slime. The liquid is drawn off and after precipitation of copper and iron present the nickel is separated either by electrolysis with a carbon anode and nickel cathode or by precipitation as hydroxide and subsequent reduction as above.

Properties of nickel.—Nickel is a lustrous silver-white metal having a slight steel-grey tinge which is very observable when it is compared with silver. It is sufficiently hard to take a fine polish. Pure nickel was prepared by Winkler by electrolysis of an alkaline solution containing ammonium sulphate and subsequent heating in hydrogen (Zeitsch. anorg. Chem. 1894, 8, 1).

Nickel is magnetic at ordinary temperatures, but at high temperatures it forms a non-magnetic variety; the transition temperature appears to be about 350°; it has a density of 8·8 at 15° and a specific heat 0·108. Its hardness is 3·5, specific resistance 6·4 (micro ohms / c.c.), breaking weight 42 kilos. per sq. mm., and melting-point 1470° (Copaux, Compt. rend. 1905, 140, 657). At a white heat it can be welded with itself, with iron, or with various alloys. Its tensile strength exceeds that of iron.

Nickel may be distilled in the electric furnace, the distillate having the same properties as the finely divided metal. It is not so volatile as manganese, but is more volatile than iron or chromium (Moissan, Compt. rend. 1906, 142, 425).

Pure nickel is not a readily oxidisable metal, and its resistance to the action of the atmosphere, and also to the action of both fresh and salt water, admits of its being ranked in these respects with the precious metals. If heated, nickel wire burns in oxygen like iron, it also becomes incandescent in nitric oxide at 200°, and when prepared by reduction is pyrophoric. It decomposes steam at a red heat, but then only slowly. It dissolves slowly in dilute sulphuric and hydrochloric acids, rapidly in nitric acid or *aqua regia*. In contact with concentrated nitric acid it becomes passive like iron; when dropped into fuming nitric acid it may be violently attacked, may become passive, or may be disintegrated to a grey magnetic powder (Hollis, Proc. Camb. Phil. Soc. 1904, 12, 253). Acetic, citric, tartaric, and oxalic acids have little or no action on nickel unless they are left in contact with the metal for a long time. Caustic soda or other alkalis may be fused in nickel vessels without any change taking place.

Hydrogen is occluded by nickel at temperatures above 200°, in quantity increasing with temperature, but very different values have been obtained for the actual amount (*cf.* Bayer and Altmayer, Ber. 1908, 41, 3062; and Sieverts, Zeitsch. physikal. Chem. 1907, 60, 129). Nickel also appears capable of absorbing its own monoxide, its tenacity and malleability being thereby reduced. Carbon monoxide and nickel cyanide are also absorbed by molten nickel with deleterious effects. To purify such nickel a process due to Fleitmann is frequently employed. It consists in adding to the fused nickel contained in a fireclay crucible, a small quantity ($\frac{1}{8}$–$\frac{1}{20}$ p.c.) of metallic magnesium. The effect of this appears to be the reduction of the oxides and the decomposition of the cyanide with formation of nickel and *volatile* magnesium cyanide. Nickel so treated can be rolled into very thin sheets, and in this condition has been welded on to sheet iron or steel to be used for the manufacture of culinary and other utensils. It can be drawn into wire and cast or forged (D. R. PP. 6365, 7569, 9405, 13304, 14172, 23500, 28460, 28924). Manganese added to the extent of 1–3 p.c. is also stated to act as a purifier and to improve the quality of the metal.

Nickel may be deposited as a brilliant metallic layer by electrolysing a solution of the double sulphate of nickel and ammonia

$$NiSO_4,(NH_4)_2SO_4,6H_2O.$$

When nickel is prepared by reducing the oxide along with carbon, the metal is somewhat brittle, and when broken the fracture has a dull-grey colour and crystalline structure.

Alloys. Nickel readily forms alloys with a variety of metals. With copper and zinc the alloys are known under a very great variety of names, *e.g. German silver*, *nickel silver*, *China silver*, *Nevada silver*, *Potosi silver*, *silveroid*, *argentan*, *packfong*, *electrum*, &c.; and on the Continent as *maillechort*, *argiroide*, *neu-silber*, *weisskupfer*. All copper-nickel alloys appear to consist of mixed crystals, no compound being formed, the freezing-point curve falling regularly from that of nickel to that of copper (Guertler and Tammann, Zeitsch. anorg. Chem. 1907, 32, 25). The addition of nickel, even in small quantity, greatly reduces the conductivity of the copper and increases its hardness. The alloy containing 2–3 p.c. nickel has been found well adapted for metal work which has to be exposed to high temperatures, *e.g.* boiler tubes; alloys of 25 p.c. nickel are also used for firebox plates.

Constantan is an alloy of 60 p.c. copper and 40 p.c. nickel used largely for electric resistances owing to its very small temperature coefficient; it is also used with copper as a thermoelectric couple for moderate temperatures.

Manganin used similarly for resistance boxes contains about 12 p.c. nickel, with 4 p.c. manganese and 84 p.c. copper, whilst another somewhat similar alloy, *nickeline*, contains about 25 p.c. nickel, 74·5 p.c. copper, and 0·5 p.c. iron.

The German silver alloys are not definite compounds but consist of homogeneous mixed crystals. They form very valuable alloys, being ductile, hard, tough, capable of welding and hammering, and they withstand atmospheric influences. They are usually prepared by melting together an alloy of copper and nickel with one of copper and zinc. The composition of German silver varies very greatly, the percentage of copper ranging from 40 to 65 p.c., that of nickel from 6 to 31 p.c., and that of zinc from 18 to 30 p.c.; small quantities of iron, lead, or cobalt being occasionally present. The Birmingham extra-white metal contains 50 p.c. copper, 30 p.c. nickel, and 20 p.c. zinc; the German silver used as a base for electroplating contains about 57 p.c. copper, 7 p.c. nickel, and 36 p.c. zinc. German silver can be soldered, a solder commonly used containing 47 p.c. copper, 12 p.c. nickel, and 41 p.c. zinc.

Platinoid is a German silver of 60 p.c. copper, 14 p.c. nickel, 24 p.c. zinc, with 1–2 p.c. tungsten, largely used for electric resistances. Aluminium to the extent of about 3 p.c. is sometimes added to improve the quality, such an alloy being used for the German silver parts of typewriters. The coinage of Switzerland up to the 20-centime piece consists of a German silver alloy with silver added; and other nickel alloys are largely used in many countries for coinage.

Added to iron or steel nickel improves the quality for many purposes, the alloy being known as nickel steel (*see* IRON).

Many of the alloys with iron are remarkable for possessing a very low coefficient of expansion. The alloy containing 46 p.c. of nickel and 0·15 p.c. carbon has a coefficient of expansion equal to that of glass, and is used under the name of *platinite* for fusing into glass, in place of the far more expensive platinum. The alloy containing 36 p.c. nickel and about 0·2 p.c. carbon has a coefficient of expansion almost zero, and is very largely used in scientific instruments under the name of *invar*—a coefficient as low as 0·0000008 can be guaranteed by the manufacturers.

Much work on alloys of nickel with various metals has been done, and a number of references are given below: with boron (Moissan, Compt. rend. 1896, 122, 424; and Jassoneix, *ibid.* 1907, 145, 240); with tin and with antimony (Vigouroux, *ibid.* 1907, 144, 639, 145, 246, 429; 1908, 147, 976); with antimony (Lossew, Zeitsch. anorg. Chem. 1906, 49, 58); with tin (Guillet, Compt. rend. 1907, 144, 752); with arsenic (Granger and Didier, *ibid.* 1900, 130, 914; Friederich and Bennigson, Metallurgie, 1907, 200); with silicon (Guertler and Tammann, Zeitsch. anorg. Chem. 1906, 49, 93; Vigouroux, Compt. rend. 1907, 142, 1270); with copper (Guertler and Tammann, Zeitsch. anorg. Chem. 1906, 49, 93; 1907, 52, 25); with aluminium (Groyer, *ibid.* 1908, 57, 113). *Cf.* also Voss, *ibid.* 1908, 57, 34.

Uses of nickel.—The chief use of nickel is in the manufacture of alloys, and in the preparation of nickel sulphate for use in electroplating.

Vessels of pure nickel for laboratory purposes are an excellent substitute for those made of iron or copper. Basins may be used for boiling with caustic alkalis or alkaline carbonates, and crucibles may be employed for fusing minerals or salts with caustic alkalis or nitrates of the alkalis. Water-baths, spatulas, and tongs of nickel are very serviceable.

Oxides of nickel. The chief oxides of nickel are the monoxide NiO and the sesquioxide Ni_2O_3.

Nickel monoxide NiO occurs native as *bunsenite*, and may be prepared by strongly heating the hydroxide $Ni(OH)_2$, carbonate $NiCO_3$, or nitrate $Ni(NO_3)_2$. It is a green crystalline powder, which turns yellow on heating. It is easily reduced to the metal when heated in hydrogen. The *hydroxide* $(NiOH)_2$ is formed as an apple-green precipitate, when a nickel salt is treated with alkali hydroxide.

The salts of nickel are derived from the monoxide. They are in general yellow when anhydrous, emerald-green when hydrated or in solution.

Nickel sesquioxide Ni_2O_3 is a black powder obtained by gently heating the nitrate or carbonate in air. It is decomposed by heat, and is probably nickelous nickelite $NiO\cdot NiO_2$.

Nickel trihydroxide $Ni(OH)_3$ is obtained as a black precipitate when a nickel salt is warmed with alkali hypochlorite or chlorine passed through the hydroxide $Ni(OH)_2$ suspended in water. According to Bellucci and Clavari, however, this precipitate is the hydrated dioxide $NiO_2\cdot xH_2O$ (Gazz. chim. ital. 1905, 14, ii. 234; Atti. R. Accad. Lincei, 1907, [v.] 16, i. 647).

The *peroxide* NiO_2 is obtained in a hydrated form by the action of hydrogen peroxide on nickel salts (Pellini and Meneghini, Zeitsch. anorg. Chem. 1908, 60, 178), and an oxide regarded as NiO_4 was obtained by Hollard (Compt. rend. 1903, 136, 229).

Nickel carbonyl, $Ni(CO)_4$. When carbon monoxide is passed over reduced nickel at 30°–80°, combination occurs, and a volatile carbonyl is formed (Mond, Langer and Quincke, Chem. Soc. Trans. 1890, 749). It is a colourless liquid, boiling at 43·2° and solidifying at −25°; its sp.gr. is 1·3185 at 17°. At 50° it has the normal vapour density. The carbonyl is soluble in organic media; its vapour is very poisonous. For its reactions, see Dewar and Jones, *ibid.* 1904, 203; Proc. Roy. Soc. 1903, 71, 427; and *v.* CARBONYLS, Vol. I, p. 687.

Nickel arsenide NiAs occurs as *kupfernickel* (*v. supra*). The *phosphide* Ni_2P is obtained in grey needles when nickel and phosphorus are heated in the electric furnace (Maronneau, Compt. rend. 1900, 130, 656; cf. Granger, *ibid.* 1896, 122, 1484; 1896, 123, 176).

Nickel boride NiB is prepared in the electric furnace, and forms brilliant prismatic crystals of sp.gr. 7·39 (Moissan, Compt. rend. 1896, 122, 424). It is decomposed when fused with alkali.

Nickel silicide Ni_2Si is prepared by heating an excess of nickel with silicon in the electric furnace until the greater part of the metal has been volatilised; and then dissolving away the remaining metal with dilute nitric acid. It is a steel-grey, metallic-looking powder of sp.gr. 7·2, and is attacked by *aqua regia* and by hydrofluoric acid (Vigouroux, Compt. rend. 1895, 121, 686).

SALTS OF NICKEL.

Nickel bromide $NiBr_2$ is produced when finely divided nickel is heated in bromine vapour. It sublimes in golden scales. The bromide is very hygroscopic, and forms a trihydrate $NiBr_2,3H_2O$. The accepted equivalent of nickel rests largely upon the results obtained by Richards and Cushmann (Zeitsch. anorg. Chem. 1898, 16, 167; 1899, 20, 352) in their analyses of anhydrous nickel bromide.

Nickel carbonate $NiCO_3$ is obtained by heating a solution of nickel chloride with calcium carbonate at 150°. It forms pale-green, microscopic rhombohedra. A hexahydrate $NiCO_3,6H_2O$ is produced by mixing nickel nitrate solution with sodium bicarbonate and saturating the cold solution with carbon dioxide. It readily loses water. The pale green precipitates obtained by adding alkali carbonate to a nickel salt are basic carbonates of variable composition.

Nickel chloride $NiCl_2$ is formed when finely divided nickel is warmed in chlorine. It can be sublimed, and forms golden scales. It dissolves in water with the evolution of heat, and a green hexahydrate $NiCl_2,6H_2O$ can be crystallised out from the solution. The anhydrous chloride readily absorbs ammonia, forming an almost white compound $NiCl_2,6NH_3$, which dissolves easily in water. Nickel chloride is soluble in alcohol.

Nickel cyanide $Ni(CN)_2$ is obtained as an apple-green precipitate by adding potassium cyanide to a solution of a nickel salt. It is easily soluble in excess of potassium cyanide, and from the solution the double salt $Ni(CN)_2\cdot 2KCN$ can be crystallised. This salt is readily decomposed by dilute acids; no double cyanides are known corresponding to ferro- and ferri-cyanides.

Nickel fluoride NiF_2 forms green prisms (Poulenc, Compt. rend. 1892, 114, 1426); it is soluble in water and forms a trihydrate $NiF_2,3H_2$.

Nickel iodide NiI_2 forms black scales; the hexahydrate $NiI_2,6H_2O$ is a bluish-green, very hygroscopic crystalline substance.

Nickel nitrate $Ni(NO_3)_2,6H_2O$ is a green salt which crystallises in monoclinic tablets. It dissolves in twice its weight of cold water and is also soluble in alcohol. Tri- and mono-hydrates are also known.

Nickel nitrite $Ni(NO_2)_2$ is of little importance itself. It forms a double salt $Ni(NO_2)_2\cdot 4KNO_2$ which is easily soluble in water, and a triple nitrite $2KNO_2\cdot Ca(NO_2)_2\cdot Ni(NO_2)_2$, which is a yellow crystalline substance only sparingly soluble in water. Similar salts are known with barium and strontium, and hence the alkaline earth metals must be absent when nickel and cobalt are to be separated by the cobaltinitrite method.

Nickel sulphate $NiSO_4$ is formed in solution when nickel, or the hydroxide or carbonate is dissolved in dilute sulphuric acid. At ordinary temperatures the salt crystallises as the green heptahydrate $NiSO_4,7H_2O$, isomorphous with magnesium sulphate. At 50°–70° the hexahydrate $NiSO_4,6H_2O$ separates, in monoclinic crystals, and a hydrate of the same composition separates at ordinary temperatures from acid solutions, but the crystals are tetragonal pyramids.

The hydrated sulphate loses water at 100°, forming the monohydrate $NiSO_4,H_2O$, and at 280° the yellow anhydrous sulphate is left. The latter absorbs ammonia, forming a pale violet powder of the composition $NiSO_4{\cdot}6NH_3$. The compound $NiSO_4{\cdot}4NH_3,2H_2O$ crystallises in dark-blue tetragonal prisms from concentrated solutions of the sulphate in ammonia.

The solubility of nickel sulphate in water, expressed as parts of the anhydrous salt per hundred parts of water, is as follows:—

Temp.	2°	16°	23°	41°	50°	60°	70°
$NiSO_4$	30·4	37·4	41·0	49·1	52·0	57·2	61·9

Nickel sulphate forms numerous double sulphates with the sulphates of other metals. Of these, the most important is *nickel ammonium sulphate* $NiSO_4{\cdot}(NH_4)_2SO_4,6H_2O$, which is largely used in the process of nickel plating and in other processes in which a salt of nickel is employed. It is obtained by dissolving either nickel or nickel monoxide in sulphuric acid, and adding ammonium sulphate to the concentrated acid solution. It is purified by recrystallisation and forms short, monoclinic prisms. The solubility, expressed as parts of $NiSO_4{\cdot}(NH_4)_2SO_4$ per hundred parts of water, is as follows:—

Temp.	3·5°	16°	20°	30°	40°	50°	68°	85°
Salt	1·8	5·8	5·9	8·3	11·5	14·4	18·8	28·6

Nickel monosulphide NiS occurs in nature as *millerite*, sometimes in brass-yellow rhombohedra, but usually in capillary crystals. It is obtained in a black, hydrated form when a nickel salt is precipitated by ammonium sulphide. For its behaviour towards acids, *v. infra*, *Detection and estimation*. For the subsulphide Ni_2S, *v.* Mourlot, Compt. rend. 1897, 124, 768, and for the sesquisulphide, *v.* Dewar and Jones, Chem. Soc. Trans. 1904, 211.

Detection and estimation. Nickel salts colour the borax bead red in the oxidising flame. The sulphide is black, and cannot be precipitated in the presence of mineral acids, but when once precipitated, it dissolves very slowly in dilute hydrochloric acid.

Nickel may be estimated as the metal, as the monoxide, as nickel dimethyl glyoximate or as nickel dicyanodiamidine; it may also be estimated volumetrically. For details of these methods, and for the separation of nickel from other metals, *v.* ANALYSIS.

Atomic weight. The equivalent of nickel has been determined by the analysis of the bromide to be 29·34 (*v. supra*, p. 669; for other methods, *v.* Russell, Chem. Soc. Trans. 1863, 58; 1869, 292; Winkler, Zeitsch. anorg. Chem. 1893, 4, 10, 462; 1894, 8, 1, 291). From its specific heat, and the isomorphism of nickel salts with those of other metals, it follows that the atomic weight of nickel is twice its equivalent, or 58·68. The carbonyl is the only compound of nickel of known vapour density.

NICOTIDINE *v.* BONE OIL; also VEGETO-ALKALOIDS.

NICOTINE *v.* VEGETO-ALKALOIDS.

NICOTINIC ACID *v.* BONE OIL.

NIGELLA SEEDS or **BLACK CUMMIN.** The seeds of *Nigella sativa* (Linn.), a ranunculaceous plant growing on the Mediterranean coasts, and in Egypt, Trans-Caucasia, and India, were found by Reinsch, in 1841, to yield 35·8 p.c. of fat oil, 0·8 p.c. of volatile oil, and only 0·6 p.c. of ash. He gave the name of *nigellin* to a bitter extract resembling turpentine, yet soluble in water as well as in alcohol, though not in ether.

By submitting 25 lbs. of fresh seed to distillation, Flückiger obtained a nearly colourless essential oil, but in smaller quantity than Reinsch. It has a slight odour, somewhat resembling that of parsley oil, with a magnificent bluish fluorescence, as already remarked by Reinsch. In a column 50 mm. long this oil deviates the ray of polarised light 9·8° to the left. Its sp.gr. is 0·8909. The chief part of it, when heated with calcium chloride in a current of dry carbonic acid, distils at 256°. Its composition corresponds with the formula $2C_{10}H_{16},H_2O$. The residual portion, which is almost entirely devoid of rotatory power, after having been rectified by means of sodium, consists of terebenes $C_{10}H_{16}$. The fat oil, extracted by means of boiling ether from seed grown in Germany, previously finely powdered (necessarily including some essential oil which imparted to the other its fluorescence), is a fluid fat which does not congeal at 15°: it consists chiefly of olein, together with a considerable amount of a solid fatty acid, probably a mixture of palmitic and myristic acids.

It is stated in the Pharmacopœia of India that Nigella seeds are carminative, and they were formerly so regarded in Europe. In the East, generally, they are used as a condiment to food, and in Greece, Turkey, and Egypt, they are frequently strewed over the surface of bread and cakes in the same manner as anise or sesame. The fixed oil of the seeds is also expressed for use.

NIGER SEED OIL is obtained from the *achenes* of *Guizotia abyssinica* (Linn.), Cass. (*Guizotia oleifera*, D.C.), a plant indigenous to Abyssinia, and largely cultivated not only in East Africa, but also in the East and West Indies. The *achenes* contain from 40 to 45 p.c. of oil. For the chemical and physical characters of this oil, *see* tables OILS, FIXED, AND FATS.

Niger seed is crushed in Hull and Marseilles, and has been used lately to an increased extent as a substitute for linseed oil in soap-making, &c.

J. L.

NIGHT BLUE. A colouring matter obtained by the action of *p*- tolyl - *α* - naphthylamine on tetramethyl-diamino-benzophenone. Resembles Victoria blue *v.* TRIPHENYLMETHANE COLOURING MATTERS.

NIGRISIN is the commercial name for a basic grey dyestuff formed when aqueous or alcoholic solutions of nitrosodimethylaniline hydrochloride are boiled. It forms a black powder soluble in water to a reddish-grey solution which is changed to blue-grey on addition of acid. 1 litre of water at 100° dissolves 80 grams of nigrisin. In sulphuric acid it forms a pure grey solution, which, on addition of water, turns to red- then blue-grey. It is oxidised by nitric acid and reduced by stannous chloride and hydrochloric acid, and by zinc dust and acid. Potassium dichromate produces a brown precipitate soluble in acetic or tartaric acid with a grey-blue, in hydrochloric acid with a red-blue colour. Nigrisin is distinguished by its purity of shade, strong colouring power, fastness, and the variety of compound shades which it is capable of yielding when mixed with other dyestuffs (Baumann, Bull. Soc. Ind. Mulhouse, 1890, 65).

Nigrisin does not require a mordant for dyeing bleached cotton, and full shades are obtained with 1–3 p.c. of the dye. Cotton mordanted with antimony tannate also takes the dye well; in this case the material is padded in a solution containing 2–10 grams of the dye per litre. It is then dried and steamed, or before drying it may be passed through 0·5 p.c. solution of potassium dichromate at 60°, when an insoluble chromate of the colour-base is formed.

Nigrisin is formed and simultaneously fixed upon the fibre when cotton is printed with the following mixture and then steamed for about 3 minutes: 100 grams of nitrosodimethylaniline hydrochloride, 1 litre of warm water, 1¼ litre of starch paste thickening, 1¼ gum tragacanth paste (6 : 100). In the presence of an organic acid a grey (similar to that formed by nigrisin on unmordanted cotton) is produced. If the organic acid is replaced by tannin, and after steaming it is fixed with tartar emetic and washed, a deep rich-grey is obtained. By varying the conditions of dyeing and by the introduction of reducing agents, white and colour discharge effects upon a grey ground are obtained (Federmann, Bull. Soc. Ind. Mulhouse, 1909, 79, 251). The grey colour mixtures can also be made to give blacks (Brandt, J. Soc. Chem. Ind. 1900, 1106).

NIGROSINES *v.* Indulines.

NILE BLUES *v.* Oxazine colouring matters.

NIOBITE *v.* Columbite; also Columbium.

NIOBIUM *v.* Columbium.

NIRVANIN is the diethylglycocoll compound of 5-amino-2-hydroxybenzoic methyl ester. It forms a hydrochloride of neutral reaction, which produces complete anæsthesia of a longer duration than that caused by cocaïne (Einhorn and Heinz, Pharm. J. 1889, 62, 95), *v.* Synthetic drugs.

NITON. Sym. Nt. At.wt. and mol.wt. 222·4. The name given by Gray and Ramsay (Proc. Roy. Soc., 1911, A, 84, 536) to the gaseous emanation of radium discovered by Dorn (Naturforsch. Ges. für Halle a S. 1900). Niton, which has only been obtained in minute quantities, is prepared by heating a compound of radium or by dissolving it in water and pumping off the gases slowly produced. Oxygen, hydrogen, carbon dioxide, and nitrogen are successively removed by means of heated copper, copper oxide, phosphoric pentoxide, fused potassium hydroxide and heated lithium respectively, the niton left is then liquefied at −150° to −170°, and the helium present, together with a little niton, is pumped off (Debierne, Compt. rend. 1909, 148, 1264; Rutherford, Phil. Mag. 1908, 16, 300).

Niton is a member of the family of inert gases. Its density, measured by means of a microbalance sensitive to 2×10^{-6} mgm. with about $\frac{1}{1400}$ mgm. of material, gave a value of 223 for the molecular weight (Gray and Ramsay, *l.c.*; Compt. rend. 1910, 151, 126), but the value 222·4 is preferred for theoretical reasons. The direct density measurements are confirmed by the effusion experiments of Debierne (Compt. rend, 1910, 150, 1740), and the diffusion experiments of Perkins (Amer. J. Sci. 1908, [iv.] 25, 461), which gave the values 220 and 235 respectively for the molecular weight (for other determinations, *v.* Rutherford and Brooks, Trans. Roy. Soc. Canada, 1901; Curie and Danne, Compt. rend. 1903, 137, 1314; Bumstead and Wheeler, Amer. J. Sci. 1904, [iv.] 17, 97; Makower, Phil. Mag. 1905, [vi.] 9, 56; Chaumont, Le Radium, 1909, 6, 106). Niton therefore occupies the position in group O of the Periodic Scheme in the same series as, and immediately preceding, radium (*cf.* Gray and Ramsay, Chem. Soc. Trans. 1909, 95, 1073; Rankine, Phil. Mag. 1911, [vi.] 21, 45).

Niton undergoes a rapid diminution in volume to one-half the original amount when it is isolated. The gas, both before and after this change, obeys Boyle's Law. Niton is condensed to a solid at the temperature of liquid air. Both liquid and solid niton are phosphorescent. The critical temperature is 104·5°, the critical pressure 62·5 atmos., and the boiling-point is −62° (Rutherford and Soddy, Phil. Mag. 1903, [iv.] 5, 561; Rutherford, *ibid.* 1909, [vi.] 17, 723; Gray and Ramsay, Chem. Soc. Trans. 1909, 95, 1073; Laborde, Compt. rend. 1909, 148, 1591). Niton possesses a definite spectrum (Ramsay and Collie, Proc. Roy. Soc. 1904, 73, 470; 1908, 81, A, 210; Rutherford and Royds, Phil. Mag. 1908, [vi.] 16, 313; Royds, *ibid.* 1909, [vi.] 17, 202; Proc. Roy. Soc. 1908, [vi.] 82, 22; Watson, *ibid.* 1909, A, 83, 50).

In the presence of niton, slow decomposition of water, ammonia, hydrogen chloride, and the oxides of carbon occurs (Ramsay, Chem. Soc. Trans. 1907, 91, 931; Cameron and Ramsay, *ibid.* 1907, 91, 1593; 1908, 93, 966, 992; Perman, *ibid.* 1908, 93, 1775; Usher, *ibid.* 1910, 97, 389; Rutherford and Royds, Phil. Mag. 1908, [vi.] 16, 812; Curie and Gleditsch, Compt. rend. 1908, 147, 345). Niton spontaneously decomposes, producing helium and other substances. For radioactive properties of niton, *v.* Radioactivity.

β-NITRANILINE RED *v.* Azo- colouring matters.

NITRANILINES. By the direct nitration of aniline, a mixture of *o*-, *m*-, and *p*-nitranilines is produced. Aniline is dissolved in 6 to 8 times the calculated quantity of nitric acid, mixed with an equal volume of sulphuric acid, the temperature being kept below 0°. The liquid is poured on to ice, and diluted with ice-water until *o*-nitraniline ceases to be precipitated. After filtration, the liquid is neutralised with sodium carbonate, and the *m*- and *p*-nitranilines separated by fractional precipitation, *p*-nitraniline being first precipitated as a yellowish-brown powder, and then the *m*- compound, which is pure yellow (Nietzki and Benckiser, Ber. 1885, 18, 295; Pinnow and Müller, *ibid.* 1889, 24, 150; Bruns, *ibid.* 1895, 28, 1954).

_o_-Nitraniline  may be prepared by the reduction of *o*-dinitrobenzene with ammonium sulphide (Körner, Gazz. chim. ital. 4, 305; *cf.* Rinne and Zincke, Ber. 1874, 7, 1374); by heating *o*-dinitrobenzene (Laubenheimer, *ibid.* 1878, 11, 1155; de Bruyn, Rec. trav. chim. 13, 121), *o*-nitrophenol (Merz and Ris, Ber. 1886, 19, 1751), *o*-nitroanisole (Salkowski, Annalen, 174, 278), or *o*-bromonitrobenzene (Walter and Zincke, Ber. 1872, 5, 114) with alcoholic ammonia; by heating *o*-nitrobenzanilide with dilute sodium hydroxide (Hübner, Annalen, 208, 278; Lellmann, *ibid.* 221, 6); by treating an aqueous solution of *o*-phenylenediamine with sodium peroxide (O. Fischer and Trost, Ber. 1893, 26, 3084); by treating oxanilide with strong sulphuric acid, nitrating the oxanilidedisulphonic acid thus formed, and decomposing the dinitro-oxanilidedisulphonic acid by boiling with water (Wülfing, D. R. PP. 65212, 66060; Frdl. iii. 44, 45). It is manufactured by gradually adding 40 kilos. of acetanilide to 80 kilos. of sulphuric acid (66°B.) with constant stirring, and keeping the temperature below 50°. A mixture of 36 kilos. of nitric acid (36°–37°B.) and 40 kilos. of sulphuric acid (66°B.) is then run in, the temperature being kept between 40° and 50°. Next day the liquid is poured into 200 litres of hot water, *o*- and *p*-nitroacetanilide being precipitated. The nitroacetanilides are deacetylated by heating an aqueous suspension with steam until complete solution occurs; the liquid is cooled to 50° and then poured on ice, *o*-nitraniline being precipitated. The *p*- compound is obtained by adding 180 kilos. of soda lye (36° B.) to the mother liquors and cooling with ice; yield 25 p.c. ortho- and 60 p.c. para- (Pokorný, Bull. Soc. Ind. Mulhouse, 1894, 280; Turner, Ber. 1892, 25, 985; Meldola, Chem. Soc. Trans. 1883, 427; Körner, Gazz. chim. ital. 4, 305).

o-Nitraniline crystallises in orange-yellow needles, m.p. 71·5°; 1 litre of water dissolves 1·256 grams at 25°; dielectric constant (*v.* Löwenherz, Zeitsch. physikal. Chem. 25, 407). Electrolytic reduction in sodium carbonate solution yields *o*-phenylenediamine (Rohde, Zeitsch. Elektrochem. 7, 339); this can also be effected by boiling with zinc and water. By boiling with ethyl chlorocarbonate, *o*-nitrophenylurethane is produced (Rudolph, Ber. 1889, 12, 1295), and with phthalic chloride *o*-nitrophthalanil is the product (Pawlewski, *ibid.* 1895, 28, 118). 3-chloro-6-nitraniline (*v.* Bad. Anil. Soda Fab. D. R. P. 206345; Chem. Soc. Abstr. 1909, i. 297).

_m_-Nitraniline  may be prepared by the reduction of *m*-dinitrobenzene with ammonium sulphide (Muspratt and Hofmann, Annalen, 57, 215; Körner, Gazz. chim. ital. 4, 305; Beilstein and Kurbatow, Annalen, 176, 44), with stannous chloride (Anschütz and Heusler, Ber. 1886, 19, 2161), or with iron and sulphuric or hydrochloric acids (Wülfing, D. R. P. 67018; Frdl. iii. 47); by treating *m*-nitrobenzanilide with dilute alkalis (Hübner, Annalen, 208, 278); by treating an aqueous solution of *m*-phenylenediamine with sodium peroxide (O. Fischer and Trost, Ber. 1893, 26, 3084).

m-Nitraniline crystallises in large yellow needles, m.p. 114° (Hübner, Annalen, 208, 298), b.p. 285°, sp.gr. 1·430 (Schröder, Ber. 1879, 12, 563). Soluble in hot water and the usual organic solvents (Carnelly and Thomson, Chem. Soc. Trans. 1883, 786). Electrolytic reduction in alkaline solution yields *m*-azoaniline (Elbs and Kopp, Zeitsch. Elektrochem. 1895, 5, 108; Wülfing, D. R. P. 108427; Chem. Zentr. 1900, i. 1175); reduction with sodium stannite in alkaline solution yields di*meta*diaminoazoxybenzene (Meldola, Chem. Soc. Trans. 1896, 7), and in hot alkaline solution *m*-azoxyaniline is formed (Poirrier and Rosenstiehl, D. R. P. 44045; Frdl. ii. 436). By boiling with phthalic chloride, *m*-nitrophthalanil is produced (Dobreff, Ber. 1895, 28, 939; Pawlewski, *ibid.* 1894, 27, 430; 1895, 28, 1118). For methylation, *v.* Staedel and Bauer, *ibid.* 1886, 19, 1939; chlorination, *v.* Körner and Contardi, Atti. R. Accad. Lincei. 1909 [v.], 18, i. 93; bromination, *ibid.* 1908 [v.], 17, i. 465; iodination, *ibid.* ii. 679).

_p_-Nitraniline  may be prepared by heating *p*-nitrophenol (Merz and Ris, Ber. 1886, 19, 1753), or *p*-chloronitrobenzene (Engelhardt and Latschinow, Zeitsch. Chem. 1870, 232; Clayton Aniline Co., D. R. P. 148749; Chem. Soc. Abstr. 1904, i. 393) with strong aqueous ammonia; by boiling *p*-nitrobenzanilide with dilute potassium hydroxide (Hübner, Annalen, 208, 278); by oxidising *p*-nitrosoaniline (O. Fischer, *ibid.* 286, 154); by treating an aqueous solution of *p*-phenylenediamine with sodium peroxide (O. Fischer and Trost, Ber. 1893, 26, 3084); by nitrating benzylidineaniline with equal quantities of sulphuric and nitric acids, and dissolving out the product with water (Bayer and Co., D. R. P. 72173; Frdl. iii. 48); and by nitrating acetanilide (*v. o-Nitraniline*).

p-Nitraniline crystallises in long yellow needles, m.p. 147° (Hübner, *l.c.*); sp.gr. 1·424 (Schröder, Ber. 1879, 12, 563); readily soluble in hot water and the usual organic solvents (Carnelly and Thomson, Chem. Soc. Trans. 1883, 786). Electrolytic reduction in the presence of sulphuric acid yields *p*-diaminobenzene sulphate (Noyes and Dorrance, Ber. 1895, 28, 2349), but in the presence of sodium carbonate *p*-phenylenediamine is the product (Rohde, Zeitsch. Elektrochem. 7, 339). *p*-Phenylenediamine is also formed by reduction with zinc and water, or with hyposulphurous acid (Goldberger, Oester. Chem. Zeit. 3, 470). By heating with ethyl chlorocarbonate, *p*-nitrophenylurethane is formed (Hager, Ber. 1884, 17, 2625); and with phthalic chloride *p*-nitrophthalanil (Dobreff, *ibid.* 1895, 28, 939; Pawlewski, *ibid.* 1894, 27, 3430; 1895, 28, 1118).

For chlorination, *v.* Flürscheim, Chem. Soc. Trans. 1908, 1772; oxidation with hypochlorites, *v.* Bayer & Co., D. R. P. 83525; Frdl. iv. 1017;

AZO- derivatives of the nitranilines, *v.* AZO-COLOURING MATTERS; constitution of the nitranilines, *v.* Hirsch, Ber. 1903, 36, 1898; absorption spectrum, *v.* Baly, Edwards and Stewart, Chem. Soc. Trans. 1906, 514; mercury salts, *v.* Jackson and Peakes, Amer. Chem. J. 1908, 39, 567; condensation products with chloral, *v.* Wheeler and Weller, J. Amer. Chem. Soc. 1902, 24, 1063.

2 : 3-**Dinitraniline**  may be prepared by heating 2 : 3-dinitracetanilide with sulphuric acid (Wender, Gazz. chim. ital. 19, 226); orange-yellow needles, m.p. 127°; soluble in alcohol.

2 : 4-**Dinitraniline**  may be prepared by heating 2 : 4-dinitrosuccinanil (Gottlieb, Annalen, 85, 24) or 2 : 4-dinitracetanilide (Rudnew, Zeitsch. Chem. 1871, 202) with potassium hydroxide; by heating 1-chloro-2 : 4-dinitrobenzene (Engelhardt and Latschinow, *ibid.* 1870, 233), 1-bromo-2 : 4-dinitrobenzene (Clemm, J. pr. Chem. [ii.] 1, 145), 2 : 4-dinitroanisol, (Salkowski, Annalen, 174, 263), or 2 : 4-dinitrophenol (Barr, Ber. 1888, 21, 1542) with alcoholic ammonia. Yellow crystals, m.p. 176°; insoluble in water, soluble in alcohol and ether. On reduction with ammonium sulphide, *o*- and *p*-nitrophenylenediamines are produced (Kehrmann, Ber. 1895, 28, 1707); by boiling with alcoholic potassium cyanide, 2 : 4-dinitroaminophenol is formed (Lippmann and Fleissner, Monatsh. 7, 95), and with potassium hydroxide, 2 : 4-dinitrophenol (Willgerodt, Ber. 1876, 9, 979). For derivatives, *v.* Jaeger, Proc. K. Akad. Wetensch. Amsterdam, 1906, 9, 23.

2 : 5-**Dinitraniline**  may be prepared by heating 2 : 5-dinitracetanilide with sulphuric acid (Wender, Gazz. chim. ital. 19, 233); orange-yellow needles, m.p. 137°; readily soluble in alcohol.

2 : 6-**Dinitraniline**  may be prepared by heating 2 : 6-dinitroanisol (Salkowski, Annalen, 174, 273) or 1-iodo-2 : 6-dinitrobenzene (Körner, J. 1875, 345) with alcoholic ammonia; yellow needles, m.p. 138°; soluble in alcohol.

3 : 4-**Dinitraniline**  may be prepared by heating 3 : 4-dinitracetanilide with sulphuric acid (Wender, Gazz. chim. ital. 19, 233); citron-yellow needles, m.p. 154°; soluble in alcohol, almost insoluble in ether.

3 : 5-**Dinitraniline**  may be prepared by reducing 1 : 3 : 5-trinitrobenzene with ammonium sulphide (Bader, Ber. 1891, 24, 1653); yellow needles, m.p. 159°; soluble in alcohol and ether, almost insoluble in benzene.

2 : 4 : 6-**Trinitraniline**, *Picramide*  may be prepared by heating 1-chloro-2 : 4 : 6-trinitrobenzene with ammonia (Pisani, Annalen, 92, 326) or by nitrating *o*- or *p*-nitranilines (Witt and Witte, Ber. 1908, 41, 3090); dark yellow needles, m.p. 188°. By reduction with tin and hydrochloric acid 2 : 4 : 6-triaminophenol is formed (Hepp, Annalen, 215, 350; Salkowski, *ibid.* 174, 261). By heating with potassium hydroxide, picric acid is produced (*q.v.*).

2 : 4 : 5-**Trinitraniline**  is obtained by nitrating *m*-nitracetanilide (Witt and Witte, *l.c.*), m.p. 183°.

2 : 3 : 4 : 6-**Tetranitraniline**  is prepared by nitrating *m*-nitraniline, 2 : 3- or 2 : 4-dinitranilines (Flürscheim and Simon, Chem. Soc. Proc. 1910, 81); yellow crystals, m.p. 212°.

NITRATED OILS *v.* OILS, FIXED, AND FATS.

NITRATINE, *Soda-nitre*, or *Chile saltpetre* (Span. *Salitre sodico*). Sodium nitrate ($NaNO_3$) is by far the most abundant of the few naturally-occurring mineral nitrates. In the provinces of Tarapaca and Antofagasta, in northern Chile, the nitrate deposits occur along a narrow belt of country where the westwardly sloping pampas abut against the coast range at an altitude of about 3000 feet. This district extends from the town of Tarapaca in the north to that of Taltal in the south—a distance of nearly 400 miles—and embraces an area of over 8000 square miles. The salt bed has a thickness of 1 to 6 feet and is overlain by 2 to 20 feet of gypsum, clay, sand, and gravel. The crude salt, called 'caliche,' is granular in texture and more or less cavernous; its colour is white, violet, bright yellow, or brown. It consists of from 20 to 60 p.c. of sodium nitrate, together with much sodium chloride and sulphate, and smaller amounts of soluble calcium and magnesium salts, potassium perchlorate, iodides, iodates, borates, &c. In the purification of the salts by re-crystallisation, iodine is a valuable by-product.

Chile saltpetre is largely used as a fertiliser, and for the preparation of potassium nitrate and nitric acid, used for the manufacture of explosives, &c. The quantity annually exported is about two million tons, valued at about £9 per ton.

See G. P. Merrill, The Non-Metallic Minerals, 2nd ed. New York, 1910; Estadística Minera de Chile en 1906 i 1907, Santiago de Chile, 1909, vol. iii. For references to the literature, *v.* F. W. Clarke, Data of Geochemistry (Bull. U. S. Geol. Survey, No. 330), 1908. L. J. S.

NITRE. *Potassium nitrate v.* POTASSIUM.

NITRE, CUBIC, *v.* SODIUM AND NITRATINE.

NITRIC ACID *v.* NITROGEN.

NITRIFICATION *v.* SOILS.

NITRILES. Prussic acid, being tautomeric in character, gives rise to two classes of esters, the *normal cyanides* or *nitriles* and the *isocyanides, isonitriles* or *carbylamines.*

The **nitriles** all contain the $-C{\equiv}N$ group, and they can be regarded either as hydrocarbons with one hydrogen atom replaced by the CN group, or as acids in which the COOH group has been converted into the CN group; *e.g.* CH_3CN is known either as methyl cyanide or as acetonitrile. The nitriles were discovered in 1834 by Pelouze, who obtained propionitrile by distilling barium ethyl sulphate with potassium cyanide.

Methods of preparation.—(a) *Aliphatic nitriles.*

(1) By heating alkyl halides (preferably iodide) with potassium cyanide in alcoholic solution at 100°.

(2) By distilling the salts of alkyl-sulphuric acids with potassium cyanide. (In each of these methods a little *iso*cyanide is also produced.)

(3) By heating alkyl *iso*cyanides to 250°.

(4) By treating cyanogen chloride with zinc alkyl. (In the above four methods the carbon chain is lengthened.)

(5) By the dry distillation of the acid amide or of the ammonium salt of the acids with phosphorus pentoxide or other dehydrating agent.

(6) By passing the acids together with a stream of ammonia through a red-hot tube.

(7) By converting the aldehydes into aldoximes, which are then dehydrated by acetic anhydride.

(8) By treating primary amines containing more than five carbon atoms with potassium hydroxide and bromine.

(b) *Aromatic nitriles.* By methods 3, 5, and 7.

(4) By diazotising a primary aromatic amine and decomposing the diazo- chloride thus formed with cuprous cyanide or with potassium cyanide and copper sulphate.

(5) By the action of potassium hydroxide and bromine on the primary arylalkylamines.

(6) By distilling the acids with potassium or lead thiocyanate.

(7) By replacing the hydrogen atoms of the hydrocarbons directly with $-CN$ by passing cyanogen into the boiling hydrocarbon mixed with aluminium chloride.

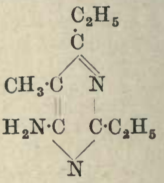
(8) By desulphurising the mustard oils with metallic copper.

(9) By heating the diarylthioureas with zinc dust.

(10) By distilling the formanilides with strong hydrochloric acid or with zinc dust.

(11) By distilling the alkali benzene sulphonates with potassium cyanide or with potassium ferrocyanide.

Properties (*aliphatic* and *aromatic*).—The nitriles are colourless volatile oils, which have an ethereal odour, are not very soluble in water, and distil unchanged. They are easily hydrolised by acids or alkalis into ammonia and the corresponding acid, the temperature required to effect this change being higher in the aromatic than in the aliphatic series. If an alcoholic solution of hydrochloric or sulphuric acid is used to carry out the hydrolysis, the ester is produced. In this case the triple link between carbon and nitrogen is completely destroyed, but there are many instances in which the nitriles behave as unsaturated compounds, the reactions being additive. Thus nitriles, when heated with water at 180°, or when treated with alkaline hydrogen peroxide at 40°, combine with a molecule of water to form acid amides. Similarly with acids they form diacylamines; with acid anhydrides, triacylamines; with sulphuretted hydrogen, thioamides; with hydroxylamine, amidoximes; with nascent hydrogen, amines (Mendius Reaction); with hydrochloric acid, iminochlorides or imino-ethers, depending on the use of aqueous or alcoholic solutions. In common with other unsaturated compounds, the nitriles form polymerisation products. By treatment with sodium in ether, bimolecular indifferent substances are produced; thus aceto-nitrile yields the imino-nitrile of acetoacetic acid  $\begin{array}{l}CH_3{\cdot}C{=}NH\\ \quad|\\ CH_2{\cdot}CN\end{array}$. On treatment with sodium in the absence of any solvent, trimolecular compounds are produced; in the case of the aliphatic series these are strongly basic substances, amino-pyrimidines, propionitrile yielding amino-methyl-diethyl-pyrimidine



(*v.* PYRMIDINES), while the aromatic nitriles yield cyanuric compounds containing the tricyanogen ring. From dicarboxylic acids two nitriles can be produced, the half-nitrile or nitrilic acid and the dinitrile, *e.g.* oxalic acid yields the dinitrile, oxalonitrile, which is dicyanogen, and the half-nitrile, oxalonitrilic acid, which is cyanoformic acid, and is known only in the form of esters. Similarly phthalic acid yields the dinitrile, phthalonitrile and the half-nitrile *o*-cyanobenzoic acid, which on heating changes into phthalimide (*v.* PHTHALIC ACID). For individual aliphatic nitriles, *v.* arts. METHYL, ETHYL, &c., and acids from which they are derived.

Benzonitrile, *Phenyl cyanide,* $C_6H_5{\cdot}CN$ occurs in coal tar oil (Krämer and Spilker, Ber. 1890, 23, 83). It may be prepared by the prolonged heating of phenyl *iso*cyanide at 200°–220° (Weith, Ber. 1873, 6, 213); by the dry distillation of ammonium benzoate (Fehling, Annalen, 49, 91); or by distilling the aqueous solution with baryta (Laurent and Gerhardt, J. 1849, 327; Wöhler, Annalen, 192, 362), lime (Anschütz and Schültz, *ibid.* 196, 48), phosphorus pentoxide (Buckton and Hoffmann, *ibid.* 100, 115), phosphorus pentachloride (Henke, *ibid.* 106, 276), or phosphorus pentasulphide (Henry, Ber. 1869, 2, 307); by distilling benzaldoxime with acetic anhydride (Lach, *ibid.* 1884, 17, 474); by diazotising aniline, and decomposing the diazobenzene chloride thus formed with potassium cyanide and copper sulphate (Sandmeyer, *ibid.* 2563); by distilling benzoic acid with potassium thiocyanate (Letts, *ibid.* 1872, 5, 673); by passing cyanogen into boiling benzene in the presence of aluminium chloride (Desgrez, Bull. Soc. chim. [iii.] 13, 735); by heating benzene and cyanogen chloride or bromide in the presence of aluminium chloride (Friedel and Crafts, Ann. Chim. Phys. [vi.] 1, 528; Merz and Weith, Ber. 1877, 10, 756); by the interaction of potassium fulminate and benzene in the presence of aluminium chloride (Scholl, Ber. 1899, 32, 3496); by treating potassium benzoate with cyanogen bromide (Cahours, Annalen, 108, 319); by desulphurising phenyl mustard oil with metallic copper (Weith, Ber. 1873, 6, 213); by distilling formanilide in a stream of hydrogen over heated zinc (Gasiorowski and Merz, *ibid.* 1885, 18, 1002); by heating potassium benzene sulphonate (Merz, Zeitsch. Chem. 1868, 33), or triphenylphosphate (Scrughan, Annalen, 92, 318; Heim, Ber. 1883, 16, 1771) with potassium cyanide; by treating benzamide, potassium cyanate or thiocyanate with benzoyl chloride (Limpricht, Annalen, 99, 117; Schiff, *ibid.* 101, 33); by heating chloro- or bromobenzene with potassium ferrocyanide at 400° (Merz and Weith, Ber. 1875, 8, 918; 1877, 10, 749); by heating iodobenzene and silver cyanide at 300° (Merz and Schelnberger, Ber. 1875, 8, 1630); by treating a mixture of brombenzene and cyanogen chloride in ethereal solution with sodium (Klason, J. pr. Chem. [ii.] 35, 83); by the interaction of ethylene dicyanide and benzoic acid (Matthews, J. Amer. Chem. Soc. 1898, 20, 650); by heating hippuric acid either alone or better with anhydrous zinc chloride at 240° (Limpricht and Uslar, Annalen, 88, 133; Gössmann, *ibid.* 100, 74); by passing dimethylaniline through a heated tube (Nietzki, Ber. 1877, 10, 474); and by the interaction of magnesium nitride and benzoic anhydride (Emmerling, *ibid.* 1896, 29, 1635).

Benzonitrile is a colourless oil, having an odour resembling that of benzaldehyde, b.p. 190·7° (corr.), sp.gr. 1·0101 at 15°/15° (Perkin, Chem. Soc. Trans. 1896, 1244; Kopp, Annalen, 98, 373), m.p. −12·9° (Schneider, Zeitsch. physikal. Chem. 19, 157); soluble in alcohol and ether, and in 100 parts of boiling water. On boiling benzonitrile with potassium hydroxide it is hydrolysed to benzoic acid and ammonia, while by digesting it for many hours with dilute potassium hydroxide at 40°, benzamide is produced (Rabaut, Bull. Soc. chim. [iii.] 21, 1075). Benzylamine is formed by reduction with alcoholic hydrochloric acid and zinc (Mendius, Annalen, 121, 144). According to Sabatier and Senderens (Compt. rend. 1905, 140, 482), hydrogenation in the presence of reduced nickel at 200° yields toluene and ammonia; but Frebault (*ibid.* 1036) states that by embedding the nickel in iron filings to ensure an even temperature, at 250° the products are benzylamine, dibenzylamine and possibly a trace of tribenzylamine. Chlorine in the presence of sunlight yields benzonitrile hexachloride (Matthews, Chem. Soc. Trans. 1900, 1273).

Benzonitrile oxide, *v.* Wieland, Ber. 1907, 40, 1667; Werner and Buss, Ber. 1894, 27, 2193. Addition compounds with platinous chloride, *v.* Hofmann and Bugge, *ibid.* 1907, 40, 1772; Ramberg, *ibid.* 2578).

The *iso***cyanides** contain the group $-N{=}C$ (Nef, Annalen, 1892, 270, 267; 1895, 287, 265). They were first prepared in 1866 by Gautier by treating alkyl iodides with silver cyanide. Later Hofmann obtained them by the interaction of potassium hydroxide, chloroform and primary amines. They are also formed in small quantity in some of the methods for preparing the nitriles (*v. supra*).

The *iso*cyanides are colourless, volatile liquids, having a most disagreeable odour, and are readily soluble in alcohol and ether, sparingly so in water. Though the *iso*cyanides are not basic, yet they combine with hydrochloric acid in ethereal solution to form compounds of the type $2R{\cdot}NC,3HCl$, but these substances are unstable to water. The *iso*cyanides are more easily hydrolysed than the nitriles, dilute acids or water at 180° effecting this, the products being formic acid and primary amines. Glacial acetic acid converts them into alkylformamides by the addition of one molecule of water. On reduction there are formed secondary amines, one of the groups being methyl.

Alkyl *iso*cyanides *v.* arts. METHYL, ETHYL, &c.

Phenyl *iso*cyanide, *Phenylcarbylamine*

$$C_6H_5{\cdot}N{=}C$$

may be prepared by the interaction of aniline, chloroform, and potassium hydroxide in alcoholic solution at 50° (Hofmann, Annalen, 144, 117; Nef, *ibid.* 270, 274); or by the action of chloroform and dry powdered caustic alkali on aniline in the absence of any solvent (Biddle and Goldberg, *ibid.* 310, 7); by the action of chloroform, carbon tetrachloride, hexachlorethane, bromoform, iodoform, or chloral on phenyl hydrazine in the cold (Brünner and Vuilleumier, Chem. Zentr. 1908, ii. 588).

Phenyl *iso*cyanide, when freshly prepared, is a green liquid; after a few minutes it changes to a pale blue, then to a dark blue liquid, and finally, after some months to a brown resin, b.p. 165° (with decomposition), sp.gr. 0·9775 at 15°/15°. By passing dry hydrogen chloride into a dry ethereal solution of phenyl *iso*cyanide the hydrochloride $2C_6H_5{\cdot}NC,3HCl$ is formed; this is decomposed by water (Nef, Annalen, 270, 303). By passing chlorine into the dry ethereal solution a chloride is obtained; this chloride can also be prepared by passing chlorine into phenyl mustard oil (Nef, *ibid.* 282), and on treatment with water at 100°, *sym*-diphenylurea, carbon dioxide, hydrochloric acid, and aniline are the products. Bromide, *v.* Lengfield and Stieglitz, Amer. Chem. J. 17, 101. Phenyl *iso*cyanide is readily hydrolysed by dilute acids into aniline and formic acid. Glacial acetic acid converts it into formanilide, and a trace of acetanilide; thioacetic acid yields acetanilide (Pawlewski, Ber. 1899, 32, 1425). It combines with sulphur, yielding phenyl mustard oil (Weith, *ibid.* 1873, 6, 210); with sulphuretted hydrogen it yields thioformanilide. By heating phenyl *iso*cyanide at 200°–220°, benzonitrile is produced (Weith, *ibid.* 213). Addition compounds with platinous chloride, *v.* Hofmann and Bugge, Ber. 1907, 40, 1772; Ramberg, *ibid.* 2578.

NITROBENZENE *v.* BENZENE.

NITROCELLULOSES *v.* EXPLOSIVES.

NITROCINNAMIC ACID *v.* CINNAMIC ACID.

NITROCRESOL *v.* NITROPHENOLS AND THEIR HOMOLOGUES.

NITRO DYES *v.* AURANTIA; NAPHTHALENE; and PICRIC ACID.

NITROGEN. Symbol N. At.wt. 14·01. Nitrogen was discovered in 1772 by Rutherford, Professor of Botany in the University of Edinburgh. He found that when a small animal was allowed to breathe air in a confined space for a time, and the carbon dioxide thereby produced removed by absorption, a gas still remained which was incapable of supporting respiration. Lavoisier first established the individuality of this gas, and clearly demonstrated its existence in the atmosphere. From its incapacity to support life he gave it the name of *azote;* the name nitrogen, denoting that the gas is an essential constituent of nitre, was subsequently given to it by Chaptal.

Occurrence.—Nitrogen is one of the most widely diffused of the elements, and occurs free in the air, of which it constitutes four-fifths by volume, or, more accurately, 78·06 p.c. (Leduc, Compt. rend. 1896, 123, 805). Volcanic gases contain considerable quantities of nitrogen, and the air-bladders of certain fishes, the bone-cavities of many birds, as well as the cavities of plants, all contain the gas in the free state. It occurs in many meteorites. The nebulæ consist, in part, of free nitrogen, and it is contained in the atmosphere of the sun.

Nitrogen, in a state of combination with oxygen, exists in the air as nitric and nitrous acids, and, combined with hydrogen, as ammonia. According to Hayhurst and Pring (Chem. Soc. Trans. 1910, 868) nitrous gases are present in the atmosphere, in quantities which vary from time to time, and are usually greater at high than at low altitudes, to the extent of about 1 in 3,000,000. These compounds are consequently present in rain-water. Nitrogen is an essential constituent of animal and vegetable organisms, and is found in many minerals, but chiefly in saltpetre or potassium nitrate, and Chile saltpetre or sodium nitrate.

PREPARATION.—(A) *From the Atmosphere.*

(α) By chemical separation of the oxygen with some reagent with which it easily reacts—

(1) By passing air over reduced iron (Brunner).

(2) With hydrogen over platinum sponge (Dumoulin).

(3) Over heated copper turnings (Dumas and Boussingault), or better, mixed with ammonia gas (Lupton, Chem. News, 1876, 33, 90), or with hydrogen (Hulett, J. Amer. Chem. Soc. 1906, 27, 1415).

(4) By absorption with alkaline pyrogallol (Liebig, Annalen, 1851, 77, 107).

(5) With copper and aqueous ammonia (Berthelot, Bull. Soc. chim. [ii.] 13, 314).

(6) With manganous and ferrous hydroxides (Flight, Chem. News, 1882, 45, 105).

(7) With phosphorus.

In these cases, after removal of carbon dioxide and water vapour, the gas obtained is at the most 99 p.c. pure, as the inert gases are still present.

Amongst the many patents for the production of nitrogen on this principle are those of Frank and Caro (nitrogen from combustion gases, *e.g.* from gas producers, D. R. P. 204882, May 22, 1907), Cyanide Ges. m.b. H. (D. R. P. 218671, Nov. 25, 1908; from air passed over copper in specially designed apparatus), Kassner (D. R. PP. 233383, and 234849, May 29, 1910, by absorbing the oxygen with calcium plumbate, alkali manganate, &c.), and Acker (Nitrogen Co. New York, Eng. Pat. 24413, 1910).

(β) By fractional distillation of liquid air. The bulk of the uncondensed gas is nitrogen, and the vapour boiling off from the liquid is mainly the more volatile nitrogen, the liquid after standing in a Dewar flask for some time being practically pure oxygen (*v.* Stock and Nielson, Ber. 1906, 39, 3393).

For the distillation of mixtures of liquid nitrogen and oxygen, *v.* Baly (Phil. Mag. 1900, [v.], 49, 517), Inglis and Coates (Chem. Soc. Trans. 1906, 886), Inglis (Phil. Mag. 1906, [vi.] 11, 640).

Erdmann (Ber. 1906, 39, 1207) describes a commercial method for condensing large quantities of nitrogen, in practically pure condition.

Many forms of apparatus designed for the production of nitrogen by this means have been patented. Of these the best known is the

LINDE NITROGEN SEPARATOR.

In the article OXYGEN, vol. iv., Fig. 1 illustrates the Linde oxygen separator, and in the description of that apparatus it is shown how it is possible to obtain pure liquid oxygen at the bottom of the rectification column, whilst the nitrogen vapours leaving the top of the column can never contain less than 7 p.c. of oxygen. Reference is also made to a modification of the Linde process due to Claude, by means of which small quantities of pure nitrogen may be obtained from an oxygen separator. For the production of pure nitrogen in large quantities, Linde employs a modified construction of his separator, which is illustrated diagramatically in Fig. 1.

In this apparatus, as in the oxygen one, the circular upper portion of the casing is made of wood and contains in its centre the rectification column A, whilst the base, constructed of wood in the form of a hexagon, contains the vaporising or distilling chamber B. All clearance spaces are packed with sheep's wool, or other suitable insulating material in order to prevent the penetration of heat from the outside. C is the counter-current interchanger, constructed in the form of a large copper spiral pipe, and containing three smaller pipes of different sizes *d*, *e*, and *f*. The vertical pipe C is an extension of the main spiral pipe to the top of the rectification column A. The pipe coil d_1 shown in the vaporising chamber is connected at one extremity with pipe *d* contained in the counter-current interchanger. The other extremity of this pipe is connected to the inlet of the valve box G to the outlet of which another pipe d_2 is connected, as shown. This pipe is carried upwards and enters the rectification column near the middle, where it is fitted as shown with a rose-end, the function of which will be explained later. The coil f_1, also shown in the vaporising chamber, is connected at one extremity with the pipe *f* contained in the counter-current interchanger. The other extremity of this pipe is connected to the inlet of the valve box H to the outlet of which another pipe f_2 is connected, as shown. This pipe is carried upwards and enters the rectification column near the top, where it is fitted, as shown, with a rose-end, the function of which will be described later. The short pipe e_1 communicates at one end with the top of the vaporising chamber and is connected at the other end to the extremity of the pipe e contained in the counter-current interchanger.

Two gas compressors are employed in conjunction with the separator, one working at high pressure and the other at low pressure. A fore-cooler as described in connection with the oxygen separator (*v.* OXYGEN) may also advantageously be used. This fore-cooler is kept cold by means of a carbonic acid or ammonia machine, and is interposed between the compressors and the separator, so that the compressed gases leaving the compressors at normal atmospheric temperatures, become reduced to a temperature well below the freezing-point of water before they enter the separator. With this preliminary description of the essential parts, the working of the apparatus can now be readily followed.

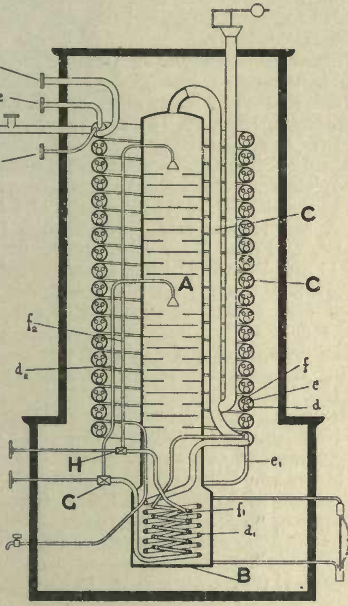


FIG. 1.

There are, as in the case of all such apparatus, two stages in the working.

First, the preliminary cooling down and production of liquid, and *second* the separation of pure nitrogen.

The preliminary cooling may be effected by charging the vaporiser B with liquid air, separately produced; or air at normal atmospheric temperature (or less where a fore-cooler is employed) and at a pressure of about 2000 lbs. per square inch is conveyed from the high-pressure gas compressor through the small pipe f of the counter-current interchanger. (Although only one pipe f is shown, several of these are generally employed.) This compressed air then passes through the pipe coil f_1 in the vaporiser B to the inlet of the valve box H. At this point, by the adjustment of the valve spindle, the air is caused to expand from a high to a low pressure and is discharged at this low pressure through the rose-ended pipe f_2 into the top of the rectification column. This expanded air fills the column and flows away through the outlet C into the counter-current interchanger in a reverse flow to the incoming high pressure air, leaving the apparatus through the pipe C. As a branch of this pipe is coupled to the intake of the high-pressure compressor, it is obvious that the same air circulates through the apparatus with a regenerative cooling effect, until a temperature is ultimately reached at which the expanded air begins to liquefy and collect in that state round the coils in the vaporiser B. The quantity of liquid thus collected is registered outside the apparatus by means of an ordinary coloured liquid which is contained in a glass tube j enclosed in a pressure-equalising circuit, as indicated.

When the vaporiser B is nearly filled with liquid, the second stage is reached in which the apparatus can be employed for the continuous production of nitrogen.

During the production of liquid in the vaporiser B, separation of oxygen and nitrogen has been taking place, first through simple fractional evaporation, and subsequently through rectification, as fully described under OXYGEN.

The nitrogen issuing from the pipe C has also been getting steadily purer in quality owing to the fact that it has been undergoing continuous treatment in an enclosed circuit. For the continuous production of pure nitrogen, it is, however, necessary to introduce a supplementary supply of liquid air, and as it is impossible by simple rectification to disengage nitrogen vapours from liquid air with less than 7 p.c. of oxygen, further treatment of the nitrogen has obviously to be employed in order to eliminate the residual oxygen. This is effected in the following manner:—

The air to be treated is supplied by the low-pressure compressor, already referred to, at normal atmospheric temperature (or less), and at a pressure of about 60 lbs. per square inch through the pipe d of the counter-current interchanger. This low-pressure air, thus cooled nearly to its temperature of condensation, then passes through the pipe coil d_1 in the vaporiser B, where its latent heat is transferred to the surrounding liquid, and it is itself entirely condensed, whilst at the same time evaporating an approximately equal quantity of the surrounding liquid. The pressure is then reduced by means of the valve G, and the liquid at atmospheric pressure is discharged into the lower part of the rectification column through the rose-ended pipe d_2. It is there rectified by the ascending vapours from the chamber B to a content of 7 p.c. of oxygen, whilst the liquid descending into the vaporising chamber is nearly pure oxygen. The nitrogen containing 7 p.c. of oxygen rises to the top of the column and is discharged from the apparatus through the pipe C and the main pipe C of the counter-current interchanger. Now, as already explained, a branch of the pipe C is coupled to the intake of the high-pressure compressor. Part of the outflowing nitrogen, therefore enters that compressor, and passing through the high-pressure circuit in the manner already described, is liquefied and discharged at the top of the rectification column through the rose-ended pipe f_2. This liquid containing 7 p.c. of oxygen is, according to Baly's experiments (*v.* Fig. 3, OXYGEN), able to purify the vapours encountered by it down to about 2 p.c. of oxygen. Part of these are again drawn into the high-pressure system and condensed, and flowing into the column, continue automatically to displace oxygen from the rising vapours until pure nitrogen only is discharged from the pipe C. Part of this nitrogen continues to circulate through the high-pressure system for scrubbing purposes, but the major part is collected for use through the vertical branch on the pipe C. Oxygen vapours are abstracted from the apparatus through the pipes e_1 and e.

It is found that an installation of this description will produce approximately one cubic metre of nitrogen per ½ I.H.P.

(B) *By Chemical Means.*—(1) By passing chlorine through a strong solution of ammonia

$$8NH_3+3Cl_2=6NH_4Cl+N_2.$$

The ammonia must be in excess, otherwise nitrogen chloride may be formed. Anderson (Chem. News, 5, 246) states that so obtained the nitrogen always contains oxygen. Ammonia is removed by passing through sulphuric acid.

(2) By adding metallic zinc to fused ammonium nitrate.

(3) By heating ammonium nitrite, or a mixture of ammonium chloride, and potassium nitrite: $NH_4NO_2=2H_2O+N_2$. This method gives nitric oxide in small quantity. If this is removed by ferrous sulphate solution, some is always evolved again on shaking, whilst with potassium permanganate oxygen is liberated in varying quantities (*v.* Knorre, Chem. Zentr. 1903, [i.] 125). The best method of procedure is to take 1 part $NaNO_2$, 1–2 parts $(NH_4)_2SO_4$, and 1 part $K_2Cr_2O_7$, warm the solution, and wash the gas evolved with a solution of 5 vols. saturated $K_2Cr_2O_7$ solution and 1 vol. concentrated H_2SO_4.

(4) By heating ammonium dichromate, or a mixture of ammonium chloride and potassium dichromate $(NH_4)_2Cr_2O_7=Cr_2O_3+4H_2O+N_2$.

(5) By heating glycerol (2 parts) and NH_4NO_3 (1 part) (Mai, Ber. 1901, 34, 3805).

The reaction commences at 190°, but once started proceeds without further heating till the temperature has fallen to 150°. A few drops of sulphuric acid cause the reaction to proceed more regularly and at a lower temperature. CO_2 is present in small quantity. The yield of nitrogen is nearly theoretical.

(6) By heating a mixture of dry ammonium nitrate and ammonium chloride

$$4NH_4NO_3+2NH_4Cl=Cl_2+12H_2O+5N_2.$$

(7) By passing a mixture of (*a*) nitric oxide, or (*b*) nitrous oxide, with ammonia over heated copper gauze or platinised asbestos. The nitrogen is purified by passing through dilute H_2SO_4, over fused KOH, through concentrated H_2SO_4, and finally over red-hot copper gauze (Baxter and Hickey, Amer. Chem. J. 1905, 33, 300).

(8) By decomposing chamber crystals with ammonium sulphate at 130° (Pelouze, Ann. Chim. Phys. 1841, [iii.] 2, 49)

$$2NO_2{\cdot}SO_3H+(NH_4)_2SO_4=3H_2SO_4+2H_2O+2N_2$$

It is also formed in other chemical decompositions, notably by the action of hypochlorites and hypobromites on ammonia and acid amides, and of nitrous acid upon amines.

Spongy platinum boiled with ammonium sulphate and sulphuric acid gives SO_2 and N_2 (Delépine, Compt. rend. 1905, 141, 886), probably in accordance with the following equations—

(1) $4H_2SO_4+Pt=Pt(SO_4)_2+2SO_2+4H_2O.$
(2) $3Pt(SO_4)_2+2(NH_4)_2SO_4=2N_2+3Pt+8H_2SO_4.$

This explains the loss of nitrogen when platinichlorides of organic bases are estimated by the Kjeldahl method.

Properties.—Nitrogen is a colourless, inodorous, tasteless, neutral gas. Its density has been determined by many observers (*v.* Ramsay, Chem. News, 1899, 79, 13), and the discrepancy between the densities of atmospheric and chemically prepared nitrogen led to the discovery by Rayleigh and Ramsay of argon.

The density (air=1) and weight of 1 litre at N.T.P. are respectively 0·96737 and 1·25092 (Rayleigh, Proc. Roy. Soc. 1898, 62, 209), 0·96717 and 1·25070 (Leduc, Compt. rend. 1898, 126, 413), these giving for H=1 the values 14·002 and 14·004 respectively (Leduc, *ibid.* 1908, 146, 399).

The density of atmospheric nitrogen (containing the inert gases) is 0·97209 (Rayleigh *l.c.*).

Rayleigh's later determinations (Proc. Roy. Soc. 1904, 73, 153) give the densities (H = 1) at atmospheric and at very low pressures as 14·003 and 14·009 respectively. B.p. —195·0° (Dewar, *ibid.* 1902, 69, 360); —195·9 (Grunmach, Sitzungsber. K. Akad. Wiss. Berlin, 1906, 679); —195·55 (Alt, Ann. Physik. 1906, [iv.] 19, 739).

Olzewski (Compt. rend. 1884, 99, 133) gives the b.ps. at high pressures as follows—

P. in atm.	35	31	17
°C.	—146	—148·2	—160·5

See also Baly (Phil. Mag. 1900, [v.] 49, 517) and Fischer and Alt (Sitzungsber. K. Akad. München, 1902, 113).

	Baly	Dewar	Fischer and Alt.
M.p.	—210·52	—210·5	—210·48

Critical pressure 32·29 atm., critical temperature —146·25° (Wroblewski, Compt. rend. 1885, 100, 979). Critical volume 42·6 c.c.; critical density 0·0235 (Dewar, Proc. Roy. Soc. 1904, 73, 251).

Sp.gr. of liquid nitrogen.

°C.	Sp.gr.	Observer
—193·93	0·8084	Inglis and Coates.
	0·8010	Baly and Donnan.
—195·5	0·8042	Dewar.
—198·3	0·8297	Inglis and Coates.
	0·8218	Baly and Donnan.

Sp.gr. of solid nitrogen.

—210·5	0·8792	Dewar.
—252·5	1·0265	Dewar.

Molecular volume at 0° abs. (calc.)=25·49 (Dewar, Proc. Roy. Soc. 1904, 73, 251). Specific volume at m.p. 221·3 c.c. (*ibid.* 1902, 69, 360). Sp.ht. of liquid nitrogen for temperature range of —196° to —208° is 0·430±0·008 (Alt, Ann.

Physik. 1904, [iv.] 13, 1010). Sp.ht. of gaseous nitrogen 0·2348 between 0° and 200° (Regnault); 0·2419 from 20° to 440°; 0·2464 from 20° to 630°; 0·2492 from 20° to 800° (Holborn and Austin, Sitzungsber. K. Akad. Wiss. Berlin, 1905, 175), and has a mean value $0{\cdot}2350+0{\cdot}000019\theta$ between 0° and θ° (Holborn and Henning, Ann. Physik. 1907, [iv.] 23, 809).

Latent heat of vaporisation at b.p. 50·4 cal. (Dewar, Proc. Roy. Soc. 1905, A, 76, 325): at b.p. 47·65, at −202°, 49·42, at −210°, 51·61 (Alt, Ann. Physik. 1906, [iv.] 19, 739).

Vapour pressure at m.p. 93·5 mm.; from Fischer and Alt's values of the vapour pressures near the m.p. the m.p. calculated by Ramsay and Young's method is −210·24°. For atmospheric nitrogen the vapour pressure at the m.p. is 90·2 mm., and the calculated m.p. is −210·47°. The lowering of 0·23° is brought about by argon (1·70 gram per 100 grams N) from which the molecular depression is calculated as 5·39 and from this the latent heat of fusion is 14·49 cal. (Estreicher, Bull. Acad. Sci. Cracow, 1903, 831).

Surface tension 8·514±0·02 dynes/cm. (Grunmach, Sitzungsber. K. Akad. Wiss. Berlin, 1906, 679). Tables showing variation of surface tension and density of liquid nitrogen with temperature are given by Baly and Donnan (Chem. Soc. Trans. 1902, 907).

The available pressure, volume, and thermal data for nitrogen at low temperatures have been collected and analysed by Plank (Physikal. Zeitsch. 1910, 11, 633).

Coefficient of expansion of liquid nitrogen varies from 0·002996 at 11°–132° abs. under 6 mm. to 0·003674 at 100° abs. under 1000 mm. (Erdmann, Ber. 1906, 39, 1207), and that of gaseous nitrogen 0·003643 from 0° to 1067° (Jacquerod and Perrot, Compt. rend. 1904, 138, 1032). The compressibility of gaseous nitrogen has been studied by Regnault, Natterer, Cailletet, Amagat (Ann. Chim. Phys. 1893, [vi.] 29, 68, 505), and Rayleigh (Proc. Roy. Soc. 1905, 74, 446). For the data the original papers must be consulted.

For viscosity constants of pure and atmospheric nitrogen, *v.* Markowski (Ann. Physik. 1904, 14, 742).

The inversion temperature of the Joule-Kelvin phenomenon for atmospheric nitrogen is 243° at 159 atm. and 163° at 30 atm. (Olzewski, Bull. Acad. Sci. Cracow, 1906, 792; *v.* also Porter, Phil. Mag. 1910, [vi.] 19, 888). Refractive index of gaseous nitrogen 1·000297 (Ramsay and Travers. Zeitsch. physikal. Chem. 1898, 100, 25), and of liquid nitrogen 1·2053 (Liveing and Dewar, Phil. Mag. 1893, [v.] 36, 328; *v.* also Cuthbertson, Proc. Roy. Soc. 1910, 83, A, 151). Electromagnetic rotation 0·000127 (Kundt and Röntgen, Wied. Ann. 1880, 10, 257).

Solubility.—Liquid oxygen at −195·5° dissolves 458 times its volume, or 50·7 p.c. of its weight of gaseous nitrogen (Erdmann and Bedford, Ber. 1904, 37, 1184). The solution obeys Henry's law, and liquid nitrogen therefore has the normal molecular weight, although oxygen dissolved in nitrogen is associated (Inglis and Coates, Chem. Soc. Trans. 1906, 886). Grunmach, however, from its surface tension calculates its molecular weight in the liquid state to be 37·3 (Sitzungsber. K. Akad. Wiss. Berlin, 1906, 679).

Solubility in water.

Temp.	0°	10°	20°	30°	40°	50°
cc. per litre	23·00	18·54	15·54	13·55	12·15	11·02

(Fox, Trans. Faraday Soc. 1909, 5, 68; *see* also Winckler, Zeitsch. physikal. Chem. 1892, 9, 171). For solubility in alcohol see Carius, Annalen, 1855, 94, 136; in petroleum see Gniewosz and Walfisz, Zeitsch. physikal. Chem. 1887, 1, 70; in glycerol and *iso*butyric acid see Drucker and Moles, *ibid.* 1910, 75, 405; in solutions of organic substances see Hûfner, *ibid.* 1907, 57, 611.

Wood charcoal absorbs ten times as much nitrogen at −185° as at 0° (Dewar, Compt. rend. 1904, 139, 261).

Chemical properties.—Nitrogen is not combustible, and does not support combustion, and in the free state is remarkable for its inactivity. It may, however, be made to unite directly with boron, silicon, magnesium, titanium, tantalum, and tungsten. It is absorbed by a mixture of magnesium powder and lime, and, under certain conditions, combines with hydrogen, oxygen, and carbon, as, *e.g.*, when a series of electric sparks is passed through oxygen and nitrogen gases standing over a solution of caustic alkali, when a nitrate of the metal is produced. Traces of nitric acid and ammonium nitrate are produced by burning hydrogen gas mixed with nitrogen in an atmosphere of air or oxygen. Nitrogen can unite with hydrogen to form ammonia when the gases are in the nascent state. Carbon and nitrogen unite directly when nitrogen gas or atmospheric air is passed over an ignited mixture of charcoal and potash, or charcoal and baryta.

Nitrogen reacts slightly with steam at 2000°: $N_2+2H_2O=2NO+H_2$ (Tower, Ber. 1905, 38, 2945).

If, however, the pure gas is subjected to the action of the electric discharge from a Leyden jar it undergoes a remarkable change in physical and chemical properties. The gas glows for some time after the discharge has been discontinued, exhibiting a characteristic band spectrum, with green, yellow, and red bands of about equal intensity. If passed through a glass tube moderately heated at one point the glow disappears locally. If strongly heated, the glow is permanently extinguished. Its brilliancy is increased during cooling by liquid air, but at the coolest part it is finally extinguished. Yellow phosphorus combines violently, iodine gives a magnificent blue flame, and sulphur and arsenic give faint blue and green flames respectively on being heated in the gas so treated. It combines with sodium and mercury on warming, forming with the latter an explosive compound, line spectra of the elements being developed, as is the case with cadmium, magnesium, potassium, zinc, and lead. When compound substances are volatilised in the gas, their band spectra are produced. It also reacts with organic halogen compounds, and with acetylene, with formation of a brilliant cyanogen spectrum. With nitric oxide nitrogen peroxide is produced, probably as represented by the equation $2NO+N=NO_2+N_2$ (Strutt, Proc. Roy. Soc. 1911, 85, A, 219).

A detailed account of the spectrum is given by Fowler and Strutt (*ibid.* 1911, 85, A, 377). For the spectrum of nitrogen, *v.* also Deslandres (Compt. rend. 1902, 134, 747), Mosengeil (Ann. Physik. 1906, [iv.] 20, 833), Walter (*ibid.* 1906, [iv.] 20, 327), Nasini and Anderlini (at 3000°, Gazz. chim. ital. 1906, 36, ii. 561), Purvis (in strong magnetic field, Proc. Camb. Phil. Soc. 1906, 13, 354), Angerer (at low temperatures, Ann. Physik. 1910, [iv.] 32, 549), Helm (long-waved portion, Zeitsch. wiss. Photochem. 1910, 8, 405), Wien (canal rays, Physikal. Zeitsch. 1910, 11,377), Croze (infra red, Compt. rend. 1910, 150, 860).

Nitrogen is an essential constituent of many of the most potent and valuable medicines, as well as of some of the most powerful poisons, *e.g.* quinine, morphine, prussic acid, and strychnine. The slight affinity existing between nitrogen and other elements gives a peculiar character to its compounds, many of which are extremely prone to decomposition. Many nitrogen compounds, especially those which contain the oxygenated radicle *nitryl* (NO_2), are highly explosive, as in the case of the picrates, certain azo compounds, gun-cotton, the fulminates of silver and mercury, nitroglycerine, &c.

HALIDES OF NITROGEN.

Nitrogen fluoride was supposed by Warren (Chem. News, 55, 289) to be formed when a saturated aqueous solution of ammonium fluoride was electrolysed, oily drops being noticed at the negative pole, which exploded violently when connected with the positive pole or in contact with organic matter, glass, or silica. Ruff and Geisel (Ber. 1903, 36, 2677) find, however, that nitrogen fluorides do not exist; that electrolysis of ammonium fluoride gives only pure fluorine, and that Warren's substance was probably nitrogen chloride produced from ammonium chloride present as an impurity.

Nitrogen chloride NCl_3. First prepared by Dulong in 1812 by the action of chlorine on an aqueous solution of ammonium chloride

$$NH_4Cl+3Cl_2=NCl_3+4HCl.$$

The reaction has been studied by Noyes and Lyon (Amer. Chem. J. 1900, 23, 460). Balard (Ann. Chim. Phys. 1834, [ii.] 57, 225) prepared it by the action of hypochlorous acid, and Hentschel (Ber. 1897, 30, 1434, 1792) by that of sodium hypochlorite on ammonium chloride.

It is also formed in the electrolysis of a concentrated ammonium chloride solution (Kolbe, J. pr. Chem. 1847, 41, 137), this being the method best suited for lecture experiments (*v.* Meyer, Ber. 1886, 21, 26; Hofer, Chem. Zeit. 1896, 20, 470).

By adding a calcium hypochlorite solution saturated with hydrochloric acid to ammonium chloride solution, and shaking with benzene the NCl_3 formed is dissolved in the benzene (Hentschel, Ber. 1897, 30, 2642).

By covering 150 c.c. of carbon tetrachloride with a concentrated aqueous solution of ammonium chloride, and passing in chlorine gas with vigorous shaking, and then washing with water, a bright yellow solution of the substance is obtained.

It is a yellowish volatile very pungent smelling oil, the vapour of which strongly attacks the eyes and mucous membrane; sp.gr. 1·653, b.p. 71°. It detonates on being heated to 93°, or when brought into contact with organic matter, phosphorus, arsenic, ozone, and alkalis. Metals, and strong acids, resins, and sugar do not cause its explosion, which is, however, brought about by exposure to strong light.

It dissolves in benzene, ether, chloroform, carbon tetrachloride, and carbon disulphide, giving highly refracting sulphur-yellow solutions, stable in the dark, but slowly decomposing in light. Its benzene solution has been used for chlorinating organic substances (Hentschel, *l.c.*; *ibid.* 1898, 31, 246). Heat of formation −38,477 cal. (Troost, Compt. rend. 1868, 69, 204).

The formula NCl_3 was assigned to it by Dulong (Schweigger's J. Chem. Pharm. 1812, 8, 32), Bineau (Ann. Chim. Phys. 1845, [iii.] 15, 82), and Deville and Hautefeuille (Compt. rend. 1869, 69, 152). Davy (Phil. Trans. 1813, 103, 1, 242) found the chlorine to be in excess of that required for this formula. Porret, Wilson and Kirk (Gilb. Ann. 1814, 47, 56, 59), and Gladstone (Chem. Soc. Trans. 1854, 7, 51) concluded that hydrogen was present (the latter giving the formula as N_2HCl_5), but the methods of analysis were not accurate. Gattermann determined the chlorine directly by decomposing a weighed quantity of the carefully purified and dried substance with concentrated ammonia, thus forming ammonium chloride, in which the chlorine was estimated as silver chloride, the result closely agreeing with the formula NCl_3 (Ber. 1888, 21, 755; *v.* also Hentschel, *l.c.*). This formula was confirmed by Chapman and Vodden (Chem. Soc. Trans. 1909, 141), who determined the ratio of nitrogen to chlorine, and also proved the absence of hydrogen.

Seliwanoff (Ber. 1894, 27, 1012) represents its hydrolysis with water as follows—

$$NCl_3+3H_2O \rightleftarrows NH_3+3HClO.$$

This explains the easy reduction to ammonia, and the apparently greater solubility in hydrochloric acid than in sulphuric acid or water, since hydrochloric acid destroys hypochlorous acid. This is confirmed by Chapman and Vodden by shaking the CCl_4 solution with moderately concentrated HCl, removing any NCl_3 from the aqueous solution, and distilling with KOH, when ammonia is obtained in quantity—

$$\begin{gathered} NCl_3+3H_2O \rightleftarrows NH_3+3HClO \\ HClO+HCl \rightleftarrows Cl_2+H_2O \\ NH_3+HCl \rightleftarrows NH_4Cl. \end{gathered}$$

Nitrogen bromide is said to be formed as a dark red highly explosive volatile oil by adding potassium bromide to nitrogen chloride under water, and is possibly formed in a manner similar to the chloride, but no definite compound has been isolated.

Nitrogen iodide was first prepared by Courtois, and has since been obtained in a variety of ways, viz. by digesting aqueous ammonia with powdered iodine (Stas) or alcoholic iodine solution (Serullas, Ann. Chim. Phys. 1829, [ii.] 42, 200), or a solution of iodine in *aqua regia*, or directly with iodine chloride in potassium iodide solution (Schönbein; Guyard, Compt. rend. 1883, 97, 526); from alcoholic ammonia and iodine solutions (Bunsen), and from ammonium iodide and bleaching powder (Gladstone, Chem. Soc. Trans. 1855, 51).

It forms copper-coloured crystals, light red by transmitted light, sp.gr. 3·5, very readily exploded by shock, warming, or exposure to strong light. It is never obtained free from hydrogen, and at low temperatures gives molecular compounds with varying quantities of ammonia, viz. $NI_3{\cdot}NH_3$, $NI_3{\cdot}2NH_3$, $NI_3{\cdot}3NH_3$, $NI_3{\cdot}12NH_3$ (Hugot, Ann. Chim. Phys. 1900, [vii.] 21, 5; Ruff, Ber. 1900, 33, 3025). The compound $NI_3{\cdot}NH_3$ is usually isolated, this formula representing its structure (Chattaway and Orton, Amer. Chem. J. 1900, 24, 331; Silberrad, Chem. Soc. Trans. 1905, 55).

Silberrad finds it to react with zinc ethyl as follows—

$$(1)\ NH_3{\cdot}NI_3+3Zn(C_2H_5)_2 \\ =3ZnC_2H_5I+NH_3+N(C_2H_5)_3$$

$$(2)\ 2NH_3+Zn(C_2H_5)_2=Zn(NH_2)_2+2C_2H_6$$

According to Seliwanoff (Ber. 1894, 27, 1012) its hydrolysis with water is as follows—

$$NH_3{\cdot}NI_3+3H_2O \rightleftarrows 2NH_4IO+HIO.$$

It is reduced by H_2S, SO_2, As_2O_3, similarly to NCl_3. Hydriodic acid liberates iodine, hydrochloric acid forms iodine chloride, hydrocyanic acid iodine cyanide, and alkalis a mixture of iodide and iodate. It reacts with organic iodides (Silberrad and Smart, Chem. Soc. Trans. 1906, 172).

NITROGEN AND SULPHUR.

Nitrogen sulphide was first prepared by Fordos and Gélis (Compt. rend. 1850, 31, 702), who assigned to it the formula SN.

It is obtained by passing dry ammonia gas into a solution of sulphur dichloride in carbon disulphide or benzene solution.

According to Francis and Davis (Chem. Soc. Trans. 1904, 259), it is best prepared from a 10–15 p.c. solution of S_2Cl_2 in benzene, into which a rapid current of dry ammonia is passed until red fumes appear, after which the liquid is cooled and the current continued for a short time longer. The ammonium chloride is filtered off, and on evaporation of the filtrate, orange-red prisms are obtained which, recrystallised from boiling benzene, toluene, or carbon disulphide, melt at 185°. It is more stable than previous observers have stated, its supposedly greater tendency to explode probably being due to impurities present, as indicated by the lower melting-points given by them (*cf.* Schenck, Annalen, 1896, 290, 171). It may be sublimed under reduced pressure. Crystallographic constants (Artini, Chem. Zentr. 1906, i. 1774)

$$[a:b:c=0{\cdot}8806:1:0{\cdot}8430\ ;\ \beta=89°\ 20']$$

Its formation is usually represented by the equation—

$$8NH_3+3S_2Cl_2=6NH_4Cl+2NS+S_4$$

but according to Ruff and Geisel (Ber. 1904, 37, 1573), the relation of the yield to the composition of the sulphur chloride employed indicates SCl_4 to be concerned in the reaction—

$$12SCl_4+16NH_3=3S_4N_4+48HCl+2N_2.$$

Its molecular formula is S_4N_4 (Schenck, *l.c.*; Muthmann, Ber. 1896, 29, 340; Francis and Davis, *l.c.*).

With chlorine in chloroform solution, the *tetrachloride* $N_4S_4Cl_4$ is formed, which crystallises on cooling in magnificent yellow crystals which decompose on heating—

$$N_4S_4Cl_4=2N_2+2S_2Cl_2.$$

It is excessively unstable, giving a black tarry mass on exposure to moist air (Demarçay, Compt. rend. 91, 854; Muthmann and Seiter, Ber. 1897, 30, 627).

Demarçay also describes the compound $(SN)_3Cl$, as produced by adding the requisite proportion of nitrogen sulphide to the tetrachloride in chloroform solution. This is probably *thio-trithioazylchloride* N_3S_4Cl, obtained by the action of N_4S_4 upon S_2Cl_2 in chloroform solution, or by heating N_4S_4 with acetyl chloride. It is an intensely yellow crystalline powder, which explodes a few minutes after becoming dry. It readily absorbs ammonia.

Muthmann and Seiter (*l.c.*) also describe the following derivatives—

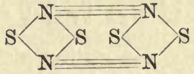
Thio-trithioazylnitrate $N_3S_4NO_3$, obtained as sulphur yellow prisms when the chloride is dissolved in concentrated nitric acid and evaporated *in vacuô*. Its solution in water darkens after a few minutes, giving a black deposit. When dry it is very explosive.

Thio-trithioazylbromide N_3S_4Br is formed by the action of N_4S_4 on S_2Br_2 in CS_2 solution, or of bromine on the chloride in CS_2 solution, or by exposing the tetrabromide of nitrogen sulphide (prepared similarly to the chloride) to moist air. It is stable in air.

Thio-trithioazyliodide N_3S_4I is prepared from solutions of the chloride and potassium iodide in ice cold water. It is very unstable.

Thio-trithioazylthiocyanate N_3S_4CNS, from ice-cold solutions of the chloride or nitrate and potassium thiocyanate, forms lustrous bronze leaflets, fairly soluble in benzene and chloroform which resist the action of the air. These compounds have the constitution—

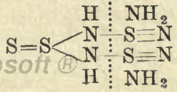
Schenck assigns to N_4S_4 the constitutional formula—



but Ruff and Geisel (*l.c.*) regard the divalence of the sulphur atoms as improbable, and suggest the formula—

which is supported by its reaction with metallic iodides in anhydrous liquid ammonia. Lead iodide gives olive green prisms of the dithio-di-imide, $Pb{\cdot}N_2S_2{\cdot}2NH_3$, and mercury iodide bright yellow crystals of the thio-di-imide, $Hg{\cdot}N_2S{\cdot}NH_3$, but in neither case is precipitation complete, and the mother liquor from the lead salt gives the mercury compound with mercury iodide, whilst that from the mercury salt gives the lead compound with lead iodide. These facts are accounted for by the supposition that in ammonia solution dissociation of the above molecule takes place into the ions—

$$N{\equiv}S{\cdot}NH_2 \text{ and } S{=}S(NH)_2$$



Nitrogen sulphide reacts with a number of metallic chlorides giving additive compounds (Wölbing, Zeitsch. anorg. Chem. 1908, 57, 281); with amines (Schenck, *l.c.*); with acetic acid and its halogen derivatives (Francis, Chem. Soc. Trans. 1905, 1836); with aromatic aldehydes (Davis, *ibid.* 1831); with hydrofluoric acid (Ruff and Thiel, Ber. 1905, 38, 549).

Stannous chloride does not combine, but on warming in benzene solution the N_4S_4 is reduced with formation of yellow lustrous leaflets, m.p. 152°, of the empirical formula NSH. It is not combustible or explosive. NH_3 is evolved on heating with KOH (Wölbing, *l.c.*).

According to Moissan (Compt. rend. 132, 510), the reaction $10S+4NH_3 \rightleftarrows 6H_2S+N_4S_4$ is reversible; nitrogen sulphide can be obtained from sulphur and ammonia in presence of silver iodide.

Dry HCl reacts as follows—

$$N_4S_4+12HCl=4NH_3+4\underbrace{S+12Cl}$$

showing that sulphur is united to nitrogen by 12 valencies, and hence, in agreement with Ruff and Geisel's formula, no N atoms are linked. Ht. of formation of $N_4S_4-81{,}900$ cal. (Berthelot and Vieille, Ann. Chim. Phys. 1882, [v.] 28, 202).

A blue modification of the yellow sulphide N_4S_4 is described by Burt (Chem. Soc. Trans. 1910, 1171) as obtained by subliming the latter over silver gauze. It is much less volatile, and evidently formed from an unstable intermediate reduction product which loses nitrogen.

A liquid sulphide N_2S_5 is obtained when N_4S_4 and CS_2 are heated together at 100° for two hours under 5 atm. pressure (Muthmann and Clever, Zeitsch. anorg. Chem. 1897, 13, 200).

Oxides and Oxyacids of Nitrogen.

Nitrous oxide. *Laughing gas*, N_2O. First obtained by Priestley in 1772, by the action of easily oxidisable substances, such as potassium sulphide or sulphite, on nitric oxide. NO is also reduced to N_2O by iron or zinc filings, or stannous chloride.

Nitrous acid and nitrites yield N_2O when reduced by platinum black, and by sodium amalgam.

Nitric acid and nitrates give N_2O among their reduction products with various reducing agents, especially from zinc and dilute nitric acid or a mixture of equal parts of nitric and sulphuric acids diluted with eight to ten parts of water.

It is usually supposed not to be formed by direct union, *v.*, however, method (6), *infra.* Warburg and Leithäuser (Sitzungsber. K. Akad. Wiss. Berlin, 1908, 148) find that Siemen's ozoniser gives N_2O and N_2O_5, and that the spark between platinum electrodes gives NO_2 and N_2O, the alternating arc at high potential in dry air giving only NO_2.

No combination between nitrogen and oxygen is effected under the influence of ultraviolet light (Berthelot and Gaudechon, Compt. rend. 1910, 150, 1517).

The best methods in practice are—

(1) Campari's method (Chem. Zentr. 1888, 1569), by heating to boiling a mixture of 5 parts stannous chloride, 10 parts hydrochloric acid of sp.gr. 1·21 and 0·9 parts of nitric acid of sp.gr. 1·38. These proportions should be adhered to, or the gas is liable to be evolved with explosive irregularity (*v.* also Gay Lussac, Ann. Chim. Phys. 1847, [iii.] 23, 229).

(2) By reduction of nitrous acid with hydrazine—

$$N_2H_4+HNO_2=NH_3+N_2O+H_2O$$

(Francke, Ber. 1905, 38, 4102).

(3) By decomposition of ammonium nitrate by heat; $NH_4NO_3=N_2O+2H_2O$. The decomposition begins at about 170°, and becomes explosive unless carefully regulated. Organic impurities must be absent, and also ammonium chloride, otherwise CO_2 and Cl_2 respectively are formed (Soubeiran, J. Pharm. Chim. 1826, 13, 332).

Lidoff (J. Russ. Phys. Chem. Soc. 1903, 35, 59) recommends mixing the nitrate with sand, and washing the gas with ferrous sulphate solution, afterwards drying it with an emulsion of ferrous sulphate in concentrated sulphuric acid.

(4) By Thilo's method (Chem. Zeit. 1894, 18, 532), patented in 1894. An equimolecular mixture of ammonium sulphate and sodium nitrate is heated at 240°. A regular and quiet evolution of nitrous oxide results.

(5) By the reaction between sodium nitrite and hydroxylamine hydrochloride solutions, NO being removed ferrous sulphate solution—

$$NH_2OH+HNO_2=N_2O+2H_2O$$

(Meyer, Pollak's modification, Annalen, 1875, 175, 141).

(6) Pictet (Fr. Pat. 415594, April 19, 1910) and Södermann (*ibid.* 411785, Jan. 21, 1910) obtain it from the nitrogen-oxygen flame, produced electrically or by other means, under suitable conditions. At a definite part of the flame, ascertained spectroscopically or in other ways, the chief product is N_2O, and by rapid and efficient cooling at this point the gas may be obtained in 25 p.c. yield.

Properties.—Nitrous oxide is a colourless gas with pleasant odour and sweetish taste. Density (air=1) 1·5301 (Leduc, Compt. rend. 1905, 140, 642), 1·5297 (Rayleigh, Proc. Roy. Soc. 1905, 74, 181). Weight of one litre 1·9774 grams (Guye and Pintza, Compt. rend. 1905, 141, 51), 1·9777 (Rayleigh), 1·9780 (Leduc).

Coeff. of expansion 0·0037067 (Jolly). For its volume-pressure relations, *v.* Rayleigh (Proc. Roy. Soc. 1905, 74, 406).

Viscosity coeff. 0·0001353 at 0°; 0·0001815 at 100° (Wüllner, Wied. Ann. 1876, 4, 321).

Refractive index for sodium light 1·00516. Magnetic rotation 16·02 (Becquerel, Compt. rend. 1880, 90, 1407; *v.* also Dufour, *ibid.* 1908, 147, 1471). Sp.ht. at const. vol. 0·15130 at 0°; 0·17384 at 100° (Wüllner, *l.c.*). Sp.ht. at const. press. 0·1983 at 0°; 0·2212 at 100° (Wiedermann, Pogg. Ann. 1875, 157, 1).

Cp./Cv.=1·31 at 0°; 1·2724 at 100°.

Heat conductivity 0·0000350 at 0°; 0·0000506 at 100°.

It is easily liquefied, and was first obtained in liquid form by Faraday (Phil. Trans. 1823, 189). It is colourless, mobile, and has a low refractive index (1·193 at 16°, according to Bleikrode, 1·3305 at 90°, according to Liveing and Dewar); b.p. −89·8° (Ramsay and Shields, Chem. News, 1893, 67, 190; −89·4° (Grunmach, Sitzungsber.

K. Akad. Wiss. Berlin. 1904, 1198); m.p. −102·3° (Ramsay and Shields, *l.c.*). Critical temp. and press. 36·4°, 73·07 atm. (Cailletet and Matthias); 35·4° and 75·0 atm. (Dewar, Phil. Mag. 1884, [v.] 18, 210).

Density at b.p. 1·2257 (Grunmach). Surface tension at 89·3°, 26·323 dynes/cm. Calculated molecular weights using the critical values given above are 43·26 and 43·78 respectively, hence N_2O has the same molecular weight in both states (Grunmach). The vapour pressures are tabulated by Regnault (J. 1863, 70) and Villard (Ann. Chim. Phys. 1897, [vii.] 10, 387).

For densities of liquid N_2O and its saturated vapour, *v.* Cailletet and Mathias (Compt. rend. 1886, 102, 1202 ; Villard (*ibid.* 1894, 118, 1096). Mol. heat of volatilisation 2900 cal. (−20°), 2600 (0°), 400 (35°) (Cailletet and Mathias, Ann. Chim. Phys. 1890, [vi.] 21, 69). Heat of formation −21,700 cal.

Solubility in water at	5°	10°	15°	20°	25°
	1·048	0·8778	0·7377	0·6294	0·5443

(Geffcken, Zeitsch. physikal. Chem. 1904, 49, 257).

Findlay and Creighton (Chem. Soc. Trans. 1910, 549) show that it obeys Henry's Law.

$$\text{At } 25^\circ \quad \frac{\text{Conc. liquid phase}}{\text{Conc. gaseous phase}}=0·592.$$

For its solubility in alcohol, *v.* Carius (Annalen, 1855, 94, 139).

Nitrous oxide is decomposed into its elements on strongly heating. This is shown by its power to support the combustion of phosphorus, carbon, sulphur, etc., when burning sufficiently vigorously to start the decomposition of the gas. At 500°, only about 1·5 p.c. is decomposed, but at 900° decomposition is practically complete. Hunter (Zeitsch. physikal. Chem. 1905, 53, 441) finds its decomposition to be mainly bi-molecular, $2N_2O=2N_2+O_2$, and gives the velocity coefficients at various temperatures. It also decomposes slightly under pressure. At 600 atm. and 420°, slight decomposition occurs with increase in volume (Briner and Wroczynski, Compt. rend. 1910, 150, 1324).

Mixed with oxygen and submitted to the action of ultra violet light it gives nitrogen and higher oxidation products (Berthelot and Gaudechon, Compt. rend. 1910, 150, 1517).

It is readily reduced by hydrogen on passing the mixed gases through a red-hot tube, or over platinum or palladium sponge. It is analysed by explosion with hydrogen (Hempel, Zeitsch. Elektrochem. 1906, 12, 600). The velocity of explosion is 2305 metres per sec. (Dixon, Chem. News, 1891, 64, 70). It oxidises a large number of metals and lower oxides, and reduced nickel brings about its reduction with hydrogen to water and nitrogen (Sabatier and Senderens, Compt. rend. 1902, 135, 278) Potassium and sodium, when slightly heated in the gas, form the peroxides, but when strongly heated produce the nitrates.

Nitrous oxide is a valuable anæsthetic for short operations. Prolonged inhalation causes death. Mixed with about one-fourth its volume of oxygen it produces an exhilarating and intoxicating effect. For a discussion of its preparation and requisite purity for use as an anæsthetic, *v.* Baskerville and Stevenson (J. Ind. Eng. Chem. 1911, 3, 579).

Hyponitrites may be regarded as salts of this oxide, though the acid is not formed by its solution in water. At low temperatures a solid hydrate $N_2O·6H_2O$ is formed (Villard, Ann. Chim. Phys. 1897, [vii.] 11, 289).

Nitric oxide NO differs from the other oxides in being neither an acid anhydride as N_2O,N_2O_3, and N_2O_5, nor a mixed anhydride, as N_2O_4. It was the first oxide of nitrogen investigated (Priestley, 1772).

It is usually said to be the first oxidation product of elementary nitrogen (*v.* however *Nitrous Oxide*) and is formed by direct union by a number of methods. It is produced together with ozone in the silent electric discharge, and has an inhibiting effect upon the formation of ozone (Manchot, Ber. 1908, 41, 471).

It is produced (also along with ozone) when air is slowly led over a glowing Nernst filament (Fischer and Marx, Ber. 1906, 39, 3631), and in various flames, *e.g.* C_2H_4, CO, and H_2, as well as in the electric arc, electric spark, and at white-hot solid surfaces (Haber and Coates, Zeitsch. physikal. Chem. 1909, 69, 337).

In the combustion of hydrogen in air at ordinary pressures, practically no nitric oxide is formed, but at 20 atm., 0·3 molecules of NO are produced for every 100 of water. With equal mixtures of N_2 and O_2, the yield though small at low pressures is as much as 3 mols. per 100 of water at 15 atm. (Wolokitin, Zeitsch. Elektrochem. 1910, 16, 814).

The conditions under which the union is most efficient have been studied by Haber and his co-workers (*v.* Haber and others, Zeitsch. Elektrochem, 1910, 16, 810, and earlier papers), Nernst and others. Briefly, a high temperature favours a rapid rate of formation, and a high yield of NO, but also favours dissociation. Hence rapid cooling is necessary at the moment of formation, which is realised by sweeping the gases out of the region of the arc, or by forming and interrupting the arc successively several thousand times a second, or by playing the arc in different regions of the space. The gases passing out of the chamber contain 1–2 p.c. of NO by volume. For practical details, *v.* NITROGEN, ATMOSPHERIC, UTILISATION OF.

Nitric oxide is also produced by the action of a variety of reducing agents upon nitric and nitrous acids and the higher oxides.

The most convenient methods are—

(1) Nitric acid of sp.gr. 1·2 on metallic copper.

$$3Cu+8HNO_3=3Cu(NO_3)_2+4H_2O+2NO$$
$$(3Cu+N_2O_5=3CuO+2NO)$$

(*v.* Kämmerer, Ber. 1885, 18, 3064).

(2) An alkaline nitrate on a solution of ferrous chloride in hydrochloric acid.

$$6FeCl_2+2NaNO_3+8HCl$$
$$=6FeCl_3+2NaCl+4H_2O+2NO$$

(Pelouze; Gay Lussac, Ann. Chim. Phys. 1847, [iii.] 23, 203).

(3) Deventer's method (Ber. 1893, 26, 589) of dropping a mixture of potassium nitrite and ferrocyanide into dilute acetic acid.

$$K_4Fe(CN)_6+HNO_2+CH_3COOH$$
$$=K_3Fe(CN)_6+H_2O+CH_3COOK+NO$$

(4) Aqueous ferric chloride on sodium nitrite.

$$FeCl_3+3NaNO_2=Fe(NO_2)_3+3NaCl$$

$$2Fe(NO_2)_3+3H_2O=2Fe(OH)_3+3NO_2+3NO.$$

If the $NaNO_2$ is placed under carbon disulphide and hydrated $FeCl_3$ in carbon disulphide suspension added, the NO_2 remains dissolved in the carbon disulphide (Matuschek, Chem. Zeit. 1905, 29, 31).

(5) SO_2 into warm HNO_3 of sp.gr. 1·15.

$$3SO_2+2HNO_3+2H_2O=2H_2SO_4+2NO$$

(Weber, Pogg. Ann. 1867, 130, 277).

Moser (Zeitsch. anal. Chem. 1911, 50, 401) considers the best methods are—

(*a*) Reduction of HNO_2 in H_2SO_4 with Hg.

(*b*) Reduction of HNO_2 with HI.

The gas is purified by absorption in concentrated ferrous sulphate solution, from which it is expelled again on gently heating. It is also absorbed by potassium permanganate or dichromate.

Properties.—Nitric oxide is a colourless gas, of density 1·0387 (Leduc, Compt. rend. 1893, 116, 322). Wt. of one litre at N.T.P. 1·3402 (Gray, Chem. Soc. Proc. 1903, 66; Guye and Davila, Compt. rend. 1905, 141, 826). Cp. 0·23175 (Regnault), Cp./Cv. 1·40. Coeff. of expansion (mean) between −140° and 0°, 0·0037074 (Adventowski, Bull. Acad. Sci. Cracow, 1909, 742). Viscosity coeff. 0·000168 (Meyer and Springmühl, Pogg. Ann. 1873, 148, 526).

Refractive index for white light 1·000303 (Dulong); for sodium light 1·000297 (Mascart, Zeitsch. physikal. Chem. 1891, 7, 25), 1·0002939 (Cuthbertson and Metcalfe, Proc. Roy. Soc. 1908, A, 80, 406).

Nitric oxide shows very little divergence from Boyle's law (Jacquerod and Schener, Compt. rend. 1905, 140, 1384). It is with difficulty condensed to a colourless liquid.

B.p.	M.p.	Crit. temp.	Crit. press.	Observer
−153·6°	−167·0°	−93·5°	71·2 atm.	Olzewski[1]
−150·2°	−160·6°	−92·9°	64·4 atm.	Adventowski

For b.pts. at pressures other than atmospheric, *v.* Olzewski (*l.c.*). V.p. at m.p. 168 mm.

The vapour pressure curve of the liquid would appear to indicate that polymerisation of the molecules takes place at very low temperatures. This is borne out by the high sp.gr. of the liquid at its b.p. (1·269) (Adventowski, *l.c.*).

Heat of formation of NO −21,575 cal. (Thomsen), −21,600 cal. (Berthelot, Compt. rend. 1874, 78, 162).

SOLUBILITY IN WATER.

°C.	Absorption coeff.	°C.	Absorption coeff.
0	0·07381	40	0·03507
5	0·06461	50	0·03152
10	0·05709	60	0·02954
15	0·05147	70	0·02810
20	0·04706	80	0·02700
25	0·04323	90	0·02648
30	0·04004	100	0·02628

(Winkler, Ber. 1901, 34, 1408; *v.* also Zeitsch. physikal. Chem. 1892, 9, 171).

It is more soluble (0·316 at 0°) in alcohol (Carius, Annalen, 1885, 94, 138). For its solubility in H_2SO_4, *v.* Lunge (Ber. 1885, 18, 1391); Tower (Zeitsch. anorg. Chem. 1906, 50, 382).

Nitric oxide is the most stable oxide of nitrogen. At 700° only 0·5 p.c. is dissociated into nitrogen and oxygen, and at 1000° only 3–4 p.c. The dynamics of the equilibrium have been studied by Muthmann and Hofer (Ber. 1903, 36, 438); Nernst (Zeitsch. anorg. Chem. 1906, 49, 213); Jellinek (*ibid.* 1906, 49, 229), and Brode (Zeitsch. Elektrochem, 1905, 11, 752).

At ordinary temperatures it combines with oxygen with production of ruddy fumes (*v.* Emich, Monatsh. 13, 86) characteristic of the peroxide, but at the temperature of liquid air the product is always nitrogen tetroxide, whatever the proportions taken, even if both the oxygen and nitrogen are in the gaseous state provided the temperature be below −110°. N_2O_3 is transformed by oxygen to N_2O_4 only above −100°, and N_2O_4 is reduced by NO to N_2O_3 at temperatures below −150° (Francesconi and Sciacca, Gazz. chim. ital. 1904, 34, i. 447). Nitric oxide may be reduced in a variety of ways, giving nitrogen, ammonia, and in a few instances nitrous oxide. Hydrogen sulphide and alkaline sulphides, sulphurous acid, and phosphine give N_2O largely. Metals reduced in hydrogen are readily oxidised at a low temperature with formation of nitrogen. Passed with hydrogen over nickel, ammonia and some nitrogen are produced (Sabatier and Senderens, Compt. rend. 1902, 135, 278). The reaction commences at 300° and then proceeds at 120°, the production of ammonia being almost quantitative (Neogi and Adhicány, Zeitsch. anorg. Chem. 1910, 69, 209).

With hydriodic acid, ammonia is produced. Stannous chloride gives hydroxylamine and ammonia (Chesnau, Compt. rend. 1899, 129, 100) and in alkaline solution hyponitrite as well. Chromous salts give ammonia in neutral solution, hydroxylamine in acid solution (Kohlschütter, Ber. 1904, 37, 3053). Alkaline pyrogallol reduces it to nitrous oxide (Oppenheimer, *ibid.* 1903, 36, 1744).

It also reacts with oxidising agents. H_2O_2 gives nitrous and nitric acids; PbO_2, Pb_3O_4, MnO_2, Ag_2O in water give nitrite; $KMnO_4$ gives nitrate; iodine nitric acid (Schönbein), ClO_2 gives N_2O_4, and hypochlorous acid nitric acid (Balard).

In the dry state it acts on many oxidising agents, forming nitrite and nitrate (Auden and Fowler, Chem. News, 1895, 72, 163). It gives N_2O_3 with N_2O_4 at low temperatures (*v.* under *Nitric trioxide*).

It is slowly decomposed by potash, forming KNO_2 and N_2 (*v.* also Emich, Monatsh. 1892, 13, 90), and according to Moser (Zeitsch. anal. Chem. 1911, 50, 401) it cannot be preserved unchanged over water, partly owing to dissolved oxygen, and partly to hydrions of the water

$$4NO+2H_2O=2HNO_2+H_2N_2O_2$$

(*cf.* Zimmermann, Monatsh. 1905, 26, 1277).

The latter gives N_2O, and also ammonium nitrite, $3H_2N_2O_2=2N_2O_3+2NH_3$ (*cf.* Hantzsch and Kauffmann, Annalen, 1896, 292, 317), which further breaks down giving nitrogen in increasing quantity with the length of time the

---

[1] Compt. rend. 1885, 100, 940.

gas remains over water. The moist gas can, however, be preserved unchanged over mercury.

Fluorine gives NO_2F (*q.v.*); iodine does not react; chlorine and bromine give the corresponding halide (*v.* under *Nitrous acid*).

If allowed to remain at high pressures in a sealed tube it becomes bluish green, and drops of blue liquid appear, first noticed at about 28 atms. If hydrochloric acid be also present, NOCl is formed, the change being probably represented by

$$6NO = 2N_2O_3 + N_2$$
$$N_2O_3 + 2HCl = 2NOCl + H_2O$$

(Briner and Wroczynski, Compt. rend. 1909, 149, 1372).

It is absorbed by a number of acids and salts, forming compounds of whose constitution little is known, which break down again on dilution with water, or gently heating.

H_2SO_4 in presence of oxygen yields

$$NO{\cdot}OSO_3H$$

(Lunge, Ber. 1885, 18, 1384).

It reacts with nitric acid (*v.* Saposhnikoff, J. Russ. Phys. Chem. Soc. 1901, 33, 506, and under HNO_3) and is absorbed by phosphoric acid (Reinsch, J. pr. Chem. 1843, 28, 385), arsenic, and some organic acids, and by many halides, such as those of B, Si, Bi, Fe, Cu (for example $BiCl_3{\cdot}NO$; $2FeCl_3{\cdot}NO$) (Besson, Compt. rend. 1889, 108, 1012; Thomas, Ann. Chim. Phys. 1898, [vii.] 13, 145). $FeSO_4$ gives the compound $FeSO_4{\cdot}NO$ (Manchot and Zechentmayer, Annalen, 1906, 350, 368; *v.* Hûfner, Zeitsch. physikal. Chem. 1907, 59, 416; Asher, *ibid.* 1908, 62, 622) which has been isolated in red leaflets (Manchot and Huttner, Annalen, 1910, 372, 153). Conductivity of NO in $FeSO_4$ solutions (Zimmermann, Monatsh. 1905, 26, 1277). It combines with Ni, Co and Mn sulphates (*v.* Hûfner, *l.c.*; Asher, *l.c.*).

$Fe_2(SO_4)_3{\cdot}NO$ is formed from ferric sulphate in 90 p.c. H_2SO_4 solution (Manchot, Zeitsch. physikal. Chem. 1910, 372, 179).

The violet colouration produced by NO in solutions of $CuSO_4$ in concentrated H_2SO_4 is due to the formation of an easily dissociated compound $CuSO_4{\cdot}NO$ (Manchot, Annalen, 1900, 375, 308).

A number of other iron-nitric oxide-sulphur derivatives of uncertain constitution are described by Hofmann and Wrede (Zeitsch. anorg. Chem. 1896, 11, 288, and previous references), Marie and Marquis (Compt. rend. 1896, 122, 137), Bellucci and Venditori (Atti. R. Accad. Lincei. 1905, [v.] 14, i. 98), Manchot (Zeitsch. angew. Chem. 1911, 24, 13) and Raschig (*ibid.* 160).

Complex cyanogen compounds are described by Miolatti (Zeitsch. anorg. Chem. 1900, 25, 318); complex nitrates and chlorides of the type $Co(NH_3)_5(NO)X_2$ by Sand and Singer (Annalen, 1903, 329, 190) and other complex amines containing NO by Werner.

Nitrogen trioxide, *Nitrous anhydride*, N_2O_3. When nitric oxide and nitrogen peroxide are mixed, or when half the corresponding atomic proportion of oxygen is added to nitric oxide a gas of the composition N_2O_3 is obtained which condenses to a liquid and solid of the same composition. In the two latter states it behaves as a homogeneous body N_2O_3, and chemically as such at higher temperatures, but physically as an equimolecular mixture of NO and N_2O_4, the third component N_2O_3 being present only in minimum quantity.

Preparation.—(1) By reduction of nitric acid of suitable concentration by a reducing agent, usually starch or As_4O_6. According to Lunge (Ber. 1878, 11, 1229), acid of sp.gr. 1·20 gives NO, acid of sp.gr. 1·35 N_2O_3, and sp.gr. 1·5 practically all NO_2. As, however, the product varies with the concentration, obviously a pure compound cannot be obtained, as the concentration is changing throughout the experiment, and Ramsay and Cundall (Chem. Soc. Trans. 1885, 187) recommend acid of initial concentration 1·5 as the most suitable. The arsenious oxide and nitric acid are carefully heated on the water bath in a large retort or distilling flask. The action is apt to become very violent. The gas is dried over solid calcium chloride and liquefied by ice and salt. If N_2O_4 is in excess a bluish-green liquid results, which, on volatilising in a current of NO and recondensing, yields an indigo blue liquid at −10°. Its ready dissociation into NO and N_2O_4, the former of which is only liquid at −165°, the latter easily condensable, renders the removal of the last traces of N_2O_4 exceedingly difficult.

(2) By oxidation of nitric oxide with oxygen. At temperatures below −100° the product from any proportions of these gases is always N_2O_3 (*v.* under *Nitric oxide*).

(3) By oxidation of liquid nitrogen bypassing electric discharges through liquid air. So formed it remains suspended in the liquid air as a flocculent green substance, strongly resembling precipitated chromic hydroxide, but on evaporation of the excess of air is left as a slightly blue amorphous powder, which melts at −111°, and then assumes a deep blue colour which persists after resolidification in liquid air (Helbig, Atti. R. Accad. Lincei. 1903, [v.] 12, i. 166; Fischer and Braemar, Ber. 1906, 39, 940). According to Scarpa (Gazz. chim. ital. 1907, 37, ii. 185), NO is formed in the region of the arc, and in the boiling air combines further with oxygen, giving N_2O_3, which under favourable conditions may be complete, since N_2O_3 is solid at temperatures lower than the critical dissociation temperature. The best form of apparatus is described.

(4) By reduction of N_2O_4 by NO (Péligot, Ann. Chim. Phys. 1841, [iii.] 2, 58; Porschnew, Zeitsch. anorg. Chem. 1894, 7, 214). On saturating liquid N_2O_4 with NO and subsequently cooling dark blue crystals of N_2O_3 separate, m.p. −103°, no other compound being formed. The eutectic mixture (63·6 N_2O_4, 36·4 NO), melts at −112° (Wittorff, J. Russ. Phys. Chem. Soc. 1904, 36, 857).

N_2O_3 is also produced by action of water on lead chamber crystals, and on nitrogen peroxide.

Properties.—N_2O_3, at ordinary temperatures, gives a brown gas which has a density corresponding to a mixture of NO and NO_2, allowing for polymerisation of the latter (Ramsay and Cundall, Chem. Soc. Trans. 1890, 37, 590; Porschnew, *l.c.*), borne out by the fact that the spectra of NO_2 and gaseous N_2O_3 are identical (Moser, Wied. Ann. 1877, 2, 139), while the blue liquid has no definite b.p. At −21°, however, its composition is very closely N_2O_3 (Francesconi and Sciacca, Gazz. chim. ital. 1904, 34, 1, 447).

M.p. −103° (Wittorff), −111° (Helbig); sp.gr. at 0° 1·4490 (Geuther, Annalen, 1888, 245, 96).

The discovery that dissociation of ammonium chloride and other substances does not take place in complete absence of moisture led to a similar investigation of N_2O_3 (Baker and Baker, Chem. Soc. Trans. 1907, 1862). Bulbs containing known weights of the carefully prepared and dried liquid were broken in a Lunge nitrometer over dry mercury (which is practically unaffected), and the densities so found varied from 43·2–48·6, that of undissociated N_2O_3 being 38. On admitting concentrated H_2SO_4 absorption took place so rapidly that the impact of the mercury endangered the tube, whereas a mixture of NO and N_2O_4 is only comparatively slowly absorbed. Further determinations with a special V. Meyer apparatus (*ibid.* 1900, 647) varied from 38·1 to 62·2, the samples being taken from several preparations which had been condensed at different temperatures and dried for varying lengths of time, and containing varying proportions of the polymeric N_4O_6, which, however, was not obtained in the pure condition.

In the hope that in solution at low temperatures the higher polymeride would be present in greater amount, molecular weight determinations were made in benzene solution, but the values obtained were 83, 83·2, and 95, showing this not to be the case. N_2O_3 is without action on benzene.

As usually prepared it mixes with water, giving a blue-green liquid which above 0°, by further concentration, evolves NO, and on dilution gives nitrous acid; but according to Baker it is practically insoluble in water and sinks, forming NO and N_2O_4, the latter dissolving in the water.

With concentrated H_2SO_4, *nitrosylsulphuric acid* (*q.v.*) is formed.

Oxygen is without action below −110°. Above −100° it is converted into N_2O_4 (*v.* under NO). As an oxidising agent on metals it behaves as a mixture of NO and NO_2, NO being formed at low temperatures, and N_2 at higher temperatures. Like N_2O_4 it is absorbed by alkalis, but more rapidly, and it is supposed that it is the N_2O_3 in the equilibrium

$$NO+NO_2 \rightleftarrows N_2O_3$$

which is absorbed (*cf.* le Blanc, Zeitsch. Elektrochem. 1906, 12, 544). This is borne out by the fact that liquid N_2O_3 at −22° is instantly absorbed by NaOH, whereas liquid N_2O_4 reacts only slowly (Foerster and Blich, Zeitsch. angew. Chem. 1910, 23, 2017).

Its solution in carbon tetrachloride reacts with one of SO_3 precipitating *sulphonitrous anhydride* $(SO_3)_3(N_2O_3)_2$ in needles, m.p. 190°–200°; b.p. 302°–305°/728 mm. Hence Provostaye's *nitrosyl sulphate* (Ann. Chim. Phys. 1840, [ii.] 73, 362), m.p. 217°–230°; b.p. 360° is therefore of greater complexity than $(SO_3)_2N_2O_3$, probably $(SO_3)_6(N_2O_3)_3$. The *tetrasulphate* is also known (Pictet and Karl, Bull. Soc. chim. 1908, [iv.] 3, 1114).

Nitrosyl perchlorate $NO{\cdot}OClO_3{\cdot}H_2O$ separates in leaflets when N_2O_3 is passed into concentrated perchloric acid (Hofmann and Ledtwitz, Ber. 1909, 42, 2031). With unsaturated carbon compounds it forms additive compounds.

Nitrogen peroxide, or **tetroxide** ("hyponitric acid"). This oxide is only capable of existing as NO_2 in a pure condition within narrow limits of temperature. At low temperatures the polymerised product N_2O_4 is the stable form, which dissociates on rise of temperature into NO_2, but this in turn is easily dissociated on further rise of temperature into NO and oxygen.

Preparation.—It is produced by oxidation of nitric oxide with oxygen, as first shown by Gay Lussac, and thus results on oxidation of nitrogen with excess of oxygen under ordinary conditions. NO and O_2 in the proportion 2 : 1, dried and well mixed by passing through a tube filled with glass or porcelain fragments, condense at −20° to a colourless crystalline mass of N_2O_4 (Dulong, Ann. Chim. Phys. 1816, [ii.] 2, 317; Péligot, *ibid.* 1841, [iii.] 2, 58). Similarly the gas resulting from the action of concentrated nitric acid on arsenious oxide is converted by excess of oxygen into N_2O_4.

Mandl and Russ (Zeitsch. angew. Chem. 1908, 21, 486) state that the rate and extent of union of NO and O_2 is affected by the character of the oxygen; for example, electrolytic oxygen is more active after passing over heated palladium, and ozonisation retards the action. According to Holwech (*ibid.* 2131), however, this is not the case, union being practically complete in each instance, and the velocity of reaction the same with oxygen from all sources.

A good yield of NO_2 is said to be obtained by passing air and steam through a thin-walled porous porcelain tube at 1600°, the diffusion of the hydrogen formed being increased by raising the inside pressure and lowering that outside the tube (Westdeutsche Thomasphosphatwerke, D. R. P. 182297).

It is also obtained by passing nitric acid vapour through a hot tube, and by heating metallic nitrates,

$$Pb(NO_3)_2=PbO+O+2NO_2.$$

Those of the alkalis evolve NO_2 when electrolysed in the fused condition (Bogorodski, J. Russ. Phys. Chem. Soc. 1905, 37, 703). It is formed by union of N_2O_3 and N_2O_5. Also by treating with fuming sulphuric acid a homogeneous mixture of alkali nitrate and nitrite, made by fusing the salts together or pouring the fused mixture into carbon tetrachloride.

$$NaNO_2+NaNO_3+H_2S_2O_7=2NaHSO_4+2NO_2.$$

Sufficient $NaHSO_4$ from a previous preparation is added to fix any free SO_3 present—

$$2NaHSO_4+SO_3=Na_2S_2O_7+H_2SO_4$$

(Winans, D. R. P. 193696).

It is evolved on warming chamber crystals with KNO_3, thus:

$$NO_2{\cdot}SO_3H+KNO_3=2NO_2+KHSO_4,$$

and by the action of nitric acid on nitrous acid or a nitrite—

$$HNO_3+R{\cdot}NO_2=R{\cdot}OH+2N_2O_2$$

(Girard and Pabst, Bull. Soc. chim. 1878, [ii.] 30, 531).

Properties.—At ordinary temperatures an orange-coloured corrosive gas of peculiar and unpleasant odour. At higher temperatures it becomes much darker in colour, turning lighter again on further rise, and finally colourless when dissociation into NO and oxygen is complete. It condenses to an orange-yellow liquid, b.p. 25°–26° (Hasenbach; Bruni and Berti, Atti. R. Accad. Lincei, 1900, [v.] 9, i. 321). At 10° it is pale yellow, and when solid colourless. M.p. −10·1° (Ramsay, Zeitsch. physikal. Chem. 1890, 5, 221), −10·95° (Bruni and Berti, *l.c.*). Critical temperature 171·2°; critical pressure 0·66 atmospheres.

In the solid state it probably exists entirely as N_2O_4, and almost entirely so in the liquid state, though not ascertained by experiment. In the gaseous state and in solution, however, its behaviour is accurately known from its vapour density measurements, which are in accord with the conclusions drawn from other physical properties, such as absorption of light, conductivity for heat, and specific heat.

The liquid is not polymerised further than N_2O_4 nor is the gas, as shown by its molecular weight in acetic acid (Ramsay and Shields, *ibid.* 1893, 12, 433; Ramsay, Chem. Soc. Trans. 1888, 53, 621).

Its further dissociation into nitric oxide and oxygen is accurately known from its density.

	−5°	−2°	0°	5°	10°	15°
Sp.gr.	1·5035	1·5020	1·4935	1·4880	1·4770	1·4740

(Geuther, Annalen, 1888, 245, 96). At +1°, 1·4903; at 21·6°, 1·4396 (Thorpe, Chem. Soc. Trans. 1880, 37, 141).

Thorpe finds the expansion of liquid N_2O_4 to be very regular, 1 vol. at 0° becoming at

5°	10°	15°	20°
1·00789	1·01573	1·02370	1·03196

The vapour densities found by various observers have been collected by Schreber (Zeitsch. physikal. Chem. 1897, 24, 651), and the dissociation constants calculated. The following values of $K=[N_2O_4]^{\frac{1}{2}}/[NO_2]$ are given—

$t°$	K
0·0	8·060
18·3	3·710
49·9	1·116
73·6	0·544
99·8	0·273

At 64° one-half of the N_2O_4 mols. are dissociated, and at 150° they are wholly dissociated (*v.* also Bodenstein and Katayama, Zeitsch. Elektrochem. 1909, 15, 244). Above 150° decomposition into NO and oxygen takes place, and at 620° is practically complete. At 184°, 5 p.c. is dissociated, and at 494° 56·5 p.c. (Richardson, Chem. Soc. Trans. 1887, 51, 397). Sp.ht. of liquid 0·477° (Ramsay, Zeitsch. physikal. Chem. 1890, 5, 221).

Apparently anomalous values, obtained by Berthelot and Ogier (Ann. Chim. Phys. 1883, 30, 382) for the sp.ht. of the gas, are explainable by its dissociation (Swart, Zeitsch. physikal. Chem. 1891, 7, 120).

Heat of formation $2N+4O=N_2O_4$ −3900 cal. (Thomsen) (9 p.c. NO_2, 91 p.c. N_2O_4). Heat of dissociation about −13,000 cal., and calculated heat of formation of undissociated N_2O_4 −2650, and of NO_2 −8125 cal. Heat of formation of liquid −2200 and −2500 cal. (for NO_2 = 46 gr.) (Berthelot, Ann. Chim. Phys. 1875, [v.] 6, 145); heat of vaporisation at 180° −4300 cal. Latent heat of fusion −32·2 to −37·2 cal.; calculated from freezing-point lowering, −33·7 (Ramsay, *l.c.*).

The heat conductivity values also reveal its dissociation (Feliciani, Chem. Zentr. 1905, i. 331). At 150°, the conductivity of NO_2 is 0·0033.

Refraction equivalent of liquid 11·8, dispersion equivalent 0·82 (Gladstone, Chem. News, 1887, 55, 300). Refractive index of vapour at 36°, 1·000503 (Dulong; *v.* Zeitsch. physikal. Chem. 1901, 36, 332). For the spectra of nitrogen peroxide, *v.* Bell (Amer. Chem. J. 1885, 7, 32). The vapour does not conduct electricity, and the liquid only slightly.

Dielectric constant (*v.* Bädeker, Zeitsch. physikal. Chem. 1901, 36, 305).

Chemical properties.—It is reduced to ammonia if passed with hydrogen over platinum black (Kuhlmann, Annalen, 1839, 29, 272), or over reduced nickel or copper (Sabatier and Senderens, Compt. rend. 1902, 135, 278). Carbon, sulphur and phosphorus burn in the gas, carbon monoxide burns to CO_2, and hydrogen sulphide to sulphur, with formation of NO.

Potassium burns with a red flame, and sodium, though not igniting, decomposes the gas at the ordinary temperature, while many metals and lower oxides are oxidised on heating to 500°, and some metals form additive compounds ("nitro metals") with the liquid N_2O_4 (Cu_2NO_2,Ni_4NO_2) similar to the carbonyl compounds (Sabatier and Senderens, Ann. Chim. Phys. 1896, [vii.] 7, 348). Other metals, such as K, Na, Hg, Pb, form the nitrate with production of NO. It also forms additive compounds with many metallic salts ($FeCl_3{\cdot}NO_2$, $SnCl_4{\cdot}NO_2$, etc.) (Thomas, *ibid.* 1898, [vii.] 13, 145) and with unsaturated organic compounds (nitrosates).

With water N_2O_4 exhibits its mixed anhydride character. With small quantities of water, however, the reaction

$$2N_2O_4+H_2O=N_2O_3+2HNO_3$$

takes place at low temperatures, two layers being formed, the lower, deep blue N_2O_3. Further dilution converts the nitrous anhydride to nitrous acid, which on rise of temperature is decomposed with evolution of NO (Schönhein, Pogg. Ann. 1848, 73, 326).

With aqueous alkalis, a mixture of nitrite and nitrate is formed (*v.* also under N_2O_3). Metallic oxides under pressure form the nitrate only, evolving NO. BaO, however, according to Dulong, forms a mixture of nitrite and nitrate at 200° (Annalen, 1862, 122, 18).

Liquid ammonia reacts explosively with solid N_2O_4 at −80°, but a current of gaseous NH_3 led over the solid at −20° reacts less vigorously, and the products are N_2, NO, H_2O, NH_4NO_3 and a trace of NH_4NO_2 (Besson and Rosset, Compt. rend. 1906, 142, 633). Dry oxygen does not oxidise it, but ozone converts it to the pentoxide. In presence of water, oxygen and oxidising agents convert it into nitric acid. It is absorbed by dilute and concentrated HNO_3 (*v.* Weber, Pogg. Ann. 1867, 130, 277; Lunge, Ber. 1879, 12, 1058). With SO_2 and SO_3 it gives various substances of not very clearly defined character (Weber, *l.c.*; Hasenbach, J. pr. Chem. 1871, [ii.] 4, 4; Friedburg, Chem.

News, 1883, 47, 52). With sulphuric acid it forms *nitrosyl-sulphuric* and *nitric acids.*

$$H_2SO_4+N_2O_4=NO_2{\cdot}SO_3H+HNO_3$$

Lunge (Ber. 12, 357).

It has been used as a solvent for cryoscopic measurements. Molecular raising of b.p. 13·7°, molecular lowering of freezing point 41° (Ramsay, Zeitsch. physikal. Chem. 1890, 5, 221; Frankland and Farmer, Chem. Soc. Trans. 1901, 79, 1356; Bruni and Berti, Gazz. chim. ital. 1900, 30, ii. 151). The liquid has been used in explosives (Settlick, Chem. Zentr. 1888, 461).

Constitution.—The formula of the dioxide may be written—

$$-N{<}^{O}_{O}\left(-N{<}^{O}_{O}\right)\text{ and }-O-N=O$$

and that of the tetroxide—

$O_2{\equiv}N{-}N{\equiv}O_2$, $O_2{\equiv}N{-}O{-}N{=}O$, $O{=}N{-}O{-}N{=}O$. The reaction with water favours the second of these. Piloty and Schwerin (Ber. 1901, 34, 1884 and 2354) suggest $O{=}N{=}O$ as the formula for the dioxide; but Divers (Chem. Soc. Trans. 1904, 110) prefers the formula $O{-}N{=}O$ for the dioxide, and for N_2O_4 advances reasons in favour of the formula $(NO)_2O_2$, "di-nitric peroxide."

iso-Nitrogen tetroxide.—According to Raschig (Chem. Zeit. 1907, 31, 359), the red vapours formed from nitric oxide and air are of different composition from that usually accepted, the first product being *iso*-nitrogen tetroxide (*a*) distinguished from the ordinary tetroxide (*b*) by its reaction with sodium hydroxide—

(*a*) $N_2O_4+2NaOH=2NaNO_2+H_2O+O$

(*b*) $N_2O_4+2NaOH=NaNO_2+NaNO_3+H_2O$.

With larger excess of oxygen the *iso-pentoxide* and a *hexoxide* and *heptoxide* are said to be formed—

$N_2O_5+2NaOH=NaNO_2+NaNO_3+H_2O+O$.
$N_2O_6+2NaOH=2NaNO_2+H_2O+3O$.
$N_2O_7+2NaOH=NaNO_2+NaNO_3+H_2O+3O$.

Nitrogen pentoxide, *nitric anhydride* N_2O_5, may be prepared as follows:—

(1) By oxidation of nitrogen peroxide with ozone (Helbig, Atti. R. Accad. Lincei, 1903, [v.] 12, i. 211; Zeitsch. Elektrochem. 1906, 12, 550).

(2) As first prepared by Deville (Ann. Chim. Phys. 1849, [iii.] 28, 241) by action of dry chlorine on silver nitrate warmed to 50°–60°.

$$4AgNO_3+2Cl_2=4AgCl+O_2+2N_2O_5,$$

the gaseous product being condensed in a freezing mixture.

(3) Most conveniently, as first obtained by Weber, by dehydration of pure nitric acid with phosphorus pentoxide, with constant cooling (Meyer, Ber. 1889, 22, 23).

The syrupy liquid produced is poured into a dry retort and distilled into a receiver surrounded by a freezing mixture. The orange-red distillate separates into two layers, the upper of which is poured into a separating funnel and cooled in ice. The crystals formed are drained, again melted and crystallised and drained from the mother liquor.

After recrystallisation it is obtained in white glistening rhombic crystals, sp.gr. 1·63, m.p. 29·5 (Berthelot, Bull. Soc. chim. 1874, [ii.] 21, 53). It boils with decomposition into N_2O_4 and oxygen at about 45°. It darkens in colour on rise of temperature, the crystals becoming yellow some time before melting, at which point it is orange coloured, further turning dark-brown as the temperature rises. Calculated molecular heat of fusion −8280 cal., and heat of evaporation −4840 cal. Heat of formation of solid N_2O_5 13,100 cal. (Berthelot, Ann. Chim. Phys. 1875, [v.] 6, 202). Hence heat of formation of gaseous N_2O_5 is practically nil. Heat evolved with one molecule of water, 2300 cal. Heat of solution in excess of water 16,200 cal. (Berthelot, *l.c.*).

N_2O_5 dissolves in water giving nitric acid. It has no action on carbon or metals. It is useful as a nitrating agent. For this purpose, Gibson (Proc. Roy. Soc. Edin. 1908, 28, 705) gives details for making large quantities. It dissolves in freshly distilled and fused sulphur trioxide, giving a practically pure product in almost theoretical yield, b.p. 218°–220°; m.p. 124°–128°, which is also obtained as a crystalline precipitate on mixing carbon tetrachloride solutions. Its formula is $(SO_3)_4{\cdot}N_2O_5$, and its probable constitution—

$$O{<}^{SO_2\cdot O\cdot SO_2\cdot O\cdot NO_2}_{SO_2\cdot O\cdot SO_2\cdot O\cdot NO_2}$$

(Pictet and Karl, Compt. rend. 1907, 145, 238).

Nitrogen hexoxide.—Hautefeuille and Chappuis observed a characteristic absorption spectrum during the passage of a silent electric discharge in air (Compt. rend. 92, 80; 94, 946, 1306). Warburg and Leithäuser (Sitzungsber. Akad. Wiss. Berlin, 1907, 229) observed the same from ozone and N_2O_5 at 0°–18°. It exists only in presence of ozone. It is suggested that is due to a higher oxide, probably N_2O_6.

Nitrous acid HNO_2. Nitrous anhydride dissolves in excess of ice-cold water with production of this acid. The solution, however, is extremely unstable, and the acid itself has never been isolated, but its metallic and ethereal salts are comparatively stable.

Nitrites are found to some extent in nature, and occur in the juices of certain plants. Their universal presence in air has been shown by Schönbein (Chem. News, 1862, 241), Warington (Chem. Soc. Trans. 1881, 220), and Hayhurst and Pring (*v.* under NITROGEN).

All nitrites are soluble in water, and the majority dissolve in alcohol.

Preparation.—Alkali and alkaline earth hydroxides and carbonates absorb N_2O_4 and N_2O_3, in the first case, giving a mixture of nitrite and nitrate, and in the second case, if NO be present in slight excess practically pure nitrite (Divers, Chem. Soc. Trans. 1899, 75, 85). On the commercial scale, the nitrous fumes electrically produced from the air are kept at 300° until absorbed, whereby oxidation of the NO only proceeds as far as N_2O_3 and on absorption (in strong nitrite solutions, which have low vapour tensions), pure nitrite is produced (Badische Anilin u. Soda Fabrik, D. R. P. 188188).

Nitrites are obtained by reduction of nitrates, and also by oxidation of nitrogen compounds richer in hydrogen.

Many nitrates are reduced to nitrites by fusing with lead, copper, carbon (Fischer, Pogg. Ann. 1848, 74, 115), sulphites (Etard, Bull. Soc. chim. 1877, [ii.] 27, 434), sulphides (Roy, Compt. rend. 1889, 108, 1251), and in solution by reduction with Na, K, Ca and other metals (Schönbein, J. pr. Chem. 1868, 105, 206), and further by electrolytic reduction, the conditions for which have been worked out by Müller and Weber (Zeitsch. Elektrochem. 1903, 9, 955, 978) and Müller and Spitzer (*ibid.* 1905, 11, 917). Silver is found to be the best cathode, reduction to nitrite being almost complete before further reduction to ammonia takes place. Using a copper anode the yield is almost quantitative.

Nitrites are also produced by oxidation of ammonia with hydrogen peroxide (Weith and Weber, Ber. 1874, 7, 1745; Hoppe-Seyler, *ibid.* 1883, 16, 1917).

Schönbein has shown that copper is oxidised when immersed in aqueous ammonia in contact with air, whilst the ammonia is at the same time oxidised to nitrite, and Traube and Biltz (Ber. 1904, 37, 3130; 1906, 39, 166) have studied the electrolytic oxidation of aqueous NaOH containing ammonia, in presence of copper hydroxide as catalyser. With a current strength of 5–15 amperes and platinum or iron electrodes, practically the whole of the anode oxygen is used up in converting the ammonia present into nitrite. The final product is nitrate.

Properties.—Though very unstable in solution it is chemically a fairly strong acid, about 20 times as strong as acetic acid. It is slowly displaced from solutions of its salts by carbon dioxide (Moore, J. Amer. Chem. Soc. 1904, 26, 959).

Conductivities at dilutions of 512, 1024, and 1536, are 150·7, 189, and 217·0 respectively (Schumann, Ber. 1900, 33, 527). Calculated velocity of nitrite ion 64·5 (Pick finds 63 from $AgNO_2$, and Vogel (Zeitsch, anorg. Chem. 1903, 35, 385) 61·7 from $Ba(NO_2)_2$), and dissociation constant 0·00045. Bauer (Zeitsch. physikal. Chem. 1902, 41, 681) finds 0·00064.

Heat of neutralisation (with baryta) 10,600 cal. (with ammonia) 9100 cal. (Berthelot, Ann. Chim. Phys. 1875, [v.] 6, 145).

Heat of formation

$$N+O_2+H+Aq=HNO_2+30,770 \text{ cal.}$$

The aqueous solution on warming evolves NO leaving nitric acid

$$3HNO_2=HNO_3+2NO+H_2O,$$

this decomposition proceeding in the cold in presence of rough surfaces (sand, glass fragments, &c.). For the dynamics of the equilibrium, *v.* Saposhnikoff (J. Russ. Phys. Chem. Soc. 1901, 33, 506), Lewis and Edgar (J. Amer. Chem. Soc. 1911, 33, 292), and of the decomposition of silver nitrite, Abegg and Pick (Zeitsch. anorg. Chem. 1906, 51, 1).

It is completely oxidised to nitric acid by the usual oxidising agents. Its oxidation by hydrogen peroxide and subsequent precipitation with 'nitron' acetate is recommended by Busch (Ber. 1906, 39, 1401) as a good method of estimation. (For its detection and estimation, *v.* under ANALYSIS.)

It also behaves as an oxidising agent, being itself reduced to NO, $H_2N_2O_4$, N_2O, NH_2OH, or even further to N_2 and NH_3 by reducing agents such as stannous chloride, hydrogen sulphide, sodium amalgam (Divers, Chem. Soc. Trans. 1899, 75, 87), and by electrolytic reduction (Tanatar, Ber. 1896, 29, 1039).

The primary reduction product appears to be the radical NOM′, which gives hyponitrite by condensation, and hydroxylamine and ammonia by reduction (*v.* under *Hyponitrous Acid*).

With hydrazine the following quantitative reaction takes place—

$$N_2H_4+HNO_2=N_2O+NH_3+H_2O.$$

There is no evolution of nitrogen as Girard and Saporta (Bull. Soc. chim. 1904, [iii.] 31, 905) state (Francke, Ber. 1905, 38, 4102).

Constitution.—The molecular weight from cryoscopic measurements in aqueous solution is in accordance with the formula HNO_2 (Saposhnikoff, J. Russ. Phys. Chem. Soc. 1909, 41, 1704).

In most of its reactions its behaviour indicates the constitution $O{=}N{\cdot}OH$, but it may have the constitution $O_2{\equiv}N{\cdot}H$. The fact that many nitrites readily evolve NO_2 on heating, and give nitroparaffins with alkyl iodides, would suggest the latter to be correct (Divers, Chem. Soc. Trans. 1885, 47, 205; Kieseritzky, Zeitsch. physikal. Chem. 1899, 28, 421). As, however, alkyl nitrite is also produced in yield which varies with the alkyl iodide used, this latter reaction affords no definite clue to its constitution.

Ley, on the other hand, shows that mercurous nitrite exists in solution as an oxy salt (Ber. 1899, 32, 1357), and the reduction of nitrous acid to hyponitrous acid also points to an oxy-structure.

ACID HALIDES OF NITROUS ACID.

Nitrosyl fluoride NOF is prepared by the action of nitrosyl chloride on silver fluoride. A small flask containing NOCl cooled to −5° is attached to one end of a long platinum tube containing the silver fluoride, and kept at 200°–250°, and the NOCl slowly distilled through. The product is condensed in a small platinum flask cooled in liquid air, and on fractionation gives a colourless gas, b.p. −56°, m.p. −134°. In the cold, silicon, boron, red phosphorus, and sodium take fire in the gas, and antimony is at once acted on, the fluoride and nitric oxide being formed. Lead, aluminium, bismuth, and copper are slowly attacked, but iodine, sulphur and carbon do not react even on heating. Brown fumes are produced in moist air and with water, hydrofluoric and nitrous acids being formed. Its analysis and vapour density (1·683 air=1) are in agreement with the formula NOF. It closely resembles *nitryl fluoride* NO_2F (*q.v.*) in chemical and physical properties, but differs from it in its behaviour towards water and iodine. It gives additive compounds with arsenic and antimony pentafluorides (Ruff and Stäuber, Zeitsch. anorg. Chem. 1905, 47, 190; Ruff, Stäuber, and Graf, *ibid.* 1908, 58, 325).

Nitrosyl chloride NOCl is obtained—

(1) By direct union of NO and chlorine (Gay Lussac, Ann. Chim. Phys. 1848, [iii.] 23, 203).

The best procedure is to pass a mixture of the dried gases in the proportion 2 : 1 over finely granulated animal charcoal at 40°–50°, under slight pressure (Francesconi and Bresciani, Atti. R. Accad. Lincei, 1903, [v.] 12, 1175).

Its formation at low temperatures has been studied by Boubnoff and Guye (J. Chim. Phys. 1911, 9, 290). After removing excess of NO at −160° to −150°, an excess of chlorine (3·4 p.e.) above that required for the formula NOCl always remains, but is expelled at −80°. Tilden and others have shown that no higher oxychloride exists, and this is confirmed by the liquidus curve, which, however, denotes the existence of a highly dissociative additive compound, probably $NOCl{\cdot}Cl_2$, at about −109°.

(2) By distillation of *aqua regia*.

(3) By distillation of potassium nitrite with phosphorus pentachloride.

(4) By heating nitrosyl sulphuric acid with sodium chloride.

$$NO_2{\cdot}SO_3H+NaCl=NOCl+NaHSO_4$$

(Tilden, Chem. Soc. Trans. 1874, 630, 852; Girard and Pabst, Bull. Soc. chim. 1878, [ii.] 30, 531).

(5) By action of nitrosamines on hydrochloric acid (Lachmann, Ber. 1900, 33, 1035).

(6) By action of hydrochloric acid on N_2O_4 (Müller, Annalen, 1862, 122, 1), and on N_2O_3 (*v.* Briner and Wroczynski, under *Nitric Oxide*).

(7) By action of NO on $FeCl_3$ (Thomas, Compt. rend. 1895, 120, 447).

Nitrosyl chloride is a ruby-red mobile liquid, b.p. −5·6°/751 mm., giving lemon-yellow crystals, m.p. −61° to −60°. Critical temperature 163°–164° (Francesconi and Bresciani, *l.c.*). Vapour density (2·29–2·32 at 10°) is in agreement with the formula NOCl. Sp.gr. of liquid 1·4165 at −12°; 1·4250 at −15°; 1·4330 at −18° (Geuther, Annalen, 1888, 245, 96).

It is fairly stable towards heat, dissociation being first measurable at 700° (Sudborough and Miller, Chem. News, 1890, 62, 1307).

With water it at once gives nitrous and hydrochloric acids, and with metallic oxides forms the nitrite and chloride of the metal (Sudborough, Chem. Soc. Trans. 1891, 59, 655).

It forms double compounds with many metallic chlorides, some of which decompose on heating, evolving NO

$$CuCl{\cdot}NOCl \rightarrow CuCl_2+NO$$

while others are stable and may be sublimed *e.g.* —$AuCl_2{\cdot}NOCl$— and with unsaturated organic compounds forms addition products like N_2O_3 and N_2O_4.

With amines nitrogen is evolved and the chloride formed

$$R{\cdot}NH_2+NOCl=RCl+N_2+H_2O$$

(Solonina, J. Russ. Phys. Chem. Soc. 1898, 30, 431). For its action on mercaptans, *v.* Tasker and Jones (Chem. Soc. Trans. 1909, 1910).

Absorption spectrum (*v.* Magnanini, Zeitsch. physikal. Chem. 1889, 4, 427).

Sulphur trioxide forms *nitrosyl sulphonic chloride* $NO_2{\cdot}SO_2Cl$.

Nitrosyl bromide NOBr is obtained as a dark-brown liquid (1) by direct union of NO and bromine at −7° to −15° (Laudolt, Annalen, 1861, 116, 177); (2) by action of NaBr on $NO_2{\cdot}SO_3H$ (Girard and Pabet, *l.c.*).

It boils at −2° with dissociation, thus differing from the chloride, which it resembles in its chemical properties.

Landolt's *dibromide* $NOBr_2$ and Muir's *tribromide* $NOBr_3$ are mixtures of the monobromide with bromine (Frölich, Annalen, 1884, 224, 270).

The corresponding iodine compound has not been isolated.

Reaction of Nitrous and Sulphurous Acids.

The following equations represent the changes which occur—

(1) $HNO_2+H_2SO_3=[NO{\cdot}SO_3H]$ nitrosulphonic acid (1);

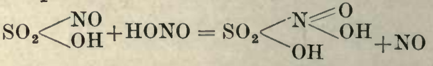
(2) $HNO_2+2H_2SO_3=HO{\cdot}N(SO_3H)_2$ hydroxylamine disulphonic acid (2);

(3) $HNO_2+3H_2SO_3=N(SO_3H)_3$ nitrilo sulphonic acid (3).

The existence of (1) was postulated by Raschig, but has never been isolated, a mixture of equivalent quantities of the two acids giving a very unstable liquid, which by further action of nitrous acid gives—

Nitrosisulphonic acid $HO_2N{\cdot}SO_3H$, also obtained by Sabatier (Compt. rend. 1896, 123, 255) by reduction of nitrosylsulphuric acid.

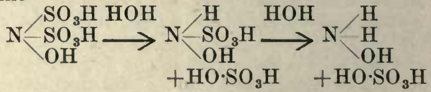
According to Raschig (Zeitsch. angew. Chem. 1905, 18, 1281) its formation and constitution are represented as follows—



$$SO_2\begin{array}{l}\diagup NO\\ \diagdown OH\end{array}+HONO=SO_2\begin{array}{l}\diagup N\begin{array}{l}\diagup\!\!\diagup O\\ \diagdown OH\end{array}\\ \diagdown OH\end{array}+NO$$

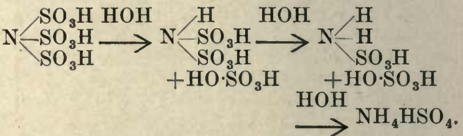
v. also Lunge and Berl (*ibid.* 1906, 19, 808, 857, and 881). The solution of the free acid, and of the copper salt, is blue. The iron salt is red.

Acid hydrolysis of (2) produces successively hydroxylamine sulphonic acid and hydroxylamine—



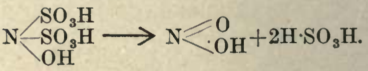
$$N\begin{array}{l}\diagup SO_3H\\ -SO_3H\\ \diagdown OH\end{array}\xrightarrow{HOH}N\begin{array}{l}\diagup H\\ -SO_3H\\ \diagdown OH\end{array}\xrightarrow{HOH}N\begin{array}{l}\diagup H\\ -H\\ \diagdown OH\end{array}$$
$$+HO{\cdot}SO_3H \qquad +HO{\cdot}SO_3H$$

Acid hydrolysis of (3) produces successively imino sulphonic acid, amino sulphonic acid, and ammonia—



$$N\begin{array}{l}\diagup SO_3H\\ -SO_3H\\ \diagdown SO_3H\end{array}\xrightarrow{HOH}N\begin{array}{l}\diagup H\\ -SO_3H\\ \diagdown SO_3H\end{array}\xrightarrow{HOH}N\begin{array}{l}\diagup H\\ -H\\ \diagdown SO_3H\end{array}$$
$$+HO{\cdot}SO_3H \qquad +HO{\cdot}SO_3H$$
$$\xrightarrow{HOH}NH_4HSO_4.$$

Hydrolysis by alkalis usually regenerates the sulphite and nitrite—



$$N\begin{array}{l}\diagup SO_3H\\ -SO_3H\\ \diagdown OH\end{array}\longrightarrow N\begin{array}{l}\diagup\!\!\diagup O\\ \diagdown OH\end{array}+2H{\cdot}SO_3H.$$

For further details, and conditions under which these compounds are formed *v.* Hydroxylamine.

Hyponitrous acid $H_2N_2O_2$. The sodium salt of this acid was obtained by Divers (Proc. Roy. Soc. 1871, 19, 425) by reduction of the nitrate (*v.* also Maumené, Compt. rend. 1870, 70, 146), but though its metallic salts and diethyl ester have been known for some time the free acid has only recently been isolated in the solid state. It is prepared—

(1) By condensation of nitrous acid with hydroxylamine, usually the sodium or silver salt with the sulphate or hydrochloride, in aqueous solution (Wislicenus, Ber. 1893, 26, 771; Paal, *ibid.* 1026) or free hydroxylamine and N_2O_3 in methyl alcoholic solution (Kauffmann, Annalen, 1898, 299, 98).

(2) By oxidation of hydroxylamine—

(*a*) With metallic oxides, as CuO, HgO, Ag_2O (Hantzsch and Kauffmann, *ibid.* 1892, 292, 317);

(*b*) With sodium hypobromite (Kolotow, J. Russ. Phys. Chem. Soc. 1891, 23, 1, 3),

(3) By reduction of NO, HNO_3, and, still better, HNO_2. A dilute sodium amalgam is used, and the temperature kept low. The hyponitrite is most stable in excess of alkali. After reduction any hydroxylamine formed is destroyed by HgO, and the liquid, after neutralising with HNO_3, precipitated with $AgNO_3$, or the hydroxylamine may be further reduced by sodium amalgam, and the ammonia removed by evaporation *in vacuô* over sulphuric acid.

(4) By alkaline hydrolysis of certain oxy-amino- compounds, $OH{\cdot}NH{\cdot}SO_3H$ (Divers and Haga, Chem. Soc. Trans. 1899, 77),

$$OH{\cdot}NH{\cdot}SO_2C_6H_5$$

(Piloty, Ber. 1896, 29, 1559); $OH{\cdot}N{=}NO_2H$ (*q.v.*) behave in this way.

The most convenient procedure is to treat the sodium salt of hydroxylamine disulphonic acid (easily obtained by the action of sulphurous acid on sodium nitrite) with concentrated or fused alkali, when it is obtained by precipitation with $AgNO_3$ as the silver salt in 60 p.c. yield (Kirschner, Zeitsch. anorg. Chem. 1897, 16, 424; *v.* also Hantzsch and Sauer, Annalen, 1898, 299, 89; Wieland, *ibid.* 1903, 329, 225). The methods described for the reduction of nitrites by aluminium amalgam, iron hydroxide, and fusion with iron filings are useless.

The free acid may be isolated by decomposing the silver salt with an ethereal solution of hydrochloric acid, and evaporating the filtrate in a desiccator. It is thus obtained in white, crystalline leaflets, very explosive, decomposing on friction, contact with solid KOH or acid vapours, and often spontaneously.

It dissolves very readily in water, readily in alcohol, and is fairly soluble in most organic solvents.

Its decomposition into N_2O and H_2O is not reversible. Small amounts of nitric and nitrous acids are formed at the same time (*v.* further Ray and Ganguli, Chem. Soc. Trans. 1907, 1886; Divers, Chem. Soc. Proc. 1908, 16). Heat of formation $2N+O+Aq.=H_2N_2O_2Aq.-57{,}400$ cal. (Berthelot, Ann. Chim. Phys. 1889 [vi.] 18, 571). It can be oxidised to nitric acid by bromine and by $KMnO_4$. It is not reduced by sodium amalgam (Divers), but yields hydrazine with sodium bisulphite (*v.* Brackel, Ber. 1900, 33, 2115).

It forms neutral and acid salts, the latter very unstable, only the acid ammonium salt being known in the pure state. The neutral salts are mostly insoluble in water, and can be obtained by precipitation. Esters of hyponitrous acid are obtained by action of the iodide on silver hyponitrite.

The *ethyl ester* is a yellow oil (Zorn, Ber. 1878, 11, 1630), and the *benzyl ester* a low-melting solid (Hantzsch and Kauffmann, *l.c.*).

Constitution.—The molecular weight determined by the cryoscopic method corresponds with the formula $H_2N_2O_2$, which, with its modes of formation and acid properties points to its being *diazodihydroxide.* Hantzsch considers it to be the anti-form, assigning the syn-structure to the isomeric *nitramide* (*q.v.*) owing to the great ease with which even salts of the latter evolve N_2O in solution—

Nitramide. Hyponitrous acid.

Nitric acid HNO_3. This is, with the exception of ammonia, the earliest compound of nitrogen investigated, its preparation being known to the Egyptians. In the ninth century Geber obtained it by distilling nitre with blue vitriol and alum, and it was known under various names, such as *aqua fortis, spiritus nitri acidus,* and *spiritus nitri fumans Glauberi.* Its composition was investigated by Lavoisier (1776) and by Lavoisier and Priestley (1784–1786).

Occurrence.—It is found in nature in combination with NH_4, Na, K, Ca, Mg, and in smaller quantities with Al and Fe. It is produced by atmospheric electrical discharges, and by oxidation of nitrogenous organic matter through the medium of nitrifying bacteria, subsequently combining with ammonia in the air, and with the various bases present in the soil, and occurs in largest quantity as Chile saltpetre ($NaNO_3$) and Bengal saltpetre (KNO_3).

Preparation.—Being the highest oxidation product of nitrogen it is produced by the action of suitable oxidising agents upon all the less oxygenated compounds.

Ammonia is oxidised to nitric acid by atmospheric oxygen in presence of catalytic agents such as $Cu(OH)_2$, Cu, Fe, Ni, Pt (Kuhlmann, Annalen, 1839, 29, 281; Schönbein, J. pr. Chem. 1859, 70, 129; Kraut, Annalen, 1856, 136, 69). Lead manganate and permanganate, sodium manganate and lead chromate also bring about this oxidation (Motay, Ber. 1871, 4, 891; Schwarz, Dingl. poly. J. 1875, 218, 219) upon which principle the patents of Ostwald (Eng. Pat. 698) and Bayer and Co. (D. R. P. 168272) depend.

According to Schmidt and Böcker (Ber. 1906, 39, 1366) the primary oxidation product is NO (*v.* further Smith, Chem. Soc. Trans. 1906, 473).

Ammonia gas is oxidised by heated MnO_2 and Fe_2O_3 to ammonium nitrate, and its solution by ozone, H_2O_2, H_2CrO_4, $KMnO_4$, and by electrolytic and biochemical oxidation.

Nitrous acid is similarly oxidised to nitric acid. Nitrogen and its lower oxides are only oxidised by oxygen to N_2O_4, unless water is present, when nitric acid is formed (*v.* also NITRIC ACID, MANUFACTURE OF; ATMOSPHERIC, NITROGEN, UTILISATION OF).

Properties.—By distillation in a current of CO_2, 98 p.c. acid can be obtained. Fractional crystallisation gives a product with maximum purity of 99·4±0·1 p.c. Absolute nitric acid only exists in the form of snow-white crystals, m.p. −41°. On melting, a yellow liquid results which is a solution of nitric anhydride and water in nitric acid (Küster and Munch, Zeitsch. anorg. Chem. 1905, 43, 350).

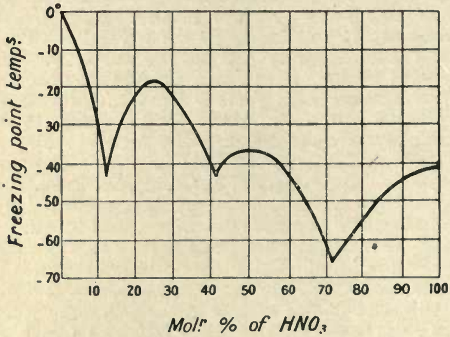
The physical properties show discontinuities which point to the existence of various hydrates. The freezing-point curve (p. 692), constructed from the values of Pickering (Chem. Soc. Trans. 1893, 63, 436) and Küster and Kremann (Zeitsch. anorg. Chem. 1905, 41, 1), shows two maxima, at −18·5° and −38°, corresponding to

$$HNO_3,3H_2O$$

and HNO_3,H_2O respectively; and three minima, corresponding to the cryohydrates (1) ice $+HNO_3,3H_2O$ (m.p. −43°); (2)

$$HNO_3,3H_2O+HNO_3,H_2O$$

(m.p. −42°); and (3) HNO_3,H_2O+HNO_3 (m.p. −66°).



According to Erdmann (Zeitsch. anorg. Chem. 1902, 32, 431; Zeitsch. angew. Chem. 1903, 16, 1001) orthonitric acid $N(OH)_5$, crystallises in needles, stable below −15°, m.p. −35°, b.p. 40°–40·5°/13 mm. Octobasic nitric acid $O[N(OH)_4]_2$, m.p. −39°, tribasic nitric acid $O{=}N(OH)_3$, m.p. −34°, and tetrabasic nitric acid $O[NO(OH)_2]_2$, m.p. −65·2°, are also described. Independent evidence for the existence of the ortho-acid is obtained from the refractive index curves (Veley and Manley, Proc. Roy. Soc. 1901, 69, 86; Chem. Soc. Trans. 1903, 1015), and from the absorption spectra (Hartley, Proc. Roy. Soc. Dublin, 1905, [ii.] 10, 373), but the existence of the polybasic acids is disputed (Küster and Kremann, Zeitsch. anorg. Chem. 1904, 41, 1; Küster, Zeitsch. angew. Chem. 1903, 16, 1079).

The freezing-points of dilute solutions and the corresponding dissociation values are given by Jones (Zeitsch. physikal. Chem. 1893, 12, 630) and Jones and Getman (Amer. Chem. J. 1902, 27, 433). The change in the value of the molecular lowering with concentration is indicated by the following selected values—

Gram mols. HNO_3 per litre	Molecular lowering
0·001054	3·7951°
0·01153	3·7294°
0·1059	3·5269°
0·25	3·501°
0·5	3·621°
1·0	3·796°
2·0	4·174°
3·0	4·603°

The densities, and the changes in density with temperature, of nitric acid solutions of different concentrations have been determined by Lunge and Rey (Zeitsch. angew. Chem. 1891, 165) and Veley and Manley (*l.c.*), and afford further evidence of the existence of hydrates (Veley and Manley).

The following table is constructed from Lunge and Rey's values—

$d_4^{15°}$	p.c. HNO_3	$d_4^{15°}$	p.c. HNO_3
1·00	0·10	1·30	47·49
1·05	8·99	1·35	55·79
1·10	17·11	1·40	65·30
1·15	24·84	1·45	77·28
1·20	32·36	1·50	94·09
1·25	39·82	1·52	99·67

Density of normal HNO_3 solution (63·13 grams per litre) = 1·0318 at 18·6° (Kohlrausch, Wied. Ann. 1865, 26, 161), 1·0324 at 18° (Loomis, *ibid.* 1897, 60, 532).

The expansion of dilute solutions with temperature has been studied by Forch (Wied. Ann. 1895, 55, 100) and Ostwald (J. pr. Chem. 1877, [ii.] 16, 385), and that of concentrated solutions by Küster and Kremann, who find two breaks in the otherwise continuous concentration, at 54·0 p.c. HNO_3 and 77·77 p.c. HNO_3, corresponding to $HNO_3,3H_2O$, and HNO_3,H_2O respectively.

For the conductivity of nitric acid solutions, *v.* Kohlrausch (Wied. Ann. 1885, 26, 161), Arrhenius (Zeitsch. physikal. Chem. 1889, 4, 96), Loomis (Wied. Ann. 1897, 60, 547), Veley and Manley (Proc. Roy. Soc. 1897, 62, 223), and Küster and Kremann (*l.c.*). The existence of the above hydrates is again indicated; two irregularities in the conductivity curve occurring at 25 and 50 mols. p.c. HNO_3, corresponding to the compounds $HNO_3,3H_2O$ and HNO_3,H_2O respectively, and a third at 96–100 p.c. HNO_3, at which concentration irregularities also occur in the density and freezing-point curves, pointing to the commencement of anhydride formation previously mentioned.

Nitrates dissolved in concentrated nitric acid increase its conductivity in proportion to the amount dissolved (Bouty, Compt. rend. 1888, 106, 595, and 654).

The viscosity of nitric acid has been determined by Graham (Phil. Trans. 1861, 153, 373), Reyher (Zeitsch. physikal. Chem. 1888, 2, 744), Paggliani and Oddone (Wied. Ann. Beibl. 11, 415), and Küster and Kreman (*l.c.*). The last-named give the following values $\eta = 1$ for water at 0°—

p.c. HNO_3	98·5	82·0	70·0	65·0	50·0	30·0	10·0	0·0
η (+15°)	0·548	1·036	1·277	1·300	1·144	0·822	0·655	0·667
η (−15°)	0·833	2·241	3·268	3·304	2·369	1·635	—	—

The maximum at about 65 p.c. corresponds to the constant boiling mixture $2HNO_3,3H_2O$ first investigated by Dalton. It is not a compound, its composition varying with the pressure. At 735 mm. it contains 68·0 p.c. HNO_3 (b.p. 120·5°) and at 1220 mm. 68·6 p.c. HNO_3 (Roscoe, Annalen, 1860, 116, 203), while, by passing indifferent gases through the acid at ordinary temperatures residues differing still more widely in composition are obtained.

The vapour tensions of nitric acid solution have been determined by Saposhnikoff (Zeitsch. physikal. Chem. 1905, 53, 225). For the higher concentrations they are as follows—

d_4	p.c. HNO_3	p.c. H_2O	p (mm. at 15°)	p.c. N in vapour
1·400	65·30	34·70	1·90	19·32
1·453	78·10	21·90	9·40	22·52
1·462	82·10	17·90	16·64	22·65
1·487	88·65	11·35	29·70	23·05
1·497	92·93	7·07	42·60	23·50
1·510	98·00	2·00	46·20	23·75

As HNO_3 contains only 22·22 p.c. N, oxides are also present in the vapour.

With mixtures of nitric and sulphuric acids, however, the vapour tension rises and then falls with increasing percentages of HNO_3. The maximum for HNO_3 of sp.gr. 1·40 occurs at 45 p.c. HNO_3 (23·5 mm.), and for HNO_3 of sp.gr. 1·48 at 67 p.c. HNO_3 (34 mm.). With the pure acids the value rises steadily to 41 mm. at 80 p.c. HNO_3, remains constant up to 92 p.c. and rises subsequently to 46 mm. with pure HNO_3 (Saposhnikoff, *ibid.* 1904, 49, 697; 1905, 51, 609). The purest obtainable nitric acid boils at 86° with partial decomposition. Under 24 mm. it boils at 21·5° (Erdmann, Zeitsch. anorg. Chem. 1902, 32, 431).

Refractive index.

$d_4^{20°}$	D line	Mol. dispn.
1·50999	1·39584	0·338
1·50875	1·36870	0·340

(Brühl, Zeitsch. physikal. Chem. 1897, 22, 373). The maximum value (1·4061 at 14·2°) is shown by 70 p.c. HNO_3, while the values for 50 p.c. and 99 p.c. acid are practically identical (Veley and Manley, Proc. Roy. Soc. 1901, 69, 86). For the absorption spectra, *v.* Hartley, Chem. Soc. Trans. 1903, 658.

Heat of formation.—

$$H+N+O_3+Aq.=HNO_3Aq.+49{,}090 \text{ cal.}$$

(Thomsen), 48,800 (Berthelot), which, by subtracting the heat of solution (7490, Thomsen; 7180, Berthelot) gives

$$H+N+O_3=HNO_3+41600 \text{ cal.}$$

Mol. heat of evaporation 7250 cal., mol. heat of fusion 600 cal. (Berthelot, Ann. Chim. Phys. 1877, [v.] 12, 530).

Specific heat.—

p.c. HNO_3	58·3	12·3	3·4	26	15	3·4
Sp.ht. .	0·6651	0·8752	0·9618	0·768	0·849	0·963

The first three are Marignac's values at 21°–52° (Annalen, 1872 (suppl.), 8, 335), the last three Thomsen's at 18°.

Chemical properties.—Nitric acid has been shown by the usual methods (rate of hydrolysis of methyl acetate, inversion of cane sugar, freezing-point lowering and conductivity) to be the strongest known acid. Accordingly it has a high value for its heat of neutralisation (with NaOH 13,680 cal.; with KOH 13,770 cal. Thomsen, Th.U. 1906, 40). Its heat of dissociation for $v=1·5–6$ is about 2800 cal. (Petersen, Zeitsch. physikal. Chem. 1893, 11, 174), for $v=10$ about 1362 cal. (Arrhenius, *l.c.*).

It dissolves readily in ether, and the ether-water partition coefficients have been determined by Bogdan, Zeitsch. Elektrochem. 1905, 11, 824; 1906, 12, 489; *v.* also Hantzsch and Sebaldt, Zeitsch. physikal. Chem. 1899, 30, 285). The molecular weight in ethereal solution is normal.

The nitrate ion is one of the most electronegative ions. Migration velocity 61·8 at 18° (Landolt-Börnstein, 1905, 237). All its salts are soluble, and there is little tendency to form complexes.

The chief characteristic of nitric acid is its remarkable oxidising power, being itself capable of reduction to HNO_2, NO_2, NO, N_2O, $H_2N_2O_2$, NH_2OH, N_2, and NH_3. Ostwald (Grundliss. d. allgem. Chemie, 1899, 440) explains the formation of these products on the supposition that nitric acid can so dissociate that it forms OH ions with the loss of positive charges—

$$\begin{array}{llll}
HNO_3 & \rightarrow NO_2^{\cdot}+OH' & \rightarrow & NO_2+OH'+\oplus \\
 & \nearrow NO_2H^{\cdot\cdot}+2OH' & \rightarrow & NO_2H+2OH'+2\oplus \\
NO(OH)_3 & & & \\
 & \rightarrow NO^{\cdot\cdot\cdot}+3OH' & \rightarrow & NO+3OH'+3\oplus \\
 & \nearrow NOH^{\cdot\cdot\cdot\cdot}+4OH' & \rightarrow & \frac{(NOH)_2}{2}+4OH'+4\oplus \\
NO(OH)_5 & & & \\
 & \searrow N^{\cdot\cdot\cdot\cdot\cdot}+5OH' & \rightarrow & \frac{N_2}{2}+5OH'+5\oplus
\end{array}$$

The oxidation potential (Ihle, Zeitsch. physikal. Chem. 1896, 19, 589) is lowered by the presence of nitrous acid, which, however, increases the rate of oxidation.

Nitric acid is not affected by hydrogen at ordinary temperatures or at 100° (Berthelot, Compt. rend. 1898, 127, 27), but is reduced by it to ammonia in presence of platinum sponge (Wagner, Dingl. poly. J. 1867, 183, 76). The concentrated acid oxidises boron on slightly warming to boric acid with evolution of NO and N_2, carbon to carbon dioxide, in the cold if finely divided, phosphorus to phosphorous, and finally to phosphoric acid (when, according to Montemartini, Gazz. chim. ital. 1898, 28, i. 397, ammonia is also produced). Sulphur is oxidised to H_2SO_4 with great readiness if finely divided, selenium to H_2SeO_3, and iodine to iodic acid with production of nitrous acid. Hydrides are also oxidised: PH_3 readily, H_2S only if NO_2 be present (acid of sp.gr. 1·18 free from NO_2 has no action: Kemper, Annalen, 1857, 102, 342), SeH_2 violently (Hofmann, Ber. 1870, 3, 660). HBr at 0° forms Br_2 and NO_2, HI yields I_2 and NO (HNO_2 in dilute solution, Eckstädt, Zeitsch. anorg. Chem. 1901, 29, 51) and HCl,NOCl (*q.v.*).

SO_2 reduces HNO_3 readily, some N_2O being formed. In presence of dilute sulphuric acid reduction is still more readily effected, with evolution of NO, and in presence of concentrated H_2SO_4 nitrosyl sulphuric acid (Weber, Pogg. Ann. 1867, 130, 277).

Ferrous salts yield NO, stannous salts NH_2OH and NH_3,$AsCl_3$ and As_4O_6 arsenic acid, and $SbCl_3$ antimonic acid.

Nitric acid attacks with more or less readiness according to their nature, and the concentration of the acid, all metals with the exception of Au, Rh, Ir, and Pt (the last-named when alloyed with other metals goes into solution, *e.g.* an alloy of 4·64 p.c. Pt and 95·35 Hg is entirely soluble (Tarugi, Gazz. chim. ital. 1903, 33, [ii.] 171) with formation of the nitrate except in the case of Sn, W, Mo, and As, when the anhydride of the corresponding acid is produced, the nitric acid itself being reduced to various stages. Sn forms stannic nitrate first, which breaks up yielding the dioxide. Sb is converted into Sb_2O_4. Briefly it may be stated that with the less reactive metals, such as Hg, Ag, Cu, Bi, reduction to the first stage only takes place, and is probably not due to the agency of nascent hydrogen, but to nitrous acid, the influence of which on the reactivity of nitric acid was first noticed by Millon (J. Pharm. Chim. 1842, [iii.] 2, 179). Thus, with copper—

(i.) $Cu+4HNO_2=Cu(NO_2)_2+2H_2O+2NO$;
(ii.) $Cu(NO_2)_2+2HNO_3=Cu(NO_3)_2+2HNO_2$;
(iii.) $HNO_3+2NO+H_2O=3HNO_2$.

The nitrous acid thus continuously produced at once decomposes—

$$3HNO_2=HNO_3+2NO+H_2O,$$

nitric oxide being evolved (Veley, Roy. Soc. Trans. 1891, 182, A, 279).

From the equilibrium

$$3NO_2+H_2O \rightleftarrows 2HNO_3+NO$$

it is evident that with concentrated acid the product is NO_2.

The most complete reduction (to N_2 and NH_3) takes place with the more electro-positive metals such as Sn, Co, Ni, Fe, Cd, Zn, Mn, Mg. Thus Zn and very dilute acid give ammonia, whilst with Sn reduction is less complete, hydroxylamine being one of the products. With more reactive metals, such as Mg, some hydrogen (which may be regarded as the primary product) escapes oxidation. The action is greatly affected by conditions, being slow at first, accelerating as the reduction products, which act catalytically, accumulate. Further, different concentrations yield different products, and hence as the concentration changes during the reaction, mixed products in varying proportions are usually obtained. With Zn, in intermediate concentrations, even nitrous oxide and nitrogen may be found in considerable quantities amongst the gaseous products. For further details, *v.* Acworth and Armstrong (Chem. Soc. Trans. 1877, 32. 54), Montemartini (Atti. R. Accad. Lincei, 1892, [v.] 1, i. 63), Walker (Chem. Soc. Trans. 1893, 63, 845), Higley (Amer. Chem. J. 1899, 21, 377), Stillmann (*ibid.* 1897, 19, 711), Bijlert (Zeitsch. physikal. Chem. 1899, 31, 131), Gladstone (Phil. Mag. 1900, [v.] 50, 231), Stausbie (J. Soc. Chem. Ind. 1908, 27, 365; 1909, 28, 274), Rennie (Chem. Soc. Trans. 1908, 1162), Dunstan and Hill, passivity in (Chem. Soc. Trans. 1911, 1853).

Electrolytic reduction, as shown by Schönbein and Brewster, yields first nitrous acid, and finally ammonia. The nature of the product depends on the temperature, current strength, material of cathode, and its potential, and upon whether the solution is acid or alkaline. With a mercury cathode only hyponitrite is formed (Zorn, Ber. 1879, 12, 1509), with a copper cathode, ammonia (Ulsch, Zeitsch. Elektrochem. 1897, 3, 546).

Nitric acid of 40 p.c. strength containing 1 p.c. of dissolved nitrous gases yields NO (99–100 p.c.) at the cathode on electrolysis (Meister, Lucius and Brüning, Eng. Pat. 10522, May 1, 1911; *v.* Müller and Weber, Zeitsch. Elektrochem. 1903, 9, 955; Müller, *ibid.* 978; Müller and Spitzer, *ibid.* 1905, 11, 509; Ber. 1905, 38, 1190; and Tafel, Zeitsch. anorg. Chem. 1902, 31, 289). The mechanism of the reaction is not clearly understood. Tafel finds that though nitric acid is reduced only to NH_2OH by mercury or well-amalgamated electrodes, copper reduces it to ammonia, and yet has no action on hydroxylamine itself.

Metallic nitrates are normal salts (in only a very few instances are acid or basic salts obtained, and then only under special conditions) which are readily soluble in water, and in many cases in alcohol, or acetone, stable in aqueous solution, and which usually crystallise in the anhydrous form.

Nitric acid forms nitro derivatives with many organic compounds, and with alcohols yields esters.

On contact with the skin substances of bright yellow colour (xantho-proteic acids) are produced. Its chemical properties are best represented by the formula

$H{-}O{-}N\begin{smallmatrix} \nearrow O \\ \searrow O \end{smallmatrix}$.

Estimation (*v.* ANALYSIS).—The most characteristic test is the red colour developed with brucine and concentrated H_2SO_4. Arbutin and berberine under similar conditions yield a deep yellow, and a dark brownish-red colour respectively (Reichard, Chem. Zeit. 1906, 30, 790).

Cinchonamine nitrate is nearly insoluble in water (Howard and Chick, J. Soc. Chem. Ind. 1909, 28, 53).

Di-9-10-monoxyphenanthrylamine dissolved in conc. sulphuric acid forms a delicate test for nitric acid in presence of other oxidising substances. As a reagent, 0·1 gram is dissolved in 1 litre of conc. sulphuric acid and 0·1 gr. of the substance to be tested is added to 2 c.c. of the reagent, when, if nitrates be present, the blue colour turns to a claret-red. Nitrous acid does not alter the colour unless it becomes oxidised to nitric acid (Schmidt and Lumpp, Ber. 1910, 43, 787 and 794).

Fuming nitric acid. A red, fuming liquid with powerful oxidising properties, produced by adding to concentrated HNO_3, nitrous acid, nitrogen trioxide, or nitric oxide, by distilling nitre with potassium acid sulphate, and also by adding kieselguhr saturated with formaldehyde to the concentrated acid (Vanino, Ber. 1899, 32, 1392).

As prepared by any of these methods it contains free NO_2 (Marchlewski, Zeitsch. anorg. Chem. 1892, 1, 363), and in the case where NO is used may be supposed to be formed either by direct union with oxygen, or as represented by the equation $2NO+HNO_3+H_2O \rightarrow 3HNO_2$, the latter then giving NO_2 with the excess of HNO_3. The intermediate production of nitrous acid is shown by addition of water, when it becomes green, blue, and finally colourless (*v.* further Marchlewski and Liljenstein, Zeitsch. anorg. Chem. 1892, 2, 18; 1894, 5, 288).

The specific gravities of the fuming acid of different NO_2 content are given by Lunge and Marchlewski (Zeitsch. angew. Chem. 1892, 1).

Fuming nitric acid oxidises organic compounds to carbon dioxide and water, any sulphur present being converted into H_2SO_4, and phosphorus into H_3PO_4 (Carius, Ber. 1870, 3, 697).

Aqua regia. First obtained by Geber in the eighth century by dissolving salammoniac in *aqua fortis.* Also formed by mixing HCl and HNO_3. The reaction is represented by

$$HNO_3+3HCl=2H_2O+NOCl+Cl_2$$

(*v.* Tilden, J. 1874, 214; Goldschmidt, Annalen, 1880, 205, 372). So named on account of its solvent action on the noble metals.

Pernitric acid HNO_5 is said to be obtained as the silver salt as a black crystalline mass on electrolysing $AgNO_3$ solution (Mulder and Heringa, Rec. trav. chim. 1898, 17, 129). Its existence is doubtful.

ACID HALIDES OF NITRIC ACID.

Nitryl fluoride NO_2F is formed by the action of excess of fluorine on nitric acid at the temperature of liquid air. It is a gas which attacks the mucous membrane, m.p. −139°, b.p. −63·5°; v.d. 2·17–2·31 (air=1) calculated for NO_2F

2·26. It does not combine with hydrogen, sulphur, or carbon, but attacks boron, silicon, phosphorus, arsenic, antimony, iodine, alkali, and alkaline earth metals, aluminium, iron and mercury. With water the quantitative reaction $NO_2F + H_2O = HF + HNO_3$ takes place. It reacts with many organic compounds (Moissan and Lebeau, Compt. rend. 1905, 140, 1573).

Nitryl chloride NO_2Cl (Müller, Annalen, 1862, 122, 1; Odet and Vignon, Compt. rend. 1870, 70, 96) and *nitryl bromide* NO_2Br (Hasenbach, J. pr. Chem. 1871, [ii.] 4, 1) are, according to Gutbier and Lohmann (J. pr. Chem. 1905, [ii.] 71, 182) non-existent.

NITRIC ACID, MANUFACTURE OF. At the present time the nitric acid of commerce is obtained by distilling nearly equal weights of 'oil of vitriol' and sodium nitrate in iron retorts. The residue consists of a fused mixture of sodium sulphate and disulphate ($Na_2S_2O_7$) which may also contain sodium hydrogen sulphate ($NaHSO_4$) if the heating has not been carried so far as to drive off the last traces of water. This fused residue is discharged into iron pans where it solidifies, or it may be run into the pan of a salt-cake furnace, mixed with salt and converted into salt cake. A part of the nitre cake now produced is also converted into sodium sulphide.

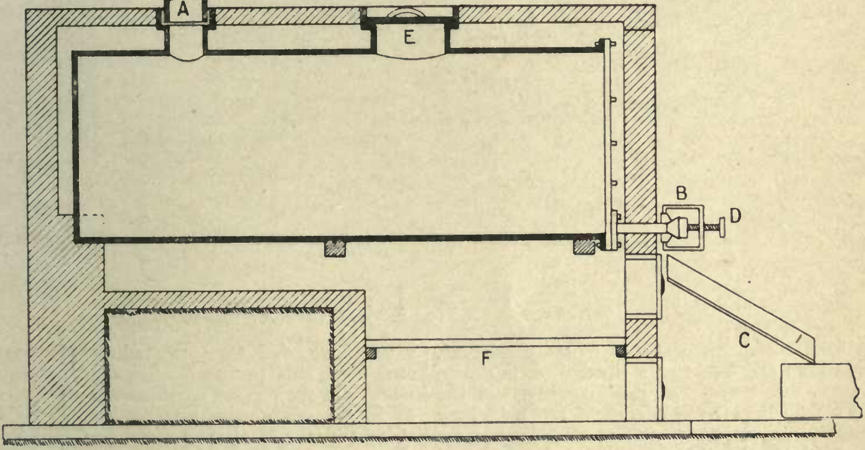


Fig. 1.

Since the specific heat of strong nitric acid is low, the fuel consumption need not be large, and for the same reason the vapour is easily condensed. When nitric acid boils, decomposition into water and nitric oxide takes place. The condensed nitric acid will, therefore, usually contain nitrous acid. This may be avoided by keeping the condensed distillate hot until it escapes from the cooling worm. If very strong sulphuric acid and previously melted sodium nitrate are used, the nitric acid obtained will be very strong. If water is present, the first distillate will be strongest and the last distillate nearly pure water. Formerly the mixture was such that sodium sulphate remained in the retort, but this is now considered poor practice since a longer time and more fuel are required and the sodium sulphate must be dug out of the retort. In most installations a horizontal cylindrical cast-iron retort is used, something like that shown in Fig. 1. Sodium nitrate and sulphuric acid are introduced at E and the nitric acid distils off through A. At the end of the distillation the retort is emptied by turning the screw stopper D, the fused residue falling into the trough C. Another form of retort devised by Hart is shown in cross-section in Fig. 2. The cylinder, of cast iron, is supported on trunnions and is inverted at the end of the distillation. The form of pot retort emptied by dipping out the liquid contents, frequently described, is quite inadmissible in good practice as the workmen are exposed to the fumes of nitric acid, and the operation is needlessly

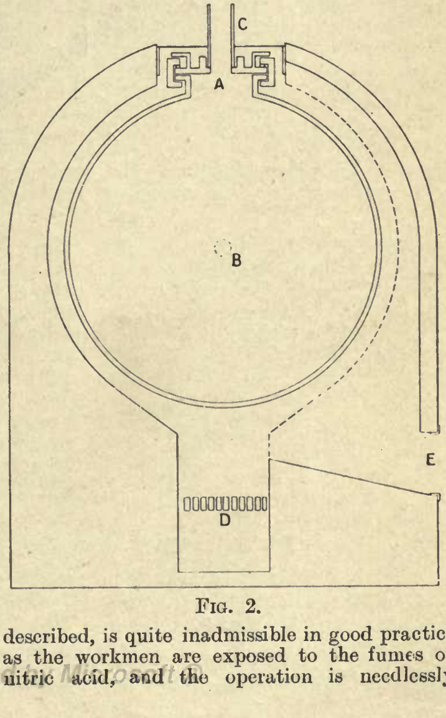

Fig. 2.

expensive. A workable pot retort used in the Valentiner system is shown in Fig. 8.

Condensers.—In the older installations air condensation was relied upon, and this answers well in cold climates, especially in winter, but in summer the surface exposed must be very large and the distillation slow, which results in high fuel and labour cost and small output so that cooling by water is commonly used in the larger plants.

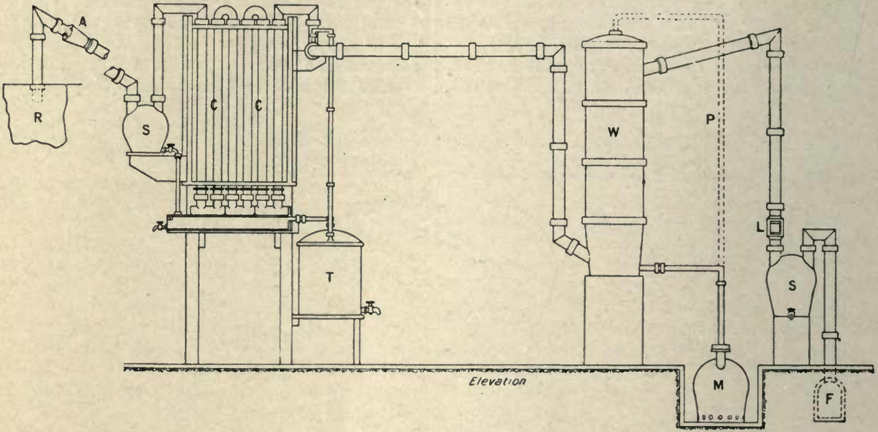

FIG. 3.

Guttmann's apparatus. This condenser, devised by the late Oscar Guttmann, is shown in Figs. 3 and 4. The gases coming from the still R pass into the enlargement A. Here they produce an injector action and suck in a quantity of air through the perforations in the socket pipe, this air causing oxidation of the nitrous to nitric acid. The nitric vapours are led to a preliminary receiver S, and from this to the water-cooled condensing battery of six vertical earthenware pipes. These fit into a connecting pipe below. From this, three pipes, not shown, carry the acid to the cooling trough made of earthenware with transverse pipes through which cooling water circulates. Samples may be taken and the trough emptied by means of a tap. The condensed acid overflows into the collecting vessel T. The apparatus is usually erected in pairs requiring only one cooling trough. Uncondensed gases pass into the tower W. This is filled with stoneware balls presenting a very large surface. The acid condensed here is pumped up repeatedly through the tower, and when

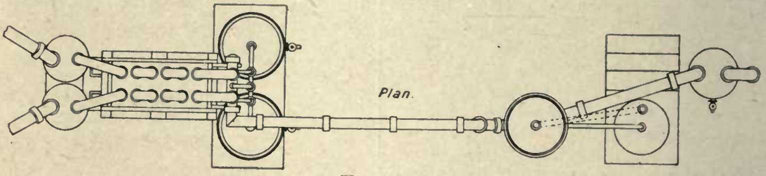

FIG. 4.

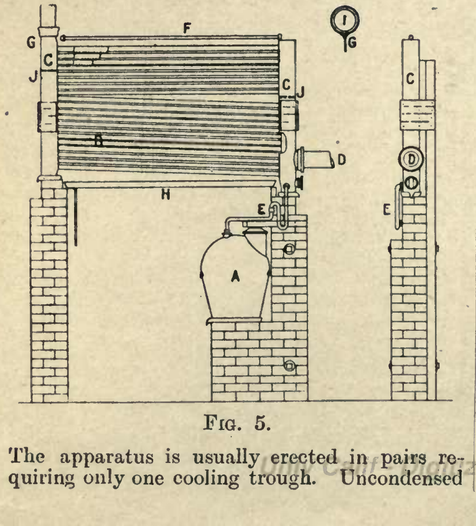

FIG. 5.

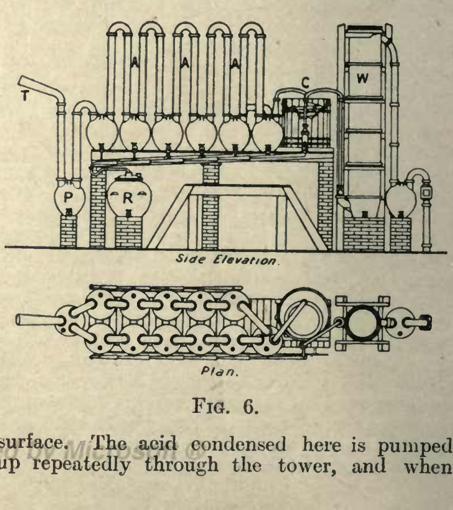

FIG. 6.

it has reached the strength 38°B. it is added to the next charge in the still. The loss of acid is claimed not to exceed 0·60 p.c. Ten hours are required to run off a charge of one ton nitrate, 2 hours for emptying and refilling. Two double batteries for 10,800 lbs. sodium nitrate require, with tower and automatic montejus, a space of 30×45×18 feet. The total cost for a double battery of four stills, including building and erection, is estimated at £1450. This will produce in 24 hours 9820 lbs. nitric acid of 96½ p.c. requiring four men and 15 cwt. coal.

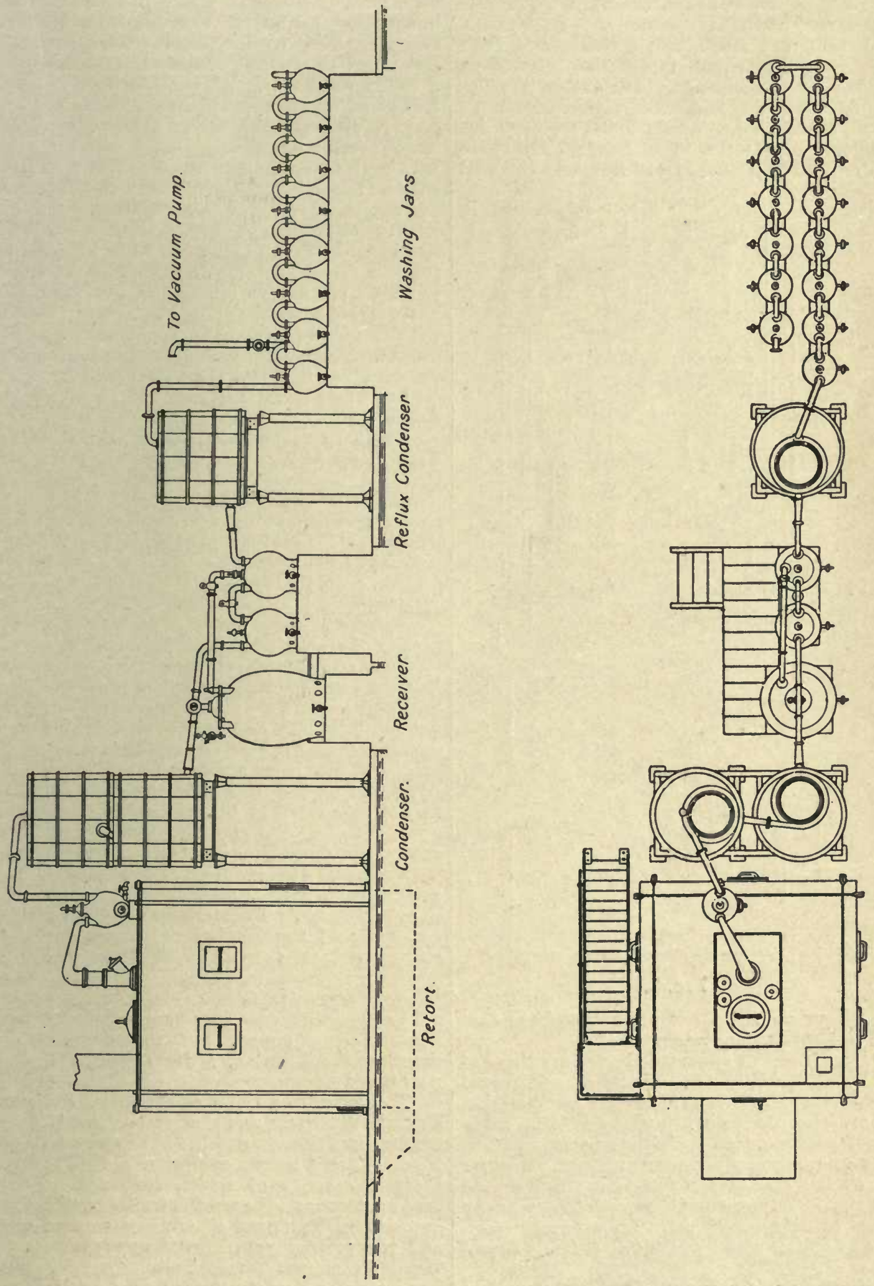

Fig. 7.

Hart's apparatus is shown in Fig. 5. Vapour from the retorts passing through the pipe D is divided, passing through the glass tubes B. These are two metres long, with a diameter of about 4½ centimetres. The cooling water is showered upon a cotton cloth surrounding the upper tube and then drops upon the next lower tube. Even distribution of the cooling water is effected by cutting the two selvedge edges into saw teeth as shown at G and on the upper left-hand corner of the elevation. The glass tubes, being thin, are much better conductors than stoneware pipes, and much less surface is required for condensation. The cost of installation is, therefore, less than with Guttmann's system amounting to about £1200 for 9820 lbs. nitric acid of 96½ p.c. in 24 hours. The space required is about 30×30×18 feet, and the coal and labour do not differ materially from that used in Guttmann's system.

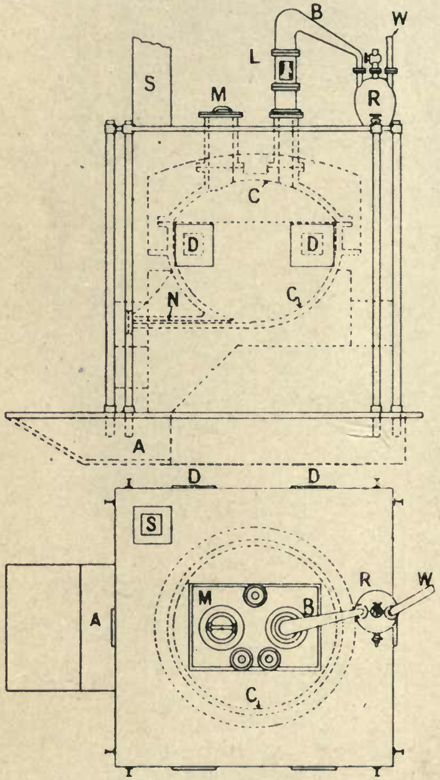

Fig. 8.

Other forms of apparatus in use are those of Dr. Uebel, the Griesheim apparatus, and that of Mr. James M. Thomson in use at Waltham Abbey. In Thomson's apparatus the nitric acid is condensed at a high temperature. The retort has an iron pipe passing through the cover and at the end of the distillation the melted bisulphate is blown out through this pipe by means of compressed air. An air-cooled condensing system sold by Doulton & Co. is shown in Fig. 6.

Distillation in vacuum. This is the method used in Valentiner's process, in which the outlet pipe from the still, Figs. 7 and 8, passes into a small tourill half filled with pumice stone, in which any acid or salt coming over as foam is collected. The vapours then pass through two large water-cooled stoneware coils in series. By a three-way cock the condensed acid at the beginning and end of the operation may be collected in one large receiver, and the 96 p.c. acid, forming about 80 p.c., coming over in the intervening period is collected in a separate receiver. The vapour then passes into the lower end of another stoneware coil acting as a reflux condenser. Then come eight tourills, half of which are half filled with water and half empty, placed alternately. Finally, there are seven tourills alternately empty and half filled with milk of lime. The last tourill is connected with a 12-inch vacuum pump with 16-inch stroke running at 60 revolutions per minute.

For the method of vacuum distillation, lower fuel consumption, purer acid, since less decomposition results, greater durability of the stoneware, no leakage to annoy the workmen, and hence larger yield are claimed. The first cost of the apparatus is, however, very heavy as compared with other systems. Recent improvements are described in U.S. Patent 920224.

Nitric acid from atmospheric air, *v.* Nitrogen, Atmospheric, utilisation of. E. H.

NITROGEN, ATMOSPHERIC, UTILISATION OF. Many nitrogenous substances, more particularly nitrates and ammonium salts, are largely used as plant manures, for though natural formation of nitrogenous bodies does take place, the amount so produced is not nearly sufficient to supply the want of the soil in this respect, more particularly in view of the wastage of combined nitrogen which is always taking place, from bacterial action and from the present system of sewage disposal.

The natural sources from which a soil obtains its supply of nitrogenous substances are electrical discharges in the atmosphere, causing the union of oxygen and nitrogen, with ultimate formation of nitrates and nitrites. By these means it has been estimated that every acre of ground in this part of the world is enriched to the extent of 11 lbs. of combined nitrogen annually. In the tropics, where thunderstorms are more frequent, the amount is larger.

Further, certain leguminous plants, *e.g.* peas, beans, vetch, and clover, possess root nodules, which, by the aid of certain bacteria, are able to fix atmospheric nitrogen, and consequently their growth enriches the soil with nitrogenous products. This discovery was made by Hellriegel in 1866.

Until recently one of the principal nitrogenous manures was guano, but the deposits are practically exhausted, Chile saltpetre having now taken its place.

The supply of Chile saltpetre is, however, limited. The raw material or 'caliche' is not pure sodium nitrate, and has to be recrystallised, which is not a simple operation in Chile, where there is scarcity of water, fuel, and labour. As a consequence, the most accessible and richest deposits in Tarapaca have been worked out, and the greater part of the new districts in Toco, Antofagasta, and Taltal contain, with few exceptions, raw material of much inferior quality to the old and richer deposits of Tarapaca. No trustworthy estimates of the amount of caliche in Chile are obtainable, and whilst it is sometimes stated that the supply will outlast the demand, it seems probable that the actual amount varies from 50,000,000 to 120,000,000 tons, the latter figure corresponding, at the present rate of increased annual consumption, to 42 years' supply, and the former to 21 years' supply.

A third substance used for supplying the soil with nitrogen in the combined form is ammonium sulphate, resulting as a by-product in the manufacture of coal gas, during which process only a small percentage of the nitrogen contained in coal is recovered as ammonia.

The nitrogen contained in ammonia is said to be only nine-tenths as valuable as the nitrogen of saltpetre when used as a manure, and even less when used in large quantities; and, further, in the event of the Chile saltpetre beds becoming exhausted, coal cannot supply all the combined nitrogen which is necessary for the cultivation of the soil, unless more rational methods are employed for the recovery of ammonia.

Moreover, ammonia and nitric acid are not solely used as manures. Numerous colouring matters, explosives such as dynamite and guncotton, or the smokeless powders, *e.g.* melinite, &c., all contain nitrogen, and nitric acid is required for the preparation of these substances and also largely in inorganic technical chemistry. Ammonia is used for manufacturing purposes, *e.g.* the ammonia soda process for the preparation of sodium bicarbonate; also in the laboratory and in the liquid state for ice machines. In addition, there are other important nitrogenous products, such as the cyanides, used for electroplating and in the extraction of gold from its ores. It is not, therefore, a matter for surprise, that many attempts have been made to manufacture nitrogenous products from the practically inexhaustible supply of nitrogen around us in the atmosphere, which is calculated to contain 4000 billion (4,041,200,000,000,000) tons; or, in other words, the air over every acre of ground contains 31,000 tons of nitrogen, or over every 11 acres 354,000 tons, *i.e.* approximately the amount contained in the Chile saltpetre exported in 1909.

Formation of Ammonia.

In considering the methods which may be employed for the fixation of atmospheric nitrogen, mention may be first made of the direct formation of ammonia from its elements nitrogen and hydrogen, for which purpose both these gases have to be isolated. The results of the work done up to the present in this direction have not been of a very hopeful nature, even when the reaction is carried out in the presence of catalysers, because it is reversible, so that at temperatures sufficiently high to cause the formation of ammonia an equilibrium mixture is obtained, containing only a fraction of a p.c. of ammonia.

The Badische Anilin und Soda Fabrik have recently taken up and are experimenting on a method of manufacturing ammonia directly from nitrogen and hydrogen which may prove to be of great importance, though no information from the technical point of view is at present forthcoming.

The process, which is due to Haber (Zeitsch. Elektrochem. 1910, 16, 244), consists in compressing a mixture of 1 part of nitrogen and 3 parts of hydrogen, in presence of a catalyst, the best being osmium, when at a pressure of 175 atmospheres and a temperature near 550°, about 8 p.c. by volume of ammonia is formed. The gases pass from the compression cylinder through a cooling arrangement, where the ammonia liquefies and may be drawn off, whilst the uncombined gases are returned to the compression chamber. Use is made of the heat generated during the reaction to raise the temperature of fresh quantities of gases before they are admitted to the pressure vessel.

Owing to the comparative rarity of osmium, and to the increasing demand for the element in connection with the manufacture of metallic filament lamps, another catalyst has been sought, and crude uranium, resulting when a mixture of uranium oxide and carbon is heated to incandescence between the poles of an electric arc, is now employed, as at a pressure of 175–200 atmospheres it falls to a fine powder, which possesses very high catalytic power.

The necessary nitrogen can be obtained from the atmosphere by using a Linde apparatus, and the hydrogen is produced at a relatively low cost from coal or coke, or by passing steam over heated iron.

The main technical difficulty would appear to be the construction of apparatus of any size capable of withstanding a pressure of 175–200 atmospheres.

Another type of method for the preparation of ammonia is exemplified by passing nitrogen over a heated mixture of magnesium and lime, when the gas is readily absorbed, and the product evolves quantities of ammonia when acted on by water. Methods based on this principle would not, however, appear to have any technical future before them.

There is a very different story to unfold as a result of the observation of Dawes in 1835 that the salt-like substances formed in the preparation of iron in blast furnaces were cyanides. The researches of Bunsen and Playfair about 1840 showed that these cyanides are formed by the union of atmospheric nitrogen with the potassium and carbon compounds in the blast furnace, and as a result a works was started in Grenelle for the manufacture of potassium cyanide by passing nitrogen over a white-hot mixture of coal and potashes or potassium hydroxide. In the next year a factory was built at Newcastle-on-Tyne with twenty-four ovens, but was given up in 1847 owing to the cost of production.

In 1862 Marguerite and de Sourdeval made the important discovery that the absorption of nitrogen took place more readily by using barium hydroxide or carbonate instead of potassium hydroxide, and from the barium cyanide so formed ammonia could be obtained by suitable treatment, whilst at the same time barium hydroxide was regenerated, and could be used over again. Many further modifications of this process were tried, in all of which a mixture as alkali or alkaline earth compounds with coal—*i.e.* a carbide forming mixture—was employed; and if they did not result in complete success, they, at all events, very considerably furthered the solution of the problem of the fixation of atmospheric nitrogen.

In 1869 Berthelot showed that acetylene

and nitrogen interacted to form hydrogen cyanide or prussic acid, and expressed the opinion that cyanides would ultimately be formed by the action of nitrogen at high temperatures on carbides. It was not, however, until 1894, when Moissan and Wilson found that calcium and barium carbides could be prepared in large quantities by heating together barium or calcium oxides with coke in an electric furnace, that the possibility of realising Berthelot's idea became a practical certainty, as proved by the researches of Frank and Caro in 1895–1897.

Moissan demonstrated that the pure carbides would not absorb nitrogen, whereas Frank and Caro proved that impure carbides absorbed large amounts of nitrogen, giving either barium cyanide or a mixture of barium cyanamide and carbon, according to the following equations—

$$BaC_2+N_2=Ba(CN)_2$$
$$BaC_2+N_2=BaNCN+C,$$

and both products formed sodium cyanide on fusion with sodium carbonate

$$Ba(CN)_2+Na_2CO_3=BaCO_3+2NaCN$$
$$BaNCN+C+Na_2CO_3=BaCO_3+2NaCN.$$

As a result a cyanide company was formed by Siemens and Halske, the Deutsche Bank, and the Frankfurt Gold and Silberscheideanstalt, and the whole process was modified as a result of the discovery that when calcium carbide is used instead of barium carbide no cyanide, but only cyanamide, is obtained—

$$CaC_2+N_2=CaNCN+C,$$

and, again, the mixture of calcium cyanamide and carbon can be converted into cyanide by fusion with alkali carbonates and chlorides—

$$CaNCN+C+Na_2CO_3=CaCO_3+2NaCN.$$

The crude mixture of calcium cyanamide and carbon is now known as 'Kalkstickstoff,' 'Stickstoffkalk,' or 'Nitrolim,' and works for the manufacture of this substance to the extent of 165,000 tons per annum have been completed in Norway, Germany, Austria-Hungary, Italy, France, Switzerland, the United States of America, the Central Provinces of India, and Japan, and are projected in South Africa and Canada. Great Britain is at present the notable exception.

The largest of these works is that of the North-Western Cyanamide Company, situated at Odda, on the Hardanger Fjord, Norway. It was constructed with British capital, and organised to manufacture a special acetylene plant designed for a dry process. Owing to the uncertainty of the supply of carbide, several undertakings, including the Alby Works in Sweden, combined for the construction of new factories, and at the present time there are at Odda a hydro-electric power installation, producing 23,000 electrical horse-power; the Alby Carbide Works, with an annual output of 32,000 tons of carbide; and the North-Western Cyanamide Works with an output of 20,000 tons of nitrolim annually.

The electric power for driving the works is derived from the river Tysse, with its source in the Ringedalsvand, which has a summer water level 1430 feet above the sea. The water passes by subterranean tunnel to the lower Vetlevand and thence again by tunnel to a basin constructed at the top of the precipitous slope of ground around the Hardanger Fjord. Then it falls through iron pipes 1350 feet directly on to the turbines in the power house, which is constructed close to the water level of the fjord, and contains six turbines of the Pelton wheel type and dynamos which work on the three-phase alternating system, with a tension of 12,000 volts and a frequency of 25 per second. They run 375 revolutions per minute, developing 4600 horse-power, and the output of the each generator~~s~~ is 4400 electric horse-power. Each turbine is coupled directly to its corresponding generator, and five sets run synchronously to produce at the present time 20,000 horse-power at the terminals of the switch-board at Odda, 3¾ miles distant, though the supply of water is ample to produce 80,000 horse-power when required.

Manufacture of Carbide. The calcium carbide used for making nitrolim is manufactured by the Alby Carbide Company by fusing together lime (as free as possible from magnesia and alumina) with anthracite coal brought from Wales. There are five lime-kilns, each of a capacity of 30 tons, and four of these supply the lime necessary for twelve electric carbide furnaces, each of 1400 kilowatts capacity, worked at 2800°–3000°, and capable of yielding 7–8 tons of carbide per 24 hours.

Preparation of Nitrogen. At Odda the necessary nitrogen is obtained from the atmosphere by using a Linde apparatus, which is run by a 200 horse-power electric motor, and is the largest yet made, being capable of producing 13,000 cubic feet of nitrogen per hour.

Air drawn through two towers, A, A, containing sodium hydroxide liquor to free it from carbon dioxide, is compressed (compressors, B,B,B,B) to about 4 atmospheres, cooled by passage through a water tower, C, and then a reversing air cooler, DD (cooled by cold oxygen or nitrogen from other parts of the apparatus), where the water contained in the air is condensed, and ice forms. This is got rid of by periodically reversing the direction of the flow of gas. The air next passes to an ammonia cooler, E, where the temperature is reduced to −20° or −25°, when practically all moisture is removed, and almost pure and dry air passes to a separator and rectifying column, F, where it is further cooled by an oppositely flowing current of nitrogen or oxygen evaporating from the liquid state. The air passes from this still at a very low temperature, and is led into a coil immersed in a tank of liquid oxygen, where it liquefies, being at a pressure of 4 atmospheres. From this coil it is allowed to expand through a throttle valve, with the result that a large portion is obtained in the liquid state, and at approximately atmospheric pressure. The liquid air is then led to a point near the top of the rectifying column, filled with glass marbles, over which it trickles. On its way down it meets an ascending current of gas evaporating from the liquid below, which gas is rich in oxygen (about 54 p.c.), and as the oxygen has a higher temperature of liquefaction than the liquid air which it meets in the rectifier, it is condensed by an equivalent proportion of nitrogen being distilled off from the descending liquid (at atmospheric pressure oxygen boils at −183° and nitrogen at −196°). The latter enters a tank at the bottom of the tower enriched in oxygen, while the gas passing off is nearly pure nitrogen, which is rendered quite pure by further rectification. As it is not possible to free air altogether from moisture and carbon dioxide before its admission to the rectifying column, these impurities are reduced to the solid state, and can be removed, but gradually choke the apparatus, every part of which is therefore in duplicate, and the working period of one part is from 6 to 10 days (*v.* NITROGEN).

At Westeregeln the method employed for preparing nitrogen is to pass air over heated copper, and subsequently to reduce the copper oxide formed with generator gas.

Caro's method consists in passing producer gas over a mixture of copper and copper oxide; all oxygen and carbon monoxide are got rid of, and there results a mixture of carbon dioxide and nitrogen, from which the carbon dioxide is absorbed by sodium bicarbonate.

Manufacture of nitrolim. In the preparation of nitrolim it is of the greatest importance that the nitrogen used should be pure, as the presence of (*a*) water would cause the decomposition of the carbide yielding acetylene—

$$CaC_2+2H_2O=Ca(OH)_2+C_2H_2;$$

(*b*) oxygen would increase the proportion of carbonate of lime at the expense of the cyanamide, and thus reduce the percentage of nitrogen; (*c*) carbon monoxide and carbon dioxide both act on calcium carbide, liberating carbon in the form of graphite—

$$CaC_2+CO=CaO+3C$$
$$2CaC_2+CO_2=2CaO+5C.$$

Moreover, when carbon dioxide acts on nitrolim at the temperature of the absorption process, nitrogenous compounds are decomposed with separation of carbon. Thus Caro (Chem. Trade Journ. 1909, 44, 621) has shown that a specimen of nitrolim containing 19·67 p.c. of nitrogen and 11·89 p.c. of carbon, when treated with carbon dioxide at 800°, gave a product containing 6·93 p.c. of nitrogen and 17·34 p.c. of carbon, whilst at 1000° the product contained 22·78 p.c. of carbon and only 1·82 p.c. of nitrogen.

Absorption process.—The absorption of nitrogen depends on the physical condition of the carbide, on the proportion of lime, sulphides, phosphides, carbon and carbides present, and as to whether the carbide is freshly treated or after prolonged storage. The reaction

$$CaC_2+N_2 \rightleftarrows CaNCN+C$$

(in which the carbon is liberated in the form of graphite) is exothermic and reversible, this latter at a temperature of 1360° for a certain specimen of carbide examined by Caro. For this reason the glowing carbide, as it comes from the electric furnaces (worked at a temperature of 2800°–3000°) cannot be directly treated with nitrogen. But on cooling, the carbide sets to a rock-like mass which is not permeable to nitrogen, it must therefore be crushed, an operation carried out in an air-tight apparatus in order to prevent access of moisture, which would, as already mentioned, decompose the carbide.

The furnaces are of two types, those heated internally and those heated externally. The latter, which are in use at Piano d'Orte, are similar in design to the well-known retorts used in the manufacture of coal gas, but they are

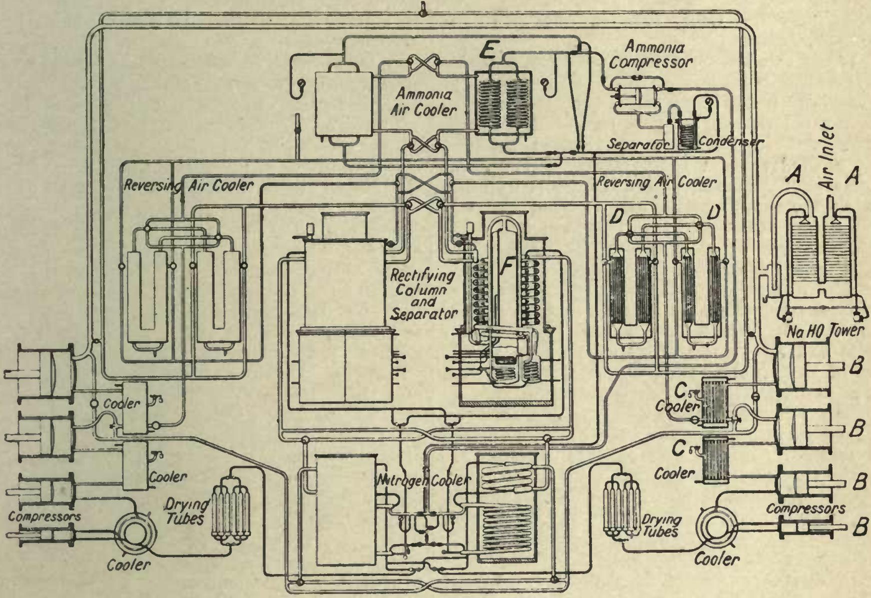

FIG. 1.

Diagram of the Linde Plant used at Odda.

open to several serious objections. The exothermic nature of the reaction causes overheating of the furnace walls and consequent rapid wear; the reaction may easily reach the point at which it becomes reversible, and the product, which has a considerably less bulk than the starting material, sets to a rock-hard mass on the outer walls of the furnace, from which it has to be removed by force. A good deal of work has been done in the direction of obviating these difficulties by lowering the reaction temperature by the addition of small amounts of certain salts, *e.g.* calcium chloride or calcium fluoride (Bredig, Zeitsch. Elektrochem. 1907, 13, 605, 610, 612; Foerster and Jacoby, *ibid.* 1909, 15, 820; Caro, Zeitsch. angew. Chem. 1910, 23, 2405).

When calcium chloride is used the reaction temperature is lowered to 700°–800°, cyanamide formation increasing with the amount of calcium chloride for a given time and temperature; but in the case of calcium fluoride, where the reaction temperature is 900°, the capacity of saturation of nitrogen is approximately the same, whether using 1, 2, 5, or 10 p.c. of calcium fluoride, the best results being obtained with 2 p.c.

If the limitation of absorption of pure carbide at temperatures under 1000° is due to the cyanamide forming a protecting layer over the carbide, which at higher temperatures melts and allows the entry of nitrogen to the rest of the carbide, then the action of calcium chloride or calcium fluoride is simply a lowering of the softening-point of this layer. There can be no doubt that the different influences exerted by calcium chloride and calcium fluoride are due to the differences in the melting-points of the salts (calcium fluoride, 1330°; calcium chloride, 780°), and these melting-points are further influenced (lowered) by admixture with carbide and cyanamide.

Calcium cyanamide, as already mentioned, passes readily into calcium cyanide when fused with certain salts, and the question naturally arises whether the use of calcium fluoride or chloride in the preparation of cyanamide would not tend to increase the amount of cyanide in the resulting product. Calcium cyanamide contains normally less than 0·1 p.c. of cyanide, and Foerster and Jacoby have proved that the amount is not influenced by the use of calcium salts in its preparation, though it is increased considerably when chlorides of the alkali metals are employed.

The work just alluded to is not only of theoretical interest, but has a practical bearing, for the process, due to Polzeniusz, and employed by the Gesellschaft für Stickstoffdünger at Westeregeln consists in treating a mixture of calcium carbide and calcium chloride (up to 10 p.c.) with nitrogen, the reaction temperature being about 700°. The resulting substance is known as 'Stickstoffkalk,' and has the approximate composition N=20; Ca=45·0; C=19·5; Cl=6·5; impurities=9 p.c. The technical importance of the process is shown by the fact that the Westeregeln company has built another large works at Knapsack, in the neighbourhood of Cologne, where 8000–10,000 tons of 'Stickstoffkalk' can be produced annually.

The above-mentioned objections to the externally heated furnace do not hold good when electric furnaces are employed, as by the North Western Cyanamide Company at Odda, in which the heating is effected within the mass and with very different results. The electric retorts proper are made of fireproof material, lined with sheet iron, and are transported between the charging hopper and the furnace by an overhead electric trolley. These retorts are placed in broad, not very high, thermally insulated drums, which do not come in contact with the heated mass. Each furnace has suitable regulating valves and small control meters. The nitrogen is delivered under pressure into the retorts, which are then heated to 800° by the passage of an electric current through a finger-thick pencil of carbon placed in the axis of the retort. Under each furnace a transformer is located converting a voltage of 11,100–50, giving 28,000 amperes. The absorption of nitrogen is allowed to proceed for from 30 to 40 hours, and saturation is made apparent by the controlling gas meter coming to a standstill. The reaction is not so strongly exothermic that when once started it will go on to completion, but it does so if the current is stopped, when a certain relation exists between the cyanamide formed and the unacted on substance, and since the heat generated is then used for the continuation of the reaction there can be no superheating, and therefore no reversal of the process. Moreover, as the reaction takes place from inside outwards, the shrinkage of material tends inwards, consequently there is a minimum wear of furnace material, and the product can be easily removed from the retort. During the process the carbide is converted into a hard mass, not unlike coke, which is removed from the furnace, after cooling by a current of air for 8–12 hours, ground to a fine powder in an air-tight plant, and then forms the 'nitrolim' of commerce.

This substance contains 57–63 p.c. of calcium cyanamide, corresponding to a total nitrogen content of 20–22 p.c.; 20 p.c. of lime; 7–8 p.c. of silicic acid, iron oxide, and alumina; 14 p.c. of carbon in the form of graphite, also very small amounts of urea, calcium carbamate, and guanidine, but the amounts of these latter substances increase when the nitrolim has been stored or exposed to the action of water vapour.

In the furnace house at Odda there are 196 electric furnaces, seven in a row, each capable of taking 300 kilogram charges and of producing about 1 ton of nitrolim per week.

Uses of nitrolim. The primary use of nitrolim, at the present time, is as a nitrogenous manure, and a considerable number of field experiments have been made on various crops in the United Kingdom. Accounts of the experiments carried out by Dr. Voelcker at Woburn for the Royal Agricultural Society are described in the Journals of that Society for the years 1908, 1909, and 1910, and the results of experiments made at Rothamsted under the direction of Mr. A. D. Hall are detailed in the annual reports issued by the Lawes Agricultural Trust for 1909 and 1910. Abstracts of numerous reports issued by various agricultural colleges and institutions will be found in the monthly summaries of agricultural experiments in Vol. XVI. and XVII. of the Journal of the Board of

Agriculture (*see* also this Journal, Vol. XIV. 652: Vol. XVI. 1006).

Nitrolim is converted by superheated steam into calcium carbonate and ammonia, but its decomposition in the soil is certainly not of such a simple nature. On exposure to moist air it spontaneously disengages small quantities of ammonia, but cyanamide is also formed,

$$CaNCN+CO_2+H_2O=CaCO_3+H_2NCN,$$

which may then be transformed into urea—

$$H_2NCN+H_2O=CO(NH_2)_2,$$

this latter substance yielding ammonium carbonate by the process of ammonic fermentation—

$$CO(NH_2)_2+2H_2O=(NH_4)_2CO_3.$$

Ammonium carbonate can be directly or indirectly assimilated by plants, indirectly after first being converted into nitric acid by the nitrifying bacteria. According to the conditions of the soil, other substances may be formed, *e.g.* basic calcium cyanamide, dicyandiamide, which latter substance, according to the opinion originally expressed by Immendorff, is toxic to plant life. It does not kill them when applied in proper quantity, but in excess it causes a considerable diminution in the crop. Analytical methods for the determination of the amounts of cyanamide and dicyandiamide have been suggested by Brioux (Ann. Chim. anal. 1910, 15, 341; *see* also Caro, Zeitsch. angew. Chem. 1910, 23, 2405).

Ammonium sulphate from nitrolim. When nitrolim is treated with superheated steam all its nitrogen is given off in the form of ammonia,

$$[C+CaNCN]+3H_2O=CaCO_3+2NH_3+C$$

and at Spandau, near Berlin, at Piano d'Orte, and at Odda plants have been constructed for the preparation of considerable quantities of ammonium sulphate by this method, in which all the lime and one-third of the necessary carbon are regained in a form suitable for the preparation of carbide.

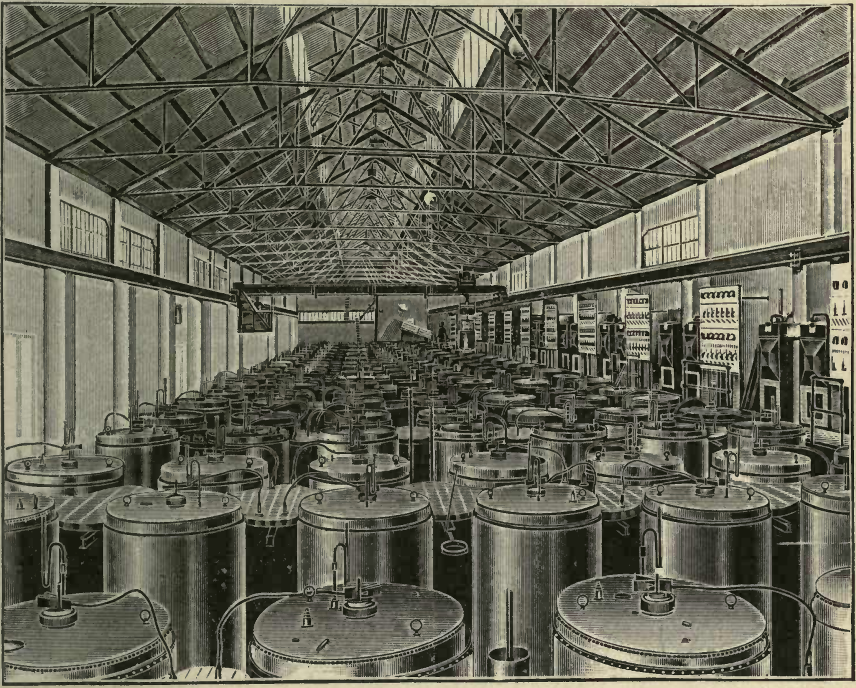

FIG. 2.

Odda Furnace House.

Nitric acid from nitrolim. The fact that ammonia can be converted into nitric acid by oxidation in presence of a catalytic agent has been known for a long time, but the desirability of making this a manufacturing process has not been given much attention until recent years; partly on account of the comparative scarcity of ammonia, and also because the action does not take place wholly in accordance with the equation $NH_3+2O_2=HNO_3+H_2O$; but other products, including elementary nitrogen, may be formed, $2NH_3+3O_2=2N_2+6H_2O$. The process has now been perfected by Ostwald, so that nitric acid is the sole product, being produced in 85–90 p.c. of the theoretical amount and of a purity rendering it suitable for use in the manufacture of explosives.

A plant has been in constant operation for some time at the works of the Lothringen Colliery Company at Gerthe, near Bochum, which is producing upwards of 1800 tons of nitric acid or 1200 tons of ammonium nitrate annually.

Carefully purified ammonia is mixed with air and passed through enamelled iron tubes to a chamber containing a special platinum catalyser, where the amount of nitric acid formed is largely influenced by the rate at which the mixture of gases is passed over the contact agent. The product passes through aluminium tubes to a condensing plant, consisting of six towers packed with broken earthenware over which nitric acid trickles and circulates continually, thus exposing a large amount of cooling surface. The acid formed contains 55 p.c. HNO_3, but further condensing arrangements can be added, whereby acid of 66 or 92 p.c. HNO_3 can be produced. The acid is at once neutralised with ammonia, and the resulting ammonium nitrate sent out into commerce.

The world's rights, other than in Westphalia and Rhineland for the production of nitric acid by this method have been taken over by the Nitrate Products Company Limited, and works will shortly be erected either near the Thames, the Scheldt, or at Odda, where the necessary ammonia will be produced directly from nitrolim.

Frank and Caro have suggested instead of platinum a mixture of thoria and ceria, and state that, though this method of making nitric acid is not the shortest, it is technically the most economical, and therefore specially applicable where power is scarce or expensive.

Cyanides from nitrolim. Cyanides are now manufactured from nitrolim by the Stickstoffwerke at Spandau, by a reaction represented by the following equation $C+CaNCN \rightleftarrows Ca(CN)_2$, and since the nitrolim contains the requisite amount of carbon it is only necessary to add some fusible material to effect this change. The raw fluxed substance is used for gold extraction, and is quite as good as pure potassium cyanide for this purpose.

It will be seen from the above equation that the process is a reversible one, and, moreover, the nitrolim $CaNCN+C \rightleftarrows CaC_2+N_2$ may form carbide at the temperature of the reaction, and this carbide would act on the cyanide as follows $Ca(CN)_2+CaC_2=2CaNCN+2C$. Exact details of the manufacture of cyanides at Spandau are not forthcoming, but 'by using appropriate furnaces, special appliances for melting and cooling the material,' the difficulties have been overcome, and cyanamide may be quantitatively converted into cyanide. Pure potassium cyanide is obtained from the resulting melt in the ordinary way, modified to suit the special conditions, and is put on the market in the form of briquettes.

Dicyandiamide, which is produced as a decomposition product of nitrolim by cold water $2CaNCN+4H_2O=2Ca(OH)_2+(H_2NCN)_2$, is used in the preparation of organic dyestuffs and in place of ammonium oxalate as a deterrent for reducing the temperature of combustion of explosives. In consequence of the high percentage of inert nitrogen (66·6 p.c.) in dicyandiamide, it evolves strong pressure in guns, but its decomposition produces little heat, unlike the other constituents of explosives, which contain more carbon and hydrogen. This is of importance with ordnance powders, *e.g.* cordite, which rapidly destroy rifling on account of the high temperature of combustion.

Various other substances may be produced by treating an aqueous solution of nitrolim with acids; among these are urea, guanidine, nitroguanidine, &c., which are manufactured at Spandau.

Ferrodur is a mixture of nitrolim and other materials used for case hardening and tempering iron and steel. It produces an extraordinary depth of hardened surface without deteriorating the material.

FORMATION OF NITRIC ACID.

Another and quite distinct type of method employed for the fixation of nitrogen involves the direct combination of nitrogen and oxygen.

The observation that the two gaseous elements, nitrogen and oxygen, are capable of direct combination was established by Priestley in 1784, who found that a slow union took place on passing electric sparks through the mixture. Cavendish confirmed and extended this observation in 1785, after having previously (1781) shown that the combustion of hydrogen in excess of air gave water containing nitric acid, and (1784) that the same result might be obtained when a mixture of hydrogen and air was exploded. But though patents were taken out by Newton and Le Febre in 1859 for the use of electricity in causing the union of nitrogen and oxygen, it was not till 1890 that the examination of the problem came into prominence.

In 1892 Sir William Crookes showed an experiment on the flame of burning nitrogen, in which air was caused to burn with the production of nitrous and nitric acids by the passage of a strong induction current, and in 1897 Lord Rayleigh published his Observations on the Oxidation of Nitrogen Gas, made in the course of the experiments which led him and Sir William Ramsay to the discovery of argon. In the actual experiment a glass vessel of 50 litres capacity contained a burning electric flame causing the combination of nitrogen and oxygen. The resulting oxides of nitrogen were absorbed by allowing a fountain of sodium hydroxide solution to play on the top of the vessel containing the arc, serving the double purpose of keeping the vessel cool and of presenting a large amount of absorbing surface. The practical result calculated from Lord Rayleigh's figures, was that 1 kilowatt hour would be required to form 50 grams of nitric acid. Lord Rayleigh pointed to the electrical difficulties of producing a steady high-tension flame for oxidising nitrogen, and though his apparatus could scarcely be made to apply to technical purposes, it is not too much to say that he was the first to show the possibility of fixing atmospheric nitrogen in an economical manner, proportionate to the electric energy expended.

It is interesting to note that an Englishman, McDougall (1899), in conjunction with Howles, was the first to establish a somewhat small, though complete, plant for the production of nitric acid from air, and, though the exploit had to be given up, the lessons learnt from it have been of the utmost importance for the solution of the problem. In 1902 Bradley and Lovejoy founded the Atmospheric Products Company (capital $1,000,000), which utilised the power of the Niagara Falls as the source of electricity; but owing to the comparative smallness of the yield (430 kilos. saltpetre per kilowatt year), coupled with the complexity of the apparatus, as well as the initial expense, the plant was closed down in 1904.

The method due to Kowalski and Moscicki resulted from the observation that the output of nitric oxide was increased by using a current of very high frequency and voltage; but it has apparently been abandoned, chiefly on account of the difficulties connected with the high voltage employed. A new form of furnace has been invented by Moscicki and is being experimented with at Fribourg, but no details of the process are at present forthcoming.

The first real practical success was attained by Birkeland, in Christiania (1903), when working in conjunction with Eyde, the Scandinavian French Company, founded by Birkeland and Eyde, established a factory at Notodden, in Norway, known as the Norsk Hydroelektrisk Kvaelstofaktieselskab. Work is carried on in the factory day and night, week-day and Sunday, some 300-400 people being employed in three shifts of 8 hours each. The electric power is derived from the Svaelgfoss, about 1½ miles up the valley, and it is interesting to note that the water falling over the Rjukanfoss, where 227,000 electric horse-power are to be developed, generates in its passage to the Hitterdal lake, 40,000 horse-power at the Svaelgfoss, 15,000 horse-power at the Lienfoss, and 20,000 horse-power at the Tinfoss, thus making a total of 75,000 horse-power at Notodden. It is calculated that the total available horse-power of Norway is 5-6,000,000, and of all Europe 50-60,000,000.

The problem of preparing nitric acid from air, has also been taken up in other countries than Norway, notably by the Badische Aniline and Soda Fabrik, who built an experimental works at Christiansand, in Norway, and in 1906, in conjunction with its two allied firms—the Farbenfabriken vorm. Fried. Bayer & Co. (Elberfeld) and the Actiengesellschaft für Anilinfabrikation in Berlin—an agreement was come to with the Scandinavian French Company, forces were united, and two new Norwegian companies were floated.

1. A power company (Kraft Aktieselskab), with a capital of 16,000,000 kronen, whose duty it is to develop and bring into harness further Norwegian waterfalls.
2. The Norsk Saltpeterverker, with a capital of 18,000,000 kronen, which is concerned in building and running Norwegian saltpetre factories making use of the power supplied by the first company.[1]

In addition to the Notodden factory belonging exclusively to the Norsk Hydroelektrisk Company, works are to be erected at Matre and Tyin falls, probably at the Vaunna Falls, and have been erected at the Rjukan Falls, near to Notodden (*cf.* Scott-Hansen, Faraday Society Lecture, May, 1911). These latter falls, where the total height for power purposes is over 1500 feet, will be harnessed in two stages, and are expected to yield 227,000 electric horse-power. The first power station is practically completed, as are the works at Saaheim, 3 miles lower down the valley. The produce of the works will be carried by a light railway, built for the purpose, from Saaheim to Rollag (18-19 miles) on Lake Tinn; thence the railway trucks are transported by steam ferry along the lake to Tinnosit (18-19 miles), where they again join the new railway to Notodden (9 miles). At present everything is taken by lighter from Notodden to Skien, where it is loaded into ocean-going vessels, but at no very far distant time the locks on the waterways and lakes between Skien and Notodden are to be increased to the necessary size to allow sea-going vessels to load up at Notodden.

Some theoretical considerations.—Sir William Crookes and Lord Rayleigh pointed out that in the union of nitrogen and oxygen electricity only works thermally, supplying the necessary energy in the form of heat, the primary product of the reaction—nitric oxide—being endothermic. But the reaction $N_2+O_2=2NO$ is incomplete, as it is reversible, and an equilibrium mixture is attained when a small but definite amount of nitric oxide is produced. Nitric oxide is not stable above 1200°, and the amount formed at this temperature is extremely small. Even at 1500° only one-tenth of a p.c. of the nitrogen in the air is converted into nitric oxide, and a very much higher temperature is necessary to bring about a reasonable degree of oxidation. Muthmann and Hofer, and especially Nernst (Zeitsch. anorg. Chem. 1906, 49, 213) and his pupils, have studied this question, and the following table gives an idea of the results obtained:—

Temperature. Absolute C	Volume per cent. NO observed	Volume per cent. NO calculated
1811	0·37	0·35
1877	0·42	0·43
2033	0·64	0·67
2195	0·97	0·98
2580	2·05	2·02
2675	2·23	2·35
3200	5·0 (about)	4·39

It is apparent that an essential of success must consist in heating the air to as high a temperature as possible, followed by very rapid cooling to a temperature at which the decomposition of the nitric oxide takes place so slowly as to be inappreciable—*i.e.* below 1000°. This rapid cooling can be more efficiently carried out on small scale experiments than on the large scale, and, consequently, the actual yields obtained in the manufacture of nitric oxide are always smaller than trial experiments would indicate. It must be remembered that every chemical change occupies a certain time, and that the equilibrium in this reaction does not occur instantaneously, so that the more rapid the cooling the more efficient the process becomes.

Further, as nitrogen and oxygen unite in the proportions $O_2:N_2$, the mixture of these gases in the atmosphere (21 p.c. oxygen, 78 p.c. nitrogen by volume) is not the most favourable for the formation of nitric oxide, and Haber and König have shown that when a mixture of equal volumes of nitrogen and oxygen are used the resulting gases contain as much as 14 p.c. of nitric oxide; but this is a point which at present

---

[1] Since this article was written the Scandinavian French Company have bought all German interests in the manufacture of nitric acid from the atmosphere, which probably means that the Schönherr furnace and absorption system have not proved themselves to be better than those of Birkeland and Eyde.

would not appear to have much technical bearing, partly on account of the cost of production of the required oxygen, and partly because a very large proportion of the gases pass through the process unchanged and are lost.

It has been stated that the electric arc brings about the union of nitrogen and oxygen simply by the heat generated; but, on the other hand, many research workers have shown that nitric oxide is produced by the silent electric discharge, and Warburg (Zeitsch. Elektrochem. 1906, 12, 540; Ann. Physik. 1906, [iv.] 20, 743; 1907, 23, 203) has expressed the opinion that the kinetic energy of the gases produced by the electric discharge is directly used in the formation of nitric oxide, before the state of heat equilibrium is reached.

Holwech (Zeitsch. Elektrochem. 1910, 16, 369) has described experiments on the formation of nitric oxide by passing air through short electric arcs (0·8–4 mm.) with water-cooled anode, after the manner first proposed by Morden, whose results are confirmed. Generally speaking, the shorter the arc and the more slowly the air is supplied, the greater the concentration of nitric oxide, the maximum obtained being 9 p.c., and the yield of nitric acid 70–80 grams per kilowatt hour. As the temperature of the arc did not exceed 3000° (absolute), at which temperature the purely thermal equilibrium between oxygen, nitrogen, and nitric oxide corresponds with approximately 4 p.c. nitric oxide, the formation of the latter in these experiments must be due to collisions of ions, whereas in the low-tension arcs used industrially the phenomenon is probably purely thermal. Haber and Holwech (Zeitsch. Elektrochem. 1910, 16, 810) have also studied the formation of nitric oxide in the arc under pressure.

Many methods (*cf.* Haber and König, Zeitsch. Elektrochem. 1910, 16, 18) for causing the union of nitrogen and oxygen have been proposed in which the air is heated to a sufficiently high temperature by the combustion of certain substances, *e.g.* Haber's process, consisting in burning carbon monoxide with air under pressure, but they all suffer from the difficulty of obtaining a really high temperature, and from the fact that the oxides of nitrogen formed are mixed with enormous quantities of other gaseous products of combustion, especially water vapour (not the case in Haber's process), hence the difficulty of cooling the gases is greatly increased.

In the development of the technical problem of the oxidation of atmospheric nitrogen, only those processes have so far had any success which use electric energy as the means of bringing about the reaction, and of the various furnaces which have been proposed, those of Birkeland and Eyde, Schönherr and Pauling, may be quoted as typical examples.

The Birkeland and Eyde arc flame. In this type of furnace an electric arc is produced in a highly magnetic field.

When two pointed copper electrodes, attached to a high tension alternator, are placed horizontally between the poles of a powerful electromagnet in such a way that the terminals of the electrodes are in the middle of the magnetic field the electric arc flame assumes the form of a disc. Strictly speaking, the arc is blown into a half disc at every half period, but the impression on the eye is that of a quietly burning disc. When the length of the electric arc increases, the electric resistance becomes greater, until it becomes so great that a new electric arc starts from the points of the electrodes. The formation of these disc flames has been explained by Birkeland as follows (Faraday Society Lecture, 1906):—

‘At the terminals of the closely adjacent electrodes, a short arc is formed, thus establishing an easily movable and ductile current-conductor in a strong and extensive magnetic field, *i.e.* 4000–5000 lines of force per square centimetre in the centre. The arc thus formed then moves in the direction perpendicular to the lines of force, at first with an enormous velocity, which subsequently diminishes; and the extremities of the arc retire from the terminals of the electrodes. While the length of the arc increases, its electric resistance also increases, so that the tension is heightened until it becomes sufficient to create a new arc at the points of the electrodes. The resistance of this short arc is very small, and the tension of the electrodes, therefore, sinks suddenly, with the consequence that the outer long arc is extinguished. It is assumed that while this is taking place the strength of the current is regulated by an inductive resistance in series with the flame. In an alternating current all the arcs with a positive direction of current run one way, while all with a negative direction run the opposite way, presupposing the magnetising to be effected by direct currents. In this way a complete, luminous, circular disc is presented to the eye. When the flame is burning it emits a loud noise, from which alone an impression may be obtained

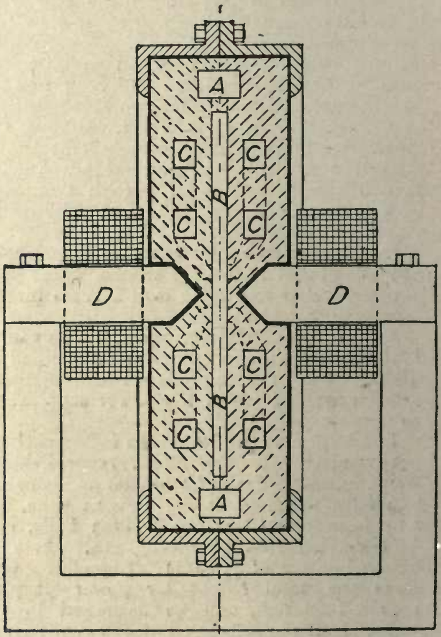

FIG. 3.

Original type of furnace.

of the number of arcs formed per second in the flame, a matter which may, however, be more minutely investigated by means of an oscillograph.'

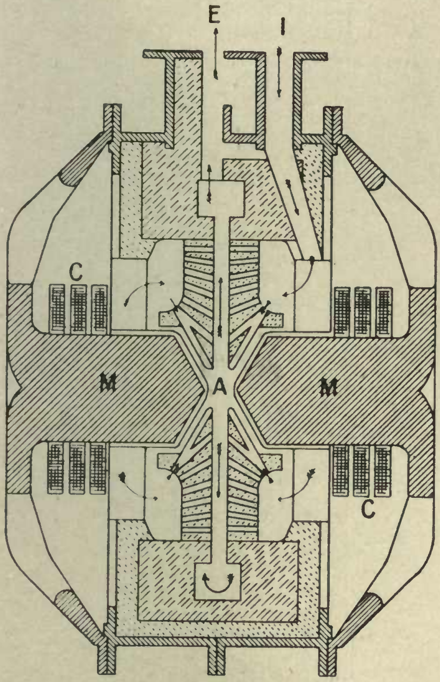

Fig. 4.
New type of furnace showing the passage of the gases.

For the purpose of utilising this alternating current disc flame (*cf.* Eyde, Journ. Royal Soc. Arts, 1909, 57, 568), it is enclosed in a special iron furnace, lined with fire-clay brick, and these linings are found to wear very well, for, in spite of the enormously high temperature of the disc flame, the temperature on the walls does not rise above 800° during normal working, owing to the cooling effect of the current of air.

The fire chamber of the furnace, B, Fig. 3, is from 5–15 cm. wide in the direction of the lines of force, and is made of perforated chamotte. It contains the electrodes, which are not shown in Fig. 3, but their position relative to the magnets D, D, may be seen in Fig. 5.

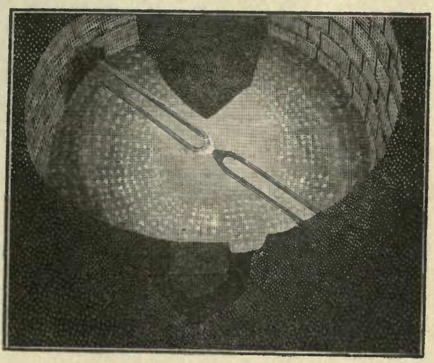

Fig. 5.
Birkeland and Eyde arc flame.

Air is driven by means of a Roots' blower to the flame along the channels marked C and through the chamotte lining of the fire chamber in an evenly distributed supply. After passing the flame in a radial direction it arrives at a peripheral channel A, whence it is conducted away to the oxidation towers. The passage of the gases through the furnace may be more easily followed by examining the section of a newer type of furnace shown in Fig. 4. The electrodes are made of 2·5 cm. thick copper tubing, through which water passes to cool

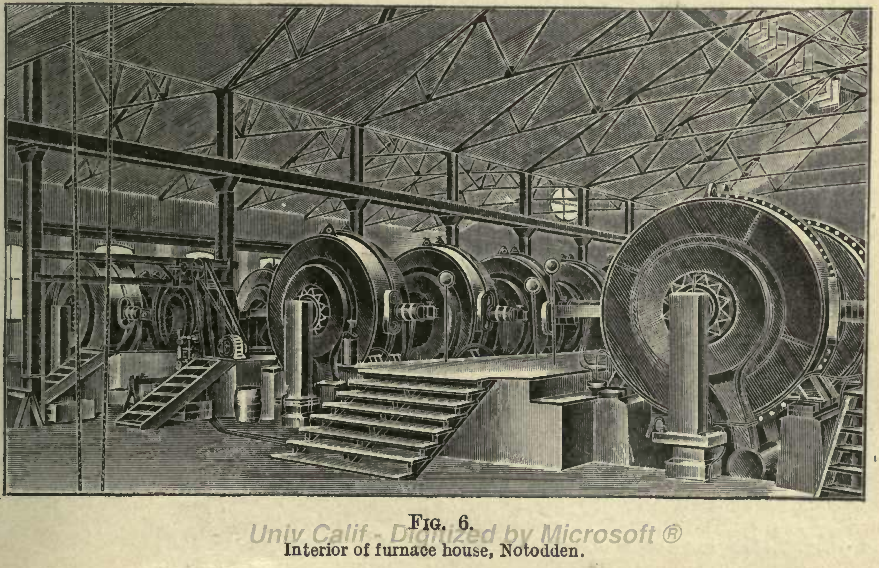

Fig. 6.
Interior of furnace house, Notodden.

them, and they are capable of taking up 1500 horse-power, giving a flame of 1·8 metres in diameter. They are exchanged and repaired after being in use for about 400–500 hours, the exchange itself taking about 15 minutes to accomplish. The temperature of the flame exceeds 3000° or, perhaps, 3500°, and the temperature of the escaping gases of which 26,000–28,000 litres pass every minute through each furnace, may vary between 800 and 1000°. In all thirty-six furnaces have been installed at Notodden, each employing 800 kilowatts, and with a working tension of 5000 volts.

Larger furnaces are being experimented with, one of 3000 kilowatts being in regular use, and it has been proved that the yield of nitric acid increases directly with increase in kilowatt power of the furnace.

The Schönherr arc flame. As already mentioned, the fixation of atmospheric nitrogen has occupied the attention of the Badische Anilin and Soda Fabrik, and as a result Schönherr, in conjunction with the engineer, Hessberger, has succeeded in bringing out an arc flame which, from the results obtained at the experimental works at Christiansand, is claimed to possess advantages over the Birkeland and Eyde flame. Whether this is so or not, has not been definitely decided, but extensive experiments are at present being carried out at Notodden to decide the point, and the new works at Rkujan will be fitted with the furnaces which, as a result of these experiments, are proved to have the greatest efficiency, when all the various manufacturing details have been fully worked out (*cf.* footnote, p. 705).

The Schönherr arc flame differs essentially from that of the Birkeland and Eyde, inasmuch as magnets and magnetic fields are done away with entirely, the arc being produced inside an iron tube of comparatively small diameter (Electrotechnische Zeit. 1909, 30, 365, 397).

The construction of the furnace is seen in Fig. 7. The iron tube A contains at its lower extremity the electrode insulated from the rest of the furnace. It consists of a strong copper body, B, pierced through its axis and cooled with water. Through the axis passes an iron bar, C, which can be pushed forward as required, and constitutes the actual electrode from which the arc starts at the point D. All the wear comes upon this bar, and at the intense heat of the arc becomes covered with a layer of melted ferric oxide, which slowly evaporates. As this proceeds the iron bar is gradually pushed forward, and its actual position can be observed through the peep-hole E. F is an igniting rod for starting the arc. The air enters the furnace as indicated, and at G passes into the iron tube through several series of tangential openings, situated one above the other, and regulated by means of the movable sleeve H. This device gives the entering air a rotary motion, which causes the arc once started from D, to travel up the tube A, and the air current is so regulated that the arc ends in the upper water-cooled portion of the iron tube, somewhere between K and M, which portion of the furnace can be observed through the peep-holes N and O. Under these circumstances the arc burns as steadily as a candle flame. The passage of the air through the furnace is indicated by the

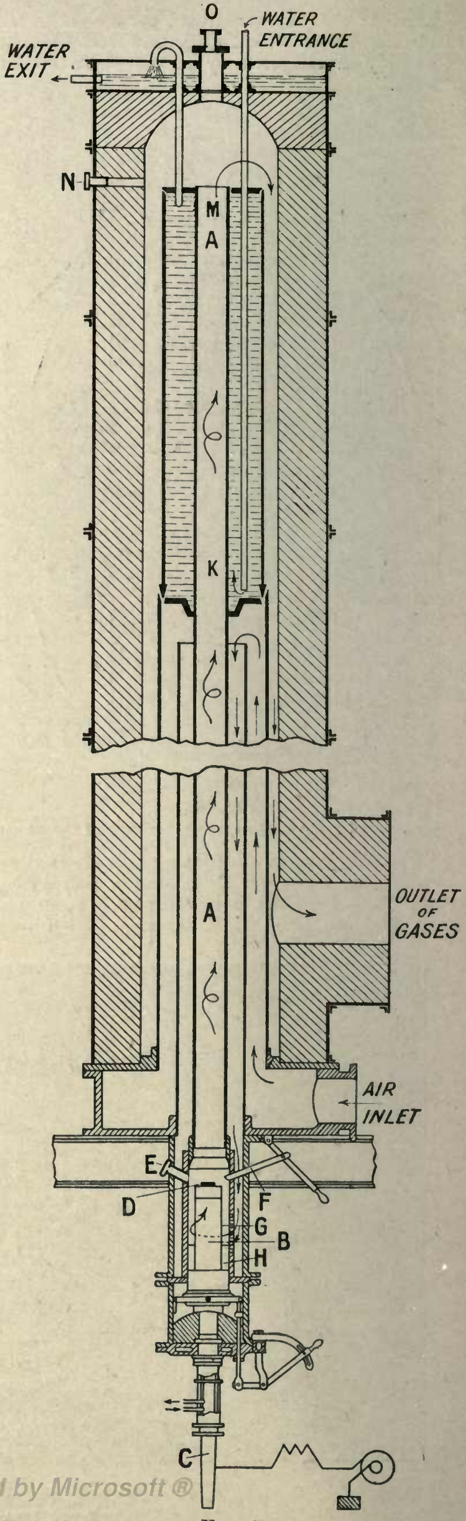

Fig. 7.

arrows, and it will be noticed that the incoming air is heated (to a temperature of about 500°) by the outgoing gases.

The furnace is connected electrically to earth, so that any part of the apparatus can be handled with impunity, except only the insulated electrode. The experimental furnaces at Christiansand are fed with about 600 horse-power at 4200 volts, and, although it appears possible to build furnaces which could consume 2000 horse-power, those regularly used will be built for 750 horse-power, and will require about 40,000 cubic feet of air every hour, and the arcs produced will be nearly 7 yards long. Though this arrangement departs from the principle of only allowing the gases to remain in contact with the arc flame for as short a time as possible (as it is obvious that the air will require a not inconsiderable time to travel from one end of the tube to the other), the gases leaving the tube contain about 2 p.c. of nitric oxide.

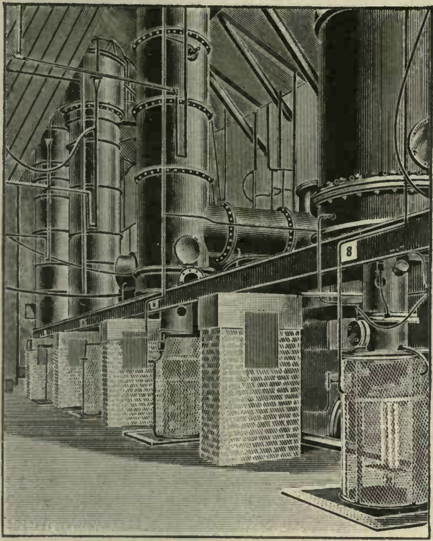

FIG. 8.
Experimental Furnaces at Christiansand Works.

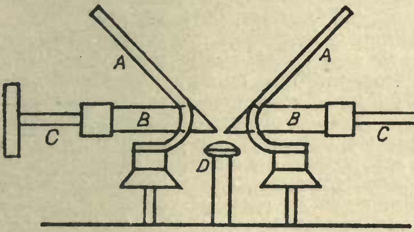

FIG 9.

The Pauling arc flame. In the production of this flame (Russ, Zeitsch. Elektrochem. 1909, 15, 544) the main electrodes AA, Fig. 9, are bent into the shape of a V, and at the lowest point of the V (40 mm. wide) they form a vertical slot, through which are introduced narrow 'lighting knives,' B, B, which can be brought together by an adjusting arrangement, CC, until only separated by a few millimetres.

The arc lighted at the narrowest portion of the spark gap, shows a tendency to rise, owing mainly to the upward pull of the hot gases, but it is interrupted at every half period of the alternating current, only to be reformed at the lowest and narrowest part of the electrodes. A high speed current of previously heated air is introduced into the V formed by the electrodes, through a nozzle, D, so shaped as to cause the air to diverge and surround the whole length of the electrodes. This device has the further effect of blowing out and broadening the arc, the flame so produced burning with remarkable steadiness from the electrical point of view, and in practice having a length of 1 metre.

The iron electrodes are cooled with water, and last approximately 200 working hours; whilst the lighting knives are very thin (so as not to interfere with the motion of the air), and consequently burn away quickly, hence the necessity for adjustment from time to time. The furnace gases are cooled by 'so-called circulation air,' which is introduced sideways into the upper portion of the flame, at a lower speed than the main air current, thus exerting a suction effect on the flame, causing it to be drawn out, and further broadened. The gases leave the furnace at a temperature of 700°–800°, and contain 1·5 p.c. of nitric oxide.

This flame is employed by the 'Salpetersäure Industrie Gesellschaft Gelsenkirchen' in their works at Patsch, near Innsbruck, where 15,000 horse-power are available. The present type of furnace (of which there are twenty-four at Patsch) takes 400 kilowatts at a tension of about 4000 volts, and 600 cubic metres of air per hour, but larger furnaces taking 1500–2000 kilowatts are being installed.

The success of this process has been sufficient to warrant the erection of a second works (10,000 horse-power) at Legnano, near Milan, and another factory (10,000 horse-power) under the auspices of 'La Société Nitrogene' at La Roche-de-Dame in the south of France, in both of which the Pauling flame is used.

A comparison of the efficiency of these three flames is given by Haber and Koenig (Zeitsch. Elektrochem. 1910, 16, 11) as follows—

	Yield. Grams HNO_3 per kilowatt-hour	Concentration p.c. NO
Pauling	60	1–1·5
Birkeland and Eyde	70	2·0
Schönherr	75	2·5

But the actual amount of nitric oxide produced is not the only factor which has to be taken into account industrially, and among many other points for consideration is whether the heat produced in the arc is sufficient, and can be utilised for the carrying out of all the necessary evaporation processes without the use of coal, as is the case at Notodden (*cf.* footnote, p. 705).

THE OXIDATION TOWERS.

The volume of air treated at the Notodden factory is between 700,000 and 800,000 litres per minute, and as it contains a little more than 1 p.c. of nitric oxide, or stated in the form in which all calculations of combined nitrogen are expressed in the works, 30 mg. HNO_3 per litre, the problem of oxidising this gas and absorbing the resulting nitrogen peroxide becomes a very difficult one, for the more dilute the gas the more difficult the operation. The gases leave the furnaces at a temperature of 800°–1000° and are cooled as rapidly as possible (to prevent decomposition of the nitric oxide into nitrogen and oxygen) by passage through a series of tubes contained in four Babcock and Wilcox boilers working at 130 lbs. pressure, and then through tubes in the evaporation tanks, this utilisation of heat having entirely done away with the use of coal in the works. At present provision has not been installed for the fullest possible economy of heat, but when this has been effected it will mean that, in addition to the amount required to evaporate approximately 120,000 litres of water daily, there will be an excess of steam sufficient to generate 1200 kilowatts of electric power.

The temperature of the furnace gases is lowered in the above mentioned manner to 200°–250°, and as the reaction $2NO+O_2=2NO_2$ commences at about 500°, nitrogen peroxide begins to form. The gases are then conducted through a special cooling apparatus composed of a series of aluminium tubes over which water is flowing, where their temperature is further lowered to 50°; then they pass into the so-called 'oxidation chambers,' consisting of vertical iron cylinders with acid-proof lining, where the conversion of nitric oxide into nitrogen peroxide continues till the composition of the gases leaving the chambers is approximately 98 p.c. of air and 2 p.c. of a mixture of 75 p.c. nitrogen peroxide and 25 p.c. nitric oxide.

The Absorption Towers.

The conversion of nitrogen peroxide into nitric acid takes place in the absorption system, consisting of three series of stone towers, whose internal dimensions are 6 × 20 metres, each series containing five towers, three acid towers and two alkali towers. The former are ten-sided, built of granite and bound together with iron rods; they have a capacity of 600 cubic metres, and are filled with broken quartz, over which water, or the dilute nitric acid formed, is constantly flowing.

The alkali towers are cylindrical, of 700 cubic metres capacity, and are made of wood, bound round with iron rods; they are filled with broken quartz, over which a solution of sodium carbonate flows. The three acid towers, in which there is a slightly diminished pressure owing to solution of oxides of nitrogen, absorb 80 p.c. of the nitrous gases, the residue (all but 2 p.c.) being extracted by passage through the two alkali towers with formation of a solution of sodium nitrite containing some sodium nitrate. The total absorption thus amounts to 98 p.c.

Centrifugal fans, constructed of aluminium, are placed on each row of towers to assist the passage of the gases on their way from the furnaces through the absorption system. The absorption of the nitrous gases takes place so that the first tower always contains the strongest acid and the weakest acid is formed in the third tower. The liquid is allowed to flow through the third tower until it attains a strength of 5 volume p.c. HNO_3, when it is pumped to the top of the second tower. Here it circulates till a strength of 20 volume p.c. HNO_3 is reached, when the acid passes to the third tower where in actual practice a 40 volume p.c. acid is formed, though 50 or even 60 p.c. HNO_3 can be produced. The system is arranged so that just as much fresh water is admitted to the third tower as corresponds in quantity with the 40 volume p.c. acid drawn from the first tower.

The main reactions taking place are the absorption of nitrogen peroxide and nitrogen trioxide, with formation of nitrous and nitric acids—

$$2NO_2+H_2O=HNO_3+HNO_2,$$
$$N_2O_3+H_2O=2HNO_2;$$

but with increasing concentration nitrous acid becomes more and more unstable in aqueous solution, so that a further process takes place, resulting in the formation of more nitric acid and nitric oxide $3HNO_2=2NO+HNO_3+H_2O$, and, under certain condition of temperature and amount of water present, the instability of nitrous acid becomes so great that only nitric acid is formed; the practical result being that in the first tower not only the strongest nitric acid, but an acid free from nitrous acid is produced. The nitric oxide passes on from tower to tower, is oxidised and absorbed according to the first of the above equations, so that the amount of nitrous acid increases in each succeeding tower, until in the fifth tower nearly pure sodium nitrite is formed. The raw product of manufacture at Notodden is the 40 volume p.c. nitric acid obtained from the first absorption tower, and an idea of the energy used compared with the combined nitrogen found, may be gathered from the statement that 1 kilowatt year gives rise to 550–600 kilos. of nitric acid (HNO_3).

Among other methods which have been proposed for the absorption of the furnace gases may be mentioned that of Schloessing, in which quicklime in the form of briquettes is treated with the gases while still hot. At first calcium nitrite is formed, but under the influence of air and nitrous gases, this is converted into nitrate, so that the final product, obtained directly, is calcium nitrate in the solid form.

At present no attempt is made further to concentrate this acid, and the four finished products exported from the works are 'Nitrate of Lime,' 'Sodium Nitrite,' 'Ammonium Nitrate,' and 'Sodium Nitrite Nitrate.'

Nitrate of lime. The raw nitric acid is run through a series of granite tanks filled with limestone, until the liquid contains not more than 0·5 p.c. of nitric acid, which is neutralised by the addition of lime. The liquid is then evaporated in vacuum pans until it has a sp.gr. 1·9, and is then run into iron drums holding 380 litres, when it sets to a hard mass and is thus exported for chemical purposes; or it is run on to shallow trays and when cold is broken up, ground to a coarse powder, and sent out as a manure in wooden casks. It varies in appearance from red-brown to black, according to the nature of the limestone from which it is made, and has the following composition—

N=13·1 p.c., corresponding to 77·0 p.c. $Ca(NO_3)_2$
Water . . . . 21·5 ,,
Insoluble in water—
Fe_2O_3; Al_2O_3; humus . 1·5 ,,

The amount produced is about 50 tons per day, or 20,000 tons per annum.

Sodium nitrite. Originally at Notodden no nitrite was prepared. Milk of lime was used as absorbent in the alkali towers, and the resulting liquid was treated with some of the dilute nitric acid from the first tower, when nitrous fumes were evolved, which were again passed into the acid absorption towers

$$Ca(NO_2)_2+2HNO_3=Ca(NO_3)_2+H_2O+NO_2+NO.$$

The nitrate of lime was worked up in the manner described above.

At the present time sodium carbonate is employed in the fourth and fifth absorption towers, and the liquid from these towers is evaporated under ordinary pressure till it has a boiling-point of 130°. It is then run into shallow tanks, allowed to crystallise, centrifuged and dried in a Bühler's drying apparatus, Fig. 10. A is an air heater, B a pump, whereby air raised to a temperature of 100° is forced through the apparatus in the direction indicated by the arrows. The sodium nitrite enters at the entrance roller C and is forced through the drying tube into the cyclone D. The air is filtered in the air filter E and escapes through the outlet tube H. The passage of the sodium nitrite through the apparatus occupies 5–7 seconds, when it collects in the cyclone and is removed directly into casks by means of the outlet roller K.

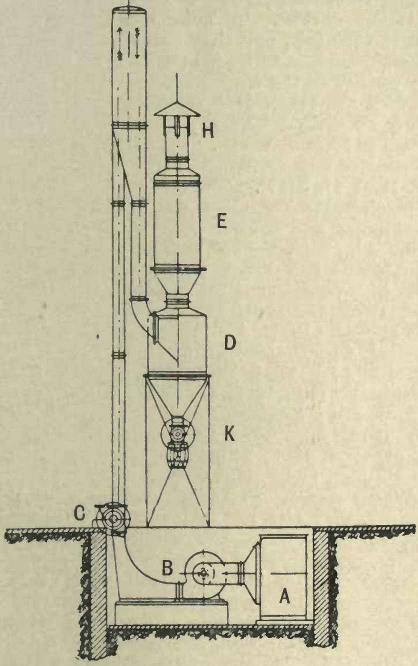

Fig. 10.

The sodium nitrite so obtained, of which about 13 tons are made per day, is a fine white crystalline powder containing 99 p.c. $NaNO_2$, the remaining 1 p.c. being composed of water, sodium nitrate, and sodium carbonate. The mother liquor from the first crop of crystals is again evaporated till it has a boiling-point of 130°, when it yields a second quantity of pure sodium nitrite. On repeating the process for the third time an 80 p.c. sodium nitrite is produced and purified by crystallisation. The mother liquor from the third crop gives rise to—

Sodium nitrite nitrate, which is a yellow, crystalline material containing about 50 p.c. sodium nitrite, 43 p.c. sodium nitrate, and 7 p.c. of moisture, together with some sodium carbonate and sodium chloride. About 2 tons are produced per day, and the substance is used instead of Chile saltpetre in the manufacture of sulphuric acid by the lead chamber process.

Nitrites may also be produced directly from the furnace gases by employing sodium carbonate or milk of lime as absorbing agents, taking care to maintain the temperature between 200° and 300°, and certain other conditions, so that during absorption the gases contain equal quantities of nitrogen peroxide and nitric oxide, when the reaction takes place in accordance with the equation $NO_2+NO+Na_2CO_3=2NaNO_2+CO_2$. The Badische Anilin and Soda Fabrik manufacture in this way at Christiansand all the sodium nitrite they require for the preparation of colouring matters at their Ludwigshafen works.

Ammonium nitrate is prepared at Notodden by neutralising the 40 p.c. nitric acid with pure ammonia liquor (sp.gr. 0·880) imported from England. The resulting liquid is filtered, evaporated in vacuum pans until it has a sp.gr. 1·35, and is then allowed to crystallise. The crystals are centrifuged and dried in a Bühler's apparatus, when they contain 99·9 p.c. NH_4NO_3. Eight tons are made per day, although 15 tons could be manufactured.

Concentrated nitric acid. As already mentioned, no attempt is made at Notodden to manufacture concentrated nitric acid, but at Gelsenkirchen the raw acid (35–40 p.c. HNO_3) is concentrated to 60 p.c. HNO_3 by utilising the heat from the furnace gases; and by distillation with concentrated sulphuric acid a 98 p.c. acid can be produced. During the process the sulphuric acid is reduced in strength to 79–80 p.c., but may again be concentrated.

Another process consists in mixing the dilute nitric acid with polysulphates at a temperature of 110°–130°, and distilling the mixture when the nitric acid is obtained in concentrated form. By raising the temperature of the residue to 250°–300° the water, which has been retained by the polysulphates, is driven off, and the regenerated polysulphates, after cooling to 110°–130°, can be used over again.

Fuller details of the processes referred to will be found in the references given in the text, or in the following:—

NITROPHENINE YELLOW *v.* Primuline and its Derivatives.

NITROPHENOLS AND THEIR HOMOLOGUES. Phenol may be nitrated very readily, and to produce the mono-nitro derivatives it is sufficient to treat it with dilute nitric acid in the cold. The *ortho-* and *para*-nitrophenols, together with some tarry matter, are thus formed. The *ortho-* compound is separated by steam distillation, whilst the non-volatile *para-* compound is purified by repeated crystallisations from xylene (Hofmann, Annalen, 1857, 103, 347; Fritsche, *ibid.* 1859, 110, 150; Schall, Ber. 1883, 16, 1901; Neumann, *ibid.* 1885, 18, 3320).

If the nitric acid is vigorously stirred, during and for about half an hour after the addition to it of the phenol, an 18 p.c. yield of *p*-nitrophenol is obtained without any formation of tar. The best yield is obtained at 25°. Below 4° nitration cannot be effected (Hart, J. Amer. Chem. Soc. 1910, 32, 1105; *v.* Pictet, J. Soc. Chem. Ind. 1911, 683).

Phenol may be first condensed with an aromatic sulphonic chloride in presence of an alkali, the ester so formed, on nitration, yields, without formation of tarry products, a dinitro derivative, which on hydrolysis with an aqueous solution of a caustic alkali, yields the alkali salt of *p*-nitrophenol, together with that of *o*-nitrotoluene-*p*-sulphonic acid (Eng. Pat. 24193, 1895; J. Soc. Chem. Ind. 1897, 40). *o*-Nitrophenol, almost free from the *p*-isomeride, may be obtained by converting phenol into the *p*-sulphonate, then nitrating it with sodium nitrate and sulphuric acid; on hydrolysis the HSO_3 group is removed (Paul, *ibid.* 1897, 62); or by treating nitro-benzene with potash (Wohl, Ber. 1899, 32, 3486).

m-Nitrophenol is not formed by the direct nitration of phenol, but it may be prepared by boiling diazotised *m*-nitraniline with water (Bantlin, *ibid.* 1878, 11, 2100; Henrique, Annalen, 1882, 215, 323).

The polynitrophenols are obtained by nitrating phenol with concentrated nitric acid, usually in the presence of sulphuric acid; by nitrating the lower nitro compounds or their sulphonates; by treating the hydrocarbon with nitric acid in presence of mercury or mercury compounds, in which case the nitro and hydroxyl groups are introduced simultaneously into the benzene nucleus (Eng. Pat. 17521; D. R. P. 214045; J. Soc. Chem. Ind. 1907, 1194; *ibid.* 1909, 1167; Chem. Zentr. 1908, i. 1005); and by other methods (Wender, Gazz. chim. ital. 1889, 19, 222; Oliveri-Tortorici, *ibid.* 1898, 28, 306; Reverdin and de la Harpe, Chem. Zeit. 1891, 16, 45; Frankland and Farmer, Chem. Soc. Trans. 1901, 1356; Robertson, *ibid.* 1902, 1475; Lobry de Bruyn, Rec. trav. chim. 13, 153; Pinnow and Koch, Ber. 1897, 30, 2857; Reverdin and Bucky, *ibid.* 1906, 39, 2679; Matuschek, Chem. Zeit. 1905, 29, 115; D. R. P. 91314; Frdl. iv. 40).

The nitrophenols are colourless or yellow crystalline substances. They are more acidic than the phenols, and they decompose alkaline carbonates. The nitrophenols may be reduced very readily to the corresponding amines, some of which are themselves valuable dyes, or are readily condensed with suitable aromatic compounds to form dyestuffs. By partial reduction nitroamines may be obtained (Hofer and Jakob. Ber. 1908, 41, 3187). The use of nitrophenols as precipitants for alkaloids is discussed by Rosenthäler and Görner (Zeitsch. anal. Chem. 1910, 49, 340). The constitution of the nitrophenols has given rise to an important series of investigations by Hantzsch and others (Ber. 1902, 35, 1001, 1005; *ibid.* 1906, 39, 1073; *ibid.* 1907, 40, 330, 1556; Zeitsch. physikal. Chem. 1908, 61, 227; *see* also Rabe, *ibid.* 1901, 38, 175; Witt, Ber. 1876, 9, 522; Korczynski, *ibid.* 1909, 42, 167; Chem. Zentr. 1910, ii. 384; Scharwin, J. Russ. Phys. Chem. Soc. 1910, 42, 237; Seyewetz and Poizat, Compt. rend. 1909, 148, 1110; Baly, Edwards and Stewart, Chem. Soc. Trans. 1906, 514).

Whilst themselves colourless, or only faintly coloured, they give rise to two series of highly-coloured alkali salts—yellow and red, and on this account they were regarded as pseudo-acids. This view has been confirmed by the preparation of two series of ethers. The colourless phenol ethers are obtained under ordinary conditions of alkylation, and have the formula $NO_2\cdot C_6H_4OR$. The isomeric red ethers are much more difficult to prepare, owing, it is supposed, to their instability and to the ease with which they change into their colourless isomeride. The red ethers are formed by the action of alkyl iodide on the silver salts of the nitrophenols. The materials must, however, be absolutely pure and dry, and the reaction is commenced at 0° and then raised to ordinary temperature. The red ethers, which have not been obtained quite pure, melt at least 20° below the colourless ethers; they are much more soluble in all solvents, giving coloured solutions, and on standing alone, and more readily in solvents or in the presence of hydrochloric acid, change into the colourless isomerides. The smallest trace of water hydrolyses them, forming the free nitrophenol, and this explains why, when a silver salt of a nitrophenol is alkylated without special precautions, free nitrophenol is often produced.

To explain the formation of the coloured salts and ether, it is supposed that nitrophenols and their derivatives, and also their homologues, may exist in two tautomeric modifications  $C_6H_4{<}\begin{matrix}OR\\NO_2\end{matrix}$ and  $C_6H_4\begin{matrix}/O\\|\\\backslash NO\cdot OR\end{matrix}$ (where R=H, a metal, or an alkyl radicle), of which the first is colourless, the second coloured; thus the constitution of the free colourless nitrophenols corresponds to the first formula, whilst the coloured nitrophenols, being much paler than their salts, correspond partly to the first, partly to the second formula. The coloured ethers correspond to the second formula, whilst the metallic salts, forming two series of coloured salts, have the two formulæ  $\underset{KO_2}{C_6H_4}\begin{matrix}/O\\|\\\backslash N\end{matrix}$ and  $C_6H_4\begin{matrix}/O\\|\\\backslash N{-}O_2K\end{matrix}$, of which the latter probably corresponds with the red salts, the former with the yellow salts. The orange salts sometimes obtained are probably solid solutions of the yellow and red salts (Hantzsch, Ber. 1907, 40, 330).

o-**Nitrophenol** $C_6H_4(NO_2)OH$ forms pale yellow needles or prisms, m.p. 44°, b.p. 214°, sp.gr. 1·447 (Schröder, Ber. 1879, 12, 563; Merz and Ris, *ibid.* 1886, 19, 1749). It has an aromatic smell, is sparingly soluble in cold water, more readily so in hot water, also in alcohol or ether. It behaves as a much stronger acid than the *p*- and *m*-isomerides.

m-**Nitrophenol** forms thick yellow crystals, m.p. 96°, b.p. 194°/70 mm. (Bantlin, *l.c.*); m.p. 93°, sp.gr. 1·827 at 19° (Fels, Zeitsch. Krystalographie, 1900, 32, 374). It is non-volatile in steam, and it is readily oxidised by Caro's reagent on warming, yielding 3- and 4-nitro-catechols, a part of it, however, being decomposed (Bamberger and Czerkis, J. pr. Chem. 1903, [ii.] 68, 480).

p-**Nitrophenol** forms colourless needles, m.p. 114°. It is non-volatile in steam, yields *p*-aminophenol when boiled with zinc-dust and water, and when electrolysed in sulphuric acid forms *p*-aminophenolsulphonic acid. It reacts with alkali sulphide in presence of a copper salt, forming a green dyestuff (D. R. P. 101577; Chem. Zentr. 1899, i. 1091). *p*-Nitrophenol has been proposed for use as an indicator instead of methyl orange (Spiegel, Zeitsch. angew. Chem. 1904, 17, 715; J. Soc. Chem. Ind. 1904, 182; Goldberg and Naumann, *ibid.* 1903, 928). When heated with aqueous ammonia under pressure both the *o*- and the *p*-isomerides yield the corresponding nitraniline (Merz and Riz, *l.c.*). By mixing any of the mononitrophenols with quinine in presence of water, compounds are said to be obtained which are almost insoluble in water or dilute acid, and which may be used as internal antiseptics (U. S. Pat. 1005137 of 1911; J. Soc. Chem. Ind. 1911, 1333).

The nitrophenols may be sulphonated by treating them with fuming sulphuric acid, or in the case of the *ortho*- compound by chlorosulphonic acid. Mercury accelerates the reaction (Post, Annalen, 1880, 205, 38; Nietzki and Lerch, Ber. 1889, 21, 3221; Gnehm and Knecht, J. pr. Chem. 1906, [ii.] 73, 519; *ibid.* 74, 92).

The sulphonic derivatives may also be formed by nitrating the required phenolsulphonic acid (Post and Stuckenberger, Annalen, 1880, 205, 45; Post, Ber. 1874, 7, 1323; D. R. P. 27271; Frdl. i. 324; J. Soc. Chem. Ind. 1885, 203; *see* also D. R. P. 114529; Chem. Zentr. 1900, ii. 1000).

Like phenol itself, the mono- as well as the polynitro compounds form a number of metallic salts, ethers, and other compounds.

2 : 3-**Dinitrophenol** (Bantlin, *l.c.*) has m.p. 144°.

2 : 4-**Dinitrophenol** forms rhombic prisms, m.p. 114°–115° (Gauhe, Annalen, 1868, 147, 67; Pinnow, *l.c.*). It is much more poisonous than picric acid. When warmed with sulphur and sodium sulphide it gives a black dye for cotton (D. R. P. 98437; Chem. Zentr. 1898, ii. 912). Ostromisslensky has prepared another 2 : 4-**dinitrophenol**, m.p. 85·1° (J. Russ. Phys. Chem. Soc. 1906, 38, 1351).

2 : 5-**Dinitrophenol**, yellow needles, m.p. 108°, volatile in steam (Reverdin and Bucky, *l.c.*); m.p. 104° (Bantlin).

2 : 6-**Dinitrophenol**, light yellow, fine needles, m.p. 63°–64° (Hübner, Babcock and Schaumann, Ber. 1879, 12, 1346).

3 : 4-**Dinitrophenol**, long silky colourless needles, m.p. 134° (Bantlin, *l.c.*).

3 : 5-**Dinitrophenol** has m.p. 122° (Lobry de Bruyn, *l.c.*; Heller, Ber. 1909, 42, 2191).

2 : 4 : 6-**Trinitrophenol**, *v.* Picric acid.

2 : 4 : 5-(β-)**Trinitrophenol**, glistening needles, m.p. 96° (Henrique, *l.c.*).

2 : 3 : 6-(γ-)**Trinitrophenol**, small needles, m.p. 117°–118° (Henrique, *l.c.*).

2 : 3 : 5-**Trinitrophenol** is obtained by boiling diazotised trinitroaminophenol with absolute alcohol until nitrogen ceases to be evolved. It forms yellow needles, m.p. 119°–120°, and becomes ochreous and opaque when dried at 100°. It dyes silk and wool with a more orange shade than picric acid (Meldola and Hay, Chem. Soc. Trans. 1909, 1382).

2 : 3 : 4 : 6-**Tetranitrophenol**, golden-yellow needles, m.p. 130°, sometimes with explosion (Nietzki and Blumenthal, Ber. 1897, 30, 184); m.p. 140° (Blanksma, Rec. trav. chim. 1902, 21, 254). It dyes wool and silk an intense red-yellow colour. When boiled with water it forms trinitroresorcinol.

2 : 3 : 5 : 6-**Tetranitrophenol** is known in the form of its ethyl ether, m.p. 115° (Blanksma, *ibid.* 1905, 24, 40).

Pentanitrophenol $C_6(NO_2)_5OH$, m.p. 190°, when boiled with water is transformed into trinitrophloroglucin (Blanksma, *ibid.* 1902, 21, 254).

The polynitrophenols, when treated with potassium cyanide, yield the corresponding purpuric acids (Borsche and Böcker, Ber. 1903, 36, 4357; *ibid.* 1904, 37, 1843, 4388).

Nitraminophenols may be obtained by nitrating acetaminophenols, or, better, acetaminophenol acetate or similar compounds, then eliminating the acetyl group by hydrolysis (Reverdin and Dresel, *ibid.* 1904, 37, 4452), and also by other methods.

4-Nitro-2-aminophenol is obtained by the action of ammonium sulphide on 2 : 4-dinitrophenol. Crystallises with 1 mol. H_2O, m.p. 80°–90°, the anhydrous salt has m.p. 142°–143° (Post and Stuckenberg, *l.c.*; Kehrmann and Gauhe, Ber. 1897, 30, 2132).

5-Nitro-2-aminophenol may be prepared by nitrating the ethenyl derivative of *o*-aminophenol in the cold with a mixture of equal parts of nitric (40°B.) and sulphuric (monohydrate) acids; the product is then decomposed with concentrated hydrochloric acid. It forms yellow needles, m.p. 201°–202°. It yields fast bluish- and greenish-black azo dyes for wool (Eng. Pats. 7910, 7910A, 1905; D. R. P. 165650; J. Soc. Chem. Ind. 1905, 1298).

6-Nitro-2-aminophenol forms red needles, m.p. 110°–111° (Post and Stuckenberg, *l.c.*).

For a number of other mononitro-amino- and acetaminophenols, *see* Hähle, J. pr. Chem. 1891, [ii.] 43, 62; Kehrmann and Gauhe, Ber. 1898, 31, 2403; Meldola and Stephens, Chem. Soc. Trans. 1906, 925; *see* also J. Soc. Chem. Ind. 1905, 796).

When *p*-aminophenol is dissolved in a small quantity of glacial acetic acid, and acetic anhydride is added, the amino group is acetylated. To the solution at 0°, twice the calculated quantity of nitric acid (sp.gr. 1·5), diluted with twice the volume of acetic acid, is added in small portions at a time. The product is then poured into water and neutralised with ammonia, 2 : 6-*dinitro*-4-*acetaminophenol* is thus formed. It forms dense ochreous needles, m.p. 182° (Meldola and Hay, Chem. Soc. Trans. 1905, 1203).

When converted into its sodium derivative and reduced with aqueous sodium sulphide, it yields 2-*nitro*-6-*amino*-4-*acetaminophenol*

$$NHAc{\cdot}C_6H_2(NO_2)(NH_2)OH,$$

brownish-red needles, m.p. 190°, which forms an orange-yellow diazo derivative when treated with nitrous acid (Cassella & Co. D. R. P. 172978, 1906).

4 : 6-Dinitro-2-aminophenol (*Picramic acid*) may be prepared by adding zinc-dust and ammonia solution to a warm aqueous or methyl alcoholic solution of picric acid until the solution is distinctly alkaline. The mixture is boiled for an hour with occasional addition of ammonia, after which it is filtered, the excess of ammonia evaporated on the water-bath, and a slight excess of acetic acid is added. It is then evaporated to dryness, and the residue is recrystallised from boiling water. The acid forms fine red crystals, m.p. 165°, which burn, but do not detonate on sudden heating. It does not precipitate albumin, albumoses, peptone, or alkaloids. Its alkali salts yield deep red solutions, which are turned yellowish-green by acids, and may, therefore, be used as indicators in alkalimetry (Frébault and Aloy, J. Pharm. Chim. 1904, 20, 245; Bull. Soc. chim. 1905, [iii.] 33, 495; Borche and Heyde, Ber. 1905, 38, 3938).

Acetic anhydride reacts with sodium picramate at 60°, and the resulting product, when reduced at 80° by sodium sulphide, and then treated with acid, yields

4-Nitro-2-amino-6-acetaminophenol, which is hydrolysed by acids to 4-*nitro*-2 : 6-*diaminophenol*, the diazonium compound of the latter yielding azo dyes (Cassella, D. R. P. 161341; D. R. PP. 112819, 113241, 111327, 112280, 110711; Chem. Zentr. 1900, ii. 463, 509, 512, 547, 698).

2 : 6 Dinitro-4-aminophenol (iso*picramic acid*) forms thin yellow needles, m.p. 170° (decomp.). The corresponding acetamino derivative, treated with alkali sulphides, forms a compound which readily yields azo dyestuffs for wool, very fast to washing, milling, and light (Reverdin and Dresel, Ber. 1905, 38, 1593; Eng. Pat. 24409, 1903; J. Soc. Chem. Ind. 1904, 1025).

For other dinitroaminophenols, *see* Reverdin and Dresel, *l.c.*; Reverdin, Ber. 1907, 40, 2848; *ibid.* 1909, 42, 1523; Reverdin and Delétra, *ibid.* 1906, 39, 125; Meldola and Hay, Chem. Soc. Trans. 1907, 1481.

2 : 3 : 5-Trinitro-4-acetaminophenol

$$C_6H_2(OH)(NO_2)_3NH{\cdot}COCH_3$$

is obtained by nitrating diacetyl-*p*-aminophenol with cold fuming nitric acid, the mononitrodiacetyl derivative thus obtained is then further nitrated by dissolving it in a mixture of fuming nitric and strong sulphuric acid, when the above trinitro compound is formed. It crystallises in yellow needles, m.p. 178°–179° (decomp.), and owing to the great mobility of the meta- NO_2 group it forms a remarkably active synthetic agent (Meldola, Chem. Soc. Trans. 1906, 1935).

The acetyl group may be removed by dissolving it in concentrated sulphuric acid at the ordinary temperature, then placing the containing vessel in boiling water for a few minutes until a drop of the liquid, mixed with cold water, gives a red precipitate—if the latter is brown the reaction has gone too far and decomposition has set in. The liquid is cooled and poured on to ice. The *trinitroaminophenol* forms deep red needles decomposing at about 145°. It may be diazotised in the cold with sulphuric acid and sodium nitrite (Meldola and Hay, *ibid.* 1909, 1378; Meldola and Kuntzen, *ibid.* 1033; *ibid.* 1910, 444; *ibid.* Proc. 340).

NITROCRESOLS.

The cresols are directly nitrated with difficulty, a small yield of the mononitro products being obtained (Staedel, Annalen, 1883, 217, 49; Khotinsky and Jacopson-Jacopmann, Ber. 1909, 42, 3097). The alkali salts of their sulphonic acid derivatives may be converted into their mononitro derivatives much more readily; the HSO_3 group in the latter cannot, however, be eliminated, but by reduction they may be converted into the corresponding amino compounds which may be readily decomposed into aminocresols and sulphuric acid (Schultze, Ber. 1887, 20, 410).

3-Nitro-*o*-cresol

$$C_6H_3Me(OH)NO_2, (Me : OH : NO_2=1 : 2 : 3)$$

is obtained together with the 5-nitro derivative by dropping a glacial acetic acid solution of *o*-cresol into a cold mixture of 3 parts of nitric acid (sp.gr. 1·4) and 6 of acetic acid (Hirsch, *ibid.* 1885, 18, 1512; Noelting and Wild, *ibid.* 1339). It forms long yellow prisms, m.p. 69·5°, volatile in steam.

4-Nitro-*o*-cresol (Me : OH : NO_2=1 : 2 : 4) is best prepared by diazotising 4-nitro-2-toluidine in 10 p.c. sulphuric acid at 0°, and then dropping the product into boiling dilute sulphuric acid (Ullmann and Fitzenham, *ibid.* 1905, 38, 3790); it forms large yellow crystals, m.p. 118°.

5-Nitro-*o*-cresol, prepared by treating 5-nitro-2-toluidine with sodium nitrite and sulphuric acid, or with concentrated caustic soda, forms fine, white, silky needles which, when dried at 100°, have m.p. 94·6°–95° (Neville and Winther, *ibid.* 1882, 15, 2978).

6-Nitro-*o*-cresol, m.p. 142°–143°, having an intensely sweet smell, is formed from the corresponding nitrotoluidine by treating it with sodium nitrite and sulphuric acid (Ullmann, *ibid.* 1884, 17, 1961).

2-Nitro-*m*-cresol ($CH_3 : OH : NO_2 = 1 : 3 : 2$) is obtained, together with the 4- and 6-nitro derivatives, by nitrating *m*-cresol. It is volatile in steam and soluble in water, but has not been obtained pure. Its methyl ether forms colourless crystals, m.p. 88°–89° (Khotinsky and Jacopson-Jacopmann, *l.c.*).

4-Nitro-*m*-cresol, yellow crystals, m.p. 56°, is formed as above. It is volatile in steam, but insoluble in water, and can thus be separated from the 2-nitro derivative.

5-Nitro-*m*-cresol, m.p. 60°–62°; 90°–91° when anhydrous, is obtained by treating 5-nitro-*m*-toluidine with nitric acid (Neville and Winther, *l.c.*).

6-Nitro-*m*-cresol, m.p. 129°, is obtained as above. It is volatile in steam, and can thus be separated from the 2- and 4-nitro derivatives.

2-Nitro-*p*-cresol ($CH_3 : OH : NO_2 = 1 : 4 : 2$) may be obtained by boiling diazotised 2-nitro-*p*-toluidine (Neville and Winther, *l.c.*), but it is best prepared by nitrating *p*-tolyl carbonate $CO(OC_7H_7)_2$ (m.p. 117°); the 2-nitro-*p*-tolyl carbonate $CO(OC_7H_6NO_2)_2$ thus obtained forms yellow needles, m.p. 143°–144°, which, when hydrolysed with boiling aqueous caustic soda, or sodium carbonate, yields the 2-nitro-*p*-cresol, yellow prisms, m.p. 77° (D. R. P. 206638; J. Soc. Chem. Ind. 1909, 328).

With fuming sulphuric acid 2-nitro-*p*-cresol yields acetyl acrylic acid (Schultz and Löw, Ber. 1909, 42, 577).

3-Nitro-*p*-cresol, formed by treating 3-nitro-*p*-toluidine with nitric acid or concentrated caustic soda, forms yellow needles, m.p. 33·5°, b.p. 125°/22 mm., 114·5°/7·5 mm., sp.gr. 1·2399 at 38·6°/4° (Noelting and Wild, *l.c.*; Brasch and Freyss, Ber. 1891, 24, 1960).

3 : 5-Dinitro-*o*-cresol
($CH_3 : OH : NO_2 : NO_2 = 1 : 2 : 3 : 5$)
forms long yellow crystals, m.p. 86°–87° (Cazeneuve, Bull. Soc. chim. 1900, [iii.] 17, 201; Noelting and Salis, Ann. Chim. Phys. 1885, [vi.] 4, 105). Heated with ammonia at 180° it yields dinitrotoluidine (Barr, Ber. 1888, 21, 1543). It acts as a violent poison (Weyl, *ibid.* 1887, 20, 2835).

2 : 6-Dinitro-*p*-cresol, yellow needles, decomposes when heated, forming a violet sublimate (Knecht, Annalen, 1882, 215, 87).

3 : 5-Dinitro-*p*-cresol, m.p. 85°, is obtained by nitrating *p*-cresol in acetic acid solution with strong nitric acid (Frische, *ibid.* 1884, 224, 138; Staedl, *l.c.*; Chamberlain, Amer. Chem. J. 1897, 19, 533), and by a variety of other methods.

2 : 4 : 6-Trinitro-*m*-cresol, formed when *m*-cresol is nitrated, long, yellow needles, m.p. 109·5° (Murmann, Chem. Zentr. 1904, ii. 436; Noelting and Salis, Ber. 1881, 14, 987; and *l.c.*).

Tetranitro-*m*-cresol $CH_3{\cdot}C(OH)(NO_2)_4$, m.p. 175°, is converted into trinitroorcinol by boiling water (Blanksma, Proc. K. Akad. Wetensch, Amsterdam, 1906, 9, 278).

The relative sensitiveness to the shock of a falling weight of various metallic salts of trinitrophenol and cresol is discussed by Kast (Zeitsch. ges. chiess. and Sprengstoffw. 1911, 6, 7, 31, 67).

Dinitrocresol (Victoria yellow) is sometimes used for colouring food. It may be detected by digesting the finely-powdered sample of macaroni or other food with alcohol, filtering, evaporating to a small bulk and tasting—if it is bitter, picric acid is probably present. Then warm the solution for a few minutes with a little pure hydrochloric acid, cool and drop a fragment of zinc into the basin. After standing in the cold for ½–2 hours the solution will become bright blood-red if dinitrocresol is present, and a beautiful blue in the presence of picric acid (Fleck, J. Soc. Chem. Ind. 1887, 50).

Like the nitrophenols, the nitrocresols also form metallic, amino, and a variety of other derivatives.

2-Ethylphenol or phlorol forms one *mononitro*-derivative, a yellow oil, b.p. 212°–215°, and one *dinitro*- derivative (Béhal and Choaz, Bull. Soc. chim. 1894, [iii.] 11, 309).

NITROXYLENOLS.

3 : 5-Dinitro-1 : 2 : 4-xylenol
$C_6H(OH)(NO_2)_2(CH_3)_2(CH_3{:}CH_3{:}OH{:}NO_2{:}NO_2) = 1 : 2 : 4 : 3 : 5$
forms yellow needles, m.p. 126°–127° (Noelting and Pick; Ber. 1888, 21, 3158).

5-Nitro-1 : 3 : 4-xylenol also forms yellow needles, m.p. 72° (Hodgkinson and Limpach, Chem. Soc. Trans. 1893, 105; Francke, Annalen, 1897, 296, 199).

Symmetrical xylenol has been nitrated by dissolving 5 grms. in 50 c.c. of equal parts of ordinary, and of 20 p.c. fuming, sulphuric acid, the solution is warmed for 15 mins. on the water-bath. After cooling 11·6 grms. of nitric acid of sp.gr. 1·415 are added, the whole, after standing, is warmed on the water-bath, and finally poured into 300 c.c. of water. The precipitate is filtered, washed, and dissolved in boiling water, and the potassium salt of the symmetrical trinitroxylenol is precipitated by adding potassium chloride in excess to the hot solution. It forms brown-yellow crystals, from which the free phenol may be liberated by boiling dilute hydrochloric acid. It forms colourless crystals, m.p. 104°, resembles picric acid in many respects, but is less soluble in water than picric acid and dyes wool in redder shades, whereas the corresponding trinitrocresol gives greenish-yellow colours. Unlike both these substances, it also gives no reaction with potassium cyanide (Knecht and Hibbert, Ber. 1904, 37, 3477; Blanksma, Rec. trav. chim. 20, 422).

Carvacrol forms a 5-*mononitro derivative*
$CH_3(C_3H_7)C_6H_2{\cdot}NO_2(OH)(CH_3 : C_3H_7 : NO_2 : OH = 1 : 4 : 5 : 2)$,
yellow crystals, m.p. 77°–78° (Mazara and Plancher, Gazz. chim. ital. 1891, 21, ii. 155), m.p. 87° (Kehrmann and Schön, Annalen, 1900, 310, 109); and a 3 : 5-*dinitrocarvacrol*, yellow needles, m.p. 117° (Dahmer, *ibid.* 1904, 333, 346).

Thymol yields an almost colourless 6-*nitrothymol*
$CH_3(C_3H_7)C_6H_2(OH)NO_2(CH_3 : C_3H_7 : OH : NO_2 = 1 : 4 : 3 : 6)$,
m.p. 140° (Kehrmann and Schön, *l.c.* 107); a

2 : 6-*dinitrothymol*, m.p. 55° (Oliveri and Tortorici, Gazz. chim. ital. 1898, 28, i. 308).

2 : 5 : 6-*Trinitrothymol*, yellow needles, m.p. 111° (Maldotti, *ibid.* 1900, 30, ii. 365).

NITROCATECHOLS.

3-Nitrocatechol

$C_6H_3(OH)_2NO_2(OH : OH : NO_2 = 1 : 2 : 3)$, obtained by nitrating an ethereal solution of catechol with fuming nitric acid, forms long yellow needles, m.p. 86°, non-volatile in steam (Wesselsky and Benedikt, Monatsh. 1882, 3, 386).

4-Nitrocatechol, yellow needles, m.p. 174°, may be prepared by treating catechol with potassium nitrite and dilute sulphuric acid (Benedikt, Ber. 1878, 11, 362), and by other methods (D. R. P. 81298 ; Frdl. iv. 121 ; Dakin, Amer. Chem. J. 1909, 42, 490). It is also non-volatile in steam.

3 : 5-**Dinitrocatechol**, yellow needles, m.p. 164°, is formed by nitrating catechol diacetate with fuming nitric acid (Nietzki and Moll, Ber. 1893, 26, 2183).

NITRORESORCINOLS.

2-Nitroresorcinol

$C_6H_3(OH)_2NO_2(OH : OH : NO_2 = 1 : 3 : 2)$ may be prepared by adding 22 grms. of resorcinol to 150 c.c. of fuming sulphuric acid (sp.gr. 1·875), and warming on the water-bath; the 2 : 4-disulphonic acid thus formed is then nitrated with a mixture of 12·6 grms. nitric acid (sp.gr. 1·52), and 40 grms. of the fuming sulphuric acid. After 12 hours the mixture is poured into water and distilled with steam (D. R. P. 145190 of 1904). It forms crystals, m.p. 85°, and, when reduced with tin and hydrochloric acid, yields the corresponding amino derivative, whilst if reduced with iron and acetic acid, it forms chiefly benzoylamino resorcinol

$$C_6H_3(OH)_2NH(COC_6H_5),$$

m.p. 187° (Kauffmann and Pay, Ber. 1906, 39, 323). It yields a nitroso, halogen, metallic, and other derivatives (Kauffmann and Franck, *ibid.* 2722 ; *ibid.* 1907, 40, 3999).

2-Nitroresorcinol may be coupled with diazonium chloride and azo dyes have been prepared from the resulting product (Kauffmann and Pay, *l.c.*).

4-**Nitroresorcinol**, m.p. 115°, is formed like the 2-nitro derivative (Ehrlich, Montash. 1887, 8, 426 ; Hemmelmayr, *ibid.* 1905, 26, 185).

5-**Nitroresorcinol** has m.p. 158° (Blanksma, Proc. K. Akad. Wetensch, Amsterdam, 1906, 9, 278).

2 : 4-**Dinitroresorcinol** $C_6H_2(OH)_2(NO_2)_2$ may be obtained by treating the corresponding nitroso compound with cold nitric acid (sp.gr. 1·3) (Kostanecki and Feinstein, Ber. 1888, 21, 3122). It forms yellow needles, m.p. 147°–148° (Hemmelmayr, *l.c.*). For various derivatives and other methods of preparation, *see* Lippmann and Fleissner, Monatsh, 1887, 7, 98 ; Jackson and Koch, Amer. Chem. J. 1899, 21, 511 ; Jackson and Warren, *ibid.* 1891, 13, 179 ; *ibid.* 1904, 32, 297 ; Hemmelmayr, *l.c.*

4 : 6-**Dinitroresorcinol**, m.p. 214·5°, is formed by mixing resorcinol diacetate with 4–5 times its volume of well-cooled, fuming nitric acid (Schiaparelli and Abelli, Ber. 1883, 16, 872).

When 100 grms. of resorcinol is nitrated it yields a dinitro derivative, which, when stirred with 1000 grms. of 20 p.c. ammonia solution at ordinary temperature, yields a brown solution which soon deposits green crystals. The aqueous solution of the latter, when suitably thickened, printed on fabrics and steamed, gives brown shades very fast to soap and light. It can also be applied in conjunction with various acid and basic dyestuffs with or without mordants (D. R. P. 207465 ; J. Soc. Chem. Ind. 1909, 361).

Seven parts of mononitroresorcinol, heated with 10 parts of aniline, and 100 of hydrochloric acid for about an hour on the water-bath, yields a compound which dyes iron-mordanted tissues a greyish-blue and alumina mordanted tissues a blue shade.

Dinitroresorcinol (8 parts), similarly treated with 30 parts of resorcinol and 6 of hydrochloric acid, yields a dyestuff which dyes tissues mordanted with iron oxide, alumina or chromic oxide, yellowish-brown shades.

Mono- and dinitroresorcinol, heated alone with hydrochloric acid, also yield dyestuffs, which, however, are deficient in dyeing power (Poirrier and Ehrmann, Bull. Soc. Ind. Mulhouse, 1906, 76, 69).

2 : 4 : 6-**Trinitroresorcinol** (*Styphnic acid*) may be obtained by the prolonged action of nitric acid on various gums or resins ; or on wood extracts (Böttger and Will, Annalen, 1846, 58, 269) ; by the action of fuming nitric acid on *m*-nitrophenol or on trinitrophenol (Bantlin, Ber. 1878, 11, 2101) ; by the action of a mixture of concentrated nitric and sulphuric acids on resorcinol (Merz and Zitter, Ber. 1879, 12, 681, 2037 ; *cf.* Guerewitsch, *ibid.* 1899, 32, 2425) ; by the oxidation of dinitroresorcinol (Fitz, *ibid.* 1875, 8, 631 ; Bendikt and Hübl, Monatsh. 1881, 2, 326) and by other methods.

Styphnic acid forms large yellow hexagonal crystals, m.p. 175·5° ; is readily soluble in alcohol or in ether and in 88 parts of water at 62. It gives a number of metallic salts, ethers and molecular compounds with various organic compounds (Gibson, Chem. Soc. Trans. 1908, 2098 ; Ullmann and Bruck, Ber. 1908, 41, 3939). Alkylamine derivatives are described by Jerusalem (Chem. Soc. Trans. 1909, 1285).

Tetranitroresorcinol has m.p. 152° (Blanksma, *l.c.*).

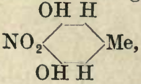
Hydroquinone or *quinol* (1 : 4-dihydroxybenzene) yields a *mononitro derivative*

$$C_6H_3(OH)_2NO_2,$$

m.p. 133°–134° (Elbs, J. pr. Chem. 1893, ii. 48, 179), and a 3 : 5-*dinitroquinol*, pale yellow leaflets, m.p. 135° (Shaw, Chem. Soc. Trans. 1911, 1609).

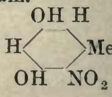
NITRO-ORCINOLS.

Mononitro-orcinol exists in two modifications : α- *derivative*, orange-coloured crystals, m.p. 127°,



, is formed by the interaction of an ethereal solution of orcinol and the molecular equivalent of fuming nitric acid (sp.gr. 1·515). Is volatile in steam.

β- *Modification*, m.p. 122°,



, is

formed like the α- derivative, but is non-volatile in steam. It forms brown crystals containing benzene of crystallisation, and yields green potassium and yellow silver salts (Henrich and Meyer, Ber. 1903, 36, 885).

2 : 4-**Dinitro-orcinol** $C_6H(CH)_3(OH)_2(NO_2)_2$ forms deep yellow leaflets, m.p. 164·5° (Henrich, Monatsh. 1897, 18, 162); another dinitro-derivative known as **β-dinitro-orcinol,** m.p. 109°–110°, has also been described (Leeds, Ber. 1881, 14, 483).

Trinitro-orcinol $C_6CH_3(OH)_2(NO_2)_3$, formed by nitrating orcinol and also by other methods (Merz and Zeller, *ibid.* 1879, 12, 2038; Cazeneuve and Hugouneuq, Bull. Soc. chim. 1888, 50, 643), long yellow needles, m.p. 162°–163·5°, is feebly explosive above its melting-point.

NITROPYROGALLOLS.

5-**Nitropyrogallol**
$C_6H_2(OH)_3NO_2,H_2O(OH : OH : OH : NO_2 = 1 : 2 : 3 : 5)$
is obtained by the action of nitric acid on pyrogallol in ethereal solution at 0°. Forms brownish-yellow needles, or prisms which lose water of crystallisation at 100°, then melt at 205° (Barth, Monatsh. 1882, 1, 882).

4-**Nitropyrogallol,** m.p. 162°, is formed by boiling nitropyrogallol carbonate with water (Einhorn, Cobliner and Pfeiffer, Ber. 1904, 37, 114).

4 : 6-**Dinitropyrogallol,** yellow needles, m.p. 208°, is formed by the action of a mixture of sulphuric and nitric acids on pyrogallol carbonate (Einhorn, Cobliner, and Pfeiffer, *l.c.*).

NITROPHLOROGLUCINOLS.

Phloroglucinol yields a **mononitro derivative** $C_6H_2(OH)_3(NO_2)(OH : OH : OH : NO_2 = 1 : 3 : 5 : 2)$ when nitrated with weak nitric acid. It forms reddish-yellow leaflets (Hlasiwetz, Annalen, 1861, 119, 200).

Trinitrophloroglucinol $C(OH)_3(NO_2)_3$ is formed by treating phloroglucinol triacetate or trimethyl phloroglucinol with fuming nitric acid (Nietzki and Mol, Ber. 1893, 26, 2185; Blanksma, *l.c.*). Yellow crystals; loses water of crystallisation at 100°, sublimes at 130°, m.p. 167° (anhydrous), explosive at higher temperatures. A large number of halogen nitro derivatives of the nitrophenols and their homologues are known: for some recent literature *see* Dahmer, *l.c.*; D. R. PP. 160304, 234742; J. Soc. Chem. Ind. 1905, 886; *ibid.* 1911, 884; Zincke and Klostermann, Ber. 1907, 40, 679; Heller, *ibid.* 1909, 41, 2191; and *l.c.*; Zincke and Breitweiser, *ibid.* 1911, 44, 176; Robertson, Chem. Soc. NITROTOLUENE *v.* TOLUENE.

NJAVE OIL *v.* OILS, FIXED, AND FATS.

NJIMO WOOD. This wood is obtained from the interior of the Cameroons, and contains a principle which is said to act like pepsin. The drug is found in commerce partly in billets with but little bark, partly as thick circular sections of the root uniformly covered with bark. The wood of both stem and root possesses a beautiful yellow colour, that of the former being dashed with red. It is easily reduced to powder with a rasp, and possesses an odour like musk. It contains numberless circular pores, which contain yellow resin. The alcoholic extract of the drug is yellow by transmitted light, but exhibits a green fluorescence resembling uranium glass. It appears to contain no alkaloid. The resin contains a bitter substance with a faint aromatic smell (Hugo Schulz, Pharm. Zeit. 31, 350; J. Soc. Chem. Ind. 5, 501).

Cyclo-**NONANONE** *v.* AZELAIC ACID.

NONDECATOIC ACID $CH_3[CH_2]_{17}COOH$ is obtained from octadecyl cyanide (Schweitzer, J. 1884, 1193); m.p. 66·5°, b.p. 297°–299° (100 mm.).

NONOIC ACIDS $C_9H_{18}O_2$.

1. *n-Nononic acid* or *Pelargonic acid*

$$CH_3[CH_2]_7COOH$$

is contained as an ether in the oil from *Pelargonium roseum* (Pless, Annalen, 59, 54), and may be obtained by the oxidation of oil of rue (from *Ruta graveolens* [Linn.]) (Perrot, *ibid.* 105, 64), and of oleic acid (Redtenbacher, *ibid.* 59, 52). Also formed by the oxidation of stearolic acid ($C_{18}H_{32}O_2$) (Limpach, *ibid.* 190, 197); by boiling normal octyl cyanide with potash (Zincke and Franchimont, *ibid.* 164, 333); by melting undecylenic acid with potash (Krafft, Ber. 1882, 1691); and by heating the barium salt of sebacic acid with sodium methoxide (Mai, Ber. 1889, 2136); m.p. 12·5°, b.p. 253°–254°, sp.gr. 0·9068 at 17°/17°.

The characteristic odour of the quince is probably due to ethyl pelargonate. This ester (b.p. 227°–228°; sp.gr. 0·8655 17·5°/4°) is prepared commercially for flavouring common wines, brandy, &c., from the oxidised products of oil of rue.

2. *isoNonoic acid, methylhexyl acetic acid,* or *α-methyloctoic acid* $CH_3[CH_2]_5CH(CH_3)COOH$ is formed by boiling methylhexyl carbinol cyanide with potash (Kullhem. Annalen, 173, 319); b.p. 244°–246° (corr.), sp.gr. 0·9032 at 18°/. Almost insoluble in water; readily soluble in alcohol and ether.

3. *isoHepthyl acetic acid* or *β-methyloctoic acid* $CH_3[CH_2]_5CH(CH_3)CH_2{\cdot}CO_2H$. Obtained by heating *iso*heptyl malonic acid; b.p. 232°. Insoluble in water; soluble in alcohol and ether (Venable, Ber. 13, 1652).

NONTRONITE. A hydrated ferric silicate of a light-green colour, which, on the expulsion of water, changes to a dark chestnut-brown; opaque, fracture uneven; lustre resinous; unctuous to the touch, and somewhat harder than talc. Specimens found at Heppenheim, in the Bergstrasse, and at Andreasberg gave numbers agreeing with the formula

$$Fe_2O_3{\cdot}3SiO_2,5H_2O$$

(Thorpe, Proc. Lit. and Phil. Soc. Manchester, 1869, 1).

NOPAL. The Mexican name of the cactaceous opuntia, upon which the cochineal insect (*Coccus cacti*) breeds.

NORDHAUSEN ACID. *Fuming oil of vitriol* or *pyrosulphuric acid, v.* SULPHURIC ACID.

NORMAL POWDER *v.* EXPLOSIVES.

NORWAY SPRUCE RESIN *v.* RESINS.

NOSEAN *v.* LAPIS-LAZULI.

NOSOPHEN *v.* SYNTHETIC DRUGS.

NOTTINGHAM WHITE. *Flake white v.* PIGMENTS.

NOVACULITE *v.* OILSTONE AND WHETSTONE.

NOVAINE *v.* CARNITINE.

NOVARGAN, NOVASPIRIN *v.* SYNTHETIC DRUGS.

NOVOCAINE. Trade name for *p*-aminobenzoyldiethylaminoethanol hydrochloride used as a substitute for cocaïne. Fine white needles, m.p. 156°, very soluble in water (*v.* SYNTHETIC DRUGS).

NOYAU *v.* LIQUEURS AND CORDIALS.

NUCIN or **JUGLONE.** This substance, obtained by Vogel and Reischauer from walnut husks, has been shown by Bernthsen to be an oxynaphtho-quinone $C_{10}H_6O_3$ (Ber. 1884, 1945).

NUN. This name is given to the fatty product of an insect found in Yucatan. It is a yellowish-brown fatty mass, which has a neutral reaction, absorbs oxygen from the air, melts at 48·9°, and resolidifies between 26·7° and 24·9°; dissolves easily in ether, benzene, chloroform, or oil of turpentine, but is insoluble in alcohol; saponifies with difficulty, yielding a pungent-smelling acid called *niïc acid,* and a volatile oil, together with palmitic and stearic acid. Ammonia colours it red. Its solution in turpentine oil is converted, by exposure to the air, into a resinous syrup (A. Schott, Chem. News. 22, 110).

NUT-GALLS *v.* GALL-NUTS.

NUTMEG. The nutmeg is the kernel of the fruit of *Myristica fragrans* (Houtt) (*v.* Mace). When gathered the fruit is slowly dried, either in the sun or by artificial heat, the hard shell is removed and the nutmegs (except in the case of those from Penang) washed in milk of lime. The nuts are then sorted into grades according to their size, the larger and denser being the most valuable. Those which are shrivelled are reserved for the production of ground nutmeg, of which, however, little, if any, appears on the market.

The true nutmeg is oval or nearly spherical in shape, from 20 to 25 mm. long and from 15 to 18 mm. wide. It is wrinkled longitudinally with a groove marking the position of the raphe. In cross section it has a marbled appearance. It has a pleasant and characteristic odour and a hot aromatic taste.

Composition.—The preponderating constituents are a fixed oil, starch, albuminoids, and fibre; the flavour and therapeutic action are due to the volatile oil.

According to Winton, Ogden, and Mitchell (U.S. Dep. Agric. Bureau of Chemistry, Bulletin 66, 1902), nutmeg has the composition—

	Max.	Min.
Moisture	10·83	5·79
Ash, total	3·26	2·13
,, sol. in water	1·46	0·82
,, insol. in HCl	0·01	0·00
Ether extract, volatile	6·94	2·56
,, ,, non-volatile	36·94	28·73
Alcohol extract	17·38	10·42
Reducing matter by acid conversion } calc. as starch	25·60	17·19
Starch by diastase method	24·20	14·62
Crude fibre	3·72	2·38
Nitrogen	1·12	1·05

(For earlier analyses by Richardson, *v.* U.S. Dept. of Agric. Div. of Chemistry, Bull. 13, pt. 2, 1887.)

The sole use of nutmeg is as a flavouring agent, but the volatile oil is employed in medicine as an aromatic and carminative. In large doses it produces epileptiform convulsions.

The expressed oil of nutmeg (*Adeps myristicae*) is used in plasters and hair lotions as a mild stimulant. It consists mainly of the fixed oil, but usually contains substantial proportions of the volatile oil also. When freed from this it has the following constants:—m.p. 29°–30° C.; saponification value, 184–186; iodine value, 56–59·5 (Parry, Food and Drugs, p. 235).

Adulteration.—As nutmegs are almost invariably sold whole, *i.e.* unground, adulteration is very rare in this country.

The substitution of the long nutmeg (*M. Argentea*) cannot be regarded as legitimate, being much inferior in flavour, still less that of wild nutmegs from *M. Malabarica* or other species of *Myristica.* Both would be detected at once by the complete absence of aroma, and also by their different shape and size. Worm-eaten nuts may be passed off as sound after stopping the holes and coating with lime. This will be revealed by careful inspection. More or less exhausted nuts may be detected by the reduced fat content.

Standards.—The United States standards for nutmeg are as follows: The fixed ether extract shall be not less than 25 p.c., the ash not greater than 5 p.c., the ash insoluble in hydrochloric acid not greater than 0·5 p.c., and the crude fibre not over 10 p.c.

C. H. C.

NUTMEG BUTTER *v.* MYRISTICA FATS.

NUTMEG-OIL (syn. *Oil of Mace*) is the essential oil of the nutmeg, and is extracted by bruising the fruit and submitting the paste to the action of steam; after which the mass is pressed between metal plates, when the oil slowly exudes. The yield of oil reaches 2–3 p.c. of the nutmegs so treated. The colour of this oil is reddish-yellow; it possesses the aroma of the nutmeg and is employed for scenting soaps and perfumery; and sometimes also in medicine.

The purest commercial oil of nutmeg is resolvable by fractional distillation into the following bodies:—1. A soft brown resin (about 2 p.c. of the oil) not volatile at 300°, and having the composition $C_{40}H_{56}O_5$. 2. Liquids boiling at

260°–280° and 280°–290°, the composition of which may be represented by the formula $(C_{10}H_{13}O_2)_n$. 3. An oxidised oil, $C_{10}H_{16}O$, boiling at 212°–218°. 4. A mixture, boiling at 173°–179° (about 15 p.c. of the original oil), of a terpene $C_{10}H_{16}$, with a small quantity of cymene. 5. A hydrocarbon boiling at 163°–164°, consisting of a terpene with a trace of cymene, amounting to 70 p.c. of the original oil.

From these results it may be inferred that the hydrocarbon boiling at 167°, called by Gladstone myristicene (Chem. Soc. Trans. [ii.] 10, 3), is a mixture of two or more terpenes with perhaps a little cymene.

The oxidised body ($C_{10}H_{16}O$) is myristicol. It is converted by heat into an isomeric (or polymeric) modification boiling at a higher temperature, and subsequently into a resin having the same composition. Myristicol treated with dehydrating agents yields cymene, and when treated with phosphorus pentachloride it is converted into a compound $C_{10}H_{15}Cl$, which is resolved by prolonged boiling into hydrogen chloride and cymene.

The cymene contained in the portion of the nutmeg hydrocarbon which boils at 163°–164°, may be isolated by treating the mixture with sulphuric acid so as to polymerise the terpene present (the cymene is not altered by the treatment), then shaking with water and distilling in a current of steam. The cymene thus obtained is quite pure, and amounts to about 8 p.c. of the hydrocarbon boiling at 163°–164°.

The terpene of nutmeg-oil may be converted into cymene by combining it with bromine and distilling the resulting dibromide $C_{10}H_{16}Br_2$, whereby it is resolved into 2HBr and $C_{10}H_{14}$ (Wright, Chem. Soc. Trans. [ii.] 11, 549), *v.* OILS, ESSENTIAL.

NUTS. The name given to various seeds, some the produce of large trees, *e.g.* walnut, chestnut; others of shrubs, *e.g.* filbert; some even of small leguminous plants, *e.g.* pea nuts.

Nuts are, as a rule, rich in nitrogenous matter and in oil, and when palatable and digestible, afford a concentrated and nutritious food.

The following analyses, chiefly from American sources (Bull. 28, U.S. Dept. of Agric. 1899), will serve to show the average composition of the edible portions of many varieties of nuts:—

	Water	Protein	Fat	Carbo-hydrates	Ash
Almonds . .	4·8	21·0	54·9	17·3	2·0
Beechnuts .	4·0	21·9	57·4	13·2	3·5
Brazil nuts .	5·3	17·0	66·8	7·0	3·9
Chestnuts, fresh	45·0	6·2	5·4	42·1	1·3
Chestnuts, dried	5·9	10·7	7·0	74·2	2·2
Cocoanut . .	14·1	5·7	50·6	27·9	1·7
Filberts . .	3·7	15·6	65·3	13·0	2·4
Hickory nuts .	3·7	15·4	67·4	11·4	2·1
Pea nuts . .	9·2	25·4	38·6	24·4	2·0
Pecaus . :	2·7	9·6	70·5	15·3	1·9
Pistachio nuts .	4·2	22·3	54·0	16·3	3·2
Walnuts . .	2·5	18·4	64·4	13·0	1·7

H. I.

NUX VOMICA (*Noix vomique*, Fr.; *Krahenaugen, Brechnuss*, Ger.). Among the numerous species of *Strychnos* distinguished for their toxic properties the best known is *S. Nux vomica* (Linn.), a medium-sized tree which is found throughout Southern and Eastern Asia and in the northern part of Australia. The seeds of the fruit of this tree constitute the nux vomica of commerce. They were introduced into Europe during the sixteenth and seventeenth centuries, and have gradually become an important article of *materia medica*. They are known in the market as 'Bombay,' 'Cochin,' and 'Madras' seeds. The finest specimens which have been examined are grown in Ceylon. In small doses nux vomica acts as a powerful nervous stimulant affecting certain nerve centres, particularly the medulla oblongata. Other parts of the tree possess similar physiological activity, notably the bark, which has attracted attention as an adulterant of cusparia or angustura and as such is called False Angustura Bark (*v.* CUSPARIA BARK). For further botanical and historical particulars, *v.* Flück. a. Hanb. 428; Bentl. a. Trim. 178; Oberlin and Schalgdenhauffen (J. Pharm. Chim. [iv.] 28, 225); Dunstan and Short (Pharm. J. [iii.] 13, 1053; 15, 1 and 156); Rosoll (Monatsh. 5, 94); Greenish (Pharm. J. [iii.] 15, 60); and Ford, Ho Kai and Crow (*ibid.* [iii.] 17, 927).

The poisonous action of nux vomica depends upon the presence of the two well-known bitter alkaloids, *strychnine* and *brucine*. The former was isolated from the seeds in 1818 by Pelletier and Caventou (Ann. Chim. Phys. [ii.] 10, 142; 26, 44), and the latter, a year later, from the bark and seeds, by the same chemists (*ibid.* [ii.] 12, 118; 26, 53). That strychnine is also present in the bark was shown by Shenstone in 1877 (Pharm. J. [iii.] 8, 445; 9, 154). These alkaloids are widely distributed among the species of the *Strychnos* genus. The *S. Ignatii* (Berg.), a climbing plant of the Philippine Islands, the seeds of which constitute the St. Ingatius' Beans, contains both alkaloids. Strychnine indeed was discovered by Pelletier and Caventou in the seeds of this plant (*cf.* Flückiger and Meyer, Pharm. J. [iii.] 12, 1; Flück. a. Hanb. 431; Bentl. a. Trim. 179; Crow *ibid.* [iii.] 17, 970; and Ford, Ho Kai and Crow, *ibid.* [iii.] 18, 75). Strychnine and brucine are found also in *S. Tieuté* (Lesch.) of Java, the active ingredient in the Upas-Tieuté arrow poison (Pelletier and Caventou); in *Lignum colubrinum* or snake-wood, from *S. colubrina* (Linn.), a Malabar tree (Berdenis, J. 1866, 710; H. G. Greenish, Pharm. J. [iii.] 9, 1014), and *S. Gauthieriana* (Piérre), the tree which yields the *hoang-nan* of China (*cf.* Planchon, J. Pharm. Chim. 1877, 384; Räber, Y.-Bk. Ph. 1881, 138). The Indian drug *bidara laut* derived from *S. ligustrina*, examined by H. G. Greenish, was found to contain brucine only (Pharm. J. [iii.] 9, 1013). Other poisonous species of *Strychnos* depend upon the alkaloid curarine for their activity (*v.* CURARA); and the African shrub *akazga*, apparently belonging to the same genus, contains a nearly related base *akazgine* (Frazer, J. pr. Chem. 104, [i.] 51).

For the extraction of the alkaloids from the seeds, besides the process employed by Pelletier and Caventou, numerous other methods have been suggested. The most noteworthy are those of Corriol (J. Pharm. Chim. [i.] 11, 492), Soubeiran (*ibid.* [iii.] 45, 230), Winckler (Mag. Ph. 19, 261), Neuhaus (Neu. Jour. Trommsdorf, 11, 2, 198), Duflos (Berz. J. 28, 2, 208), O. Henry

(J. Pharm. Chim. [ii.] 16, 752), N. E. Henry (*ibid.* [ii.] 8, 401), Lebourdais and Tilloy (*ibid.* [iii.] 23, 406), Wittstein (Darstell. und Prüfung, 215), Wittstock (Berz. Lehrb. 3rd ed. 6, 296), and Geiseler (Arch. Pharm. [ii.] 2, 73). Of these that of Wittstein is the best known and has formed the basis of most of the methods now in use. In all cases it is necessary in the first place to reduce the seeds to a powder, an operation which is rendered difficult by their horny nature. Perhaps the best mode of procedure is that recommended by Dunstan and Short (Pharm. J. [iii.] 13, 1053). The seeds are split and then subjected to a temperature of 100° for 3 hours, after which treatment they admit of being powdered in a drug-mill. The powder, according to Wittstein, is exhausted with 40 p.c. alcohol and the solution obtained is distilled and evaporated until the residue is equal in weight to the powder employed. A solution containing one-fiftieth of this weight of normal lead acetate is then added and the precipitated lead salts separated. The filtrate is concentrated to one half, mixed with calcined magnesia and allowed to stand a week, when the alkaloids will have precipitated. They are extracted from the precipitate by treatment with 80 p.c. alcohol, and on evaporating this solution are obtained in an impure condition. Washing with 40 p.c. alcohol removes the brucine and colouring matter and leaves the strychnine. Ammonia is now generally substituted for magnesia, when only 12 hours' standing is necessary. Crude strychnine thus obtained may be purified by further washing with 40 p.c. alcohol, or as suggested by Prescott (Y.-Bk. Pharm. 1879, 97) more dilute alcohol may be advantageously employed until the washings cease to give the colour reaction with nitric acid for brucine. Another plan is to convert it into a salt, such as the nitrate, recrystallise the salt several times and regenerate the base. Strychnine consists of rhombic prisms (Schabus, J. 1854, 516; Kenngott, J. 1855, 567) which melt at 268° (Löbisch and Schoop, Monatsh. 6, 858) and have a sp.gr. of 1·359 at 18° (Clarke, Ber. 12, 1399). Solubility in 100 parts of cold water, 0·014; benzene, 0·607; 95 p.c. alcohol, 0·936; ether, 0·08; fusel oil, 0·55 (Dragendorff, J. 1865, 739; *cf.* Crespi, Gazz. Chim. ital. 13, 175). Many of the neutral salts of strychnine are almost insoluble in water, and hence precipitation of the alkaloid occurs where, as is sometimes the case, salts of strychnine are prepared for medical administration in aqueous solution together with alkaline bromides or iodides (*cf.* Lyons, Pharm. J. [iii.] 8, 1048). For other characters and reactions of strychnine *v.* VEGETO-ALKALOIDS.

To obtain brucine from the mixed alkaloids extracted from nux vomica several methods are employed beside those already mentioned, and the seeds are sometimes worked directly for this base. The latter plan was adopted by Shenstone, who prepared brucine quite free from strychnine. The powdered seeds were extracted with alcohol containing one-sixth part of water, and the solution concentrated by distillation and evaporation to the consistence of a thick syrup. From this the alkaloids were extracted by water containing 0·3 p.c. of sulphuric acid. To the acid solution an excess of sodium carbonate was added, and the precipitate, which formed after a few hours, was collected and dissolved in chloroform. The chloroformic solution was then shaken several times with water, to which sulphuric acid was gradually added. The first washings were kept alkaline, but the last ones were made distinctly acid. In this way crystallisation during the operation is prevented. The solution of alkaloidal sulphate was next treated in a shallow dish with an atmosphere of ammonia gas, when some of the base separated in crystals. These were washed with dilute alcohol, which on spontaneous evaporation left brucine, not quite free, however, from traces of strychnine. These were finally removed by conversion into hydriodide and regeneration of the alkaloid (Chem. Soc. Trans. 39, 453). The crude alkaloids may also be separated by taking advantage of the different behaviour of brucine and strychnine acetates when heated on a water-bath, when the strychnine salt loses its acid and becomes comparatively insoluble in water (Flückiger, Arch. Pharm. [iii.] 6, 404); or of the action of dilute nitric acid on the picrates (Gerock, *ibid.* [iii.] 27, 158); or of the different solubility of their chromates (Horsley, J. 1856, 758); or of their ferrocyanides (Dunstan and Short, Pharm. J. [iii.] 14, 290; *cf.* Beckurts, Ph. Centh. 4, 325). By the last-mentioned process the mixed alkaloids, in a dilute solution containing a slight excess of sulphuric acid, are treated with potassium ferrocyanide, when after standing several hours the whole of the strychnine is precipitated, leaving the brucine in solution. Brucine crystallises from dilute alcohol in monoclinic prisms or plates containing $4H_2O$ (Lüdecke, Ber. 10, 838), which lose water at 105° and melt at 178° (Claus and Röhre, Ber. 14, 773). The physiological action is similar but less intense than that of strychnine; but, unlike strychnine and like curarine, it is not poisonous when taken into the stomach, but acts fatally when injected under the skin (Brunton, Chem. Soc. Trans. 47, 143). It is very slightly soluble in cold water, though much more so than strychnine. It is soluble in cold alcohol, chloroform, and volatile oils; but insoluble in ether and fats. For other characters and reactions, *v.* VEGETO-ALKALOIDS.

Nux vomica seeds also contain *igasuric acid*, discovered by Pelletier and Caventou (Ann. Chim. Phys. [ii.] 10, 167; 26, 54), with which the alkaloids are supposed to be combined, and a small proportion of a glucoside, *loganin*, $C_{25}H_{34}O_{14}$, first obtained by Dunstan and Short from the fruit pulp which contains it in larger quantities (Pharm. J. [iii.] 14, 1025; 15, 4). The 'igasurine' of Desnoix (J. Pharm. Chim. [iii.] 25, 202) and Schützenberger (Compt. rend. 46, 1234) has been shown by Jörgensen (J. pr. Chem. [ii.] 3, 175) and Shenstone (Chem. Soc. Trans. 37, 235; 39, 453) to be impure brucine. Igasuric acid is isolated from the lead precipitate obtained in the preparation of the alkaloids. The igasuric acid obtained by Pelletier and Caventou was crystalline while other investigators have always obtained it in an amorphous state. It would seem to be a variety of tannic acid (Ludwig, Arch. Pharm. [iii.] 2, 137; Corriol, J. Pharm. Chim. 19, 155; Marsson, Annalen, 72, 296), and Sander (Arch. Pharm. 235, 133) has regarded it as identical with caffetannic acid. Gorter, however (*ibid.* 247, 197), finds that it is identical with the chlorogenic acid $C_{32}H_{28}O_{19}$, obtained by him from coffee berries. Loganin consists of colourless prisms which melt at 215°. It dissolves easily in water and alcohol, but less so in chloroform or benzene. Warmed with sulphuric acid it develops a red colour which changes to purple. Boiled with dilute acids it breaks up into glucose and *loganetin*. It occurs in the pulp of the fruit of Ceylon nux vomica to the extent of 5 p.c. (Dunstan and Short). In addition to these constituents nux vomica seeds contain about 11 p.c. of *proteids* (Flück. a. Hanb.); 4 p.c. of *fat* or fatty oil (Flück. a. Hanb.; Meyer, J. 1875, 856; T. E. Greenish, Pharm. J. [iii.] 12, 581; Dunstan and Short; Harvey and Wilkes, J. Soc. Chem. Ind. 24, 718), together with *mucilage* and *sugar*.

Several methods have been suggested for the estimation of the alkaloids in nux vomica. The most important are those of Dragendorff (C. Wertbestimmung, St. Petersburg, 1874; Zeitsch. Chem. [ii.] 2, 27) and Dunstan and Short (Pharm. J. [iii.] 13, 665 and 1053). Dragendorff's method, which gives accurate results, consists in extracting the powdered seeds with dilute sulphuric acid, nearly neutralising the solution with magnesia, and evaporating to a syrup. From this the alkaloids are extracted by treating it first with 90 p.c. and afterwards with 50 p.c. alcohol. The alcoholic solutions are then distilled until the residue is concentrated to one-fifth of the original volume. The slightly acid solution is then shaken with benzene, which removes fat and other substances, but does not dissolve the alkaloidal salts. Treatment with magnesia sets the alkaloids free and they are extracted by benzene or chloroform, the solution evaporated and the residue dried and weighed. The method of Dunstan and Short is simpler. The powdered seeds are exhausted with a mixture of three volumes of chloroform and one volume of alcohol. From this solution the alkaloids are separated by shaking with dilute sulphuric acid, which dissolves them as acid sulphates. By treatment of the acid solution with ammonium hydroxide and chloroform, the free bases are extracted, and on evaporation of the chloroform solution are obtained in a sufficient state of purity for weighing. Examined by this method, 'Bombay' seeds gave from 3·14 to 3·90 p.c.; 'Cochin' seeds 3·04 and 3·60 p.c., and 'Madras' seeds 2·74 and 3·15 p.c. of total alkaloids (Dunstan and Short). Keller's method (Chem. Soc. Abstr. 1894, 490; 1897, 84) in which the powdered beans are extracted with a mixture of ether and chloroform gives very accurate results.

A method for the estimation of strychnine and brucine when mixed as in the alcoholic extract of nux vomica was based on the insolubility of strychnine ferrocyanide in dilute sulphuric acid, the corresponding brucine salt being soluble (Dunstan and Short, Year Book Pharm. 1883, 469; Holst and Beckurts, Arch. Pharm. [iii.] 25. 313). This method, however, according to Schweissinger (*ibid.* [iii.] 12, 579, 609; Stoeder, Chem. Zentr. 1899, i. 506), does not give a satisfactory separation. Other methods are the oxidation of brucine by potassium permanganate which leaves the strychnine unaltered (Sander, Zeitsch. anal. Chem. 37, 132), or similar oxidation by nitric acid (Keller, Zeitsch. Oesterr, Apoth.-Ver. 1903, 587; Gordin, Arch. Pharm. 240, 641; Howard, Annalen, 30, 261; Reynolds and Sutcliffe, J. Soc. Chem. Ind. 25, 512).

The percentage of strychnine in the total alkaloids from nux vomica varies from 43·9 to 45·6. The alkaloids in the St. Ignatius' bean contain a larger percentage of strychnine, 60·7–62·8 (Sander, Arch. Pharm. 235, 133).

The experiments of Siebold (Pharm. J. [iii.] 7, 283), Dunstan and Short (*ibid.* [iii.] 14, 292, 441, and 443), and Conroy (*ibid.* [iii.] 14, 461) proved that the pharmaceutical preparations of nux vomica, the extract and tincture, vary materially in alkaloidal strength. To employ only the alkaloids for medical purposes would obviate this want of uniformity, but they are not believed to possess the whole of the therapeutic activity represented by the extract or tincture. The liquid extract of nux vomica of the British Pharm. 1898, is, therefore, standardised to contain 1·5 grams of strychnine in 100 c.c. the alkaloid being estimated by the ferrocyanide process. A. S.

NYCANTHES ARBOR-TRISTIS (Linn.). This is a large shrub with rough leaves and sweet scented flowers occurring in the sub-Himalayan and Tarai tracts; also in Central India, Burmah, and Ceylon. The flowers open towards evening and fall to the ground on the following morning. The corolla tubes are orange coloured and give a beautiful but fleeting dye, which is mostly used for silk, sometimes in conjunction with 'kusum' or turmeric, occasionally with indigo and kath (Watts, Dict. Econ. Prod. of India, 1891, 5, 434).

According to Hill and Sirkar (Chem. Soc. Trans. 1907, 91, 1501) these flowers yield a red crystalline colouring matter *nycanthin*. An aqueous decoction treated with 1 p.c. of hydrochloric acid, is warmed gently for several hours, the precipitate collected and extracted with boiling alcohol. The extract heated with 1 p.c. hydrochloric acid deposits the colouring matter in red flakes which are washed with alcohol, and crystallised from pyridine or phenylhydrazine.

Nycanthin separates from pyridine in minute regular hexagons, and from phenylhydrazine in rhombic crystals; these are yellow, while wet, but brick red when dry, and melt between 225° and 230°. It dissolves in alkalis to form a yellow solution from which it appears to be reprecipitated unchanged by acids, and contains no methoxyl group. With sulphuric acid it gives a most intense blue colour, which, however, rapidly turns yellow, and in this respect resembles bixin, the colouring matter of annatto (*Bixa Orellana* [Linn.]).

The analyses of Hill and Sirkar (*l.c.*) agree closely with $C_{20}H_{27}O_4$ or $C_{15}H_{20}O_3$, but of these formulæ the former appears to be preferable. *Acetylnycanthin* $C_{20}H_{26}O_4 \cdot C_2H_3O$, and the bromine compound $C_{20}H_{15}O_{18}Br_5$, amorphous powders, have been prepared by these authors. Mannitol was also isolated from the flowers.

For dyeing purposes the material (silk or cotton) is simply steeped in a hot or cold decoction of the flowers. The addition of alum and lime juice to the dye-bath is said to render the colour more permanent.

According to Perkin (private communication) the flowers of the *Cedrela Toona* (Roxb.), also employed as a dyestuff in India, yield a small quantity of crystalline red colouring matter, which closely resembles and is probably identical with nycanthin. A. G. P.

O.

OAK-BARK. The oak tree is generally barked from the beginning of May till the middle of July. The barkers make a longitudinal incision with a mallet furnished with a sharp edge, and a peculiar incision by means of a barking-bill. The bark is then removed by peeling-irons, the separation being promoted, when necessary, by beating the bark. It is stacked in pieces about 2 feet long (*v.* Leather).

OAK-GALLS *v.* Gall nuts.

OAK-VARNISH *v.* Varnish.

OATS *v.* Cereals.

OBLITINE *v.* Carnitine.

OBREGUIN. A substance intermediate in character between the fats and resins, occurring in Mexico on the twigs of *Althaea rosea* (Cav.). Nearly insoluble in water; easily soluble in ether, chloroform, or turpentine oil. On evaporation its solutions form a colourless, odourless mass, of the consistency of turpentine. Saponifiable by alkalis.

OBSIDIAN. A vitreous volcanic rock, generally jet-black or of dark bottle-green tint, and nearly opaque, except on the thin edges, which are translucent. Obsidian results from the rapid cooling of rocks of acid type, such as rhyolite, the corresponding glass in the basic series being termed *tachylyte.* Microscopic examination of obsidian usually reveals the presence of numerous enclosures, known as crystallites and microlites, which may be so abundant as to render the rock opaque and devitrified. Many obsidians present a banded structure, while others are spherulitic. An analysis of obsidian from Iceland gave: SiO_2, 75·28; Al_2O_3, 10·22; Fe_2O_3, 4·24; CaO, 1·81; MgO, 0·25; K_2O, 2·44; Na_2O, 5·53; H_2O, 0·23 p.c. Obsidian, when fractured, presents a sharp-cutting edge, and hence in parts of Mexico where the material is abundant, as at the Cerro de Navajas ('Hill of Knives'), it was used by the Aztecs for knives, razors, and arrow-heads. It has also been employed by savages in other volcanic countries. Obsidian has occasionally been cut and polished as a gem-stone, but displays too little colour, even when thin, and is, moreover, too soft for general use. A dark variety with a silvery sheen is, however, used for ornamental purposes in Siberia, while a brownish-red streaked variety, known as 'mahogany-obsidian,' has been employed to a limited extent as a decorative material in the United States. On Obsidian Cliff, Yellowstone National Park, *v.* J. P. Iddings, Seventh Ann. Rep. U.S. Geol. Sur. 1888. F. W. R.

OCCLUSION (*occludo*, to enclose). Graham's term for the process of absorption or condensation of gases within the pores of a substance, *e.g.* the absorption of hydrogen by platinum and palladium, or the condensation of marsh-gas or fire-damp in coal.

OCHRE. A name applied to various native pigments, distinguished according to colour as yellow, brown, and red ochres, and consisting essentially of ferric hydroxides (represented by the mineral species limonite and turgite), usually more or less earthy by admixture with clay or sand. Deposits of fine yellow ochre occur in the Lower Greensand of Shotover Hill, near Oxford. Red and brown ochres are commonly associated with iron-ores, especially with the hæmatite occurring in pockets in the carboniferous limestone, and have been worked in South Wales, the Forest of Dean, near Bristol, at Brixham in Devonshire, Ulverston in Lancashire, and near Workington in Cumberland. Some of the finest ochres of commerce are obtained from France, and are known as Auxerre and Rochelle ochres. In the United States, ochres are worked in connection with many deposits of iron-ore, especially in Virginia and Pennsylvania. Ochre is deposited by the water of chalybeate springs and by the waters issuing from mines; in some cases such material is collected. Red ochre is formed as a by-product in the roasting of iron-pyrites. Some ochres are so pure as to be ready for use after having been simply dried, ground, and bolted; while others require careful preparation by washing and levigating. Sometimes the material is roasted to obtain the required shade of deep brown or red. The value of an ochre depends, not only on its colour, but on the proportion of oil required to be mixed with it for use as a pigment. The presence of finely-divided silica is not always detrimental to an ochre, inasmuch as it may enable the paint to adhere to fibres of the wood to which it is applied, and by filling up spaces may improve its covering power. Coarse ochre is extensively employed in the manufacture of oilcloth and linoleum, while the finer kinds of ochre are valued by the paper-maker for staining the pulp to its required tint, being especially used in the manufacture of brown paper. In commerce the term 'ochre' is frequently restricted to the pale yellowish-brown varieties. In mineralogy, on the contrary, it is extended to a variety of metallic oxides and other compounds formed as products of alteration and occurring as earthy incrustations on the minerals from which they have been derived by atmospheric action. Thus the mineralogist recognises such bodies as antimony-ochre, bismuth-ochre, molybdic-ochre, nickel-ochre (an arseniate), uranium-ochre (a sulphate), and wolfram-ochre. *See* G. P. Merrill, The Non-Metallic Minerals, 2nd ed. 1910; T. L. Watson, Ochre Deposits of Georgia, Bull. Georgia Geol. Survey, 1906, No. 13 (*v.* Umber). L. J. S.

OCHROITE *v. Cerium metals.*

OCRE DE RU. *Brown ochre v.* Pigments.

OCTITOL *v.* Carbohydrates.

OCTOIC ACIDS. $C_8H_{16}O_2$.

1. *n. Octoic acid* or *caprylic acid*

$CH_3[CH_2]_6COOH$.

Exists as a glyceride in butter, and in human fat, and especially in cocoa-nut oil. It is also found in cheese, among the products of the distillation of fat by superheated steam, and in many fusel oils, partly free and partly in combination with different alcohol radicles. It may be prepared by oxidising normal octyl alcohol (Zincke, Annalen, 152, 9) or by the dry distillation of oleic acid (Gottlieb. *ibid.* 57, 63). It melts at 16·5° and boils at 237·5°, sp.gr. 0·9100 at 20°/4°. Sparingly soluble in cold water: 400 parts of water at 100° dissolve 1 part of the acid; readily soluble in alcohol or ether (Zincke, *l.c.*).

2. *Dipropylacetic acid, α-propylvaleric acid* $(C_3H_7)_2CH{\cdot}COOH$ is obtained by boiling ethyl dipropylacetoacetate with potash (Burton, Amer. Chem. J. 3, 389), or by heating dipropylmalonic acid (Fürth, Monatsh. 3, 319; *v.* also method of Oberreit, Ber. 1896, 2000); b.p. 219·5°, sp.gr. 0·9215 at 0°/4°. Sparingly soluble in water.

3. *Iso-octoic acid* is obtained by the oxidation of *iso*-octylalcohol (Williams, Chem. Soc. Trans. 1879, 128), b.p. 218°–220°, sp.gr. 0·911 at 20°/4°.

4. *Octoic acid* from *iso*dibutylene

$C(CH_3)_3CH_2{\cdot}CH(CH_3)COOH$

formed by the oxidation of the hydrocarbon; boils at about 215° with partial decomposition (Butlerow, Annalen, 189, 72). Probably identical with *iso*-octoic acid.

5. *Ethylbutylacetic acid, α-ethylhexoic acid* $CH_3[CH_2]_3CH(C_2H_5)COOH$. Obtained by the oxidation of corresponding alcohol (Raupenstrauch, Monatsh. 8, 115).

6. *Ethylisobutylacetic acid, α-ethyl-γ-methylvaleric acid* $(CH_3)_2CH{\cdot}CH_2{\cdot}CH(C_2H_5)COOH$. Obtained by heating ethyl*iso*butylacetoacetate with alkali and alcohol (Guye and Jeanprêtre, Bull. Soc. chim. [iii.] 13, 183), b.p. 219°–220° (729 mm.); sp.gr. 0·906 at 20°/4°.

OCTYL *Capryl* C_8H_{17}. The eighth alcohol-radicle of the series C_nH_{2n+1}. Like other members of this series, it cannot exist in the free state; when liberated from its compounds it is converted into dioctyl $C_{16}H_{34}$, a body isomeric and perhaps identical with ceryl hydride.

The compounds of this radicle occur in petroleum, in the seeds of the common- and cow-parsnip, and in the products of the distillation of some varieties of coal.

OCTYL ALCOHOL $C_8H_{17}{\cdot}OH$. A large number of isomeric alcohols with this formula are possible, but only the following have been prepared:—

(1) **Normal octyl alcohol,** *α-hydroxy octane* $CH_3[CH_2]_7OH$, occurs in the fruit of *Heracleum Sphondylium* (Linn.), the cow-parsnip, as the acetic acid ester (Zincke, Annalen, 152, 1; Möslinger, *ibid.* 185, 26); and as the acetate and butyrate in the oil of *Heracleum villosum* (Fisch.) (Franchimont, Ber. 1871, 822). Oil expressed from the ripe fruit of *Peucedanum sativum* (Benth. and Hook.), the common parsnip, is almost pure octyl butyrate (Renesse, Annalen, 166, 80). It boils at 195·5° and has sp.gr. 0·8375 at 0° (Zander, Annalen, 224, 84).

(2) **Methyl hexyl carbinol,** *β-hydroxy octane* $CH_3[CH_2]_5CH(OH)CH_3$, b.p. 179°–179·2° at 762 mm. (Schiff, *ibid.* 220, 103), 177·6°–177·8° at 745·4 mm. (Brühl, *ibid.* 203, 28); sp.gr. 0·8193 at 20°/4° (Brühl). Heat of combustion 1,262,105 cal. (Lugunin, Ann. Chim. Phys. [v.] 25, 141).

It is formed by the distillation of alkaline ricinoleates with excess of potash (Moschnin, Annalen, 87, 111; Bouis, *l.c.*; Städeler, J. 1857, 358; Dachauer, Annalen, 106, 269; Schorlemmer, *ibid.* 147, 222). By the distillation of the saponified oil of the seed of *Jatropha curcas* (Linn.) (Silva, Zeitsch. Chem. 1869, 185).

It is a limpid, oily, inactive liquid, with a strong aromatic odour, soluble in alcohol, ether, wood-spirit, and acetic acid; insoluble in water. It dissolves phosphorus, sulphur, iodine, fused zinc chloride, fats, resins, and copals.

Preparation.—Castor oil (which contains sodium ricinoleate) is distilled with excess of potash; the portion which passes over between 176°–180° is collected and purified by fractional distillation.

On oxidation it yields, first, methyl-hexyl ketone $MeCOC_6H_{13}$; subsequently acetic and normal caproic acids are formed. It reduces silver oxide (but not nitrate) when heated with it, forming a metallic mirror. With hydrochloric acid, phosphorus pentachloride, bromine or iodine and phosphorus, &c., it exhibits the usual reactions of secondary alcohols. The ketone $C_6H_{11}Cl_2{\cdot}CO{\cdot}CCl_3$ is produced on saturation with chlorine (A. Brochet, Bull. Soc. chim. [iii.] 13, 120).

(3) **Methyl** *iso***hexyl carbinol,** *β-hydroxy-ζ-methyl heptane* $CH_3{\cdot}CH(OH)[CH_2]_3CH(CH_3)_2$ is produced by the reduction of methyl *iso*hexyl ketone $CH_3{\cdot}CO[CH_2]_3CH(CH_3)_2$ (Welt, Ann. Chim. Phys. [vii.] 6, 135). It boils at 167°–169°, and has a sp.gr. 0·8174 at 21°. It is optically active $[\alpha]_D^{24°}=4{\cdot}69°$.

(4) **Methyl dipropyl carbinol,** *δ-hydroxy-δ-methyl heptane* $CH_3{\cdot}C(C_3H_7)_2OH$, has been prepared by Gortaloff and Saytzeff by the action of 262 grams methyl iodide and excess of zinc on 70 grams butylene (J. pr. Chem. [ii.] 33, 204). It is a liquid boiling at 161·5°, and of sp.gr. 0·82479 at 20°. On oxidation with chromic acid it yields chiefly acetic and propionic acids.

(5) **γ-Hydroxy-δ-ethyl hexane**

$(C_2H_5)_2CH{\cdot}CH(OH)C_2H_5$

may be prepared from bromoacetyl bromide and zinc ethyl (Winogradow, Annalen, 191, 140). It boils at 164°–166°, and on warming with hydrogen iodide yields the iodide.

(6) **Diethylpropylcarbinol,** *δ-hydroxy-δ-ethyl hexane* $(C_2H_5)_2C(C_3H_7)OH$ is prepared from butyl chloride and zinc ethyl (Butlerow, Bull. Soc. chim. [ii.] 5, 17). The product is left for several days till it becomes viscid, it is then heated, acidified with hydrochloric acid and distilled. It has an alcoholic, camphoraceous odour, is lighter than water, in which it is slightly soluble and boils at 145°–155°. On oxidation with chromic acid it yields propionic and acetic acids.

(7) **Diethyl** *iso***propyl carbinol,** *γ-hydroxy-δ-methyl-γ-ethyl pentane* $CH(CH_3)_2C(OH)(C_2H_5)_2$ is produced together with ethyl *iso*propyl carbinol and ketone from *iso*butyryl chloride (1 mol.) and zinc ethyl (2 mols.). The reagents are

mixed and allowed to stand in ice for three days and subsequently left together for five or six months, after which the mixture is treated with ice water (Grigorovitch and Pawloff, J. Russ. Phys. Chem. Soc. 23, 169). It boils at 159·5°–161° at 750 mm. and has sp.gr. 0·8463 at 0°.

(8) **Di*iso*butyl hydrate** $C_8H_{17}OH$. Two alcohols of this name are known. (1) A primary alcohol of unknown constitution. It boils at 179°–180° at 765 mm. (uncorr.) remains fluid at −17° and has sp.gr. 0·841 at 0°/4°, 0·828 at 20°/4° (Williams, Chem. Soc. Trans. 1879, 127). (2) A secondary alcohol obtained mixed with the primary and separated from it by fractionation. It boils at 160°–163°/75·5 mm. and has sp.gr. 0·820 at 15°/4°.

(9) ***Iso*dibutol,** *β-hydroxy-βδδ-trimethylpentane* $(CH_3)_3C{\cdot}CH_2{\cdot}C(CH_3)_2OH$, boils at 146·5°–147·5°, and has sp.gr. 0·8417 at 0°/0°. It is a colourless viscid liquid, with a musty camphoraceous odour. It is prepared from di*iso*butylene hydriodide and silver hydroxide. On oxidation it yields acetone, trimethylacetic acid, acetic acid, and octoic acid $C_8H_{16}O_2$, and a ketone $C_7H_{14}O$ (Butlerow, Annalen, 189, 53).

(10) **Octylene hydrate** $C_8H_{17}OH$ is of uncertain constitution. The iodide results from the action of hydriodic acid on octylene. The alcohol is a clear liquid, boiling at 174°–178°, and of sp.gr. 0·811 at 0°. On oxidation acetic acid, caproic acid, and a ketone $C_8H_{16}O$ are obtained.

OCTANES, C_8H_{18}. Eighteen isomeric hydrocarbons having this formula are theoretically possible, and of these twelve have been prepared. Two of these occur in American petroleum (Mabery and Hudson, Amer. Chem. J. 1897, 19, 255), and are found in the portion boiling between 115° and 130°. *n*-Octane is found among the light oils obtained by distilling Wigan cannel coal at a low temperature (Schorlemmer, Chem. Soc. Trans. 1862, 419). Ligroin consists essentially of hydrocarbons having the formulæ C_7H_{16} and C_8H_{18} (Pelouze and Cahours, Annalen, 127, 197).

(1) ***n*-Octane,** *octyl hydride* $CH_3[CH_2]_6CH_3$, b.p. 125·6° (corr.), sp.gr. 0·71883 at 0°/4° (Thorpe, Chem. Soc. Trans. 1880, 217); b.p. 124·7°/760 mm., sp.gr. 0·7068 at 15°/15°, $n_{\mathrm{D}}^{25^\circ}$ 1·3963 (Clarke, J. Amer. Chem. Soc. 1911, 33, 520; *cf.* Schorlemmer, Annalen, 161, 281).

Occurs in American petroleum; prepared by reducing *sec*-octyl iodide with zinc and hydrochloric acid (Schorlemmer, *ibid.* 152, 152), or *n*-octyl iodide with sodium amalgam (Zincke, *ibid.* 152, 15); by the action of sodium on *n*-butyl iodide (Schorlemmer, *l.c.*); by heating sebacic acid with baryta (Riche, *ibid.* 117, 265).

Colourless liquid, having a faint ethereal smell. On warming with nitric acid (sp.gr. 1·42) mono- and dinitro-octane, acetic, succinic and oxalic acids, and carbon dioxide are obtained (Worstall, Amer. Chem. J. 1898, 20, 212).

(2) **β-Methylheptane,** *iso-octane*
$CH_3[CH_2]_4CH(CH_3)_2$,
b.p. 116·0°/761 mm.; sp.gr. 0·7035 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·3944. Has been synthesised by Clarke (J. Amer. Chem. Soc. 1909, 31, 107).

(3) **γ-Methylheptane**
$CH_3[CH_2]_3CH(CH_3)CH_2{\cdot}CH_3$,
b.p. 117·6°/760 mm.; sp.gr. 0·7167 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·4022. Has been synthesised by Clarke (*ibid.* 558). The method of Welt (Ann. Chim. Phys. [vii.] 6, 121) does not yield a pure product.

(4) **δ-Methylheptane**
$CH_3[CH_2]_2CH(CH_3)[CH_2]_2CH_3$,
b.p. 118·0°/760 mm.; sp.gr. 0·7217 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·3978. Has been synthesised by Clarke (Amer. Chem. J. 1908, 39, 87).

(5) **βγ-Dimethylhexane**
$CH_3[CH_2]_2CH(CH_3)CH(CH_3)_2$,
b.p. 113·9°/758 mm.; sp.gr. 0·7246 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·4075. Has been synthesised by Clarke (J. Amer. Chem. Soc. 1911, 33, 520).

(6) **βδ-Dimethylhexane**
$CH_3{\cdot}CH_2{\cdot}CH(CH_3)CH_2{\cdot}CH(CH_3)_2$,
b.p. 110·0°/763 mm.; sp.gr. 0·7083 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·3986. Has been synthesised by Clarke (*ibid.* 1908, 30, 1144).

(7) **βε-Dimethylhexane,** *diisobutyl*
$(CH_3)_2CH[CH_2]_2CH(CH_3)_2$,
b.p. 108·53° (corr.), sp.gr. 0·711 at 0°/4° (Thorpe, Chem. Soc. Trans. 1880, 219); b.p. 108·25°/760 mm.; sp.gr. 0·6991 at 15°/15°, $n_{\mathrm{D}}^{25^\circ}$ 1·3930 (Clarke, J. Amer. Chem. Soc. 1909, 31, 585; *cf.* Schiff, Annalen, 220, 88).

Prepared by the action of sodium on *iso*butyl iodide (Wurtz, *ibid.* 96, 365) or on a mixture of *iso*amyl and *iso*propyl iodides (Schorlemmer, *ibid.* 144, 188; Kolbe, *ibid.* 69, 261); for other methods, *v.* Clarke, *l.c.* Colourless mobile liquid with ethereal odour and burning taste. Oxidation with chromic acid yields acetic acid and carbon dioxide.

(8) **γδ-Dimethylhexane**
$CH_3{\cdot}CH_2{\cdot}CH(CH_3)CH(CH_3)CH_2{\cdot}CH_3$,
b.p. 116·5°/759 mm.; sp.gr. 0·7270 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·4038 (Clarke, J. Amer. Chem. Soc. 1911, 33, 520). Prepared by the action of sodium on β-iodobutane (Norris and Green, Amer. Chem. J. 1901, 26, 313).

(9) **γ-Ethylhexane**
$CH_3[CH_2]_2CH(C_2H_5)CH_2{\cdot}CH_3$,
b.p. 118·8°–119°/766 mm.; sp.gr. 6·7175 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·3993. Has been synthesised by Clarke and Riegel (J. Amer. Chem. Soc. 1912, 34, 674), who state that it is probably one of the hydrocarbons found by Mabery and Hudson in American petroleum.

(10) **ββγ-Trimethylpentane**
$CH_3{\cdot}CH_2{\cdot}CH(CH_3)C(CH_3)_3$,
b.p. 110·5°–110·8°/760 mm.; sp.gr. 0·7219 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·4164. Has been synthesised by Clarke and Jones (*ibid.* 170).

(11) **β-Methyl-γ-ethylpentane**
$CH_3{\cdot}CH_2{\cdot}C(C_2H_5)CH(CH_3)_2$,
b.p. 114·0°/760 mm.; sp.gr. 0·7084 at 15°/15°; $n_{\mathrm{D}}^{25^\circ}$ 1·3996. Has been synthesised by Clarke (Amer. Chem. J. 1908, 39, 574).

(12) **Hexamethylethane** $C(CH_3)_3C(CH_3)_3$, a crystalline substance; m.p. 96°–97°; b.p. 105°–106°. Prepared by the action of sodium on *tertiary*-butyl iodide (Lwow, Bull. Soc. chim. [ii.] 35, 169).

Octyl chlorides.

Normal chloride, *a-chlorooctane*
$CH_3[CH_2]_6CH_2Cl$,

b.p. 179·5°–180°; sp.gr. 0·8802 at 16°, 0·87857 at 15° (Perkin, J. pr. Chem. [ii.] 31, 495).

Preparation.—By the action of hydrochloric acid gas on octyl alcohol (Zincke, Annalen, 152, 4). A limpid liquid, soluble in absolute alcohol and in ether, insoluble in water.

Secondary chlorides. (1) *β-Chlorooctane* $CH_3[CH_2]_5CHCl{\cdot}CH_3$, b.p. 175° (Bouis, Annalen, 92, 398), 170°–172° (Schorlemmer, Chem. Soc. Trans. 1876, 419), 168°–172° (Pelouze and Cahours, Annalen, 129, 91); sp.gr. 0·892 at 18° (Schorlemmer), 0·895 at 16° (Pelouze and Cahours).

Formation.—By the action of hydrogen chloride or phosphoric chloride on methylhexylcarbinol (Bouis); by the action of hydrogen chloride on octylene (Berthelot, Annalen, 104, 185); by the action of chlorine on octane (Schorlemmer; Würtz, J. 1863, 509; Pelouze and Cahours).

Properties.—A colourless liquid, with a strong smell of oranges.

Reactions.—It does not precipitate salts of silver. It is decomposed by potassium or sodium in the cold, yielding dioctyl $C_{16}H_{34}$. By repeated distillation with sodium, hydrogen is evolved and octylene C_8H_{16} is formed.

(2) The octyl chloride prepared from petroleum octane exhibits the same reactions as that obtained from the alcohol, but on treatment with concentrated acetic acid and potassium acetate, octylene and octyl acetate are formed in equal quantities, whereas the chloride from the carbinol yields three times as much octylene as octyl acetate (Schorlemmer, Annalen, 152, 152).

(3) *Diisobutyl chloride*, b.p. 165°; sp.gr. 0·8834 at 10·5° (Schorlemmer, *ibid.* 144, 190).

Tertiary chlorides. (1) *δ-Ethyl-δ-chlorohexane* $CH_3{\cdot}CH_2{\cdot}CCl(C_2H_5)CH_2{\cdot}CH_2{\cdot}CH_3$, b.p. 155°. A liquid with a peculiar, unpleasant odour. Prepared by the action of phosphoric chloride on the diethylpropylcarbinol (Butlerow, Bull. Soc. chim. [ii.] 5, 17).

(2) *Diethyl isopropylcarbinol chloride, δ-methyl-γ-ethyl-γ-chloropentane.* From diethyl*iso*propyl carbinol and phosphorus pentachloride (Grigorovitch and Pawloff, J. Russ. Phys. Chem. Soc. 23, 169). Boils at 150°–155° with decomposition.

(3) *Isodibutol chloride. βδδ-trimethyl-β-chloropentane* $(CH_3)_3C{\cdot}CH_2{\cdot}CCl(CH_3)_2$. Boils with decomposition at 145°–150°; sp.gr. 0·890 at 0°. It is formed by the action of fuming hydrochloric acid on di*iso*butylene at 100° (Butlerow, Annalen, 189, 51).

Octyl bromides.

(1) **Normal,** *α-bromooctane* $CH_3[CH_2]_6CH_2Br$, b.p. 198°–200°; sp.gr. 1·116 at 16°; 1·1178 at 13° (Perkin, Chem. Soc. Trans. 1896, 1237). A colourless liquid prepared by the action of bromine and phosphorus on *n*-octyl alcohol.

(2) **Secondary,** *β-bromooctane*

$CH_3[CH_2]_6CHBr{\cdot}CH_3$

b.p. 187·5°–188·5° at 741 mm.; sp.gr. 1·0989 at 22° (Lachowicz, Annalen, 220, 185).

Preparation.—By treating methylhexyl carbinol with bromine and phosphorus, or by saturating the carbinol with hydrogen bromide at 0°, and heating for a few hours to 100°.

Properties.—It is an oily liquid, resembling the chloride in smell; it is soluble in alcohol but not in water. It boils with decomposition and leaves a carbonaceous residue when distilled. It precipitates silver salts in alcoholic solution, but less readily than the iodide.

Octyl iodides.

Normal, *α-iodooctane* $CH_3[CH_2]_6CH_2I$, b.p. 220°–222°; sp.gr. 1·338 at 16° (Zincke, Annalen, 152, 1).

Preparation.—By the action of iodine and phosphorus or of hydrogen iodide on the alcohol (Möslinger, *ibid.* 185, 55). It is a colourless liquid which reddens on warming; it is soluble in absolute alcohol or in ether, but insoluble in water (Zincke).

Secondary iodides. (1) *β-iodooctane*

$CH_3[CH_2]_5CHI{\cdot}CH_3$

It boils with decomposition at 211° (Bouis, Ann. Chim. Phys. [iii.] 44, 131); 193° (Squire, Chem. Soc. Trans. 1855, 108).

Preparation.—By the action of iodine and phosphorus on methylhexylcarbinol. It is an oily liquid with an odour of oranges, reddening on exposure to light. With sodium or potassium it behaves like the chloride. When heated with mercury, mercurous iodide, octylene, and free hydrogen are formed. The alcoholic solution precipitates silver salts.

(2) *Octylene hydriodide*, b.p. 120°; sp.gr. 1·33 at 0°, 1·314 at 21°. An amber-yellow liquid insoluble in water; it is decomposed by light, and by the action of mercury in the cold.

Tertiary iodide. *Isodibutol iodide, βδδ-trimethyl-β-iodopentane* $(CH_3)_3C{\cdot}CH_2{\cdot}CI(CH_3)_2$ is formed by the action of hydriodic acid on di*iso*butylene. It is decomposed by water (Butlerow, Annalen, 189, 52).

Octyl ethers. *Normal octyl ether* $(C_8H_{17})_2O$. From *iso*heptyl carbinol, b.p. 280°–282°; sp.gr. 0·8050 at 17°, 0·82035 at 0°/0° (Dobriner). An oily liquid easily soluble in hot alcohol or ether. It is prepared by the action of sodium octoxide on the *iso*primary iodide (Möslinger, *ibid.* 185, 57; Dobriner, *ibid.* 243, 10).

Mixed ethers. *Methyl normal octyl ether* $CH_3{\cdot}O{\cdot}C_8H_{17}$, boils at 173°; sp.gr. 0·8014 at 0°/0° (Dobriner, *ibid.* 243, 4).

Ethyl normal octyl ether, boils at 189·2°; sp.gr. 0·8008 at 0°/0° (Dobriner, *l.c.*).

Propyl normal octyl ether, boils at 207·0°; sp.gr. 0·8039 at 0°/0° (Dobriner, *l.c.*).

Butyl normal octyl ether, boils at 225·7°; sp.gr. 0·8069 at 0°/0° (Dobriner, *l.c.*).

Amyl normal octyl ether, boils at 220°; sp.gr. 0·6080 at 20°/ (Wills, J. 1853, 509).

Heptyl normal octyl ether, boils at 278·8°; sp.gr. 0·8182 at 0°/0° (Dobriner, *l.c.*).

All are colourless, mobile liquids, soluble in alcohol and ether, but not in water, prepared by the action of iodides of the radicles on sodium octoxide (Wills).

Octyl sulphides. (1) *Primary sulphide* $(C_8H_{17})_2S$. Boils with decomposition over 310°; sp.gr. 0·8419 at 17°/17°. A faintly-yellow mobile liquid soluble in warm alcohol, and miscible with ether. It is prepared by the action of an alcoholic solution of potassium sulphide on normal octyl chloride (Möslinger, Annalen, 185, 60). Sulphuric acid forms with it a white amorphous mass probably of *octyl sulphone* $(C_8H_{17})_2SO_2$; mercuric chloride gives crystalline needles of $C_8H_{17}S{\cdot}HgCl_2$. It forms no compound with the alkyl iodides.

(2) *Secondary sulphide.* An oily liquid

lighter than water and having an unpleasant smell. It is prepared by heating an alcoholic solution of sodium sulphide with secondary octyl iodide until the mixture becomes turbid, and then allowing the sulphide to separate out. It is slightly soluble in alcohol and decomposes on heating.

Methyl hexyl ketone $C_6H_{13}\cdot CO\cdot CH_3$. A liquid with an aromatic odour, b.p. 171°; sp.gr. 0·817 at 17°. It is obtained as a by-product in the preparation of the alcohol, also by the oxidation of the alcohol, and by the distillation of a mixture of calcium œnanthylate and calcium acetate (Staedler, J. pr. Chem. [i.] 72, 241). On oxidation it yields acetic and caproic acids. With the acid sulphites of the alkaline metals it forms compounds which crystallise in pearly scales.

Ethereal salts of primary octyl. The following constants have been determined by Gartenmeister (Annalen, 233, 249):—

	B.p. °	Sp.gr. $\frac{0°}{0°}$	Sp.gr. $\frac{\text{B.p.}}{0°}$	Ratio of vol. at b.p. to vol. at 0°	Specific volume
Formate .	198·1	0·8929	0·7156	1·2477	220·3
Acetate .	210·0	0·8847	0·6981	1·2672	245·8
Propionate	226·4	0·8833	0·6860	1·2876	270·5
Butyrate .	242·2	0·8794	0·6751	1·3028	295·6
Valerate .	260·2	0·8784	0·6618	1·3272	322·6
Caproate .	275·2	0·8748	0·6509	1·3440	349·6
Heptoate	290·4	0·8757	0·6419	1·3651	376·2
Octoate .	305·9	0·8755	0·6318	1·3858	404·3

These esters are all colourless liquids soluble in or miscible with alcohol and ether. The first six are prepared by the action of the silver salts of the acids on the bromides or iodides of octyl. The heptoate is prepared by the action of sulphuric and heptoic acids on octyl alcohol. The octoate is obtained as a by-product in the oxidation of octyl alcohol.

Normal octyl acetate occurs naturally in the ethereal oil of *Heracleum Sphondylium* (Linn.); it is a mobile fluid with a pleasant odour of apples and a burning spicy taste. The butyrate occurs in the oil of the seeds of *Peucedanum sativum* (Benth. and Hook.).

Octyl acetoacetic ester $C_{14}H_{26}O_3$, b.p. 280°–282° (not corr.); sp.gr. 0·9354 at 18·5°/17·5°. A clear, highly refractive liquid, obtained by the action of sodium acetoacetate on octyl iodide. It decomposes on hydrolysis into octyl acetone and octyl acetic acid (Guthzeit, Annalen, 204, 2).

Octyl benzoate $C_6H_5\cdot COOC_8H_{17}$, b.p. 305°–306°. A colourless liquid with a weak aromatic odour easily soluble in alcohol and ether (Zincke, *ibid.* 152, 1).

Octyl sulphuric acid is prepared from concentrated sulphuric acid and octyl alcohol. The barium salt $Ba(C_8H_{17}SO_4)_2$ forms large anhydrous nacreous plates very slightly soluble in hot water and alcohol. The potassium salt

$$KC_8H_{17}SO_4$$

forms a white soluble semi-crystalline mass with a soapy feel.

Octyl nitrite, b.p. 175°–177°; sp.gr. 0·862 at 17°. Obtained by heating octyl alcohol saturated with nitrous acid to 100° (Eichler, Ber. 12, 1887).

Octyl allophanate $NH_2CO\cdot NH\cdot COOC_8H_{17}$. Shining needles melting at 155°–160°, soluble in hot alcohol. Obtained by the action of chloroformamide on the alcohol.

Ethereal salts of secondary octyl. From methylhexylcarbinol.

Secondary octyl acetate, b.p. 193° (Bouis, Annalen, 44, 135); 191°–192° (Dachauer, *ibid.* 106, 269). A mobile liquid with a pleasant fruity odour, lighter than water, soluble in alcohol and ether, and also without change in not too concentrated sulphuric acid. It is easily saponified by potash. It is prepared (1) by the action of acetic acid or of an alkaline acetate and sulphuric acid upon the secondary alcohol; (2) by the action of silver or potassium acetate on the haloid compounds of the secondary alcohol; (3) by the action of acetyl chloride on sodium octoxide.

The *monochloroacetate* is prepared by passing hydrogen chloride into a mixture of equivalent quantities of the alcohol and monochloroacetic acid and heating for 30 hours. B.p. 234°; sp.gr. 0·9904 at 10°. It is a colourless neutral mobile oil with an ethereal odour and burning taste. It is soluble in alcohol and ether.

The *di-* and *tri-chloracetates* are prepared in a similar manner by substituting dichloro- or trichloroacetic acid. The trichloroacetate requires less heating. The former boils at 244°, the latter at 260°. They are colourless ethereal oils, lighter than water (Gehring, Compt. rend. 104, 1000).

Secondary octyl nitrate $C_8H_{17}O\cdot NO_2$. A liquid with a pleasant smell resembling ethyl acetate. It begins to boil at 80° but soon decomposes. It is lighter than water, is soluble in alcohol, and is prepared by the action of silver nitrate on octyl iodide in alcoholic solution (Bouis).

Secondary octyl nitrite $C_8H_{17}O\cdot NO$. A dark-yellow mobile liquid, b.p. 165°–166°; sp.gr. 0·881 at 0°. Obtained by the action of glyceryl trinitrite on the alcohol. It is soluble in ether and chloroform, and is decomposed by acids and by alcohol (Bertoni, Chem. Zentr. 1887, 35).

Secondary octyl sulphuric acid is obtained by the action of concentrated fuming sulphuric acid on methylhexyl carbinol. It is a colourless syrupy strongly acid liquid, easily soluble in water and alcohol; the diluted acid is decomposed on boiling into secondary octylic alcohol and sulphuric acid. It dissolves iron, zinc, &c., with evolution of hydrogen, and completely neutralises the bases.

The *barium salt* forms flexible nacreous plates containing three molecules of water on separating from a hot solution, or mammillary aggregations with two molecules of water on evaporating in a vacuum. It is soluble in water and alcohol, and has at first a bitter, then a sweet taste. It turns red on standing, blackens at 100°, and decomposes without melting.

The *calcium salt* forms white laminæ with a soapy feel and bitter taste.

The *potassium salt* $KC_8H_{17}SO_4,\frac{1}{2}H_2O$ forms white shining plates with a greasy feel; the taste is at first bitter, then sweet. It is soluble in water and alcohol, reddens and is decomposed at 100°.

Octyl phosphoric acid is formed by digesting octyl alcohol with glacial phosphoric acid. It forms soluble salts with lead or barium (Bouis).

Octyl palmitate and **stearate** are formed by prolonged heating of the alcohol with the respective acids to 200° in sealed tubes. The palmitate melts at 8·5°, the stearate at −4·5° (Hanhart, Compt. rend. 47, 230).

Octyl carbamate is formed by the action of cyanogen chloride on the alcohol, b.p. 135° (under 20 mm. pressure). It is very soluble in alcohol, from which it separates out in colourless crystals melting at 54°–55°. At ordinary pressures it boils with decomposition at 230°–232°, with partial conversion into cyanuric acid.

Octyl thiocyanate $C_8H_{17}\cdot S\cdot CN$, b.p. 142°, is formed by the action of KCNS on the secondary iodide (Jahn, Ber. 8, 805).

Octyl thiocarbimide $C_8H_{17}\cdot N:CS$. A colourless liquid, b.p. 234°, formed by Hofmann's reaction from octylamine by mixing with carbon disulphide in alcoholic or ethereal solution, evaporating to dryness and adding silver nitrate or mercuric, or ferric chloride to the solution of amine salt of the resulting carbaminic acid, and distilling in steam.

Octyl thiocarbamide $C_8H_{17}\cdot NH\cdot CSNH_2$, m.p. 112·5°, formed by the action of ammonia on the preceding compound. It is soluble in alcohol and ether, and separates out from its solution in colourless laminæ (Jahn, Ber. 8, 803).

OCTYLAMINES.

Only the following have been prepared—

(1) **Primary amines.**

(*a*) **Normal octylamine,** *α-aminooctane*

$$CH_3[CH_2]_6CH_2\cdot NH_2$$

is prepared by heating *n*-octyl iodide with alcoholic ammonia to 100° (Renesse, Annalen, 166, 85). It is also produced by treating octyl alcohol with ammonio-zinc chloride at 280° (Merz and Gasiorowski, Ber. 1884, 629); and by reducing nitrooctane with iron filings and acetic acid (Eichler, *ibid.* 1879, 1885); and in a purer condition by decomposing octyl phthalimide with concentrated hydrochloric acid at 200° (Mugdan, Annalen, 298, 145).

It is a colourless basic oil which takes up CO_2 from the air, and boils at 175°–177°/745 mm. In contact with water it forms white crystalline needles. With bromine and potash an oily compound $C_8H_{17}NBr_2$ is formed, which is converted on boiling with soda into heptyl cyanide $C_7H_{15}CN$ (Hofmann, Ber. 1884, 1920). The *hydrochloride* $C_8H_{17}NH_2,HCl$ is easily soluble in water and alcohol; the *platinichloride*

$$(C_8H_{17}NH_2)_2H_2PtCl_6$$

forms yellow leaves soluble with difficulty in alcohol and water; the *picrate*

$$C_8H_{17}NH_2\cdot C_6H_2(NO_2)_3OH$$

crystallises from alcohol in oblong tables, melting at 112°–114° (Hoogewerff and Dorp, Rec. trav. chim. 6, 387).

(*b*) **Secondary octylamine,** *β-aminooctane,* is prepared by treating secondary octyl iodide from castor oil with ammonia; or methyl hexyl carbinol with ammonio-zinc chloride at 280° (Merz and Gasiorowski, Ber. 1884, 364). It boils at 162·5° (Jahn, *ibid.* 1875, 805); 175° (Bouis, J. 1855, 526); sp.gr. 0·786. It is a colourless, bitter, very caustic inflammable liquid with an ammoniacal fishy odour. It is insoluble in water, but precipitates metallic salts and dissolves silver chloride. On heating with secondary octyl iodide, ammonium iodide, octylene, polyoctylenes and the iodide of secondary octylamine are formed (Jahn, *l.c.*). The *hydriodide* $C_8H_{20}NI$ forms large plates easily soluble in water; the *hydrochloride* $C_8H_{20}NCl$ is a very deliquescent solid which crystallises *in vacuô* in large nacreous plates; the *aurichloride* $C_8H_{20}NAuCl_4$ forms shining yellow laminæ, resembling lead iodide; the *platinichloride* $(C_8H_{20}N)_2PtCl_6$ separates from boiling solution in brilliant golden yellow scales soluble in alcohol or ether.

(2) **Secondary amines.**

(*a*) **Dinormal octylamine** $C_8H_{17})_2NH$ is produced together with *n*-octylamine by the action of ammonia on octyl iodide (Renesse, Annalen, 166, 85); or by treating octyl alcohol with ammonio zinc chloride at 280° (Merz and (Gasiorowski). It crystallises in needles, melting at 36°, and boiling at 297°–298°. It is soluble in alcohol and ether, and has a strong tallow-like odour. The *hydrochloride* forms plates soluble in alcohol; the *platinichloride*

$$(C_{16}H_{35}N\cdot HCl)_2\cdot PtCl_4$$

crystallises in small scales.

(*b*) **Di-secondary-octylamine** $(C_8H_{17})_2NH$ is prepared by heating methyl hexylcarbinol and ammonio-zinc chloride to 280° (Merz and Gasiorowski). It is an oil with an aromatic odour boiling at 260°–270°. The *hydrochloride* $C_{16}H_{36}NCl$ forms small leaves; the *platinichloride* $(C_{16}H_{35}N\cdot HCl)_2PtCl_4$ forms a brown mass; the aurichloride $C_{16}H_{35}NHAuCl_4$ crystallises from alcohol in golden yellow laminæ.

(3) **Tertiary amines.**

(*a*) **Tri-normal-octylamine** $(C_8H_{17})_3N$ is formed in moderate quantity along with the mono- and di- compounds by heating octyl alcohol with ammonio-zinc chloride to 260°–280°. When pure it forms a white crystalline mass, but is usually obtained as a nearly colourless oil of agreeable odour. It boils at 365°–367°, is readily soluble in ether and absolute alcohol, but not in water. Most of its salts are liquid; the *platinichloride* $((C_8H_{17})_3NHCl)_2PtCl_4$ forms a glutinous mass insoluble in water.

(*b*) **Tri-secondary-octylamine** $(C_8H_{17})_3N$ is obtained in the same way from methylhexyl carbinol. It is a liquid boiling at 370°. It forms an oily hydrochloride. The *platinichloride* $(C_{24}H_{51}NHCl)_2PtCl_4$ is a reddish-brown resin.

Primary octyl phosphine. B.p. 184°–187°; sp.gr. 0·8209 at 17°. A limpid, mobile, highly refractive liquid, soluble in alcohol, ether, benzene, and glacial acetic acid. It is obtained by the action of phosphonium iodide and zinc oxide upon normal octyl iodide at 170° (Möslinger, Annalen, 185, 65).

Nitric acid oxidises the solution in glacial acetic acid to *octylphosphinic acid,* an amorphous compound soluble in hot acetic acid. Oxygen, bromine, and iodine act less energetically upon octyl phosphine than upon the phosphines of the lower members of the series. Fuming hydriodic acid forms *octyl phosphonium iodide* $PH_3C_8H_{17}I$, a semi-crystalline mass which decomposes on standing, or on solution in ether or benzene.

Octonitrile, *heptyl cyanide* $C_7H_{15}CN$, boils at 194°–195°; sp.gr. 0·8201 at 13·3° (Felletar, J. 1868, 634); b.p. 198°–200° (Hofmann, Ber. 1884, 1410).

n-**Octyl cyanide,** *pelargonic nitrile,* boils at 214°–216°; sp.gr. 0·786 at 16°/4° (Hell and Kitrosky, *ibid.* 1891, 985; Eichler, *ibid.* 1879, 1888).

Octoamide, *caprylamide* $C_7H_{15}CO\cdot NH_2$, crystallises in leaves melting at 97°–98° (Aschan, Ber. 1898, 2348), 110° (Felletar, J. 1868, 624).

It is prepared by dropping the acid chloride into ammonia (Aschan, *l.c.*), or by heating ammonium octoate (Hofmann, Ber. 1882, 983). It is very slightly soluble in boiling water, and not at all in cold.

Nitro-octane. A liquid boiling at 205°–212°, obtained together with octyl nitrite by the action of silver nitrite on primary octyl iodide (Meyer, Annalen, 171, 23; Eichler, Ber. 1879, 1883).

Octyl nitrolic acid $C_8H_{16}NO{\cdot}NO_2$. An oily body formed from nitro-octane by saturating its solution in 10 volumes of water with nitrous fumes. Concentrated sulphuric acid decomposed it into octoic acid and nitrous oxide (Eichler, Ber. 12, 1885).

BENZENE DERIVATIVES OF PRIMARY OCTYL.

Octylbenzene $C_6H_5{\cdot}C_8H_{17}$. A colourless oil with a sweet taste, b.p. 261°–263° (uncorr.); sp.gr. 0·849 at 15°/15°; b.p. 262°–264°; sp.gr. 0·852 at 14° (Ahrens, Ber. 1886, 2717) (Schweinitz, *ibid.* 640). It is obtained by the action of sodium on a mixture of bromobenzene and normal octyl bromide in ethereal solution; or from bromobenzene, normal octyl iodide and sodium (Lepinski, Ber. 1898, 938). It is miscible with alcohol, ether, or benzene.

Chloro-octylbenzene $C_6H_4ClC_8H_{17}$ is a yellowish odourless oil soluble in alcohol and ether, b.p. 270°–275°. It is prepared by the action of chlorine and iodine on octylbenzene (Ahrens, Ber. 1886, 2719).

Bromo-octylbenzene $C_8H_{17}{\cdot}C_6H_4Br$, b.p. 285°–287°, resembles the chloro derivative, and is prepared by warming octyl benzene with bromine water (Schweinitz, Ber. 1886, 642).

p-**Iodo-octylbenzene.** A heavy oil, b.p. 318°–320°, prepared from *p*-amino-octylbenzene (*q.v.*) by the diazo- reaction (Beran, Ber. 1885, 136). By treating octylbenzene, diluted with petroleum, with iodine and mercuric oxide, a yellow oil is obtained, which is probably identical with the preceding compound.

The corresponding derivative of the secondary alcohol (from castor oil) is a yellow oily liquid, b.p. 304°–305°. On oxidation with chromic acid both yield *p*-iodobenzoic acid.

m-**Nitro-octylbenzene** $NO_2{\cdot}C_6H_4{\cdot}C_8H_{17}$. Crystallises in long needles which melt at 123°–124° and sublime at a high temperature. It is prepared by the action of fuming nitric acid upon octylbenzene in the cold. It is slightly soluble in alcohol and chloroform. With potassium permanganate it yields *m*-nitrobenzoic acid (Ahrens, Ber. 1886, 2725).

o-**Nitro-octylbenzene** is a thick yellow aromatic oil which decomposes at 100°. It is prepared by treating octylbenzene with fuming nitric acid and warming after filtering off the precipitated crystals of *m*-nitro-octyl benzene (Ahrens, *l.c.*).

p-**Nitro-octylbenzene** which forms small yellow lustrous needles melting at 204°, and soluble in alcohol or ether, is found in the residue from the meta- and ortho- compounds (Ahrens, *l.c.*).

Dinitro-octylbenzene $C_8H_{17}{\cdot}C_6H_3(NO_2)_2$ forms crystals melting at 226°, but subliming below this temperature. It is soluble in alcohol and ether and is formed by the action of fuming nitric acid on the crystals of the meta- compound (Ahrens).

o-**Amino-octylbenzene hydrochloride**

$$C_8H_7{\cdot}C_6H_4{\cdot}NH_2,HCl$$

occurs in small lustrous white plates which redden on heating. It is formed by reducing the nitro derivative with tin and hydrochloric acid (Ahrens, Ber. 1886, 2717).

p-**Amino-octylbenzene,** a colourless liquid, b.p. 310°–311°, volatilises in steam. It is obtained by the action of aniline hydrochloride, or of aniline and zinc chloride on primary octyl alcohol (from *Heracleum* oil). A similar derivative may be prepared from the secondary alcohol (from castor oil), b.p. 290°–292° (corr.) (Beran, Ber. 1885, 132).

Formylphenoctylamine, *formylamino-octylbenzene,* $C_8H_{17}{\cdot}C_6H_4{\cdot}NH{\cdot}CHO$ is obtained by the action of formic acid on *p*-aminoctylbenzene. It forms scales which melt at 56° and are soluble in alcohol or ether (Beran, Ber. 1885, 135).

Acetylphenoctylamine, *acetylamino-octylbenzene* $C_8H_{17}{\cdot}C_6H_4NH{\cdot}C_2H_3O$, is formed from *p*-amino-octylbenzene and acetic anhydride. It forms thin plates melting at 93°, and soluble in alcohol or ether (Beran).

Benzoylphenoctylamine, *benzoylamino-octylbenzene* $C_8H_{17}{\cdot}C_6H_4NHBz$, is obtained from *p*-amino-octylbenzene and benzoyl chloride. It forms scales melting at 117° and soluble in alcohol or ether. The corresponding derivative of the secondary alcohol forms white needles melting at 109° (Beran).

p-**Octylbenzonitrile** is obtained by distilling formylphenoctylamine with zinc-dust; b.p. 312°. It is converted by oxidation into *p*-octylbenzoic acid.

Octylbenzene sulphonic acid. A thick syrupy strongly acid liquid formed by the action of Nordhausen acid on octylbenzene. Silver salt $C_8H_{17}{\cdot}C_6H_4{\cdot}SO_3Ag,H_2O$. Barium salt

$$(C_{14}H_{21}SO_3)_2Ba,H_2O.$$

Lead salt $(C_{14}H_{21}SO_3)_2Pb,3H_2O$ (Schweinitz, Ber. 1886, 640).

TOLUENE DERIVATIVES OF PRIMARY OCTYL.

Amino-octyltoluene (*Toloctylamine*)

$$C_8H_{17}C_6H_3MeNH_2$$

is prepared by treating the normal alcohol with *o*-toluidine and zinc chloride. It is a colourless oil which boils at 324°–326°, and forms a well-crystallised hydrochloride, sulphate, and oxalate (Beran, Ber. 1885, 146).

Acetyltoloctylamine $C_8H_{17}{\cdot}C_7H_6{\cdot}NHAc$ forms slender white needles, m.p. 81°, soluble in alcohol and ether (Beran, *l.c.*).

Benzoyltoloctylamine $C_8H_{17}{\cdot}C_7H_6{\cdot}NHBz$ forms lustrous scales, m.p. 117°, soluble in alcohol. These toluene derivatives are prepared in a manner analogous to the corresponding benzene derivatives (Beran, *l.c.*).

THIOPHEN DERIVATIVES OF PRIMARY OCTYL.

(Schweinitz, Ber. 1886, 644 *et seq.*)

Octylthiophen $C_8H_{17}{\cdot}C_4H_3S$ is formed by the action of sodium on octyl bromide and iodothiophen, b.p. 257°–259°; sp.gr. 0·8181 at 20·5°/20·5°. It is soluble in ether.

Bromo-octylthiophen $C_4SH_2Br{\cdot}C_8H_{17}$ boils at 285°–290° and solidifies at 5°.

Iodo-octylthiophen $C_4SHI{\cdot}C_8H_{17}$ is a yellow oil which solidifies at 0°; sp.gr. 1·2614 at 20°/20°.

Both the bromo and iodo compounds are prepared analogously to the corresponding benzene derivatives.

Octylacetothienone $C_8H_{17}\cdot C_4SH_2\cdot COMe$, an oil with a garlic-like odour, b.p. 350°–355°, and **Octyldiacetothienone** $C_8H_{17}\cdot C_4SH(COMe)_2$, a yellow syrup, are prepared by the action of acetyl chloride and aluminium chloride on octylthiophen.

Octylthiophen-di-carboxylic acid

$$C_8H_{17}\cdot C_4SH(COOH)_2$$

is obtained in microscopic needles melting at 185°, by the action of potassium permanganate on the mono and diacetyl derivatives. Barium, copper, and silver salts have been prepared.

$\beta\beta$-Methyloctylthiophen $C_8H_{17}\cdot C_4SH_2Me$ is obtained by the action of sodium on $\beta\beta$-methyl iodothiophen and octyl bromide. It is a colourless oil boiling at 270°–275°, and on strongly cooling it solidifies to a crystalline mass which melts at 10°. The monobromo derivative $C_8H_{17}C_4SHMeBr$ melts at 20°.

OCUBA WAX *v.* Wax.

ODORINE. A volatile base found by Unverdorben in bone-oil. Probably impure picoline.

iso-**ŒNANIC ACID** *v.* Heptoic acids.

ŒNANTHIC ACID *v.* Heptoic acids.

ŒNANTHIC ETHER. According to Liebig and Pelouze (Annalen, 19, 241), there is found in wine a small quantity of a body termed by them œnanthic ether. It is a very mobile liquid, with a strong vinous smell, and of a disagreeable taste; readily soluble in ether and alcohol, but very sparingly soluble in water. This ether is now prepared commercially for flavouring common wines, brandy, &c., from the oxidised products of oil of rue. According to A. Fischer (Annalen, 115, 247) the artificial product is a mixture of capric and caprylic acids. Many fusel oils contain both these acids, and amyl caprate is found in several Hungarian wines.

ŒNANTHOL, *œnanthaldehyde, heptaldehyde, normal œnanthic,* or *heptoic aldehyde,* $C_6H_{13}CHO$, is one of the products of the dry distillation of alkaline ricinoleates and of the action of nitric acid on stearic and margaric acids. It is also formed when fats and oils turn rancid (Scala, Chem. Zentr. 1898, i. 439).

The following method of preparation may be employed:—

Castor oil, which consists essentially of the glyceride of ricinoleic acid, is rapidly distilled until the residue becomes resinous, thus converting the greater part of the ricinoleic acid into œnanthol and hendecatoic acid:—

$$C_{18}H_{34}O_3 = C_6H_{13}CHO + C_{11}H_{20}O_2.$$

The distillate is rectified, and the part coming over between 90° and 180° is shaken with a saturated solution of acid sodium sulphite, and is warmed and filtered. The mass of the double salt $C_6H_{13}CHO\cdot HNaSO_3,H_2O$, separating out on cooling, is pressed between filter paper, mixed with a solution of sodium carbonate, and distilled in a current of steam. The œnanthol which floats on the distillate is separated and dried over anhydrous sodium sulphate or calcium chloride (Bussy, Annalen, 1846, 60, 246; Erlenmeyer and Sigel, *ibid.* 1875, 176, 342).

The yield of œnanthol is increased when the castor oil is distilled under reduced pressure (Krafft, Ber. 1877, 10, 2035; Jourdan, Annalen, 1880, 200, 102).

A better yield is obtained by distilling the ethyl or preferably the methyl ester of ricinoleic acid at ordinary pressure. The distillate is redistilled, treated with sodium bisulphite and the crystalline mass thus obtained is washed with ether and well drained. The œnanthol can then be isolated in the ordinary way (Haller, Compt. rend. 1907, 144, 462).

Œnanthol is also prepared by the following process: Castor oil or rape oil is heated in an iron boiler to 160°, and air is blown through, the source of heat is then removed and the temperature of the mass rises spontaneously to 220°. The vapours are condensed and the oily layer is treated with sodium bisulphite. The œnanthol is then separated as above (D. R. P. 167137; Frdl. 1905–07, 40).

Œnanthol reacts with diazoacetic ester yielding non-crystalline ethyl œnanthyliden-1:2-dioxynonylate, b.p. 200°/14 mm. On saponification the latter yields an acid which on boiling with acetic acid decomposes with formation of œnanthol (Dieckmann, Ber. 1910, 43, 1027).

Œnanthol is a highly refractive, very mobile, colourless liquid, of pungent aromatic smell, boiling at 154° at 747 mm. pressure, and having at 15° a sp.gr. of 0·8231 (Perkin, jun., Ber. 1882, 15, 2802; D. R. P. 126736, 1902), b.p. 152·2°–153·2° (corr.) sp.gr. 0·82264 at 15° (Perkin, Chem. Soc. Trans. 1884, 476), b.p. 42°–43°/10 mm., sp.gr. 0·8250 at 20° (Semmler, Ber. 1909, 42, 1161). It is slightly soluble in water, and dissolves in all proportions in alcohol and ether. Œnanthol rapidly oxidises on exposure to air. It reduces silver nitrate.

When heated at 190° in sulphuric acid, it blackens and a small quantity of carbon monoxide and much sulphur dioxide are evolved (Bistrzycki and Fellmann, Ber. 1910, 43, 776).

With nitric acid, œnanthol yields dinitrohexane, hydroxylamine and heptoic acid (Ponzio, J. pr. Chem. 1896, [ii.] 53, 431). Œnanthol reacts with cyanacetic acid in the presence of piperidine forming $\alpha\gamma$-dicyano-β-hexyl-glutaric acid, m.p. 142° (D. R. P. 156560; Frdl. 1902–04, 738; *see* also Guareschi, Chem. Zentr. 1903, ii. 193; Annalen, 1903, 325, 205). It also reacts with malonic acid forming Δ' nonylenic acid (D. R. P. 156560; Harding and Weizmann, Chem. Soc. Trans. 1910, 299).

Œnanthol condenses with aniline (Miller, Ber. 1892, 25, 2020); with aniline sulphite (Eibner, Chem. Zentr. 1901, i. 1360; Speroni, Annalen, 1902, 325, 354); with acetone (Rupe and Hinterlach, Ber. 1907, 40, 4764); with oxalacetic ester in presence of ammonia (Simon and Conduché, Ann. Chim. Phys. 1907, [viii.] 12, 5), and with hydrazobenzene (Russow, J. pr. Chem. 1909, [ii.] 80, 511). It also reacts with a number of other substances (Fittig and Reechelmann, Annalen, 1889, 255, 126; Miller, *l.c.*; Fischer and Giebe, Ber. 1897, 30, 3054; Knoevenagel, Ber. 1898, 31, 730; Claisen, *ibid.* 1014; Neuberg and Neimann, *ibid.* 1902, 35, 2049; Lees, Chem. Soc. Proc. 1902, 213; Tschitschenko, J. Russ. Phys. Chem. Soc. 1906, 38, 482; Schlotterbeck, Ber. 1907, 40, 479; Braun, *ibid.* 1908, 41, 2169; Semmler, *l.c.*).

Œnanthaldoxime boils at 100·5°/14 mm. It only solidifies partially and the solid part melts at 55·5° (Bourgeois and Dambmann, Ber. 1893, 26, 2856). It forms a number of derivatives (Goldschmidt and Zanoli, Ber. 1892, 25, 2573; Comstock, Amer. Chem. J. 1897, 19, 485; Conduché, Ann. Chim. Phys. 1908, [viii.] 13, 5; Irvine and Moodie, Chem. Soc. Trans. 1908, 102).

ŒNANTHYLIC ACID *v.* Heptoic acid.

ŒNOCYANIN, the colouring matter of black grapes and red wines, is of colourless origin, and becomes blue through oxidation, and probably hydration, which may be shown by placing a green grape picked from a bunch which is just beginning to turn red in a vacuum of 1–2 mm. over boiled sulphuric acid for 3 or 4 days, or sufficient time to allow of the grape becoming hard and dry. The colour becomes yellow, but, on admitting air, moisture and oxygen are rapidly absorbed, the colour changing to blue black at the same time (Maumené, Compt. rend. 95, 924). Œnocyanin cannot be extracted from grape marcs and lees of wine, but is obtained from red wines destined for distillation by the following method: the wine is treated with sufficient basic lead acetate to precipitate the colouring matter, the precipitate is collected on a filter and washed until the filtrate contains only traces of lead (24 hours). The precipitate is weighed moist and the dry substance and lead oxide are determined in an aliquot portion. The remainder is then treated with exactly the calculated quantity of sulphuric acid and filtered hot. The colouring matter passes into the filtrate and is obtained in the form of a syrup soluble in water or alcohol by evaporating the solution to the required consistency after adding glycerol in the proportion of 10 grams of glycerol to the extract from 1 litre of wine. The solution of œnocyanin thus obtained is used for increasing the colour of poor wine and also for colouring confectionery and liqueurs. Œnocyanin is not a uniform substance and its proportion in red wines varies from 9·2 to 18·7 grams per litre (Cari Mantrand, Bull. Soc. chim. 1906, 35, 1017, 1022).

ŒNOLIN. The name given to the natural red colouring matter of wine precipitable by lime or basic lead acetate. Is brown-red whilst moist, but nearly black when dry, giving a violet-red or brown-red powder, readily soluble in alcohol, and in water acidulated with vegetable acids. Is said to have the composition $C_{20}H_{20}O_{10}$, and to form a lead compound $C_{20}H_{18}O_{10}Pb$ (Glénard, Compt. rend. 47, 268; Varenne, Bull. Soc. chim. [ii.] 29, 109). For the estimation of œnolin and œnotannin in wines, *v.* F. Jean, Compt. rend. 93, 966.

ŒNOMETER. A hydrometer designed for determining the alcoholic strength of wines.

OIL-GAS *v.* Gas, oil.

OIL, MINERAL, *v.* Petroleum.

OIL OF AMBER *v.* Oils, essential, and Resins.

OIL OF HARTSHORN *v.* Bone oil.

OIL OF VITRIOL *v.* Sulphuric acid.

OILS, ESSENTIAL. The word 'oil' appears to be derived from the Greek *elaia*, the olive tree, through the Latin *oleum*, and the French *huile*. It would seem to have been originally applied to liquids which like olive oil are insoluble in water, combustible, and more or less viscid, and this may be regarded, save for a few unimportant exceptions, such as oil of vitriol, as the signification which the word has retained.

Two kinds of oil are recognised, fixed or fatty oils (*v.* Oils, Fixed, and Fats) and essential or volatile oils.

A scientific definition of the term 'essential' or volatile oils is not possible, but they may be for general purposes defined as substances of an oily nature obtained from, as a rule, vegetable sources, possessed usually of odour, generally liquid, although sometimes semi-solid at ordinary temperatures, and volatile without decomposition.

The constituents of some essential oils are decomposed either in whole or part when the oils are distilled by themselves, and some even under steam distillation.

The essential oils occur in various parts of the plant, in some instances distributed throughout the plant, in others restricted to a particular portion, *e.g.* in the petals of the flowers as in the rose, in the bark and leaves as in the cinnamon, and in the flower and rind of the fruit as in the orange and lemon.

The functions of the essential oil in plant life are not thoroughly understood. Obviously the more powerful odours are of value in attracting insects for fertilisation by pollen, but this has no direct connection with the plant life.

The majority of essential oils are probably correctly classified as by-products of the changes of cell life in the plant, the oils in some instances occurring in conjunction with resins, forming a series of bodies known as oleo-resins.

The researches of Charabot and his colleagues on the varying proportions of oil in plants at different periods of their growth, as well as differences in the constitution of such oils, have been of great value in determining the suitability of soil, and conditions for the growth of plants for distillation of essential oils, and also for determining the period for collection of distillation material.

Space does not permit of reference to the detail of such experiments, but a few of the general conclusions may be thus briefly summarised:—

The odorous compounds first appear in the young green organs of plants, and continue to form and accumulate until the flowering period, when the activity slackens. They migrate by diffusion from the leaf to the stem, and thence into the inflorescence. A portion enters into solution and penetrates into the tissues where it becomes deposited. When fertilisation takes place, a quantity of essential oil is consumed in the inflorescence, or is lost by evaporation. Probably the green organs continue to produce odorous constituents, but experiments show that during fertilisation there is a net loss of these bodies. It is therefore obvious that in most cases the best yield of essential oil is obtained before fertilisation takes place. After fertilisation the oil again increases in the green parts of the plant.

Esters have their origin in the green parts of the plant by the direct combination of acids on the alcohols previously formed. Esterification appears to be assisted by enzymes which act as dehydrating agents. Chlorophyll, however, appears to be the important factor in effecting the condensations which build up complex substances from simpler bodies.

The addition of mineral salts to the soil, such as the chlorides of potassium, sodium and ammonium, sulphates of sodium, potassium, ammonium, iron and manganese, nitrates and phosphates of sodium and potassium, appears to favour the formation of esters in peppermint plants.

In some instances oils are formed as a result of the decomposition of a glucoside by a ferment, as in the case of almond oil from the glucoside amygdalin by the ferment emulsin. The general characters of essential oils vary over a very wide range, and even essential oils of the same species grown in different parts of the world may show considerable variations in constitution. As a class the oils are lighter than water, although to this rule there are exceptions, such as cinnamon, cassia, clove, wintergreen, &c. They are almost insoluble in water, although sufficiently so to impregnate water with their odour. As already stated the majority of the volatile oils are liquid at ordinary temperatures, the oils consisting of liquid constituents or solid constituents dissolved in liquids.

In some instances the oils are semi-solid or almost solid in character. Although the words are of little scientific value the solid portion of oils are still described as *stearoptenes*, and the liquid portions as *oleoptenes* or *elœoptenes*.

The methods of production may be divided into three principal classes.

(1) Distillation :
    (*a*) From the plant ;
    (*b*) From oleo-resinous exudations.
(2) Mechanical processes.
(3) Extraction by solvents.

1. The methods of production of volatile oils by distillation from the wood, leaves, flowers or fruit by means of water, which is the usual method employed, have been much modified in recent years, and much attention has been devoted to improvements in modes of distillation and condensation. In some few instances fire heat is still used for distillation, the practice being retained by some of the distillers of lavender and peppermint oils in the Mitcham district. The usual method, however, is to pass steam through the material suitably arranged on trays—for example, in the case of the umbelliferous fruits, or to pass live steam through the material.

All the essential oils are readily volatile in the vapour of water. Many of the essential oils are distilled from their primary material under reduced pressure, the vapour passing over at a much lower temperature, with the corresponding advantage that the oil is not subjected to temperature likely to lead to decomposition. Modern stills have a capacity of 600–1200 gallons or more, and are usually made of copper with removable domes having water-sealed joints with latch fastenings to keep them in position. They are mounted on brickwork bases with steel framework, and have bottoms raised in the centre to effect absolute drainage. The stills are fitted with discharge pipes and also with steam heating coils constructed of copper with traps for the condensed water, which is led back into a tank for feeding the steam boiler. The still heads taper to a narrow pipe which leads to the condenser. The false bottom and cages in which the material is placed rest upon brackets fitted into the inside of the still. They are usually made of galvanised iron and the false bottom is perforated to enable the water to drain away. Above the stills chain lifting tackle is fitted to steel girders to facilitate emptying and refilling.

The condensers usually consist of coils surrounded by cold water, which is kept continually flowing through them from the bottom upwards. The condensed distillate is collected in separators fitted with strainer plates and a series of draining taps. The condensed water is forced back into the stills by steam ejectors to be used in a subsequent distillation.

Distillation from oleo-resinous exudations. Many of the oleo-resins of different degrees of viscidity are used for the distillation of volatile oils—the most important being the oleo-resin used for the distillation of turpentine, and the essential oil distilled from such bodies as copaiba, &c. The oleo-resin is caused to exude from the living tree by making incisions, usually V-shaped, after stripping off the bark. The incisions are first made about 8 inches above the root, and the oleo-resin which exudes is collected in wooden vessels. The exudation commences about March and continues till the end of August or the beginning of September. The crude oleo-resin thus obtained is then distilled with water.

2. *Mechanical production.* Mechanical processes are employed in the case of lemon, orange, bergamot, and lime oils, which are obtained from the peel of the fruit. *The sponge process*, which is usually employed in Sicily, and Calabria, is essentially as follows : The fruit is first soaked in water for a short time and the peel is then removed in three slices, each slice being pressed flat by the fingers against a sponge. The oil glands are burst by the pressure and the oil, together with a considerable quantity of water and some juice, is absorbed by the sponge. The sponge is squeezed from time to time into a bowl and the oil separated from the water and filtered in closed filters.

The Écuelle process is employed in Northern Italy and the South of France. An écuelle is a saucer-shaped vessel, 8–10 inches in diameter, made of tinned copper, the inside of which is covered by short spikes about a quarter of an inch long. The bottom is connected by a hollow tube through which the oil passes to a collecting vessel. The whole fruit is placed on the écuelle and by rapid rotatory motion the oil glands are burst and the oil is ejected. An oil of inferior quality is obtained by subjecting the residual fruits to pressure or by macerating in warm water. A still inferior oil is obtained by distillation.

In the *Scorzetta process* the fruits are cut into halves, the pulp is removed by a spoon and the peel is twisted and pressed against a sponge. The pulp is used for the production of lemon juice and the peel is salted.

Machines are also used for the production of these oils, especially that of bergamot, by means of which the fruits are brought into contact with small knives which puncture or rupture the oil glands. The oil is drawn out of the vessel by means of vacuum pumps and steam is sometimes admitted to facilitate the process. Machine made oils, however, are usually inferior to those produced by hand processes. An illustration of one form of mechanical press is figured in the Perfumery and Essential Oil Record, March, 1910, 61.

3. *Extraction by solvents.* Extraction processes are employed principally for the delicate floral essences which are partially decomposed by distillation, such as jasmine and tuberose. Three kinds of processes are used, (*a*) those in which a volatile solvent is used; (*b*) those in which a non-volatile oil or fat is employed; and (*c*) those in which a current of moist air is used.

The volatile solvents commonly employed are alcohol, benzene, ether, chloroform, light petroleum, carbon disulphide, acetone, and tetrachlorethane. The simplest form of extraction is by percolation, either in the cold or at the boiling-point of the solvent on the principle of the Soxhlet apparatus. On the removal of the solvent a mixture of oil, resin, and colouring matter results, from which floral essences are prepared by solution in alcohol. In some cases the extracts are purified by distillation under reduced pressure with steam.

The extraction by non-volatile solvents is typified by the *enfleurage process.* A pure neutral fat, such as purified lard, is melted in trays, technically known as 'chassis,' and the fresh flowers are laid on the fat for a short time, then removed and replaced by fresh flowers until the fat has become saturated. The fat is then removed and sold as 'pomades,' which are employed in the manufacture of perfumes, being extracted by means of warm alcohol in closed vessels. Olive oil is also used for jasmine and violet flowers, the fresh flowers being macerated in the oil or placed on trays containing linen cloths soaked in the oil. The oil is then pressed out and may be extracted by means of alcohol.

In the *moist air process,* hot air is passed through a series of wet sponges and then over the flowers and into a volatile solvent which retains the perfume, and which can afterwards be removed. The advantage of this process is that only volatile bodies are extracted, colouring matters and resins being left in the raw material.

The main constituents of essential oils may be conveniently divided into the following important classes: terpenes and sesquiterpenes, alcohols, aldehydes, ketones, phenols and allied compounds.

Terpenes. The principal terpenes occurring in essential oils are pinene, camphene, fenchene, limonene, dipentene, terpinene, terpinolene, phellandrene, sylvestrene, carvestrene, thujene, sabinene, santene. The first three belong to the bicyclic series, the structure being in the form of a double ring. The other terpenes may be regarded as derivatives of cymene, which they closely resemble in molecular constitution. Limonene, dipentene, carvestrene, sylvestrene, and terpinolene may be regarded as dihydrocymenes, containing two ethylene linkages and have the formula $C_{10}H_{16}$. Menthene and carvo-menthene are tetrahydrocymenes and have the formula $C_{10}H_{18}$. On reduction they yield hexahydrocymenes. The terpenes are characterised by the melting-points of their derivatives.

Sesquiterpenes. These have the general formula $C_{15}H_{24}$ and boil at a temperature above 250°. They have a high refractive index and yield halogen derivatives which are somewhat difficult to purify. The more important ones occurring in essential oils are cadinene, caryophyllene, cedrene, humulene, santalene, and zingiberene. Olefinic sesquiterpenes occur in oils of citronella, lime, and lemon.

For further details as to characters and composition of this class of substances *see* art. TERPENES.

Alcohols. The alcohols of the paraffin series found in essential oils comprise geraniol, linalool, nerol, and citronellol. These belong to the unsaturated series containing one or more double linkages.

Alcohols of the benzene series are benzyl, cinnamyl, and anisyl alcohols and phenyl-ethyl-alcohol. Terpineol, terpene hydrate, borneol. pulegol, thujyl alcohol, fenchyl alcohol, sabinol and menthol are derivatives of the terpenes. Among sesquiterpene alcohols, santalol, cedrol, guaiol, patchouli alcohol, and the so-called 'camphors' of cubebs and matico may be mentioned. With the exception of santalol these are solid compounds.

Esters of many of these alcohols also occur in essential oils, chiefly those of acetic, propionic, butyric, valeric, tiglic, benzoic, salicylic, cinnamic, and anthranilic acids. The percentage of esters is found by saponification with alcoholic potash and many oils are valued according to their ester content. It should be pointed out, however, that probably other constituents absorb potash under the conditions of saponification and the determination of the saponification number is not strictly a measure of the esters present. It is useful, however, for purposes of comparison. Two to five grammes of the oil are heated on a water-bath for an hour with 20 c.c. of normal alcoholic potash and the excess of potash titrated with normal sulphuric acid.

The alcohols are determined by acetylation and subsequent estimation of the acetic esters formed. The usual method of procedure is to heat 10 c.c. of the oil with an equal volume of acetic anhydride and 2 grams of anhydrous sodium acetate for 2 hours to boiling-point. The oil is then thoroughly washed by shaking with successive quantities of water and afterwards dried by shaking with anhydrous sodium sulphate. 2–5 grammes of the acetylated oil is then neutralised and saponified with 20 c.c. of normal alcoholic potash for an hour and the excess of potash titrated with normal acid, using phenolphthalein as indicator. The percentage of alcohol in the original oil is calculated from the formula $\frac{M}{1000} \times \frac{X \times 100}{W-(0{\cdot}042X)} =$ p.c. alcohol, where M is the molecular weight of the alcohol, W the weight of acetylated oil, and X the number of c.c. of normal alcoholic potash absorbed.

Aldehydes. The aldehydes of the paraffin series found in essential oils are furfural, acetaldehyde, citral, and citronellal. Those belonging to the benzene series are benzaldehyde, salicylic aldehyde, cinnamic aldehyde, anisic aldehyde, and cumic aldehyde.

The usual method employed for the determination of cinnamic aldehyde in cinnamon and cassia oils and for the determination of citral in lemongrass oil is as follows:—

Five c.c. of the oil are shaken with a hot solution of sodium bisulphite (35 p.c.), freshly prepared, and heated in a water-bath for an hour, or until the solid aldehyde bisulphite compound is completely dissolved. A flask with the neck graduated in tenths of a cubic centimetre is employed and the uncombined oil is driven up into the neck of the flask and the volume noted after cooling. The difference between the volume of the original oil and the volume of the residual oil represents the proportion of citral or cinnamic aldehyde, and multiplied by 20 gives the percentage by volume.

For the determination of citral in lemon oil the hydroxylamine process is recommended (*see* Perfumery and Essential Oil Record, November, 1910, 263–264).

Ketones. The more important ketones occurring in essential oils are carvone, pulegone, menthone, camphor, fenchone, and thujone. Methyl-heptyl-ketone and methyl-nonyl-ketone occur in the oil of rue and methyl-heptenone in the oils of lemongrass, citronella, and lignaloe.

The best absorption process for the estimation of carvone is as follows:—

Five c.c. of the oil is introduced in a 200 c.c. flask with the neck graduated in tenths of a cubic centimetre. 25 c.c. of a 20 p.c. solution of neutral sodium sulphite is then added and a few drops of phenolphthalein solution. It is then placed in a water-bath and thoroughly shaken, when a red colour is immediately produced due to the liberation of free caustic alkali. A 10 p.c. solution of acetic acid is added from a burette to maintain neutrality, and the mixture heated until no more free alkali is liberated, the time required being usually about 45 minutes. The uncombined oil is then driven into the neck of the flask and the volume read off after cooling. The difference between the volume of the original oil and that of the residual oil multiplied by 20 will give the percentage by volume of carvone. For pulegone in oil of pennyroyal litmus is a better indicator.

The above process may also be used for the determination of benzaldehyde in almond oil, cinnamic aldehyde in cinnamon and cassia oils and citral in lemongrass oil.

Phenols (*v. also* art. TERPENES AND TERPENE DERIVATIVES). The chief phenols found in essential oils are thymol, carvacrol, and eugenol (*q.v.*). These bodies are soluble in solutions of alkaline hydroxides, and may be extracted by shaking the oils with a solution of caustic potash or soda. They differ from acids in not being soluble in alkaline carbonates.

The method usually adopted for the estimation of phenols in essential oils is as follows: 5 c.c. of the oil is heated for an hour in a water-bath with a 5 p.c. aqueous solution of potash with frequent agitation. A flask with the neck graduated in tenths of a cubic centimetre is employed for the purpose, and the uncombined oil is driven into the graduated neck by the addition of a further quantity of potash solution. The proportion of phenols absorbed is calculated by deducting the measure of uncombined oil from the volume of the original oil, which gives the proportion of phenols by volume. If the proportion by weight is required the specific gravity of the oil and the uncombined portion must be taken into account.

Phenol derivatives. Anethole is the methyl ether of *p*-propenyl phenol. It is the chief constituent of anise oil and star anise oil and also occurs in oil of fennel. It is a crystalline substance, melting at 21° and boiling at 232°; sp.gr. 0·986 at 25°.

Iso-anethole (*estragole*) is the methyl ether of *p*-allyl-phenol. It occurs in estragon oil, and also in anise and fennel oils. It is a colourless liquid having a density of 0·971 and boiling at 215°–216°.

Safrole is the methylene ether of allylpyrocatechol. It is the principal constituent of sassafras oil, and occurs in the high boiling fractions of camphor oil and in cinnamon leaf oil. It is a colourless liquid, boiling at 233°; sp.gr. 1·108.

Other phenol derivatives are diosphenol, found in oil of buchu, chavicol, a constituent of bay oil and betel leaf oil, and chavibetol, occurring in betel leaf oil.

Unclassified constituents of essential oils. Apiole occurs in oil of parsley and its isomer dill-apiole in East Indian oil of dill.

Cineol or eucalyptol occurs in oils of wormseed, cajeput and eucalyptus, and in smaller quantities in oils of rosemary, lavender, spike, sage, laurel, cinnamon, and camphor.

Compounds containing nitrogen and sulphur occur in essential oils derived from plants rich in albuminous matter. The more volatile compounds, such as trimethylamine and sulphuretted hydrogen (the latter being formed during the distillation of carraway oil) are usually lost in the distillation process.

Hydrocyanic acid occurs together with benzaldehyde in oil of bitter almonds. Carbon disulphide is found in black mustard oil, dimethyl sulphide in American peppermint oil and allyl sulphide in oil of garlic. Allyl-*iso*thiocyanate is the chief constituent of black mustard oil, resulting from the decomposition of the glucoside potassium myronate in the presence of the ferment myrosin. It is obtained synthetically from allyl iodide and potassium thiocyanate.

EXAMINATION OF ESSENTIAL OILS.

Physical characters. In the analysis of essential oils it is usual to first determine the physical characters, such as the specific gravity, optical rotation, refractive index, boiling range, and solubility.

The *specific gravity* is the density at 15° compared with the weight of an equal volume of water at the same temperature, and is usually taken by means of a specific gravity bottle of 10 c.c. or 25 c.c. capacity. Anise oil and otto of rose are generally taken at 20° and 30° respectively in comparison with water at 15°C. Oils which contain water should be first dried by agitation with anhydrous sodium sulphate.

Optical rotation. The optical rotation of essential oils is usually taken in a 100 mm. tube by means of a polarimeter, using sodium light. The specific rotation applied to pure substances is the optical rotation in a 100 mm. tube divided by the specific gravity. It is expressed by the term $[\alpha]_D$.

The refractive index is the ratio of the sine of the angle of incidence to the sine of the angle of refraction for the D line (sodium light) and is expressed by the term n_D. It is usually given for a temperature of 20° and decreases with rise of temperature to the extent of 0·0004 to 0·0006 for each degree Centigrade. Refractometers are of various types, but the direct reading instrument made by Zeiss is the one most suitable for the examination of essential oils (*v.* REFRACTOMETER). The temperature is kept constant by passing a stream of water through the two prisms between which the oil is placed.

The melting-point of an oil is best determined by placing about 3 c.c. in a test-tube, and congealing it by immersion in a freezing mixture. The tube is then immersed in a beaker of water and the temperature of the water slowly raised until the oil is just completely melted, a thermometer being used to stir the oil continuously. For crystalline solids a capillary tube should be employed.

The boiling-point of a substance depends on the pressure of the atmosphere, the standard pressure being equal to 760 mm. of mercury. The correction for variation of pressure is made as follows: $T=T_1+0{\cdot}0375\ (760-p)$ where T is the true boiling-point, T_1 the observed boiling-point, and p the observed pressure. For accurate determination a correction may be made for the portion of the stem of the thermometer not surrounded by the vapour of the boiling liquid. This is made as follows: $T=T_1+0{\cdot}000154\ t.d.$ where T is the true boiling-point, T_1 the observed boiling point, t the number of degrees exposed to the atmosphere and d the difference between the temperature of the boiling liquid and that of the surrounding atmosphere.

Fractional distillation of essential oils is usually carried out under reduced pressure which should not exceed about 25 mm. A three-bulbed flask or a fractionating column is sometimes used, better separations being thus obtained. The characters of the various fractions are exceedingly useful in detecting adulteration.

Methods for the determination of alcohols, esters, aldehydes, ketones, and phenols are given under the various constituents.

Solubility. The solubility of an oil is often a good criterion of purity. It is usually determined by shaking 1 c.c. of the oil with 1, 2, 3, or more c.c. of alcohol of various strengths. The strengths generally employed are 70, 80, 90, and 95 p.c., and these must be carefully adjusted to the correct specific gravity. Each oil has a definite solubility value and the test serves to detect adulteration or the presence of oxidised or resinified products. Petroleum floats in 70 p.c. alcohol, fixed oils sink. A definite standard temperature should be adopted, say 20°C.

DETECTION OF ADULTERANTS.

Turpentine oil may be readily detected in oils which contain no pinene, the latter being the chief constituent of turpentine oil. It is usually found in the first fraction distilled, and generally reduces the specific gravity and affects the solubility. Its presence is proved by the formation of pinene hydrochloride (m.p. 125°) and its nitrosochloride (m.p. 103°).

Cedar wood, copaiba, and *gurjun balsam oil.* These are usually found in the last fractions since their chief constituents are sesquiterpenes. They have a high refractive index and high specific gravity, and are only soluble in absolute alcohol. Copaiba oil rotates −5° to −35° (African +20°), cedarwood oil −25° to −45°, and gurjun balsam −35° to −130°.

Alcohol may be detected by its low boiling-point, low specific gravity, low refractive index, and by the iodoform test. Oils containing alcohol form milky mixtures with water. It may be extracted by washing the oil with water.

Acetone may be detected in a similar manner.

Fatty oils leave an oily stain when exposed on blotting paper. With the exception of castor oil they are insoluble in alcohol. They usually increase the ester value of an oil and increase the non-volatile residue. Fatty oils have a very high boiling-point, and are therefore found in the residue left on distillation, where they may be detected by the acrolein test.

Artificial esters have usually a high boiling-point and may be detected in the last fractions of an oil by saponifying with aqueous potash and identifying the products of hydrolysis.

Glyceryl acetate, ethyl citrate, tartrate, oxalate, and succinate have been used for adulteration purposes.

Petroleum (mineral oil, kerosene, &c.) is less soluble in alcohol than most oils. It has a low specific gravity and refractive index, and is not saponified by potash. It is also unaffected by nitric and sulphuric acids.

PRINCIPAL ESSENTIAL OILS.

Absinthe oil (wormwood oil) is distilled from the leaves and tops of *Artemisia absinthium* (*N.O. Compositæ*), a herbaceous plant growing in Europe, Northern Africa, and Northern Asia, and cultivated in the United States of America. The yield is from 0·5 to 1·0 p.c. It is of a dark green or bluish colour having a sp.gr. of 0·920–0·955. It contains thujone (tanacetone), thujyl alcohol, acetic and valeric esters, phellandrene, pinene, and cadinene. It is used in the preparation of absinthe, in conjunction with other essential oils (*v.* ABSINTHE).

Ajowan oil is distilled from the fruit of *Carum ajowan* (Bentham and Hooker) or *Ptychotis ajowan* (D.C.) (*N.O. Umbelliferæ*). Cultivated in India, Egypt, Persia, and Afghanistan. The yield is from 3 to 4 p.c.; sp.gr. 0·900–0·930; slightly dextro-rotatory. Contains thymol (40–55 p.c.), cymene, and a terpene hydrocarbon. Ajowan oil is the chief source of thymol (methyl *iso*propyl phenol), which is extracted from the oil by freezing or by means of caustic soda, precipitating with hydrochloric acid and recrystallising from alcohol. Thymol melts at 50°–51°, and boils at 230°.

Bitter almond oil. Obtained by distillation with water from the marc left after expression of the fixed oil from the seeds of bitter almonds *Prunus Amygdalus*, var. *amara* (*N.O. Rosaceæ*). The oil results from the action of a nitrogenous ferment *emulsin*, found in both sweet and bitter almonds, on the glucoside amygdalin which exists only in the bitter almond. The reaction occurs in the presence of moisture as follows:—

$$\underset{\text{Amygdalin.}}{C_{20}H_{27}NO_{11}}+2H_2O=\underset{\text{Benzaldehyde.}}{C_7H_6O}+\underset{\text{Hydrocyanic acid.}}{HCN}+\underset{\text{Glucose.}}{2C_6H_{12}O_6}$$

Benzylcyanhydrin is formed by the interaction of the benzaldehyde with the hydrocyanic acid. The yield of essential oil varies, partly according to the quality of the almonds, partly according to the proportions of sweet almonds mixed with the bitter. The marc yields on an average 1 p.c. of oil corresponding to about 0·5 p.c. from the original almonds; sp.gr. 1·045–1·070; it is optically inactive and consists of benzaldehyde (about 90 p.c.), hydrocyanic acid (4–6 p.c.), and benzylcyanhydrin or mandelonitrile ($C_6H_5 \cdot CH(OH)CN$).

The hydrocyanic acid may be removed by redistillation with lime and ferrous sulphate or by agitation with sodium acid sulphite, crystallising the double salt and distilling the crystals with caustic soda. Essential oil of almonds is very rapidly oxidised on exposure to moist air forming benzoic acid, but when carefully dried by immersing in it a piece of calcium chloride it is said to keep indefinitely. It may be adulterated with artificial benzaldehyde or with alcohol. The former, if free from chlorine compounds, is impossible to detect; the latter is detected by shaking with water and applying the iodoform test to the washings.

A similar oil almost identical in character with oil of bitter almonds is obtained from peach and apricot kernels.

Amber oil is a mixture of terpenes boiling between 130° and 140° obtained by the destructive distillation of amber. Mixed with rectified spirit and ammonia it was formerly used in medicine under the name *Eau de Luce*. By the action of nitric acid a mixture of resins is produced, formerly known as 'artificial musk.' Genuine oil of amber is now very rarely found in commerce, much of the oil used medicinally for embrocations being obtained from amber resin (*colophony* (*q.v.*)) by destructive distillation.

Anise oil. Distilled from the fruit of *Pimpinella Anisum* (Linn.) (*N.O. Umbelliferæ*), grown in Europe, and from the fruit of the star anise, *Illicium verum* (Hook.) (*N.O. Magnoliaceæ*), cultivated in China. The latter is the source of most of the anise oil of commerce. The yield of oil from the star anise fruits is 2–4 p.c., that from the pimpinella anise seldom exceeding 2 p.c. The characters and constituents of the two oils are practically identical; sp.gr. 0·975–0·990 at 20°/15°, rising on keeping; 0°–2° seldom dextrorotatory; μ1·552–1·558; soluble in 3 vols. of 90 p.c. alcohol; it congeals about 10°, remelting at 15°–19°. It contains anethole 80–90 p.c., methyl chavicol, anisic aldehyde, anisic acid, anisic ketone, pinene, phellandrene, and safrole. Important changes take place in the oil on keeping, the melting-point being lowered and the density increasing. It is employed medicinally as a carminative and expectorant and as a flavouring agent.

Asafœtida oil. Distilled from the gum resinous exudation from the root of *Ferula Assa-fœtida* (Linn.) (*N.O. Umbelliferæ*), and probably other species growing in Persia and Afghanistan. It yields by distillation 3–7 p.c. of oil; sp.gr. 0·975–0·990; rotation about −10°. It contains organic sulphur compounds having the formulæ $C_7H_{14}S_2$, $C_8H_{16}S_2$, $C_{10}H_{20}S_2$, pinene, and a sesquiterpene. The proportion of sulphur compounds present varies according to the species of *Ferula* from which the gum resinous exudation has been obtained.

Bay oil. Distilled from the leaves of *Pimenta acris* (Kostel) (*Myrcia acris* [DC.]) (*N.O. Myrtaceæ*), largely grown in the West Indies. The yield is from 2 to 3 p.c.; sp.gr. 0·965–0·995; rotation −0° 30′ to −2°. It contains eugenol, methyl-eugenol, chavicol, methyl-chavicol, pinene, dipentene, phellandrene, myrcene, and citral. When distilled with water the oil separates into two layers, one lighter, the other heavier, than water. These are mixed to obtain a normal oil. It is sometimes adulterated with other eugenol-containing oils, notably those of clove and pimento.

Bergamot oil. Obtained by expression from the peel of the fresh unripe fruit of *Citrus Bergamia* (Risso) (*N.O. Rutaceæ*) cultivated in Calabria and Sicily. The process used for extraction is similar to that used for lemon oil. One hundred fruits yield 2½–3 ozs. of oil, which is limpid and of yellowish or greenish-yellow colour; sp.gr. 0·881–0·886; rotation +8° to +24°, rarely exceeding +18°; esters calculated as linalyl acetate, 36–42 p.c.; non-volatile matter after heating 2 hours on water-bath, 5–6 p.c. It contains linalool, linalyl acetate, octylene, pinene, camphene, limonene, dipentene, limene (sesquiterpene), bergaptene (stearoptene). The oil is subject to considerable adulteration with added esters, including terpinol acetate, ethyl citrate, &c., together with terpenes from allied species of citrus.

Buchu oil. Distilled from the leaves of *Barosma betulina* (Bartl. & Wendl.), and other species (*N.O. Rutaceæ*), a shrub indigenous to Cape Colony. It yields from 1 to 2 p.c. of oil; sp.gr. 0·940–0·960. It contains diosphenol, limonene, dipentene, menthene, the constituents varying according to the species of *Barosma* used for distillation (*see* Pharm. J. 3rd series, 796–797).

Cajuput oil. Distilled from the leaves of *Melaleuca Leucadendron* (Linn.) (*N.O. Myrtaceæ*), indigenous to India, North Australia, the Malay Archipelago, and the Molucca Islands. It is a green or bluish-green limpid oil having an aromatic camphoraceous odour resembling eucalpytus oil; sp.gr. 0·919–0·930; rotation 0°–4°. It contains cineol (45–60 p.c.), terpineol, pinene, butyric, valeric, and benzoic aldehydes. The green colour of the oil is due to contamination with copper, which can be removed by distillation or by shaking the oil with a solution of citric or tartaric acid or potassium ferrocyanide.

Calamus oil. Distilled from the rhizome of the sweet flag, *Acorus Calamus* (Linn.) (*N.O. Aroideæ*), found on the banks of many European rivers and cultivated in India. The yield is from 1·5 to 3·5 p.c.; sp.gr. 0·960–0·970; rotation +10° to +35°. It contains pinene and a sesquiterpene and unidentified oxygenated constituents. The Japanese oil is probably derived from the rhizome of *Acorus gramineus* (Soland). It has a density of 0·990–1·000. It is used in the preparation of cordials and liqueurs and in perfumery.

Camphor oil. A by-product in the manufacture of camphor from the wood of the camphor tree, *Cinnamomum Camphora* (Nees & Eberm.) (*N.O. Lauraceæ*), found in China, Japan, and Formosa. The oil varies considerably in character, but may be divided into two distinct classes, (1) the light fractions consisting principally of terpenes, (2) the heavy fractions containing more or less safrole, which is largely used in the preparation of heliotropin: sp.gr. (1) 0·860–0·950, (2) 0·950–1·100; rotation (1) +12° to +32°, (2) 0° to +12°. Camphor oil contains camphor, terpineol, safrole, eugenol, cineol, pinene, phellandrene, dipentene, and cadinene.

Cananga oil *v. Ylang Ylang.*

Caraway oil. Distilled from the fruit of *Carum Carvi* (Linn.) (*N.O. Umbelliferæ*), which is cultivated in England, Holland, Germany. Russia, and Morocco. The yield is from 4 to 6 p.c.: sp.gr. 0·900–0·920; rotation +75° to +82°; refractive index (25°) 1·485–1·497; at least 50 p.c. should distil above 200°. It contains carvol or carvone (45–55 p.c.), limonene, dihydrocarveol, and dihydrocarvone. Much of the oil is partially decarvonised, the carvone being employed extensively for the production of the liqueur 'Kummel' (*v.* LIQUEURS).

Cardamom oil. Distilled from the seeds of *Elettaria Cardamomum* (Maton), var. *β.* (*N.O. Zingiberaceæ*), growing wild, and cultivated in Ceylon, Malabar, and Mysore. The cultivated Ceylon variety furnishes the greater part of the oil of commerce. The yield is from 3 to 8 p.c.: sp.gr. 0·924–0·947 at 25°; rotation +22° to +46°. The wild Ceylon oil is inferior in quality, having a density of 0·895–0·910 and a rotation of +12° to +13°. Cardamom oil contains cineol 5–10 p.c., *d*-terpineol, limonene, and terpinene.

Cascarilla oil. Distilled from the bark of *Croton Eluteria* (Benn.) (*N.O. Euphorbiaceæ*), a native of the Bahama Islands; the yield is from 1·5 to 3 p.c.: sp.gr. 0·890–0·930; rotation +2° to +5°. It contains cymene, limonene, eugenol, cascarillic, stearic, and palmitic acids, and two sesquiterpenes.

Cassia oil. Distilled from the bark, leaves, and twigs of *Cinnamomum Cassia* (Blume.) (*N.O. Lauraceæ*), indigenous to Cochin China and cultivated in China. The yield is from 0·5 to 2 p.c.: sp.gr. 1·050–0·065; rotation +1° to −1°; refractive index 1·585 to 1·605; soluble in 3 vols. 70 p.c. alcohol. It contains cinnamic aldehyde 75–85 p.c., cinnamic esters, and terpenes. It may be adulterated with resin, petroleum, and fatty oils. The oil is sold in various grades according to cinnamic aldehyde percentage, the lower grades being usually reduced by the addition of resin.

Cedarwood oil. Distilled from the bark of *Juniperus virginiana* (Linn.), the red cedar (*N.O. Cupressineæ*). Often obtained from the waste shavings from the manufacture of cedar pencils: sp.gr. 0·940–0·960; rotation −25° to −45°; refractive index, 1·50–1·51. The chief constituent is cedrene (sesquiterpene). It contains 8–10 p.c. of cedrol or cedar camphor, which is a crystalline sesquiterpene alcohol melting at 78°–80°. It is largely used in perfumery and soap manufacture as a fixative for perfumes, and for microscopic purposes on account of its high refractive index. Cedar leaf oil, obtained from the leaves of *J. virginiana*, is dextro-rotatory +55° to +65°, and has a sp.gr. of 0·883–0·888. It contains limonene, cadinene, borneol, and bornyl esters.

Commercial cedar leaf oil is probably derived from *Thuya occidentalis* (Linn.), and other allied trees. It has a density of 0·860–0·920 and optical rotation −3° to −24°.

Cherry laurel oil is distilled from the leaves of *Prunus Lauro-cerasus* (Linn.) (*N.O. Rosaceæ*), an evergreen shrub indigenous to south-eastern Europe and Asia Minor. It has a density of 1·050–1·065 and contains benzaldehyde, prussic acid, and traces of benzyl alcohol. It differs very little from oil of bitter almonds. It is obtained as a by-product in the preparation of cherry laurel water (B.P.), which is standardised to contain 0·1 p.c. of prussic acid, and is used for medicinal purposes.

Cinnamon oil. Distilled from the bark of *Cinnamomum zeylanicum* (Nees) (*N.O. Lauraceæ*), a native of Ceylon. The yield is from 0·5 to 1 p.c.: sp.gr. 1·000–1·040; rotation 0° to −1°; refractive index 1·565–1·582; soluble in 3 vols. of 70 p.c. alcohol. It contains cinnamic aldehyde (55–75 p.c.), terpenes (phellandrene) and traces of eugenol. Oils containing a high aldehyde content (over 75 p.c.) may contain cassia oil or artificial cinnamic aldehyde. These oils have a higher refractive index than 1·582. English distilled oils have a low specific gravity, low aldehyde content, and a much finer aroma than heavier oils.

Cinnamon leaf oil, distilled from the leaves and twigs of the same tree, contains 75–85 p.c. of eugenol and safrole, and only traces of cinnamic aldehyde: sp.gr. 1·045–1·060; rotation −1° to +1°; refractive index 1·533–1·536. The oil distilled from the root contains eugenol, safrole, camphor, benzoic aldehyde, and benzoic esters.

Citron or **cedrat oil.** Obtained by expression from the rind of the fruit of *Citrus Medica* (Linn.) (*N.O. Rutaceæ*). The citron is very similar to lemon oil but contains a slightly higher percentage of citral. It is not now an article of commerce, but efforts are being made to grow the fruit in Corsica for the production of the oil. Factitious oils are offered under both names composed of the oils of other species of *Citrus*.

Citronella oil is distilled from the fresh grass *Andropogon Nardus* (Linn.), (*Cymbopogon Nardus* [Rendle]) (*N.O. Gramineæ*), which is largely grown in Ceylon and in the Straits Settlements. The yield is from 0·5 to 1·0 p.c.; the Ceylon oil has sp.gr. 0·900–0·915; rotation 0° to −21°; refractive index 1·480–1·482: the Java oil has sp.gr. 0·885–0·910; rotation 0° to −10°; refractive index 1·465–1·468. Citronella oil contains geraniol, citronellal, camphene, dipentene, limonene, and traces of linalool, borneol, methyl heptenone, methyl eugenol, and sesquiterpenes. It is largely used in cheap soap perfumery. The Ceylon oil contains a large proportion of geraniol, the total acetylisable constituents amounting to 58–65 p.c. In the Java variety the citronellal predominates and the proportion of acetylisable constituents is higher (75–90 p.c.) since citronellal is converted into *iso*pulegol acetate on acetylation. There are at least two varieties of citronella grass cultivated: (1) the 'Lena batu' type; (2) the 'Mahi Penghiri' type. The Ceylon oil is largely adulterated with Russian petroleum, the proportion of 12½–15 p.c.

having passed the solubility test which has been long in vogue. Attempts are being made to establish a standard for the sale of the Ceylon oil on geraniol content in the same way as cassia and other essential oils are on their percentage of odorous constituents.

Clove oil is distilled from the flower buds of *Eugenia caryophyllata* (Thunb.) (*N.O. Myrtaceæ*), indigenous to the Molucca Islands and cultivated in Zanzibar and Pemba, Sumatra, Penang, Madagascar, Seychelles, Mauritius, and West Indies. The yield is from 15 to 20 p.c.; the stems yield about 6 p.c. It has sp.gr. 1·047–1·065 (eugenol 1·070; caryophyllene 0·908); rotation 0° to −1·30°; refractive index 1·528–1·540; soluble in 3 vols. of 70 p.c. alcohol. It contains eugenol (85–95 p.c.) and eugenol esters, caryophyllene, methyl alcohol, furfural, traces of amyl methyl ketone and methyl benzoate. The oil is very largely used for the production of vanillin.

Copaiba oil is distilled from the oleo-resin or balsam of copaiba, which is an exudation from the trunk of *Copaifera Lansdorfii* (Desf.) and other species of copaiba (*N.O. Leguminosæ*), indigenous to Brazil and northern S. America. The Para variety gives the highest yield of oil (60–65 p.c.), the Bahia yielding about 50 p.c., the Maranham and Maracaibo about 40 p.c.: sp.gr. 0·895–0·918; rotation −7° to −25° (occasionally higher); refractive index 1·495–1·500. It is chiefly composed of sesquiterpenes (caryophyllene). African copaiba oil is dextro-rotatory about +20°, but lævo-rotatory oils can be obtained from the wood of young branches. Gurjun balsam oil has a lævo-rotation of −35° and upwards. It gives an intense violet colour when dissolved in glacial acetic acid and treated with a few drops of nitric acid.

Coriander oil is distilled from the fruit of *Coriandrum sativum* (Linn.) (*N.O. Umbelliferæ*), cultivated in most European countries. Russian, Moravian, and Thuringian fruits yield 0·8–1·0 p.c.; French, Dutch, and Italian 0·4–0·6 p.c.: sp.gr. 0·870–0·885; rotation +8° to +13°; refractive index 1·463–1·467; soluble in 3 vols. of 70 p.c. alcohol. It contains coriandrol (*d*-linalool) and *d*-pinene. The body which gives the characteristic odour is unknown. It may be adulterated with orange and lemon terpenes or turpentine oil, which affect the solubility and the rotation.

Cubeb oil is distilled from the dried unripe fruit of *Piper Cubeba* (Linn.) (*N.O. Piperaceæ*), chiefly imported from Java. The yield is from 10 to 18 p.c.; sp.gr. 0·910–0·930; rotation −25° to −40°; refractive index 1·495–1·496; soluble in 3–10 vols. of 90 p.c. alcohol. It contains dipentene, *l*-pinene, camphene, cadinene, and cubeb camphor, a crystalline sesquiterpene alcohol (m.p. 68°–70°, b.p. 245°).

Cummin oil is distilled from the fruits of *Cuminum Cyminum* (Linn.) (*N.O. Umbelliferæ*), also known as the Roman caraway. It is cultivated in Syria, Morocco, Malta, and the East Indies. The yield is from 2·5 to 4·0 p.c.; sp.gr. 0·910–0·930 (East Indian 0·893–0·899); rotation +4° to +8°; good oils dissolve in 3 vols., but inferior oil may require 8–10 vols. of 80 p.c. alcohol. It contains cuminic aldehyde (cuminal) 20–30 p.c., cymene, and a dextro-rotatory terpene, b.p. 156°, probably pinene.

Dill oil is distilled from the fruit of *Anethum* (*Peucedanum*) *graveolens* (Benth. & Hook.), *N.O. Umbelliferæ.* Indigenous to the Caucasus and Mediterranean countries, cultivated in Bavaria, Thuringia, and Roumania. The yield is from 3 to 4 p.c.; sp.gr. 0·895–0·915 (usually over 0·900); rotation +70° to +80°; refractive index 1·483–1·488; soluble in 3 vols. of 90 p.c. alcohol, 5–8 vols. of 80 p.c. alcohol. It contains carvone (40–60 p.c.), limonene, and phellandrene, but no dill apiol. East Indian and Japanese dill oils obtained from *Anethum* (*Peucedanum*) *Sowa* (Roxb.) have a sp.gr. 0·948–0·970, and a rotation of +41° to +51°. They contain dill apiol, a body heavier than water, b.p. 285°.

Eucalyptus oil. Distilled from the leaves of many species of *Eucalyptus* (*N.O. Myrtaceæ*), that of *Eucalyptus globulus* (Labill.) being chiefly prized though the oils of other species often contain more eucalyptol. The bulk of the oil of commerce is now derived from *E. dumosa* (A. Cunn.), but several hundred species are known and employed for distillation. *See* Baker and Smith's researches (Pharm. J. 4, [ix.] 315; [xvii.] 314; [xxi.] 356, 382). Indigenous to Australia, Tasmania, and New Zealand; cultivated in Spain, Algeria, and California. The yield is from 0·8 to 1·5 p.c. The following are the characters of oils of high eucalyptol content as required by the British Pharmacopœia: sp.gr. 0·910–0·930; rotation +10° to −10°; refractive index 1·469–1·475; cineol (eucalyptol) 55–80 p.c.; most oils are soluble in 3 vols. of 70 p.c. alcohol. Oils containing much phellandrene and but little cineol such as that of *E. amygdalina* (Lab.) have a lower density (0·855–0·890) and a higher lævo rotation (−25° to −80°). Eucalyptus oil contains cineol (eucalyptol), pinene, phellandrene, cymene, piperitone, aromadendrene, aromadendral, esters of eudesmic acid, eudesmol or eucalyptus camphor, and traces of amyl alcohol, valeric, butyric, and caproic aldehydes. The medicinal reputation of eucalyptus oil was largely founded on oils from *E. amydalina*, which are of low eucalyptol content. It is not by any means proved that the value of the oil is dependent on eucalyptol.

The oils of *Eucalyptus citriodora* (Hook.) and *E. maculata* (Hook.) do not contain cineol, but consist almost entirely of citronellal. They have sp.gr. 0·870–0·905; rotation 0° to +2°.

Geranium oil (*Rose-Geranium oil* or *Pelargonium oil*) is distilled from the leaves of *Pelargonium odoratissimum* (Soland), *P. capitatum* (Soland), and *P. roseum* (R.Br.) (*N.O. Geraniaceæ*). Indigenous to South Africa, but largely cultivated in France, Spain, Algeria, and the island of Reunion. The yield is 0·15 to 0·35 p.c.; soluble in 3 vols. of 70 p.c. alcohol.

Geranium oil contains geraniol, citronellol, and probably linalool, acetic, butyric, tiglic, and valerianic esters. The Spanish oil commands the highest price. The French and Algerian oils come next, and the Bourbon, which is usually darker in colour and has a characteristic odour, is of lowest value (*v.* table on p. 738).

Indian geranium oil (*Turkish Geranium oil*) *v. Palmarosa oil.*

Ginger oil is distilled from the rhizome of *Zingiber officinale* (Rosc.) (*N.O. Zingiberaceæ*): indigenous to tropical Asia, and cultivated in the East and West Indies and in Africa. The yield

——	French	Algerian	Reunion (Bourbon)	Spanish
Sp.gr.	0·895–0·905	0·890–0·900	0·890–0·895	0·889–0·898
Rotation	−7° to −10°	−6° to −10°	−8° to −11°	−10° to −15°
Esters calculated as geranyl tiglate	22–28 p.c.	20–29 p.c.	27–34 p.c.	35–42 p.c.
Total alcohols as geraniol .	about 75 p.c.	about 75 p.c.	about 80 p.c.	about 70 p.c.

is from 1 to 3 p.c.; sp.gr. 0·872–0·885; rotation −25° to −45°; refractive index 1·4885–1·4950. It contains phellandrene, camphene, and a sesquiterpene zingiberene, also traces of cineol, borneol, and citral.

Ginger grass oil is an inferior kind of palmarosa oil. Its botanical source is still uncertain, though it is probably derived from a species of *Andropogon* (*N.O. Gramineæ*). It has sp.gr. 0·930–0·940; rotation +18° to +32°; esters 10–25 p.c.; total alcohols calculated as geraniol 70–90 p.c. It contains geraniol, geranyl acetate, dihydrocuminol, and traces of limonene, dipentene, carvone, and an aldehyde not identified.

Juniper oil is distilled from the berries of *Juniperus communis* (Linn.) (*N.O. Coniferæ*) and is produced chiefly in Hungary, where it is obtained as a by-product in the manufacture of gin. The Italian berries produce the best yield of oil, viz. 1–1·5 p.c. The oil has sp.gr. 0·860–0·890, increasing with age; rotation −3° to −12°, occasionally slightly higher; refractive index 1·472–1·488; soluble when freshly distilled in 4 vols. of 95 p.c. alcohol. It contains pinene, cadinene, juniper-camphor, and a small proportion of esters. Pinene occurs to the extent of 25–60 p.c., and cadinene to the extent of 15–25 p.c. Juniper-camphor consists of a sesquiterpene alcohol (m.p. 165°–166°).

Lavender oil, principally used in commerce is distilled from the fresh flowering herb *Lavandula vera* (DC.) [*L. officinalis* (Chaix.)] (*N.O. Labiatæ*), and other species growing on the higher slopes of the Alps. The distillation is carried out on the spot by means of portable stills, to save cartage of the fresh herb. The oil distilled in the lower districts is inferior to that of the higher. It has sp.gr. 0·883–0·895 (occasionally higher); rotation −3° to −9°; esters calculated as linalyl acetate 25–45 p.c.; total alcohols as linalool 60–70 p.c.; soluble in 3 vols. of 70 p.c. alcohol. Contains linalool, geraniol, nerol, linalyl acetate, pinene, limonene, traces of cineol and thymol and a small quantity of sesquiterpene.

English lavender oil, distilled in Surrey, Suffolk, and Hertfordshire, has similar characters, but contains only 7–10 p.c. of esters calculated as linalyl acetate. It contains more cineol than the French oil, which may be adulterated with artificial esters, ethyl oxalate, citrate, tartrate, benzoate, succinate, benzyl benzoate, &c. Admixture with spike oil is detected by the odour, and by the reduction of ester percentage.

Spike lavender oil or *spike oil* is distilled from the flowering herb *Lavandula Spica* (Cav. Desc.), which grows in the lower mountainous regions of France, Spain, and Italy. Sp.gr. 0·905–0·915; rotation +1° to +4°; total alcohols calculated as borneol 25–45 p.c.; esters as linayl acetate 4–6 p.c.; soluble in 3 vols. of 70 p.c. alcohol. Contains linalool, borneol, camphor, cineol, terpineol, *d*-camphene, and a sesquiterpene.

Lemon oil is obtained by mechanical means from the fresh peel of *Citrus Limonum* (Risso) (*N.O. Rutaceæ*), which is largely cultivated in Southern Italy and Sicily. It is also grown in Spain, Portugal, Southern France, and in the West Indies, California, and Australia. It is produced in Sicily between November and March. Sp.gr. 0·857–0·862; rotation +57° to +65°; refractive index (25°) 1·474–1·476. Contains limonene (about 90 p.c.), pinene (traces), citral (4–5 p.c.), octyl, nonyl, and decyl aldehyde, geraniol and linalool, and their acetic esters, camphene, phellandrene and a sesquiterpene, limene, identical with bisabolene.

Lime oil is obtained by mechanical means from the peel of the fresh fruit of *Citrus Limetta* (Risso) (*C. Medica*) (*N.O. Rutaceæ*), and is produced in Italy in December and January. It resembles oil of lemon in odour, but the citral odour is more pronounced: sp.gr. 0·872–0·885; rotation +35° to +40°; refractive index 1·484–1·485. Contains pinene, limonene, dipentene, citral (6–10 p.c.), linalool and its acetic ester, and limettin (m.p. 147°).

Distilled lime oil is an oil of inferior quality obtained by distillation from the peel of the fruits of *Citrus Medica*, var. *acida*, grown in the West Indies, chiefly Montserrat: sp.gr. 0·856–0·868; rotation +34° to +41°; refractive index 1·470–1·471. Contains pinene, limonene, dipentene, cymene, terpineol, and a sesquiterpene, limene (bisabolene).

Myrtle oil is distilled from the leaves of *Myrtus communis* (Linn.) (*N.O. Myrtaceæ*), grown in Spain, Italy, the South of France, and Cyprus. It is a yellowish or greenish oil with a pleasant odour: sp.gr. 0·890–0·915; rotation +10° to +30°. Contains pinene, dipentene, cineol, and a camphor $C_{10}H_{16}O$, b.p. 195°–200°. The fraction, b.p. 160°–180°, is sold as *myrtol*, and contains cineol.

Mustard oil is obtained from the seeds of the black mustard, *Brassica nigra* (Koch) (*N.O. Cruciferæ*) after expressing the fixed oil. The pressed cake is macerated in water at 60°–70° for several hours, when a reaction takes place between the glucoside *sinigrin* (potassium myronate) and the ferment *myrosin* with the production of essential oil of mustard. It is a colourless or pale yellow mobile liquid, with an intensely pungent odour and blistering properties: sp.gr. 1·014–1·032; refractive index 1·525–1·535; optically inactive; distils between 148° and 156°. It consists almost entirely of allyl *iso*thiocyanate $C_3H_5N : C : S$ (95–99 p.c.), with traces of allyl cyanide. Artificial mustard oil is prepared by distilling allyl iodide with an alcoholic solution of potassium thiocyanate.

Nutmeg oil is distilled from the seed of *Myristica fragrans* (Houtt.) (*N.O. Myristicaceæ*). Indigenous to the Molucca, Banda, and Sunda Islands. The yield is from 8 to 15 p.c. Sp.gr.

0·865–0·920; rotation +14° to +28°. Contains pinene, camphene, dipentene, terpineol, myristicol (a mixture of alcohols, terpineol, linalool, borneol, and geraniol), myristicin, and *iso*myristicin, myristic acid, safrol, eugenol, *iso*eugenol, esters of formic, acetic, butyric, and octoic acids.

Oil of mace is practically indistinguishable from it, the oil being almost identical in character and composition. It is derived from the *arillus* of the nutmeg fruit.

Orange oil is obtained by expression from the peel of the fresh fruit. It consists principally of two kinds, the sweet oil from *Citrus Aurantium* (Linn.), and the bitter oil from *C. Bigaradia* (Loisel.) (*N.O. Rutaceæ*), the latter being usually of somewhat higher value. The tree is indigenous to Southern Asia, but largely cultivated in Southern Europe, Northern Africa, and the West Indies. The two oils are only distinguishable by odour. The bitter oil has sp.gr. 0·848–0·853, and rotation +91° to +98°. The sweet oil has sp.gr. 0·846–0·852, and rotation +96° to +99°. *Oil of Mandarin orange* derived from *Citrus Bigaradia*, var. *sinensis*, which is cultivated in China has a density of 0·852–0·859, and an optical rotation of +65° to +75°. *Oil of Tangerine orange* has characters almost identical. Orange oil consists principally of limonene (over 90 p.c.), with small quantities of citral, citronellol, decyl aldehyde, terpineol, linalool, methyl anthranilate, and citraptene.

Orange flower oil (*Neroli oil*) is distilled from the fresh flowers of the bitter and sweet orange, the former being known as '*Bigarade*,' the latter as '*Portugal*.' It is principally distilled in the South of France. The petals are separated from the sepals, covered with water and heated by a coil of steam pipes. The aqueous distillate separated from the oil is sold as orange flower water. It has sp.gr. 0·870–0·880; rotation +0° to +5°; ester content 7–20 p.c. Contains limonene, pinene, dipentene, terpineol, linalool, geraniol, and nerol and their acetic esters, methyl anthranilate and paraffin hydrocarbons.

Orange leaf oil generally known as *Petitgrain oil*, since it was originally obtained from the small immature fruits, is now distilled from the leaves and young shoots of the bitter and sweet orange, the former commanding the higher price. The best oil comes from the South of France, Spain, and Algeria; a slightly inferior quality is exported from Paraguay. The French oil has sp.gr. 0·885–0·900; rotation −5° to +3°; esters calculated as linalyl acetate 50–85 p.c.; soluble in 3 vols. of 70 p.c. alcohol. Contains limonene, linalool, geraniol, nerol, and their acetic esters, a sesquiterpene and stearoptene. The Paraguay oil has sp.gr. 0·884–0·890; rotation 0·0° to +5°; esters calculated as linalyl acetate, 45–65 p.c.; soluble in 1 in 3 vols. 80 p.c. alcohol. Contains pinene, dipentene, camphene, and esters of terpineol and geraniol.

Origanum oil *v. Thyme oil.*

Peach kernel oil *v. Bitter almond oil.*

Palmarosa oil or **Indian geranium oil**, sometimes incorrectly termed *Turkish geranium oil*, is distilled from the grass *Andropogon Schœnanthus* (Benth.) (*Cymbopogon martini*) (*N.O. Gramineæ*), a plant widely distributed in India and found also in tropical Western Africa. The young grass is known by the native name *Motya*, the older grass being termed *Sonfiya*, the former yielding the better oil. It has sp.gr. 0·885–0·895; rotation −2° to +2°; esters 5–11 p.c.; total alcohols calculated as geraniol 75–95 p.c.; soluble in 3 vols. of 70 p.c. alcohol. Contains geraniol, acetic and caproic esters, and traces of citronellol, methyl heptenone, and dipentene. The oil is now sometimes mixed with certain oils rich in geraniol produced from other grasses.

Parsley oil is distilled from the fruit of *Carum Petroselinum* (Benth. and Hook.) (*Petroselinum sativum*) (*N.O. Umbelliferæ*), indigenous to Asia Minor and the Mediterranean countries, cultivated in all moderate climates. It is colourless, yellowish or yellowish-green, partially solid at ordinary temperatures: sp.gr. 1·050–1·100; rotation −5° to −10°. Contains apiol (m.p. 30°, b.p. 294°) and terpenes, probably *l*-pinene. The oil from the root is similar in character, whilst that from the fresh herb has a lighter specific gravity.

Patchouli oil is distilled from the fresh and dried leaves of *Pogostemon Heyneanus* (Benth.) (*P. Patchouly*, Benth.) (*N.O. Labiatæ*), which is cultivated in the Straits Settlements and in the West Indies. The Java oil is probably derived from a different species. It has sp.gr. 0·970–0·995; rotation −50° to −68°; patchouli alcohol, $C_{15}H_{26}O_2$, 50–60 p.c.; soluble in 5 vols. of 90 p.c. alcohol. Contains patchouli alcohol (m.p. 56°), also termed patchouli camphor, cadinene, benzaldehyde, and cinnamic aldehyde.

Pennyroyal oil is obtained from the fresh herb, *Mentha Pulegium* (Linn.) (*N.O. Labiatæ*), and is principally distilled in Spain, Southern France, and Algeria. The oil of American pennyroyal or hedeoma oil is obtained from *Hedeoma pulegioides* (Pers.), which is widely distributed in North America. The two oils are very similar in character; the European oil has sp.gr. 0·930–0·960; rotation +13° to +35°; the American oil has sp.gr. 0·925–0·960; rotation +18° to +22°. Both oils are soluble in 3 vols. of 70 p.c. alcohol and contain pulegone (b.p. 221°–222°) as the chief constituent.

Pepper oil is distilled from the unripe berries of *Piper nigrum* (Linn.) (*N.O. Piperaceæ*), cultivated in Southern India, the Philippines, and the West Indies. It is colourless or yellowish-green, and has sp.gr. 0·870–0·900; rotation −5° to +2°. Consists almost entirely of terpenes and sesquiterpenes, phellandrene being the only constituent actually identified.

Peppermint oil is distilled from the fresh and dried flowering herb *Mentha piperita* (Linn.) (*N.O. Labiatæ*), of which several varieties have been obtained by cultivation. The commercial oil can be classified into three distinct varieties, English, American, and Japanese. The English is of two kinds, 'black' and 'white.' The 'white mint' oil is considered superior in quality. The greater bulk of commercial oil is American, but this is inferior to the English oil. Japanese and Chinese peppermint oil is the chief source of menthol, of which it contains from 70 to 90 p.c. Much of the Japanese oil imported has been partially dementholised and contains only about 40 p.c. of total menthol.

Most oils dissolve in 3–4 vols. of 70 p.c. alcohol, but become turbid with more alcohol unless rectified by redistillation. They contain menthol, and menthyl esters, menthone, pinene,

——	English	American	Japanese
Specific gravity	0·900–0·910	0·900–0·920	0·900–0·910
Rotation	−22° to −33°	−25° to −33°	−30° to −42°
Total menthol	58–66 p.c.	50–60 p.c.	70–90 p.c.
Esters calculated as menthyl acetate	Black, 5–7 p.c. White, 8–15 p.c.	— 8–14 p.c.	— 3–6 p.c.

phellandrene, cineol, acetaldehyde, dimethyl sulphide, and a sesquiterpene. The oils are now largely distilled in the South of France and Italy from plants originally imported from Mitcham (England). For the characters of the oils and other particulars, *see* Perfumery and Essential Oil Record, 1910, 292–300.

Pimento oil (*oil of allspice* or *Jamaica pepper*) is distilled from the unripe fruit of *Pimenta officinalis* (Lindl.) (*N.O. Myrtaceæ*), indigenous to the West Indies; sp.gr. 1·040–1·055; rotation 0° to −4°; phenols 60–75 p.c.; soluble in 3 vols. of 70 p.c. alcohol. Contains eugenol and eugenol methyl ether, cineol, phellandrene, caryophyllene, and palmitic acid.

Pine oils (*Turpentine oil*) (sometimes called spirits of turpentine) is derived from various species of *Pinus* (*N.O. Coniferæ*). The oleo-resin occurs in special resin ducts in the woody portion of the trees. The living tree is 'tapped,' and the oleo-resin or turpentine which exudes is collected. The oleo-resin on distillation with water yields oil of turpentine and the residue is known as *colophony resin.* It is obtained principally in North America, but is also produced largely in Northern Europe and the mountainous districts of Central Europe. American turpentine oil is derived principally from *Pinus palustris* (Mill.) (*P. australis*) and *P. Tæda* (Linn.); the French from *Pinus Pinaster* (Soland), and the Russian from *Pinus sylvestris* (Linn.). The American is chiefly met with in English commerce; the French variety more commonly on the Continent. Russian turpentine is inferior in quality as it has a strong characteristic odour and is not easily deodorised. Swedish turpentine is principally derived from *P. sylvestris*, and closely resembles the Russian product.

——	American	French	Russian
Sp.gr.	0·855–0·877	0·855–0·874	0·855–0·874
Rotation	+1° to +6°	−18° to −40°	+5° to +16°

Most turpentine oils dissolve in 5–8 vols. of 90 p.c. alcohol, but the solubility increases with age owing to the formation of soluble oxidation products. They are soluble in an equal volume of glacial acetic acid. Oil of turpentine is composed almost entirely of hydrocarbons, chiefly pinene, with traces of oxidation products such as formic and acetic acids and resin. Camphene and dipentene are usually present and traces of aldehyde. Turpentine oil readily oxidises to resinous substances on exposure to air and light, and on this property depends its use in paints and varnishes.

Pine needle oils or **Pine leaf oils** are obtained from the fresh leaves of various species of *Pinus.* The chief varieties found in English commerce are those of *Pinus Pumilio* (Haenke) and *Abies sibirica.* The oil from *Pinus Pumilio*, official in the British Pharmacopœia of 1898, is distilled in Hungary and the Austrian Tyrol from the leaves and twigs. It contains little pinene, consisting principally of phellandrene and sylvestrene, whilst cadinene has been found in the higher boiling fractions. Only a small proportion of esters is present.

Oil of Abies sibirica is distilled from the fresh leaves and twigs in Northern Russia and the slopes of the Ural mountains. It has a strong characteristic odour and contains 30–40 p.c. of esters chiefly bornyl acetate. It is more soluble than other pine oils, forming a clear solution in an equal volume of 90 p.c. alcohol.

Oil of Pinus sylvestris (*Fir wool oil*) was official in the 1885 edition of the British Pharmacopœia, but the genuine oil is now practically unobtainable. It consists chiefly of *d*-pinene and contains only a small proportion of esters. *Oil of Abies pectinata* (D.C.) [*A. Alba* (Mill.)], is a fragrant oil distilled principally in Switzerland. It contains limonene as well as pinene and a sesquiterpene. The oil from the cones of the same species, known as *templin oil*, is much lighter in density and has a higher optical rotation. It consists principally of limonene.

Characters of Pine-needle Oils.

——	Specific gravity	Rotation	Esters	Distilling between 155°/165°
P Pumilio . . .	0·863–0·875	−6° to −14°	5–7 p.c.	0–12 p.c.
A. sibirica . . .	0·900–0·920	−32° to −42°	30–40 p.c.	5–10 p.c.
P. sylvestris . . .	0·868–0·925	+5° to + 7°	3–11 p.c.	40–65 p.c.
A. pectinata . . .	0·870–0·875	−20° to −60°	5–12 p.c.	0–10 p.c.
A. pectinata (cones) . .	0·853–0·870	−60° to −75°	0–5 p.c.	5–10 p.c.

Pine tar oils are by-products in the manufacture of charcoal and wood tar by the dry distillation of resinous wood. They have an empyreumatic odour and are usually yellow or light brown in colour. They contain pinene, sylvestrene, and dipentene, together with decomposition products. The crude oil is purified by distillation with milk of lime. German pine-tar oil has a sp.gr. of 0·865–0·870, and an optical rotation of +18 to +22°. About 25 p.c. distils below 165°.

Rose oil (*Otto of roses, Attar of roses*) is obtained by distilling the fresh flowers of *Rosa damascena* (Mill.) (*N.O. Rosaceæ*), which is cultivated principally in Bulgaria and on the slopes of the Balkans, and also in France and Germany. It is largely produced by the Bulgarian peasants in primitive stills. It is a light yellow or slightly greenish oil forming a crystalline mass below 18°; sp.gr. 0·853–0·862 at 30°/15°; rotation −2° to −4°; refractive index at 25°, 1·460–1·465; total alcohols calculated as geraniol 70–75 p.c.; m.p. after solidification 18°–22°. The odorous portion is soluble in 70 p.c. alcohol, but the stearoptene is practically insoluble and can be separated by filtration from the alcoholic solution. The odorous portion consists chiefly of geraniol and citronellol (20–25 p.c.). Traces of phenyl ethyl alcohol, nerol and farnesol are also present. The odourless stearoptene exists to the extent of 10–16 p.c., and consists of two hydrocarbons melting at 22° and 40° respectively, the mixture melting at about 34°. Otto of roses was formerly much adulterated, and is even now to some extent with geraniol and citronellol and oils containing these bodies (Perfumery and Essential Oil Record, 1910, 188 and 217).

Rosemary oil is distilled from the leaves of *Rosmarinus officinalis* (Linn.) (*N.O. Labiatæ*). Indigenous to the Mediterranean countries, principally France, Spain, and Italy. The leaves are collected after the flowering period and are dried for a few days in the sun before distilling. The oil is produced in limited quantity in Great Britain, this variety commanding a very high price. It has sp.gr. 0·900–0·920; rotation +0° to +15° (sometimes lævo-rotatory); total alcohols calculated as borneol 10–18 p.c.; esters calculated as bornyl acetate 2–6 p.c.; soluble in 10 vols. of 80 p.c. alcohol. Contains pinene, camphene, cineol, camphor, borneol, and bornyl acetate.

Rosewood oil (oil of *Bois de Rose, male*) is obtained by the distillation from the wood of *Licaria guianensis* (Aublet) [? *Ocotea caudata* (Mez.)] (*N.O. Lauraceæ*), collected in French Guiana. A similar oil is obtained from the wood of *Protium altissimum* (March.), known as *Bois de Rose femelle* (*see* Perfumery and Essential Oil Record 1910, 32). Rosewood oil has sp.gr. 0·870–0·880; rotation −15° to −17°; soluble in 3 vols. of 70 p.c. alcohol. Contains linalool, geraniol, terpineol, nerol, and traces of methyl heptenone.

Linaloe oil (*Lignaloe oil*) is an oil of similar composition obtained from the wood of *Bursera Delpechiana* (Poiss.), *B. Aloëxylon* (Engl.), and other species. It is principally distilled in Mexico: sp.gr. 0·875–0·895; rotation −5° to −12° (sometimes dextro-rotatory); soluble in 3 vols. of 70 p.c. alcohol. Contains linalool, with geraniol, *d*-terpineol, and methyl heptenone.

Rue oil is distilled from the herb *Ruta graveolens* (Linn.) (*N.O. Rutaceæ*), which is indigenous to Europe. Other species are also cultivated in Algeria, *Ruta* (*bracteosa*) *chalepensis* (Linn.) and *R. montana* (Mill.). It has sp.gr. 0·830–0·840; rotation +0° to +2·30°; m.p. +9° to +10°; soluble in 3 vols. of 70 p.c. alcohol. Consists principally of methylnonyl ketone, with some methylheptylketone. Traces of methyl anthranilate give the fluorescent appearance to the oil.

Sage oil is distilled from the fresh leaves of *Salvia officinalis* (Linn.) (*N.O. Labiatæ*). Indigenous to the Northern Mediterranean countries: sp.gr. 0·915–0·925; rotation +10° to +25°; soluble in 3 vols. of 80 p.c. alcohol. The Spanish oil has a lavender-like odour and contains linalool probably derived from admixture with lavender plants.

Sandal-wood oil is distilled from the wood of *Santalum album* (Linn.) (*N.O. Santalaceæ*). Indigenous to the mountains of India and cultivated under Government control: sp.gr. 0·973–0·985; rotation −13° to −21°; total santalol 90–96 p.c.; soluble in 6 vols. of 70 p.c. alcohol at 20°. Contains santalol, a mixture of two sesquiterpene alcohols $C_{15}H_{24}O$, santalal (an aldehyde), santalene, and santene.

West Indian sandalwood oil, derived from *Amyris balsamifera* (Linn.), is lighter in density (0·960–0·967), and has a rotation of +24° to +29°.

Sassafras oil is distilled from the root of *Sassafras officinale* (Nees.) (*Laurus Sassafras* (Nees.)) (*N.O. Lauraceæ*), a native of North America, Canada, the United States, and Mexico. The best yield of oil is obtained from the root bark: sp.gr. 1·065–1·095; rotation +1° to +4°; soluble in 2 vols. of 90 p.c. alcohol. Contains safrol (80–90 p.c.), pinene, phellandrene, camphor, eugenol, and cadinene. Safrol can be separated by fractional distillation and cooling, but commercial safrol is usually obtained from camphor oil.

Savin oil is distilled from the fresh leaves and twigs of *Juniperus Sabina* (Linn.) (*N.O. Coniferæ*). Distilled in Great Britain and Germany: sp.gr. 0·910–0·930; rotation +40° to +68°; esters calculated as sabinyl acetate 36–47 p.c.; total sabinol 45–55 p.c. Contains sabinol, and sabinyl acetate, pinene, sabinene, furfural, decyl aldehyde, dihydro-cuminol, cadinene. French savin oil is derived from *J. phœnicea* (Linn.) and contains a large percentage of pinene. It is lighter in density (about 0·890), has a much lower rotation (+4° to +5°) and contains only about 10 p.c. of esters and 17 p.c. of total sabinol.

Spearmint oil is distilled from the fresh herb *Mentha viridis* (Linn.) (American) and *Mentha crispa* (Linn.) (German), and probably other species of *Mentha* (*N.O. Labiatæ*): sp.gr. 0·920–0·940; rotation −36° to −48°; soluble in an equal volume of 90 p.c. alcohol, but becoming opalescent on dilution. Contains carvone, phellandrene, limonene, pinene, and traces of valerianic esters. The body having the characteristic odour, according to Elze, is the acetic ester of dihydrocuminol.

Star anise oil *v. Anise oil.*

Tarragon oil or **Estragon oil** is distilled from the flowering herb *Artemisia Dracunculus* (Linn.) (*N.O. Compositæ*). Indigenous to Siberia and cultivated in Europe, used in the manufacture of sauces: sp.gr. 0·890–0·960; rotation +2° to +9°; soluble in 10 vols. of 80 p.c. alcohol. Contains estragol (methyl chavicol), phellandrene, *p*-methoxycinnamic aldehyde, and an olefinic terpene.

Terebene *v. Terpenes.*

Thyme oil. Red Thyme oil is distilled from the fresh flowering herb *Thymus vulgaris* (Linn.) (*N.O. Labiatæ*). It is principally grown in the mountainous parts of Southern France. Spanish thyme oil is probably derived from a species of *Origanum*, as it contains carvacrol but no thymol. Oil of wild thyme from *Thymus serpyllum* contains but a small proportion of phenols. French oil has sp.gr. 0·905–0·930; rotation (after redistillation) 0° to −2°; phenols absorbed by 5 p.c. solution of potash 20–45 p.c.; Spanish oil has sp.gr. 0·930–0·950; phenols absorbed by 5 p.c. solution of potash 40–70 p.c. Thyme oil is soluble in 2 vols. of 80 p.c. alcohol, and contains thymol and carvacrol, cymene, pinene, borneol, and linalool.

Origanum oil is distilled from various species of origanum, the oil imported from Trieste being chiefly derived from *Origanum hirtum* (Link.), that from Asia Minor from *O.* (*smyrnæum*) *Onites* (Linn.), and Cyprus oil from *Origanum Majorana* (Linn.) (*N.O. Labiatæ*).

—	Trieste	Smyrna	Cyprus
Sp.gr. . .	0·940–0·980	0·915–0·945	0·960–0·970
Rotation . .	0° to −1°	−3° to −13°	—
Phenols (absorbed by 5 p.c. solution of potash) .	60–85 p.c.	25–60 p.c.	78–84 p.c.

All are soluble in 3 vols. 70 p.c. alcohol and contain carvacrol and cymene; Smyrna oil contains linalool; Cyprus oil contains origanene and traces of hydroxymethoxycymene.

Verbena oil. True vervain oil is distilled from the leaves of *Verbena triphylla* (L'Hérit.) (*Lippia Citriodora* (H. B. & K.)), which is cultivated for decoration purposes in Spain and the South of France, the oil being distilled only in small quantities: sp.gr. 0·894–0·918; rotation −12° to −16°; contains 21–38 p.c. of citral.

Indian verbena oil or **lemongrass oil** has largely replaced the true verbena oil, as it contains a higher percentage of citral. It is distilled from the grasses *Andropogon citratus* (DC.) and *A. flexuosus* (Nees.). The former is the source of the Ceylon and Straits Settlements oil, the latter of the Malabar and Cochin. *A. citratus* is also cultivated in the West Indies, but the West Indian oil is lighter in density and less soluble than the East Indian variety.

—	East Indian	West Indian
Sp.gr. .	0·895 to 0·905	0·877 to 0·887
Rotation .	+3° to −3°	+2° to −2°
Solubility .	1 in 3 volumes of 70 p.c. alcohol	Not soluble in 90 p.c. alcohol

The chief constituent is citral, of which good oils contain 75–85 p.c. Other constituents are methyl heptenone, limonene, and dipentene. An oil of similar constitution, and containing a still higher percentage of citral, is derived from the leaves of *Backhousia citriodora* (F. Muell.) (*N.O. Myrtaceæ*), a small tree indigenous to Queensland. It has a sp.gr. of 0·895–0·900, is optically inactive, and contains about 95 p.c. of citral.

Wintergreen oil is distilled from the leaves of *Gaultheria procumbens* (Linn.) (*N.O. Ericaceæ*). Indigenous to the United States. The oil is produced by a kind of fermentation from a glucoside *gaultherin* by the action of an enzyme. It has sp.gr. 1·180–1·187; rotation −0°25′ to −1°. Consists almost entirely of methyl salicylate (over 99 p.c.) with traces of an alcohol, ester, ketone, or aldehyde, and a paraffin hydrocarbon melting at 65°. An oil almost identical with the foregoing is obtained from the bark of *Betula lenta* (Linn.), the sweet birch (*N.O. Betulaceæ*). This is now largely sold as wintergreen oil. It differs from true wintergreen oil in being optically inactive. Methyl salicylate is produced synthetically on a large scale, and its detection in oil of wintergreen is very difficult and can only be found by the practised nose.

Wormseed oil. The European oil is distilled from the unexpanded flower buds of *Artemisia maritima* (Linn.) (*N.O. Compositæ*) and other species. Indigenous to Southern Russia and the Levant. Owing to the high price of raw material it is very scarce and has been almost entirely superseded by the American oil. Levant wormseed oil has a sp.gr. of 0·915–0·940, and is lævo-rotatory from −1° to −5°. Contains cineol, dipentene, terpinene, terpineol, and a sesquiterpene.

American wormseed oil is derived from the seeds of *Chenopodium ambrosioides*, var. *anthelminticum*. It has sp.gr. 0·950–0·990; rotation −5° to −10°; saponification about 8·5 (after acetylation about 280). Contains cymene, sylvestrene, camphor, and ascaridol (60–65 p.c.), a body closely allied to cineol, decomposing violently on heating to about 150°. Ascaridol has a density of 1·008.

Ylang Ylang oil is distilled from the flowers of *Cananga odorata* (Hook.) (*N.O. Anonaceæ*). Indigenous to the Malay archipelago and cultivated in the Phillippine Islands.

Cananga oil consists usually of the higher fractions and contains a greater proportion of sesquiterpenes, but in some districts the entire oil is sold as cananga oil. The majority of samples fall within the following limits—

—	Ylang Ylang	Cananga	Manila oil
Sp.gr. .	0·930–0·960	0·910–0·940	0·900–0·945
Rotation	−38° to −45°	−17° to −55°	−22° to −50°
Sapon. No.	95–130	45–100	71–154

Ylang ylang oil forms a clear solution with 1–1½ vols. of 90 p.c. alcohol, becoming turbid on further addition of alcohol. Contains methyl and benzyl acetates and benzoates, linalool, geraniol, eugenol, *iso*eugenol, methyl ether of *p*-cresol, methyl salicylate, methyl anthranilate, and an odourless sesquiterpene alcohol melting at 138°. Cadinene is also present. For other commercial varieties the following characters have been recorded :—

—	Reunion oil	Madagascar	Seychelles
Sp.gr. .	0·939–0·967	0·961–0·981	0·924–0·958

J. C. U.

OILS (FIXED) and **FATS.** Oils and fats are distributed throughout the vegetable and animal kingdoms from the lowest organisms up to the most highly organised forms of vegetable and animal life, and are found in almost all tissues and organs. The vegetable oils and fats are deposited in considerable quantities in the seeds, and are associated there with starch, nitrogenous substances, &c., to serve as nourishment to the embryo. Exceptionally, oil has been found in considerable quantities in the rhizomes of *Cyperus esculentus* (Linn.). In the animal organism, oils and fats are mainly enclosed in the cellular tissues of the intestines and in the tissues nearest the outer skin.

The fatty (fixed) oils and fats form a well-defined and homogenous group of substances, passing through all gradations of consistency, from oils which are fluid even below the freezing-point of water, up to the hardest fats which melt at about 50°. Therefore no sharp distinction can be made between fatty oils and fats. Nevertheless, it is convenient to apply the term 'oil' to those glycerides which are fluid below about 20°, and the term 'fat' to those which are solid above this temperature.

The natural oils and fats may, for practical purposes, be looked upon as consisting in the main of mixtures, in varying proportions, of the triglycerides described under GLYCERIN.

No natural oil or fat consists of one simple triglyceride, although some of the vegetable fats derived from the *Myristicaceæ* contain very small quantities only of fatty acids other than myristic. The natural oils and fats must rather be looked upon as mixtures of at least two or three triglycerides, the most important of which would be represented by trilaurin, trimyristin, tripalmitin, tristearin, triolein, trilinolin, trilinolenin, triclupanodonin, and triricinolein. The glycerides of hydnocarpic and chaulmoogric acids are characteristic of the fats of the chaulmoogra group (*q.v.*). Other glycerides occurring in much smaller quantities are glycerides containing butyric acid (in butter fat), caproic, caprylic, capric acids (in butter fat, cocoa-nut oil, palm nut oil), lauric acid (in cocoa-nut oil, palm nut oil, dika fat), and arachidic acid (in arachis oil).

A systematic survey of the most important fatty acids occurring in oils and fats as glycerides is given in the table on p. 744.

In consequence of the discovery of mixed glycerides, the question whether mixed glycerides occur in the natural fats far more frequently than has been assumed hitherto has become a very important one. A good deal of evidence goes to show that the amount of simple triglycerides in such common fats as, *e.g.*, tallow and lard is very small indeed, and that the bulk of the triglycerides consists of mixed glycerides. At present, however, our knowledge is still too limited to justify any definite expression of opinion as to the exact composition of the glycerides in the natural oils and fats (*cf.* also GLYCERIN).

To sum up, oils and fats must not be looked upon as chemical individuals, but rather as representatives of natural species which vary, although within certain narrow limits, according to the climate and soil in which the plants producing them are grown; or, in the case of animal fats, according to the climate, the race, the age of the animal, and especially the food, and also to some extent the idiosyncrasy of the individual.

In nature, apparently, only triglycerides occur. Monoglycerides and diglycerides are, as a rule, not met with in freshly-prepared fats. (The occurrence of the diglyceride of erucic acid in a specimen of crude rape oil is due to the fact that that specimen had become rancid, with the formation of lower glycerides than a triglyceride.)

Monoglycerides and diglycerides (*see also* GLYCERIN) have hitherto been obtained only synthetically. As they have not acquired any practical importance, the reader is referred to the list of monoglycerides and diglycerides collated in Lewkowitsch's Chem. Technology, vol. i. 6.

From the table given on p. 744, it will be gathered that, for practical purposes, a classification of oils and fats can be based on the nature of the fatty acids as measured by their degree of unsaturation. This is best ascertained by determining the magnitude of the iodine absorption of the natural oils and fats, whereby a most important measure of the amount of unsaturated glycerides contained in a given oil or fat, is found. In a classification based on the iodine value the old grouping of oils into *drying oils*, *semi-drying oils*, and *non-drying* oils is implicitly contained.

The apparently antiquated sub-division into vegetable and animal oils and fats did not rest on a scientific basis, until it had been found possible to differentiate chemically between cholesterol and phytosterol (*q.v.*). All evidence goes to show that cholesterol occurs only in oils and fats of animal origin and is characteristic thereof, whereas phytosterol (sitosterol and its congeners) has been found hitherto only in vegetable oils and fats. Based on these two principles, the author has put forward a scheme of classification of the natural oils and fats (Conférence, Bull. Soc. chim. 1909) which is arranged in the following synoptic table:—

I. VEGETABLE OILS AND FATS.

A. *Vegetable Oils.*

1. Drying oils.
2. Semi-drying oils—
   - (*a*) Cottonseed oil group.
   - (*b*) Rape oil group.
3. Non-drying oils—
   - (*a*) Almond oil group.
   - (*b*) Olive oil group.
   - (*c*) Castor oil group.

B.—*Vegetable Fats.*

1. Chaulmoogra oil group.
2. Laurel oil group.
3. Palm oil group.
4. Myristica group.
5. Cacao butter group.
6. Cocoanut oil group.
7. Dika fat group.

II. ANIMAL OILS AND FATS.

A. *Animal Oils.*

1. Marine animal oils—
   - (*a*) Fish oils.
   - (*b*) Liver oils.
   - (*c*) Blubber oils.
2. Terrestrial animal oils—
   - (*a*) Semi-drying oils.
   - (*b*) Non-drying oils.

B.—*Animal Fats.*

1. Drying fats.
2. Semi-drying fats.
3. Non-drying fats—
   - (*a*) Body fats.
   - (*b*) Milk fats.

The tables, pp. 746-748, furnish a list of the most important oils and fats, arranged according

—	Chemical composition	Boiling-point		Melting-point °C.	Characteristic of
		Under mm. pressure	°C.		
I. Acids of the Acetic series, $C_nH_{2n}O_2$—					
Acetic acid . .	$C_2H_4O_2$	760	119	17	Spindle-tree oil, Macassar oil.
Butyric acid . .	$C_4H_8O_2$	760	162·3	−6·5	Butter fat, Macassar oil.
*iso*Valeric acid (?) .	$C_5H_{10}O_2$	760	173·7	−51	Porpoise and dolphin oils.
Caproic acid . .	$C_6H_{12}O_2$	770	202–203	−8	Butter fat, cocoa-nut oil, palm nut oil.
Caprylic acid . .	$C_8H_{16}O_2$	761	236–237	16·5	
Capric acid . .	$C_{10}H_{20}O_2$	760	268–270	31·3	
Lauric acid . .	$C_{12}H_{24}O_2$	100	225	43·6	Laurel oil, cocoa-nut oil.
Myristic acid . .	$C_{14}H_{28}O_2$	100	250·5	53·8	Mace butter, nutmeg butter.
Palmitic acid . .	$C_{16}H_{32}O_2$	100	271·5	62·62	Palm oil, Japan wax, myrtle wax, lard, tallow, etc.
Stearic acid . .	$C_{18}H_{36}O_2$	100	291	69·32	Tallow, cacao butter, etc.
Arachidic acid . .	$C_{20}H_{40}O_2$	—	—	77	Arachis oil.
Behenic acid . .	$C_{22}H_{44}O_2$	60	306	83–84	Ben oil.
Lignoceric acid . .	$C_{24}H_{48}O_2$	—	—	80·5	Arachis oil.
II. Acids of the Acrylic or Oleic series, $C_nH_{2n-2}O_2$—					
Tiglic acid . . .	$C_5H_8O_2$	760	198·5	64·5	Croton oil.
Hypogæic acid . .	$C_{16}H_{30}O_2$	15	236	33–34	Arachis oil.
Oleic acid . . .	$C_{18}H_{84}O_2$	100	285·5–286	6·5	Most oils and fats.
Rapic acid . .	$C_{18}H_{34}O_2$	—	—	—	Rape oils.
Erucic acid . .	$C_{22}H_{42}O_2$	30	281	33–34	Rape oils, fish oils.
III. Acids of the Linolic series, $C_nH_{2n-4}O_2$—					
Linolic acid . .	$C_{18}H_{32}O_2$	14	228	—	Soya bean oil, Maize oil, cotton-seed oil.
Telfairic acid . .	$C_{18}H_{32}O_2$	13	220–225	—	Koëme oil.
Elæomargaric acid .	$C_{18}H_{32}O_2$	—	—	48	Tung oil.
IV. Acids of the Cyclic (Chaulmoogric) series, $C_nH_{2n-4}O_2$—					
Hydnocarpic acid .	$C_{16}H_{28}O_2$	—	—	59–60	Hydnocarpus, Lukrabo, and Chaulmoogra oils.
Chaulmoogric acid .	$C_{18}H_{32}O_2$	20	247–248	68	
V. Acids of the Linolenic series, $C_nH_{2n-6}O_2$—					
Linolenic acid . .	$C_{18}H_{30}O_2$	—	—	—	Linseed oil.
*iso*Linolenic acid .	$C_{18}H_{30}O_2$	—	—	—	
VI. Acids of the Clupanodonic series, $C_nH_{2n-8}O_2$—					
Clupanodonic acid .	$C_{18}H_{28}O_2$	—	—	liquid	Fish, liver, and blubber oils.
VII. Acids of the Ricinoleic series (hydroxylated acids), $C_nH_{2n-2}O_3$—					
Ricinoleic acid . .	$C_{18}H_{34}O_3$	15	250	4–5	Castor oil.
VIII. Dihydroxylated acids of the series $C_nH_{2n}O_4$—					
Dihydroxystearic acid	$C_{18}H_{36}O_4$	—	—	141–143	Castor oil.
IX. Acids of the series $C_nH_{2n-2}O_4$ (dibasic acids)—					
Japanic acid . .	$C_{21}H_{40}O_4$	—	—	117·7–117·9	Japan wax.

to the classification set out in the foregoing table. There are added the botanical and zoological sources, the proportions of oil or fat contained in the seeds or fruits of the plants, the iodine values of the oils and fats, and their principal uses.

The determination of oils and fats in the raw materials of the oil and fat industries is effected in the chemical laboratory by heating the finely divided substance with ether, petroleum ether, or similar solvents. The comminution of hard oil seeds can be effected in a porcelain mortar, which is finally washed out with the solvent so as not to lose any fatty matter which has exuded. It is also feasible to apply an ordinary coffee-grinder, but in this case it is more difficult to avoid loss of fat. In laboratories where such determinations are carried out frequently, special grinding machines are used and loss is obviated by squeezing a large quantity of seeds through the machine. In case the substances contain a considerable amount of moisture, it is best to dry them previously, provided the oil or fat does not suffer an injurious change thereby. If oxidation of the oil or loss of volatile substances is to be expected, the oil or fat may be extracted from the moist substances by means of petroleum boiling below 80°. Ether is most satisfactory for general use, but with this solvent the substance must be dried first. Carbon disulphide and chloroform may also be used, but in this case also it is necessary to dry the substance previous to extraction. The choice of the solvent is by no means immaterial; thus carbon disulphide (which is largely used in France) extracts a larger amount of substances than do ether or petroleum (*cf.* Lewkowitsch, Chem. Technology, [i.] 213).

The most convenient apparatus for the extraction of fat is the one devised by Soxhlet (Szombathy) (see Fig. 1). 10–15 grams of the comminuted substance are filled into a cartridge of filter-paper, easily prepared by rolling filter-paper round a cylindrical piece of wood of suitable size, and folding it up at one end. The cartridge is filled with the substance and transferred to the extractor E. Care must be taken that the syphon tube be not stopped up by the paper case; nor should the cartridge be filled to the top, lest some particles of the substance be washed over by the solvent and carried away. To be quite safe, it will be found advisable to place a plug of (extracted) cotton-wool on the top of the substance, or to close the top by folding the paper over it. The tube N is then fitted by means of a cork to a flask charged with about 50 c.c. of the solvent (petroleum, ether, chloroform, &c.). Another portion of the solvent is carefully poured on to the substance in E, until it commences to run off through the syphon S. Finally, an inverted condenser is fitted to E, and the whole apparatus is placed on a water-bath. In using this form of Soxhlet's extractor there is always some doubt as to the exact time when the extraction is complete, and, as a rule, the operation lasts much longer than necessary, involving both loss of time and solvent. To avoid this, Lewkowitsch has a tap fitted on to the syphon tube, so that some of the solvent can be withdrawn at any time to ascertain the progress of extraction (*see* Fig. 2). If the substance to be extracted has been collected on a filter, the simplest plan is to fold the filter and place it at once in the extractor.

When the extraction is complete, the flask containing the solution is detached from the extractor the solvent is distilled off on the water-bath, and the fat dried in an air-bath at a temperature not exceeding 100°–110°, until the weight remains fairly constant.

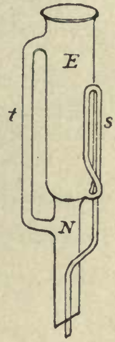

FIG. 1.

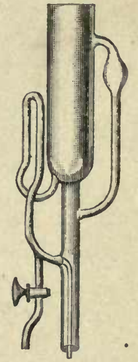

FIG 2.

In case the substance has not been dried completely and ether has been used, it is advisable to extract the residue once more with light petroleum. The drying of the residue is effected by placing the flask in a drying oven, heating to 100°–105°, and turning the contents round the walls of the flask at frequent intervals. If the minute drops of water which collect at the bottom of the oily layer have disappeared, the drying may be considered to be completed. This must be confirmed by re-weighing after further drying for half an hour. In the case of drying oils, it is best to heat the flask in an oil-bath at the temperature of 100°–105°, while a slow current of carbon dioxide or of hydrogen is allowed to pass over the surface of the oil.

TECHNICAL PREPARATION OF OILS AND FATS.

Rendering.—Since oils and fats have served the human race as one of the most important articles of food, the methods of preparing oils and fats may be considered to date back as far as the history of the human race itself. The crudest methods of 'rendering' oils from seeds and fruits, which are still practised at present in Central Africa, in Indo-China, the Malay Archipelago, and the South Sea Islands, consist in allowing the broken fruits to melt by the heat of the sun, when the exuding oil runs off and is collected. The production of palm oil by the natives, as also of the preparation of best cocoanut oil by boiling the fruit kernels with water, are more modern developments of this method, which culminates in the *boiling-out method* practised on the largest scale by 'rendering' animal fats and oils from the tissue, as is done in the preparation of tallow, lard, whale oil, cod-liver oil, &c. The most modern practice in the carrying out of this process, as worked in the enormous packing houses (rendering establishments) in America (tallow, lard, bone fat), and in the modern whale oil and fish oil rendering

I. VEGETABLE OILS AND FATS.

A. Vegetable Oils.

	Oil.	Source	Proportion of oil in seed or fruit	Iodine value	Used in the production of
	1. *Drying Oils.*				
	Perilla . .	Perilla ocymoides	35·8	206·1	Varnishes.

	Maize: corn .	Zea Mays	6–10	113–125	Edible oil, soap.
	Beech nut . .	Fagus sylvatica	43–45	111–120	Edible oil, burning oil.
	Kapok . .	Bombax pentandrum (Eriodendron anfractuosum)	30–32	116	Edible oil, soap.
	Cotton seed .	Gossypium herbaceum	24–26	108–110	Edible oil, soap.
	Sesamé . .	Sesamum orientale, S. indicum	50–57	103–108	Edible oil, soap.
	Curcas, purging nut	Jatropha curcas	55–57	98–110	Medicine, soap.
	Brazil nut . .	Bertholletia excelsa	73	90–106	Edible oil, soap.
(*b*) Rape oil group	Croton . .	Croton tiglium	53–56	102–104	Medicine.
	Ravison . .	Wild Brassica campestris	33–40	105–117	Lubricants, burning oil.
	Hedge Mustard .	Raphanus Raphanistrum	35–40	105	
	Rape (colza) .	Brassica campestris	33–43	94–102	Lubricant, burning oil.
	Black Mustard .	Brassica nigra (Sinapis nigra)	31–33	116·1	Soap.
	White Mustard .	Brassica alba (Sinapis alba)	85–86	92–103	Soap.
	Radish seed .	Raphanus sativus	45–50	92–112	
	Jamba . .	Brassica campestris var.	24	95	Burning oil, lubricant.
	3. *Non-Drying Oils.*				
(*a*) Almond oil group	Cherry kernel .	Prunus cerasus	35–36	110–114	Edible oil, burning oil, soap.
	Apricot kernel .	Prunus armeniaca	40–45	96–108	Perfumery, medicine.
	Plum kernel .	Prunus domestica Prunus damascæna	25		
	Peach kernel .	Prunus persica	32–35	93–108	Perfumery, medicine.
	Almond . .	Prunus amygdalus	45–55	93–100	Perfumery, medicine.
(*b*) Olive oil group	Arachis (groundnut)	Arachis hypogæa	43–45	83–100	Edible oil, soap.
	Hazel nut . .	Corylus avellana	50–60	83–90	Edible oil, perfumery, lubricant.
	Olive . .	Olea europæa	40–60	79–88	Edible oil, lubricant, burning oil, soap.
	Olive kernel .	Olea europæa	12–15	87	Edible oil, lubricant, burning oil, soap.
	Ben . .	Moringa oleifera	35–36	82	Edible oil, perfumery, lubricant.
(*c*) Castor oil group	Grape seed .	Vitis vinifera	10–20	96	Edible oil, burning oil.
	Castor . .	Ricinus communis	46–53	83–86	Medicine, soap, Turkey red oil, lubricant.

B. Vegetable Fats.

	Fat.	Source	Proportion of oil in seed or fruit	Iodine value	Used in the production of
	Laurel oil group—				
	Laurel oil	Laurus nobilis	24–26	68–80	Medicine.
Palm oil group	Mowrah seed oil	Bassia latifolia	50–55	63	Edible fat, soap, candles.
	Mahua butter	Illipe latifolia			
	Mowrah butter	Bassia longifolia	50–55	58–63	Edible fat, soap, candles.
	Illipe butter				
	Macassar oil Kusum oil	Schleichera trijuga	70·5	48–69	Medicine.
	Palm oil	Elaeis guineensis, E. melanococca	16–44	53	Candles, soap.
Myristica group	Mace butter Nutmeg butter	Myristica officinalis	38–40	40–52	Medicine, perfumery.
	Phulwara butter	Bassia butyracea	50–52	42	Edible fat.
	Shea butter (Galam butter)	Bassia Parkii	49–52	56	Edible fat, soap, candles.
Cacao butter group	Mkányi fat	Stearodendron Stuhlmannii	67	41·9	Soap, candles.
	Malabar tallow	Vateria indica		37–40	Edible fat.
	Cacao butter	Theobrama cacao	44–50	32–41	Chocolate.
	Chinese vegetable tallow	Stillingia sebifera (Croton seb.)	22	28–32	Soap, candles.
	Kokum butter (Goa butter)	Garcinia indica	49	33	Edible fat.
	Borneo tallow	Shorea stenoptera, Hopea aspera	45–50	15–31	Edible fat, candles.
Cocoa-nut oil group	Mocaya oil	Cocos sclerocarpa	60–70	24	Edible fat, soap.
	Maripa fat	Palma (?) Maripa	—	17	,, ,,
	Palm kernel oil Palm nut oil	Elaeis guineensis E. melanococca	45–50	13–14	,, ,,
	Cocoa-nut oil	Cocos nucifera, C. butyracea	20–25	8–9	Edible fat, soap, candles.
Dika fat group	Dika oil (oba oil, wild mango oil)	Irvingia gabonensis	60–65	5·2	Edible fat.
	Japan wax	Rhus succedanea, R. vernicifera	25	4–10	Polishes.
	Myrtle wax	Myrica cerifera, M. carolinensis	20–25	2–4	Soap, candles (?).

II. ANIMAL OILS AND FATS.

A. Animal Oils.

Oil	Source	Iodine value	Principal use
1. *Marine Animal Oils.*			
(*a*) Fish oils—			
Menhaden	Alosa menhaden	140–173	Currying leather; soap making.
Sardine	Clupea sardinus	161–193	,, ,, ,,
Japanese sardine	Clupanodon melanosticta	187	,, ,, ,,
Salmon	Salmo salar	161	Currying leather.
Herring	Clupea harengus	124–142	,, ,,

Sturgeon	Accipenser sturio	125·3	,, ,,
Sprat	Clupea sprattus, Cuv.	122–142	,, ,,
(*b*) Liver oils—			
Cod liver	Gadus morrhua	167	Medicine, currying leather.
Skate liver	Squatina vulgaris	157·3	,, ,, ,,
Tunny liver	Thynnus vulgaris	191·1	,, ,, ,,
Shark (arctic)	Scymnus borealis	115	Currying leather.
Coal fish	Gadus merlangus (virens)	161·1	,, ,,
Hake liver	Merluccius commun. (vulgaris)	—	,, ,,
Ray liver	Raja clavata (batis)	—	,, ,,
Ling liver	Molva vulgaris	132–151	,, ,,

II. ANIMAL OILS AND FATS—*continued.*

A. Animal Oils.

Oil	Source	Iodine value	Principal use
(*c*) Blubber oils—			
Seal . .	Phoca vitulina	137–147	Burning, currying leather.
Whale . .	Balæna mysticetus	121–136	Burning, soap-making, fibre dressing, currying leather.
Dolphin, black fish			
Body oil .	Delphinus globiceps	99–126	Lubricating oil for delicate machinery.
Jaw oil .		33	
Porpoise—			
Body oil .	Delphinus phocæna	119	
Jaw oil .			
	2. Terrestrial Animal Oils.		
Non-Drying oils—			
Sheep's foot .	Ovis aries	74	Lubricating.
Horses' foot .	Equus caballus	74–90	„
Neat's foot .	Bos taurus	67–73	Lubricating, leather.
Egg . .	Gallus domesticus	68–82	Leather dressing.

B. Animal Fats.

	Fat	Source	Iodine value	Principal use
		1. Drying Fats.		
	Ice bear . .	Ursus maritimus	147	Pharmacy.
	Rattlesnake .	Crotalus durissus	106	Pharmacy.
		2. Semi-drying Fats.		
	Blackcock .	Tetrao urogallus	121·1	
	Hare . . .	Lepus timidus	102·2	
	Rabbit, wild .	Lepus cuniculus	99·8	
	Rabbit, tame .	Lepus cuniculus	67·6	
	Wild duck . .	Anas boschas	84·6	
	Domestic duck .	Anas boschas	58·5	
	Horses' fat . .	Equus caballus	75–85	Edible fat, soap.
		3. Non-drying Fats.		
Body fats	Horse marrow fat	Equus caballus	77–81	Food, soap.
	Domestic goose .	Anser cinereus		Food.
	Wild goose . .	Anser ferus	99·6	
	Lard . . .	Sus scrofa	66	Food, soap.
	Hog, wild . .	Sus scrofa	76·6	
	Beef, marrow .	Bos taurus	55	Pomades
	Bone . . .	Bos; Ovis	46–56	Soap, candles.
	Tallow, beef .	Bos taurus	38–46	Food, soap, candles, lubricants.
	Tallow, mutton .	Ovis aries	35–46	Food, soap, candles, lubricants.
Milk fat	Butter . .	Bos taurus	26–38	Food.

works, consists essentially in cutting up the fatty tissues into small fragments, which are transferred into vessels containing water, wherein the comminuted mass is heated by steam, either under ordinary pressure in open vessels or under higher pressure in digesters. The fat gradually exudes and collects on the top of the water whilst the membranous matter ('greaves') falls to the bottom. The fat is then drawn off from above the aqueous (gluey) layer, and strained through sieves or filters. The 'greaves' are placed in hair or woollen bags and submitted to hydraulic pressure, whereby a further portion of oil or fat is obtained. In the case of those animal fats which are intended for edible purposes, such as lard or suet for margarine, the greatest cleanliness must, of course, be observed, and the temperature must be kept as low as possible in order to obtain a perfectly 'sweet' and pure material.

Pressing.—The preparation of oils and fats from small oleaginous seeds, such as linseed and rape seed, was practised originally by crushing the seeds and grinding between stones, as is still done in India. A more modern development, still in vogue in Manchuria in the production of soya bean oil, consists in bruising the seeds and reducing them under an edge-stone, heating the meal in an open pan, and pressing out the oil in a wedge-press, the wedges being driven home by hammers. The screw-press used in vineyards served as a model for the construction of the primitive olive-press. The several stages through which the industry of oil presses developed from these early beginnings of machinery to the Dutch wedge-press, until it reached the most complete form of modern oil-pressing plant, cannot be detailed here, and the reader is therefore referred for a rapid survey to Lewkowitsch's Chemical Technology, [ii.] 1–15. It must suffice here to state that the most modern presses in vogue at present are the *Marseilles press*, the *Anglo-American press*, and the *cage press* (clodding-press), which have reached their present completeness through the combination of the inventions of the hydraulic-press by Joseph Bramah (1795), and of the accumulator by William George (later Lord) Armstrong (1843). It is due to the early application of these inventions in this country, that England secured the supremacy in the oil-crushing trade in the latter half of the last century and has been able to retain it, notwithstanding severe foreign competition.

The sequence of operations in treating oil seeds, oil nuts, &c., for the separation of the oils they contain is, at the present time, as follows: As a preliminary operation the oil seeds and nuts are freed from dust, sand, and other impurities by sifting in an inclined revolving cylinder or sieving machine, covered with woven wire, having meshes varying according to the size and nature of the seed operated upon. This preliminary purification is of the greatest importance, especially for the preparation of *edible oils and fats.* In the case of those seeds amongst which are found pieces of iron (hammer heads and nails, amongst palm kernels, &c.), the seeds are passed over magnetic separators, which retain the pieces of iron. The seeds and nuts are then decorticated (when required), the shells removed, and the kernels ('meats') converted into a pulpy mass or meal (in older establishments by crushing and grinding between stones in edge-runners) on passing through a hopper over rollers consisting of (five) chilled-iron or steel cylinders mounted vertically like the bowls of a calendar. These rollers are finely grooved so that the seed is cut up whilst passing in succession between the first and second rollers in the series, then between the second and the third, and so on to the last, when the grains are sufficiently bruised, crushed, and ground. The distance between the rollers can be easily regulated so that the seed leaving the bottom roller has the desired fineness. The comminuted mass, forming a more or less coarse meal, is either expressed in this state or subjected to a preliminary heating, according to the quality of the product to be manufactured. For the preparation of edible oils and fats the meal is expressed in the cold, after having been packed into bags and placed in hydraulic presses under a pressure of 300 atmospheres or more. The cakes are allowed to remain under pressure for about 7 minutes. The oil exuding in the *cold* dissolves the smallest amount of colouring matter, &c., and hence has suffered least in its quality. Oils so obtained are known in commerce as 'cold-drawn oils,' 'cold-pressed oils,' 'salad oils,' 'virgin oils.'

By pressing in the cold, obviously only part of the oil or fat is recovered. A further quantity is obtained by expressing the seed meal at a somewhat elevated temperature, reached by warming the comminuted seeds or fruits either immediately after they leave the five-roller mill, or after the 'cold-drawn oil' has been taken off. Of course, the cold-pressed cakes must be first disintegrated, which may be done under an edge-runner. The same operation may be repeated once more. Thus oils of the 'second expression' and of the 'third expression' are obtained.

In the case of oleaginous seeds of low value (cotton-seed, linseed) it is of importance to express in one operation the largest possible quantity of oil. Hence the bruised seed is, after leaving the five-roller mill, generally warmed at once in a steam-jacketed kettle fitted with a mixing gear, by passing steam into the jacket, and sending at the same time some steam through a rose, fixed inside the kettle, into the mass while it is being agitated. This practice is a survival of the older method of moistening the seed with a little water, while the seeds were bruised under edge-runners, so as to lower the temperature and facilitate the bursting of the cells. The warm meal is then delivered through measuring boxes into closed press-bags ('scourtins' of the 'Marseilles' press), or through measuring boxes, combined with an automatic moulding machine, into cloths open at two sides (Anglo-American press), so that the preliminary pressed cakes can be put at once into the hydraulic press. In the latest constructions of cage presses, the use of bags is entirely dispensed with, a measured quantity of seed falling direct into the circular-press cage and being separated from the material forming the next cake by a circular plate of sheet iron.

The method of expressing is exclusively employed wherever the pressed cakes are used as cattle food. These cakes retain a notable amount of oil or fat—from 5 to 10 p.c.—which must, however, not be considered as lost, inasmuch as the fat constitutes a most valuable and, indeed, even necessary constituent of cattle food.

Extraction by solvents. In those cases where the full yield, or approximately full yield, of the oil contained in the seeds is aimed at, the comminuted seeds are extracted with volatile solvents, such as petroleum hydrocarbons, boiling below 120°, and carbon disulphide. As these solvents are highly inflammable, an endeavour is made at present to extract by means of the non-inflammable carbon tetrachloride and other chloro derivatives of ethane (such as dichloro-ethylene $C_2H_2Cl_2$, trichloro-ethylene C_2HCl_3, perchloro-ethylene C_2Cl_4, tetrachloro-ethane $C_2H_2Cl_4$, and pentachloro-ethane C_2HCl_5). At present the high price of these solvents still militates against their general employment, in addition to some other drawbacks in their use.

The apparatus employed on a large scale

depends on the temperature at which the extraction is carried out. In the main two types of extracting apparatus may be differentiated, viz. for extraction in the cold and for extraction in the hot. The seed is prepared in a similar manner as for pressing, except that it is not reduced to a fine meal, so as not to impede the percolation of the solvent through the mass. In the case of *cold extraction* the seed is placed in a series of closed vessels, through which the solvent percolates by displacement, on the 'counter-current' system. A battery of vessels is so arranged that one vessel can always be made the last of the series to discharge finished meal and to be recharged with fresh meal, so that the process is practically a continuous one. The solution of the extracted oil or fat is then transferred to a steam-heated still, where the solvent is driven off and recovered by condensing the vapours in a cooling coil, to be used again. The last remnant of volatile solvent in the oil is driven off by a current of open steam blown through the oil in the warm state. The extracting process *in the hot* is carried out in an apparatus, the principle of which is exemplified by the well-known Soxhlet extractor. The comminuted seed is placed on trays or baskets inside a vessel connected with an upright refrigerator, and is surrounded there by the volatile solvent. On heating the solvent with steam through a coil or jacket, the vapours rise through and around the meal. They pass into the refrigerator, where they are condensed and fall back as a liquid through the meal, percolating it on their way downwards, and reaching the bottom of the vessel as a more or less saturated solution of oil in the solvent. The solvent is again evaporated, leaving the oil at the bottom of the vessel until the extraction is deemed finished. The solution of fat is then run off into a still, as described already, and the last traces of solvent are driven out. The solvent is recovered and used again.

The meal left after extraction is not suitable for cattle food, and no extracted meal can be sold in this country for feeding purposes. On the Continent, however, frequent endeavours are being made to sell (and even recommend under specious 'scientific' pretensions) extracted meal for feeding purposes, and although Agricultural Associations in many cases stipulate that no extracted meal should be accepted by farmers, yet a considerable amount of extracted meal finds its way, chiefly on the Continent, into 'compound cakes.'

With regard to the merits and demerits of the last two mentioned processes—expression and extraction—the adoption of either must largely depend on local conditions and the objects for which the products are intended. Wherever the cake is the main product, expression will commend itself as the most advantageous process. Where, however, the fatty material forms the main product, as in the case of palm kernel oil, or sesamé and cocoa-nut oils from damaged seeds (which would no longer form proper cattle food), the process of extraction will be preferred, especially when the price of oil is high. In some cases the combination of the two processes commends itself, as in the production of olive oil. The fruits are expressed, and after the edible qualities and best classes of oils for technical purposes have been taken off by expression, the remaining pulp is extracted by means of solvents. This process is known under the name of the mixed process (*huilerie mixte*) [*v.* OLIVE OIL].

Refining and *bleaching.* The oils and fats prepared by any of the methods described above are, if obtained from perfectly fresh ('sweet') material, and in their fresh state, practically neutral. If care be exercised in the process of rendering animal oils and fats, or expressing vegetable oils in the cold, the products are, as a rule, sufficiently pure to be delivered to the consumer, after a preliminary settling has allowed any mucilaginous matter, such as animal or vegetable fibres or other impurities, as also traces of moisture, to separate out. This spontaneous clarification was at one time the only method in vogue. This process is now shortened by filtering oils through filter presses, or otherwise brightening them, *e.g.* by blowing with air. In many cases these methods still suffice for the production of commercial oils and fats.

In special cases, such as the preparation of edible oils and fats, a further improvement in colour, and at the same time greater purity is obtained by filtering the oils over charcoal, or over natural absorbent earths, such as fuller's earth. Where this process does not suffice, as in the case of cocoanut oil or palm kernel oil, a preliminary purification in a current of steam must be resorted to before the final purification, described above, is carried out.

Oils, intended for table use, which deposit 'stearine' in winter, must be freed from such solid fats. This is done by allowing the oil to cool down to a low temperature and pressing the cold oil through cloths in a press, when a limpid oil exudes, which remains proof against cold. Such oil is termed 'winter oil.' Thus whereas most olive oils are naturally non-congealing oils, the Tunisian and Algerian olive oils deposit so much 'stearine' that they must be 'demargarinated.' Similar methods are employed in the production of lard oil, edible cotton-seed oil, &c.

For *refining* oils and fats intended for edible purposes only the foregoing methods, which may be summarised under the name of *physical methods*, can be used; the only chemicals permissible are alkalis or alkaline earths to remove any free fatty acids present. Treatment with other chemicals renders the oils and fats unfit for consumption. Therefore all bleaching and refining processes involving other means than those enumerated can only be employed for technically used oils and fats, such as lubricating oils, burning oils, paint oils, soap-making oils, &c.

Bleaching with the aid of chemicals requires great circumspection. There is no universal method of oil-refining applicable to any and every oil or fat. Not only must each kind of oil or fat be considered as a special problem, but frequently even varieties of one and the same oil or fat are apt to cause the same difficulties as would a new individual. In many cases purification by means of sulphuric acid, invented and patented by Charles Gower in 1792 (frequently ascribed to Thénard), is still usefully applied. It consists in treating the oil with a small percentage of a more or less concentrated sulphuric acid, according to the nature of the oil or fat. The acid not only takes up water, but it acts on the suspended impurities, carbonising them to some extent, and thus causing them to coagulate and fall down in the form of a flocculent mass, which carries with it mechanically other impurities which have not been acted upon. This method is chiefly used in the refining of linseed and rape oils.

Purification by means of strong caustic soda was first recommended as a general process by Louis C. Arthur Barreswil, his suggestion being to heat the oil and add 2–3 p.c. of caustic soda. In most cases the purification consisted in removing the free fatty acids from rancid oils and fats, the caustic soda forming a soap with the fatty acids, which would either rise as a scum and lift up impurities with it, or fall to the bottom and carry them down. This process is a useful one in the case of cotton-seed oil. As a rule, however, it is very precarious, since emulsions are formed which in many cases altogether prevent the separation of oil. After the treatment with sulphuric acid or caustic soda, the oils must be washed to remove the last traces of chemicals. The water is then allowed to settle out, and the oils are finally filtered.

The number of chemicals which have been proposed from time to time for the purification of oils and fats is almost legion, and so long as the nature of oils and fats was little understood, a secret trade in oil-purifying chemicals flourished. With our present knowledge most of these chemicals may be removed into the limbo of useless things.

The general methods of bleaching, besides those mentioned already as physical methods (viz. filtration over charcoal or absorbent earth), are chiefly methods based on treatment with oxygen or by chlorine. The methods of bleaching by oxygen include all those which aim at the bleaching by exposure to the air and to sunlight (as in the case of artists' linseed oil), or where oxygen or ozone is introduced in the form of gas or is evolved by chemicals, such as manganese dioxide, potassium dichromate, or potassium permanganate and sulphuric acid. In the process of bleaching by means of chlorine either bleaching powder or dichromates and hydrochloric acid are used. It must again be emphasised that no general rule can be laid down as to which process should be employed in each given case. There is still a wide field open for the application of proper processes for the removal of impurities and colouring matters without, however, running the risk of attacking the oil or fat itself.

Hence the attention of inventors has been directed during the last few years to the exploitation of this subject and a considerable number of processes and chemicals have been suggested. Thus bleaching by means of ultra-violet rays has, through the introduction of the 'uviol lamp,' gained favour and the bleaching of linseed oil by these means has been patented. It is stated that other oils also can be bleached with the aid of ultra-violet rays ('uviol oils').

Peroxides (sodium peroxide, calcium peroxide, and barium peroxide), persalts (such as perborates, persulphates, percarbonates of sodium or potassium), organic peroxides (benzoyl peroxide, acetyl peroxide, acetone peroxide), further sodium and calcium hydrosulphites, basic zinc formaldehyde-sulphoxylate and other similar preparations have been suggested and have also been used in practice occasionally. A number of these preparations are sold under fancy names, but notwithstanding a number of laudatory articles persistently launched into the technical press, by interested parties, no favourable statement can be made as to their permanent usefulness or superiority over the reagents named above. Most of these strongly acting chemicals produce a temporary effect, but frequently the colour 'reverts.' In other cases they introduce such complications into the routine of the oil refiners and of soap and candle manufacturers that it is impossible to recommend them without very serious qualification.

Even after such purification as has been described above, small quantities of non-glyceridic substances remain dissolved. Some of these must be considered as entirely foreign (adventitious) substances, *e.g.* traces of colouring matters, chromogenetic substances (producing the colour reactions which are characteristic of some oils and fats), ethereal oils, resinous matters, sulphur compounds, and cyanogenetic glucosides.

Other substances are constant concomitants of the natural products, and must therefore be looked upon, to some extent at least, as constituents thereof. The most important of these are phytosterol and cholesterol, inasmuch as the presence or the absence of one or other enables us to recognise a specimen as a vegetable or animal oil or fat. Of less importance are aliphatic alcohols (such as myricyl or ceryl alcohol) and lecithin, although the latter is of very great importance from a physiological point of view (*see* GLYCERIN).

Hydrocarbons, which have been hitherto considered as of little importance, occur more frequently in natural oils and fats than has been ascertained hitherto. More attention is now being paid to their occurrence, as they will probably furnish a means of identifying individual oils and fats.

In their liquid state oils and fats penetrate easily into the pores of dry substances; if dropped on paper they leave a translucent spot—grease spot—which cannot be removed by washing with water and subsequent drying (difference from glycerol spots).

A curious effect, caused by the presence of the minutest quantities of oils and fats, has been described by Lightfoot. Camphor, crushed between layers of paper without having been touched with the fingers, rotates when thrown on to water, but a trace of oil or fat on the surface of the water causes the rotation to cease immediately; it is sufficient to touch the water with a needle which has been passed previously through the hair.

The *specific gravity* of oils and fats varies between the limits 0·910 and 0·975 at 15·5°. The specific gravity alone only exceptionally furnishes a means of identifying an individual oil. Hence the 'oleometers' which were formerly credited with the power of detecting individual oils are now practically abandoned. Castor oil alone can be identified by its exceptionally high specific gravity.

The *solidifying point* of those oils which are fluid at the ordinary temperature range from a few degrees above zero down to −28° C. (linseed oil). (For melting and solidifying points of individual oils and fats, *cf.* tables at the end of this article.)

Although at first sight little importance should be ascribed to the melting and solidifying points, inasmuch as from some oils there separate out on standing glycerides containing solid acids (in practice frequently termed ‘ stearine ’ or ‘ margarine ’), they are, from a technical point of view, of importance as they are a measure of the consistence and furnish reliable guidance in the preparation of ‘ demargarinated edible oils ’ or ‘ racked ’ fish and cod-liver oils. For the manufacture of such demargarinated oils, the natural oils are exposed to a low temperature. The solid glycerides then separate out as a deposit and the clear limpid oil can be drawn off as an upper layer after sufficient time has been allowed for subsidence. When the solid glycerides separate out in a crystalline form, this slow and cumbersome process can be shortened by cooling (refrigerating) the oils artificially and filtering the liquid portion from the solid at a low temperature. The limpid oils thus obtained are sold in commerce as ‘ winter oils.’

Demargarinating is employed on a large scale in the case of cotton-seed oil, whale oil, tallow, and some Algerian and Tunisian olive oils.

The *refractive index* of the natural oils and fats varies within certain limits which, though narrow, are sufficiently characteristic, if observed through accurate optical instruments, to allow a differentiation of the individual oils and fats to a certain extent. This will be further explained below under *Analysis*, but it may be pointed out here that exaggerated importance has frequently been attached to the interpretation of the results of refractometric observation.

The majority of oils and fats have practically no action on the *plane of polarised light*, the small deviations observed in sensitive polariscopes being chiefly due to adventitious substances, such as cholesterol or phytosterol or resinous or volatile ethereal substances, as in the case of sesamé oil, cocoa-nut oil, cod-liver oil.

There are, however, several oils which are distinguished by notable rotations; this is more particularly the case with the oils belonging to the Chaulmoogra group, and it is thus possible by means of the polariscope alone to identify an oil as belonging to this class, as has been done by the author in the case of ‘ cardamom fat ’ (*see Chaulmoogra oil group*). Notable rotations are also afforded by castor oil and stillingia oil.

Solubility.—Natural oils and fats may be considered as completely insoluble in pure water. On shaking vigorously with large quantities of water, minute quantities are dissolved, as is evidenced by allowing the emulsions formed at first to become clear by standing and shaking out the clear aqueous layer with ether.

Oils and fats dissolve in their turn small quantities of water, which can be expelled by warming at 100°. From the foregoing it follows that the emulsifying power of water as regards oils and fats is practically *nil*. It can, however, be increased to a very notable extent by addition of small quantities of soap and a number of other substances (*see* Lewkowitsch, Chem. Tech. [iii.] 88, *Emulsified Oils and Fats*).

With the exception of castor oil, oils and fats dissolve but very sparingly in *cold alcohol*. Boiling alcohol, however, dissolves somewhat larger quantities, especially of those oils and fats which contain glycerides of the lower fatty acids; but on cooling, nearly all the dissolved substance separates out. The solubility is considerably increased by the presence of free fatty acids; if the amount of the latter be large, exceeding about 30 p.c., even cold alcohol will readily effect dissolution.

Oils and fats dissolve very readily in ether, carbon disulphide, chloroform, carbon tetrachloride, trichlorethylene (and its congeners), benzene, paraffin oils, and light petroleum. Castor oil, however, forms an exception as regards the two last-mentioned solvents. Triacetin is insoluble in carbon disulphide and in petroleum ether.

Oils and fats dissolve *sulphur* and *phosphorus* at the ordinary temperature to a slight extent. Certain pharmaceutical preparations, notably phosphorised oils, are thus prepared.

The *smell* and *taste* of oils and fats, although frequently characteristic of the individual oils and fats, is due to the presence of certain foreign matters. Thus in the case of fats belonging to the Myristica group the presence of an ethereal oil imparts the taste of mace. In the case of cocoanut oil the peculiar taste appears to be due to the presence of some ethereal ketones (occurring also in the essential oil of rue). It may be accepted that in their purified state oils and fats are entirely devoid of free fatty acids, and are practically odourless and tasteless. Hence absolutely neutral oils have an insipid taste, and what is considered as a peculiarly characteristic taste is due to minute traces of foreign substances or to small quantities of free fatty acids.

When freshly rendered, animal fats contain but very small quantities of *free fatty acids*. Oils and fats of vegetable origin, however, even in their fresh state, contain appreciable amounts of free fatty acids. This may be due to the fact that in all seeds there are present enzymes which hydrolyse glycerides, the acid necessary for inducing the hydrolysis being supplied in the form of carbonic acid, which is always present in seeds.

Oils and fats do not suffer any loss when heated at temperatures of 150°–180°. However, oils and fats containing notable quantities of free volatile fatty acids, such as rancid butter fat, and cocoanut oil, lose in weight, no doubt through volatilisation of free fatty acids; it is not certain that glycerides of the lower fatty acids volatilise as well.

Provided prolonged contact with air is avoided, most oils and fats can be heated to a temperature of about 250° without undergoing a chemical change. (Some oils and fats become paler in consequence of the destruction of dissolved colouring matters, *e.g.* linseed oil.) On being heated above 250°, up to 300°, some oils, especially the drying oils, undergo a change which may be described as due to polymerisation. Thus linseed oil is converted into a thick oil, having a considerably higher specific gravity than that of ordinary linseed oil. On this reaction is based the manufacture of *Polymerised Oils. Linseed oil* is converted by heating above 250° into 'varnishes' (not to be confounded with oil-varnishes containing linseed oil, gums, and oil of turpentine), which, according to their specific gravity, are graded in commerce as 'thin varnish' (sp.gr. 0·966), 'medium varnish' (sp.gr. 0·972), 'strong varnish' (sp.gr. 0·974), 'extra strong varnish' (sp.gr. 0·978). These oils find application in lithographic printing and in the preparation of printer's ink, also as 'bird-lime,' and in the manufacture of plastic masses. Hence these oils are also known in the trade as '*lithographic varnishes.*' *Tung oil* is converted by heating to 250° into a jelly-like mass, 'polymerised tung oil,' used in the preparation of oil varnishes and even in the manufacture of linoleum. *Polymerised Safflower oil* is prepared in a similar manner from safflower. In India this product has been prepared by the natives for many centuries, and is known as 'Roghan' ('Afridi wax'). *Castor oil* especially lends itself to the preparation of polymerised oil, owing to the chemical constitution of *ricinoleic acid* (of which it contains considerable quantities), by prolonged heating, as is practised, *e.g.*, in the preparation of cognac oil, when a spongy, very bulky indiarubber-like mass is obtained (for which a solvent has not yet been found). The polymerisation can be accelerated in some cases by the addition of 'condensing agents,' such as concentrated sulphuric acid, aluminium chloride, and zinc chloride.

When oils and fats are heated beyond 250°, decomposition sets in, with the formation of volatile products, the most prominent of which is *acroleïn*. The intense odour of acroleïn, which all fats emit when heated above 300°, is one of the most characteristic reactions, enabling one to distinguish rapidly fatty oils and fats from mineral and ethereal oils. Amongst the volatile products obtained on heating oils and fats to high temperatures are found, besides volatile acids and sebacic acid, hydrocarbons of the ethane, ethylene, and aromatic series (and perhaps also naphthenes), the quantity of which is considerably increased when the destructive distillation takes place under pressure. This fact lends strong support to the theory that the natural petroleum hydrocarbons owe their origin to the destruction of oils and fats. The vegetable fats generally offer much greater resistance to their conversion into hydrocarbons under pressure than do animal oils and fats. If an optically active fat is distilled destructively, the hydrocarbons formed exhibit optical activity (Lewkowitsch, Ber. 1907, 4161). Before gas-making from coal was generally adopted, illuminating gas was frequently prepared from fatty oils. In this connection it may be interesting to remember that Faraday discovered benzene in condensed gas made from whale oil.

As these changes are most important, special attention must be paid to the influence which *light, air,* and *moisture* exert, both separately and conjointly.

Effect of light.—The action of light alone, air and moisture being excluded, has hitherto not been studied thoroughly. It is well known that oils and fats acquire a paler colour under the influence of insolation, some oils even becoming colourless. The application of insolation to industrial purposes is well exemplified by the method of bleaching linseed oil, cod-liver oil, and olive oil under glass or in glass bottles. Since pure glycerides are themselves colourless, the light can only affect the foreign substances dissolved in them. This is further proved by the fact that insolated cotton seed oil does not reduce silver nitrate so readily as does cottonseed oil kept in the dark, and that exposure to light destroys those minute traces of chromogenetic substances which give rise to colour reactions that have for a long time been erroneously considered as characteristic (*v. infra*). It would appear that the specific action of light is due especially to the ultra-violet rays (*see* above under *Bleaching*).

Effect of air.—When studying the effect of air we must clearly discriminate between the influence of the ordinary atmosphere—which necessarily includes the action of oxygen, moisture, and light (diffused daylight, direct sunlight)—and the influence of *dry* air, to the exclusion of moisture and light. The effect of the atmosphere on oils and fats varies in a very marked degree with the chemical composition of the glycerides. As a general rule, it may be stated that the greater the proportion of unsaturated fatty acids in the glycerides of oils and fats, the greater is their power to absorb oxygen. The chemical change is most marked in the case of drying oils; it becomes gradually less pronounced with the decrease of the power of absorbing iodine, as we pass through the classes of semi-drying oils and non-drying oils down to the solid fats. Marine animal oils occupy a position similar to that of drying oils. The oxygen absorption power of the various oils and fats will be considered below in the section *Analysis*. Drying oils thicken at first and form an elastic skin on the surface. If exposed in sufficiently thin layers, as, for instance, if spread on wood or glass, they are finally converted into a transparent, yellowish, flexible substance, insoluble in water, alcohol, and also, to a very great extent, in ether. While this energetic oxidation takes place, heat is developed to such a degree that if the drying take place in presence of organic substances in a fine state of division, offering a large surface to the atmosphere (cotton waste, woollen rags), spontaneous combustion will ensue. The non-drying oils remain more or less unchanged. The semi-drying oils occupy an intermediate position. The gradations between the various classes are, however, by no means so distinct as to warrant the drawing of hard and fast dividing lines between the three classes.

The action of air is intensified by spreading oils and fats over finely divided metals (lead powder, copper powder), the metals acting as accelerators or catalysts. This reaction is used for analytical purposes in the determination of the oxygen absorption power of oils (*v. infra*).

Dry air, to the exclusion of moisture and light, has no action on oils and fats, at the ordinary temperature. They will therefore remain unchanged for practically an indefinite length of time, if kept protected from moisture and light. Since it is very difficult to exclude the last traces of moisture when storing oils and fats, such moisture as gains access to the oils and fats will exercise a slight action in the manner described in the following paragraph, that is to say, small amounts of fatty acids will be formed, but rancidity need not set in.

Effect of moisture.—The effect of moisture (always present in the atmosphere) is a far-reaching one. In order fully to understand its effect, it is necessary to consider the action of water on oils and fats.

At temperatures up to about 150° water does not attack glycerides, but if the temperature be raised to 200° or more, the triglycerides are finally decomposed (hydrolysed) into their proximate components, glycerol and fatty acids, whilst the elements of water are assimilated. This action appears to have been observed first by Appert in 1823.

The hydrolysis thus produced at high temperatures is greatly accelerated if the action of the water is assisted by suitable chemical agents (catalysts). If such agents are present, it is possible to reduce the temperature. Thus, by the assistance of concentrated sulphuric acid, the chemical change may be effected at a temperature of about 120°. The temperature required for the chemical change may be further reduced to about 100° by employing strong hydrochloric acid. A still further reduction of temperature can be effected by the introduction of strong bases in alcoholic solution (*see Saponification*). Finally, the change may be brought about by water even at the ordinary temperature, if naturally occurring ferments, such as lipase, or steapsin, are intimately intermixed with the oils and fats. Fat-hydrolysing enzymes seem to occur in most, if not in all, oleaginous seeds, and no doubt play an important part in the utilisation of the fatty reserve products stored in the seeds. During the germination of the seeds, hydrolysis takes place, and free fatty acids are liberated; hence, it appears very likely that the presence of small quantities of free fatty acids, which are always found in even the freshest vegetable oils and fats, is due to the slight action of these enzymes on the glycerides stored in the seeds. The absence of suitable conditions in ungerminated seeds would appear to lead to limiting very sensibly the progress of hydrolysis. Such conditions are the presence of sufficient water and of small amounts of a mineral acid (carbonic acid, *v. supra*), or of a strong fatty acid (such as acetic acid). If water acidified with small quantities of such acids be churned up with oils and fats, and suitable enzymes be introduced into the mixture, hydrolysis of the glycerides takes place gradually at first, but rises, at the optimum temperature, to a considerable extent within a comparatively short time (*see Saponification*). Thus the ferment contained in castor seed is capable of effecting practically complete hydrolysis in the course of a few days. Similarly acting ferments, such as 'catalase,' may reasonably be assumed to be contained in commercial animal fats to a smaller or greater extent, according to the care exercised in the separation of the animal tissue from the rendered fat.

Accepting, then, as a fact the occurrence of small quantities of fat-hydrolysing enzymes in those commercial oils and fats which have not been heated to such temperatures that inhibition of the enzymic action must set in, we shall be able to understand those changes which oils and fats undergo on exposure to the atmosphere. As is well known, they acquire thereby a disagreeable smell and an acrid taste; and the presence of free, non-volatile fatty acids, as also of small quantities of volatile acids, can be observed. We comprise these changes under the term 'rancidity,' and we express this by stating that the oils and fats have become 'rancid.'

The effect of light, air, and moisture can now be explained as follows: In the presence of sufficient moisture and acid, enzymes are enabled to accelerate hydrolysis so that a certain proportion of the glycerides may give rise to the production of diglycerides (and monoglycerides) and free fatty acids within a comparatively short time (a few days or a few weeks according to the conditions). Hence the first postulate is that free fatty acids should make their appearance.

It is well known that oils and fats, if kept fully protected from light, air, and moisture, retain indefinitely their state of neutrality, whereas if they are not carefully preserved, moist air easily gains access (as in imperfectly corked bottles, barrels, &c.), and free fatty acids, of the same composition as those which are combined with glycerol in the neutral fat, are produced. The quantity of enzymes in filtered commercial oils and fats being very small, the amount of hydrolysis effected in such oils and fats will be restricted; hence the proportion of free fatty acids in commerical oils and fats does not, as a rule, exceed a few per cent. If, however, oils and fats be allowed to remain in contact with the organic matter from which they have been obtained, such as the marc of fruits (as in the case of olive oil, palm oil, and cocoa-nut oil), or animal tissues (as in the case of 'rough fat,' blubber, fish livers), or casein, &c. (as in the case of butter), the hydrolysis of the glycerides increases somewhat rapidly and may reach very high proportions. Thus the so-called bagasse olive oils (*i.e.* oils expressed from exposed olive marc) contain as much as 70 p.c. of free fatty acids. Palm oil may even undergo complete hydrolysis, and hence be found to consist almost exclusively of fatty acids. In all these cases we can satisfactorily explain the formation of a high proportion of fatty acids by the conjoint action of water and enzymes. It appears, therefore, unnecessary to invoke the action of air and light in order to explain the presence of free fatty acids.

The author, therefore, ascribes the primary cause of rancidity, namely, the formation of free fatty acids, to the action of moisture in the presence of soluble ferments which act as catalysts or accelerators. The occurrence of small quantities of free fatty acids even in refined oils and fats (edible oils and fats), would thus be explained. Yet these oils and fats are by no means rancid. Indeed, the presence of the free fatty acids imparts a slight, not unpleasant, flavour; for it is well known that completely neutral oils and fats have an insipid taste.

Hence, rancidity is not due, as is still widely believed, to the presence of free fatty acids alone; in other words, rancidity must not be considered as coterminous with acidity. The frequent confounding of these two terms is caused by the fact that acid oils and fats are frequently rancid as well. It is only when oxygen and light gain access to the acid fats that the conditions favouring the setting in of rancidity are provided. Rancidity is rather due to the direct oxidation of free fatty acids by the oxygen of the air, assisted and intensified by the exposure to light. Oxygen and light must act simultaneously, either of these agents alone being unable to produce rancidity; hence, the greater the surface offered to the atmosphere, the more rapidly will they be able to exercise their influence.

Oils (liquid fats) turn rancid more readily than solid fats. This agrees with the fact that liquid fats are much more easily hydrolysed in the fermentative process (*see Saponification*) than are solid fats, such as tallow. Whether fats containing glycerides of the lower fatty acids (butter fat, cocoa-nut oil), are more liable to become rancid than the fats containing glycerides of the higher fatty acids (cacao butter, tallow, &c.) has not yet been decided experimentally. It may, however, be taken as a general rule, that the higher the proportion of insoluble saturated fatty acids, and the lower the percentage of unsaturated glycerides in the fat, the less will be its liability to turn rancid. This rule, however, appears to break down in the case of cocoa-nut oil and of Japan wax, which differ greatly in the composition of their constituent glycerides.

Whilst it may then be taken as proven that rancidity is due to the simultaneous action of moisture, oxygen, and light, very little is known as to the actual chemical change which the liberated free fatty acids undergo. The observation that rancid fats contain free fatty acids had been made before 1814, and both steam distillation and extraction with alcohol were proposed for their removal. The opinion has also been frequently expressed that the bodies characteristic of rancid fats are aldehydes (oenanthaldehyde) and similar substances. Hence the usual reagents employed for the detection of aldehydes have been suggested as a chemical mean of differentiating rancid fats from acid fats.

In the present state of our knowledge we are still unable to ascertain rancidity by chemical means alone; nor does there appear to be any need for a chemical test, as we may rely on the taste and smell as the best means of ascertaining whether an oil or fat is rancid or not.

Some isolated observations regarding the chemical changes suffered by rancid fats are given in a table, published by Lewkowitsch (Analyst, 1899, 327).

Action of oxygen. If air, or better still oxygen, be blown through fatty oils at the temperature of boiling water, oxidation takes place. So much heat is thereby evolved that the oxidation process continues without further heating. On this reaction is based the industry of 'blown oils.'

Blown Oils.

The most notable change produced by the action of oxygen is an increase in density (hence they are also termed 'thickened oils'). The oils thus obtained simulate castor oil in their density and viscosity, but differ from it in that they are soluble in light petroleum. Hence, these oils are known in the trade also as 'soluble castor oils.' The similarity to castor oil, as also the high acetyl values of the blown oils, led to the opinion that glycerides of hydroxylated acids are formed, but the fatty acids actually produced differ from the castor oil fatty acids and form a special class of fatty acids, comprised by the author under the term 'oxidised acids.' Fatty oils belonging to the class of semi-drying oils lend themselves specially to the manufacture of 'blown oils.' Thus in commerce there are obtainable: blown maize oil, blown cotton seed oil, blown rape oil, and blown castor oil. The specific gravity of these oils is increased by the formation of oxidised acids and may reach, according to the time of treatment with air, as high values as 0·96 and above. The chemistry of the oxidised oils has been investigated by Lewkowitsch (*see* Chem. Tech. [iii.] 134). Blown oils are also prepared from fish liver and blubber oils, and are used in the leather industries as also in the production of compound lubricating oils. In the case of drying oils the oxidation process proceeds much further, finally yielding jelly-like or even solid elastic masses. Thus linseed oil dries on exposure to the atmosphere in a thin film to an elastic, thin skin. Blown soya bean oil also yields a viscous somewhat elastic mass.

Boiled Oils.

Extensive use is made of this action in the industries of boiled oils, paint oils, and varnishes. The boiled oils were up to a few decades ago prepared exclusively by 'heating' linseed oil, as also other drying oils, with a small quantity of suitable metallic oxides or metallic salts—driers, siccatives (*see* DRIERS and LINSEED OIL)—over free fire to temperatures varying from 210° to 260°.

It had been found that linseed oil, after heating with lead oxide, absorbed oxygen more rapidly than did linseed oil not so prepared, and whereas raw linseed oil requires about 3 days for drying to an elastic skin, the drying process is so much accelerated by the treatment with lead oxide over free fire, that linseed oil so prepared will dry even within 6–8 hours to an elastic skin.

What reaction takes place during the process of boiling is not yet fully known. A slight decomposition of the glycerides undoubtedly occurs, as is proved by the evolution of acroleïn vapours during the boiling; but such decomposition of the linseed oil is very limited, as the 'boiled oil,' like the polymerised linseed oils (lithographic varnish), still yields almost its full amount of glycerol. Moreover, practical experience has proved that boiled oils must be made from glycerides, since 'boiled oils' cannot be obtained from linseed oil fatty acids, or from ethyl esters of the mixed linseed oil fatty acids.

The process of boiling with 'driers' appears to be an empirical way of producing metal salts (lead salts or manganese salts) of the fatty acids of the boiled oils, partial saponification of the glycerides taking place at the high temperature to which the oils were subjected while being 'boiled.' These lead (or manganese) salts of the fatty acids are able to act as oxygen carriers in the process of 'drying,' when the boiled oils are exposed to the atmosphere either in their original state or in admixture with pigments, gum-resins, &c. This would lead to the explanation that the driers act as catalysts, a small quantity only being required to accelerate the oxidation, so that the oils finally yield a skin. These views find support in the modern methods of preparing 'boiled oils.'

Thus at present the bulk of the 'boiled oils' is obtained by heating linseed oil with driers to a temperature of about 150° only. The process is carried out by introducing the oil into a cylindrical vessel provided with a heating coil and agitating gear, so as to produce an intimate intermixture between oil and drier, while they are heated to the desired temperature.

According to the quality and the amount of drier added, and the length of time during which the oil is heated ('boiled'), *pale* or *dark* oils are produced. The former are known in commerce as 'pale-boiled oils,' the latter as 'double-boiled oils.' The temperature can be reduced even to 120° by merely dissolving 'liquid driers' (solutions of lead linoleate, &c., in linseed oil), and assisting the operation, if required, by a current of air.

These boiled oils have the property of absorbing oxygen from the air at a much more rapid rate than does raw linseed oil, and the time required for the formation of a skin is thereby much shortened.

The chemical change which takes place when a vegetable oil 'dries' to a solid elastic skin, is but very imperfectly understood. The final product appears, however, to be the same, whether raw linseed oil be allowed to absorb oxygen from the atmosphere slowly, or whether the 'drying' be accelerated by previously converting the oil into 'boiled' oil, or the raw linseed oil be treated in a current of oxygen or ozone at a somewhat elevated temperature, after having been intermixed with driers. Mulder's opinion, that in the first stage the glyceridic constituent of the oil is oxidised and that the liberated fatty acids take up oxygen and are converted into the anhydride of 'hydroxylinoleic' acid (*i.e.* the anhydride of hydroxylated linseed oil fatty acids), a neutral substance, insoluble in ether, termed by him 'linoxyn,' must be rejected as erroneous, for this view postulates that hydrolysis of the glycerides precedes oxidation. It has been pointed out already that the solid skin is not formed when the mixed fatty acids are exposed to the atmosphere. Moreover, Bauer and Hazura have shown that, at any rate in the first stage of oxidation, the glyceridic constituent of the linseed oil remains intact, and that the oil is converted by exposure in thin layers into a substance simulating in its properties Mulder's 'linoxyn,' but still representing a glyceride. This substance was assumed by Bauer and Hazura to be hydroxylinolein (*i.e.* a mixture of hydroxylinolin and hydroxylinolenin).

Fahrion applied Engler and Weissberg's autoxidation theory to this problem, and in the light of this theory he regards the linseed oil as an 'acceptor,' and the driers, especially lead and manganese, which are readily converted into peroxides, as autoxidisers or catalysers. He further argues that some facts seem to show that the drying process may also be considered as a molecular autoxycatalysis, and that driers can therefore only be looked upon as pseudo-catalysers (pseudo-autoxidisers), they causing the addition of hydroxyl groups, and leading to the formation of a secondary autoxidiser. The latter in its turn would take up oxygen in its molecular form, and become converted into a hydroperoxide of a metal and hydrogen peroxide.

Genthe, in an elaborate physico-chemical study of the drying of linseed oil, has shown by a series of experiments that the drying process would appear to represent a special case of autocatalysis, inasmuch as his results correspond approximately to numbers obtained by means of the equation $dx/dt=k(m+x)\ (a-x)$ (the equation propounded by Ostwald for autocatalytic reactions). The substance which acts as the auto-catalyst could, however, not be isolated, and the assumption is made that it has the character of a peroxide. The so-called 'blown boiled oils' would, therefore, be linseed oils, in which peroxides are pre-formed, and the accelerating action which old oil of turpentine possesses would be due to the high proportion of peroxide it contains. (It must, however, not be overlooked, that the peroxide has not yet been isolated.) The 'driers' would thus have to be considered as pseudo-catalysts, their function being to accelerate the drying process by assisting in the formation of autocatalysers ('peroxides').

Boiled oils are not (yet) oxidised oils, but do become oxidised when exposed to the atmosphere, forming the well-known skin which paints (that is intimate mixtures of boiled oil and pigments) form on the painted objects.

The oxidation of linseed oil can be much accelerated by blowing linseed oil in the same manner as is done in the preparation of blown oils (*see* above). This process is carried out in the manufacture of *linoleum*, when boiled linseed oil is allowed to run over 'scrim' (a light cotton fabric) hanging down from the ceiling of a high building, the temperature of which is kept at about 100° F. A portion of oil solidifies on the fabric; the oil which drains off is again pumped up and allowed to run down until the layers of the semi-solid mass have reached (after several weeks) the thickness of about half an inch. The solidified oil obtained by this method is termed 'scrim oil.'

Another method consists in passing a current of oxygen gas through linseed oil intermixed with a drier and heated by steam in jacketed pans. When the maximum amount of oxygen has been absorbed, the mass forms a thick viscous fluid, which will still flow while hot, but on cooling solidifies to a substance similar to the 'scrim oil.' During the 'blowing' partial hydrolysis and oxidation of the glycerol formed takes place, as notable quantities of acroleïn vapours escape. The semi-solid oil so obtained has not the same elastic properties which the 'scrim oil' possesses. (Both processes were invented by F. Walton, in 1860 and 1863 respectively.) The solid linseed oil is used in the manufacture of linoleum.

In a third process, known as the Taylor-Parnacott method, the linseed oil is thickened at a high temperature in a current of air.

The *non-drying oils* are less readily attacked by oxygen, and solid fats only suffer a change if heated to a high temperature.

Action of ozone.—Ozone has no action on the glycerides of saturated fatty acids. The glycerides of unsaturated fatty acids are, however, easily acted on by ozone, each pair of doubly-linked carbon atoms absorbing 1 molecule of ozone.

According to Harries, 'perozonides' appear to be formed first, which are easily converted into stable ozonides (*see* OLEIC ACID).

Action of hydrogen. Hydrogen gas under ordinary conditions or under pressure, or even if evolved in *statu nascendi*, either electrolytically or by means of sodium amalgam, has no action on the glycerides of higher unsaturated fatty acids.

Sabatier and Senderens, however, furnished by their method of reducing organic substances by means of hydrogen in the presence of finely divided metals, especially of finely divided nickel, an easy means of converting the glycerides of unsaturated fatty acids into practically completely saturated glycerides. Thus whale oil, cotton-seed oil, sesamé oil, &c., can be reduced to hard tallow-like substances which practically absorb no iodine. The same effect can be obtained by using colloidal palladium (Paal and Roth) or simply finely divided palladium. A somewhat considerable number of patents has been taken in this direction, all of them claiming modifications of the fundamental process of Sabatier and Senderens.

Action of chlorine.—Chlorine acts on oils and fats with evolution of hydrochloric acid, glycerides of chlorinated fatty acids being formed. At the same time chloro addition products are obtained. Hitherto it has not been possible to moderate the action of chlorine to such an extent that chloro addition products be obtained exclusively. Attempts are being made at present to find applications for chlorinated oils and fats in the arts.

Action of bromine.—Bromine acts in a manner similar to chlorine, although much less violently, so that it is possible to limit the reaction in the case of unsaturated glycerides so far, that bromo addition products only are obtained. Hence it is possible to obtain on a practical scale brominated oils and fats. Such products are recommended for pharmaceutical purposes. Thus bromine compounds of sesamé oil are sold as 'bromipin.'

Action of iodine. Iodine is only slowly absorbed when mixed with oils or fats, but it does not yield substitution products. The assimilating power of oils or fats for iodine varies with the chemical constitution of their glycerides and also with the temperature, but never reaches that theoretical amount, which is indicated by the iodine value of oils and fats (*see* above). Iodised oils and fats have also been introduced into pharmacy. Thus 'iodipin' is a derivative of sesamé oil, containing about 25 p.c. of iodine.

Complete saturation of the unsaturated glycerides with halogens can be effected in the cold, if an alcoholic solution of iodine and mercuric chloride, or a solution of iodine monochloride or iodine monobromide in glacial acetic acid, is allowed to act on a dilute solution of oils or fats. The glycerides of the unsaturated acids absorb in that case 1 molecule of iodine chloride, or iodine monobromide, for each pair of doubly-linked carbon atoms, with the formation of saturated compounds. On this action is based one of the most important analytical operations practised in the examination of oils and fats, viz. the determination of the iodine value (*v. infra*).

Chloro-iodo, as also iodo-bromo fats and oils prepared by the above-described reaction are being introduced (or attempted to be introduced) into pharmacy.

Action of sulphur chloride.—Sulphur chloride acts energetically on fats. The reaction appears to consist in an absorption of the elements of sulphur chloride, much as iodine chloride is absorbed by the unsaturated carbon atoms (*see* above). The action of sulphur chloride would, therefore, appear to consist in the conversion of unsaturated (fatty acids or their) glycerides into saturated compounds.

In the two tables shown on page 758 a systematic examination made by Lewkowitsch (of the products obtained by the action of sulphur chloride) has been collated in a synoptic manner.

The sulphur chloride reaction finds technical application in the manufacture of rubber substitutes (*see Vulcanised oils*, below).

Action of sulphur.—Sulphur has no chemical action on oils and fats in the cold. At higher temperatures, however, from 120°-160°, all oils (since they contain glycerides of unsaturated fatty acids), notably linseed oil, castor oil, rape oil, cotton-seed oil, and marine animal oils, assimilate sulphur, and it would appear that the sulphur is absorbed much in the same manner as oxygen is absorbed by oils. On cooling, the sulphur does not separate out; on saponifying the sulphurised oils in the cold, sulphurised fatty acids are obtained whilst very little sulphuretted hydrogen is evolved. On heating the sulphurised fatty acids to 130°-200°, however, sulphuretted hydrogen escapes in large quantities, and substitution of hydrogen in the molecule of the fatty substance by sulphur seems to take place. The action of sulphur on oils is made use of in the manufacture of vulcanised oils.

Vulcanised Oils.

Vulcanised oils, 'rubber substitutes,' are prepared by a process simulating the vulcanising of india-rubber, namely, either by treating oils with sulphur at a somewhat elevated temperature (comparable to the 'hot cure' of vulcanising india-rubber), or by treatment with sulphur chloride in the cold (corresponding to the 'cold cure' in the vulcanising of india-rubber). Hence the term 'vulcanised oils' is applied to these products.

According to the process used, the vulcanised oils are differentiated in the trade as 'brown' (black) and 'white substitutes' respectively.

The ‘white substitutes’ contain, therefore, a considerable proportion of chlorine, which is, of course, absent from the ‘brown’ (black) substitutes; thus it is possible easily to distinguish by chemical means between the two classes of rubber substitutes.

The white substitutes form a yellowish, elastic, crumbly substance of oily smell and neutral reaction; the brown (black) substitutes occur in commerce either as sticky lumps or as a coarsely ground powder.

Oils and Fats treated with Sulphur Chloride; 5 grams of Fat, 2 c.c. of Sulphur Chloride, and 2 c.c. of Carbon Disulphide.

A. *Products completely soluble in Carbon disulphide.*

Class of oil	Kind of oil	—
Vegetable fats	Mowrah seed oil	Mass does not thicken
	Palm oil	
	Palm nut oil	
	Cocoa nut oil	
Animal fats .	Lard	
	Butter fat	
	Beef tallow	
	Mutton tallow	

B. *Products not completely soluble in Carbon Disulphide.*

Class of oil	Kind of oil	Solidifies after minutes		Soluble in carbon disulphide
		In the cold	On the water-bath	
				p.c.
Drying oils	Linseed	10	2	14·4
	Tung	1½	—	—
	Hemp seed	11	—	9·2
	Poppy seed	21	—	10·6
Fish oils	Japan fish	9	—	12·4
Liver oils	Cod liver, pure	15	—	4·4
	,, ,, rancid	1½	—	6·4
Blubber oils	Seal	11	—	4·4
	Whale	13	—	3·0
Semi-drying oils	Cotton seed	20	4	24·0

	Rape	12	2	4·2
	Croton	18	—	25·4
Non-drying oils	Peach	26	—	4·8
	Almond, sweet	27	—	4·0
	Almond, bitter	28	—	3·4
	Arachis	30	—	6·0
	Olive	22	4	4·2
	Castor	½	at once	3·8
	Sheep's foot	36	—	6·0
	Horses' foot	20	—	13·6
	Neat's foot	23	—	9·4
	Lard	10	—	15·0
	Tallow	12	—	29·8

To manufacture the white substitutes a suitable oil, especially rape oil, castor oil, soya bean oil, maize (corn) oil (also sesamé or arachis oil), is dissolved in carbon tetrachloride, in a wooden, earthenware, or enamelled iron vessel. While the oil is agitated, sulphur chloride is run in, the agitation being continued until the mass has solidified. The reaction is accompanied by evolution of hydrogen chloride.

The brown substitutes are manufactured by heating oils with sulphur at 160°. In the United States considerable quantities of brown substitutes are made from maize (corn) oil by heating 50 parts of oil at 240°, and mixing with it about 20 parts of molten sulphur.

Action of nitric acid. Concentrated nitric acid attacks oils and fats, acting on them violently, with copious evolution of red fumes. Hot dilute nitric acid oxidises oils and fats gradually. *Fuming nitric acid*, in presence of concentrated sulphuric acid, reacts with linseed oil and castor oil to form ‘nitrated’ oils, the nature of which has not yet been investigated, although they have found technical application.

Nitrated Oils.

The nitrated oils are viscid liquids, heavier than water; thus the product obtained from linseed oil has the sp.gr. 1·112, that from castor oil 1·127. Nitrated castor oil is insoluble in carbon disulphide. The composition of these substances is not yet known; they contain 4–5 p.c. of nitrogen. Samples examined by the author had high saponification values, varying from 278·5 to 286·5. The most prominent property of these products is that of forming homogeneous compounds with nitro-cellulose. Thus a mixture of 1 part of nitrated castor oil with 9 parts of nitro-cellulose yields a product resembling ebonite. Solutions of these compounds in acetone have been proposed as varnishes, as a basis for paint, and for enamelling leather. By heating ‘nitrated oils’ at 130°, or by oxidising them with lead peroxide, rubber-like substances are obtained.

Action of nitrous acid. On treatment with nitrous acid the non-drying oils become solid, or acquire the consistence of butter, according to the proportion of triolein (trierucin) they contain, triolein (trierucin) being converted into the solid isomeride trielaïdin (tribrassidin). Drying and marine animal oils, on the other hand, remain liquid under the same treatment.

The different behaviour of the drying and marine animal oils is explained by the fact that while ‘oleic’ (erucic) acid is converted by nitrous acid into a solid isomeride, elaïdic (brassidic) acid, linolic, linolenic, and clupanodonic acids remain liquid under the same conditions. Hence the non-drying oils yield solid masses, whereas the semi-drying and the drying and marine animal oils give more or less liquid products, according to the predominance of the glycerides of oleic acid. The fact that fuming nitric acid has the property of thickening olive and almond oils appears to have been observed first by Boyle in 1661. Poutet, in 1819, proposed this reaction, known as the *elaïdin* test, for the detection of adulterants in olive oil. The test is carried out in the following manner (viz. in the modification suggested by Archbutt); 18 grams of mercury are placed in a dry stoppered 50-c.c. cylinder, and 15·6 c.c. of nitric acid, sp.gr. 1·42, are added from a burette. The nitrous acid is entirely absorbed with production of a green colouration; as long as the reagent retains its green colour, it is fit for use. Eight grams of the reagent are shaken up with 96 grams of the oil in a wide-mouthed stoppered-bottle, placed in water at the required temperature, and again shaken at intervals of 10 minutes during 2 hours.

In the early history of oil analysis, before the present scientific (quantitative) methods (*v. infra*) were known, this test afforded some guidance. It was even attempted to base a classification of the oils on it, but such a classification must lead to inconclusive results. Although this test was somewhat extensively practised here as also in France, it may be said to have been abandoned in *this* country, as the results indicated by the elaïdin test are in every respect much less valuable than those furnished by the iodine test. Nevertheless, the elaïdin test is still being used, notably in France, in the examination of olive oils. In the comparative examination of almond oil and its congeners this test may afford some little information of a discriminative nature. In order to obtain trustworthy results, it is indispensable to institute side by side with the oil under examination, under exactly the same conditions, tests with standard oils of known purity.

Action of concentrated sulphuric acid. If oils, which, of course, contain glycerides of unsaturated fatty acids, be mixed with the acid very gradually, and at a low temperature, glycerides of a complex constitution are formed. The formation of these products is indicated by a notable rise of temperature. (The antiquated 'Maumené test' is based on the measurement of the rise of temperature (*see* Lewkowitsch, Chem. Techn. of Oils, &c. [i.] 384).) Thus, on treating olive oil with concentrated sulphuric acid a compound was obtained which may be regarded (Geitel) as a mixed glyceride of oleic acid, stearic acid, hydrogen sulphate, and hydroxystearic acid, having the formula—

$$C_3H_5[O{\cdot}C_{18}H_{33}O][O{\cdot}C_{18}H_{34}(SO_4H)O][O{\cdot}C_{18}H_{34}(OH)O].$$

This product is very unstable in the presence of water. On boiling with water it is rapidly decomposed into compounds which form a complete emulsion with water and fats; on agitating the emulsion with steam, complete hydrolysis to glycerol and fatty acids is brought about (*see Saponification*). This reaction is employed on a large scale in the manufacture of Turkey-red oils.

Turkey-red Oil.

Turkey-red oil is a fatty substance used in the preparation of the cotton fibre for dyeing and printing Turkey-red. The part which the Turkey-red oil plays is not fully understood; opinions differ as to whether it exercises a physical or a chemical action. The advocates of the former explanation assume that the oil protects the lake formed on the fibre, much as boiled linseed oil serves to protect a painted surface. The supporters of the chemical theory hold that the Turkey-red oil combines with alumina and finally with the colouring matter to form a compound lake. In those cases, however, where chemical combination with formation of a lake is excluded on account of the chemical constitution of the colouring matter, the physical theory appears to commend itself. Hence Turkey-red oil is not a mordant proper, but acts as a fixing agent in so far as it imparts to the dyed fabric a better and superior lustre, which does not belong to the unoiled fibre. The sulphonated oils would appear to the author to be absorbed by the fibre in the same manner as glycerol (from soft soaps) is fixed on the fibre on washing woollen goods.

Before the process of sulphonating castor oil was discovered (1875), rancid olive oil and sulphonated oils (such as sulphonated olive oil) were used as Turkey-red oils. At present Turkey-red oil is prepared by allowing concentrated sulphuric acid to run slowly into castor oil, with constant stirring, taking care that the temperature of 35° is not exceeded. If necessary, the mass must be cooled, for secondary reactions take place at temperatures above 35° with liberation of sulphurous acid. The product is then mixed with a small quantity of water and the dilute acid allowed to settle out as a lower layer. This is drawn off and the oil washed with a solution of Glauber's salt, until the washings are only slightly acid. Finally ammonia is added, until a sample gives a clear solution with a small quantity of water. Some manufacturers use soda instead of ammonia, or a mixture of ammonia and soda. Since the sulphonated oil is not completely neutralised by alkali, the resultant product still possesses a strong acid reaction.

The portion of sulphonated castor oil soluble in water contains principally ricinoleo-sulphuric acid, which is easily hydrolysed to some extent by boiling with dilute acids into sulphuric acid and ricinoleic acid, whereas another portion is converted into inner anhydrides of ricinoleic acid. The portion of castor Turkey-red oil insoluble in water consists chiefly of free ricinoleic acid and small quantities of neutral (unacted-on) oil, and also of anhydrides of ricinoleic acid (*cf.* also Lewkowitsch, Chem. Tech. [iii.] 155 *et seq.*).

At a temperature exceeding 100° *concentrated sulphuric acid* reacts energetically with all oils and fats, partly carbonising them and hydrolysing them, whereby glycerol and sulpho compounds of fatty acids are formed. On steaming, the latter are decomposed into sulphuric acid and fatty acids. On this reaction is based the 'acid saponification' process employed in the candle industry (*see* SAPONIFICATION).

Dilute sulphuric acid, even at temperatures of 100°, does not act on oils and fats (Lewkowitsch).

A dilute solution of sulpho-aromatic compounds (Twitchell's reagent) readily effects hydrolysis of the glycerides (*see* SAPONIFICATION).

Action of hydrochloric acid. Hydrochloric acid exercises a very slow action at the ordinary temperature; at higher temperatures it behaves as a catalytic agent, and accelerates considerably the hydrolysis of oils and fats. Obviously, hydrochloric acid does not take part in the chemical change, but merely accelerates the hydrolysis primarily brought about by water (Lewkowitsch, J. Soc. Chem. Ind. 1903, 67). If a thorough intermixture as in an emulsion could be effected between fat and water, hydrolysis would proceed much more rapidly than was observed in Lewkowitsch's experiments, for it has been shown by him experimentally that the catalytic action of hydrochloric acid takes place even at the ordinary temperature in course of time.

Action of caustic alkalis and alkaline earths. Caustic alkalis and alkaline earths, if treated with oils and fats in the presence of water, act in the first instance as catalysts bringing about rapid hydrolysis of the oils and fats. The free fatty acids formed combine with the caustic alkalis and alkaline earths, yielding as a secondary product soaps of the alkaline metals and the alkaline earths. On this reaction are based the great industries of soap- and candle-making (*see* SAPONIFICATION and SOAP).

Action of ammonia and aromatic bases. Ammonia hydrolyses oils and fats to some extent if acting under pressure (*see* SAPONIFICATION). Alcoholic ammonia, on prolonged standing in the cold with oils and fats, yields amides.

Aromatic bases, such as aniline, &c., on being heated under pressure at 210°, react similarly with oils and fats. In the case of aniline, the reaction was stated to take place according to the following equation—

$$C_3H_5(OR)_3+3C_6H_5{\cdot}NH_2=C_3H_5(OH)_3+3C_6H_5{\cdot}NHR.$$

But it has been shown that this reaction is unworkable on a practical scale.

In the case of hydroxylamine, hydroxamic derivatives of fatty acids are obtained, together with glycerol, as is exemplified by the following equation—

$$C_3H_5(OR)_3+3NH_2OH=C_3H_5(OH)_3+3R(NOH)OH.$$

SYSTEMATIC EXAMINATION OF OILS AND FATS.

The simplest problem in the examination of oils and fats is to identify a given oil or fat. As the natural oils and fats represent a complicated mixture of not only simple triglycerides, but also of mixed triglycerides, it is impossible, in the present state of our knowledge, to indicate a definite course of analysis, applicable to all circumstances, such as is the case in inorganic quantitative and qualitative analysis. Yet, by adopting a systematic plan of examination, it is possible, in the majority of cases, to identify a given sample of one individual oil or fat and to ascertain whether it is a pure or adulterated specimen. In the latter case, the nature of the adulterant can generally be ascertained. The methods described below permit also to identify a mixture of two or more oils and fats and to ascertain the presence and recognise the nature of the constituents of the mixture, at least qualitatively. Frequently, it is even possible to determine quantitatively the proportion in which the component parts have been mixed. The greater the number of component oils and fats in a mixture, the more difficult becomes the examination, but if the analyst proceeds logically and combines the methods described below in a suitable manner, it will be possible in many cases to ascertain the composition of a complicated mixture with such accuracy as suffices for technical purposes.

If it be borne in mind that adulteration has almost become a fine art, and that it is being practised with the full armour of scientific knowledge by experts who are frequently some years ahead of the knowledge possessed by the analytical chemist, it will readily be understood that the analyst must select special methods and tests and adapt them to each case.

A systematic examination will deal, in the first instance, with the natural oils and fats themselves. The methods applied to this purpose may be broadly divided into physical and chemical methods.

Since all natural oils and fats contain as a common constituent the radicle glycerol, or in other words, since all oils and fats yield glycerol on saponification, the difference of the several glycerides can only be conditioned by, or due to, the difference of the fatty acids contained in the glycerides. Hence it follows that in the second place the examination of the fatty acids themselves will prove of great importance. A section is, therefore, devoted specially to the *examination of the fatty acids.*

The identification of an oil or fat as a *vegetable* or *animal* oil or fat rests, as explained above, on the occurrence of phytosterol or cholesterol in vegetable or animal oils respectively. Hence the examination of the 'unsaponifiable' furnishes an excellent means to differentiate between vegetable and animal oils. From this point of view alone, the examination of the unsaponifiable matter becomes a valuable aid in the systematic course of examination. Obviously, if a mixture of vegetable and animal oils be given, a mixture of phytosterol and cholesterol will be obtained, the resolution of which into its components may be required in many cases. The examination of the 'unsaponifiable' becomes, furthermore, most important in those cases in which adulteration has taken place with unsaponifiable oils.

One of the most important problems required to be solved by analysis is to ascertain whether a sample is pure or sophisticated with hydrocarbons. Thus the examination of the unsaponifiable matter, provided it exceed 1 or at most 2 p.c. of an oil or fat, furnishes an important clue as to adulteration. It will, therefore, be most convenient to subdivide this section under the following three heads :—

I. Examination of Oils and Fats.
II. Examination of Fatty Acids.
III. Examination of the Unsaponifiable Matter.

Correct interpretation of indications afforded by the following tests and strict logical reasoning enable us, in the majority of cases, to narrow down, by a process of elimination, the range of possible constituents of a mixture to such an extent that the practised analyst will but rarely be confronted with the impossibility of arriving at approximate accuracy at least. In order to facilitate the interpretation of the results obtained with the aid of the following methods, the characteristic values of the most important oils and fats are arranged in a practically natural system in the tables collated at the end of this article. With the aid of these tables, it will not be difficult to identify a single individual. If, in the course of a commercial analysis, the limits of our present knowledge have been reached, the application of methods that have not yet been used for the case under consideration will suggest itself. This happens not infrequently in the examination of technical products.

For a number of examples, giving a clue as to how complicated mixtures may be examined, the reader is referred to Lewkowitsch's Chem. Techn. [i.] 509.

I. Examination of Oils and Fats.

The methods described under this head may be broadly divided into physical and chemical methods. With the physical methods may be incorporated suitably the so-called organoleptic methods, comprising odour, taste, colour, and consistence.

Examination by physical methods.

Odour and *taste* are especially characteristic of the oils of marine animals. In the case of solid fats, the *red colour* indicates preliminarily raw palm oil. The *consistence* at ordinary temperature gives a rapid indication as to whether the specimen belongs to oils or fats. In most cases, however, these organoleptic methods afford some help to the expert only. In the case of edible oils and fats, odour and taste must be considered as very important criteria, as rancidity is most readily recognised by taste and by taste alone, the chemical methods recommended by some writers for this purpose being superfluous. The following physical methods are of importance :—

Specific gravity. The specific gravity of the liquid oils is best determined by means of a pyknometer or a hydrostatic balance. In the case of solid fats, the specific gravity is most readily taken at a temperature at which the fat is liquid. Suitable temperatures are 40° in the case of fats liquid at that temperature. In other cases, the temperature of boiling water is usually resorted to. In the tables given at the end of this article, the specific gravities have been added. Speaking generally, it may be stated that the specific gravity number does not afford such important information as has been allotted to it at a time before the quantitative methods have been worked out. Still, castor oil would be recognised at once by its exceptionally high specific gravity.

Melting and solidifying points. Fats do not melt so sharply as is the case with chemically pure substances. Hence fats, if examined in a capillary tube, melt within several degrees, the fats softening at first, then melting at the edge of the substance, becoming transparent at the same time until they are melted completely. Therefore, some uncertainty obtains as to which temperature should be regarded as the melting-point. Some observers denote as melting-point that temperature, at which the fat which has been allowed to solidify in a small tube open at both ends, softens sufficiently to be driven up by the hydrostatic pressure of water. Others again denote that temperature as the melting-point at which the fat drops off the mercury bulb of a thermometer, which has previously been dipped into the melted fat and allowed to cool. Hence, it is imperatively necessary to state in each case by what method the melting-point has been determined. It is, therefore, customary in commerce to agree between buyer and seller as to the method. It is important to note that the freshly melted sample does not indicate the true melting-point, which is only ascertainable after the sample has been kept for 24 hours. In the case of cacao butter, even an interval of two or more days is required. The melting-points of most fats are given in the tables at the end of this article. It may be pointed out that, as a rule, it is preferable to determine the solidifying point of the *fatty acids* prepared from the oils and fats (*v. infra*).

Refractive index.—The determination of the refractive index—which can be carried out in a very simple and rapid manner, thanks to the construction of the oleorefractometer by Amagat and Jean, and especially that of the butyrorefractometer by Zeiss—forms one of the simplest preliminary tests in the examination of oils and fats, and especially in the examination of butterfat and lard. Owing to the ease and rapidity with which this 'characteristic' can be determined, the previously raised objections against observations with the aid of an ordinary refractometer have given place to a widely held over-estimation of the importance of this test. The observer should, therefore, be warned against placing too much importance on the indications of the refractometer and, as stated already, should only consider it as a preliminary test, the indications of which must be supported and corroborated by other methods (*cp.* Lewkowitsch, Chem. Tech. [i.] 245, 247 ; [ii.] 682).

Thus, in the case of butterfat, a glance at a sample in the refractometer may decide whether the specimen is grossly adulterated or not. But if the number be only slightly abnormal, or even if so-called 'normal numbers' have been found, the purity of the specimen is not yet proven, as it is easy, *e.g.*, to prepare specimens of margarine containing cocoa-nut oil which show the same refraction as a normal butter fat. Even if abnormal numbers have been obtained, this would not prove adulteration. It would be entirely erroneous to look upon the refractometric method as permitting the identification of an oil or fat. Equally erroneous would be the attempt to deduce quantitative interpretations as to the proportions of an adulterant from the deviation from normal numbers. The refractive indices of most oils are contained in the tables at the end of this article. By comparing these numbers with the iodine values, it will be gathered that there is a certain, although by no means definite, correlation between the refractive indices and the iodine values. For the description of refractometers, see Lewkowitsch, Chem. Techn. [i.] 247, and art. REFRACTOMETER.

Rotatory power. The determination of the rotatory power has not been practised extensively in the examination of oils and fats for the reasons stated above. Since, however, oils belonging to the 'Chaulmoogra group' can be identified readily —and indeed have been the means of identifying the 'Cardamom oil'—(see CHAULMOOGRA OIL GROUP) the polarimetric method is destined to find a wider application.

Solubility test. Almost all oils and fats are easily soluble in the usual organic solvents, hence the solubility test has little importance. Only castor oil is distinguished from all other natural oils and fats by its ready solubility in alcohol.

Examination by Chemical Methods.

The most important chemical methods employed in the examination of oils and fats have for their object the determination of certain numerical values which depend on the nature of the fatty acids occurring in the oils and fats.

These numbers represent only a measure of the amounts of the several fatty acids or fatty acid groups present in the oils and fats, without, however, expressing their absolute quantity. Hence these methods have been suitably termed 'quantitative reactions.' In addition to these quantitative reactions there are also at the disposal of the analyst a number of 'qualitative reactions.'

(a) *Quantitative Methods.*

The numerical values which are ascertained by means of quantitative methods are divided by the author into two classes.

(*a*) 'Characteristics,' *i.e.* those numbers which depend entirely on the specific nature of an oil or fat and hence assist most materially in identifying a given oil or fat.

(*b*) 'Variables,' *i.e.* those numbers which allow us to judge of the quality of a given oil or fat. These numbers naturally vary with the state of purity, rancidity, age, etc., of a given specimen.

The *characteristics* will be considered under the following heads.

(1) Saponification Value.
(2) Iodine Value.
(3) Reichert (Reichert-Meissl or Reichert-Wollny) Value.

The *variables* will comprise :—

(1) Acid Value.
(2) Amount of Glycerol, expressed in per cent.
(3) Amount of Unsaponifiable Matter, expressed in per cent.

Midway between these two classes stands the 'acetyl value' which, in some cases, must be considered a 'characteristic,' whereas in other cases it is a 'variable.'

(A) **Characteristics.**

1. *Saponification Value.*

The saponification value indicates the number of milligrams of potassium hydroxide required for the complete saponification of one gram of an oil or fat; in other words, it represents the amount of potassium hydroxide, expressed in tenths per cent., requisite to neutralise the total fatty acids in one gram of an oil or fat.

The saponification value is determined as follows :—Weigh off accurately, in a flask holding 150–200 c.c., 1·5 to 2 grams of the purified and filtered sample. Next run into the flask 25 c.c. of an approximately semi-normal alcoholic solution of caustic potash, measuring it off by means of a pipette. It is not necessary to add exactly 25 c.c., but care must be taken that for each determination precisely the same volume is used. Then attach a long cooling tube or an inverted condenser to the flask, and heat on the boiling water-bath for half an hour so that the alcohol is kept simmering; in order to accelerate saponification, the contents should be mixed by imparting to the flask a rotary motion. When the saponification is deemed to be complete, allow to cool a little, add 1 c.c. of a 1 p.c. phenolphthalein solution and titrate back the excess of potash with semi-normal hydrochloric acid. In case too much alcohol has been volatilised, it is advisable to add some alcohol (previously neutralised) or to add normal acid at first and to complete the titration with semi-normal acid.

It is necessary to make a blank test by treating the same amount of alcoholic potash in exactly the same manner as is done with the sample.

Example.—Weighed off 1·532 grams of olive oil, and saponified with 25 c.c. of alcoholic potash solution. Required for titrating back, 12·0 c.c. semi-normal acid; further, required for the blank test, 22·5 c.c. of the same acid. Therefore a quantity of caustic potash, corresponding to $\frac{(22{\cdot}5-12{\cdot}0)0{\cdot}0561}{2}$ grams = 294·5 milligrams KOH was employed for saponification. Hence, used for 1 gram of fat $\frac{294{\cdot}5}{1{\cdot}532}$ milligrams KOH = 192·2 milligrams KOH. The saponification value of the sample of olive oil is, therefore, 192·2.

The saponification values of neutral glycerides (esters of fatty acids) vary, of course, with the nature of the fatty acids; the lower the molecular weight of the fatty acids (or, what amounts to the same, of the esters), the more potash will be required to neutralise the fatty acids of 1 gram of oil or fat, or, in other words, the higher will be the saponification value. To illustrate this more clearly, the saponification values of some pure triglycerides are subjoined in the table on next page.

It will be gathered from the numbers given in the tables at the end of this article that the saponification values of the majority of natural oils and fats lie in the neighbourhood of 193 to 195. In the case of unknown samples, wide deviations from this number in either direction will at once enable the analyst to single out individual oils or fats. Thus, oils belonging to the rape oil group are characterised by a considerably lower saponification value, viz. about 175. The lower saponification values of these oils find their explanation in the large proportion of erucin they contain. In the case of castor oil, the lower value is due to the presence of hydroxylated fatty acids.

On the other hand, large deviations in the opposite direction enable us to single out a number of oils and fats and hence render their recognition a comparatively easy task. Thus the high saponification value of the fluid portion of dolphin and porpoise oils are indicative of a high proportion of lower fatty acids. A prominent example of a fat having a characteristically high saponification value is butter fat; hence by the saponification value alone, butter fat can be differentiated from margarine. High saponification values are also characteristic of fats consisting preponderantly of glycerides of myristic acid, and especially of the members of the cocoa-nut oil and dika fat groups.

If mineral oils or other unsaponifiable substances are intermixed with the fatty substances, then, naturally, the indications furnished by the saponification values alone, if accepted without any further investigation, would be entirely misleading, since the unsaponifiable matter depresses the saponification value. Thus, to take an example, an oil having the saponification value 193, if adulterated with 10 p.c. of mineral oil, would show a saponification value of about

SAPONIFICATION VALUES OF TRIGLYCERIDES.

Triglycerides	Formula	Molecular weight	Saponification value
Simple Triglycerides—			
Acetin	$C_3H_5(O{\cdot}C_2H_3O)_3$	218	772·0
Butyrin	$C_3H_5(O{\cdot}C_4H_7O)_3$	302	557·3
Valerin	$C_3H_5(O{\cdot}C_5H_9O)_3$	344	489·2
Caproin	$C_3H_5(O{\cdot}C_6H_{11}O)_3$	386	436·1
Caprylin	$C_3H_5(O{\cdot}C_8H_{15}O)_3$	470	358·1
Caprin	$C_3H_5(O{\cdot}C_{10}H_{19}O)_3$	554	303·7
Laurin	$C_3H_5(O{\cdot}C_{12}H_{23}O)_3$	638	263·8
Myristin	$C_3H_5(O{\cdot}C_{14}H_{27}O)_3$	722	233·1
Palmitin	$C_3H_5(O{\cdot}C_{16}H_{31}O)_3$	806	208·8
Stearin	$C_3H_5(O{\cdot}C_{18}H_{35}O)_3$	890	189·1
Olein	$C_3H_5(O{\cdot}C_{18}H_{33}O)_3$	884	190·4
Linolin	$C_3H_5(O{\cdot}C_{18}H_{31}O)_3$	878	191·7
Hydnocarpin	$C_3H_5(O{\cdot}C_{16}H_{27}O)_3$	794	211·9
Chaulmoogrin	$C_3H_5(O{\cdot}C_{18}H_{31}O)_3$	878	191·7
Linolenin	$C_3H_5(O{\cdot}C_{18}H_{29}O)_3$	872	193·0
Clupanodonin	$C_3H_5(O{\cdot}C_{18}H_{27}O)_3$	866	194·3
Ricinolein	$C_3H_5(O{\cdot}C_{18}H_{33}O_2)_3$	932	180·6
Arachin	$C_3H_5(O{\cdot}C_{20}H_{39}O)_3$	974	172·7
Erucin	$C_3H_5(O{\cdot}C_{22}H_{41}O)_3$	1052	160·0
Cerotin	$C_3H_5(O{\cdot}C_{26}H_{51}O)_3$	1226	137·3
Melissin	$C_3H_5(O{\cdot}C_{30}H_{59}O)_3$	1394	120·7
Mixed Triglycerides—			
Oleodipalmitin (Dipalmitoölein)	$C_3H_5(O{\cdot}C_{16}H_{31}O)_2(O{\cdot}C_{18}H_{33}O)$	832	202·3
Stearodipalmitin (Dipalmitostearin)	$C_3H_5(O{\cdot}C_{16}H_{31}O)_2(O{\cdot}C_{18}H_{35}O)$	834	201·8
Oleopalmitostearin (Stearopalmitoölein)	$C_3H_5(O{\cdot}C_{16}H_{31}O)(O{\cdot}C_{18}H_{33}O)(O{\cdot}C_{18}H_{35}O)$	860	195·7
Palmitodistearin (Distearopalmitin)	$C_3H_5(O{\cdot}C_{18}H_{35}O)_2(O{\cdot}C_{16}H_{31}O)$	862	195·2
Oleodistearin	$C_3H_5(O{\cdot}C_{18}H_{33}O)(O{\cdot}C_{18}H_{35}O)_2$	888	189·5
Dioleostearin	$C_3H_5(O{\cdot}C_{18}H_{33}O)_2(O{\cdot}C_{18}H_{35}O)$	886	189·9

175, and might, therefore, be mistaken for a rape oil if no further tests were applied.

If colophony (rosin) be dissolved in the fatty substance, the saponification value will remain unaffected, provided rosin of about the same saponification value be used. With a rosin of a lower saponification value than that of the oil or fat, the saponification value of the mixture would, of course, be somewhat depressed.

2. *Iodine Value.*

The iodine value indicates the percentage of iodine chloride absorbed by an oil or fat, expressed in terms of iodine. Theoretically, the acids belonging to the oleic and ricinoleic series should absorb two atoms of chlorine or iodine, or one molecule of iodochloride. Hence the glycerides of these acids should absorb six atoms of chlorine or iodine, or three molecules of iodochloride. Similarly, the acids of the linolic series should assimilate four atoms of halogens or two molecules of iodochloride; whereas the members of the chaulmoogric series would assimilate only two atoms of halogens or one molecule of iodochloride, on account of the cyclic arrangement of some carbon atoms; the members of the linolenic series six atoms of halogens or three molecules of iodochloride, and the members of the clupanodonic series eight atoms of halogens or four molecules of iodochloride.

These rules apply, however, only to doubly-linked carbon atoms. Trebly-linked pairs of carbon atoms, the occurrence of which in fatty acids (and hence in natural oils and fats) has not yet been definitely ascertained, do not absorb the theoretical amount of halogens.

The determination of the iodine value has been introduced into fat analysis by von Huebl and is carried out either in the manner indicated originally by Huebl or in the modification proposed by Wijs. The author's experience leads him to recommend the latter modification as more convenient and reliable. Since, however, Wijs' method has not yet been accepted as generally as it deserves, both methods will be described here.

Huebl's method.—From 0·15–0·18 gram of a drying or a marine animal oil, 0·2–0·3 gram of a semi-drying oil, 0·3–0·4 gram of a non-drying oil, or 0·8–1·0 gram of a solid fat, are weighed off accurately, and placed in a bottle of 500–800 c.c. capacity provided with a well-ground stopper. The weighing off is best done in a small weighing bottle, the cork of which is fitted with a finely drawn out tube so that a certain number of drops of an oil or of a previously melted fat can be easily taken out with the aid of an india-rubber tube fixed on the top. The fat is dissolved in 10 c.c. of chloroform, or carbon tetrachloride, and 25 c.c. of an 'iodine solution' are run in from a pipette. (This iodine solution is prepared by dissolving 25 grams of pure iodine on the one hand, and 30 grams of mercuric chloride on the other hand, in 500 c.c. of 95 p.c. of alcohol. Both solutions are kept separate and the quantity required for an experiment must have been prepared 24 hours before by mixing equal volumes of the two solutions. The mixture must not be used immediately after preparation, since the solution of iodochloride rapidly changes its titre after preparation. Although even after 24 hours' standing, the mixture still slowly changes its titre, it remains sufficiently constant during an experiment.) The pipette is always emptied in the same manner: this is best done by allowing it to drain until two or three drops have run out. In order to prevent loss of iodine by volatilisation, it is advisable to moisten the stopper with potassium iodide solution. The solvent and the iodine solution should give a clear solution on shaking, otherwise more solvent must be added. The bottle is then allowed to stand in a dark place. Should the deep brown colour of the solution disappear after a short time, another 25 c.c. of the iodine solution must be run in, an excess of iodine being essential for the reaction to become complete. The solution, after two hours, must still exhibit a deep brown colour. Most of the iodine is absorbed during the first two hours. The reaction then slows down; it cannot be considered complete in less than six to eight hours in the case of solid fats and non-drying oils, and twelve to eighteen hours in the case of drying oils and fish oils. Semi-drying oils require 8 to 10 hours. After standing for the requisite number of hours, from 15 to 20 c.c. of a 10 p.c. potassium iodide solution are run in, the liquid is well shaken and then diluted with 400 c.c. of water. The appearance of a red precipitate of mercuric iodide at this stage would indicate that an insufficient amount of potassium iodide had been employed, therefore more must be added. The excess of free iodine, part of which will be in the aqueous solution, whereas the remainder is dissolved in the solvent, is titrated with a standardised thiosulphate solution by running the latter into the bottle until, after repeated agitation, both the aqueous and the chloroform (carbon tetrachloride) layers are but faintly coloured. A few drops of a starch solution are next added and the titration is then brought to an end. Immediately before or after this titration, 25 c.c. of the original iodine solution are standardised in exactly the same manner. The difference between the two results corresponds to absorbed halogen, and is calculated in terms of iodine to units per cent. of the sample. The number thus found is termed the iodine value.

Example.—Weighed off 0·3394 gram of lard, dissolved in 10 c.c. of carbon tetrachloride, added 25 c.c. of iodine solution, which required in a blank experiment 60·9 c.c. of thiosulphate solution, 16·45 c.c. of which were equivalent to 0·2 gram of iodine. For titrating back the excess of iodine in the experiment, there were required 39·6 c.c. of thiosulphate solution. Hence, the absorbed iodine corresponds to 60·9–39·6=21·3 c.c. of thiosulphate solution.

Since 16·45 c.c. of thiosulphate solution are equivalent to 0·2 gram of iodine, 21·3 c.c. correspond to $\frac{0{\cdot}2\times 21{\cdot}3}{16{\cdot}45}=0{\cdot}2589$ gram of iodine. Hence 0·3394 gram of lard absorb 0·2589 gram of iodine, or 100 grams absorb $\frac{0{\cdot}2589\times 100}{0{\cdot}3394}=76{\cdot}28$ grams of iodine. The iodine value of the lard is, therefore, 76·28.

(With regard to the theory of the complicated chemical reactions occurring in Huebl's solution, *v.* Lewkowitsch, Chem. Techn. [i.] 316.)

Wijs' method. The solution required for Wijs' method is prepared by dissolving separately 7·9 grams (the theoretical figure is 7·9617) of iodine trichloride and 8·7 grams (the theoretical figure is 8·6670) of iodine in glacial acetic acid on the water-bath, taking care that the solutions do not absorb moisture. The two solutions are then poured into a 1000 c.c. flask, and the flask is filled up to the mark with glacial acetic acid.

A cheaper way of preparing the solution is to dissolve 13 grams of iodine in a litre of glacial acetic acid, then to determine accurately its content of iodine, and to pass washed and dried chlorine gas through the solution until the titre of the original iodine solution is doubled. A little experience will readily show when this point is reached, as a very distinct change of colour takes place when all the iodine has been converted into iodine monochloride.

The glacial acetic acid must be pure, and should be tested by heating with potassium dichromate and concentrated sulphuric acid; even after prolonged standing a green tinge should not be noticeable.

The iodine value is determined in exactly the same manner as described above for the Huebl solution. It is, however, preferable to use carbon tetrachloride since chloroform frequently contains alcohol. Wijs' iodine solution can be used immediately after preparation and possesses the great advantage over Huebl's solution in that it keeps its strength unchanged for a considerable length of time. Hence, in ordinary work, a blank test is not required in each case, and the determination of the iodine value can be carried out almost as rapidly as the determination of the saponification value. Wijs' solution has the further advantage that in the case of fats and non-drying oils the absorption of iodochloride is complete after half an hour, in the case of semi-drying oils after about 1 hour, and in the case of drying oils and marine animal oils in from 2 to 6 hours, according to the unsaturation of the glycerides.

The iodine value is one of the most important characteristics in the analysis of oils and fats, as this number permits us to classify the oils and fats in a practically natural system. This will be gathered from an inspection of the tables given at the end of this article.

If a given sample of oil or fat contains the glycerides of one unsaturated fatty acid of known composition in admixture with glycerides of saturated fatty acids, it is possible to calculate the absolute amount of the glyceride of that unsaturated fatty acid. In cases of this kind, the following table will be found useful. It will also guide the analyst as to the direction which further research should take in the case of samples of unknown composition, when, of course, the proportion of glycerides of unsaturated fatty acids cannot be calculated from the iodine value alone.

IODINE VALUES OF UNSATURATED FATTY ACIDS AND OF THEIR TRIGLYCERIDES (Lewkowitsch).

Acid.	Formula.	Iodine value of	
		Fatty acid.	Triglyceride.

3. *Reichert* (*Reichert-Meissl, Reichert-Wollny*) *Value.*

The Reichert (or Reichert-Meissl) value indicates the number of cubic centimetres of decinormal potash or soda solution requisite for the neutralisation of that portion of the soluble volatile fatty acids which is obtained from 2·5 (or 5) grams of an oil or fat by the Reichert distillation process.

Reichert, who originated this method, used 2·5 grams of fat. Meissl, as also Wollny, proposed 5 grams, which is now generally employed. It must, however, be pointed out that the Reichert-Wollny value is not twice the Reichert value, but mostly 2·2 of the Reichert value. Since Wollny's process has been adopted by a Joint Committee of the Government Laboratory and the Society of Public Analysts as the standard method for the determination of the soluble volatile fatty acids in margarine and butter the Reichert-Wollny process alone will be described.

Reichert-Wollny process. Five grams of liquefied fat are introduced into a 300 c.c. flask, of the form shown in Fig. 3 (length of neck 7–8 cms., width of neck 2 cms.). Two c.c. of a caustic soda solution, prepared by dissolving 98 p.c. sodium hydroxide in an equal weight of water—protected from the action of atmospheric carbon acid—and 10 c.c. of (about 99 p.c.) alcohol are added, and the mixture is heated for 15 minutes under a reflux condenser, connected with the flask by a **T**-piece, in a bath containing boiling water. The alcohol is evaporated off by heating the flask on the water-bath for about half an hour, or until the soap is dry. One hundred c.c. of hot water, which has been kept boiling for at least 10 minutes (to drive out all dissolved carbonic acid, the retention of which would vitiate the result), are added, and the flask is heated until the soap is dissolved. Forty c.c. of normal sulphuric acid and three or four fragments of pumice or broken pipe-stems are added, and the flask is at once connected with a condenser by means of a glass tube, 7 mm. wide, and 15 cms. from the top of the cork to the bend. At a distance of 5 cms. above the cork is a bulb 5 cms. in diameter. The flask is supported on a circular piece of asbestos, 12 cms. in diameter, having a hole in the centre 5 cms. in diameter, and is first heated by a very small flame, to fuse the insoluble fatty acids, but the heat must not be so great as to cause the liquid to boil; when fusion is complete the heat is increased, 110 c.c. are distilled off into a graduated flask, the distillation lasting about 30 minutes (from 28 to 32 minutes); the distillate is shaken, 100 c.c. are filtered off, transferred to a beaker, 0·5 c.c. of phenolphthalein solution (1 gram in 100 c.c. alcohol) is added, and the filtrate is titrated with decinormal soda or baryta solution. In precisely the same manner (with the same reagents), a blank test should be made, and the amount of decinormal alkali required to neutralise the distillate ascertained. This should not exceed 0·3 c.c. The volume of decinormal solution of alkali used, less the figure obtained in the blank experiment, is multiplied by 1·1. The number so found is the Reichert-Wollny value.

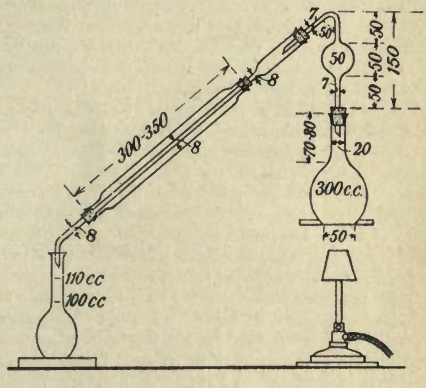

FIG. 3.

The Reichert-Meissl value (see tables at the end of this article) is practically identical with the Reichert-Wollny value. The Reichert-Meissl value of the majority of oils and fats, that is of those the saponification value of which is less than 200, is below 0·5. All oils and fats, the saponification value of which exceeds 200, are characterised by Reichert-Wollny values exceeding 1·0. The Reichert-Meissl value furnishes important indications regarding the nature of an oil or fat; thus butter fat is most prominently characterised by its high Reichert-Meissl value of about 27 to 29; the fats belonging to the cocoa-nut oil group by Reichert-Wollny values of 5 to 8, and dolphin and porpoise oils by Reichert-Meissl values varying from 47 to 120 (see tables at the end of this article).

Leffmann and Beam proposed the method of saponification with a concentrated solution of caustic soda in glycerol. This process is convenient owing to its rapidity, and has therefore been introduced by Polenske in the examination of butter fats, suspected of being adulterated with cocoa-nut oil. The method is carried out as follows: 5 grams of butter fat are placed in a 300 c.c. flask and heated with 20 c.c. of a solution of caustic soda in glycerol (prepared by dissolving 100 grams of caustic soda in an equal weight of water and mixing 20 c.c. of this solution with 180 c.c. of pure concentrated glycerol) over a naked flame for 2–3 minutes, until the water has evaporated off and the liquid has become clear. The values obtained by Leffmann and Beam's method are practically identical with those furnished by the Reichert-Wollny process, as the author can testify from his own experience.

It must be distinctly understood that by the Reichert method only a portion of the volatile fatty acids is recovered in the distillation process. The volatile fatty acids passing over consist, in the case of butter fat, preponderantly of butyric acid with which caproic, caprylic, and capric acids are admixed. In the case of cocoa-nut and palm-nut oils, butyric acid is absent, caproic and caprylic acids preponderating in the distillate. By filtering the distillate, caproic, caprylic, and capric acids are removed to the largest extent and are thus not accounted for in the Reichert-Wollny value.

Both Müntz and Coudon in France and Polenske in Germany extended the Reichert process by introducing a method for the approximate determination of the *insoluble* volatile fatty acids which pass over in the Reichert distillation process. Thus, after the Reichert-Meissl value has been determined, subsequently a second important value, affording a measure of the *insoluble volatile acids*, can be ascertained.

In the determination of this new value, the greatest attention must be paid to minute details and especially to the form of apparatus employed. Whereas Müntz and Coudon's apparatus is confined to France, Polenske's method has found application in this country, especially for the reason that this method closely followed the Reichert-Wollny process, and is in fact carried out in conjunction with it and in one and the same apparatus. As this method affords the best means of detecting cocoa-nut and palm-kernel oils in butter fat and in margarine, the process deserves the attention of the analyst.

Polenske saponifies 5 grams of filtered (butter) fat, by the Leffmann-Beam process, with 20 grams of glycerol and 2 c.c. of caustic soda solution (prepared from equal parts of sodium hydroxide and water) in a 300 c.c. flask by heating over a free flame. The solution is allowed to cool below 100°, 90 c.c. of water are added, and the mass dissolved by warming on the water-bath to about 50°. The solution must be clear and almost colourless. In case a brown solution be obtained, the test must be rejected. Fifty c.c. of dilute sulphuric acid (containing 25 c.c. of pure concentrated sulphuric acid in 1000 c.c.) and some *powdered* pumice are added to the hot soap solution; the flask is then immediately attached to the condenser. The apparatus to be employed must correspond in all details to the dimensions given in Fig. 4. The heat must be so regulated that within 19 to 20 minutes 110 c.c. are distilled off; the cooling water must be supplied at such a rate that the distillate does not drop into the 110 c.c. flask at a higher temperature than 20° to 23°. As soon as 110 c.c. have distilled over, the distillation is interrupted, the flask is removed, and is replaced by a 20 c.c. measuring cylinder.

The distillate, which must not be shaken up, is immersed almost completely in water at 15°. After about 5 minutes the neck of the flask is slightly tapped, so that the oily drops floating on the surface may adhere to the walls of the flask. After a further 10 minutes, the consistence of the insoluble acids is noted, with a view to ascertaining whether they form a solid (semi-solid) mass or oily drops. The contents of the flask are then mixed by turning the corked flask four or five times upside down, avoiding, however, violent shaking. 100 c.c. are filtered off through a filter of 8 cms. diameter, and titrated with decinormal caustic potash, as is done in the determination of the Reichert-Meissl value. In order to remove the soluble acids completely, the insoluble volatile acids on the filter are washed three times in succession with 15 c.c. of water, which have been passed severally through the tube of the condenser, the 20 c.c. measuring cylinder, and the 110 c.c. flask. These wash-waters are thrown away. In order to collect the insoluble volatile acids adhering to the tube of the condenser, the measuring cylinder, and the 110 c.c. flask, these vessels are rinsed three times in succession with 15 c.c. of neutralised 90 p.c. alcohol, and the alcoholic washes poured through the filter, each quantity being allowed to drain before a fresh wash is poured on the filter. The alcoholic filtrate is then titrated with decinormal alkali. The figure thus obtained has been termed 'new butter value' or 'Polenske value,' but the author prefers the term *titration number of insoluble volatile acids*, a term which has been adopted in France and Belgium. The titration value of the insoluble volatile acids lies in the case of butter fats as a rule between 2 and 4, in the case of cocoa-nut oil between 15 and 20, and in the case of palm-kernel oil between 10 and 12. (For a full discussion of this 'value,' see Lewkowitsch's Chem. Techn. [ii.] 695.)

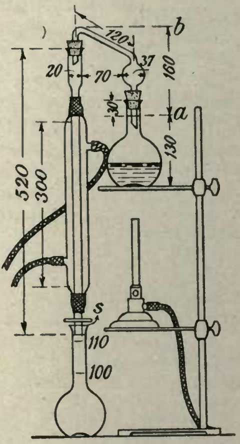

Fig. 4.

Acetyl Value.

The acetyl value indicates the number of milligrams of caustic potash (KOH) required for the neutralisation of the acetic acid obtained on saponifying one gram of an acetylated oil or fat.

The determination of the acetyl value of oils and fats is based on the principle that glycerides containing hydroxylated fatty acids assimilate, on being heated with acetic anhydride, one or more acetyl groups, according to whether the fatty acids contain one or more alcoholic hydroxyl groups. The chemical change consists in the replacing of the hydrogen atom of the alcoholic hydroxyl group or groups by the radicle of acetic acid, as explained by the following equations :—

$$C_3H_5[O{\cdot}C_{18}H_{32}O(OH)]_3+3(C_2H_3O)_2O$$

Ricinolein. Acetic anhydride.

$$=C_3H_5[O{\cdot}C_{18}H_{32}O(O{\cdot}C_2H_3O)]_3+3C_2H_4O_2$$

Acetyl ricinolein. Acetic acid.

$$C_3H_5[O{\cdot}C_{18}H_{31}O(OH)_4]_3+6(C_2H_3O)_2O$$

Sativin. Acetic anhydride.

$$=C_3H_5[O{\cdot}C_{18}H_{31}O{\cdot}(O{\cdot}C_2H_3O)_4]_3+6H_2O$$

Tetra-acetyl sativin.

The determination of the acetyl value (first proposed by Benedikt) is carried out in the form given to it by Lewkowitsch : 10 grams, or any other convenient quantity, are boiled with twice the amount of acetic anhydride for 2 hours in a round-bottomed flask attached to an inverted condenser. The solution is then transferred to a beaker of about 1 litre capacity, mixed with 500 to 600 c.c. of boiling water and heated for half an hour, while a slow current of carbon dioxide is passed into the liquid through a finely drawn-out tube reaching nearly to the bottom of the beaker ; this is done to prevent bumping. The mixture is then allowed to separate into two layers, the water is siphoned off, and the oily layer again boiled out in the same manner three successive times. The last trace of acetic acid is thus removed ; this is ascertained by testing with litmus paper. Prolonged washing beyond the required limit causes slight dissociation of the acetyl product. This would lead to too low an acetyl value. The acetylated product is then filtered through a dry filter-paper, and dried in an oven to remove water.

About 5 grams of the acetylated product are then saponified by boiling with alcoholic potash, as is done in the determination of the saponification value. If the 'distillation process' be adopted, it is not necessary to work with an accurately measured quantity of standardised alcoholic potash. In case the 'filtration process' be used, the alcoholic potash must be measured exactly. (It is advisable to use in either case a known volume of standard alkali, as one is then enabled to determine the saponification value of the acetylated oil or fat.) Next the alcohol is evaporated off and the soap dissolved in water. From this stage onwards, the determination is carried out either by (*a*) the distillation process, or (*b*) the filtration process.

(*a*) *Distillation process.*—Add dilute sulphuric acid (1 : 10), more than is required to saturate the potash used, and distil the liquid in a current of steam : 600–700 c.c. of water are distilled off. As a rule, this will be quite sufficient, and the last 100 c.c. will be found to require no more than 0·1 c.c. of decinormal alkali. Then titrate the distillate with decinormal potash, using phenolphthalein as an indicator, multiply the number of c.c. by 5·61, and divide by the weight of substance taken. This gives the *acetyl value.*

(*b*) *Filtration process.*—Add to the soap solution a quantity of standardised sulphuric acid, exactly corresponding to the amount of alcoholic potash employed, and warm gently, whereupon the fatty acids will readily collect on the top as an oily layer. (If the saponification value has been determined, it is, of course, necessary to take into account the volume of acid used for titrating back the excess of potash.) Filter off the liberated acids, wash with boiling water until the washings are no longer acid, and titrate the filtrate with decinormal alkali. The acetyl value is calculated in the manner shown above (*a*).

Both methods give identical results ; the latter requires less time and will, therefore, be found more convenient. The distilled water used in determining this value by either the distillation or filtration process must be carefully freed from carbonic acid by previous boiling, as otherwise serious errors ensue.

Pure triglycerides containing no hydroxylated acids have no acetyl value ; pure glycerides of hydroxylated fatty acids yield acetyl numbers which are in complete agreement with theory. In these cases, the acetyl value is a 'characteristic.' In the case of triglycerides containing, in addition to hydroxylated fatty acids, soluble acids as well, the acetyl value determined as described above would, of course, include soluble acids. The 'apparent' acetyl value obtained in such a case must, therefore, be diminished by the amount of alkali required for the saturation of the soluble fatty acids in order to obtain the *true* acetyl value. The amount of alkali required for the saturation of the soluble volatile acids must be ascertained by a blank test. Since acetyl values are also furnished by mono-glycerides and diglycerides (occurring in oils and fats having notable acid values), by free alcohols (such as phytosterol), and oxidised acids, and since all these substances occur in varying amounts in natural oils and fats, especially in those which have been exposed to the atmosphere and have become rancid, the acetyl value must, in these cases, be considered a 'variable.'

B. Variables.

1. *Acid Value.*

The acid value indicates the number of milligrams of potassium hydroxide required to saturate the free fatty acids in one gram of an oil or fat ; or, in other words, it gives the amount of potassium hydroxide, expressed in tenths per cent., necessary to neutralise the free fatty acids in an oil or fat. This value is therefore a measure of the free fatty acids in an oil or fat.

For the determination of the acid value of an oil or fat, about 5 grams of a sample (if available) are mixed with neutral or neutralised alcohol (purified methylated spirit) and titrated with aqueous or alcoholic caustic potash or caustic soda, using phenolphthalein as an indicator.

Example.—Weighed off 3·254 grams of tallow. Required for neutralising the free fatty acids 3·5 c.c. of decinormal caustic potash (or soda) or 3·5×5·61 milligrams KOH. The amount of KOH required for 1 gram of tallow, *i.e.* its acid value, is therefore

$$A=\frac{3{\cdot}5\times5{\cdot}61}{3{\cdot}254}=6{\cdot}03$$

The acid value is frequently expressed in per cent. of oleic acid. Since the molecular weight of oleic acid, 282, is approximately five times 56·1 (the molecular weight of KOH), and the acid value expresses the amount of KOH in tenths per cent., a rapid and in most cases sufficiently accurate method of converting the acid value into per cent. of oleic acid is to multiply the former by 0·5. In the case of cocoa-nut oil and palm-kernel oil fatty acids, this procedure would not be applicable, as their mean molecular weight lies, as a rule, between 210–220.

2. *Glycerol.*

If natural oils and fats represented neutral triglycerides, it would be possible to calculate the amount of glycerol obtainable on saponification from the following equation:

$$C_3H_5(OR)_3+3KOH=C_3H_8O_3+3KOR.$$

In the case of pure triglycerides, the proportion of glycerol obtainable being a 'characteristic' (see GLYCERIN), the quantity of glycerol yielded by an oil or fat can be calculated from the saponification value. In the case of natural oils and fats, a calculation of this kind will lead to erroneous results, not only on account of the (small) quantity of 'unsaponifiable matter' that is always present, but chiefly on account of the free fatty acids and mono- and di-glycerides which occur in natural oils and fats in variable quantities. Therefore, in the case of natural oils and fats, the percentage number of glycerol must be looked upon as a 'variable.'

This 'variable' stands in that general relation to the acid value that the higher the acid value, the smaller the yield of glycerol.

In order to determine the proportion of glycerol which an oil or fat yields on saponification, it is best to apply the 'acetin process' (*see* GLYCERIN) after a 'crude glycerin' has been prepared in the following manner:—

Twenty grams of the oil or fat are saponified (as described under *Saponification value*) with alcoholic potash, and the alcohol is driven off on a water-bath. The resulting soap is decomposed with sulphuric acid and the liberated fatty acids are filtered off. The filtrate is neutralised with an excess of barium carbonate and boiled down on the water-bath until most of the water has been driven off. The residue is exhausted with a mixture of ether and alcohol, the ether-alcohol driven off, for the most part, by gently heating on the water-bath, and the residue then left is dried in a desiccator and weighed. It is not necessary to dry until constant weight is obtained, as the actual glycerol present is determined in the crude product by the acetin method.

3. *Determination of the Unsaponifiable Matter.*

The author comprises under the term 'unsaponifiable matter' all those substances that are insoluble in water, or do not combine with caustic alkalis to form soluble soaps. Most oils and fats contain, in their natural state, small quantities of unsaponifiable matter which consists to a great extent either of phytosterol in the case of vegetable oils and fats, or of cholesterol in the case of animal oils and fats. Other alcohols and hydrocarbons represent the smaller part of the 'unsaponifiable matter.'

Preparatory to the determination of the unsaponifiable matter, the oil or fat must be saponified as described above under *Saponification value.* In many cases it will, therefore, be found convenient to combine the determination of the saponification value with that of the unsaponifiable matter. But the amount of oil or fat taken should not be less than 5 grams. The unsaponifiable matter is determined as follows:—

Saponify 5 grams of the sample with 25 c.c. of double normal alcoholic potash in a flask under a reflux condenser and evaporate off the bulk of the alcohol. The residual soap is dissolved in 50 c.c. of hot water, and transferred to a separating funnel of about 200 c.c. capacity, using about 20–30 c.c. of water for rinsing the dish. After cooling, add 30–50 c.c. of ether and shake the solution thoroughly. Addition of a little alcohol will accelerate the separation. The soap solution is then run off into another separating funnel and is again exhausted with fresh ether. As a rule, two extractions will suffice; it is, however, safer to extract a third time. The ethereal solutions are united, washed with a small quantity of water to free them from any dissolved soap, and transferred to a tared flask. The ether is distilled off on the water-bath, and the residue dried at 100° and weighed.

In the case of most oils and fats ether should be preferred to light petroleum (which is largely used on the Continent). In order to counteract the property of light petroleum to dissolve alkaline soaps, the petroleum layer holding the unsaponifiable matter in solution should be washed with 50 p.c. alcohol instead of with water.

The above method must not be used in the case of oils and fats which have admixed with them vegetable or animal waxes, as the alkali salts of the fatty acids are not readily soluble in water nor even in dilute alcohol. In such cases, it is best to neutralise the soap solution with acetic acid, using phenolphthalein as an indicator, and to precipitate with barium chloride or lead acetate. The residue is then washed, dried, mixed with sand and extracted in a Soxhlet apparatus with petroleum boiling below 80°. If it be desirable to ascertain whether cholesterol or phytosterol or both, or animal or vegetable waxes or mineral oils, &c., be present, the unsaponifiable matter should be prepared in sufficient quantity to admit of further examination (*see* below *Examination of the Unsaponifiable Matter*).

(b) *Qualitative Methods.*

A large number of qualitative methods which were formerly in vogue, such as the elaïdin test, the sulphur chloride test, the thermal reactions with sulphuric acid (Maumené test), bromine or sulphur chloride, have been practically superseded by the determination of the iodine value. Inasmuch as the latter yields the same information in a more reliable and less ambiguous fashion than the tests enumerated, they need not be described here. (For a description of these methods, *see* Lewkowitsch, vol. I, chap. vii.) More important are the qualitative methods described below, inasmuch as they frequently furnish important data for the recognition of some oils and especially as they are usable for the valuation thereof. In cases where the quantitative methods do not supply full information the qualitative methods may be applied with advantage. The following qualitative methods are described here :—

(1) Oxygen absorption test.
(2) Bromide tests.
(3) Colour tests.

(1) Oxygen Absorption Test.

The absorption of oxygen from the atmosphere has a very important bearing on the liability of oils to cause spontaneous combustion when spread in a finely divided state on fibrous organic substances (*see* WOOL OILS). It is also of very great importance in the industries of paint oils, boiled oils, and varnishes.

It has been pointed out already that the iodine absorption of oils and fats stands in close relationship to the absorption of oxygen, and that the latter property, being a measure of the drying power of oils, was formerly used for purposes of classification. It has also been explained that the classification based on the iodine value includes the sub-division of oils into drying, semi-drying, and non-drying oils.

If a convenient method were known for the accurate determination of the oxygen which is absorbed during the drying process, it would be possible to class the determination of the drying power, or, as it might be termed, the 'oxygen value,' amongst the quantitative tests.

Determinations by earlier observers were made in a very unsystematic fashion, insufficient regard having been paid to such important factors as temperature, influence of light, moisture of the atmosphere, thickness of layer exposed, age of the oil, &c.

Since the drying of an oil requires a protracted length of time, attempts were made to accelerate the process of drying by mixing with the oils finely divided lead (Livache) or finely divided copper (Huebl; Lippert). Livache's lead powder is prepared by precipitating a lead salt with zinc, washing the precipitate rapidly in succession with water, alcohol, and ether, and finally drying *in vacuô.* The test is carried out as follows : Spread about 1 gram of lead (or copper) powder, weighed off accurately on a somewhat large watchglass, in a thin layer, and allow to fall on to it from a pipette 0·6 to 0·7 grams (not more) of the oil to be tested, placing each drop separately on the lead (or copper) powder, taking care that the drops do not run into one another. Then allow the watchglass to stand at the ordinary temperature exposed to light.

In this process, linseed oil reaches the maximum absorption within a few days, whereas under ordinary conditions the same result is only arrived at after a much longer time has elapsed. Livache states that drying oils absorb the maximum quantity of oxygen after 18 hours, or, in some cases, after three days, whereas non-drying oils do not gain in weight before the lapse of four or five days. Weger condemns Livache's process, and recommends that larger quantities of lead should be used, so that for 0·2 grams of oil there should be taken at least 2 grams of lead powder. But even in that case the results were not found to be satisfactory.

Lippert, as also Weger, undertook a systematic study of the drying power of oils, by exposing them in very thin layers on glass plates to the action of the atmosphere. It was found that glass could not be replaced by any other material lighter in weight; thus celluloid, gelatin, and even ebonite were found useless. Sheets of mica, although useful for the work, are too easily damaged, and even sheets of thin metals have the drawback of being too easily creased. Necessary precautions in this test are: that the glass be perfectly clean, free from dust, and that the oil be spread with the greatest possible care in an evenly thin layer. If the layer is of uneven thickness, increase of weight might occur at one place, whilst simultaneously in a thinner layer loss of weight might take place. A series of experiments showed that the thinner the layer of oil exposed, the more rapidly is oxygen absorbed at the commencement of the experiment, but after 24 hours an equilibrium seems to be established. The thicker the layer the smaller is the increase, but if the layer is too thin, unreliable results will be obtained. The best conditions seem to be reached by spreading the oil so that about 0·0005 gram is used per square cm. of a glass plate.

The process is an extremely tedious one, and depends on the accuracy with which decimilligrams can be ascertained. Besides, the method does not yield absolute values, and can only be used as a guide in comparative tests. It must, however, depend on the given circumstances whether this process should be applied. For if it is merely a question of discriminating between drying, semi-drying, and non-drying oils, the iodine value will not only be the most convenient sorting test, but will, at the same time, furnish quantitative results. It should be noted, however, that the iodine value must not be accepted as tantamount to defining the drying power. To take a striking example, fish and liver oils absorb approximately as much iodine as do the best drying oils, and yet they are greatly inferior to the latter as regards oxygen absorption power. Furthermore, fish and liver oils differ most materially from the 'drying oils,' in that they do not form a skin as does linseed oil.

Fish and liver oils are best differentiated from the drying oils by the bromide test.

(2) Bromide Test.

On the strength of Hazura's investigations of the bromine derivatives of the unsaturated fatty acids, Hehner and Mitchell devised a process, best applied in the following manner, which embodies some modifications worked out in the author's laboratory : Dissolve 1 to 2 grams of oil in 40 c.c. of ether, to which a few c.c. of glacial acetic acid have been added, cool the solution in a corked flask to 5°, and add bromine drop by drop until the brown coloration remains permanent. If the temperature were allowed to rise too high, evolution of hydrogen bromide would become noticeable ; in that case, the experiment must be repeated. After standing for 3 hours at a temperature of 5°, the liquid is passed through a filter, and the precipitate is washed four times in succession, using each time 10 c.c. of chilled ether. The residue is finally dried in a water-oven to constant weight. In the following table a number of experiments are collated which have been carried out by Hehner and Mitchell, by the author and by his assistants Walker, Warburton, and Stadler.

Kind of Oil	Yield of insoluble bromides from glycerides per cent.	Observer
Linseed (iodine value 181)	23·14; 23·52	Walker and Warburton
Linseed (iodine value 186·4)	24·17	Lewkowitsch

In the author's opinion, derived from very extensive practice with this method, it is preferable to apply the 'bromide test' to the isolated fatty acids (*see* below).

(3) Colour Tests.

A very large number of colour reactions have been proposed from time to time, and are still being proposed, for the recognition of individual oils.

Colour reactions were chiefly resorted to for lack of better methods; they have been superseded in the majority of cases by the 'quantitative reactions.' It should be borne in mind that many colour reactions quoted in older text-books, and perpetuated even in more modern treatises, were not always obtained with typical samples, little or no regard having been paid to their source, their mode of purification, their age, and all that variety of circumstances which influence the colour produced by the reagents. In consequence of progress made in technical processes, a large number of impurities, which were in fact the very substances that gave origin to the colours supposed to be characteristic of the oils or fats, have ceased to occur in commercial samples.

A colour reaction can only be considered of some value if it be produced by a well-defined substance, occurring naturally in an oil or fat, and characteristic of it to such an extent that the sample may be identified by that reaction. Obviously, these characteristic substances which only occur in minute quantities should not be easily removable in the course of the usual manufacturing processes.

An extensive inquiry made by the author (J. Soc. Chem. Ind. 1894, 617, and Chem. Techn. [i.] 398-400) into the colour reactions, has led him to conclude that only the following tests can be considered:—

Baudouin's test.—This test, originally proposed by Camoin, is indicative of sesamé oil, inasmuch as a substance which occurs in this oil gives with hydrochloric acid and sugar a characteristic red colouration. Since cane sugar yields lævulose and furfural, Villavecchia and Fabris proposed to carry out this test in the following manner, which can be thoroughly recommended:—

Place 0·1 c.c. of a 2 p.c. alcoholic furfural solution in a test-tube, add 10 c.c. of the oil to be tested, and 10 c.c. of hydrochloric acid of sp.gr. 1·19; shake the mixture for half a minute and allow to settle. In the presence of sesamé oil, even if it be less than 1 p.c., the aqueous layer will acquire a distinct crimson colour. In the absence of sesamé oil, the lower layer is either colourless, or has at most (as in the case of a very rancid though pure olive oil) a dirty yellow colour. The great sensitiveness of this reaction has led to the compulsory ear-marking of margarine, in several continental countries, by the legally prescribed addition of 5–10 p.c. of sesamé oil to margarine. In case an oil or fat has already been coloured with a colouring matter furnishing a red colouration with hydrochloric acid alone (which not unfrequently occurs in the case of margarine coloured with 'butter colour'), the colouring matter must be previously removed by frequent shaking out with concentrated hydrochloric acid. In many cases, however, the colouring matter contained in the sesamé oil is destroyed at the same time.

Halphen's Colour Test.—This test indicates cotton-seed oil and is carried out in the following manner: 1 to 3 c.c. of the oil is dissolved in an equal volume of amyl alcohol; to this is added 1 to 3 c.c. of carbon disulphide holding in solution 1 p.c. of sulphur (flowers). The test-tube containing the mixture is then immersed in boiling water, and kept therein for some time. The carbon disulphide evaporates off; in the presence of cotton-seed oil a deep red colouration appears in the course of 5 to 15 minutes. This colour reaction is most characteristic; it is possible to detect thereby 5 p.c., and even less, of cotton-seed oil admixed with other oils and fats, *e.g.* olive oil or lard. In case the proportion of cotton-seed oil is very small, the test-tube must be kept in the water-bath for 20 to 30 minutes, or preferably in a salt-bath at 105°. Mixtures of olive and arachis oils containing 1 p.c. of cotton-seed oil, gave, in the author's laboratory, distinct colourations after 25 to 30 minutes. Over-estimation of this test must, however, be guarded against as, on the one hand, cotton-seed oil, which has been heated at 180°–250°, no longer yields the red colouration. On the other hand, it must be remembered that on feeding cows and pigs with cotton-seed cake, the chromogenetic substance passes into the milk fat of cows and into the lard. It must, also, be noted that no quantitative interpretation should be based upon the depth of the red colouration obtained, even if the presence of cotton-seed oil has been placed beyond doubt.

It should further be noted that kapok oil and baobab oil give the same colour reaction, the last-named oil with even greater intensity than cotton-seed oil.

Becchi's Colour Test.—This test is much less reliable than Halphen's test and is only described here because it is still largely used in the South of Europe (France, Italy). It is safest, if Becchi's test must be applied, to use it in the form suggested by Tortelli and Ruggeri: Five grams of the liquid fatty acids of the suspected sample are dissolved in 10 c.c. of alcohol, and 1 c.c. of a 5 p.c. silver nitrate solution is added; the sample is then heated on a water-bath at 70°–80°. Cotton-seed oil acids reduce the silver immediately, whereas the fatty acids of olive oil and other oils remain clear for some time. Even cotton-seed oils—which have been heated at 250° for 10 and 20 minutes respectively—can be recognised when present in as low a proportion as 10 p.c. in olive oil, on allowing the liquid acids of the mixed oil to stand in the hot water-bath for several hours.

Nitric Acid Test.—This test may be used in many cases for the preliminary identification of cotton-seed oil. The test is best carried out with nitric acid of 1·375 sp.gr. (Lewkowitsch). A few c.c. of the sample are shaken energetically with an equal measure of nitric acid of the specified gravity 1·375, and the sample is allowed to stand for some time, up to 24 hours. Cotton seed oil gives a coffee-brown colouration which is characteristic of this oil to such an extent that admixtures of 10–12 p.c. of cotton-seed oil with olive oil can be detected in certain cases. But even here circumspection is necessary, as the coffee-brown colouration given by some specimens of cotton-seed oil is not characteristic of all cotton-seed oils. Of importance is the observation made by the author, viz. that a specimen of heated cotton-seed oil which no longer gives the Halphen test still gives a brown colouration with nitric acid, and also that the fatty acids from heated cotton-seed oil showed the colouration distinctly.

It may be repeated that the last three colour tests, which are employed for the detection of cotton-seed oil, should only be used with the greatest circumspection. In any case they can only serve as preliminary or confirmatory tests.

Liebermann-Storch Reaction.—This colour test is exceedingly reliable for the detection of rosin oils: 1 to 2 c.c. of the sample under examination are shaken, in a test-tube, with acetic anhydride at a gentle heat; after cooling, the acetic anhydride layer is drawn off by means of a pipette, and tested by adding one drop of sulphuric acid of 1·53 sp.gr. (This acid contains 62·53 p.c. of SO_4H_2; it is prepared by mixing 34·7 c.c. of concentrated sulphuric acid with 35·7 c.c. of water.) If rosin oil is present, a fine violet (fugitive) colour is immediately produced. If less than 1 to 2 c.c. are available, the test can be done on a watch-glass, by stirring the liquid with acetic anhydride and allowing a drop of sulphuric acid to run down the side. It should be borne in mind that cholesterol gives a similar colour reaction.

Sulphuric acid test.—All sulphuric acid colour reactions described in the older literature of this subject are unreliable with the exception of the test for liver oils. This is best carried out in the following manner:—1 drop of oil is dissolved in 20 drops of carbon disulphide and 1 drop of concentrated sulphuric acid is added. In the presence of liver oils, a beautiful violet-blue colour appears at once, changing afterwards into red and brown. The colouration is not only caused by the presence of cholesterol but also by some 'lipochromes' which are extracted from the liver in the course of preparing the oils.

II. Examination of Fatty Acids.

In case the preceding methods, described under A and B, have not furnished sufficient information for the identification of a specimen, it becomes necessary to examine the free fatty acids.

If great accuracy is required it is not permissible to examine the fatty acids as obtained by the decomposition of the soap solution—resulting on saponification of the oils and fats—as the separated fatty acids naturally retain the unsaponifiable matter. Rather is it necessary to remove the unsaponifiable matter previous to the decomposition of the soap solution by the methods described above.

A list of the natural fatty acids likely to be met with in the examination has been set out in the table, p. 744. It will be found convenient to have the few indications given above amplified by the following notes.

I. ACIDS OF THE ACETIC SERIES: $C_nH_{2n}O_2$.

These acids contain a normal chain and are best characterised for analytical purposes by their property of not absorbing any iodine, *i.e.* their iodine value is *nil*. The lowest members of the series are miscible with water in every proportion. The solubility in water decreases rapidly with the increase of the number of carbon atoms in the molecule. Capric acid is practically insoluble in cold water, somewhat more soluble in hot water. Lauric acid is very slightly soluble in boiling water. The higher acids are practically insoluble in water.

Taking solubility in water as a basis of classification we may, for analytical purposes, subdivide these fatty acids into *soluble* and *insoluble* fatty acids. The acids up to caprylic acid are termed *soluble* fatty acids; the higher fatty acids, from myristic acid upwards, are the *insoluble* fatty acids. Capric and lauric acids occupy, also as regards solubility, an intermediate position. The lead salts of the higher fatty acids, commencing with palmitic acid, are insoluble in ether.

Acetic Acid *v.* vol. i. p. 7.

Butyric Acid *v.* vol. i. p. 591.

*iso***Valeric Acid** *v.* VALERIC ACID.

Caproic acid, $C_6H_{12}O_2$, discovered by Chevreul in 1818, is not miscible with water, although it is, to some extent, soluble in it; sp. gr. at 20°/4° is 0·924; $n_D^{20}=1{\cdot}41635$; its odour is like that of sweat: 100 c.c. of water dissolve 0·822 gram at 15°.

Methyl ester, sp.gr. 0·9309 at 0°; b.p. under 760 mm. pressure, 149·6°; under 15 mm. pressure, 52°–53°.

Ethyl ester, sp.gr. 0·8890 at 0°; sp.gr. 0·8732 at 20°; sp.gr. 0·8594 at 40°; b.p. 165·5°–166° under 735·8 mm. pressure.

Caprylic acid, $C_8H_{16}O_2$, discovered by Lerch (1844) in butter fat: sp.gr. 0·9270 at 0° and 0·9100 at 20°/40°; n^{20}_{D}1·42825. One part dissolves in 400 parts of boiling water; the dissolved acid separates out almost completely on cooling: 100 c.c. of water at 15° hold in solution 0·079 gram of acid. The acid has an intense odour of sweat. It also occurs in the oils belonging to the cocoa-nut oil group.

Methyl ester, sp.gr. 0·8942 at 0°; sp.gr. 0·887 at 18°; solidifying point −40° to −41°; b.p. 192°–194° under 760 mm.; 95° under 25 mm., 83° under 15 mm. pressure.

Ethyl ester, sp.gr. 0·8842 at 0°; 0·8730 at 16°; solidifying point, −47° to −48°; b.p. 207°–208°.

Capric acid, $C_{10}H_{20}O_2$, like the foregoing two acids, is characteristic of the milk fats and the oils of the cocoa-nut group. It occurs in wool yolk as potassium salt. The acid crystallises in fine needles, sp.gr. 0·930 at 37°; 0·8858 at 40; n^{40}_{D}1·42855. It is almost insoluble in cold water; one part dissolves in about 1000 parts of boiling water. The acid has a goat-like smell, which becomes more distinct at the temperature of its melting-point.

Methyl ester, boils at 223°–224° under 760 mm. and at 114° under 15 mm., solidifies at −18°.

Ethyl ester, sp.gr. 0·862; b.p. 243°–245°.

Lauric acid, $C_{12}H_{24}O_2$, is characteristic of the oils of the cocoa-nut oil and dika fat groups. At the ordinary temperature the acid is solid, and crystallises from alcohol in needles. It is the first acid of the acetic series that cannot be distilled at ordinary pressure without undergoing (slight) decomposition: sp.gr. 0·883 at 20°/4°; 0·875 at 43·6°/4; 0·8642 at 60°/4°; n^{60}_{D} 1·42665; n^{76}_{D} 1·4236. Lauric acid is slightly soluble in large quantities of boiling water; on distilling its aqueous solution, it passes over to an appreciable extent with the vapours. The laurates of the alkali-metals differ from the corresponding salts of the higher fatty acids in that they require large quantities of salt for ‘salting out’ (*v.* SAPONIFICATION).

Methyl ester, b.p. 141° under 15 mm.; 148° under 18 mm.; m.p. +5°.

Ethyl ester, sp.gr. 0·8671 at 19°; solidifying point −10°; b.p. 269° under ordinary pressure.

Myristic acid, $C_{14}H_{28}O_2$, is characteristic of all the fats belonging to the *Myristica* group (*see* MYRISTICA FATS). It was discovered by Playfair in nutmeg butter. It is also stated to occur as cetyl myristate in spermaceti and, in combination with unknown alcohols, in wool wax. The acid crystallises in laminæ; sp.gr. 0·8622 at 53·8°/4°; 0·8584 at 60°/4°; n^{60}_{D} 1·43075; $n^{76·5}_{D}$ 1·4248; is completely insoluble in water; when boiled with water, about 7·7 p.c. is carried over with the vapour; it dissolves with difficulty in cold alcohol and ether.

Methyl ester, b.p. 167°–168° under 15 mm. pressure; m.p. 18°.

Ethyl ester, boils at 295° under ordinary pressure, and *in vacuô* at 102° or 124°; solidifies at 10·5°–11·5°; sparingly soluble in alcohol or ether, more readily soluble in light petroleum.

Palmitic acid, $C_{16}H_{32}O_2$, occurs in most vegetable and animal fats; and notably in large quantities in palm oil (from which it was first isolated in a pure state by Fremy); in Chinese vegetable tallow, Japan wax, and myrtle wax. It occurs also in spermaceti and in opium wax as ceryl palmitate, in beeswax as myricyl palmitate.

Palmitic acid has been prepared artificially on a large scale by melting oleic acid with caustic alkali, hydrogen being evolved; in addition to palmitic acid smaller quantities of oxalic and acetic acids are formed. This process has been abandoned as impracticable.

Palmitic acid forms tufts of finely crystalline needles; the melted acid solidifies on cooling to a nacreous, scaly, crystalline mass. It boils between 339° and 356° with slight decomposition; distils unchanged under a pressure of 100 mm. at 271·5°; under a pressure of 15 mm. at 215°, and *in vacuô* at 138°–139°. On a large scale it is distilled with the aid of superheated steam; sp.gr. 0·8527 at 62°/4°; 0·8412 at 80°/4°; $n^{74·5}_{D}$ 1·4284; n^{80}_{D} 1·42693. It is not readily soluble in cold alcohol; 100 c.c. of methylated alcohol (sp.gr. 0·8183) dissolve at 0° from 1·2 to 1·3 grams; 100 c.c. of 95 p.c. (by volume) alcohol hold in solution at 0°, 0·56 gram; 100 parts of absolute alcohol dissolve, at 19·5°, 9·32 parts. It dissolves very easily in boiling alcohol; light petroleum does not dissolve it very readily.

The metallic salts of palmitic acid resemble very closely those of stearic acid (*v. infra*), but they possess a somewhat greater solubility. Palmitic acid is determined quantitatively in palmitates by precipitating their solutions with hydrochloric acid, washing the precipitate with water, dissolving it in absolute alcohol or ether, evaporating to dryness, and finally drying in a desiccator over sulphuric acid.

Methyl ester, b.p. 196° under 15 mm. pressure; m.p. 28°.

Ethyl ester, b.p. 122° *in vacuô*; m.p. 24·2°.

Stearic acid, $C_{18}H_{36}O_2$, occurs very abundantly in many vegetable and animal fats, especially in the hard ones, such as cacao butter, shea butter, and tallow. The higher the melting-point of a fat, the higher is, as a rule, the proportion of stearic acid it contains. Stearic acid can be obtained synthetically by the reduction of less saturated acids, containing an open chain of 18 carbon atoms (oleic, linolic, linolenic, clupanodonic) by means of hydrogen in the presence of a suitable catalyst, such as nickel or palladium. It forms white, nacreous laminæ, melting at 69·32° to a perfectly colourless liquid which, on cooling, solidifies at 69·3° to a crystalline translucent mass; boils under ordinary pressure at about 360° with slight decomposition; *in vacuô* it distils unchanged. On a large scale it is distilled in a current of superheated steam without any decomposition. Under 100 mm. pressure it boils at 291°, under 15 mm. at 232°, and *in vacuô* at 154·5°–155·5°: sp.gr. 0·8454 at 69·2°/4°, 0·8386 at 80°/4°. At 11° its sp.gr. equals that of water; at more elevated temperatures it floats on water, as it expands more quickly than the latter: n^{80}_{D} 1·43003.

Like palmitic acid it possesses neither smell nor taste; it is greasy to the touch and produces a grease-spot on paper. Insoluble in water; in hot alcohol it dissolves easily; it is less soluble in absolute alcohol than palmitic acid, one part of stearic acid requiring 40 parts of alcohol. 100 c.c. of alcohol, sp.gr. 0·818 (at 15·5°) hold in solution at 0° 0·0814 gram, if the solution be prepared with about 3 grams of stearic acid, but owing to supersaturation, the dissolved amounts fluctuate considerably, depending on the amount of stearic acid used. Thus, with 7 grams of stearic acid, varying quantities of dissolved stearic acid from 0·0810 rising up to 0·1082, have been found (Lewkowitsch). Stearic acid dissolves easily in ether.

Potassium stearate $KC_{18}H_{35}O_2$, forms crystals having a greasy lustre; dissolves in 6·6 parts of boiling alcohol. On diluting the hot aqueous solution with a large proportion of water, pearly laminæ of an acid stearate,

$$KC_{18}H_{35}O_2.C_{18}H_{36}O_2,$$

separate. The salt is insoluble in ether, light petroleum, carbon disulphide, and chloroform. (Difference from potassium oleate.)

Sodium stearate, $NaC_{18}H_{35}O_2$, closely resembles the potassium salt. In the crystalline state it forms lustrous laminæ.

Ammonium stearate, $(NH_4)C_{18}H_{35}O_2$, loses part of its ammonia on being warmed in aqueous solution, and is converted into the acid salt. The same change takes place when the ammonia soap is allowed to stand over concentrated sulphuric acid in a desiccator.

Calcium, strontium, and barium stearates form crystalline precipitates, practically insoluble in alcohol. The insoluble salts are, to some extent, hydrolysed on washing with water. Thus barium stearate gives up to the water barium oxide, and free stearic acid (which can be extracted with alcohol) remains behind with the undissociated residue. The *magnesium* salt crystallises in microscopical laminæ; it is nearly insoluble in cold alcohol, but sufficiently soluble in boiling alcohol to allow it to be crystallised from its solution. The *lead* salt melts at 115°–116° without undergoing decomposition; it is very sparingly soluble in ether (difference from oleic acid), and still less in light petroleum. 50 c.c. of absolute ether dissolve 0·0074 gram of lead stearate. In hot benzene, lead stearate dissolves, but separates almost completely on cooling to 8°–12°. In absolute alcohol, lead stearate is very sparingly soluble. Stearic acid cannot be determined quantitatively by weighing its calcium or barium salts, a method which has been proposed repeatedly.

Methyl ester, b.p. 214°–215°; m.p. 38°.

Ethyl ester, boils *in vacuô* at 139° or 154°; it melts at 36·7°.

Arachidic acid, $C_{20}H_{40}O_2$, discovered by Goessmann (1854), occurs in notable quantities in arachis oil; it has also been found in butter fat. It crystallises in small lustrous scales, sparingly soluble in cold alcohol; dissolves easily in boiling alcohol. 100 parts of 90 p.c. alcohol dissolve at 15°, 0·022 parts, and at 20°, 0·045 parts of arachidic acid. It dissolves readily in ether, chloroform, light petroleum, or benzene.

Methyl ester, m.p. 54·5°.

Ethyl ester, b.p. 284°–286° under 100 mm. pressure; m.p. 50°.

Behenic acid, $C_{22}H_{44}O_2$, melts at 80°–82° and solidifies at 79°–76°. Synthetical behenic acid from erucic acid melts at 83°–84° and solidifies at 79°–77°. It boils under 60 mm. pressure at 306° and crystallises in needles; it is less soluble in alcohol than in ether. 100 parts of alcohol dissolve at 17°, 0·102 gram; 100 parts of ether, at 16°, 0·1922 gram.

Ethyl ester, m.p. 48°–49°.

Lignoceric acid, $C_{24}H_{48}O_2$, occurs in arachis oil, in association with arachidic acid; crystallises from alcohol in white flocks of silky lustre, which become scaly and show nacreous lustre when pressed between filter-paper; sparingly soluble in cold alcohol, dissolves readily in benzene, ether, or carbon disulphide.

Methyl ester, m.p. 56·5°–57°.

Ethyl ester, m.p. 55°; distils without undergoing decomposition at 305°–310° under a pressure of 15–20 mm.

II. ACIDS OF THE ACRYLIC OR OLEIC SERIES, $C_nH_{2n-2}O_2$.

These acids absorb two atoms of halogen from Huebl's or Wijs' iodine solution. By means of hydrogen, in the presence of a catalyst, they are readily reduced to the corresponding acids of the acetic series. By oxidation with a dilute solution of potassium permanganate in alkaline solution, the unsaturated acids are converted into the corresponding saturated hydroxylated acids (*v. infra*). On melting with caustic alkalis, they are broken up into lower acids; thus oleic acid yields palmitic, acetic, and other acids. During this reaction, a migration of the double linkage takes place. Some of the higher acids, notably oleic and erucic acids, are changed into crystallisable isomerides when treated with a small quantity of nitrous acid at the ordinary temperature, or with sulphurous acid or bisulphites at high temperatures and under pressure.

The unsaturated acids are more readily soluble in alcohol than the saturated acids having the same number of carbon atoms. The lead salts of these acids are readily soluble in ether, with the exception of erucic acid which dissolves with difficulty only in cold ether.

Ozone is readily assimilated by oleic acids, forming perozonides, which are easily converted into the more soluble ozonides (*see* Lewkowitsch, Chem. Techn. [i.] 142).

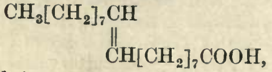
The action of concentrated sulphuric acid or anhydrous zinc chloride on the higher members of this series is a very complicated one (*v. infra* and also SAPONIFICATION).

Tiglic acid, $C_5H_8O_2$ (an isomeride of angelic acid), occurs in croton oil; crystallises in triclinic columns, melting at 64·5°, and boiling at 198·5° under ordinary pressure; sp.gr. 0·9641 at 76°.

Hypogaeic acid, $C_{16}H_{30}O_2$, occurs naturally in arachis oil. It has been prepared synthetically from stearolic acid and crystallises in needles melting at 33°–34°, boiling at 236° under a pressure of 15 mm., and at 230° under a pressure of 10 mm. By nitrous acid it is converted into *gaïdic acid*.

Oleic acids. Theory predicts a number of different 'oleic acids,' according to the position which the doubly linked carbon atoms occupy in the molecule, quite apart from stereo-isomerides obtained by the action of nitrous acid on the several 'oleic acids.' Here only the more important members of this group can be described.

(*a*) **Ordinary Oleic acid**



$$\begin{array}{l}\mathrm{CH_3[CH_2]_7CH}\\ \qquad\quad\|\\ \qquad\quad\mathrm{CH[CH_2]_7COOH,}\end{array}$$

is found in most vegetable and animal fats, especially in the liquid ones, in combination with glycerol. Pure oleic acid is best prepared from tallow (which practically does not contain any less saturated acids than oleic acid), by saponifying with caustic potash, precipitating the soap solution with lead acetate, and extracting the dried lead salt with ether. The dissolved lead salt is decomposed by hydrochloric acid under ether, the liberated acid dissolved in ammonia, and the solution precipitated by barium chloride. The barium salt is dried, dissolved in hot alcohol, and the hot solution allowed to crystallise. The crystallised salt is decomposed either by strong mineral acid or by tartaric acid. The acid so prepared still contains some palmitic and stearic acids, owing to the solubility of the lead salts of the solid acids in the ethereal solution of lead oleate.

Pure oleic acid is a colourless liquid free from odour. It crystallises in the form of needles, solidifying at 4°, and melting at 6·5°; an allotropic form melts at 16°. Sp.gr. 0·898 at 14°; or 0·8908 at 11·8°/4, 0·898 at 15°, 0·895 at 20°, 0·889 at 30°, 0·875 at 50°, 0·854 at 78·4°.

On distilling oleic acid under ordinary pressure, it is partially broken up into water, and into carbonic, acetic, caprylic, and capric acids; at the same time, sebacic acid and hydrocarbons are formed. In a current of superheated steam, however, it passes over unchanged at a temperature of about 250°. This is, indeed, the method by which oleic acid is prepared on a manufacturing scale in candle-works. It is insoluble in water, dissolves readily in cold alcohol, even if the alcohol be somewhat dilute. On adding large quantities of water to the alcoholic solution, the acid is thrown out.

Nitrous acid at the ordinary temperature converts oleic acid into elaïdic acid. The same change takes place when the acid is treated with sodium bisulphite under pressure at 175°–180°, or with sulphurous acid, under pressure, at 200°. The change, however, is not complete, as the reaction is a reversible one.

On blowing air through oleic acid at 120° for 2, 4, 6, and 10 hours, the author obtained respectively 0·62, 2·6, 3·5, and 6 p.c. of 'oxidised' acids, insoluble in light petroleum (*v. infra*); the specific gravities of the products rose in the same order from 0·8980 to 0·9098, 0·9121, 0·9123, and 0·9238 respectively. Similarly, on digesting oleic acid with sulphur at a temperature between 130° and 150°, sulphur is absorbed, without evolution of sulphuretted hydrogen; apparently an addition-product is formed. At higher temperatures, from 200°–300°, sulphuretted hydrogen is evolved.

Oleic acid dissolves in concentrated sulphuric acid in the cold, and forms stearic-acid-hydrogen sulphate, $C_{18}H_{35}(SO_4H)O_2$; on boiling this product with water, sulphuric acid is split off and ι-hydroxystearic acid is formed conjointly with a small quantity of stearolactone (Geitel), (*see* SAPONIFICATION). A similar change takes place on heating oleic acid with zinc chloride to 185°. By the catalytic reduction of oleic acid with hydrogen, oleic acid is converted quantitatively into stearic acid (*see* Lewkowitsch, J. Soc. Chem. Ind. 1908, 489).

Sodium oleate, $NaC_{18}H_{33}O_2$. The pure salt is prepared by crystallisation from absolute alcohol (not from dilute alcohol). It dissolves in 10 parts of water at 12°, or in 20·6 parts of alcohol, sp.gr. 0·821 at 13°. It also dissolves in 100 parts of boiling ether. The anhydrous salt melts at 232°–235°.

Potassium oleate, $KC_{18}H_{33}O_2$, forms a transparent, jelly-like mass, which is far more readily soluble in water, alcohol, and ether than the sodium salt. One part of the salt requires for complete solution 4 parts of water, or 2·15 parts of alcohol, or 29·1 parts of boiling ether.

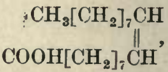
Ammonium oleate, $NH_4C_{18}H_{33}O_2$, forms 'liquid crystals.'

The metallic oleates are mostly soluble in alcohol, benzene, chloroform, carbon tetrachloride, carbon disulphide, nitrobenzene, pyridine, or light petroleum; some oleates are also soluble in ether.

Methyl ester, sp.gr. 0·879 at 18°; boils under a pressure of 15 mm. at 212°–213°.

Ethyl ester, sp.gr. 0·871 at 16°.

(*b*) **Elaïdic acid**



$$\begin{array}{l}\qquad\mathrm{CH_3[CH_2]_7CH}\\ \qquad\qquad\qquad\|\\ \mathrm{COOH[CH_2]_7CH}\end{array}$$

, discovered by Boudet (1832), is obtained by allowing nitrous acid fumes, or a nitrite and nitric acid, to act on oleic acid at the ordinary temperature; after a short time, the oleic acid is changed into its stereoisomeride, elaïdic acid. The separation of elaïdic acid from the unchanged oleic acid is readily effected by crystallisation from alcohol or ether, or by separating the lead salts by means of ether or benzene. It crystallises from alcohol in plates, melting at 44·5°; sp.gr. 0·8505 at 79·4°/4°. It can be converted, in its turn, into ordinary oleic acid by boiling iodostearic acid, prepared from elaïdic acid, with alcoholic potash; simultaneously some '*iso*öleic' acid is formed.

(*c*) ***iso*Oleic acid (Para-oleic), Solid Oleic acid**, was described as an individual acid by M., C., and A. Saytzeff and was prepared by distilling ι-hydroxystearic acid under diminished pressure, when a mixture of ordinary oleic and '*iso*öleic' acids, together with some unchanged hydrostearic acid, passed over.

The constitution $CH_3[CH_2]_{14}CH{=}CH{\cdot}COOH$ ascribed to this acid, has been shown to be erroneous. Arnaud and Pasternak (Compt. rend. 150, 1525) state that '*iso*öleic' acid is not an individual, but represents a mixture of several acids from which hitherto the ordinary 9 : 10-elaïdic acid, the ordinary 9 : 10-oleic acid, an 8, 9-elaïdic acid, and a hydroxystearic acid, $C_{18}H_{36}O_3$, could be isolated, but these acids do not yet exhaust the number of acids occurring in the mixture hitherto considered as '*iso*öleic' acid.

(*d*) **Rapic acid,** $C_{18}H_{34}O_2$, is the 'oleic acid' occurring in rape oil; it does not solidify on cooling nor does it yield a solid isomeride when acted upon with nitrous acid.

Erucic acid, $C_{22}H_{44}O_2$, discovered by Darby (1849), occurs in the oils belonging to the rape oil group. The acid crystallises from alcohol in long fine needles. Erucic acid simulates in its properties ordinary oleic acid; thus it is converted by nitrous acid into its stereoisomeride, *brassidic acid*; it is reduced by suitable treatment to the saturated behenic acid. On being melted with caustic potash, it splits up into acetic and arachidic acids.

'*isoErucic*' acid is obtained by boiling iodobehenic acid with alcoholic potash. No doubt this acid like *iso*öleic acid will be found to consist of a mixture of acids.

III. Acids of the Linolic Series, $C_nH_{2n-4}O_2$.

The acids belonging to this series are characterised by their property of absorbing four atoms of halogen, or two molecules of iodochloride. Hence these acids must be looked upon as containing two pairs of doubly-linked carbon atoms. They readily absorb oxygen on exposure to the air; this important property is made use of in the arts (*Drying oils*). They assimilate two molecules of ozone. On oxidation with potassium permanganate solution in the cold they yield tetrahydroxylated acids (*v. infra*). Nitrous acid does not convert them into solid isomerides. By suitable treatment with hydrogen they are converted into acids of the saturated series. It appears, therefore, that the acids belonging to this series are open chain acids.

Linolic acid, $C_{18}H_{32}O_2$, occurs in considerable proportions in drying and semi-drying oils. Pure linolic acid was obtained by saponifying its methyl ester. The acid is a colourless oily liquid, sp.gr. 0·9026 at 18°. On brominating linolic acid, a crystalline tetrabromide $C_{18}H_{32}O_2Br_4$, melting at 114°–115°, is obtained. On oxidising linolic acid with a dilute solution of potassium permanganate in the cold, tetrahydroxystearic (sativic) acid, $C_{18}H_{36}O_6$, melting at 173°, is formed. According to Erdmann and Bedford, there exist an α- and a β-linolic acid, the latter of which yields a liquid tetrabromide. The formation of the crystalline tetrabromide permits of the detection and also approximate quantitative determination of linolic acid.

Several other 'linolic acids' differing from the ordinary linolic acid by their yielding different tetrabromides and tetrahydroxystearic acids have been described. Thus *telfairic acid* yields a tetrabromide, melting at 57°–58°, and a tetrahydroxystearic acid, melting at 177°.

Elaeomargaric acid, $C_{18}H_{32}O_2$
$CH_3[CH_2]_3CH : CH[CH_2]_2CH : CH[CH_2]_7COOH$ (*Majima*), crystallises in rhombic plates, melting at 43°–44°. It absorbs oxygen readily from the air and is thereby converted into a resinous mass. In an alcoholic (or ethereal) solution the acid remains unchanged if protected from light. On exposure to light, however, crystals melting at 71° are deposited from the alcoholic solution. These crystals have the same composition as elaeomargaric acid. According to Maquenne, the higher melting acid, termed by Cloëz elaeostearic acid, is a stereoisomeride of elaeomargaric acid, and stands to it in the same relationship as does elaïdic acid to oleic acid. On bromination it yields a tetrabromide, which is identical with the solid tetrabromide obtained from linolic acid. On oxidising elaeomargaric acid with potassium permanganate, Kametaka obtained dihydroxystearic acid, and also azelaïc acid and an unknown crystalline substance melting at 123°–125°, soluble in water and alcohol, but insoluble in ether.

IV. Acids of the Cyclic (Chaulmoogric) Series: $C_nH_{2n-4}O_2$.

The acids belonging to this group are cyclic compounds and therefore contain only one pair of doubly-linked carbon atoms; hence they absorb only two atoms of halogen. The acids are also remarkable on account of their property of rotating the plane of polarised light.

Hydnocarpic acid, $C_{16}H_{28}O_2$, was isolated from the mixed fatty acids of hydnocarpus oil by crystallisation from alcohol. It is sparingly soluble in the usual organic solvents in the cold, with the exception of chloroform, in which the acid is easily soluble; $[\alpha]_D + 68{\cdot}1°$. On keeping, the acid becomes yellow, the melting-point, at the same time, being lowered; on distilling under diminished pressure, a brown resinous substance is left in the distilling flask.

Chaulmoogric acid, $C_{18}H_{32}O_2$, was prepared from the mixed fatty acids of chaulmoogra oil by crystallisation from light petroleum, subsequent distillation under diminished pressure and recrystallisation from alcohol. The crystals form colourless, glistening leaflets; $[\alpha]_D + 62{\cdot}1°$.

V. Acids of the Linolenic Series: $C_nH_{2n-6}O_2$.

The acids of this series assimilate six atoms of hydrogen, or three molecules of iodochloride. They are therefore assumed to contain three pairs of doubly-linked carbon atoms. They readily absorb oxygen from the air, a property of which extensive use is made in the arts (*Drying oils*). According to Molinari, they absorb three molecules of ozone. By treatment with hydrogen in the presence of a catalyst, linolenic acid is converted into stearic acid.

Linolenic acid, $C_{18}H_{30}O_2$,
$CH_3{\cdot}CH_2{\cdot}CH{:}CH{\cdot}CH_2{\cdot}CH{:}CH{\cdot}CH_2CH{:}CH[CH_2]_7CO_2H$ occurs in notable quantities in the drying oils, especially in linseed oil. According to Erdmann there exist two linolenic acids, α- and β-linolenic acid, of which the α-linolenic acid gives a crystalline hexabromide, melting at 179°. On reducing this crystalline hexabromide and again brominating the reduced linolenic acid, only 23 p.c. of the crystalline hexabromide is obtained, whence Erdmann and Bedford conclude that the reduced acid consists of a mixture of two, α- and β-linolenic, acids. The isolation and determination of the crystalline hexabromide is made use of in the analytical examination of drying oils (*v. infra*).

Pure α-linolenic acid is a colourless liquid of sp.gr. 0·9046; on exposure to the atmosphere it absorbs oxygen rapidly and increases thereby in sp.gr. The iodine value of the pure acid corresponds to that demanded by theory. On oxidising linolenic acid, a hexahydroxystearic acid (linusic acid), m.p. 203°–205°, is obtained.

***iso*Linolenic acid**, $C_{18}H_{30}O_2$. The existence of this acid was inferred by Hazura from the fact that he obtained on oxidising the mixed linseed oil acids with potassium permanganate an isomeride of linusic acid, termed *iso*linusic acid. This second hexahydroxy acid melts at 173°–175°. The existence of *iso*linolenic acid is doubtful.

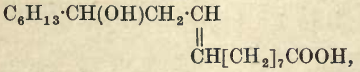
VI. ACIDS OF THE CLUPANODONIC SERIES: $C_nH_{2n-8}O_2$.

Clupanodonic acid, $C_{18}H_{28}O_2$, has been prepared from its octobromide by reduction with zinc and alcoholic hydrochloric acid. It is a pale yellow liquid having a fishy smell. The acid is characteristic of all fish, liver, and blubber oils. The most important derivative of this acid is the octobromide which permits the isolation of clupanodonic acid from a mixture of fatty acids and thus the recognition of fish, liver, and blubber oils (*v. infra*). The octobromide is insoluble in the usual organic solvents; it is only slightly soluble in hot benzene. It does not melt below 200°, but begins to blacken above this temperature.

VII. ACIDS OF THE RICINOLEIC SERIES: $C_nH_{2n-2}O_3$.

The acids belonging to this series are best characterised as 'oleic' acids in which one atom of hydrogen is replaced by a hydroxyl group. The most important representative of this series is :—

Ricinoleic acid, $C_{18}H_{36}O_3$



$$\begin{array}{l} C_6H_{13}{\cdot}CH(OH)CH_2{\cdot}CH \\ \qquad\qquad\qquad\qquad \| \\ \qquad\qquad\qquad\quad CH[CH_2]_7COOH, \end{array}$$

discovered by Bussy and Lecanu in castor oil.

Pure ricinoleic acid is miscible with alcohol and ether in every proportion. The acid contains an asymmetric carbon atom; hence it is optically active: $[\alpha]_D + 6{\cdot}25°$ to $+7{\cdot}5°$ (in acetone solution). On standing, the acid becomes spontaneously polymerised to form polyricinoleic acids, which are easily re-converted into ricinoleic acid by boiling with alcoholic potash and acidification of the soap. Ricinoleic acid assimilates two atoms of bromine or one molecule of iodochloride. The bromide is liquid. By hydrogen, in the presence of a catalyst, it is converted into hydroxystearic acid. The acid does not absorb oxygen on exposure to air. On treatment with ozone, it absorbs four atoms of oxygen, forming a perozonide.

By oxidation with an alkaline solution of potassium permanganate in the cold, two hydroxyl groups are assimilated with formation of trihydroxystearic acid. The statement by Hazura and Gruessner that two isomeric trihydroxystearic acids are formed and that consequently castor oil contains two isomeric acids, viz. ricinoleic and *iso*ricinoleic acids, is open to grave doubts (*see* Lewkowitsch, Chem. Techn. [i.] 165).

For the complicated reaction taking place on treating ricinoleic acid with concentrated sulphuric acid, *cp.* Lewkowitsch, *l.c.* On subjecting ricinoleic acid to dry distillation, optically active hydrocarbons are obtained.

Ricinelaïdic acid is formed by treating ricinoleic acid with nitrous acid. It also is optically active; $[\alpha]_D + 6{\cdot}670°$ (in absolute alcohol). The acid crystallises in needles, melting at 52°–53°.

VIII. DIHYDROXYLATED ACIDS: $C_nH_{2n}O_4$.

Dihydroxystearic acid $C_{18}H_{36}O_4$. Only one dihydroxystearic acid has been found hitherto in a natural oil; it occurs to the extent of about 1 p.c. in castor oil. The acid is insoluble in ether, petroleum ether, and benzene, slightly soluble in cold toluene, more so in the hot solvent; it dissolves in boiling alcohol and boiling acetic acid. Reducing agents readily convert it into stearic acid.

IX. DIBASIC ACIDS, ACIDS OF THE SERIES $C_nH_{2n-2}O_4$.

Three dibasic acids belonging to this series have been isolated from Japan wax by fractionating its insoluble mixed fatty acids *in vacuó*. The best known of the three acids is :—

Japanic acid, $C_{21}H_{40}O_4$, which appears to form, together with palmitic acid, a mixed glyceride. The acid crystallises from alcohol and chloroform in white laminæ; it is heavier than water; it dissolves very sparingly in water.

In addition to the above naturally occurring fatty acids, there are found in various products of the fat industries several hydroxylated acids or their inner anhydrides. These hydroxylated acids belong to the same series as the dihydroxylated, trihydroxylated, tetrahydroxylated, and hexahydroxylated acids obtained respectively from oleic, ricinoleic, linolic, and linolenic acids by oxidation with potassium permanganate in the cold. These acids are of great importance for the identification of the unsaturated fatty acids from which they have been derived.

A full description of these acids exceeds the limits of this article, all the more so as quantitative methods for their determination still require to be worked out. It must suffice, therefore, to refer to Chapters III. and VIII. of Lewkowitsch's Chem. Techn., and to the tables, p. 777, detailing briefly the properties of the more important hydroxylated acids and of their acetylated products. The second table shows that the hydroxylated acids are best characterised by their notable acetyl values.

The methods applicable to the examination of fatty acids divide themselves naturally into (*a*) physical methods; (*b*) chemical methods.

(*a*) PHYSICAL METHODS.

The physical methods, embracing the determination of the specific gravity, refractive index, rotatory power, and solubility, are applied in the same manner as described above for the glycerides.

Acid	Formula	Melting-point °C.	Solubility of the acid in					Obtained from
			Water		Alcohol		Ether	
			Cold	Hot	Cold	Hot		
α-Hydroxystearic	$C_{18}H_{35}O_2(OH)$	81–81·5	insoluble	insoluble	sparingly soluble	soluble	sparingly soluble	oleic; elaïdic acid
α-Hydroxystearic	$C_{18}H_{35}O_2(OH)$	77–79	insoluble	insoluble	sparingly soluble	less soluble than 1:10 acid	more soluble than 1:10 acid	'*iso*oleic' acid
Dihydroxy-stearic	$C_{18}H_{34}O_2(OH)_2$	137	insoluble	insoluble	sparingly soluble	soluble	sparingly soluble	ordinary oleic acid
Sativic . .	$C_{18}H_{32}O_2(OH)_4$	173	insoluble	sparingly soluble	sparingly soluble	soluble	insoluble	linolic acid
Linusic . .	$C_{18}H_{30}O_2(OH)_6$	203–205	sparingly soluble	soluble	sparingly soluble	sparingly soluble	insoluble	linolenic acid
*iso*Linusic .	$C_{18}H_{30}O_2(OH)_6$	173–175	sparingly soluble	readily soluble	soluble	soluble	insoluble	*iso*linolenic acid

Acid	Formula	Acetylated acid				Increase in weight on acetylating
		Formula	Molecular weight	Acetyl value	Saponification value	Per cent.
Hydroxystearic . . .	$C_{18}H_{35}O_2(OH)$	$C_{18}H_{35}O_2(O{\cdot}C_2H_3O)$	342	164·0	328·0	14·00

Hexahydroxystearic (linusic)	$C_{18}H_{30}O_2(OH)_6$	$C_{18}H_{30}O_2(O{\cdot}C_2H_3O)_6$	632	532·5	621·3	66·31

More important than the determination of the solidifying and melting points of the glycerides is the determination of the solidifying point of the fatty acids, as valuable information of a discriminative nature can be obtained therefrom.

The *solidifying point of the fatty acids* forms the basis of the commercial valuation of such fats as tallow, bonefat, palm oil, and other vegetable fats. This number is known in commerce as 'titre test' and denotes the solidifying point taken under exactly determined conditions (*v. infra*).

The solidifying point is not a physical constant, inasmuch as it depends on the rate of cooling of a definite quantity examined under certain conditions; hence it is obvious that by varying these conditions, different results will be obtained. For commercial purposes, it is therefore most essential that a certain *modus operandi* be adhered to as strictly as possible. The mode of procedure proposed by Dalican has been adopted in this country, in the United States, and in France. This method has proved itself reliable in the author's own experience, extending over a great number of years. Fifty grams of the fat under examination are saponified, the separated fatty acids are freed from water and finally filtered through a dry plaited filter into a porcelain dish. The fatty acids are allowed to solidify and to stand overnight under a desiccator. (At the seventh International Congress, it was agreed that in those cases where rapidity in obtaining a result was of greater importance than strictest accuracy, the fatty acids may be allowed to stand for a few hours only.) The fatty substance is carefully melted in an air-bath or over a free flame, and as much of it is poured into a test-tube, 16 cm. long and 3·5 cm. wide, as will fill the tube more than half full. The tube is then fastened by means of a cork into a wide-mouthed bottle, 10 cms. wide and 13 cms. high, and an accurate thermometer (graduated in tenths of degrees from about −5° to +60°, having a mercury bulb about 3 cms. long and 6 mm. in diameter, and carefully standardised with the aid of a 'normal thermometer'), is inserted in the fatty acids, so that the bulb is in the middle of the mass. When a few crystals appear at the bottom of the tube, the mass is stirred by giving the thermometer a rotary movement, first three times from right to left, and then three times from left to right. Next stir continually, with a quick circular movement of the thermometer, without allowing it to touch the sides of the vessel, and taking care that all solidified portions, as they form, are well stirred into the mass until the latter has become cloudy throughout. The thermometer should now be observed carefully. A good plan is to write down the temperature at short intervals. At first the mercury will continue to fall, or at least remain stationary, then it will rise suddenly some tenths of a degree and reach a maximum, remaining stationary thereat for some little time before it falls again. This point is called the 'titre' or solidifying point of the mixed fatty acids. In the case of dark coloured fats, it may be impossible to observe the separation of crystalline matter. In such cases, it is best to make a preliminary experiment which affords the necessary guidance.

In Germany, Austria, and in the United States, slightly different methods of operating have been proposed (*see* Lewkowitsch, [i.] 406–408), but as Dalican's method has been made the basis of commercial transactions in this country, the United States, and France, new proposals for determining the 'titre,' however acceptable they may appear, have little chance of superseding the established method. The following table gives a list of titre tests collated from a very large number of observations made by the author.

TITRE TESTS OF MIXED FATTY ACIDS (Lewkowitsch).

Class of oil	Kind of oil	Titre test °C.	Remarks
Drying oils	Linseed oil	20·6	
	Tung oil	37·2	
	Hemp seed oil	16·6

(*b*) *Chemical Methods.*

The chemical methods are arranged here in a logical order, so that the order of the description may serve at the same time as a guide in the technical examination. (For other methods, which involve strictly scientific examination, *see* Lewkowitsch, vol. I. Chap. XII.)

(1) Neutralisation Value—Mean Molecular Weight.

The neutralisation value indicates the number of milligrams of potassium hydroxide required to saturate one gram of the mixed fatty acids.

The determination of the neutralisation number is carried out in exactly the same manner as is described under the heading 'Acid Value.' As a rule, about 5 grams of the substance should be taken; smaller quantities should not be employed (if avoidable), as otherwise the errors of the method have too great an influence on the result. From the neutralisation number thus found, the mean molecular weight of the fatty acids can be calculated as follows: Let M be the molecular weight expressed in grams. Theory requires that M grams be neutralised by 56·1 grams of potassium hydroxide, KOH. Let n be the number of grams of potassium hydroxide found by experiment to neutralise 1 gram of fatty acids; then we have the proportion

$$M : 56{\cdot}1 :: 1 : n\text{; hence, } M = 56{\cdot}1/n.$$

n is found by multiplying the number found for 1 gram of fatty acid by 0·0561. If that number be a, we have

$$n = a \times 0{\cdot}0561.$$

By substitution we obtain

$$M = \frac{56{\cdot}1}{a \times 0{\cdot}0561} = \frac{1000}{a}.$$

The following table contains the theoretical molecular weights and calculated[1] neutralisation values of pure fatty acids; they will serve as a guide to the proper interpretation of results obtained in the practical examination of mixed fatty acids.

---

[1] For H = 1; O = 16; C = 12.

NEUTRALISATION VALUES OF FATTY ACIDS.

Acids	Formula	Molecular weight	Neutralisation value. Mgrms. KOH
Acetic	$C_2H_4O_2$	60	935·0
Butyric	$C_4H_8O_2$	88	637·5
Caproic	$C_6H_{12}O_2$	116	483·6
Caprylic	$C_8H_{16}O_2$	144	389·6
Capric	$C_{10}H_{20}O_2$	172	326·2
Lauric	$C_{12}H_{24}O_2$	200	280·5
Myristic	$C_{14}H_{28}O_2$	228	246·1
Palmitic	$C_{16}H_{32}O_2$	256	219·1
Stearic	$C_{18}H_{36}O_2$	284	197·5
Oleic	$C_{18}H_{34}O_2$	282	198·9
Linolic	$C_{18}H_{32}O_2$	280	200·4
Hydnocarpic	$C_{16}H_{28}O_2$	252	222·6
Chaulmoogric	$C_{18}H_{32}O_2$	280	200·4
Linolenic	$C_{18}H_{30}O_2$	278	201·8
Clupanodonic	$C_{18}H_{28}O_2$	276	203·2
Ricinoleic	$C_{18}H_{34}O_2$	298	188·3
Arachidic	$C_{20}H_{40}O_2$	312	179·8
Gadoleic	$C_{20}H_{38}O_2$	310	181·0
Erucic	$C_{22}H_{42}O_2$	338	166·0
Cerotic	$C_{26}H_{52}O_2$	396	141·7
Melissic	$C_{30}H_{60}O_2$	452	124·1
Hydroxystearic	$C_{18}H_{36}O_3$	300	178·0
Dihydroxystearic	$C_{18}H_{36}O_4$	316	177·6
Trihydroxystearic	$C_{18}H_{36}O_5$	332	169·0
Sativic	$C_{18}H_{36}O_6$	348	161·2
Linusic	$C_{18}H_{36}O_8$	380	147·6

(2) Lactones—Anhydrides.

If the fatty acids, instead of being titrated with aqueous alkali in the cold, were boiled with an excess of alcoholic potash (*see Saponification value*), the number of milligrams of potassium hydroxide thus required to saturate 1 gram of fatty acids should be the same as that found for the neutralisation value, provided the amount of unsaponifiable matter be negligible. In other words, the neutralisation and saponification values of fatty acids should be identical. In case, however, the fatty acids contain lactones, or anhydrides of the fatty acids, which do not combine with aqueous alkali in the *cold*, and are only hydrolysed on boiling with alcoholic potash, then the saponification value of the fatty acids will be higher than the neutralisation number.

The difference between saponification and neutralisation values furnishes a measure of the lactones or anhydrides present. The determination of lactones is of importance in the commercial examination of candle materials (*v.* Lewkowitsch, [i.] 422–423).

(3) Insoluble Fatty Acids.

Three to four grams of fat are saponified as described under *Saponification Value*, using, of course, double the amount of alcoholic potash stated there. The soap is dissolved in 100–150 c.c. of water (the alcohol is driven off completely until the soap has become pasty), acidified with dilute sulphuric acid and warmed until the liberated fatty acids float on the top as a clear oily layer. This is brought on to a filter-paper of about 4–5 inches diameter, previously dried at 100° and accurately weighed in a weighing bottle or a small beaker (covered with a watch-glass). The filter-paper should be of stout material, as ordinary filtering paper readily allows the liquid to run through turbid. A good plan to prevent this is to have the filter half full of hot water, before the fatty matter is transferred to it, and to keep it full until all the liquid is added. Finally, the fatty acids are washed on the filter with boiling water until a few c.c. of the wash-water do not redden sensitive tincture of litmus. In the case of fats belonging to the cocoa-nut oil or dika fat group, as also in the case of butter fat, 2000–3000 c.c. of wash-water are required. The washing being completed, the funnel with the filter is immersed in a vessel of cold water, so that the water outside and the acid inside are at the same level. The water is then allowed to drain off, the filter is transferred to the beaker in which it had previously been weighed, is dried at 100° for 2 hours, and weighed. The fatty matter is dried for another hour or an hour and a half, and weighed again. The difference between the two weights will, as a rule, be below 1 milligram.

Strictly concordant results are not obtainable by this method, as it entails a number of inherent errors, detailed consideration of which is required in each special case (see Lewkowitsch, Chem. Techn. [i.] 424).

Most oils and fats yield about 95 p.c. of insoluble fatty acids ; only those fats which are characterised by high Reichert values yield less than 95 p.c. It should be noted that the 'fatty acids' include the unsaponifiable matter, unless the latter has been removed from the soap solution. In the majority of cases, and especially in analyses of unadulterated fats for commercial purposes, the amount of unsaponifiable matter may be neglected.

(4) Volatile Fatty Acids.

A notable amount of volatile fatty acids is indicated by a definite Reichert-Meissl value of the glycerides, as also by a notable titration number of the insoluble volatile fatty acids. The approximate separation of the soluble volatile fatty acids has been described above. (For further details and the application of the method for the determination of the volatile fatty acids in the examination of butter fat and mixtures thereof with cocoa-nut oil and palm-kernel oil, *see* Lewkowitsch, [i.] 430).

(5) Separation of Insoluble Saturated from Unsaturated Fatty Acids.

The presence of unsaturated fatty acids in the mixed insoluble fatty acids is detected in the readiest manner by determining the iodine value of the mixed fatty acids ; this method offers an additional advantage in that it furnishes a measure of the unsaturated fatty acids, much as the iodine value of the oils and fats affords a measure of the unsaturated glycerides. The mixed fatty acids as obtained from the natural oils and fats will always have a definite iodine value.

The best—although still imperfect—method of separation is based on the solubility of the lead salts of the insoluble fatty acids in ether;

in this menstruum the lead salts of the solid fatty acids, if free from liquid acids, are almost insoluble. This method is best carried out in the following manner as worked out in the author's laboratory; it consists of a combination of the several modifications of the original Gusserow-Varrentrapp method, proposed by Muter and de Koningh, and by Lane:—

3 to 4 grams of fatty acids are neutralised in a 300 c.c. flask with 50 c.c. of approximately half-normal aqueous potash. In case the original oil or fat be employed, 3–4 grams are saponified in the usual manner with 50 c.c. of approximately half-normal alcoholic potash in a 300 c.c. flask. Phenolphthalein is added, the solution is slightly acidified with acetic acid, and finally titrated with alcoholic potash until neutral. The solution is then diluted with water to about 100 c.c., 30 c.c. of a 10 p.c. solution of lead acetate are diluted with 150 c.c. of water, heated to the boiling-point and gradually run into the soap solution with constant shaking. The flask, containing the lead soap, is filled completely with hot water, and then allowed to cool. When the liquid has become clear it is poured off through a filter. As a rule, the solution is so clear that no solid particles will be found on the filter; should there be any, they must be brought back into the flask. The precipitate in the flask is washed thoroughly with boiling water, using the precaution of cooling the hot solutions before filtering, thus causing the lead salts to adhere to the sides of the flask. The last drops of water may be removed by means of a thin roll of filter-paper. It is not advisable to dry the lead salts, as in the case of drying oils they absorb oxygen from the air somewhat rapidly. Next, 150 c.c. of ether are added to the lead salts, and the flask is corked and shaken repeatedly, so that the salts may disintegrate. The flask is then attached to a reflux condenser and heated on a water-bath for some little time with frequent shaking. The lead salts of the liquid fatty acids dissolve readily in the hot ether, conjointly with some fractions of the salts of the saturated acids; undissolved salts, if any, settle out at the bottom of the flask as a fine powder. If all operations are conducted somewhat rapidly and unnecessary exposure to the air is avoided, working in an atmosphere of an inert gas can be dispensed with. The ethereal solution is then allowed to cool down to the ordinary temperature and the solution filtered through a plaited filter (kept covered with a watch-glass) into a separating funnel. The insoluble salts are brought on to the filter by washing the flask three or four times with ether, using 30 c.c. each time. The ethereal solution is then shaken with a mixture of one part of hydrochloric acid and four parts of water, in order to decompose the lead salts. The ether dissolves the free fatty acids as they are liberated, whilst the undissolved lead chloride settles out at the bottom of the separating funnel. After separation into two layers has taken place, the acid liquid is drawn off and the ethereal layer is washed with small quantities of water until the wash-water is free from acid. Finally, the ethereal solution is filtered through a small plaited filter into an ordinary flask. In case the liquid fatty acids consist chiefly of oleic acid, the results will be sufficiently accurate, if the ether be evaporated off on the water-bath and the residue dried in a water-oven. If, however, the presence of less saturated fatty acids (from linseed, soya bean, maize, marine animal oils) than oleic is suspected, the ethereal solution should be distilled off in a current of dry hydrogen or dry carbon dioxide. The flask is then immersed up to the neck in warm water, which is finally brought to the boiling-point. Thus the last traces of moisture are removed.

On the filter there remain the lead soaps of the saturated fatty acids which are decomposed by treatment with hydrochloric acid, so that the saturated fatty acids can be recovered and further examined. The determination of the iodine value of the liquid fatty acids will furnish an approximate indication of the composition of the liquid fatty acids.

(6) Separation and Determination of Individual Saturated Fatty Acids.

In the present stage of our knowledge only the following solid acids can be determined with approximate accuracy.

Arachidic acid.—The solid fatty acids obtained from 10 grams of oil by the lead-salt-ether method are dissolved in 50 c.c. of 90 p.c. alcohol. In the presence of arachidic acid, a crystalline mass separates out from the cooled solution. This consists, in the case of arachis oil, of a mixture of arachidic and lignoceric acids. The crystals are filtered off and washed on the filter, first with a measured quantity of 90 p.c. alcohol, then of 70 p.c. (by volume) alcohol which dissolves but small quantities of the crude arachidic acid. The crystals are finally dissolved by pouring boiling absolute alcohol on the filter. The filtrate is received in a porcelain dish or in a flask, evaporated to dryness, and the residue is weighed. To the weight of crude arachidic acid thus found, the quantity dissolved by the 90 p.c. alcohol used for washing (taking as basis for calculation that 100 c.c. dissolve 0·0022 gram at 15°, or 0·045 gram at 20°) is added. Finally, the melting-point of the crude arachidic acid is determined. This should be from 71° to 72° (*cf.* Lewkowitsch, Chem. Techn. [ii.] 253).

Stearic acid.—The determination of stearic acid is based on the principle stated by David, that on treating mixed fatty acids with an alcoholic solution of pure stearic acid saturated at 0°, all the lower saturated fatty acids as also the unsaturated fatty acids are dissolved, whereas stearic acid remains undissolved.

It should be noted that if any arachidic acid be present as well as stearic acid, the separated acid consists of a mixture of the two. In such cases, it is advisable first to separate off the arachidic acid by the method described above.

David's principle has been worked out by Hehner and Mitchell to a method which yields in many cases, but not in every case, reliable results (*cf.* Lewkowitsch, [i.] 452).

The stearic acid solution is prepared by dissolving about 3 grams of pure stearic acid in 1000 c.c. of warm (methylated) alcohol of sp.gr. 0·8183 (containing 94·4 p.c. of alcohol by volume) in a stoppered bottle. The bottle is immersed up to the neck in ice-water (kept in an ice-chest well protected against radiation of heat), and allowed to stand in the ice-water overnight. After 12 hours, the mother liquor is siphoned off without removing the flask from the ice-water, by means of a small thistle funnel immersed in the alcoholic solution and covered with a piece of fine calico (so as to retain the separated stearic acid crystals in the flask). The funnel is twice bent at right angles, and is best fitted into a suction bottle, so that the clear liquor can be drawn off by means of a filter-pump. The method is carried out as follows: 0·5 gram to 1 gram of the mixed fatty acids, if solid, or 5 grams if liquid, are weighed accurately in a flask and dissolved in 100 c.c. of the above alcoholic stearic acid solution. The flask is placed in ice-water overnight, the mixture is agitated the following morning while the flask is still kept in the ice-water, and then allowed to stand for at least half an hour in the ice-water in order to promote crystallisation. The alcoholic solution is then filtered off as described above, care being taken to draw off the solution as completely as possible. The residue in the flask is washed three times in succession with 10 c.c. of the alcoholic stearic acid solution, previously cooled down to 0°. The crystals adhering to the calico of the thistle funnel are then washed with hot alcohol into the flask, the alcohol is evaporated off, the residue dried at 100° and weighed. In case the melting-point be much below 68·5°, the author considers it necessary to treat the residue once more as described above. A correction of 0·005 gram should be made for the stearic acid retained on the walls of the flask and in the adhering stearic acid solution.

(7) Detection, Separation, and Approximate Determination of Individual Liquid Fatty Acids —Oleic, Linolic, Linolenic, Clupanodonic.

The liquid fatty acids are separated from the total mixed fatty acids by the lead-salt-ether method; thus preliminary information is obtained as to which fatty acids may be present. In the present state of our knowledge, attention can only be directed to the detection and determination of oleic, linolic, linolenic, and clupanodonic acids. If the iodine value be found to lie in the neighbourhood of 90, the liquid fatty acids may be considered as consisting of practically pure oleic acid. If the iodine value be much higher than in the case of the majority of pure vegetable oils, the presence of linolic and linolenic acids must be suspected; in the case of oils, belonging to the marine animal oils, the presence of clupanodonic acid must be expected: in the case of mixtures, of course, the presence of all these acids has to be assumed.

The presence of linolenic and (or) clupanodonic acids, is ascertained by the bromide test, which permits at the same time of a quantitative determination of the insoluble bromides. The bromination test can be applied to the original mixed fatty acids without it being required to separate the solid from the liquid acids. The mixed fatty acids are brominated in the same manner as already described in the bromide test: 0·3 grams of the fatty acids are dissolved in glacial acetic acid, and the solution is cooled in a corked flask to 5°. The further treatment is identical with that described above (*Bromide test*). The ether-insoluble bromo derivatives consist either of octobromide or of hexabromide, or of a mixture of both. If the melting-point of the insoluble bromides lies between 175°–180°, linolenic hexabromide derived from a drying oil has been obtained. If the bromide has not melted at 180° or not completely melted, and blackens on heating to 200° or above, then an octobromide, characteristic of a marine animal oil, is present. If a mixture of hexabromides and octobromides be suspected, the bromides are separated by boiling with benzene in which the octobromides are insoluble (*cp.* Lewkowitsch, [i.] 462). Recent researches (unpublished), made by the author, prove that it is not permissible to calculate the amount of hexabromides to drying oil, as not only a certain amount of hexabromides remains dissolved, but also because liquid isomerides of hexabromides appear to be formed.

The filtrate from the octobromides and (or) hexabromides contains in addition to some dissolved hexabromides, tetrabromides and dibromides; the former can be isolated by evaporating off the ether and treating the residue with boiling light petroleum. On cooling crystals separate out which represent, in most cases, a mixture of hexabromides and tetrabromides and exhibit melting-points lying between 170° and 136°. Thus the author found in linseed oil fatty acids after separating off, 39·37 p.c. of hexabromides of m.p. 181°, 3·09 p.c. of bromides, m.p. 151°; 7·83 p.c. of bromides, m.p. 142°, and 2·38 p.c. of bromides, m.p. 135°–136°. By repeating the treatment with ether and by renewed re-crystallisation from boiling petroleum ether, tetrabromides of the approximately correct melting-point of pure crystalline linolic tetrabromide, viz. 114°, can be obtained.

The following table contains the amounts of insoluble bromides found in the mixed fatty acids from vegetable and oils marine animal oils.

——	Kind of oil	Yield of ether-insoluble bromide from fatty acids per cent.
Hexa-bromides	Linseed (iodine value 181)	29·06; 29·34
	,, (,, ,, 184)	31·31; 30·44; 30·80
	,, ,, ,, 190·4)	38·1; 42·0
	,, liquid acids (iodine value 208)	34·9
	Candle nut	11·53; 11·23; 12·63
	Stillingia	25·78
	Safflower	1·65; 0·65
	Soya bean	5·1
	Rape	2·4; 3·4
Octo-bromides	Japan fish (old sample)	23·04; 23·32
	,, (fresh samples)	44·2; 47·1
	Deodorised fish	38·42; 39·27
	Cod liver, Norwegian	29·86; 30·36
	Newfoundland cod	39·1; 37·76
	Shark liver	12·68; 15·08
	Seal	19·83; 19·93
	Whale (old sample)	12·38; 12·44
	,, (fresh samples)	22·59; 27·77
	Herring	12·7; 21·7

In the case of semi-drying oils, which are practically free from linolenic acid and contain considerable amounts of linolic acid, the bromination can be carried out in light petroleum when linolic tetrabromide of the melting-point, 112°–113°, can be obtained readily. In this case also, isomeric, soluble bromides, especially if an excess of bromine had been used, are formed, so that the weight of the tetrabromides is much (by 50 p.c.) below the actual amount of linolic acid present. The following tables contain a number of determinations carried out in the author's laboratory.

Oil	Linolic acid calculated from separated tetrabromide
Soya Bean oil . .	21 p.c.
Maize oil . . .	28 ,,
Cotton seed oil . .	21–24 ,,
Sesamé oil . . .	15·6–16·4 ,,

(8) Determination of Oxidised Fatty Acids.

Under the term 'oxidised' acids, the author comprises a class of fatty acids occurring in those oils and fats which have been treated with oxidising agents, as in the process of blowing with air or oxygen. The change which some of the unsaturated acids undergo is not yet fully understood, but this much is certain, that through 'blowing' or 'oxidising,' a certain proportion of acids are obtained which are characterised by their insolubility in light petroleum.

The quantitative determination of oxidised acids is carried out by Fahrion's method as follows: 4 to 5 grams of the sample are saponified in the usual manner with alcoholic potash; the alcohol is evaporated off, the soap is dissolved in hot water, transferred to a separating funnel, and decomposed with hydrochloric acid. After cooling, the liquid is shaken with light petroleum (boiling below 80°) and allowed to stand until it has separated completely into two clear layers. The insoluble oxidised fatty acids will be found to adhere to the sides of the funnel or form a sediment in the petroleum layer. The aqueous layer is drawn off, the petroleum layer poured off, if necessary through a filter, and the oxidised acids are washed with light petroleum to remove adhering ordinary fatty acids. In case the amount of oxidised fatty acids be large, it is advisable to dissolve them in alkali, decompose the soap with hydrochloric acid, and shake out again with petroleum, so as to remove completely any occluded soluble fatty acids. The oxidised acids are then dissolved in warm alcohol or ether, the alcoholic or ethereal solution is transferred to a tared basin, the alcohol or ether is evaporated off, and the residue dried until the weight remains constant. Thus the proportion of oxidised acids is found. (For further information, *cp.* Lewkowitsch, [i.] 469; [iii.] 134.)

III. Examination of the Unsaponifiable Matter.

The unsaponifiable matter is isolated in substances as described above and can be immediately examined further. In case a sample under examination has not been adulterated with mineral oil, rosin oil or tar oil, the amount of unsaponifiable matter will, as a rule, be very small. As stated already, the unsaponifiable matter consists chiefly of sterols; in the case of vegetable oils of *phytosterol* (mostly *sitosterol*); and in the case of animal oils and fats of *cholesterol*.

In addition to sitosterol, there has also been found in a number of vegetable oils, *stigmasterol*; and in rape oil, *brassicasterol*. The last two phytosterols cannot be considered here (*cp.*, however, Lewkowitsch, [i.] 208, 542).

The examination of the unsaponifiable matter furnishes, therefore, a means of distinguishing between vegetable and animal oils and fats. In case a mixture of both vegetable and animal products be present, a mixture of phytosterol and cholesterol is, of course, obtained.

For the examination of the unsaponifiable matter, the isolated substance is dissolved in the smallest possible amount of absolute alcohol and allowed to crystallise. If notable amounts of colouring matters and resinous substances are absent, as a rule well-defined crystals are obtained. Otherwise, the unsaponifiable matter must be dissolved in 95 p.c. alcohol and the solution decolorised by animal charcoal. The crystals should then be examined under the microscope. Cholesterol crystallises in the forms shown in Fig. 5, sitosterol in crystals shown in Fig. 6.

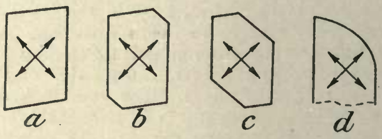

Fig. 5.

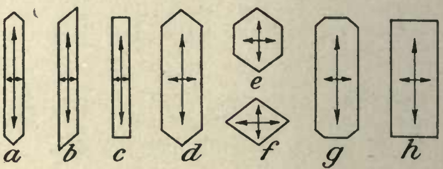

Fig. 6.

In the presence of both cholesterol and sitosterol, the microscopic examination furnishes very uncertain results (*cp.* Lewkowitsch, [i.] 472).

The uncertainty inherent in the microscopic test is removed by carrying out Boemer's phytosteryl acetate test.

Phytosteryl acetate test.—The alcoholic solution containing the crystals is brought to dryness on a water-bath, and the residue heated for 2 or 3 minutes in a small porcelain dish with acetic anhydride (2 to 3 c.c. per 100 grams of original oil or fat) over a small flame until the solution boils, the dish being covered with a watch-glass. The watch-glass is then removed, and the excess of acetic anhydride evaporated off on the water-bath. The contents of the dish are next heated with the smallest possible quantity of absolute alcohol; in order to prevent immediate solidification or crystallisation, a few c.c. of alcohol are added, when the mass is allowed to crystallise. By spontaneous evaporation, about one-half or one-third of the alcohol volatilises and the acetates crystallise out. The crystals are filtered off through a small filter, and washed with a little 95 p.c. alcohol. The acetates are brought back from the filter into the dish, dissolved in 5 to 10 c.c. of absolute alcohol, and again allowed to crystallise. The crystals are filtered off, and their melting-point is determined. Since cholesteryl acetate melts at 114·3°–114·8° (corr.), whereas crystals of sitosteryl acetate obtained from different oils and fats melt above 125°, the melting-point of the second crop of crystals will furnish *preliminary* information as to whether cholesterol only, or sitosterol only is present. Ultimate reliance should not, however, be placed on the melting-point of the second crop of crystals; for in most cases it is necessary to recrystallise the crystals at least three more times. If the melting-point of the fifth (or seventh) crop of crystals be found to lie below 115° or 116°, the absence of sitosterol can be pronounced with certainty. A gradual and distinct rise of the melting-points, above 114°, in the successive crops of crystals, is the best indication as to the procedure to be adopted.

This test is absolutely reliable, and superior to all other tests aiming at the detection of vegetable oils and fats in animal oils, such as the detection of cocoa-nut oil in butter fat or of vegetable fats and oils in lard. The sensitiveness of this test is so great that even 1 p.c. of an added vegetable oil or fat can be detected. This great sensitiveness has led to endeavours to circumvent and render illusory the indications of the phytosteryl acetate test by adding to fats adulterated with vegetable oils or fats, minute quantities of paraffin wax. For the determination of such added paraffin wax and the removal thereof, *see* Lewkowitsch, [i.] 477; [ii.] 592.

If large quantities of unsaponifiable substances have been admixed with an oil or fat—which is readily ascertained in the saponification test by obtaining an abnormally low saponification value—then fraudulent admixture with solid or liquid hydrocarbons may be considered as established. Solid hydrocarbons are recognised by their consistence and identified by their melting-points. Liquid unsaponifiable substances consist of hydrocarbons, belonging to one of the following three groups:—

(*a*) mineral oils, (*b*) rosin oils, (*c*) tar oils.

For the identification and approximate determination of these, *see* Lewkowitsch, Chem. Techn., [i.] 485.

The foregoing methods should enable the analyst to identify individual oils and fats and recognise them when mixed, and to determine approximately their relative proportion. In order to facilitate the problem, the following tables, arranged in the order of a practically natural system, should be consulted. For a number of examples which may be of assistance in the examination of complicated mixtures, cp. Lewkowitsch, [i.] chap. XI.

VEGETABLE
