Introduction

International Critical Tables is the result of the cooperative labors of a large number of specialists, each of whom has been charged with the responsibility for the critical compilation of the quantitative information available on his topic. The word "critical" in this connection means that the Cooperating Expert was requested to give in each instance the "best" value which he could derive from all the information available, together, where possible, with an indication of its probable reliability.

Through a cooperative arrangement with International Annual Tables, the Board of Editors has been able to place in the hands of each Cooperating Expert the literature references belonging to his topic for the years 1910-1923 inclusive, as compiled by the staff of International Annual Tables. For the period preceding 1910, each Cooperating Expert was directed to collect the necessary literature references from the various published handbooks, special treatises, works of reference, and other sources known to him as a specialist in the field. No attempt has been made to systematically cover the literature since 1923, although a certain amount of information published since then has been utilized.

In preparing the various sections, the Cooperating Experts were instructed,—

1. To include in the bibliography only *(a)* the sources of the data upon which their reported values actually rest, and (6) the sources of available data of the same kind pertaining to those systems for which no numerical value is given. It is not intended to be a complete bibliography of the field.
2. To omit from the tables of numerical data all those systems for which the available data (a) were of slight scientific or practical interest, or (o) were so discordant as to be of little, if any, value.
3. To set forth the results of their work in the form of text, equations, tables, graphs, or charts, as seemed most appropriate under the circumstances, having regard to the necessity of space economy.
4. To give only selected samples illustrating types in the case of very large and heterogeneous fields, such as colloids, chemical kinetics, and certain classes of industrial materials.
5. To restrict the accompanying explanatory text to the amount necessary for the intelligent use of the data. (Under this restriction, the Expert is given no opportunity to present a general discussion of his subject or of the methods by which he obtained the values given.)

In preparing the textual material for publication the Editors have been compelled, in the interest of economy of space, to enforce the restrictions imposed by sections 3 and 5 of the preceding paragraph and have freely rearranged and rewritten the text, whenever it was evident that a compression or an improvement in logical order could be so secured. With few exceptions, which are duly noted, the final form of the rewritten text was submitted to the Expert and was accepted by him.

In preparing the numerical data for publication the Editors have made no change except in their arrangement and in their mode of presentation. In making such changes the Editors have been guided by the necessity of saving space. The numerical data are in all cases those submitted by the Expert, excepting that (a) a few additional values, all duly indicated, have been inserted, and (b) when an Expert has submitted a number of values for the same nominal quantity, these have been grouped so as to make a single entry with an indication of the range covered by the values submitted, whenever such grouping seemed justifiable. In these cases, the final manner of grouping was in every case where possible submitted to and accepted by the Expert. The exceptional cases are noted as they occur.

Owing to the method of publication, *i.e.,* one volume at a time, a strictly logical arrangement of subject matter is not always followed. Among such a large number of Cooperating Experts a few instances of greatly delayed reports, arising from illness, accident, or other unforeseen causes, are to be expected; and certain sections or parts of sections, therefore, may not appear in their logical places but will be found in a later volume. The whole set of volumes is very completely indexed, however, and the user who consults the index should have no difficulty in locating any information given.

Chemical compounds are arranged in the tables by formula according to a definite system, called the " Standard Arrangement." This system is based upon a set of key numbers for the chemical elements and is fully explained in Volume One.

In order to find a given substance in the longer tables it is therefore necessary to know its chemical formula, at least approximately. If only the name is known, the formula, for most organic compounds or minerals, may be found with the aid of the name indices in Volume One, p. 174 and 280.

International Critical Tables of Numerical Data, Physics, Chemistry and Technology

Index

Volumes I - VII

INTRODUCTION

In order to facilitate the use of the Index to the seven volumes of International Critical Tables, the following statement is made regarding its arrangement and contents.

Arrangement. A straight alphabetical arrangement is used throughout, with the one exception that, under the names of the chemical compounds, the properties of the compounds are listed first and are followed by the systems (the second component being in italics) of which this compound is one component.

In systems of two or more components the *main entry* under which the data appears is the compound which would appear first in an alphabetical arrangement, without regard to the percentage composition or to the manner in which the systems are listed in the Tables. Thus data for a solution of acenaphthene in acetone will be found under acenaphthene, while those for a solution of naphthalene in acetone will be found under acetone.

According to the plan adopted for this Index, the data for a given system are listed only once, and as it is often desirable to know all the systems in which a specified compound appears there are given, after the properties of each compound, cross references to the system of which it is a component, but which, according to the alphabetical arrangement, appear in the earlier part of the Index. These cross references are in italics and carry an asterisk (*) after the component under which, in the main alphabet, the data will be found. Following the cross references are data for all other systems of which this compound is the first alphabetical component. For example, under ethyl alcohol are given, after the properties of the pure substance, nearly three columns of cross references to systems containing ethyl alcohol, for which data will be found in the main alphabet under the name carrying the *. Thus the entry, -*Acenaphthene** (which appears under ethyl alcohol) refers to the system acenaphthene-ethyl alcohol, the data for which will be found in the Index under acenaphthene. Following these cross references are all the other systems containing ethyl alcohol, with references to the place where data for these systems may be found in the Tables.

Contents: The items included in the Index are:

1. All chemical compounds and systems given in the Tables, with their properties, except in the following cases: Refractive index of organic compounds (VII: 34–62); optical rotatory power of organic compounds (VII: 356–488); absorption spectra of organic compounds and dyes (V: 320–358; VII: 173–211); electrical conductivity of weak electrolytes in aqueous solution (VI: 259–304); data on 3,359 inorganic compounds and 6,175 organic compounds (I: 106–338). The compounds listed in these sections appear in the Index only if other properties are given in the Tables. These compounds are omitted because the tables in which they appear are so arranged as to enable the user readily to determine whether or not a given compound is listed and also because it was felt that the inclusion of thousands of names of complex organic compounds was not warranted in view of the tremendous increase in size and consequent cost of the Index.
2. All industrially important compounds and materials with their properties. Many of these are listed under their trade names.
3. All minerals, rocks and miscellaneous materials, with their properties.
4. The names of various effects, equations, formulas, etc.
5. General properties and characteristics of chemical compounds and materials, such as boiling point, compressibility, melting point, refractive index, etc.

Acknowledgments: Special acknowledgment is made to the following for their assistance in indexing special sections of the Tables or for general suggestions regarding the form and contents of the Index: H. K. Benson, E. J. Crane, N. E. Dorsey, P. H. Emmett, H. E. Howe, C. A. Kraus, W. W. Nicholas, E. W. Washburn and H. T. Wensel. A large number of the experts connected with the Tables also cooperated by expressing their opinions on several questions submitted to them in the form of a questionnaire. The clerical help of Mrs. D. St. James Sweitzer, of the Research Information Service, has been of great assistance.

INTERNATIONAL CRITICAL TABLES

NATIONAL AND LOCAL SYSTEMS OF WEIGHTS AND MEASURES

CHARLES-ÉDOUARD GUILLAUME AND CHARLES VOLET

Plan.—Section A: International Metric System; list of countries in which its use was compulsory on January 1, 1925; list of those in which its use was either legally optional or partially compulsory on same date.

Section B: Other modern systems; the more important units at present in use or in use before adoption of metric system.

Section C: Weights and measures of antiquity.

Style and Abbreviations.—Only the singular number of the names of the units are used; ten meters will appear as 10 meter. Units of area and of volume will be written in the form centimeter^2 (=cm^2) and centimeter^3 (=cm^3), respectively.

ca.	Value given is only approximate.
ch.	Units have changed from time to time.
cm^2	Square centimeter = centimètre carré = Quadratzentimeter = centimetro quadrato.
current	Units, other than metric, which are now in use; some of the units included in this class are practically obsolete. (*See* Local.)
local	Units of local or native origin or derivation which are in use, but which are embraced neither by the metric system nor by that of the central government. Applies mainly to colonial possessions. (*See* Current.)
m^3	Cubic meter = mètre cube = Kubikmeter = metro cubico.
m.c.	International metric system compulsory since . . .
m.o.	International metric system legally optional since . .
older	Units used before adoption of international metric system.
older =	The older units were those of . . .
provincial	Units vary from one province or city to another.
since . . . = . . .	Since . . . the units have been the same as those of . . .
v.	*Vide* = see.
var.	Units are variable, not rigidly defined.

A. INTERNATIONAL METRIC SYSTEM

The decimal metric system, established in France by the Loi du 7 Avril, 1795, and represented by standards deposited in the Archives de France, became international on May 20, 1875, by the action of the Convention Internationale du Mètre. The new standards, of platinum-iridium, constructed at that time and serving as the basis of the international system, were copied from those of the Archives.

On January 1, 1925, the metric system was compulsory in:

Algeria
Allemagne
Argentina
Austria
Autriche
Belgium
Bolivia
Brazil
Bulgaria
Chile
Colombia
Congo, Belgian
Costa Rica
Cuba
Czechoslovakia
Denmark
Deutschland
Ecuador
Equateur
Espagne
Filippíne
Finland
France
Germany
Gioppóne
Greece
Guam
Guatemala
Haiti
Holland
Honduras
Hungary
Iceland
Italy & colonies
Japan
Kolumbien
Kongo, Belgisch
Kuba
Luxemburg
Malta
Mauritius
Mexico
Netherlands & colonies
Nicaragua
Norway
Olanda
Österreich
Panama
Pay-Bas & colonies
Philippine Islands
Peru
Poland
Porto Rico
Portugal and colonies
Rumania
Russia
Salvador
Schweden
Schweiz
Serbie-Croatie-Slovénie
Seychelles Islands
Siam
Spain
Suède
Suisse
Svézia
Svizzera
Sweden
Switzerland
Tchécoslovaquie
Tunis
Ungarn
Ungheria
Uruguay
Venezuela
Yugoslavia

On the same date, it was legally optional or partially compulsory in:

Canada
China
Egypt
Ethiopia
Great Britian
India, British
Ireland, Northern
Irish Free State
Paraguay
Turkey
United States of America

The fundamental units are: METER (m), which is the distance at 0°C between the axes of two lines ruled on the prototype deposited at the Bureau international des Poids et Mesures, Sèvres, France; KILOGRAM (kg), which is the mass of the prototype deposited at the same Bureau; and LITER (l), which is the volume of one kilogram of pure water at the temperature of its maximum density, under the pressure of one normal atmosphere.[1]

The primary units of the system are the *meter* (m), *micron* (μ) = 10^{-6} meter, *gram* (g) = 10^{-3} kilogram, *liter* (l), *are* (a) = area of a square with a side 10 meter long, and *stere* (s) = volume of a cube with an edge one meter long. The units of area [of volume], characterized by the adjective square [cubic], are *not* derived from a primary unit, but are each defined as the area [volume] of a square [cube] with side [edge] equal to the stated unit of length. The names of other secondary units are formed by attaching to the name of a primary unit certain prefixes of unvarying significance.

1 feuillette = 144
1 muid = 288

Fráncia, Isola di *v.* Mauritius.

Frankreich *v.* France.

Germany.—m.c. 1872. Since the beginning of the nineteenth century, the other units and their interrelations have been fairly definite, but before that there was great diversity. *Length:* fundamental unit was Fuss (foot), its value, depending upon the state, varied from 0.280 to 0.320 m. The one most extensively used was the Rheinlandischer Fuss (Rhenish foot) = 0.313 857 m. *Mass:* fundamental unit was Pfund

---

* For oil.

† For various products.

‡ In national system, units and their interrelations were very variable, but since 1891, have been defined by their metric equivalents.

* For ivory.

† For coffee.

‡ For rubber.

§ Toise de Perou at 16.25°C.

‖ Equivalent made legal in 1799.

¶ By measurement, in 1887, by J. R. Benoit.

** One livre de Charlemagne = 367.128 g.

††1 Marc de la Rochelle = 244.75 g
1 Marc de Limoges = 240.93 g
1 Marc de Tours = 237.87 g
1 Marc de Troyes et Paris = 260.05 g

* From 1 muid = 268.241 l by relation 144 boisseau = 1 muid (see Capacity, Liquid).

† Legal value.

‡ Derived from concrete standards.

§ From 1 muid = 268.241 l by relation 288 pinte = 1 muid.

(pound), its value generally varied little from 467 g; during transition period preceding 1872 the accepted equivalents were Pfund = 30 Loth = 300 Zeut = 3000 Korn; Centner = 100 Pfund. Older:

BAVARIA.

Gioppóne *v.* Japan.

Great Britain, Irish Free State, and Northern Ireland.—m.o. 1864. Since 1898, the national measures are convertible to metric by the legally sanctioned factors given below. National fundamental units defined thus: *Length:* The yard is distance at 62°F between axes of two lines traced on gold plugs set in a bronze bar preserved at the Standards Department of the Board of Trade. *Mass:* The pound avoirdupois is the mass of a certain platinum standard, similarly preserved. *Capacity:* The gallon is the volume of 10 pounds avoirdupois of pure water, as weighed in air against brass weights, the water and air being at the temperature of 62°F and the barometer at 30 inches. In official comparisons, the density of brass is taken as 8.143 g/cm³. Some of the units in the following tables are not in current use.

Length

1 yard* (yd.) = 0.914 3992 m
1 foot (ft.) = $\frac{1}{3}$ yd.
= 30.479 97 cm
1 inch (in.) = $\frac{1}{36}$ yd.
= 2.539 998 cm
Unit Inch
1 mil = 0.001
1 point = $\frac{1}{72}$
1 line = $\frac{1}{12}$
1 barleycorn = $\frac{1}{3}$

C. SYSTEMS OF ANTIQUITY

Our knowledge of the measures of antiquity is derived from the texts and monuments which have persisted to modern times, and some actual standards which have come down to us. The latter enable us to establish quite exact equivalence between the measures which they represent and ours. But most frequently such equivalence is only very roughly known, or is actually unknown. In this section are given only the more important or the best studied of these systems. The values given must not be taken too literally. Indeed, especially in antiquity, systems do not succeed one another; they evolve. Several may coexist among a single people; it is generally impossible to fix the dates at which these systems were used. The ancients had no capacity measures, such as ours; they weighed liquids and grains in terms of standards forming a second system of weights.

Arabian System.

SYMBOLS, BASIC CONSTANTS, CONVERSION DATA, DIMENSIONS, DEFINITIONS

BASES OF DATA CONTAINED IN I. C. T.

When many experts are cooperating in the assembling of data, it is essential that the same values for the fundamental constants and for the necessary conversion factors shall be employed by all. Consequently, at the very beginning of the work, the Editors compiled a set of accepted, or I. C. T., values for such constants and factors; and the Experts were instructed to base all their data upon these values. In the few cases in which it was not feasible to follow these instructions, the data were to be accompanied by a statement of the actual basis upon which they rest.

In compiling this list, and in choosing the accepted values of such of the quantities as were independently chosen, the Editors secured and utilized the advice of the United States Bureau of Standards, the National Physical Laboratory of Great Britain, and the Société Française de Physique. Acknowledgments are also due to Dr. F. E. Fowle, of the Smithsonian Institution, for his valued assistance in preparing the initial table of fundamental constants, and to Professors T. W. Richards and G. P. Baxter for their recommendations concerning the table of atomic weights.

The list so prepared comprised (1) a table of atomic weights (p. 43), (2) a set of nine basic constants (p. 17) (the estimated uncertainties were added at a later date), (3) twenty-one derived constants (computed directly from the nine basic constants), five conventional constants, and two experimental constants (p. 18) and (4) certain conversion factors selected from Tables 1 to 79 (p. 20–32). Although the accepted values were close approximations to the best values at that time available, it was not claimed that they were such best values.

SYMBOLS AND ABBREVIATIONS

Except as the contrary is definitely stated, the following symbols and abbreviations will always be used in the sense here indicated. Other symbols will be defined in the sections in which they are used. For those quantities which are included in the list of symbols approved by the International Association of Chemical Societies (*4*, **119**: 502; 21), the symbols so approved have, in general, been used; in some cases, this has necessitated the use of the same symbol to represent two distinct quantities; the context will serve to indicate which interpretation is correct. For explanations of the several technical terms, consult Selected Technical Terms, p. 34.

Å	Ångstrom unit
A.	Acre
A_n	Normal atmosphere
A_{45}	Atmosphere, 45° latitude
A	Atomic weight. Maximum work of a thermodynamic system
a	Are
(a)	Based on Int. ohm and Int. ampere as defined by silver voltameter. (*See* Int. elec. units, p. 27)
abs.	Absolute
ap.	Apothecaries
Av.	Average
av.	Avoirdupois
a	Van der Waal's pressure constant. Capillary constant.
BTU	British Thermal Unit
bbl.	Barrel
bd.	Board
bu.	Bushel
b	Van der Waal's volume constant
C	Centigrade
CTU	Centigrade thermal unit
C	Concentration. Molecular heat
C_1, C_2	Radiation constants of black body. (*See* definition of black body.)
C_i	Intensity coefficient. (*See* definition of black body.)
C_p, C_v	Molecular heat at constant pressure, at constant volume
c	Velocity of light in vacuo
c	Carat. Centi-
ca	Candle
ca.	*circa* = about, approximately
cal	Calorie (gram)
cd.	Cord
cf.	*Confer* = compare
cgs	Centimeter-gram-second system of units
cgse	Cgs electrostatic system
cgsm	Cgs electromagnetic system
ch.	Chain
cm	Centimeter
cm^2	Square centimeter
cm^3	Cubic centimeter
c.p.	Candle power
cu.	Cubic
cu. ft.	Cubic foot
cwt.	Hundredweight
c	Specific heat = heat capacity of the substance
c_p, c_v	Specific heat at constant pressure, at constant volume
D	Density
d	Derivative. Deci-
da	Day
deg	Thermometric degree, absolute C unless contrary is indicated
dk	Deka-
dm^3	Cubic decimeter
dr.	Dram
dwt.	Pennyweight
d	Density. Diameter
d_c	Critical density
$d^{t_2}_{t_1}$	Specific gravity at temperature t_{12}, with reference to water at temperature t_1
E	Electromotive force
E_0	Mean translational energy of molecule of ideal gas at 0°C
e	Electronic charge
e	Base of natural system of logarithms = 2.71828+
e.g.	*Exempli gratia* = for example
em	Cgsm unit of quantity of electricity
emf	Electromotive force
equiv	Electrochemical equivalent
es	Cgse unit of quantity of electricity
etc.	*Et cetera* = and so forth
et seq.	*Et sequentes* = and the following
c_0	Ratio of E_0 to T_0
F	Faraday
F	Fahrenheit
fath.	Fathom
fir.	Firkin
fl.	Fluid
fps	Foot-pound-second system of units
fpse	Fps electrostatic system
fpsm	Fps electromagnetic system
ft.	Foot
$ft.^2$	Square foot
$ft.^3$	Cubic foot
fur.	Furlong
G	Gravitation constant
g	Gram
gal.	Gallon
gi.	Gill
gr.	Grain
g	Acceleration due to gravity
g_s	Standard gravity
HP	Horse-power
H	Atomic weight of hydrogen
h	Planck's constant of action
h	Hecto-
ha	Hectare
hhd.	Hogshead
h.p.	Horse-power
hr	Hour
h	Height
Int.	International
I. C. T.	International Critical Tables
I	Electric current
ibid.	*Ibidem* = in the same place
i.e.	*Id est* = that is
in.	Inch
$in.^3$	Cubic inch
J	Radiance
J_λ	Intensity of monochromatic radiance of wave-length λ
J_m	Value of J_λ for $\lambda = \lambda_m$
K	Karat. Kelvin, or absolute C, scale of temperature
K	Constant of chemical equilibrium
k	Kilo-
kg	Kilogram
km	Kilometer
km^2	Square kilometer
k	Velocity coefficient of chemical reaction
k_0	Boltzmann's gas constant
L	Latent heat per mole
l	Liter
l.	Long
lat.	Latitude
lb.	Pound
li.	Link
liq.	Liquid
long.	Longitude
l	Length. Latent heat per gram
M	Molecular weight
$M[\alpha]$	Molecular rotatory power
$M[\omega]$	Molecular magnetic rotatory power
m_0	Mass of electron at low velocity
m	Meter. Milli-
m^2	Square meter
max.	Maximum
mg	Milligram
mi.	Mile
min	Minute

min.	Minim, Minimum
ml	Milliliter
mmf	Magnetomotive force
$m\mu$	Millimicron. Millimicro-
m	Mass
m_H	Mass of a hydrogen atom
N	Numeric
N_0	Avogadro's number
N_∞	Rydberg's universal series constant
n	Refractive index
n_a, n_k	Transport number for anion, kation
n_0	Loschmidt's number
O	Atomic weight of oxygen
oz.	Ounce
P	Pressure
pk.	Peck
pt.	Pint
p	Pressure
p_c, p_r	Critical pressure, reduced pressure
Q	Quantity
q	Quintal
qt.	Quart
q.v.	*Quod vide* = which see
R	Réaumur
R	Gas constant per mole of ideal gas. Electrical resistance.
rd.	Rod
r	Radius
r_G	Specific refractivity (Gladstone and Dale)
r_L	Specific refraction (Lorentz and Lorenz)
r_1	Radius of first Bohr ring, hydrogen
S.E.	Siemens unit
S	Entropy
s	Stere
s.	Scruple
sec	Second (mean solar unless contrary is stated)
sh.	Short
sq.	Square
sq. ft.	Square foot

T_0	Ice point, absolute C
T	Temperature on absolute C scale
T_c	Critical temperature, absolute C
t	Metric ton
t.	Troy
tn.	Ton
t	Time. Temperature C (above ice point)
t_c	Critical temperature C (above ice point)
U. S.	United States of America
V	Volume
V_0	Volume per gram-mole of ideal gas at 0°C and A_n
v.	*Vide* = see
(v)	Based on Int. ohm and Int. volt as defined by standard cell. (*See* Int. elec. units, p. 27.)
v	Volume
v_c, v_r	Critical volume, reduced volume
W	Electrical resistance
wt.	Weight
w	Wien's displacement constant
yd.	Yard
yr	Year
Z	Atomic number
α	Degree of dissociation. Angle of optical rotation
$[\alpha]$	Specific rotatory power
β	Specific heat constant
γ	Surface tension. Ratio of c_p/c_v. Gamma (magnetic unit)
Δ	Diffusion coefficient
ϵ	Dielectric constant. Electrode potential
ϵ_h, ϵ_c	Electrode potential above that of normal hydrogen, of normal calomel, electrode
η	Viscosity
θ	Angle (plane). Temperature C above ice point

κ	Susceptibility (magnetic). Electrical (volume) conductivity
Λ	Equivalent conductivity (electrical)
λ	Wave-length. $\lambda 5890$ = spectral line of wave-length = 5890Å
λ_m	Wave-length of maximum monochromatic radiance of black-body at stated temperature
μ	Permeability (magnetic). Micron, Micro-, Molecular conductivity (electrical)
$\mu\mu$	Micromicron. Micromicro-
ν	Frequency
ν_∞	Rydberg's fundamental frequency
π	Ratio of circumference of a circle to its diameter
σ	Stefan's constant (radiation)
φ	Fluidity. Angle
ψ	Luminous flux
Ω	Ohm
$[\Omega]$	Relative molecular magnetic rotatory power with reference to water
ω	Solid angle
$[\omega]$	Specific magnetic rotatory power

♏	Minim
℥	Apothecaries' ounce
ʒ	Apothecaries' dram
℈	Apothecaries' scruple
°	Degree (arc or temperature)
′	Minute of arc (sexagesimal)
″	Second of arc (sexagesimal)
%	Percent = per hundred
‰	Per thousand = 0.1 %
[ ]	Dimensional expressions are inclosed in [ ]. In text, [ ] is used to inclose a second reading. (*E.g.*, Length [diameter] of the bar is 10 cm [1 cm] = length of bar is 10 cm, diameter of bar is 1 cm)
$<$	$A < B$ [$A > B$] denotes that A is less than [greater than] B
$\nless$	Negative of $<$; $A \nless B$ denotes that A is not less than B
$\leq$	Combination of $<$ and $=$; $A \leq B$ denotes that A is equal to or less than, B
$\neq$	Is not equal to
$\equiv$	Identically equal to; used in defining symbols, etc.
$\cong$	Approximately (or essentially) equal to
∞	Infinity

FUNDAMENTAL CONSTANTS

By an *accepted*, *conventional*, or *defined* value, is meant one which is to be regarded as exactly correct for purposes of computation.[1] Thus, errors from computational approximations are avoided and do not enter into consideration in any future revision of the computed result for a discovered difference between the true and the accepted value. When the computation involves several accepted values, it is especially important that each shall be regarded as exactly correct, for only then can the result be independently revised (without complete recalculation) for changes in the values of each. For this reason the logarithms of the several accepted values are given to the full precision of Vega's seven-place table. The degree of uncertainty in the value accepted is indicated by the number of significant figures retained in the value itself, not by the logarithm.

---

[1] In every computation it is tacitly assumed that the values employed are exact. If but three digits are employed, it is assumed that all others are zero; if a computing machine is used, the assumption is carried out to the extreme limit of the machine; if logarithms are used, it is carried to the limit within which the logarithms are interpolated. To adopt an accepted or a conventional value, and to give as its logarithm an abbreviated value, is to introduce an ambiguity of a magnitude determined by the degree of abbreviation of the logarithm. But the sole object in adopting accepted or conventional values is to avoid ambiguity.

ACCEPTED BASIC CONSTANTS Units: cgs, °C, liter, A_n, absolute electric

	Quantity	Value	Uncertainty	Log_{10} (value)
c	Velocity of light	2.9986 × 10^{10} cm sec^{-1}	0.0003	10.476 9185
G	Gravitation constant	6.66 × 10^{-8} cm^3 g^{-1} sec^{-2}	0.01	$\overline{8}$.823 4742
e	Electronic charge	4.774 × 10^{-10} es	0.005	$\overline{10}$.678 8824
e	Electronic charge	*1.592 × 10^{-20} em	....	$\overline{20}$.201 9639
$\mathbf{e/m_0}$	Electronic ratio	5.305 × 10^{17} es g^{-1}	0.010	17.724 6854
$\mathbf{e/m_0}$	Electronic ratio	*1.769 × 10^7 emg^{-1}	....	7.247 7669
F	Faraday	9.6500 × 10^4 coulombs	0.0010	4.984 5273
F	Faraday	*2.893 65 × 10^{14} es	....	14.461 4458
$\mathbf{v_0}$	Volume 1 mole at 0°C, A_n	†22.4115 × 10^3 cm^3 mole^{-1}	0.002	4.350 4709
h	Planck's constant	6.554 × 10^{-27} erg sec	0.001	$\overline{27}$.816 5064
$\mathbf{T_0}$	Ice point, absolute	273.1 deg C	+0.15 to −0.05	2.436 3217
O	Atomic weight of oxygen	16.000 (by definition)	(definition)	1.204 1200

* This value is derived from the preceding one, which is the value actually accepted.

† Derived from volume at 0°C, A_{45} = 22.412 liters/g-mole on assumption $\log_{10}(A_n/A_{45}) = 0.000\ 0214$, liter = 1000.027 cm^3.

ACCEPTED CONSTANTS:—CONVENTIONAL AND NON-BASIC Units: cgs, °C, liter, A_n absolute electric, international angstrom

Quantity		Value	Log$_{10}$ (value)
	A. Derived Constants		
R	Gas constant	8.315×10^{7} erg deg^{-1} mole^{-1}	7.919 8658
R	Gas constant	0.082 06 liter atm deg^{-1} mole^{-1}	$\bar{2}.914$ 1375
R	Gas constant	1.9869 cal$_{15}$ deg^{-1} mole^{-1}	0.298 1703
N_0	Avogadro's number	6.061×10^{23} mole^{-1}	23.782 5634
n_0	Loschmidt's number	2.705×10^{19} cm^{-3} (at 0°C, A_n)	19.432 0925
k_0	Molecular gas constant	1.372×10^{-16} erg deg^{-1}	$\overline{16}.137$ 3024
E_0	Translational energy of molecules, 0°C	5.620×10^{-14} erg	$\overline{14}.749$ 7154
e_0	Ratio of E_0 to T_0	2.058×10^{-16} erg deg^{-1}	$\overline{16}.313$ 3937

	B. Conventional Constants		
A_n	Normal atmosphere	$1.0132\ 50 \times 10^{6}$ dyne cm^{-2}	6.005 7166
A_{45}	Atmosphere, latitude 45°	$1.0132\ 00 \times 10^{6}$ dyne cm^{-2}	6.005 6952
Å	Wave-length of red Cd line is	6438.4696 Å	4.808 7827
g_s	Standard gravity	980.665 cm sec^{-2}	2.991 5207
	Aberration constant	20.47″	1.311 1178
	C. Experimental Constants		
	Grating space in calcite	3.028 Å	0.481 1559
H	Atomic weight of hydrogen	1.0077	0.003 3313
	‡Liter	1000.027 cm^{3}	3.000 0117
	‡Gram calorie (20°C)	4.181 joule	0.621 2802
	‡Gram calorie (15°C)	4.185 joule	0.621 6955
	‡Gram calorie (mean)	4.186 joule	0.621 7992
	‡British Thermal Unit (39°F)	1060.4 joule	3.025 4697
	‡British Thermal Unit (mean)	1054.8 joule	3.023 1701
	‡British Thermal Unit (60°F)	1054.6 joule	3.023 0878
	‡International ohm	1.000 52 ohm	0.000 2259
	‡International ampere (v)§	0.999 90 ampere	0.999 9566
	‡International ampere (a)§	0.999 93 ampere	0.999 9696

* This value is derived from the preceding one, which is the value actually accepted.

‡ In the original list, this quantity was included solely in the list of conversion factors; its value, however, is an independently selected, *accepted* constant, and, consequently, is treated as exact in all computations.

§ (v) = Based on Int. ohm and Weston normal cell = 1.018300 Int. volts at 20°C; (a) = based on deposit of 1.11800 mg of silver per Int. ampere second.

CONVERSION FACTORS AND DIMENSIONAL FORMULAE

N. Ernest Dorsey

In the following tables are given the factors by which values expressed in other units must be multiplied in order to obtain their equivalents in units of the centimeter-gram-second (cgs) system. To convert in the reverse direction, divide by the factor given. The dimensional formula in the cgs, or any similarly constructed, system is given in the title of each table.

Conversion Factors.—With few exceptions,[1] the values given are based exclusively upon legal definitions, conventional constants, and the I. C. T. accepted values (p. 16). Consequently, they are computable to as extreme a precision as may be desired. They have been computed by means of Vega's seven-place logarithms, and it is hoped that their logarithms as given are correct to a unit in the last digit. Obviously, those factors which involve the accepted value of an experimentally determined constant will be in error by an amount determined by the error in the accepted value; but quantities converted by means of the logarithms given will retain their same relative precision, however great this may be, within the limit set by the seven-place table, and may at any time be as exactly corrected for a revision of the accepted value. This would not be true if an abbreviated logarithm were used, unless the exact value of the abbreviated logarithm itself were given. The latter would be equivalent merely to the adoption of another accepted value for the experimental constant involved;

---

[1] The exceptions are (1) astronomical unit of distance, (2) parsec, (3) sidereal second, (4) certain units of luminous intensity, (5) international electrical units prior to 1911, and (6) the data for hydrometers.

and the new value so fixed would, in general, be expressible only by an indefinite number of digits. The former procedure is to be preferred.

Frequently, the same factor applies to more than one type of physical quantity; if the units of the several types have distinctive names, separate tables are given, otherwise, not. In general, the tables are arranged in the order of increasing complexity of the dimensional formulae. Some quantities for which conversion factors are seldom required, and a few dimensionless quantities have been grouped together in Table 78. The dimensional formulae of the more important electric and magnetic units, and the numerical relations connecting these units in the three systems most frequently used, are assembled in Table 77. To find the conversion factor for a given quantity, consult the index below.

Dimensions.—Two types of dimensional equations need to be considered, *viz.:* (1) Those in which the dimensions are expressed in terms of the quantities directly involved in the phenomenon under consideration, and (2) those in which the dimensions are expressed in terms of certain fundamental units.

As an illustration of the first we may consider the force of repulsion between two point charges (e, e') of electricity situated at a distance, r, apart in a medium of dielectric constant ϵ. If this force is denoted by f, then $f = ee'/\epsilon r^2$, and we may write $[e^2] = [f\epsilon l^2]$, $[\epsilon] = [e^2 f^{-1} l^{-2}]$, etc., where [ ] denotes that we are concerned with dimensions only; $[l]$ denotes the dimension of length, $[f]$ that of force, etc. These dimensional equations are true whatever be the system of units employed. As they involve quantities, such as force, which can be expressed in terms of other units that are usually considered more fundamental, such dimensional equations will be referred to as "unreduced," in order to distinguish them from those of the second class in which the dimensions are expressed solely in terms of a small number of fundamental units.

It is evident that the dimensions of a quantity in terms of fundamental units can be assigned only in relation to a specific system of units and to a specific method of derivation. For example, (1) if the unit of volume is defined as the volume occupied by a unit mass of water when at its greatest density under a pressure of one atmosphere, then the volume so defined will be independent of the units of length and time, and will vary directly as the unit of mass: we will have $[v] = [m]$. (2) If the unit of volume is defined as the volume occupied by a mass of water (when at its greatest density, etc.) which is equal to the mass of a specified block of platinum, then the volume so defined will not change as we change our units of length, of mass, and of time: that is $[v] = [v]$. In this case $[v]$ is an independent unit and must be so regarded in all dimensional equations. (3) If the unit of volume is defined as the volume of a cube of which the edge is equal to the unit of length then $[v] = [l^3]$. A unit may be defined in any desired unambiguous manner and, in general, the dimensions of the unit will vary from definition to definition.

Dimensional equations of the second type stand in marked contrast to those of the former, in being far less general and in implying the acceptance of a very exactly defined system of units. This, however, is the type of equation which is commonly in mind when dimensional equations are mentioned, and is probably the one which is the more generally useful; the unreduced dimensional expressions (the first type), however, are often simpler, convey more detailed information, and in many cases are to be preferred. For these reasons, unreduced dimensional expressions are to be found in explanations of technical terms (p. 34); they are followed by others, the final one in each case being the fully reduced dimensions on the centimeter, gram, second, degree centigrade absolute, electrostatic system. Wherever necessary, this system of units will be denoted by the symbol *cgse* in order to distinguish it from the corresponding electromagnetic system, which will be denoted by *cgsm*. In the conversion tables, dimensional formulae only of the cgse and of the cgsm systems are given. In the cgse system, the fundamental units and their symbols are those of length $[l]$ the centimeter, of mass $[m]$ the gram, of time $[t]$ the mean solar second, of temperature $[T]$ the absolute centigrade degree, and of dielectric constant $[\epsilon]$, that of a vacuum. The fundamental units in the cgsm system differ from those in the cgse system only by the replacement of dielectric constant by magnetic permeability $[\mu]$, the unit being the permeability of a vacuum.

It should be realized that dimensional expressions give no positive information regarding the ultimate nature of the quantity to which they refer; *e.g.*, energy and torque have the same dimensions, but differ vastly in their nature.

Symbols.—(U. S.) before a logarithm denotes that it is based upon the U. S. yard; for explanation of other symbols, see Symbols and Abbreviations, p. 16.

INDEX TO TABLES OF CONVERSION FACTORS

INDEX TO TABLES OF CONVERSION FACTORS.—*Continued*

CONVERSION FACTORS

1. Length [l] (*see also* p. 1)

Unit		Value	Log$_{10}$ (value)
1 angström unit	=	1.0000×10^{-8} cm	$\bar{8}$.000 0000
1 micron	=	1.0000×10^{-4} cm	$\bar{4}$.000 0000
1 mil	=	2.5400×10^{-3} cm	$\bar{3}$.404 8346
1 inch	=	2.5400 cm	(U. S.) 0.404 8346
1 foot	=	30.480 cm	(U. S.) 1.484 0158
1 yard (U. S.)	=	91.44018 cm	1.961 1371
1 yard (British)	=	91.43992 cm	1.961 1350
1 mile, statute	=	1.6093 km	(U. S.) 0.206 6497
1 light year	=	9.4627×10^{12} km	12.976 0131
1 astronomical unit	=	1.495×10^{8} km	8.174 6712
1 parsec	=	3.084×10^{13} km	13.489 09

2. Length^{-1}; Absorptivity; Coefficient of Absorption* [l^{-1}]

Unit		Value	Log$_{10}$ (value)
1 angström^{-1}	=	1.0000×10^{8} cm^{-1}	8.000 0000
1 micron^{-1}	=	1.0000×10^{4} cm^{-1}	4.000 0000
1 mil^{-1}	=	393.70 cm^{-1}	2.595 1654
1 inch^{-1}	=	0.39370 cm^{-1}	(U. S.) $\bar{1}$.595 1654
1 foot^{-1}	=	3.2808×10^{-2} cm^{-1}	(U. S.) $\bar{2}$.515 9842
1 mile^{-1}	=	0.62137 km^{-1}	$\bar{1}$.793 3503

* Coefficient of transmission (τ) is so defined that $-\log_e \tau$ = coefficient of absorption.

3. Mass [m]; Weight (*see also* p. 1)

Unit		Value	Log$_{10}$ (value)
1 grain	=	64.799 mg	1.811 5677
1 carat (metric)	=	200.000 mg	2.301 0300
1 ounce (avoirdupois)	=	28.350 g	1.452 5458
1 ounce (apothecary) or (troy)	=	31.103 g	1.492 8090
1 pound (avoirdupois)	=	453.59243 g	2.656 6658
1 pound (apothecary) or (troy)	=	373.2417 g	2.571 9902
1 ton, short (2000 pounds)	=	907.185 kg	2.957 6958
1 ton, long (2240 pounds)	=	1016.047 kg	3.006 9138
1 slug (g_s)	=	14.594 kg	1.164 1707
1 gram mole	=	M. W.† g	
1 molecule/M. W.†	=	1.6498×10^{-24} g	$\overline{24}$.217 4366
1 assay ton	=	29.1667 g	1.464 8868

† M. W. denotes the molecular weight of the substance.

4. Mass^{-1} [m^{-1}]

Unit		Value	Log$_{10}$ (value)
1 grain^{-1}	=	1.5432×10^{-2} mg^{-1}	$\bar{2}$.188 4323
1 ounce^{-1} (avoirdupois)	=	3.5274×10^{-2} g^{-1}	$\bar{2}$.547 4542
1 ounce^{-1} (troy)	=	3.2151×10^{-2} g^{-1}	$\bar{2}$.507 1910
1 pound^{-1} (avoirdupois)	=	2.2046×10^{-3} g^{-1}	$\bar{3}$.343 3342
1 ton^{-1} (2000 pounds)	=	11.0231×10^{-4} kg^{-1}	$\bar{3}$.042 3042
1 ton^{-1} (2240 pounds)	=	9.8421×10^{-4} kg^{-1}	$\bar{4}$.993 0862
1 (gram mole)$^{-1}$	=	†(M. W.)$^{-1}$ g^{-1}	

† M. W. denotes the molecular weight of the substance.

5. Time [t]

Unit		Value	Log$_{10}$ (value)
1 second, mean solar	=	1.00273791 sidereal sec	0.001 1874
1 second, sidereal	=	0.997270 sec (mean solar)	$\bar{1}$.998 8126
1 hour (tropical, mean solar)	=	3.6000×10^{3} sec (mean solar)	3.556 3025
1 day (tropical, mean solar)	=	8.6400×10^{4} sec (mean solar)	4.936 5137
1 day (sidereal)	=	8.6164×10^{4} sec (mean solar)	4.935 3263
1 year (tropical, mean solar)	=	31.5569×10^{6} sec (mean solar)	7.499 0946
1 year (tropical, mean solar)	=	365.2422 day (mean solar)	2.562 5809

CONVERSION FACTORS.—*Continued*

6. Time^{-1}; Frequency; "Velocity" of a Process $[t^{-1}]$

1 second^{-1} (sidereal)	=	1.002738 sec^{-1} (mean solar)	0.001 1874
1 minute^{-1} (mean solar)	=	1.66667×10^{-2} sec^{-1} (mean solar)	$\bar{2}$.221 8487
1 hour^{-1} (mean solar)	=	2.77778×10^{-4} sec^{-1} (mean solar)	$\bar{4}$.443 6975
1 day^{-1} (mean solar)	=	1.15741×10^{-5} sec^{-1} (mean solar)	$\bar{5}$.063 4863
1 year^{-1} (mean solar)	=	3.16888×10^{-8} sec^{-1} (mean solar)	$\bar{8}$.500 9054
1 year^{-1} (mean solar)	=	2.73791×10^{-3} day^{-1} (mean solar)	$\bar{3}$.437 4191
1 electron-volt, quantum^{-1}	=	2.4292×10^{14} sec^{-1} (mean solar)	14.385 4575
1 joule per mole, N_0^{-1} quantum^{-1}	=	2.5173×10^{9} sec^{-1} (mean solar)	9.400 9301
1 velocity of light, (angström unit)$^{-1}$	=	2.9986×10^{18} sec^{-1} (mean solar)	18.476 9185
1 velocity of light, millimicron^{-1}	=	2.9986×10^{17} sec^{-1} (mean solar)	17.476 9185
1 velocity of light, micron^{-1}	=	2.9986×10^{14} sec^{-1} (mean solar)	14.476 9185
1 velocity of light, millimeter^{-1}	=	2.9986×10^{11} sec^{-1} (mean solar)	11.476 9185
1 velocity of light, meter^{-1}	=	2.9986×10^{8} sec^{-1} (mean solar)	8.476 9185

7. Angle $[\theta]$

1 radian	=	57.29578 degree	1.758 1226
1 circumference	=	6.28319 radian	0.798 1799
1 quadrant	=	1.57080 radian	0.196 1199

1 second	=	4.84814×10^{-6} radian	$\bar{6}$.685 5749

8. Angle^{-1} $[\theta^{-1}]$

1 circumference^{-1}	=	0.159155 radian^{-1}	$\bar{1}$.201 8201
1 degree^{-1}	=	57.29578 radian^{-1}	1.758 1226
1 minute^{-1}	=	3.43775×10^{3} radian^{-1}	3.536 2739
1 second^{-1}	=	2.06265×10^{5} radian^{-1}	5.314 4251

9. Solid Angle $[\omega]$

Entire space	=	12.5664 steradian	1.099 2099
1 hemisphere	=	6.2832 steradian	0.798 1799
1 square degree	=	3.0462×10^{-4} steradian	$\bar{4}$.483 7548

10. Solid Angle^{-1} $[\omega^{-1}]$

Entire space^{-1}	=	7.9577×10^{-2} steradian^{-1}	$\bar{2}$.900 7901
1 hemisphere^{-1}	=	1.5916×10^{-1} steradian^{-1}	$\bar{1}$.201 8201
1 square degree^{-1}	=	3.2828×10^{3} steradian^{-1}	3.516 2452

11. Temperature $[T]$ (*See also* Thermometry, p. 52)

Fahrenheit.................................. x° F = $(\frac{5}{9})(x - 32)$°C
Réaumur.................................. x° R = $(\frac{5}{4})x$°C
Absolute (Centigrade)........................ x° K = $(x - T_0)$°C
Absolute (Fahrenheit)........................ x° Rankine = $(\frac{5}{9})(x - 491.58)$°C

12. Degree^{-1} (Thermometric); Expansivity; Curie's Constant (magnetic) $[T^{-1}]$

1 per degree F	=	1.8000 per degree C	0.255 2725
1 per degree R	=	0.8000 per degree C	$\bar{1}$.903 0900
1 per degree K	=	1.000 per degree C	0.000 0000

13. Luminous Flux $[\psi]$

By definition, the total luminous flux emitted by a point source of one spherical candle power is 4π *lumen.*

14. Dielectric Constant; Electrical Inductivity $[\epsilon]$; $[\mu^{-1}l^{-2}t^{2}]$

Specific inductive capacity is of zero dimensions. It is numerically equal to the dielectric constant expressed in cgse or in fpse units.

1 cgsm unit	=	8.9916×10^{20} cgse unit	20.953 8370
1 fpse unit	=	1.0000 cgse unit	0.000 0000
1 fpsm unit	=	1.0764×10^{-3} cgsm unit	$\bar{3}$.031 9684
1 fpsm unit	=	9.6784×10^{17} cgse unit	17.985 8054

15. Magnetic Permeability; Susceptibility $[\epsilon^{-1}l^{-2}t^{2}]$; $[\mu]$

1 cgse unit	=	8.9916×10^{20} cgsm unit	20.953 8370
1 fpsm unit	=	1.0000 cgsm unit	0.000 0000
1 fpse unit	=	1.0764×10^{-3} cgse unit	$\bar{3}$.031 9684
1 fpse unit	=	9.6784×10^{17} cgsm unit	17.985 8054

CONVERSION FACTORS.—*Continued*

16. Area [l^2]

1 circular millimeter	=	7.8540×10^{-3} cm^2	$\bar{3}.895\ 0899$

1 pound weight sec foot^{-2} (g_s)	=	4.788×10^2 poise	(U. S.) 2.680 1548

40. Kinematic Viscosity [l^2t^{-1}]

1 poise centimeter^3 gram^{-1}	=	1.000 cm^2 sec^{-1}	0.000 0000
1 poise inch^3 gram^{-1}	=	16.387 cm^2 sec^{-1}	1.214 5038
1 inch^2 second^{-1}	=	6.451 cm^2 sec^{-1}	(U. S.) 0.809 6692
1 poise foot^3 pound^{-1}	=	62.43 cm^2 sec^{-1}	(U. S.) 1.795 3817

41. Diffusivity; Diffusion, Coefficient of [l^2t^{-1}]

All quantities of the thing diffusing are to be expressed in terms of the same units. Heat diffusivity is numerically equal to heat conductivity divided by the product of the density times the heat capacity (per unit of mass); all must be expressed in the same system of units.

1 liter centimeter^{-1} day^{-1}	=	1.1574×10^{-2} cm^2 sec^{-1}	$\bar{2}.063\ 4980$
1 centimeter^2 day^{-1}	=	1.1574×10^{-5} cm^2 sec^{-1}	$\bar{5}.063\ 4863$
1 inch^2 sec^{-1}	=	6.4516 cm^2 sec^{-1}	(U. S.) 0.809 6692

42. Surface Tension [mt^{-2}] (*See also* Capillary Constant, Table 43)

1 milligram weight per mm (g_s)	=	9.80665 dyne cm^{-1}	0.991 5207
1 milligram weight per inch (g_s)	=	0.38609 dyne cm^{-1}	(U. S.) $\bar{1}.586\ 6861$
1 erg per centimeter^2	=	1.00000 dyne cm^{-1}	0.000 0000
1 erg per millimeter^2	=	100.00000 dyne cm^{-1}	2.000 0000

43. (Capillary Constant)^2 [l^2]

The term "Capillary Constant" is used in two different senses; *viz.*, either to denote $a_1 = \sqrt{\gamma/\rho g}$, or to denote $a_2 = \sqrt{2\gamma/\rho g}$. English authors generally follow the former practice, and German authors the latter; neither use the subscript. γ denotes the surface tension, g the acceleration of gravity, and ρ the positive difference in the densities of the adjacent fluids.

1 inch^2	=	6.451 cm^2	0.809 6692
1 millimeter^2 (a_1^2) (g_s)	=	*9.807 dyne cm^{-1} per (g cm^{-3})	0.991 5207
1 millimeter^2 (a_2^2) (g_s)	=	*4.903 dyne cm^{-1} per (g cm^{-3})	0.690 4907
1 inch^2 (a_1^2) (g_s)	=	*6.327×10^3 dyne cm^{-1} per (g cm^{-3})	(U. S.) 3.801 1899
1 inch^2 (a_2^2) (g_s)	=	*3.163×10^3 dyne cm^{-1} per (g cm^{-3})	(U. S.) 3.500 1599

* To convert a^2, when referred to g_s, to surface tension in dynes per cm, multiply a^2 by the factor given in this table and by the difference in the densities (gram per cm^3) of the adjacent fluids; if a^2 is referred to g, multiply the resulting product by g/g_s.

44. Thermal Conductivity [$T^{-1}mlt^{-3}$]

The dimensions practically employed in expressing this property are (Heat Area^{-1} Time^{-1} per Degree Length^{-1}). Other conversion factors may be obtained by combining those of Tables 35 (Heat), 22 (Area^{-1} Time^{-1}) and 20 (Length Degree^{-1}).

1 calorie (15°) cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$	=	4.185 joules (abs.) cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$	0.621 6955
1 calorie (20°) cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$	=	4.181 joules (abs.) cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$	0.621 2802

CONVERSION FACTORS.—*Continued*

44. Thermal Conductivity $[T^{-1}mlt^{-3}]$.—*Continued*

1 British Thermal Unit (39°F) ft.$^{-2}$ sec^{-1} (°F, in.$^{-1}$)$^{-1}$	=	5.218 joules (abs.) cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$	0.717 5452
1 British Thermal Unit (mean) ft.$^{-2}$ sec^{-1} (°F, in.$^{-1}$)$^{-1}$	=	5.191 joules (abs.) cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$	0.715 2456
1 British Thermal Unit (60°F) ft.$^{-2}$ sec^{-1} (°F, in.$^{-1}$)$^{-1}$	=	5.190 joules (abs.) cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$	0.715 1633

45. Intensity of Radiation $[mt^{-3}]$ or $[ml^{-1}t^{-2}]$

The dimensions depend upon the point of view; when the receptor is considered, they are [Energy, Area^{-1}, Time^{-1}]; when the radiation itself is considered they are [Energy, Volume^{-1}]. Conversion from one to the other involves the velocity of propagation; if this is the velocity of light in vacuo, the factors are as given below; if the velocity is v cm sec^{-1}, the factors given must be multiplied by $v/(2.9986 \times 10^{10})$. For other units, combine these factors with those of Tables 19 (Volume^{-1}), 22 (Area^{-1} Time^{-1}), and 35 (Energy).

1 erg cm^{-3}	=	2.9986 × 10^{10} erg cm^{-2} sec^{-1}	10.476 9185
1 foot-pound ft.$^{-3}$ (g_s)	=	1.4357 × 10^{13} erg cm^{-2} sec^{-1}	(U. S.) 13.157 0733

46. Luminous Intensity of a Source in a Given Direction $[\psi\omega^{-1}]$

By definition of the lumen, a source of one spherical candle power emits $4\pi(= 12.566)$ lumens. (*See also* Photometric Standards, in another section (consult index).)

1 candle, International	=	1.0000	Int. lumen per steradian		0.000 0000

---

* For the purposes of International Critical Tables, c has been taken as 2.9986 × 10¹⁰ cm per sec, $\log_{10}$ c = 10.476 9185, $\log_{10}$ c⁻¹ = $\overline{11}.523\ 0815$. This is the accepted value for the velocity of light in vacuo. The best directly determined value of the ratio of the two electrical units of quantity gives c = 2.9979 × 10¹⁰ cm per sec. (Rosa and Dorsey, *Bull. U. S. Bur. Standards*, **3**: 433; 07.)

† In practice this unit is not used; the quantity given in essentially every instance is the dimensionless "specific inductive capacity," which is numerically equal to the dielectric constant expressed in cgse units.

‡ In this column are given the dimensions in terms of the practical electrical units, as these generally enter into the actual determinations of the several quantities. As three basic electrical units are employed, alternative expressions are possible. T = thermometric degree, E = potential, I = current, R = resistance.

78. Indicated Conversion Factors

a = area, C = electrical capacity, T = thermometric degree, d = density, E = electrical potential, e = electric charge, F = electrical field intensity, h = heat, m = mass, Q = quantity of magnetism, R = electrical resistance, t = time, v = volume, ϵ = dielectric constant, η = viscosity, θ = plane angle.

Name of quantity	Dimensions	Tables
Electricity		
Electric displacement	ϵF	14, 53
Polarization capacity	Ca^{-1}	56, 17
Pyroelectric constant	$ea^{-1}T^{-1}$	49, 17, 12
Specific inductive capacity	zero	
Surface density of charge	ea^{-1}	49, 17
Thermoelectric power	ET^{-1}	52, 12
Volume density of charge	ev^{-1}	49, 19
Heat, capacity	$hm^{-1}T^{-1}$	35, 21
Latent	hm^{-1}	35, 4
Reaction	hm^{-1}	35, 4
Superficial latent	ha^{-1}	35, 17
Transformation	hm^{-1}	35, 4
Radiation, index of absorption	zero	
Intensity of	$ha^{-1}t^{-1}$	35, 22
Kerr's constant (magneto-optic)	$\theta Q^{-1}a$	7, 71, 16
Reflectivity	zero	
Refraction, index of	zero	
Solubility, gases in liquids	zero	
Viscosity, kinematic	ηd^{-1}	39, 28

79. Hydrometer Scales

Unless the hydrometer is used in the liquid and at the temperature for which it is graduated, corrections must be applied for the changed capillary depression and for the expansion (or contraction) of the instrument. (The following table does not include all scales which have been used.)

T = temperature at which the instrument is to be used; r = reading of instrument; the specific gravity is with reference to water at temperature T unless another temperature is indicated in the last column.

79. Hydrometer Scales.—*Continued*

TECHNICAL EFFLUX VISCOMETERS: INTERPRETATION AND INTERCONVERSION OF READINGS

Winslow H. Herschel

Since changes are made from time to time in the standardization or method of operation of these instruments, and many old instruments are still in use, it is believed that in general the determination of kinematic viscosity from the readings of the instruments, and direct interconversions between instruments, when used at the same temperature, may be made by the use of Fig. 1, with as great precision (about 5%) as the data will warrant. It is assumed that the instruments are used in the normal manner. For the Saybolt instruments, a higher precision is occasionally justified, and may be obtained by the use of Table 2.

If the instruments are used at different temperatures, appropriate temperature corrections must be applied. For lubricating oils, the viscosity at one temperature may be estimated from that at another by the approximate empirical rule, applicable between 100° and 212°F (37.8° and 100°C), that the logarithmic viscosity-temperature graphs are straight and meet at a point, temperatures being expressed in degrees Fahrenheit. (For other temperatures see (1, 7, 8)). The location of the point of intersection for several classes of oils is given in Table 1.

Table 1.—Coordinates of Points of Intersection of Logarithmic Graphs(5)

η_0 = viscosity in poises; t_0 = temperature in °F

Class of oils	$\log_{10} \eta_0$	η_0	$\log_{10} t_0$	t_0
Paraffin base	$\bar{3}.58$	0.0038	2.77	589
Naphthene base	$\bar{3}.88$	.0076	2.57	371
Mixed base	$\bar{3}.43$	.0027	2.78	605
Fatty oils	$\bar{3}.75$	.0056	2.82	661

In estimating the viscometer reading at a given temperature for a certain type of instrument, from an observed reading at another temperature with another type of instrument, the following steps may be taken.

1. Determine the kinematic viscosity corresponding to the observed reading by means of Fig. 1.
2. Multiply by the density (g/cm³) so as to obtain the absolute viscosity (η) in poises; find the logarithm of the absolute viscosity and the logarithm of the temperature (t) of test (°F).
3. Plot the observed η, t and the η_o, t_o of the point of intersection, as given in Table 1, on logarithmic paper. Or plot the corresponding logarithms on equispaced coordinate paper. In either case, these two points locate a straight graph upon which the viscosity at the desired temperature will be found.
4. Divide the absolute viscosity at the desired temperature by the density at that temperature to get the kinematic viscosity. From this, determine, by means of Fig. 1, the corresponding time of flow on the desired viscometer.

It will be noted that the density under (2) and (4) must be the density at the temperature under consideration, and not the density at 60°F (15.6°C), which is generally the standard for such density determinations.

If an instrument is used in an irregular manner, appropriate corrections must be applied (2, 3, 6, 9).

Table 2.—Saybolt Universal and Saybolt Furol Viscometers

Units: Time (t), sec; kinematic viscosity = (η/d), poise/(g per cm³).

Saybolt Universal		Saybolt Furol	
t	η/d	t	η/d
32	0.0115	25	0.486
40	0.0417	26	0.512
50	0.0740	27	0.537
60	0.103	28	0.562
70	0.130	29	0.586
80	0.156	30	0.610
90	0.181	35	0.730
100	0.206	40	0.846
125	0.266	45	0.960
150	0.324	50	1.072
175	0.381	60	1.292
200	0.437	70	1.507
225	0.492	80	1.724
250	0.548	90	1.939
275	0.603	100	2.155
300	0.658		

For higher viscosities the kinematic viscosity is equal to 0.00220t for the Saybolt Universal, or to 0.0216t for the Saybolt Furol.

SELECTED TECHNICAL TERMS

N. Ernest Dorsey

In this section are given the definitions of numerous units, and very brief explanations of such technical terms as occur in many sections of the I. C. T. or are for other reasons more suitably considered here than elsewhere. Other terms will be explained where they occur in the body of the work. Symbolical explanations will be given wherever they appear to be satisfactory. In many cases, dimensional formulae (see p. 18) are given; these are enclosed in [ ]. Symbols are enclosed in ( ). The sequence will be: Name, symbol or symbols, dimensional formula, definition or explanation; but the symbol or formula, or both may be omitted. For the explanation of the symbols employed in the formulae and explanations, see p. 16.

Aberration, Constant of.—[θ]. tan $(V\text{-}v)/\mathbf{c}$. V, v = maximum and minimum velocity of earth in its orbit, $\mathbf{c}$ = velocity of light in vacuo.

Absolute.—(abs.). 1. An adjective, descriptive of a system of units which is based upon the smallest possible number of independent units. In this connection, every specification of a definite substance or of a vacuum is to be regarded as the introduction of an independent unit. 2. **Absolute zero.** The temperature at which the pressure of a fixed mass of an ideal gas, maintained at a constant volume, becomes zero. 3. **Absolute temperature.** The temperature reckoned from the absolute zero.

Absorption.—When the absorption of radiation by a substance is such that $J = J_o e^{-kl}$, J, J_o = intensity, l = length of path, k is the **coefficient of absorption.** k/d = coefficient of **mass absorption.** Writing $k = (4\pi k'n)/\lambda$, n = index of refraction, λ = wave length in vacuo, k' = **index of absorption.** (Some call $k'n$ the index.)

Absorptivity.—Ratio of radiant energy absorbed to that absorbed, under same conditions, by a black body.

Action, Planck's constant of.—*See* Planck.

Ampere.—Unit of electric current. **Abs. ampere** = 0.1 cgs unit. **Int. ampere** is that unvarying electric current which, when passed through a solution of silver nitrate in water, in accordance with certain specifications, deposits silver at the rate of 0.00111800 gram per second.

Ampere-turn.—Unit of mmf. Difference in magnetic potential between the faces of a coil of one turn carrying one ampere.

Ångstrom unit.—(Å). [l]. 10^{-10} meters. **International Ångstrom** defined as such a length that wave-length of red cadmium line in air at 15°C, A_n, is exactly 6438.4696 Int. Å; it = 10^{-10} m within experimental error.

Anomalistic.—Anom. year [month] = time between successive passages of earth [moon] through perihelion [perigee].

Aphelion.—Point of planet's orbit farthest from sun.

Apogee.—Point of moon's orbit farthest from earth.

Aries, First point of.—Designation of position of vernal equinox (*see* Celestial sphere); not at present in constellation Aries.

Assay ton.—[m]. 29⅙ grams; as many mg as there are troy ounces in short ton.

Astronomical unit of length.—Mean distance (*q.v.*) earth to sun; 149.50×10^6 km.

Astronomical unit of mass.—Mass of sun.

Astronomical unit of time.—Mean solar day.

Atmosphere.—[force area^{-1}], [m/lt^2]. 1. **Normal atmosphere** (A_n) defined as pressure exerted by vertical column of liquid 76 cm long, density 13.5951 grams per cm³, acceleration of gravity being 980.665 cm sec^{-2}. 2. **Atmosphere at 45°** (A_{45}) differs from A_n only in use of acceleration of gravity at sea level and lat. 45° instead of 980.655 cm sec^{-2}. 3. **British atmosphere** is based on 30 inches instead of 76 cm.

Avogadro's number.—(N_0). [m^{-1}]. Number of molecules in a mole.

Bar.—[force/area], [m/lt^2]. Internationally accepted unit of pressure; = 10^6 dyne/cm². Has also been used to denote one dyne/cm² (*cf.* Barye).

Barye.—[force/area], [m/lt^2]. The cgs unit of pressure, one dyne/cm². (In accordance with recommendation of special committee of International Congress of Physicists, Paris, 1900, and with the usage of the International Bureau of Weights and Measures.) (*cf.* Bar).

B. A. unit.—A unit of electrical resistance based on certain coils prepared in 1863–1864 by British Association for Advancement of Science.

Black Body.—One which absorbs all radiant energy incident upon it. Its radiance of wave-length λ is $J_\lambda\,d\lambda$; the **intensity,** $J_\lambda = C_1\lambda^{-5}[e^{C_2/\lambda T} - 1]^{-1}$, T = absolute temperature, C_1, C_2 are **radiation constants. Total radiance** (J) is $\int J_\lambda\,d\lambda$ taken over all wave-lengths. $J = \sigma T^4$, σ = **Stefan,** or **Stefan-Boltzmann** constant of total radiation. For each T there is a wave-length (λ_m) for which $J_\lambda (= J_m)$ is a maximum; $J_m = C_j T^5$, C_j = **intensity coefficient**; $\lambda_m = w/T$, w = **Wien's displacement constant.**

Board of Trade unit.—1. A unit of **electrical resistance** based upon certain coils preserved by British Board of Trade. 2. (B.T.u.). Unit of **work.** Generally used in England as equivalent of one kilowatt-hour. (To be distinguished from British thermal unit (BTU).)

Boltzmann's molecular gas constant.—(k_o). [ml^2/t^2T]. Gas constant (*q.v.*) per molecule.

Bougie decimale.—[$\psi\omega^{-1}$]. An old unit of luminous intensity, 0.05 Violle unit.

Brightness.—[$\psi/l^2\omega$]. Luminous intensity per unit of apparent area of the luminous surface; if emission follows Lambert's law, brightness is independent of direction of line of sight, otherwise it is not; in latter case, line of sight is assumed to be normal to the surface unless the contrary is stated.

British Thermal Unit.—(BTU). [energy], [ml^2/t^2]. Heat per pound, per °F of rise, required to produce small rise in temperature of water under pressure A_n; varies with temperature, which must be stated. **"Mean" BTU** = 1⁄180 of heat required to raise one lb. of water from 32°F to 212°F, pressure A_n. (To be distinguished from Board of Trade unit (B.T.u.).)

Bulk modulus.—[stress], [m/lt^2]. Hydrostatic pressure divided by resulting decrease in volume per unit volume. Also called **volume elasticity, cubical elasticity, resistance to compression, modulus of compression** (*cf.* compressibility).

Calorie.—[Heat], [ml^2/t^2]. 1. Heat per unit of mass, per °C of rise, required to produce small rise in temperature of water under pressure A_n; varies with temperature, which must be stated. If unit of mass is gram, it is called small calorie, gram calorie, or calorie; symbol is cal. If unit of mass is kilogram, it is called large calorie, kilogram calorie, or Calorie; symbol, Cal. (2) **Mean calorie** = 1⁄100 of heat required to raise unit mass of water from 0°C to 100°C, pressure A_n.

Candle.—(ca). [$\psi\omega^{-1}$]. Basic photometric unit of luminous-intensity. A value determined by international agreement, and maintained at certain national laboratories by means of incandescent electric lamps is known as the "International candle."

Candle per square centimeter.—[$\psi/l^2\omega$]. Brightness of surface which, in direction considered, has a luminous intensity of one candle per cm^2 of apparent area; π lamberts. Similarly: Candle per sq. in., etc.

Candlepower.—(c.p.). Luminous intensity in terms of candles.

Capacity, heat.—1. Of a substance, is heat per unit of mass, per degree of rise, required to produce a very small rise in temperature, also called **specific heat,** and **thermal capacity.** 2. Of a body, is heat, per degree of rise, required to heat the body.

Capacity, electrical.—Of body A with reference to body B is $Q/(V_A - V_B)$, all other bodies in the field being insulated and uncharged; Q = charge on A; V_A, V_B = potential of A, B.

Capacity, polarization.—Of one electrode with reference to another is its electrical capacity per unit of area.

Capillary constant.—(a). [l]. 1. **British usage:** $a_1^2 = \gamma/(d_1 - d_2)g$; γ = surface tension, g = acceleration of gravity, $(d_1 - d_2)$ = positive difference in the densities of the fluids separated by the surface. 2. **German usage:** $a_2^2 = 2\gamma/(d_1 - d_2)g$. (The subscripts to the a are usually omitted.)

Carat fine.—*See* Karat.

Càrcel unit.—A superseded unit of luminous intensity; approximately = 9.6 Int. candles.

Celestial sphere.—Sphere, concentric with earth, serving to locate angular positions of celestial bodies; its intersection with plane of earth's orbit [equator] is called **ecliptic [celestial equator]**; intersections of ecliptic and equator are called **equinoxes**; motion of equinoxes with reference to stars is called **precession of equinoxes,** it is resultant of an oscillatory and a nearly uniform motion, a fictitious equinox possessing only the latter motion is called **mean equinox.** The mean equinox through which sun passes in spring of northern terrestrial hemisphere is called mean vernal equinox, and is point from which **celestial longitude** (along the ecliptic) and **mean right ascension** (R. A.) (along the equator) are measured—positive to the east. Intersections of the sphere and the axis of rotation of earth are called **celestial poles**; that of the sphere and its diameter perpendicular to plane of ecliptic called **poles of the ecliptic.** Declinations are measured from equator along great circles passing through the poles—positive towards north; **celestial latitudes,** from ecliptic along great circles passing through poles of ecliptic—positive towards north. The pole of the sphere has a motion compounded of a nearly uniform progressive motion and a rotation about a point having the former motion; that point is called **mean pole,** its motion is the **precession of the pole,** the rotation of the true pole about the mean pole is called the nutation of the pole; mean (angular) distance between mean pole and true pole is called **constant of nutation.**

Centi-.—Prefix denoting $\frac{1}{100}$.

Centigrade.—(C). Thermometric system in which freezing point of water is called 0° and its boiling point is called 100°; pressure = A_n.

Centigrade thermal unit.—(CTU). [energy], [ml^2/t^2]. Differs from British Thermal Unit only in the substitution of Centigrade for Fahrenheit scale.

Centimeter.—(cm). 1. The cgs unit of **length,** 0.01 meter. 2. Often used to denote cgse unit of **electrical capacity.** 3. Occasionally used to denote cgsm unit of **electrical inductance.**

Centimeter-dyne.—[work], [ml^2/t^2]. One erg.

Centimeter of water [of mercury, etc.] at t°.—[force/area], [m/lt^2]. Denotes pressure exerted by a vertical column of water [of mercury, etc.] one cm long, temperature t°, at a place where acceleration of gravity is g_s ($=980.665$ cm/sec²).

Cheval-vapeur.—[work/time], [ml^2/t^3]. 1. Primary definition, 75 meter-kilograms per second. Also called **force de cheval, continental horsepower, Pferdekraft.** 2. For electrical purposes, generally regarded as exactly 736 watts; may be called **continental electrical horsepower.**

Circular inch.—(cir. in.). [l^2]. Area of a circle one inch in diameter. Similarly for **circular mil** (cir. mil), **circular millimeter** (cir. mm), etc.

Compressibility.—[lt^2/m]. Reciprocal of bulk modulus.

Compression, modulus of.—[m/lt^2]. *See* Bulk modulus.

Concentration.—1. The amount per unit of volume; may be called **volume concentration.** If amount is measured by mass, the symbol is C. 2. The mass of the material per unit of mass of the mixture containing it; may be called **mass concentration.** If both masses are expressed in terms of the same unit, this concentration is generally called the **titer** of the mixture.

Conductance.—Reciprocal of resistance.

Conductance, Specific.—*See* Conductivity, electrical.

Conductivity, Electrical.—Reciprocal of electrical resistivity (*q.v.*). 1. (κ) **Volume conductivity** = reciprocal of volume resistivity; specific conductance. 2. **Mass conductivity** = κ/d; d = density. 3. **Equivalent conductivity** (Λ) is κ/c; c = equivalents of solute per unit volume of solution. 4. **Molecular conductivity** (μ) is κ/m; m = moles of solute per unit volume of solution.

Conductivity, Thermal.—[(heat/area-time)/(T/l)]; [ml/Tt^3]. $\mathrm{d}Q/\mathrm{d}t = -k\,\mathrm{d}x\mathrm{d}y\dfrac{\mathrm{d}\theta}{\mathrm{d}z}$; k = thermal conductivity, $\mathrm{d}Q$ = amount of heat through $\mathrm{d}x\mathrm{d}y$, in direction $\mathrm{d}z$, in time $\mathrm{d}t$, $\mathrm{d}\theta$ = increase in temperature in distance $\mathrm{d}z$.

Coulomb.—The quantity of electricity transferred in one second by a current of one ampere.

Critical.—1. Any point, line, or region serving to locate a well marked **transition** may be described as critical. 2. As regards **condensation** of vapors, the temperature corresponding to the isotherm above which liquefaction is impossible is called the **critical temperature**; the vapor pressure at which the two phases are in equilibrium at the critical temperature is the **critical pressure**; volume of unit mass at the critical pressure and temperature is the **critical volume.** These three values are called the **critical constants.**

Cubic.—(cu.), (^{3}). Used in conjunction with name of unit of length to form name of a related unit of volume; *e.g.*, cubic meter (cu. m) (m^3) is name of a unit of volume equivalent to volume of a cube with edges one meter long.

Cubic centimeter atmosphere.—*See* Liter-atmosphere.

Curie.—Internationally defined as amount of radon (radium emanation) which can exist in equilibrium with one gram of radium.

Current.—(I). The current of x through a surface S is $I = \mathrm{d}x/\mathrm{d}t$, where $\mathrm{d}x$ is the amount of x which passes through S in time $\mathrm{d}t$. The density of the current through S at a given point is $\sigma_s = \mathrm{d}I/\mathrm{d}S$, where $\mathrm{d}I$ is the current at that point through an element of S of area $\mathrm{d}S$. The value of σ varies with the orientation of $\mathrm{d}S$, and for a certain orientation it is a maximum. The normal, in the direction of the flux, to the element so oriented is the **direction of the current**; and this maximum value of σ is called the **density,** or the **intensity,** of the current at that point.

Dalton.—[m]. A unit of mass, $\frac{1}{16}$ mass of atom of oxygen. Approximately $1.65_0 \times 10^{-24}$ grams.

Day.—(da). [t]. 1. **Solar day** = interval between successive transits of sun across same meridian. It is not of uniform length. 2. **Mean solar day** = average length of all the solar days in a tropical year. This is the basis of all our time measurements and is what is meant by day unless the contrary is definitely indicated. 3. **Sidereal day** = interval between successive transits of true vernal equinox. 4. The day defined by successive transits of **same fixed star** is not used in astronomical computations, and appears to have no name.

Deci-.—Prefix denoting $\frac{1}{10}$.

Declination.—1. Of **celestial objects.** *See* Celestial sphere. 2. **Magnetic declination** = angular deviation of horizontal component of earth's magnetic field from northerly measured geographic meridian; easterly deviations, positive.

Degree.—1. (°), (deg). Unit of difference in **temperature**; size depends upon thermometric scale employed. 2. (°). Unit of angle, $\frac{1}{360}$ of complete circumference. 3. (°). **Hydrometer degree** is an arbitrary unit of difference in specific gravity; its value depends upon type of hydrometer (*see* p. 31).

Deka-.—Prefix denoting 10.

Demal.—A concentration of one g-equivalent per dm^3.

Density.—1. **Volume density** = $\mathrm{d}Q/\mathrm{d}v$, $\mathrm{d}Q$ = amount of the physical quantity considered which is contained in the element of volume $\mathrm{d}v$. 2. **Density of a substance,** (d), (D), is $\mathrm{d}m/\mathrm{d}v$, m = mass. When, on a particular scale of operation, the density varies from point to point, it may be that on a larger scale it will not; then the density on the larger scale may properly be called the **apparent density** (sometimes called **bulk density**) when operations on the smaller scale are being considered. 3. **Surface density** = $\mathrm{d}Q/\mathrm{d}s$, $\mathrm{d}s$ = element of area of surface over which $\mathrm{d}Q$ is distributed.

Dielectric constant.—(ϵ). $[t^2/\mu l^2]$, $[\epsilon]$. The force (f) of repulsion between two point charges (e, e') of electricity at a distance (r) apart in a uniform medium of great extent is $f = ee'/\epsilon r^2$; ϵ depends upon the nature of the medium, and is called its dielectric constant.

Diffusion, Coefficient of.—*See* Diffusivity.

Diffusivity.—1. (Δ). $\left[\frac{\text{quantity}}{\text{area time}} \Big/ \frac{\text{vol. concen.}}{\text{distance}}\right]$, $[l^2/t]$. $\mathrm{d}Q/\mathrm{d}t = -\Delta(\mathrm{d}c/\mathrm{d}x)\mathrm{d}y\mathrm{d}z$. $\mathrm{d}Q$ = amount of Q passing through area $\mathrm{d}y\mathrm{d}z$ in direction of x in time $\mathrm{d}t$, $\mathrm{d}c/\mathrm{d}x$ = rate of increase, in direction of x, of volume concentration of Q. Also called **coefficient of diffusion.** 2. **Heat diffusivity.** $\left[\frac{\text{heat}}{\text{area} \times \text{time}} \div \frac{\text{specific heat} \times \text{density} \times \text{temp.}}{\text{distance}}\right]$, $\left[\frac{\text{heat conductivity}}{\text{density} \times \text{specific heat}}\right]$, $[l^2/t]$. $\mathrm{d}Q/\mathrm{d}t = -\Delta_t cd(\mathrm{d}T/\mathrm{d}x)\mathrm{d}y\mathrm{d}z$, Δ_t = **heat diffusivity,** c = specific heat, d = density, T = temperature. $\Delta_t cd$ = **thermal conductivity.** Δ_t also called **temperature conductivity.**

Displacement constant, Wien's.—*See* Black body.

Displacement, Electric.—*See* Induction, electrostatic.

Draconic month.—*See* Nodical month.

Dyne.—$[ml/t^2]$. The cgs unit of force. The force which, when acting continuously upon a mass of one gram and not opposed by another, will impart to the mass a uniform acceleration of one cm per sec.[2]

Dyne-centimeter.—[force · length], $[ml^2/t^2]$. The torque of one dyne acting on a lever-arm of one cm.

Ecliptic.—*See* Celestial sphere.

Elastic modulus.—Ratio of stress to resulting elastic strain. There are as many types of moduli as there are types of strain. 2. Occasionally used to denote **Young's modulus.**

Elasticity.—1. **Cubical**; *see* Bulk modulus. 2. **Longitudinal**; *see* Young's modulus. 3. **Shear**; *see* Rigidity. 4. **Torsional**; *see* Rigidity. 5. **Modulus of**; *see* Elastic modulus.

Electric displacement, field strength, etc.—*See* corresponding nouns.

Electromagnetic unit of quantity of electricity.—*See* Quantity of electricity.

Electromotive force.—(E), (emf). *See* Potential.

Electron.—Negative electrons are very small negatively charged particles observed under many, very diverse conditions. All appear to be alike in every way, including amount of charge carried. They appear to be one of the basic elements of which atoms are made.

Electronic charge.—(e). A quantity of electricity, of either sign, which is numerically equal to the electric charge carried by an electron.

Electronic mass.—(m_o). The mass of a negative electron when moving with a velocity much less than that of light.

Electronic ratio.—$(\mathrm{e}/\mathrm{m}_o)$. Ratio of electronic charge to electronic mass.

Electrostatic unit of quantity of electricity.—*See* Quantity of electricity.

Elongation.—Distance of an oscillating, or of a revolving, body from a point of reference; *e.g.*, the distance of an electron from the nucleus about which it revolves.

Emissivity.—Ratio of radiance of the body to that of a black body at same temperature. If radiation of only one wave-length is considered, it is **monochromatic emissivity**; if all wave-lengths, it is **total emissivity.** The ratio of the radiances (or of the emissivities) of two non-black bodies is called **relative emissivity** of first with respect to second.

English sperm candle.—*See* Sperm candle.

Equation of time.—*See* Time.

Equator.—1. The intersection of surface of the **earth,** or other rotating spheroid, with the plane through its center perpendicular to its axis of rotation. 2. The intersection of the surface of a **spheroid** with a plane through its center and perpendicular to any diameter chosen as axis. 3. **Celestial equator.** *See* Celestial sphere.

Equinox.—*See* Celestial sphere.

Equivalent.—(equiv). Electrochemical equivalent (briefly equivalent) of an ion—actual or potential—is its formula weight divided by its valence.

Erg.—[force · distance], $[ml^2/t^2]$. Work done by a force of one dyne while acting through a distance of one centimeter in its own direction.

Erg-second.—[work · time], $[ml^2/t]$. The action produced by one dyne acting through one cm in one sec.

Expansion, coefficient of.—*See* Expansivity.

Expansivity.—$[T^{-1}]$. 1. **Volume expansivity** = $\mathrm{d}v/(v\mathrm{d}T)$. 2. **Linear expansivity** = $\mathrm{d}l/(l\mathrm{d}T)$. v, l, T = volume, length, temperature; $\mathrm{d}v[\mathrm{d}l]$ is change in $v[l]$ produced by change $\mathrm{d}T$ in temperature.

Fahrenheit.—(F). A thermometric system in which 32° denotes the freezing, and 212°, the boiling point of water under pressure of A_n.

Farad.—Capacity of electrical condenser which is charged to a potential difference of one volt by one coulomb.

Faraday.—(F). A subsidiary unit, the electrical charge carried in electrolysis by one gram-equivalent.

Field.—The field of a physical quantity is the region of space within which phenomena characteristic of the quantity exist. The strength, or intensity, of the field at any point is measured by the magnitude at that point of some chosen, characteristic phenomenon, and the complete designation of the field includes an indication of this phenomenon; *e.g.*, electrical field of force. As force is the phenomenon most frequently chosen, and in other cases the context indicates what is intended, the explicit designation of the chosen phenomenon is quite frequently omitted.

Field intensity.—The strength, or intensity, of a field of force at any point is $\mathrm{d}f/\mathrm{d}m$, where $\mathrm{d}f$ is the mechanical force experienced by $\mathrm{d}m$, a vanishingly small amount of m placed at that point. For an **electrical field,** m is positive electricity; for a **magnetic field** it is a north magnetic pole; for a **gravitational field** it is mass. Magnetic field strength is frequently called **magnetizing force.**

Fluidity.—(φ). Reciprocal of viscosity. Also called **coefficient of fluidity.**

Flux.—1. Flux (ψ) of **vector** (V) through surface S is $\psi = \int_S V_n \mathrm{d}S$; V_n = component of V normal to $\mathrm{d}S$, integral is to be taken over S. 2. Flux of a **quantity** Q through surface is $\psi = \mathrm{d}Q/\mathrm{d}t$,

dQ = amount of Q which passes through S in time dt. 3. From **point source.** If $V = I/r^2$, where r = distance from source and I is a constant independent of direction, I is called **intensity of the source,** and $\psi = I\omega$; ω = solid angle subtended, at the source, by S (*cf.* Intensity, luminous).

Flux, Luminous.—(ψ). Flux of radiant energy expressed in terms of its power to produce luminous sensation in the human eye.

Flux, Magnetic.—Flux of magnetic induction.

Foot-candle.—$[\psi/l^2]$. Unit of illumination, one lumen per square foot.

Foot-lambert.—$[\psi/l^2\omega]$. Unit of brightness; *see* Lambert.

Foot-pound.—$[ml^2/t^2]$. Work required to raise one pound a vertical distance of one foot, where $g = 980.665$ cm/sec^2 (*cf.* meter-kilogram).

Foot-poundal.—$[ml^2/t^2]$. Work done by force of one poundal (*q.v.*) acting through a distance of one foot.

Force.—$[ml/t^2]$. That which imparts acceleration to material bodies.

Force, Electromotive.—*See* Potential.

Force, Magnetizing.—*See* Field intensity.

Force, Magnetomotive.—*See* Potential.

Force de cheval.—*See* Cheval-vapeur.

Frequency.—(ν). $[N/t]$. Number per unit of time. In case of vibrations, waves, etc., the frequency is the number of complete vibrations, of complete waves, etc., per unit of time.

Gamma.—(γ). $[\sqrt{m/\mu l t^2}]$, $[\sqrt{ml\epsilon/t^4}]$. A unit of magnetic field intensity; 0.000 01 gauss.

Gas constant.—1. (R). [work/mass-degree], $[l^2/t^2T]$. The coefficient R in the ideal gas equation $pv = RTm$; p = pressure, v = volume of the mass m at absolute temperature T. 2. (R). [work/mole-degree]. **Gas constant per mole** obtained by expressing m in moles. 3. (k). [work/molecule-degree], $[ml^2/t^2T]$. **Boltzmann's molecular gas constant:** obtained by expressing m in terms of number of molecules.

Gas, Ideal.—One which strictly satisfies the equation ($pv = RTm$) and other relations deduced from the classical kinetic theory of gases on the assumption that the molecules are infinitely small and devoid of mutual attraction.

Gauss.—$[\sqrt{m/\mu l t^2}]$, $[\sqrt{ml\epsilon/t^4}]$. The cgsm unit of magnetic field intensity.

Gaussian gravitation constant.—The square root of the intensity of the gravitational field of force of the sun at a point whose distance from the sun is the astronomical unit of length (*cf.* Gravitation constant).

Geepound.—*See* Slug.

Gilbert.—$[\sqrt{ml/\mu t^2}]$, $[\sqrt{\epsilon m l^3/t^4}]$. Electromagnetic unit of magnetic potential, of magnetomotive force. Unless contrary is indicated, it is the cgsm unit. In precise work, the International gilbert, based upon the Int. elec. units, should be distinguished from the absolute, or cgsm, gilbert.

Grade.—$[\theta]$. Unit of plane angle, $\frac{1}{400}$ of complete circumference.

Gram atom.—*See* Mole.

Gram calorie.—*See* Calorie.

Gram equivalent.—*See* Mole.

Gram formula weight.—*See* Mole.

Gram weight.—*See* Weight.

Gravitation constant.—(G). $[l^3/mt^2]$. The coefficient G occurring in the equation $f = \mathrm{G}\,(mm')/r^2$; f = force of gravitational attraction between two point masses (m, m') in vacuo, r = distance between m and m' (*cf.* Gaussian gravitation constant).

Gravity, Acceleration of.—(g), (g_s). $[l/t^2]$. Unless the contrary is indicated, this expression refers specifically to the earth, and denotes the resultant acceleration downward experienced by a freely falling body placed at the point considered. It includes centrifugal effects arising from the rotation of the earth, as well as the effects of gravitational attraction (*cf.* Gravity, standard).

Gravity, Specific.—*See* Specific gravity.

Gravity, Standard.—(g_s). $[l/t^2]$. Standard gravity is the value adopted by the International Committee on Weights and Measures as the "accepted" value of the acceleration of gravity to which all measurements involving this quantity are to be referred. Thus a pressure of x cm of mercury at t°C is to be understood as denoting the pressure exerted by x cm of mercury at t°C at a place where the acceleration of gravity is g_s. The accepted value is $g_s = 980.665$ cm/sec^2 (= 32.174 ft./sec^2).

Heat.—1. By the **heat of a process** is meant the amount of heat evolved, per unit quantity of material involved, during the isothermal process, the process proceeding in the direction indicated. The quantity of material may be expressed in terms of mass, of moles, of equivalents, etc., as may seem desirable. 2. By the **latent heat** of a transformation is meant the amount of heat absorbed per unit quantity of material transformed, the transformation proceeding in the direction indicated. Latent heat of transformation of A to B = $-$(heat of transformation of A to B) = heat of transformation of B to A.

Heat diffusivity.—*See* Diffusivity.

Heat, Specific.—*See* Capacity, and Specific heat.

Hecto-.—Prefix denoting 100.

Hefner unit.—A superseded unit of luminous intensity; approximately = 0.9 Int. candles.

Henry.—$[\mu l]$, $[t^2/\epsilon l]$. Unit of electromagnetic inductance. Defined as that inductance for which an induced electromotive force of one volt is produced when the inducing current is changed at the uniform rate of one ampere per second.

Horsepower.—(h.p.). [work/time], $[ml^2/t^3]$. 1. (HP) **Primary definition** of the term is work done at the rate of 550 foot-pounds per second. 2. For electrical purposes it is regarded as exactly = 746 watts, which is frequently called the **electrical horsepower.** 3. **Continental horsepower.** *See* Cheval-vapeur.

Humidity.—1. **Absolute humidity** of a gas is the actual amount of water vapor per unit volume of the gas. Usually expressed in terms of the actual pressure of the water vapor present. 2. **Relative humidity** of a gas = ratio of the pressure of water vapor present to the pressure of water vapor which is in equilibrium with water at the same temperature. 3. **Dew-point** of a gas is the temperature at which the pressure of water vapor in equilibrium with water is equal to the actual pressure of the water vapor contained in the gas. If the temperature of the gas be varied while its absolute humidity remains unchanged, then the dew-point is that temperature at which the relative humidity is 100%. 4. If the bulb of a thermometer be encased in a fabric which is kept wet with water (**wet-bulb**), the thermometer will record a lower temperature than if the bulb were dry (**dry-bulb**). If the circulation over the wet bulb is sufficiently rapid, the difference in the temperatures depends solely upon the total pressure of the gas, its absolute humidity, and its temperature. Hence the humidity of the atmosphere, or of any other very large volume of gas, can be readily determined by the use of wet- and dry-bulb thermometers.

Hydrometer.—An instrument which, by the extent of its submergence, indicates the specific gravity of the liquid in which it floats. Frequently, its readings are expressed in degrees (°). Various systems of graduations are in use, *see* p. 31.

Hygrometric.—Pertaining to humidity of atmosphere.

Hypsometry.—The art of measuring the elevation above sea-level. More specifically, the use of the boiling-point of water for such measurements.

Ice point.—(T_0). Temperature at which water freezes when under the pressure of one normal atmosphere.

Ideal gas.—*See* Gas, ideal.

Illumination.—$[\psi/l^2]$. The illumination at a point of a surface is the surface density of the luminous flux incident at that point.

Inch of water [of mercury, etc.] at $t°$.—Analogous to cm of water (*q.v.*)

Index of absorption.—*See* Absorption.

Index of refraction.—*See* Refraction.

Inductance.—The electrical inductance of circuit A with reference to circuit B is ψ_A/I_B; ψ_A = flux of magnetic induction through A as a result of the current I_B in B. A and B may be the same circuit.

Induction.—1. That **modification** which is acquired by a medium when it becomes the seat of a field of force, and which is evidenced by the fact that its boundaries with other media exhibit distinctive properties which they do not possess in the absence of the field. 2. The distinctive **properties** mentioned in (1); as in magnetization by induction, induced electric charges, etc. 3. **Electrostatic induction.** $[\sqrt{m/\mu l^3}]$, $[\sqrt{\epsilon m/lt^2}]$. ϵF, ϵ = dielectric constant, F = intensity of electrostatic field of force. **Electric displacement** = $\epsilon F/4\pi$. 4. **Magnetic induction** (B). $[\sqrt{\mu m/lt^2}]$, $[\sqrt{m/\epsilon l^3}]$. $B = \mu H$, μ = magnetic permeability, H = intensity of magnetic field of force. 5. **Electromagnetic induction** is the phenomenon which is characterized by the appearance, in every circuit, of a cyclical emf which is proportional to the rate of change of the flux of magnetic induction through that circuit.

Intensity coefficient.—*See* Black body.

Intensity, Field.—*See* Field intensity.

Intensity, luminous.—1. Of a **point source** in a given direction = amount of luminous flux, per unit of solid angle, which the source emits in the direction considered. 2. Of a **point of an extended source** = brightness of that point of the source; also called intrinsic brightness. 3. Of an **extended source,** in a given direction, is its intensity at a point so distant in the stated direction that the source may be regarded as a point. For nearer points the **apparent intensity** will depend upon the distance, and is defined as the intensity of that point source which at the same distance will produce the same illumination (*cf.* flux).

Intensity of magnetization.—*See* Magnetization.

Intensity of radiation.—1. The intensity of the **radiation emitted** in a specified direction by a body is the amount of radiant energy emitted in that direction, per unit of time, per unit of area, and per unit of solid angle of emission. For spectral, or monochromatic, intensity, *See* Radiance. 2. Of **received radiation,** *See* Irradiation. 3. Of **radiation in transit.** The amount of radiant power per unit area which passes through an element of area which is normal to the direction of propagation; this equals the volume density of radiant energy at the point considered.

International electrical units.—A system of electrical and magnetic units based upon the ohm, the ampere, and secondarily upon the volt, all as realized by certain concrete standards which have been internationally agreed upon, and upon the cgs units for such other quantities as may be involved. The concrete standards have been so chosen as to make the international system nearly identical with the practical system; as now defined, the outstanding discrepancy in no case exceeds 52 parts in 100 000. In distinguishing between the two systems, the units of the practical system are described as absolute, those of the other, as international. The introduction of the volt as a secondary unit defined by a concrete standard (Weston normal cell = 1.018300 Int. volts at 20°C) introduces confusion when measurements of high precision are to be recorded. In these Tables, values based upon the Int. ohm and the Int. ampere (as defined by the silver voltameter) are denoted by (a). Those based on the Int. ohm and the Int. volt (as defined by the standard cell) are denoted by (v).

Irradiation.—The radiant power, per unit of area, incident upon a surface.

Joule.—$[ml^2/t^2]$. 1. **Absolute joule** = 10^7 ergs. 2. **International joule** = work expended per second by an Int. ampere in an Int. ohm.

Karat.—(K). Denotes the "fineness of gold" in terms of parts (by weight) of gold per 24 parts of the alloy. Twenty-four g of an n karat alloy contains n g of gold, the alloy is **"n carats fine."**

Kelvin.—(K). Name applied to the absolute centigrade scale of temperature.

Kilo-.—Prefix denoting 1000.

Kilogram calorie.—*See* Calorie.

Kilogram-meter.—A torque equivalent to that of one kilogram weight acting on a lever-arm one meter long.

Kilowatt-hour.—Work expended by one kilowatt in one hour. In Great Britain it is quite generally called **Board of Trade unit** (B.T.u.).

Kinematic viscosity.—$[l^2/t]$. Ratio of viscosity to density.

Lambert.—$[\psi/l^2\omega]$. The brightness of a surface which, radiating in accordance with Lambert's law, emits a total luminous flux of one lumen per cm². For such a surface, brightness is independent of direction of the line of sight and equals $1/\pi$ lumen, per steradian, per cm² = $1/\pi$ candles per cm². If the total emission is one lumen per sq. ft., the brightness is called one **foot-lambert.**

Lambert's law.— $I = I_o \cos\theta$; $I_o[I]$ = intensity of radiation emitted in direction normal [at angle θ with normal] to the surface. In many cases this law does not express the facts.

Latent heat.—(l, L). *See* Heat.

Latitude.—(lat.). 1. The angular distance of a point from the equator of a **spheroid,** measured along a great circle passing through the poles. 2. **Celestial latitude.** *See* Celestial sphere.

Legal ohm.—A unit of resistance; so designated by the International Conference of 1884, and defined as the resistance of a column of mercury 1 mm² in cross-section and 106 cm in length at the temperature of melting ice. It was never legalized.

Light-year.—Distance traveled by light in free space in one year.

Line.—Unit of flux of magnetic induction = one maxwell.

Liter-atmosphere.—The amount of external work done when a volume is increased by one liter against an external pressure of one atmosphere.

Longitude.—(long.). 1. The longitude of a point is the angle which its axial plane makes with a fiducial one. For the **earth,** angles measured from the fiducial plane towards the west are usually considered positive. 2. **Celestial** or **astronomical** longitude. *See* Celestial sphere.

Loschmidt's number.—(n_o). $[l^{-3}]$. Number of molecules per unit volume of an ideal gas at 0°C and pressure A_n.

Lumen.—$[\psi]$. Fundamental unit of luminous flux. A uniform point source of one candle emits 4π lumens.

Luminous flux.—*See* Flux, luminous.

Luminous intensity.—*See* Intensity, luminous.

Lunar month.—The time which elapses between successive new moons. Also called synodical month.

Lux.—A unit of illumination, one lumen per square meter.

Magnetic flux.—*See* Flux, magnetic.

Magnetic induction.—*See* Induction.

Magnetic moment.—*See* Moment.

Magnetization, Intensity of.—Magnetic moment per unit of volume (*cf.* moment).

Magnetomotive force.—(mmf). *See* Potential.

Magnitude.—The **magnitude, or apparent magnitude,** (m) of a star is primarily an indication of the amount of light the earth receives from it. The value to be assigned to the latter depends upon the characteristics of the perceptive apparatus: visual, photovisual, photographic, and radiometric magnitudes are to be distinguished. Certain stars near the north pole have been chosen as standards; the numerical magnitudes assigned to them are such as represent satisfactorily the range covered by early naked-eye estimates, and satisfy the equation $m = 2.5 (\log_{10} I_0 - \log_{10} I)$, I = intensity of light from a star of magnitude m, and I_0 = that from one of magnitude zero. For Vega, $m = 0.2$; a star of $m = 6$ is near the limit of naked-eye visibility. The **absolute magnitude** M is internationally defined as the apparent magnitude the star would have if its distance were 0.1 parsec; $M = m + 5 + 5 \log_{10} \pi$, π = parallax expressed in ″.

Mass, Engineers' unit of.—*See* Slug.

Maxwell.—The cgsm unit of flux of magnetic induction.

Mean distance.—In astronomical parlance, the mean distance of a planet from the sun denotes the mean of the greatest and the least distance from the sun to the path of the planet. Similarly in other cases.

Mean spherical candlepower.—Average candlepower of a source, in all directions.

Mega-.—Prefix = 1 000 000.

Megmho.—Conductance of one reciprocal microhm.

Meter-candle.—The illumination of an element of surface one meter distant from a uniform source of one candle situated upon the normal to the center of the element. One lux.

Meter-kilogram.—$[ml^2/t^2]$. Work required to raise one kilogram a vertical distance of one meter at a place where the acceleration of gravity is 980.665 cm/sec.^{2}

Mho.—An electrical conductance of one reciprocal ohm.

Micro-.—Prefix denoting $1/10^6$.

Microhm.—10^{-6} ohm.

Micromicro-.—Prefix denoting $1/10^{12}$.

Micron.—(μ). Unit of length = $1/10^6$ m = 0.001 mm.

Mil.—0.001 in. (*cf.* Circular inch).

Milli-.—Prefix = 0.001.

Millimicro-.—Prefix = 0.000 000 001.

Minute.—1. (min). **Time,** $\frac{1}{1440}$ of a day. 2. (′). Unit of **angle,** $\frac{1}{60}$ degree. 3. (\`). **Centesimal minute** = unit of angle = 0.01 grade.

Modulus.—1. *See* Elastic modulus. 2. For the several elastic moduli—bulk, compression, elasticity, rigidity, torsion, Young's—*see* distinguishing name.

Mohs.—An arbitrary scale of hardness based upon a selected list of 10 native minerals.

Mole.—A variable, derived unit of mass; its mass is numerically equal to the molecular weight of the substance measured. The expressions **gram-mole, kilogram-mole,** etc. are used to designate the basic unit of mass employed. Similarly derived units based upon the atomic weight, the formula weight, or the equivalent are called the **gram-atom, gram-formula weight** or **gram-equivalent** when the gram is the basic unit, and correspondingly in other cases.

Molecular.—For molecular properties, *see* appropriate properties.

Molecular volume.—Volume occupied by one mole. Molecular weight divided by density.

Molecular weight.—(M). The sum of the atomic weights of all the atoms contained in a molecule.

Moment.—1. Of force (F) about a point = Fl, l = perpendicular distance from the point to the line of F. 2. Of a **couple** = product of either force times perpendicular distance between them. 3. Of a **magnet** = moment of couple acting upon it when it is at right angles to a magnetic field of unit intensity. 4. Of **inertia** about an axis = sum of the products of each element of mass times the square of its distance from the axis.

Month.—1. Period of time determined by motion of **moon.** *See* lunar, synodical, tropical, sidereal, anomalistic, nodical, draconic. 2. **Solar month** = $\frac{1}{12}$ of tropical year. 3. **Calendar month** = conventional subdivision of year.

Myria-.—Prefix = 10 000.

Node.—1. A point of a **standing wave** where the displacement is independent of the time. 2. In **astronomy,** the points where an orbital, or other, plane cuts the ecliptic; the **rising node** is the one at which the passage across the plane of the ecliptic is from south to north.

Nodical month.—Time required by the moon to pass from one rising node to the next. Also called **draconic month.**

Noon.—*See* Time.

Normal.—1. The normal to a **surface** is a line drawn perpendicular to the surface at the point considered. 2. Any **line** perpendicular to another may be said to be normal to it. 3. A **concentration** of one gram-equivalent per liter.

Normal atmosphere.—(A_n). *See* Atmosphere.

Numeric.—(N). A pure number. A dimensionless quantity.

Nutation.—*See* Celestial sphere.

Oersted.—The cgsm unit of magnetic reluctance.

Ohm.—(Ω). A unit of electrical resistance. 1. **Absolute ohm** = 10^9 cgsm units. 2. **International ohm** is the resistance, at the temperature of melting ice, offered to an unvarying electric current by a column of mercury, of constant sectional area, having a mass of 14.4521 grams and a length, at the temperature mentioned, of 106.300 cm.

Ohm-centimeter.—Unit of electrical volume resistivity. The resistivity of a material of which a uniform bar one cm^2 in sectional area has a longitudinal resistance of one ohm per cm of length. Frequently called one **ohm per centimeter cube.**

Ohm (cm, gram).—Unit of electrical mass resistivity. The resistivity of a material of which a bar, having such a uniform section that its mass per linear cm is one gram, has a longitudinal resistance of one ohm per cm of length.

Ohm (meter, mm).—Unit of electrical volume resistivity. The resistivity of a material of which a circular cylinder one mm in diameter has a longitudinal resistance of one ohm per meter.

Ohm (meter, mm^2).—Unit of electrical volume resistivity. The resistivity of a material of which a circular cylinder one square mm in sectional area has a longitudinal resistance of one ohm per meter.

Ohm (mil, ft.).—Analogous to ohm (meter, mm). Cylinder one mil in diameter, resistance of one ohm per foot.

Ohm (mile, pound).—Analogous to ohm (cm, gram).

Ohm-inch.—Analogous to ohm-centimeter.

Parallax.—1. The **annual parallax** of a star is defined as the maximum angle subtended by one astronomical unit of length at the distance of the star from the sun. 2. The **equatorial horizontal parallax** of a member of the solar system is the maximum angle subtended by the equatorial radius of the earth at the distance of the earth from the member considered.

Parsec.—The distance of a star for which the annual parallax is one second of arc.

Pentane candle.—A superseded unit of luminous intensity = one Int. candle.

Percent.—(%). The number of units of the constituent in 100 units of the mixture containing it. If units of volume are used, the ratio is called **volume percent;** if units of mass, it is called **mass percent, weight percent,** or simply **percent.** (% must be distinguished from ‰ which is frequently used to denote per thousand.)

Perigee.—That point of the moon's orbit which is nearest to the earth (*cf.* apogee).

Perihelion.—That point of a planet's, or comet's, orbit which is nearest to the sun (*cf* aphelion).

Permeability.—(μ.) The force (f) of repulsion between two rigidly magnetized poles (m, m') at a distance r apart is $f = (mm')/(\mu r^2)$; μ depends upon the material in which the poles are immersed, and is called its permeability.

Pferdekraft.—*See* Cheval-vapeur.

Phot.—An illumination of one lumen per cm^2.

Photoelectric constant.—1. **h/e.** It is $1/\nu$ of the rise in potential required to impart to a negative electron the energy it has when emitted under the action of radiation of frequency ν. 2. **hc/e.** This is λ times the rise in potential mentioned in (1). λ = wave-length in vacuo.

Planck's constant of action.—(**h**). $[ml^2/t]$. A universal constant which fixes the amount of energy contained in the individual bundles, or quanta, of radiation emitted by a radiating body. Each such bundle contains an amount of energy $= \mathbf{h}\nu$, ν = vibration frequency of the radiation. **h** is also called **Planck's quantum.**

Poise.—$[m/lt]$. The cgs unit of viscosity. If the tangential force, per unit area, which one layer of a fluid exerts upon an adjacent one is one dyne when the space rate of variation of the tangential velocity from layer to layer is unity, the viscosity of the fluid is one poise.

Poisson's ratio.—If a bar of uniform section be subjected to a pure tensile stress, the ratio of its transverse contraction per unit of transverse thickness to its elongation per unit of length is called the Poisson's ratio of the material.

Pole strength.—*See* Quantity of magnetism.

Poncelet.—Unit of power = 100 meter-kilograms per second.

Potential.—The excess of the potential at the point A over that at B, with reference to any quantity m, is the mechanical work per unit of m which must be done in carrying a very small positive amount of m from B to A. The difference in electrical potential is called **electromotive force, emf, potential difference**; in magnetic potential, is called **magnetomotive force, mmf.**

Potential gradient.—The space rate of increase in the potential. If the direction in which the rate to be measured is not stated, that corresponding to the maximum gradient is to be understood.

Pound weight.—*See* Weight.

Poundal.—The unit of force in the fps system. It is the force which, if acting continuously upon a mass of one pound, will impart to it a uniform acceleration of one foot per $second^2$ (*cf.* Dyne).

Power.—1. The time **rate of doing work.** 2. If when the two junctions of a bimetallic circuit differ in temperature by a small amount (dt), there is an open circuit emf (dE) around the circuit, then $(dE)/(dt)$ is called the **thermoelectric power** of the circuit, corresponding to the average temperature of the two junctions. 3. The **ability** to do some specific thing; as in rotatory power.

Practical electric units.—A system of electrical units based upon 10^9 cm, 10^{-11} gram, sec, and the permeability of a vacuum, as fundamental units. The units of most interest are the ohm ($=10^9$ cgsm), ampere ($=0.1$ cgsm), and volt ($=10^8$ cgsm). Frequently described as absolute (*cf.* Int. elec. units).

Precession of the equinoxes.—*See* Celestial sphere.

Pressure.—(p), (P). $[m/lt^2]$. Normal force per unit of area. A **hydrostatic pressure** is a pressure which is the same in all directions. For critical pressures, *see* Critical.

Quadrant.—1. Unit of **angle** = 90°. 2. Formerly used occasionally to denote the **henry.**

Quantity of electricity.—1. (es). The **electrostatic unit** is that quantity which when concentrated to a point and placed at unit distance from an equal point charge will exert upon it a unit force, the surrounding medium being a vacuum. 2. (em). The **electromagnetic unit** is that quantity which is transferred per unit of time across any section of an infinitely long, straight, linear conductor when the current is such that the intensity of the resulting magnetic field at unit distance from the conductor is unity. 3. For **other units**—coulomb, electronic charge, faraday—*see* corresponding names.

Quantity of magnetism.—Also called **pole strength.** 1. The **electromagnetic unit** is that quantity which when concentrated to a point pole and placed at a unit distance from an equal point pole will exert upon it a unit force, the surrounding medium being a vacuum. 2. The **electrostatic unit** is that quantity which when concentrated to a point pole and placed at a unit distance from an infinitely long, straight, linear conductor would experience a unit force as a result of a current in the conductor such that one electrostatic unit of electricity per second is transferred across each section of the conductor. 3. The **Int. electric unit** is not named, it is the same as the cgsm unit.

Quantum.—1. Certain processes are essentially discrete, and consequently parcel out into bundles the several quantities involved. If for a certain quantity and a particular process these bundles are all alike, it is now customary to call them quanta, without implying that the quantity so bundled has in itself any atomistic properties. 2. **Planck's quantum.** *See* Planck.

Radian.—An angle which encloses, of the circumference of a concentric circle, an arc = radius.

Radiance.—The radiance of a body, within the spectral range λ_1 to λ_2, is defined as the intensity of the radiant energy, having wave-lengths lying between λ_1 and λ_2, which the body emits in a direction perpendicular to its radiating surface. If the spectral range is not mentioned, all wave-lengths are to be included; this is frequently called the **total radiance.** The **spectral, or monochromatic, intensity** of the radiance of wave-length λ is defined as the ratio of the radiance within the range $(\lambda - \frac{1}{2}d\lambda)$ to $(\lambda + \frac{1}{2}d\lambda)$ to $d\lambda$, when the latter is indefinitely small (*cf.* Emissivity).

Radiation constants.—*See* Black body.

Rankine.—A name sometimes applied to the absolute Fahrenheit scale of temperature.

Réaumur.—(R). A thermometric system in which the freezing point of water is called 0°, and the boiling point, 80°.

Reflectivity.—The ratio of the intensity of the light specularly reflected from a surface to the intensity of the light incident upon it. It is a pure numeric.

Refraction.—1. The **index of refraction, refractive index,** or **refractive exponent** is $n = \sin i/\sin r$; i = angle of incidence from a vacuum upon the substance, and r = angle of refraction, each measured from the normal to the surface. 2. **Refractivity** is $(n - 1)$. 3. **Specific refractivity** (r_G) is $(n - 1)/d$. **Specific refraction** (r_L) is $(n^2 - 1)/d(n^2 + 2)$. d = mass per unit of volume. 4. **Molecular refractivity** $= Mr_G$. **Molecular refraction** $= Mr_L$. M = molecular weight. By replacing M by the atomic weight, the corresponding **atomic values** are obtained. 5. **Refractive constant** of a solute is its specific refractivity computed on the assumption that the refractivity of the solution is equal to the sum of the refractivities of its pure constituents each multiplied by the ratio of its mass per unit volume of the solution to its own density when pure.

Reluctance.—The magnetic reluctance of a body between two specified equipotential surfaces is the ratio of the difference in the two potentials divided by the flux of magnetic induction from [to] either surface to [from] the body. It has no significance unless these two fluxes are the same.

Resistance.—1. The **electrical resistance** of a body between two specified equipotential surfaces is E/I, where E is the unchanging difference in the potentials of the surfaces and I is the resulting current across any transverse section between them. 2. **Specific resistance.** *See* Resistivity.

Resistivity.—1. [resistance × length]. **Resistivity,** or **volume resistivity,** of a substance is the longitudinal resistance per unit of length of a uniform bar of the substance of unit sectional area. 2. [resistance × mass/(length)^2]. **Mass resistivity** of a substance is the longitudinal resistance per unit of length of a uniform bar of the substance of such a sectional area that it contains one unit of mass per unit of length. 3. [resistance]. **Surface resistivity** is the resistance per unit of length of a strip of the surface of unit width. It has reference solely to the current which is restricted to the surface.

Rhe.—Name proposed for cgs unit of fluidity; = one reciprocal poise.

Right ascension.—*See* Celestial sphere.

Rigidity.—If to the four faces of a cube which are parallel to a given edge there be applied tangential stresses which are equal in absolute value, perpendicular to the given edge, and so directed as to produce a pure distortion, the other two faces will be deformed into diamond shaped figures if the material is isotropic. The modulus of rigidity is defined as the quotient of the stress on any one of the faces divided by the resulting change in any one of the angles of a distorted face. Also called **modulus of shear, Coulomb's modulus, modulus of torsion** (the last is undesirable).

Rotation.—*See* Rotatory power.

Rotatory power, Optical.—1. The **natural rotatory power** is θ/l, where θ is the rotation of the plane of polarization which occurs in a path of length l. The **specific rotatory power** ($[\alpha]$) is θ/dl, d = density. The **molecular** [or **atomic**] **rotatory power** is $M\theta/dl$ [or $A\theta/dl$]; M = molecular, A = atomic weight. 2. The **magnetic rotatory power** is $\theta/(lH \cos \alpha)$, where H = intensity of the magnetic field and α = angle between H and the path of the light. It is commonly called **Verdet's constant.** From the magnetic rotatory power, the **specific** ($[\omega]$), **molecular,** and **atomic magnetic rotatory powers** are derived exactly as in the case of natural rotation. The ratio of any one of these quantities to the corresponding one for a chosen reference substance is called the **relative power.** Water is the reference substance commonly chosen, and $[\Omega]$ is used to denote the molecular magnetic rotatory power relative to water.

Rydberg's fundamental frequency, and series constant.—*See* Series, spectral.

Secohm.—A superseded name for the henry.

Second.—1. (sec). **Time,** $1/86400$ day. Mean solar day, unless contrary is indicated. 2. (″). Unit of **angle,** $1/3600$ degree. 3. (‶). **Centesimal second** = 0.0001 grade.

Seger cone.—One of a graded series of cones of refractory material which, by their softening and the resultant deformation, indicate the heat treatment to which they have been subjected.

Series, Spectral.—Spectral lines, or groups of lines, which occur in orderly sequence. Most of these sequences can be represented by an equation of the form $\frac{1}{\lambda} = A - \frac{BN}{(m + \alpha + \beta/m^2)^2}$; λ = wave-length in vacuo; m is an integer varying from one line (or group) to another; for any one series, A, B, N, α and β are constants; B is an integer; N is known as **Rydberg's constant,** its value is determined by the constitution of the radiating atom. On Bohr's theory, $N = N_\infty \frac{M}{M + \mathbf{m}_0}$, where M = mass of the atom, $\mathbf{m}_0$ = electronic mass, and $N_\infty = 2\pi^2\mathbf{m}_0\mathbf{e}^4/\mathbf{h}^3\mathbf{c}\epsilon_o{}^2$; N_∞ is known as **Rydberg's universal series constant;** $\mathbf{e}$ = electronic charge; $\mathbf{h}$ = Planck's constant; ϵ_o = dielectric constant of vacuum; $\mathbf{c}$ = velocity of light in vacuo. On this theory, B denotes the number of electrons displaced from their normal positions, m is the **principal quantum number,** α depends upon the subordinate, or azimuthal, quantum number, and $\beta = 0$. For atoms of the type of hydrogen, $\alpha = 0$, $\beta = 0$; for others $(m + \alpha + \beta/m^2)$ is frequently called the **effective quantum number,** generally it is not an integer. **Rydberg's fundamental frequency** is $\nu_\infty = \mathbf{c}N_\infty$.

Sidereal month.—The time required for the moon to complete one apparent circuit among the stars.

Siemens unit.—(S.E.). A superseded unit of electrical resistance proposed in 1860 by Werner von Siemens; defined as the resistance at 0°C of a column of mercury one meter long and of a uniform cross section = one mm^2.

Slug.—A unit of mass. 1. The mass which will acquire an acceleration of one foot per sec^2 when continuously acted upon by a force of one pound weight. Also called **geepound,** and **engineer's unit of mass.** 2. The **metric slug** is the mass which will acquire an acceleration of one meter per sec^2 when continuously acted upon by a force of one kilogram weight.

Solar month.—$1/12$ tropical year.

Solubility.—1. By solubility of the **non-gas** a in b is meant the mass of a per unit mass of b which is contained in the mixture which is in equilibrium with an excess of a. In this mixture b is said to be saturated with a. Data are frequently restricted to mass of a per unit mass of mixture, mass of a per unit volume of mixture, or moles of a per mole of mixture. 2. Solubility of a **gas** is C_s/C_g, C_s = concentration of gas in the solution, C_g = concentration of gas in overlying gas phase. 3. **Solubility product** of an ionized substance (A_nB_m) in a stated solvent = $[A]^n \cdot [B]^m$, where $[A]$ and $[B]$ denote the concentrations of the two ions when the solution is saturated with the substance.

Specific gravity.—($d_{t_1}^{t_2}$). The ratio of the mass of a certain volume of the substance at the temperature t_2 to that of the same volume of a reference substance (usually water) at temperature t_1. Frequently, but incorrectly, called density.

Specific heat.—1. **Heat capacity.** *See* Capacity. 2. **Specific heat of electricity.**—*See* Thomson effect. 3. **Einstein's specific heat constant** (β) = ratio of Planck's constant (**h**) to Boltzmann's molecular gas constant (k_0). 4. **Ratio of specific heats** = $\gamma = c_p/c_v$; c_p, c_v = specific heat at constant pressure and at constant volume, respectively.

Specific inductive capacity.—The ratio of the dielectric constant of the substance to that of a vacuum.

Specific refractive power.—Used indifferently to denote several of the refractive constants (*cf.* Refraction).

Sperm candle, English.—A superseded unit of luminous intensity = one Int. candle.

Spheradian.—*See* Steradian.

Spherical candlepower, Mean.—*See* Mean spherical candlepower.

Square.—(sq.), (^{2}). Used in conjunction with the name of a unit of length to form the name of a related unit of area; *e.g.*, square foot (sq. ft.), (ft.^{2}) is the name of a unit of area equivalent to the area of a square with edges one foot long.

Square degree.—The solid angle enclosed by a cone of vanishingly small vertex angle 2θ is $k\pi\theta^2$. If θ is expressed in radians and the unit of solid angle is so chosen that $k = 1$, that unit is called a **steradian.** If θ is expressed in degrees, and $k = 1$, the corresponding unit of solid angle is called a **square degree.** One square degree = $(\pi/180)^2$ steradians. This procedure defines a definite unit of solid angle although the solid angles enclosed in cones of finite vertex angles are not proportional to the squares of those angles.

Stefan's constant.—*See* Black body.

Steradian.—The solid angle which encloses on the surface of a concentric sphere an area = (radius)^2.

Stoichiometric.—Pertaining to the ratio of the masses of the several elements contained in a pure chemical compound.

Strain.—1. For pure distortion the strain is measured by the change in a significant angle. 2. The ratio of change in size to original size.

Stress.—The force per unit of area over which it acts.

Surface tension.—(γ). $[m/t^2]$. Owing to molecular attraction, two fluids in contact adjust themselves so that the area of their interface is a minimum, consistent with other requirements. This adjustment may be pictured as arising from a tension residing in the surface itself; to this is given the name **surface tension.** Its value is defined as the normal, tensile force, per unit of length, across any line traced on the surface.

Susceptibility.—(κ). In the electromagnetic systems of units, $4\pi\kappa$ is the excess of the magnetic permeability of the substance over that of a vacuum.

Synodical.—In astronomy, the synodical period of a body is the interval between its successive returns to the same position with reference to the plane which is perpendicular to the plane of the ecliptic and which continuously passes through the centers of the earth and the sun.

Synonical month.—*See* Lunar month.

Temperature conductivity.—*See* Diffusivity.

Tension, Surface.—*See* Surface tension.

Tenth-meter.—10^{-10} meter; one Ångstrom unit.

Thermal.—*See* Heat.

Thermoelectric power.—*See* Power.

Thomson effect.—In a region in which the temperature of a homogeneous metallic conductor varies from section to section, there exists a potential gradient which is proportional to the product of the temperature and its gradient. This is the Thomson (or Kelvin) thermoelectric effect. The constant of proportionality is called the coefficient of the effect. If the coefficient is positive, a positive electric current flowing from hot section to cooler section tends to make the temperature more uniform; it is as if the current carried heat from hot portion to cooler portion, as if the electricity had a certain specific heat. This is what Thomson called the **specific heat of electricity.** It may be either positive or negative, depending upon the metal.

Time.—**True noon,** or **local true noon,** is the instant at which the sun is bisected by the meridional plane of the observer. **Mean noon,** or **local mean noon,** is the instant at which a fictitious mean sun is bisected by the meridional plane. This **mean sun** is one endowed with such a uniform, apparent angular velocity in the equatorial plane that in one tropical year it will make exactly the same number of apparent revolutions around the earth as are made by the true sun. Time measured from the true noon is called **true,** or **apparent, solar time;** that from mean noon is called **mean time.** The excess of mean time over true time is called **equation of time.** The earth has been divided into a series of time zones, each 15° of longitude in width, so that intercourse may be facilitated by all places in each zone using the mean time corresponding to the center of the zone; this is known as **standard time.** The first zone is centered on Greenwich, England.

Titer.—*See* Concentration.

Torque.—The moment of a force.

Tropical month.—The yearly average of the time required for the moon to traverse 360° of astronomical longitude.

Twist.—If a uniform bar of free length l be clamped rigidly at one end and the other end be twisted, about the axis of the bar, through an angle θ, the twist of the bar is defined as θ/l. Similarly for other cases.

Units, Systems of.—The fundamental units in most absolute systems are those of mass, length, time, thermometric degree, and the dielectric constant (or the magnetic permeability) of a vacuum. Other units are defined in terms of these by the use of established relations, arbitrary factors being made unity. The most common systems are the centimeter-gram-second-degree Centigrade (cgs), and the foot-pound-second-degree Fahrenheit (fps) systems. *See also* International electric units, practical electric units, and absolute.

Van der Waals.—*See* Waals.

Violle unit.—A superseded unit of luminous intensity based upon the brightness of fused platinum at the temperature of solidification.

Viscosity.—If a fluid is flowing in the plane yz with velocity v it exerts upon an adjacent plane a tangential drag $= \eta(dv)/(dx)$, per unit of area. η is called the **viscosity, coefficient of viscosity,** or **coefficient of internal friction.** Unit: poise.

Viscosity, Kinematic.—Viscosity divided by density.

Volt.—The electrical potential difference which, when steadily applied to a conductor having a resistance of one ohm, will produce in it a current of one ampere (*cf.* absolute and international units). The Int. Committee authorized by the London Conference, 1908, agreed to regard the emf of the Weston normal cell at 20°C as exactly 1.0183 Int. volts. This furnishes a subsidiary definition which is slightly discordant with the primary one. These tables distinguish between the two, and between units derived from them, by using (a) to denote those based on ampere and ohm, and (v) to denote those based on volt as defined by the Weston cell.

Volt-electronic charge.—Analogous to volt-faraday.

Volt-faraday.—The work which must be done in order to transfer one faraday of positive electricity from any point to another having a potential one volt higher than the former.

Volt-second.—Unit of flux of magnetic induction. The amount defined by the change per second, of the magnetic induction through an area, required to induce around the area an emf of one volt.

Volume, Specific.—Reciprocal of the density.

Waals, Van der.—In the equation $(p + a/v^2)(v - b) = 1 + \alpha t$, a and b are known as Van der Waals' constants; $a[b]$ = pressure [volume] constant.

Watt.—Unit of power; work done at rate of one joule per second.

Watt-hour.—Work expended by one watt in one hour (*cf.* kilowatt-hour).

Wave-length.—(λ). Distance between consecutive corresponding points in a monofrequent wave train. Occasionally applied to complex waves.

Wave number.—Reciprocal of wave-length.

Weight.—The force with which a body, left to itself, is urged towards the earth. In the absolute systems of units it is numerically equal to the mass of the body multiplied by the acceleration of gravity (g) at the position considered; hence varies with position. Such expressions as **gram weight [pound weight]** are to be interpreted as meaning the weight of a gram [a pound] at a place where g has the standard value, 980.665 cm/sec.^{2}

Wien's displacement constant.—(w). *See* Black body.

Year.—(yr). Time required for earth to make one complete circuit of its orbit, as defined by its return to the same position as determined by the sun and some celestial point of reference. For the **tropical, equinoctial,** or **ordinary** year the reference point is the mean vernal equinox; for the **sidereal,** or **true,** year, it is a fixed star; for **anomalistic** year, it is perihelion of earth's orbit; for **eclipse** year, it is ascending node of moon's orbit.

Young's modulus.—If a bar of uniform section be subjected to a longitudinal tension, the ratio of this stress to the resulting elongation per unit of length is called its Young's modulus. Also called **modulus of elasticity, elastic modulus, longitudinal elasticity, coefficient of resistance to extension, modulus of traction.**

ELEMENTS AND ATOMS

ATOMIC WEIGHTS

The values given in column four were compiled for International Critical Tables (I. C. T.) by Prof. G. P. Baxter in 1923 and are those upon which all the data given in International Critical Tables are based.

Following these are shown the accepted atomic weights back to 1882. For the period since 1903 these are taken from the reports of the International Committee on Atomic Weights; for the period 1894 to 1903, from the reports of the American Chemical Society's Committee on Atomic Weights; for the year 1882, from F. W. Clarke's "A Recalculation of the Atomic Weights," reproduced in the first (1883) edition of "Landolt-Börnstein." These 1882 values (to two decimals) are given in parentheses. A date in parentheses indicates the first appearance of the element in the atomic weight table. All the values given are based upon O = 16.000.

Symbol	Atomic number	Name	I. C. T. at. wt.	Atomic weights (1925–1882)
A	18	Argon	39.91	'25, 39.91; '24–'19, 39.9; '18–'11, 39.88; '10–'03, 39.9; '02, 39.96 (1902)
Ac	89	Actinium	?	
Ag	47	Silver	107.880	'25, 107.880; '24–'09, 107.88; '08–'03, 107.93; '02–'94, 107.92 (107.92)
Al	13	Aluminium	26.96	'25, 26.97; '24–'22, 27.0; '21–'00, 27.1; '99–'96, 27.11; '95–'94, 27 (27.08)
As	33	Arsenic	74.96	'25–'10, 74.96; '09–'00, 75.0; '99–'97, 75.01; '96, 75.09; '95–'94, 75.0 (75.09)
Au	79	Gold	197.2	'25–'00, 197.2; '99–'97, 197.23; '96, 197.24; '95–'94, 197.3 (196.61)
B	5	Boron	10.82	'25, 10.82; '24–'19, 10.9; '18–'00, 11.0; '99–'96, 10.95; '95–'94, 11 (10.97)
Ba	56	Barium	137.37	'25–'09, 137.37; '08–'00, 137.40; '99–'94, 137.43 (137.01)
Be	4	Beryllium	9.02	'25, 9.02; '24–'00, 9.1; '99–'96, 9.08; '95–'94, 9 (9.11)
Bi	83	Bismuth	209.00	'25–'22, 209.0; '21–'07, 208.0; '06–'03, 208.5; '02–'00, 208.1; '99–'96, 208.11; '95, 208; '94, 208.9 (208.00)
Br	35	Bromine	79.916	'25, 79.916; '24–'09, 79.92; '08–'03, 79.96; '02–'94, 79.95 (79.95)
C	6	Carbon	12.000	'25, 12.000; '24–'16, 12.005; '15–'98, 12.00; '97–'96, 12.01; '95–'94, 12 (12.00)
Ca	20	Calcium	40.07	'25–'12, 40.07; '11–'09, 40.09; '08–'00, 40.1; '99–'97, 40.07; '96, 40.08; '95–'94, 40 (40.08)
Cb	41	Columbium	93.1	'25–'17, 93.1; '16–'09, 93.5; '08–'03, 94; '02–'00, 93.7; '99–'97, 93.73; '96–'94, 94.0 (94.03)
Cd	48	Cadmium	112.41	'25, 112.41; '24–'09, 112.40; '08–'00, 112.4; '99, 112.38; '98–'97, 111.95; '96, 111.93; '95–'94, 112 (112.09)
Ce	58	Cerium	140.25	'25–'04, 140.25; '03, 140; '02–'00, 139; '99–'98, 139.35; '97–'94, 140.25 (140.75)
Cl	17	Chlorine	35.458	'25, 35.457; '24–'09, 35.46; '08–'94, 35.45 (35.45)

THE STRUCTURE OF THE ISOLATED ATOM

(Symbols, p. 50)

H. A. Kramers

According to the fundamental postulates of Bohr's atomic theory, a series of discrete "stationary states" has to be correlated with each atom. A definite "energy-content" can be assigned to every state, and an atom in a given state can change its energy only by performing a process of "transition" to another state. The emission of a spectral line of frequency ν is correlated with a spontaneous transition from a stationary state of energy content E_1 to another of energy content E_2 by equation (1)

$$\nu = \frac{1}{\mathbf{h}}(E_1 - E_2) \tag{1}$$

The stationary state with the smallest energy is termed the "normal state" of the atom. The properties of the stationary states can, to a considerable extent, be accounted for by assuming that the electrons surrounding the nucleus have definite motions, characterized by integral values of certain quantities. These integers are called the "quantum numbers" of the stationary state in question; by their values the energy of the state is completely fixed. For general treatment of the subject, see (1, 3, 4, 10, 11, 18).

Of special interest are the recent attempts (21) to develop a rational "quantum mechanics" of the atom. This work clearly demonstrates the limited applicability of a picture of atomic structure, in which the behavior of the electrons inside the atom is visualized by orbits possessing definite kinematical properties.

Atoms Containing One Electron.—Only for atoms containing a single electron, can a fairly complete description of the electronic motion in the stationary state, and of the significance of the quantum numbers be given. The motion of the electron obeys quite approximately the laws of electrodynamics, and can be described as a Keplerian elliptic motion, with the centre of gravity of the nucleus and the electron in one focus. On this motion, a slow uniform precession in the plane of motion is superposed (effect of variability of mass or "relativity-effect"). Two quantum numbers (n, k) define the stationary states $(n, k = 1, 2, 3 \ . \ . \ .; k \leq n)$, k/n being the ratio of the minor to the major axis of the ellipse. The states are denoted by the symbol n_k.

In the **normal state,** $1_1 (n = k = 1)$, the orbit is circular; and, omitting the correction due to the relativity effect, its constants are given by equations (2)

$$\begin{aligned} a_1 &= \frac{1}{Z}\cdot\frac{\mathbf{h}^2}{4\pi^2\mathbf{e}^2\mathbf{m}_0} = \frac{r_1}{Z} = \frac{0.53}{Z} \times 10^{-8} \text{ cm} \\ \omega_1 &= \frac{Z^2}{1+\frac{\mathbf{m}_0}{M}} \times \frac{4\pi^2\mathbf{e}^4\mathbf{m}_0}{\mathbf{h}^3} = \frac{2\nu_\infty Z^2}{1+\frac{\mathbf{m}_0}{M}} = \frac{6.6Z^2}{1+\frac{\mathbf{m}_0}{M}} \times 10^{15} \text{ sec}^{-1} \\ W_1 &= \frac{Z^2}{1+\frac{\mathbf{m}_0}{M}} \times \frac{2\pi^2\mathbf{e}^4\mathbf{m}_0}{\mathbf{h}^2} = \frac{Z^2\nu_\infty\mathbf{h}}{1+\frac{\mathbf{m}_0}{M}} = \frac{2.15Z^2}{1+\frac{\mathbf{m}_0}{M}} \times 10^{-11} \text{ erg.} \end{aligned} \tag{2}$$

In **higher quantum states,** the orbital constants are, with the same approximation, given by (3, 4):

$$\begin{aligned} a_n &= n^2 a_1 = \frac{n^2}{Z} r_1 \\ \omega_n &= \frac{\omega_1}{n^3} = \frac{2Z^2\nu_\infty}{n^3\left(1+\frac{\mathbf{m}_0}{M}\right)} \\ W_n &= \frac{W_1}{n^2} = \frac{Z^2\nu_\infty\mathbf{h}}{n^2\left(1+\frac{\mathbf{m}_0}{M}\right)} \end{aligned} \tag{3}$$

$$b_{n,k} = nka_1 = \frac{nkr_1}{Z}; \ p_k = k^2 a_1 = \frac{k^2 r_1}{Z} \tag{4}$$

The number of revolutions corresponding to one rotation of the major axis, is, to a first approximation, given by (5):

$$\frac{\omega_n}{\sigma_{n,k}} = \frac{k^2}{Z^2} \times \frac{2}{\alpha^2} = \frac{k^2}{Z^2} \times 37{,}700 \tag{5}$$

$$\left(\alpha = \frac{2\pi\mathbf{e}^2}{\mathbf{hc}} = 7.30 \times 10^{-3} \cong \frac{1}{137}; \ \alpha^2 = 5.31 \times 10^{-5}\right)$$

The exact energy formula, neglecting terms containing $\mathbf{m}_0/M$, is given by (6):

$$\begin{aligned} W_{n,k} &= \mathbf{m}_0\mathbf{c}^2\left[\left\{1 + \left(\frac{\alpha Z}{n - k + \sqrt{k^2 - \alpha^2 Z^2}}\right)^2\right\}^{-\frac{1}{2}} - 1\right] \\ &= \frac{Z^2}{n^2} \times \frac{2\pi^2\mathbf{e}^4\mathbf{m}_0}{\mathbf{h}^2}\left\{1 + \alpha^2 Z^2\left(\frac{1}{kn} - \frac{3}{4n^2}\right) + \ . \ . \ . \ \right\} \end{aligned} \tag{6}$$

(For general formula for W, including terms in $\mathbf{m}_0/M$, see (9).) Figure 1 illustrates the stationary states in the hydrogen atom for which $n = 1, 2, 3, 4$. The arrows indicate the transitions giving rise to the fine-structure components of the spectral lines, H_α and H_β. The numerical constants for these states are given in Table 1.

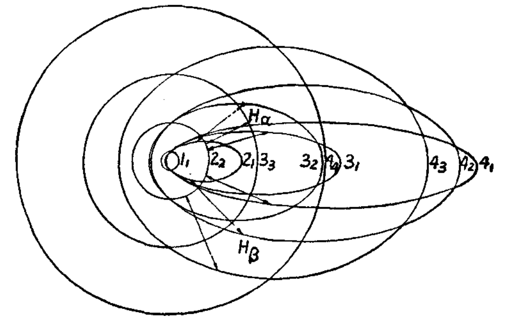

FIG. 1.—Orbits in hydrogen to $n = 4$. (*Reproduced by permission from The Journal of the Franklin Institute.*)

Atoms Containing More than One Electron.—A complete theory of stationary states is lacking. Many properties of these states can be accounted for, however, on the basis of the principles applied to atoms containing one electron. As a first approximation, each electron may be considered as moving in a central field of force due to the nucleus and the other electrons, its motion being characterized by a "principal quantum number" n and a "subordinate quantum number" k. The electronic orbit can be described as a plane periodic orbit on which a uniform precession in the plane is superposed ("central orbit" *cf.* Fig. 2).

If the position of the electron in the orbital plane is defined by polar coordinate (r, φ), the quantum numbers are defined by Sommerfeld's quantum conditions (7)

$$k = \frac{2\pi \mathbf{m}_0 \beta r^2}{\mathbf{h}} \frac{d\phi}{dt} = \frac{2\pi P}{\mathbf{h}} \qquad (n-k) = \frac{1}{\mathbf{h}} \oint \mathbf{m}_0 \beta \left(\frac{dr}{dt}\right)^2 dt \quad (7)$$

where the factor β becomes equal to 1 if the relativity effect is neglected. P is equal to the angular momentum of the electron with respect to the nucleus; the integral has to be taken over a complete period of the radial motion, from A to B (Fig. 2).

In the **normal state** the electrons are distributed in groups, each of which is characterized by its quantum numbers (n, k). On passing from the nucleus to the surface of the atom, the successive groups correspond to successive integral values of the main quantum number n ("n-quantum group"), the innermost group being characterized by $n = 1$; each group is divided into subgroups corresponding to the different values which k may take. The possibility of reconciling such a picture with the dynamical properties of quantized central orbits is closely connected with the fact that in an orbit for which $k < n$ the electron will, in each revolution, dive into and leave again all regions occupied by electronic orbits for which the principal quantum number is smaller than n but equal to or greater than k (conception of "penetrating orbits").

The maximum number of electrons which an n-quantum group can contain is equal to $2n^2$. If it contains this number, it contains sub-groups corresponding to all possible values for k ($k = 1, 2 \ldots n$), and it is said to be a **"finally completed"** group. If a group, due to the dynamical properties of the atom under consideration, contains only sub-groups corresponding to $k = 1, 2 \ldots k_0$ ($k_0 < n$) it will be in a state which is termed **"provisionally completed,"** if it contains $2k_0^2$ electrons. For example, the 4-quantum group has reached the state of a 2-group ($k_0 = 1$) in Ca (20), the state of an 8-group or 8-shell ($k_0 = 2$) in Kr (36), the state of an 18-group or 18-shell ($k_0 = 3$) in Ag (47), and its final state of a completed 32-group or 32-shell ($k_0 = 4$) in Lu (71). With the exception of the 2-groups it seems impossible to assign definite values to the number of electrons in the several sub-groups of a provisionally, or finally, completed group; in fact, the actual properties of the electronic groups seem to show that the simple conception of central orbits characterized by the symbol n_k is essentially insufficient for their description. (Originally Bohr assumed that a group of $2k_0^2$ electrons contained $2k_0$ electrons in each sub-group.) Closely connected herewith is the impossibility of assigning definite spatial arrangements to the orbits belonging to one and the same group. In Table 2 the number of electrons in each group is given as far as the theory allows of a definite statement; those in parentheses are uncertain.

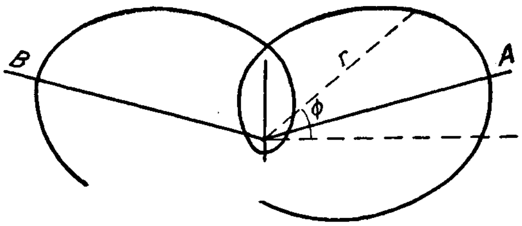

FIG. 2.—Central orbit.

From calculations based on Sommerfeld's quantum conditions and certain simplifying assumptions, a rough estimate of the dimensions of the different types of orbits may be made. Such estimates for neutral atoms and for positive ions containing only finally, or provisionally, completed groups are schematically represented in Fig. 3. The small vertical lines are so drawn that their distances from the dot at the left are proportional to the radius of the sphere inside which the electrons belonging to the respective groups are moving. The symbols $g\ (n_{1,2\ \ldots\ k_0})$ means that the corresponding groups contain g electronic orbits of principal quantum number n, and of subordinate quantum numbers from 1 to k_0.

For the calculation of the dimensions of the outermost groups it has been necessary to consider also experimental data relative to the effective gas-kinetic radii of the atoms of the inert gases, the effective radii of ions in crystals, ionic refraction, etc. As a rule the effective radii are 1.5 to 2.5 times larger than the orbital dimensions. As regards the inner groups, the estimate is rather accurate; for the outer groups, errors of the order of 10% might be expected Special mention must be made of the uncertainty in the radius of the 5-quantum group for elements heavier than barium; the radii of this group as given in Fig. 3 for the elements (72), 79, 80, 81, 82 are perhaps some 10% too high, as compared with radii of the homologous elements 47, 48, 49, 50.

For atoms containing only one electron in the outermost group, the dimensions of the orbit of this electron, and its frequency of revolution can with considerable accuracy be derived from the

frequency of the lowest frequency term in the corresponding spectral series, provided we may adhere to the simple central orbit model. Figure 4 contains a schematic picture of the orbits of the outer electron in the normal state of neutral atoms of the alkali metals, and of Cu, Ag, Au. They are all penetrating orbits, since they correspond to $k = 1$. The regions inside which the electrons of the completed groups are moving are designated by circles. The atoms of the inert gases are added for the sake of comparison. The numbers at the left of the nucleus indicate the number of electrons contained in each group; the symbols $n_{1,2}$ . . . at the right indicate the quantum numbers of the orbits contained in each group.

[For detailed calculations of electronic orbits, based on simplifying assumptions, see (12, 13, 20) (Cs and U); the work is semi-empirical. For detailed calculations on purely theoretical basis, see (15) (Ne, Na, Mg$^+$, Al^{++}, Si^{+++}, P^{++++}) and (16) (alkali metals); in Lindsay's work, the radii of outer groups in K$^+$, Rb$^+$, and Cs$^+$ seem too large, probably on account of inadequacy of assumptions regarding numbers of electrons in sub-groups, as well as of the simplifying assumptions made. For critical review of work on effective atomic radii, see (14) and for recent work (8). There is no simple direct connection between effective atomic radii and the magnitude of the space occupied by electronic orbits.]

In experiments on optical and X-ray spectra, we meet neutral atoms or atomic ions in **higher quantum states.** Several features of these states can be described on the simple central orbit model. In the case of "single excitation" all electronic orbits except one remain normal, and the other electron describes an orbit with quantum numbers which differ from those of the normal state. "Double excitation" corresponds to two electrons describing orbits different from those in the normal state, etc. We will here consider only singly-excited states.

In the stationary states (energy levels) involved in the emission of the ordinary X-ray spectra, one electron in the inner groups of the atom is lacking. In the states involved in the emission of the ordinary series-spectra, one electron belonging to the outermost group of the atom, the "series electron," moves in a central n_k orbit the dimensions of which are large as compared with those of the rest of the atom. It may move either quite outside the atomic residue or it may penetrate into it in each revolution.

As a first approximation, a non-penetrating orbit may be described as a Keplerian elliptical orbit performing a uniform precession in its plane, the shape of the ellipse being very nearly that of an n_k-orbit in an atom containing only one electron and having a nuclear charge Z^*e equal to the net-charge of the atomic residue. If the electron orbit is of the penetrating type, it may, as a first approximation, be described as a set of congruent outer Keplerian elliptical loops, connected by congruent inner loops, the angular distance between successive loops being the same. The semi-major axis, the semi-parameter p, and the semi-minor axis b of the outer loop can be found from the value of the corresponding spectral term (T) by means of the formulae

$$a = \frac{Z^*Nr_1}{T} \qquad p = \frac{k^2}{Z^*}r_1 \qquad b = \sqrt{ap} \qquad (8)$$

where $N\left(= \frac{\nu_\infty}{c} \times \frac{1}{1 + m_0/M}\right)$ is the Rydberg constant for the element in question, and Z^*e is the net-charge of the atomic residue. If we introduce the effective quantum number n^* ($n^{*2} = Z^{*2}N/T$), these formulae may be written:

$$a = \frac{n^{*2}}{Z^*}r_1 \qquad p = \frac{k^2}{Z^*}r_1 \qquad b = \frac{n^*k}{Z^*}r_1 \qquad (9)$$

The greater the ratio n^*/k (or a/b) the closer the approximation to which this description of the outer loops may be considered to hold. The maximum distance of the electron from the nucleus is equal to $a + \sqrt{a^2 - b^2}$, or very nearly equal to $2a - \frac{1}{2}p$.

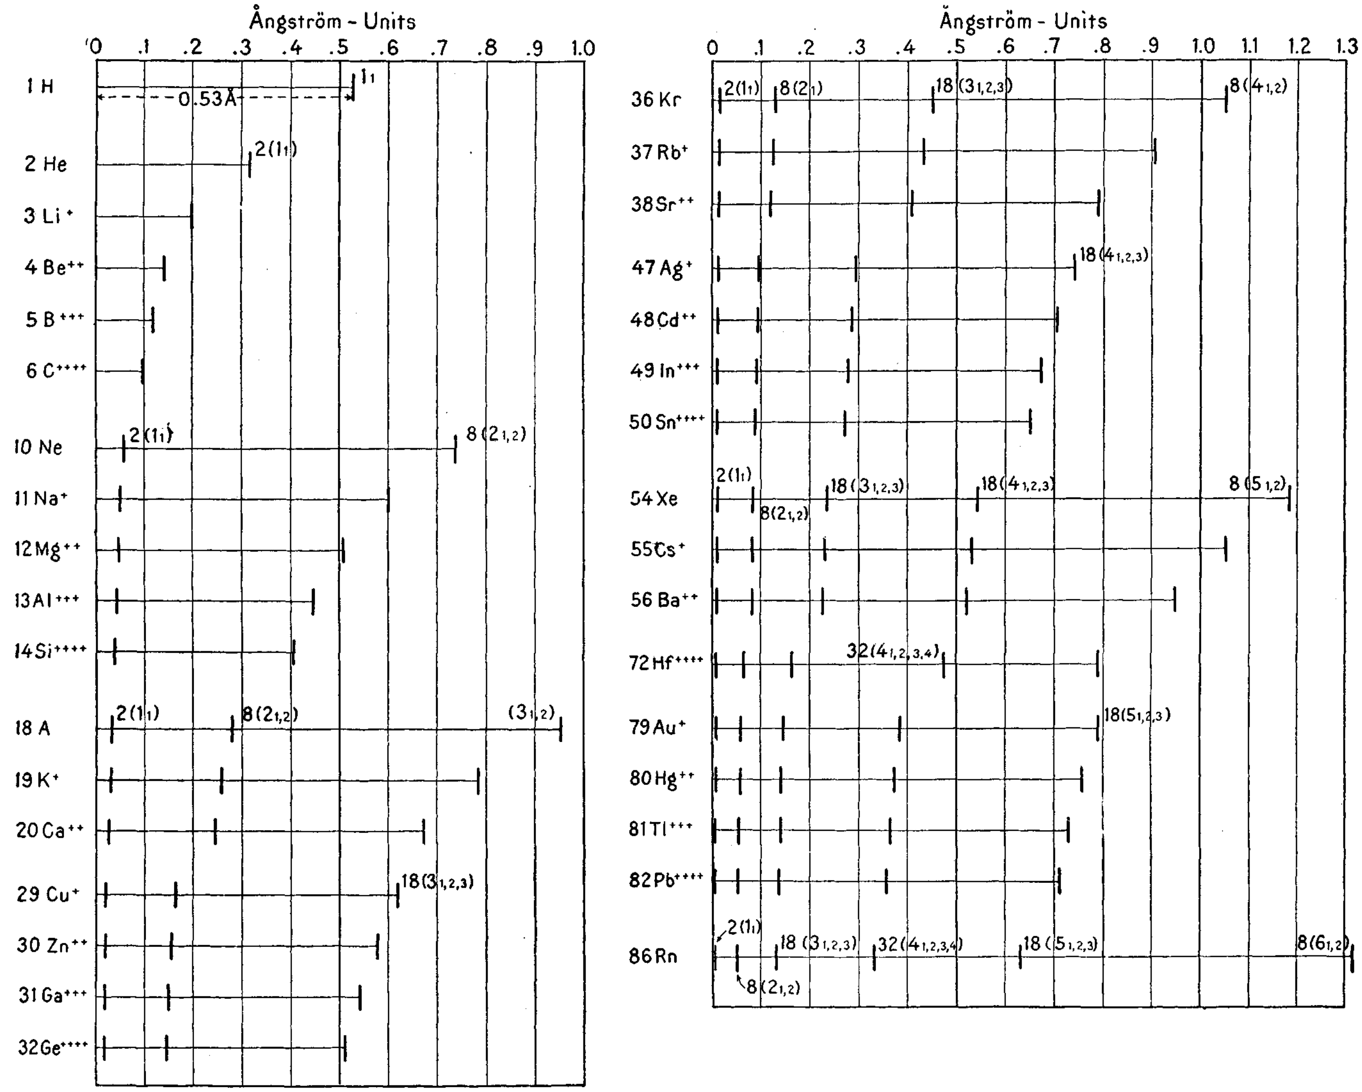

FIG. 3.—Maximum elongations of electrons of several groups.

The values to be assigned to the precessional frequency characterizing the penetrating central orbits are very uncertain. For the alkali elements, the ratio ω/σ for the n_1 orbits probably lies between 0.3 and 0.5, for the n_2 orbits (except lithium) between 0.5 and 1.0. Based on the above formulae, an illustration of the shapes of the orbits of the series electron corresponding to the stationary states of the K-atom, is given in Fig. 5. [For connection between spectra and the group structure of atoms, see ($^{6,\ 5}$); for spectra and central field of force, see ($^{12,\ 13}$); for series spectra and electronic orbits, see ($^{2,\ 7}$); for recent development of formal theory of electronic groups, see ($^{17,\ 19}$)].

SYMBOLS

The symbols **c**, **e**, **h**, **m**$_0$, λ have their usual significance (see p. 16); others which occur more than once are:

a_n	Semi-major axis of electronic orbit, state n.
$b_{n,k}$	Semi-minor axis of electronic orbit, state n, k.
k	Subordinate, or azimuthal, quantum number defining a stationary state.
M	Nuclear mass.
n	Principal quantum number defining a stationary state.

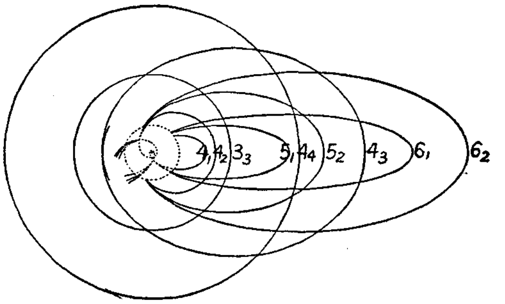

FIG. 5. —Orbits of the series electron of potassium. (*Reproduced by permission from The Journal of the Franklin Institute.*)

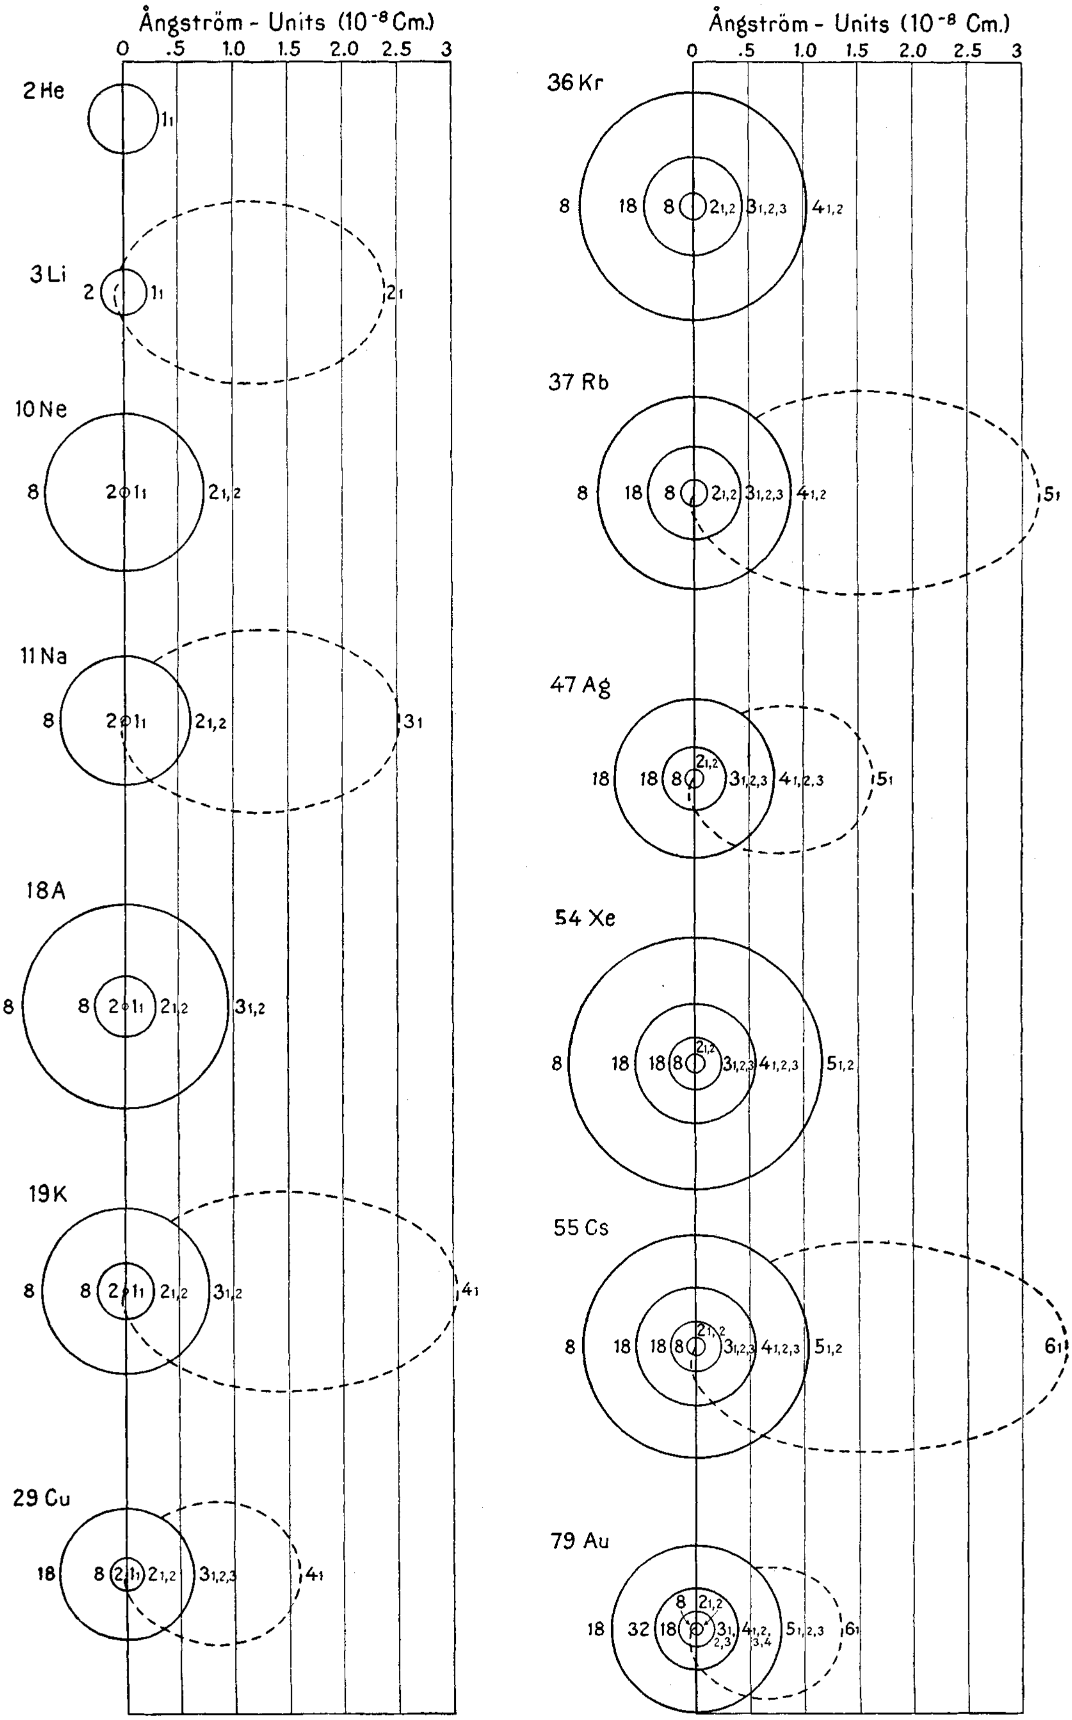

FIG. 4.—Normal orbit of outer electron.

n^*	Effective quantum number $= Z^*N/T$.
n_k	Designation of the state characterized by the numbers n, k.
N_∞	Rydberg constant.
p	Semi-parameter of the electronic orbit (semi-latus rectum).
r_1	Radius of first Bohr ring for hydrogen.
T	Spectral term = a wave number $(1/\lambda)$ of a spectral series.
v	Speed of electron in its orbit.
W_n	Energy expenditure required to remove the electron to infinity.
Z	Atomic number: Ze = nuclear charge.
Z^*e	Charge of atomic residue.
α	$2\pi e^2/hc$.
β	$(1 - v^2/c^2)^{-1/2}$
ν	Frequency of emitted radiation.
ν_∞	Rydberg fundamental frequency.
$\sigma_{n,k}$	Frequency of precession of electronic orbit.
ω_n	Frequency of revolution of electron; for penetrating orbits, the radial frequency, one revolution being from A to B, Fig. 2.

THERMOMETRY

E. F. Mueller, L. H. Adams, F. O. Fairchild and H. T. Wensel

1. THERMOMETRIC SCALES

E. F. Mueller

Centigrade or Celsius scale, °C
Fahrenheit scale, °F
Réamur scale, °R
Centigrade absolute or Kelvin scale, °K
Fahrenheit absolute or Rankine scale, °R′

By definition or as basic values adopted for I. C. T., the ice and steam points under a pressure of $1A_n$ have the following values:

Ice point: 0°C = 32°F = 0°R = 273.1°K = 491.58°R′.
Steam point: 100°C = 212°F = 80°R = 373.1°K = 703.58°R′.
°C = 5/9 (°F − 32) = 5/4°R = °K − 273.1.
°F = 9/5°C + 32 = °R′ − 459.58.

2. THE STANDARD THERMODYNAMIC SCALE

E. F. Mueller

The thermodynamic scale, which is based solely on the laws of thermodynamics and is independent of the properties of any material substance, is accepted as the standard scale of temperature. Temperatures on the thermodynamic scale are proportional to the pressures (or to the volumes) of an ideal gas in a perfect constant volume (or constant pressure) gas thermometer. The standard scale is realized in practice by use of gas thermometers, the indications of which can be reduced to the standard scale, or for higher temperatures, by use of the relations between the intensity of radiation from a black body and its temperature.

The experimental difficulties in the use of gas thermometers and the relatively low precision attainable in a single measurement have led to the introduction of a standard practical or working scale. This working scale is defined by certain base points, the temperatures of which have been determined by gas thermometer measurements, and by the indications of suitable instruments used for interpolation between the base points or for extrapolation to higher temperatures. It is possible in this way, without actually using a gas thermometer, to establish a working scale which does not differ to a demonstrable extent from the standard scale at any temperature within the range of the working scale. The practice of the various national standardizing laboratories in defining the working scale is substantially uniform at present, and it requires only minor adjustments and formal agreement to give the working scales of these laboratories the status of an international temperature scale. Such a scale would bear essentially the same relation to the standard scale, as do the international electric units to the absolute units.

The standard working scale may be defined by assigning numerical values to the temperatures defined by the boiling point of oxygen, the melting point of ice, the boiling point of water, the boiling point of sulfur, and the freezing points of antimony, silver and gold. The platinum resistance thermometer is the standard for interpolation in the range −195° to 0°C and from 0° to 650°C; the platinum-platinum rhodium thermocouple for the range from 650° to 1063°; and the luminous filament pyrometer above 1063°C.

Wien's law is accepted as expressing the brightness-temperature relation for a black body. For the purpose of defining the temperature scale above 1063°C the present practice of the national laboratories tends to favor the use of the value 1.430 cm degrees for the constant C_2 in this equation but the value 1.433 cm degrees has been adopted for I. C. T.

Reduction of Gas Thermometer Indications to the Thermodynamic Scale

The temperature t_g on the scale of a constant volume or constant pressure gas thermometer filled with any real gas, is proportional to the pressure the gas would exert or the volume it would occupy, respectively, if all of the gas were at the uniform temperature to be measured, and if the volume or the pressure, respectively, were the same at all temperatures. At 0° and 100°C, the temperature t_g is by definition identical with the thermodynamic temperature t, while at other temperatures t_g departs from t by amounts which are proportional to the pressure at 0°, called the initial pressure. The tabular values are accordingly given only for an initial pressure equivalent to 1 m of mercury.

The values of $t - t_g$ obtained by various methods cover a wide range, so that only the order of magnitude of the values can be considered as known with any certainty. The tendency in modern work in gas thermometry has been to employ hydrogen or helium as the thermometric gas, and for these gases the magnitude of $t - t_g$ is comparable with the experimental error of the gas thermometer itself, so that the importance of an exact knowledge of the departure of the scales of these gas thermometers from the thermodynamic scale is correspondingly reduced.

REDUCTION OF GAS THERMOMETER INDICATIONS, t_g, TO THE THERMODYNAMIC CENTIGRADE SCALE, t

Values of $t - t_g$ for an initial pressure of 1 meter of mercury

3. FIXED POINTS

E. F. MUELLER

t = Temperature on standard scale.
p = Pressure in millimeters of Hg (1 mm Hg = $\frac{1}{760}$ A_n) where p is between 680 and 780 mm.

BASE POINTS USED IN DEFINING THE STANDARD WORKING SCALE

(I. C. T. temperature scale)

Substance	Phenomenon	Temperature, °C
Liquid O_2	Vapor pressure	$t = \left[\begin{array}{l} -183.00 + 0.245\,(t + 273.1)\log_{10} p/760 \text{ or} \\ -183.00 + 0.0126\,(p-760) - 0.0000065\,(p-760)^2 \end{array}\right]$
Solid CO_2*	Vapor pressure	$t = \left[\begin{array}{l} -78.51 + 0.1443\,(t + 273.1)\log_{10} p/760 \text{ or} \\ -78.51 + 0.01595\,(p-760) - 0.000011\,(p-760)^2 \end{array}\right]$
Mercury*	Freezing	$t = -38.87°$
Ice	Melting	$t = 0.000°$
Steam	Condensing	$t = \left[\begin{array}{l} 100.000 + 0.1727\,(t + 273.1)\log_{10} p/760 \text{ or} \\ 100.000 + 0.0367\,(p-760) - 0.000023\,(p-760)^2 \end{array}\right]$
Sulfur	Condensing	$t = \left[\begin{array}{l} 444.60 + 0.2215\,(t + 273.1)\log_{10} p/760 \text{ or} \\ 444.60 + 0.0909\,(p-760) - 0.000048\,(p-760)^2 \end{array}\right]$
Antimony	Freezing	To be determined with resistance thermometer. t = approx. 630.5°
Silver	Freezing	t = 960.5° (reducing atmosphere).
Gold	Freezing	t = 1063°

* Not needed according to one suggested definition of the scale.

SECONDARY FIXED POINTS USEFUL IN CALIBRATING TEMPERATURE MEASURING INSTRUMENTS

(I. C. T. temperature scale)

Substance	Phenomenon	Temperature °C
Hydrogen	Boiling	$t = -252.7_5 + 0.0044\,(p-760)$
Nitrogen	Vapor pressure	$t = -195.80 + 0.0109\,(p-760)$
Naphthalene	Condensing	$t = 217.96 + 0.207_5\,(t + 273.1)\log_{10}(p/760)$
Tin	Freezing	$t = 231.8_5$
Benzophenone	Condensing	$t = 305.9 + 0.194\,(t + 273.1)\log_{10}(p/760)$
Cadmium	Freezing	$t = 320.9$
Lead	Freezing	$t = 327.4$
Zinc	Freezing	$t = 419.4_5$
Aluminum (99.85 %)	Freezing	$t = 658.9$
Copper	Freezing	t = 1083 (reducing atmosphere)
Palladium	Freezing	$t = 1555 \pm 2$
Platinum	Melting	$t = 1755 \pm 6$
Tungsten	Melting	$t = 337_0 \pm 30$

The above values are in accord with the temperature scale used throughout I. C. T. For the last three points the following slightly different values have been suggested for future adoption as secondary points on an international practical scale.

Palladium	Freezing	$t = \left[\begin{array}{l} 1555 \text{ for } C_2 = 1.430 \\ 1554 \text{ for } C_2 = 1.433 \end{array}\right]$
Platinum	Melting	$t = \left[\begin{array}{l} 1765 \text{ for } C_2 = 1.430 \\ 1763 \text{ for } C_2 = 1.433 \end{array}\right]$
Tungsten	Melting	$t = \left[\begin{array}{l} 3400 \text{ for } C_2 = 1.430 \\ 3386 \text{ for } C_2 = 1.433 \end{array}\right]$

Additional Useful Secondary Points

Substance	Formula	Phenomenon	Temperature, °C
Isopentane	C_5H_{12}	Freezing	− 159.6
Methylcyclohexane	$C_6H_{11}CH_3$	Freezing	− 126.3
Ether	$(C_2H_5)_2O$	Slow freezing (unstable)	− 123.3
Ether	$(C_2H_5)_2O$	Rapid freezing or slow melting	− 116.3
Carbon disulfide	CS_2	Freezing	− 111.6
Toluene	C_7H_8	Freezing	− 95.1
Ethyl acetate	$CH_3CO_2C_2H_5$	Freezing	− 83.6
Chloroform	$CHCl_3$	Freezing	− 63.5
Chlorobenzene	C_6H_5Cl	Freezing	− 45.2
Carbon tetrachloride	CCl_4	Freezing	− 22.9
Sodium sulfate	$Na_2SO_4\cdot 10H_2O$	Transition	32.38$_4$
Potassium dichromate	$K_2Cr_2O_7$	Melting	397.5
30.5 NaCl + 69.5 Na_2SO_4	....	Melting	637.0
Potassium chloride	KCl	Melting	770.3
Sodium chloride	NaCl	Melting	800.4
Sodium sulfate	Na_2SO_4	Melting	884.7
Potassium sulfate	K_2SO_4	Inversion	583.0
Potassium sulfate	K_2SO_4	Melting	1069.1
Nickel	Ni	Melting or freezing	1452
Cobalt	Co	Melting or freezing	1490
Lithium metasilicate	Li_2SiO_3	Melting	1202
Diopside	$CaMgSi_2O_6$	Melting	1395
Anorthite	$CaAl_2Si_3O_8$	Melting	1555

The Leiden Temperature Scale

In certain sections of International Critical Tables (where so indicated) the Leiden temperature scale will be employed. (Onnes and Hoist, *168*, No. **141a.** *64V*, **23**: 175; 14. Cath and Onnes, *168*, No. **152a.** *64V*, **26**: 437, 490; **17.** Cath, *168*, No. **152d.** *64V*, **27**: 553; 18.) The relation between the Leiden and the I. C. T. scales is shown by the following table:

Point	I. C. T.	Leiden	Leiden − I. C. T.
H_2 (B. P.)	−252.8°	−252.74°	+0.06°
O_2 (B. P.)	−183.0°	−182.95°	+0.05°
ca. −40°			+0.04

4. RESISTANCE THERMOMETERS

E. F. Mueller

Standard methods of calibration have been developed only for platinum resistance thermometers. Data on the resistance-temperature relation for particular thermometers of other metals, such as gold and lead, are available, and formulae to represent the relation have been published, but standardized methods for the calibration of such thermometers have not been developed.

The standard working scale, in the interval 0° to 650°C, is defined by means of a resistance thermometer of pure platinum, for which the relation between resistance R and temperature t is given by the equation:

$$R = R_0(1 + at + bt^2). \qquad (1)$$

This may be transformed into the Callendar equations:

$$(\mathrm{pt}) = \left(\frac{R - R_0}{R_{100} - R_0}\right)100; \; t - (\mathrm{pt}) = \delta\left[\left(\frac{t}{100} - 1\right)\frac{t}{100}\right]. \qquad (2)$$

The three constants in these equations, namely R_0, a, and b or R_0, R_{100} and δ respectively, are determined by calibration at the ice point, the steam point, and the sulfur boiling point.

The purity of the platinum must be such that $R_{100}/R_0 > 1.390$ and $R_{444.6}/R_0 > 2.645$, the latter requirement being equivalent to $\delta < 1.50$.

The Callendar equations were devised to facilitate computations by the method of successive approximations. The platinum temperature, symbol (pt), is proportional to the resistance above R_0 and the amount by which it differs from the true temperature is given by the correction term,

$$\delta\left(\frac{t}{100} - 1\right)\frac{t}{100}.$$

Consequently, a value of t sufficiently exact for use in computing the value of the correction term is readily obtained, if not by the first, then certainly by a second or third approximation.

In the interval −195° to 0°C the standard reference scale is defined by means of the platinum resistance thermometer, using the equation

$$t - (\mathrm{pt}) = \delta\left[\left(\frac{t}{100} - 1\right)\frac{t}{100}\right] + \beta\left[\left(\frac{t}{100} - 1\right)\frac{t^3}{100^3}\right]. \qquad (3)$$

The constants R_0, R_{100} and δ are determined just as for the range above 0° and the additional constant β is determined by a calibration at the boiling point of oxygen. A criterion for the purity of the platinum is that $R_{-183}/R_0 < 0.250$.

Thermometers which are not to be heated above ordinary temperatures may be calibrated at the freezing point of mercury, the CO_2 point and the oxygen point, using the interpolation formula:

$$R = R_0(1 + \mathrm{a}t + \mathrm{b}t^2 + \mathrm{c}t^4). \qquad (4)$$

The constant c in the equation is approximately equal to 5×10^{-12} and when this value is assumed, calibration at the CO_2 point may be omitted.

Equations (3) and (4) will yield substantially equivalent results, but they are not algebraically interconvertible.

Equation (1) or equation (2) may be used for temperatures up to 1000° or even 1100°C and the temperatures so determined will not depart appreciably from the standard scale.

5. TEMPERATURE SCALES DEFINED BY LIQUID-IN-GLASS THERMOMETERS

E. F. Mueller

The readings of any particular thermometer, taken when all of the liquid in the thermometer is at a uniform temperature, may be reduced to those which would have been obtained if the thermometer had been perfect and used under ideal conditions, by applying corrections for non-uniformity of the capillary bore, corrections for the change of reading due to departure of the external and internal pressures from arbitrary constant values, a correction for the departure of the ice-point reading, taken immediately *after* the temperature measurement, from the 0° mark, and a correction to allow for the value of the mean scale degree, in case the difference between the readings of the thermometer taken first at 100°C and then at 0°C, does not correspond to 100 scale degrees. The reading of a thermometer, when so corrected, may be defined as the temperature on the liquid-in-glass scale for the particular liquid and the particular kind of glass of which the thermometer is made.

The temperature scales of mercury thermometers made of French hard glass (verre dur), Jena 16^{III}, Jena 59^{III}, Jena 1565^{III} and Jena combustion tubing are defined as above. For Kew glass, the temperature scale is defined in a somewhat different way, in that the point of reference is the (single) ice point reading taken after the thermometer has been held for a sufficiently long period at ordinary temperature (about 10°C) instead of the (variable) ice point reading taken immediately after each temperature measurement. It is apparent that temperatures on the mercury-in-glass scale are not proportional to the relative increase of volume of mercury-in-glass.

Constants characteristic of the several glasses are the ice-point depression, the softening point, and the average coefficient of expansion of mercury-in-glass, between 0° and 100°C.

The ice point depression is the difference between the ice point reading of the thermometer taken after it has been kept a sufficiently long time (a few days or weeks) at 0° and the ice point reading taken immediately after the thermometer has been kept a sufficiently long time (a few minutes or hours) at 100°C. Good thermometric glasses are characterized by small ice point depression (less than 0.1°C) and rapid recovery. Some glasses have an ice point depression of nearly 1°C.

The softening point determines the upper limit of temperature at which thermometers made of the glass can be used.

The expansion coefficient is useful in calculating corrections for emergent stem.

Values of these characteristic constants are:

Glass	Ice point depression °C	Softening point °C	Coefficient of cubical exp. of mercury-in-glass 0° to 100°C
Verre dur	0.07–0.11	500	0.000158
"Kew" glass	0.20		
Jena 16^{III}	0.04–0.08	505	0.000158
Jena 59^{III}	0.03–0.04	510	0.000164
Jena 1565^{III}	0.01	660	0.000172
Jena combustion	0.03	560	

Thermometers containing alcohol, toluene or pentane are not adapted for observation at 100°C, and for such thermometers the mean scale degree is conveniently referred to the interval 0° to −78.5°, the sublimation temperature of carbon dioxide serving to fix the latter temperature.

The tabular values are the result of comparisons of mercury-in-glass thermometers with gas thermometers or platinum resistance thermometers which served to establish the standard scale of temperature. The data for Jena 16^{III} glass and Jena 59^{III} glass may be used for Corning normal and Corning borosilicate thermometer glasses respectively.

Data of this kind were of great importance during the latter part of the 19th and even during the early part of this century, when calibrated mercury-in-glass thermometers were used to distribute the standard scale of temperature. At present the data are useful principally for minor purposes, such as calculation of factors for determining emergent stem correction, calculation of setting factors for metastatic thermometers, such as the Beckmann thermometer, graduation of thermometers by mercury thread calibration in the absence of standards and thermally controlled baths, etc.

In the tables, t represents the temperature on the standard working scale (platinum resistance thermometer) except for verre dur, where t represents temperatures on the former International hydrogen scale, which in practice is not distinguishable from the standard reference scale, while t_{gl} represents corresponding temperatures on the several liquid-in-glass scales.

VALUES OF $t - t_{gl}$ FOR MERCURY-IN-GLASS THERMOMETERS

t = temperature on standard scale, t_{gl} = temperature on mercury-in-glass scale.

Emergent Stem Correction for Liquid-in-glass Thermometers

If a liquid-in-glass thermometer standardized for total immersion is used with a portion of the liquid column at a temperature below that of the bulb, the reading will be too low for this reason, and an emergent stem correction should be applied to the observed reading.

The emergent stem correction is calculated by the formula,

$$\text{Correction} = Kn(t - t_s)$$

in which

K = coefficient of cubical expansion of mercury-in-glass, per °C,

t = temperature of bulb, °C,

t_s = average temperature °C of the mercury column n°C degrees in length.

The value of t is to be determined by means of an auxiliary thermometer or thermometers, preferably with a capillary thermometer. The sign as well as the magnitude of the correction is given by the formula.

For many purposes, in using mercury-in-glass thermometers K may be treated as a constant of the glass, using the values given above for the apparent coefficient of expansion of mercury-in-glass. The value of K does, however, change with temperature. For purposes of computing the emergent stem correction, it may be considered as depending on the average of t and t_s, that is $\frac{t + t_s}{2}$ and is here so tabulated.

If the coefficients of expansion of mercury and of glass were both constant, K would also be constant. Most of the change in K is the result of the varying coefficient of the mercury, so that the change in K with temperature for one glass may with some certainty be inferred from the change for some other glass.

The use of the formula requires that t, the temperature of the bulb, be known. In case t is not known, but is to be determined from the indication of the thermometer, the reading of the thermometer may be substituted in the formula in place of t, as a first approximation and the true magnitude of the correction then calculated by means of a second, or if necessary, a third approximation.

In many cases, in calculating the emergent stem correction for thermometers containing organic liquids, it is sufficient to use the approximate value, $K = 0.001$. The tables show to what extent this is justified for pentane, toluene, and alcohol. In such thermometers, K is practically independent of the kind of glass used.

With the abandonment of the mercury-in-glass thermometer as an instrument of high precision there has been an increasing tendency to use partial immersion thermometers, graduated and standardized for a particular depth of immersion, thus avoiding the necessity of determining and applying the correction for emergent stem.

LITERATURE

(For a key to the periodicals see end of volume)

Buckingham, *31a*, **8**: 239; 12.

Example: A thermometer of Jena 59^{III} (or Corning borosilicate glass) indicated a temperature, t, of 470° after application of corrections peculiar to the instrument. The thermometer was immersed to the 150° mark, and the *average* temperature t_s of the 320° (n°) of exposed mercury column was found to be 190°. The average of t and t_s is 330° and the value of the factor K for this temperature is 0.000176. Accordingly

$$\text{Correction} = 0.000176(320)(470 - 190) = 15.8°$$

The corrected temperature is therefore 470° + 15.8° = 485.8°. Since the bulb temperature was considerably higher than 470° a second approximation may be tried:

$$\text{Correction} = 0.000176(320)(486 - 190) = 16.7°$$

The second approximation yields a corrected temperature of 470° + 16.7° = 486.7° which in view of the rather large emergent stem correction, may properly be reported as 487°.

Possible short cuts in making the second approximation will be readily apparent.

The example given is purposely somewhat exaggerated by assuming an unusually high temperature (190°) for the emergent stem, in order to show that the factor K may differ appreciably from the conventional value of 0.00016.

For computations in Fahrenheit temperatures, the proper value of K is 5/9 of the tabulated value.

6. THERMOCOUPLES

L. H. Adams

"Standard" Calibration Tables (for Use with Deviation Curve)

Standard tables such as these do not necessarily have any absolute significance; primarily, they are arbitrary reference curves which, although representing fairly well the temperature-emf functions for certain thermocouples, are intended for use with an appropriate deviation-curve. This correction-curve is determined for each couple by calibration at several—preferably three or more—fixed points within the "applicability range of the couple." This curve is constructed by plotting ΔE as ordinate ($\Delta E = E_{obs.} - E_{stand.}$) against $E_{stand.}$ as abscissa. In order to obtain the temperature corresponding to the emf indicated by the couple, the appropriate value of ΔE (as obtained from *its* deviation curve) is subtracted algebraically from the observed value of E before the latter is converted into degrees by means of the table. Example: At a certain temperature a copper-constantan couple gave an emf of 8720 microvolts. From the previously determined deviation curve of the particular couple the value of ΔE at 8720 microvolts is found to be 12 microvolts. The "standard" emf is therefore 8720 − 12 or 8708 microvolts and from the copper-constantan table this may be seen to correspond to 189.0_8°, which is the required temperature.

The fixed (*i.e.*, cold) junction is supposed to be maintained at 0°C.

Temperatures and Temperature Differences for Every 100 Microvolts

Fixed-junction Corrections

If the fixed or "cold" junction be not maintained at 0°C, a correction must be applied. This may be done by any one of several methods, of which the following are suggested:

A. Let the temperature of the fixed junction be t_c and that of the variable or "hot" junction be t. Then to the emf as read E_{t-t_c}, add the emf corresponding to t_c. This gives E_t which may at once be converted into degrees by means of the proper table.

B. Multiply the fixed-junction temperature by the factor, $f = (dE/dt)_0/(dE/dt)$, which is the ratio of the mean emf-temperature gradient between 0° and t_c to the gradient at t, and add the product to t', the uncorrected temperature. That is, $t = t' + ft_c$. These emf-temperature gradients may be obtained by taking the reciprocals of the numbers appearing in the difference columns of the calibration tables.

OPTICAL PYROMETRY

C. O. FAIRCHILD AND H. T. WENSEL

The temperature scale above the melting point of gold is based upon Wien's Law, $J_\lambda = c_1\lambda^{-5}e^{\frac{-C_2}{\lambda T}}$, in which the constant C_2 (1.433 cm deg) and the value 1336°K for the melting point of gold determine the scale. In optical pyrometry temperatures are usually measured by comparing the brightness of a glowing object with that of the filament of a lamp mounted in the image plane of a simple telescope. For highest accuracy the current through the lamp is kept at or near the value corresponding to 1336°K and higher temperatures are measured by reducing the brightness of the image of the object to match that of the filament by means of a suitable screen such as a rotating sector or an absorption glass of known transmission. The temperature is then found from the following formula derived from Wien's Law:

$$\frac{1}{T} = \frac{1}{1336} + \lambda_e \cdot \frac{\log_{10} R}{6222},$$

in which R is the transmission of the absorption device and λ_e is the "mean effective wave-length" of a color filter in the pyrometer for the temperature interval 1336° to T. Values of λ_e can be obtained in some cases by the use of Table 2.

For practical purposes the pyrometer is ordinarily calibrated in the range 700° to 1400°C (occasionally to 1550°C) in terms of filament current. A satisfactory empirical relation between the current I through the lamp filament and temperature t°C is:

$I = a + bt + ct^2 + dt^3$. For tungsten lamps with short 3 mil filaments dI/dt varies from about 0.00015 ampere per degree at 700°C ($I = 0.3$) to 0.0003 ampere per degree at 1400° ($I = 0.5$). For measurements above 1400° an absorption glass of such type is employed that $A(= \lambda_e \log_{10} R/6223)$ is a constant or varies slightly with temperature. If the spectral transmission, Tr, of the absorption device is of the form $Tr_\lambda = e^{\frac{K}{\lambda}}$, A will be a constant and equal to K/c_2. For sector discs $A = \text{constant} \cdot \lambda_e$.

TABLE I

Temperatures extrapolated from 1336°K, using Wien's Law, compared with those obtained using Planck's Law. The values in this table were computed from the relation:

$$T_p = \frac{C_2}{\lambda \log_e\left[1 + e^{\frac{c_2}{\lambda T_w}}\right]}$$

taking $\lambda = 0.65\mu$.

ARRANGEMENT OF CHEMICAL SUBSTANCES

Throughout I. C. T., except when otherwise indicated, the tabular arrangement of all chemical substances and of all systems capable of representation by formula is in accordance with a system called the "Standard Arrangement," which will now be explained and which should be learned by every user of I. C. T.

ARRANGEMENT DES SUBSTANCES CHIMIQUES

L'arrangement tabulaire de toutes les substances chimiques et de tous les systèmes susceptibles d'une représentation par formule est, dans les T. C. I., excepté lorsqu'il y a une autre indication, en accord avec un système appelé "arrangement type," (standard arrangement) expliqué ci-dessous, qui devra être appris par chaque personne qui veut utiliser les T. C. I.

Elementary Substances

All tables containing *only* elementary substances (𝔄-Tables) are arranged in alphabetical order of the symbols of the elements. In tables containing both elements and compounds (𝔄𝔅-Tables) the elements follow the "standard arrangement," *v. infra.*

Substances Élémentaires

Toutes les tables ne contenant que les substances élémentaires (Tables 𝔄) sont arrangées dans l'ordre alphabétique des symboles des éléments. Dans les tables contenant les éléments et les corps composés (Tables 𝔄𝔅) les éléments se trouvent suivant l' "arrangement type" voir *infra.*

Chemical Compounds and Other Systems Represented by Formula

The arrangement is based upon the following table of "Key-numbers" of the elements:

Composés Chimiques et Autres Systèmes Représentés Par Formule

L'arrangement est basé sur la table suivante des "nombres clés" des éléments:

KEY-NUMBERS OF THE ELEMENTS — NOMBRES CLÉS DES ÉLEMENTS

−6	−5	−4	−3	−2	−1	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
(He	Ne	A	Kr	Xe	Rn)	O	H	F	Cl	Br	I	(85)	S	Se	Te	N	P	As	Sb	Bi	C	Po	Si	Ti	Ge
						46	47	48	49	50	51	52	53	54	55	56	57	58	59	60	61	62	63	64	65
						Cr´	Mo	W	U	V	Cb(Nb)	Ta	Pa	B	Al	Sc	Y	La	Ce	Pr	Nd	(61)	Sa	Eu	Gd

Ac	Ag	Al	As	Au	B	Ba	Be	Bi	Br	C	Ca	Cb	Cd	Ce	Cl	Co	Cr	Cs	Cu	Dy	Er	Eu	F	Fe
74	32	55	13	33	54	79	75	15	5	16	77	51	29	59	4	44	46	85	31	67	69	64	3	43
					Os	P	Pa	Pb	Pd	Po	Pr	Pt	Ra	Rb	Re	Rh	Ru	S	Sa	Sb	Sc	Se	Si	Sn
					35	12	53	23	41	17	60	37	80	84	34	40	39	8	63	14	56	9	18	22

To locate a given compound, first write its "key-formula," neglecting water of crystallization, thus:

Afin de situer un composé donné, il faut d'abord écrire sa "formule-clé," en négligeant l'eau de cristallisation, ainsi:

Compound	Composé	Na_2SO_4	$HClO_4.3H_2O$	$Hg(C_{18}H_{33}O_2)_2$	$2Fe_2O_3.P_2O_5.12H_2O$	$Ni_3Pr_2(NO_3)_{12}.24H_2O$	$I_2C_6H_3SO_3H$	$(NH_4)_2CO_3$
Key formula	Formule-clé	82–8–1	4–2–1	30–16–2–1	43–12–1	60–45–11–1	16–8–6–2–1	16–11–2–1

In writing a key-formula the key-numbers must be written *in descending order.*

All chemical compounds (𝔅-Tables) are arranged in the inverse numerical order of their key-formulae. *Example:* to find the compound $Hg(C_{18}H_{33}O_2)_2$ = 30 − 16 − 2 − 1; First, turn to section 30 of the table. Then follow down the column of chemical formulae until element 16 (C) is first encountered. From this point continue until element 2 (H) is found, and then on until element 1 (O) is reached. At this point will be found all the compounds composed of the four elements Hg, C, H, and O and these compounds are arranged in an obvious manner according to the subscripts in the chemical formula. To facilitate the use of the tables, key-numbers are inserted at frequent intervals either along the top of the page or down the left hand column or both.

In looking for a chemical compound *always consult the 𝔅-Table,* the scope of which provides for *all* chemical compounds except those of the radioactive elements, of which only compounds of U, Th and Ra are given in the 𝔅-Table. For the others see p. 364. In certain of the 𝔅-Tables, at the point where key-formulae beginning with 16 occur, there will be found frequently only a few of the simpler compounds, and the reader will be referred to a

Lorsqu' on écrit une formule-clé, les nombres clés doivent être écrits *dans l'ordre des valeurs décroissantes.*

Tous les composés chimiques dans toutes les tables (Tables 𝔅.) sont arrangés d'après l'ordre numérique inverse de leurs formules-clés. *Exemple:* pour trouver le composé Hg $(C_{18}H_{33}O_2)_2$ = 30–16–2–1; il s'agit premièrement de chercher la section 30 de la table; ensuite de suivre en descendant la colonne des formules chimiques jusqu'à ce qu'on trouve l'élément 16 (C). De ce point, on continue jusqu'à ce qu'on rencontre l'élément 2 (H), et ensuite jusqu'à ce que l'élément 1 (O) soit atteint. On trouvera alors à ce point tous les composés renfermant les quatre éléments Hg, C, H et O et ces composés sont arrangés d'une manière apparante en relation avec les indices de leurs formules chimiques. Afin de faciliter l'usage des tables, les nombres-clés sont inscrits, à de fréquents intervalles, ou au haut de la page ou le long de la colonne gauche, ou aux deux places.

Pour la recherche d'un composé chimique, il s'agit de *consulter toujours la Table* 𝔅 dont le but est de renseigner sur *tous* les composés chimiques, à l'exception des éléments radio-actifs, dont seuls ceux de U, Th et Ra sont donnés dans la Table 𝔅. Pour les autres, voir p. 364. Dans certaines des Tables 𝔅, au point où les

STANCES AND SYSTEMS IN I. C. T.

DIE ANORDNUNG DER CHEMISCHEN VERBINDUNGEN

Durch die ganzen I. C. T., ausgenommen es ist etwas anderes angegeben, ist die tabellarische Anordnung aller chemischen Verbindungen und aller durch chemische Zeichen oder Formeln darstellbarer Systeme, nach der "Normal-Anordnung" (standard arrangement), durchgeführt. Sie ist im folgenden dargelegt und soll von jedem Leser der I. C. T. erlernt werden.

Elementare Stoffe

Alle Tafeln, welche *nur* elementare Stoffe (𝔄-Tabellen) enthalten, sind in alphabetischer Reihenfolge nach den Symbolen der Elemente angeordnet. In den Tafeln, welche beides, Elemente und Verbindungen (𝔄𝔅-Tabellen), enthalten, folgen die Elemente der "Normal-Anordnung." Siehe weiter unten.

Die chemischen Verbindungen und andere durch Formeln darstellbare Systeme

Die Anordnung ist auf der folgenden Tafel begründet, welche die "Schlüsselnummern" der Elemente enthält:

ORDINE DI ELENCAZIONE DELLE SOSTANZE

In tutti i volumi delle T. C. I. l'ordine in cui le sostanze ed i sistemi rappresentabili con formule sono disposti nelle tabelle è (tranne che non sia diversamente indicato) quello "standard" illustrato più avanti. Chiunque voglia servirsi delle T. C. I. deve anzitutto apprendere in che consiste questo sistema "standard."

Sostanze Elementari

Tutte le Tabelle contenenti soltanto sostanze elementari (tabelle 𝔄) sono disposte secondo l'ordine alfabetico dei simboli degli elementi. Nelle tabelle che comprendono elementi e composti (tabelle 𝔄-𝔅) gli elementi sono ordinati secondo la disposizione "Standard." *v. infra.*

Composti Chimici ed Altri Sistemi Rappresentati da Formule

La disposizione è basata sul quadro seguente di "numeri chiave" degli elementi.

Schlüsselnummern der Elemente

Numeri chiave degli elementi

21	22	23	24	25	26	27	28	29	30	31	32	33	34	35	36	37	38	39	40	41	42	43	44	45
Zr	Sn	Pb	Th	Ga	In	Tl	Zn	Cd	Hg	Cu	Ag	Au	Re	Os	Ir	Pt	Ma	Ru	Rh	Pd	Mn	Fe	Co	Ni
66	67	68	69	70	71	72	73	74	75	76	77	78	79	80	81	82	83	84	85	86				
Tb	Dy	Ho	Er	Tm	Yb	Lu	Hf	Ac	Be(Gl)	Mg	Ca	Sr	Ba	Ra	Li	Na	K	Rb	Cs	(87)				

Ga	Gd	Ge	Gl	H	Hf	Hg	Ho	I	In	Ir	K	La	Li	Lu	Ma	Mg	Mn	Mo	N	Na	Nb	Nd	Ni	O
25	65	20	75	2	73	30	68	6	26	36	83	58	81	72	38	76	42	47	11	82	51	61	45	1
Sr	Ta	Tb	Te	Th	Ti	Tl	Tm	U	V	W	Y	Yb	Zn	Zr	(61)	(75)	(85)	(87)						
78	52	66	10	24	19	27	70	49	50	48	57	71	28	21	62	34	7	86						

Um eine gegebene Verbindung aufzufinden, hat man zuerst seine Schlüsselformel aufzuschreiben, wobei man das Kristallwasser auslässt. z.B.:

Per trovare il posto di un dato composto bisogna prima scrivere la formula chiave trascurando l'acqua di cristallizzazione, p. es.:

Verbindungen	Composto	Na_2SO_4	$HClO_4.3H_2O$	$Hg(C_{18}H_{33}O_2)_2$	$2Fe_2O_3.P_2O_5.12H_2O$	$Ni_3Pr_2(NO_3)_{12}.24H_2O$	$I_2C_6H_3SO_3H$	$(NH_4)_2CO_3$
Schlüsselformel	Formula chiave	82–8–1	4–2–1	30–16–2–1	43–12–1	60–45–11–1	16–8–6–2–1	16–11–2–1

In die Schlüssselformel müssen die Schlüsselnummern in *absteigender* Reihenfolge geschrieben werden.

Alle chemischen Verbindungen (𝔅-Tabellen) sind in der umgekehrten Reihenfolge der Schlüsselformeln angeordnet. Z. B.: Um die Verbindung $Hg(C_{18}H_{33}O_2)_2$ = 30–16–2–1 zu finden, hat man zuerst den Abschnitt 30 aufzusuchen. Dann hat man den Kolonnen der chemischen Verbindungen abwärts zu folgen, bis man zuerst das Element 16 (C) antrifft, von da an setzt man weiter fort, bis das Element 2 (H) gefunden ist und dann weiter, bis das Element 1 (O) erreicht ist. Bei dieser Stelle werden alle Verbindungen gefunden werden, welche sich aus den 4 Elementen Hg, C, H, und O zusammensetzen. Diese Verbindungen sind in deutlicher Art, entsprechend der Bezeichnungsweise chemischer Formeln, angeordnet. Um den Gebrauch der Tafeln möglichst zu erleichtern, sind die Schlüsselnummern häufig an verschiedenen Stellen eingefügt. Sie befinden sich entweder am Kopf der Seiten, oder auf der linken Seite unten, oder an beiden Stellen.

Um eine chemische Verbindung zu suchen, *benütze man immer die 𝔅-Tabellen:* die *alle* chemischen Verbindungen enthalten, ausgenommen jene der radioaktiven Elemente. Von diesen sind

Nella formula chiave, i numeri chiave devono essere scritti *in ordine decrescente.*

Tutti i composti in tutte le tabelle (Tabelle 𝔅) sono disposti nell'ordine numerico inverso delle loro formule chiavi.

Supponiamo ad es. di voler trovare il composto Hg $(C_{18}H_{32}O_2)_2$ = 30–16–2–1. Prima si cerca la sezione 30 della Tabella, poi si scorre la colonna delle formule fino ad incontrare l'elments 16 (C). Da questo punto si continua finchè si trova l'elemento 2 (H), e quindi fino a raggiungere l'elemento 1 (O). Qui si trovano tutti i composti risultanti dai quattro elementi Hg, C, H e O ordinati secondo gli indici delle formule. Per facilitare l'uso delle tabelle i numeri chiave sono inseriti ad intervalli frequenti nella testata o lungo il margine sinistro della pagina, o nell'una e nell'altro.

Per cercare un composto bisogna *sempre consultare la tabella 𝔅* che contiene *tutti* i composti tranne quelli degli elementi radioattivi; di questi sono riportati nella tabella 𝔅 soltanto i composti di U, Th, Ra. Per gli altri vedi p. 364. In alcune tabelle 𝔅, laddove si trovano formule chiave che cominciano con 16, si troveranno spesso soltanto pochi composti fra i più semplici e il lettore

ℭ-Table where the remainder of such compounds will be found listed under a different arrangement known as

The ℭ-Arrangement

In this arrangement the compounds are arranged according to their empirical formulae (*including* water of crystallization), in the order C, H, with the remaining symbols alphabetical, *e.g.*, $C_6H_4I_2O_3S$. The ℭ-Tables, however, will not contain any carbon compound whose key-formula contains a number greater than 16.

SYSTEMS OF MORE THAN ONE COMPONENT

The components of each system are first arranged according to the standard arrangement, giving the order A, B, C, etc. The systems are then arranged, according to the standard arrangement, in the order of their A-components. All systems having the same A-component will be found (under that component) in the order of their B-components, etc.

In certain tables, the above plan will be based upon the ℭ-arrangement instead of the standard arrangement. Such cases will always be so indicated.

Name Indices

The chemical formulae of nearly all of the organic compounds and minerals whose properties are given in I. C. T. can be found with the aid of the extensive indices of names given on p. 174 and 280. If the name is not found there, other works of reference must be consulted for the formula. It should be noted, however, that the exact formula is not required. The compound can be readily located if only the elements composing it are known (in the case of inorganic compounds) or if only the number of carbon atoms are known (in the case of organic compounds) provided only that the user can recognize either name or formula when he sees it.

formules-clés commençant par 16 se présentent, on ne trouvera fréquemment qu'un petit nombre de composés plus simples, et le lecteur sera alors renvoyé à une Table ℭ, où le reste de ces composés se trouvera disposé d'une façon différente nommé

L'Arrangement ℭ

Dans cet arrangement, les composés sont disposés en relation avec leurs formules empiriques (l'eau de cristallisation inclusivement) dans l'ordre C, H, les symboles restants venant ensuite dans l'ordre alphabétique; par ex: $C_6H_4I_2O_3S$. Cependant les Tables ℭ ne contiendront aucun composé dont la formule-clé renferme un nombre supérieur à 16.

SYSTÈMES DE PLUS D'UN COMPOSANT

Les *composants* de chaque système sont premièrement disposés d'après l'arrangement type suivant l'ordre A, B, C, etc. Les *systèmes* sont alors arrangés, en accord avec l'arrangement type, dans l'ordre de leurs composants A. Tous les systèmes ayant le même composant A seront trouvés sous ce composant dans l'ordre de leurs composants B, etc.

Dans certaines tables, le plan sera basé sur l'arrangement ℭ au lieu de l'arrangement type. De tels cas seront toujours mentionnés.

Noms Indices (Anglais)

Les formules chimiques de presque tous les composés organiques et les minéraux dont les propriétés sont données dans les T. C. I. peuvent être trouvées au moyen des indices extensifs des noms donnés aux p. 174 et 280.

Si l'on ne trouve pas le nom à cette place, il faudra consulter d'autres ouvrages de références pour la formule. Il faut noter, cependant, que la formule exacte n'est pas nécessaire. Le composé peut être immédiatement situé si l'on ne connait que les éléments qui le composent (dans le cas des composés inorganiques), ou que les nombres des atomes de C (dans le cas des composés organiques); à la seule condition que le lecteur puisse reconnaître ou le nom ou la formule lorsqu'il la voit.

PHYSICAL PROPERTIES OF CHEMICAL SUBSTANCES

INTRODUCTION

The following tables (p. 96 to 314) are intended to serve as a source of ready reference for the *approximate* values of certain properties of chemical substances, displayed in such a manner as to be of the greatest utility. The values given may be uncertain by one or more units in the last significant figure. Non-significant figures are given in small type. Thus, 2300 indicates that the correct value lies between 1800 and 2800, with 2300 as most probable value.

More accurate values for these properties, if known, will be found in subsequent sections of I. C. T., together with their literature references.

𝔄. ELEMENTARY SUBSTANCES AND ATMOSPHERIC AIR

𝔄-Tables, p. 102. Values in parentheses are estimated, usually with the aid of the Periodic Law.

PROPRIÈTÈS PHYSIQUES DES SUBSTANCES CHIMIQUES

INTRODUCTION

Les tables suivantes (p. 96 à 314) ont été établies dans le but de servir de source de référence rapide pour les valeurs *approximatives* de certaines propriétés des substances chimiques, et sont disposées de manière à être de la plus grande utilité possible. Les valeurs données puivent être incertaines par une ou plusieurs unités de leur dernier chiffre significatif. Les chiffres non signicatifs sont donnés en petits caractères. Ainsi, 2300 indique que la valeur correcte se trouve entre 1800 et 2800, avec 2300 comme valeur la plus probable. Si l'on connait des valeurs plus précises pour ces propriétés, on les trouvera dans les sections suivantes des T. C. I., accompagnées de leurs références bibliographiques.

𝔄. SUBSTANCES ÉLÉMENTAIRES ET AIR ATMOSPHÉRIQUE

Tables 𝔄, p. 102. Les valeurs entre parenthèses sont estimées ordinairement à l'aide de la Loi périodique.

𝔅. COMPOSES CHIMIQUES. ARRANGEMENT TYPE (*v.* p. 96)

Tables 𝔅, (p. 106)

1. Formule ou formule et nom.
2. Poids moléculaire en grammes (Poids atomiques des T. C. I., *v.* p. 43.)

in den 𝔅-Tabellen nur die Verbindungen des U, Th und Ra enthalten. Für die anderen siehe Seite 364. In einigen 𝔅-Tabellen, dort wo die Schlüsselnummern mit 16 beginnen, findet man häufig nur einige wenige einfache Verbindungen. Der Leser wird dann auf die ℭ-Tabellen verwiesen, wo die restlichen derartigen Verbindungen gefunden werden können. Diese Tabellen sind nach anderen Gesichtspunkten zusammengestellt. Es ist das die

ℭ-Anordnung (ℭ-Arrangement)

Bei dieser Anordnung sind die Verbindungen nach ihrer empirischen Formel gegeben (einschliesslich Kristallwasser) und zwar in der Ordnung C, H, die restlichen Zeichen dann in alphabetischer Ordnung, z.B. $C_6H_4I_2O_3S$. Die ℭ-Tabellen enthalten jedoch keine Kohlenstoffverbindung, in deren Schlüsselformel eine Zahl grösser als 16 vorkommt.

SYSTEME MIT MEHR ALS EINER KOMPONENTE

Die Komponenten jedes einzeln Systemes sind zuerst in der Reihenfolge A, B, C, u. s. w., entsprechend des "Standard-Arrangement" anzuordnen. Die Systeme sind dann, entsprechend des "Standard-Arrangement," in der Reihenfolge ihrer A-Komponenten angegeben. Alle Systeme, welche dieselbe A-Komponente haben, werden unter dieser Komponente in der Reihenfolge ihrer B-Komponenten gefunden.

In gewissen Tabellen wird dieser Plan entsprechend der ℭ-Anordnung, an Stelle des "Standard Arrangement," gewahlt. Solche Fälle werden immer entsprechend bemerkt.

Namenverzeichnis (Englisch)

Die chemischen Formeln von so ziemlich allen organischen Verbindungen und Mineralien, deren Eigenschaften in den I. C. T. enthalten sind, können mit Hilfe des ausgedehnten Namenverzeichnisses auf Seite 174 und 280 gefunden werden. Ist der Name hier nicht auffindbar, so müssten andere Quellen für die Formel nachgesehen werden. Es soll aber bemerkt werden, dass eine genaue Formel nicht nötig ist. Die Verbindung kann bei anorganischen Verbindungen leicht aufgefunden werden, wenn nur die Elemente, die sie zusammensetzen, bekannt sind, bei organischen Verbindungen, wenn nur die Zahl der Kohlenstoffatome bekannt ist. Nötig ist es, dass der Leser entweder den Namen oder die Formel beim Ansehen erkennt.

DIE PHYSIKALISCHEN EIGENSCHAFTEN CHEMISCHER STOFFE

EINFÜHRUNG

Die folgenden Tafeln (s. 96 bis 314) sollen zur raschen Orientierung über angenäherte Werte gewisser Eigenschaften chemischer Verbindungen dienen. Sie sind in einer solchen Art angeordnet, um vom grösstmöglichem Nutzen zu sein. Die angegebenen Werte können auf einer und mehreren Stellen der letzten grossgeschriebenen Ziffer unsicher sein. Z.B. sagt die Zahl 2300 aus, dass der zwischen 1800 und 2800 liegende Wert am wahrscheinlichsten 2300 sein wird.

Genauere Werte für diese Eigenschaften können, wenn sie bekannt sind, in den weiter unten vorhandenen Abschnitten der I. C. T. zusammen mit der Literatur gefunden werden.

𝔄. ELEMENTARE STOFFE UND DIE ATMOSPHÄRISCHE LUFT

𝔄-Tabellen, Seite 102. Werte, die in den Klammern sich befinden, sind geschätzt gewöhnlich nach dem periodischem System der Elemente.

𝔅. CHEMISCHE VERBINDUNGEN. NORMAL-ANORDNUNG [STANDARD-ARRANGEMENT] (siehe S. 97)

𝔅-Tabellen, Seite 106

1. Formel oder Formel und Name.
2. Gramm-Formel-Gewicht (Atomgewichte der I. C. T. siehe S. 43.)

sarà rimandato a una tabella ℭ dove si troveranno gli altri disposti con criterio differente che viene chiamato

La Disposizione ℭ

Secondo questa i composti sono disposti in base alle formule empiriche (*compresa* l'acqua di cristallizzazione) nell'ordine C, H e con i rimanenti simboli ordinati alfabeticamente P. es. $C_6H_4I_2O_3S$. Le tabelle ℭ non comprendono però composti del carbonio che hanno un numero chiave piu grande di 16.

SISTEMI DI PIU' D'UN COMPONENTE

I *componenti* di ciascun sistema sono dapprima disposti secondo la disposizione tipo, nell'ordine A, B, C, etc. I *sistemi* sono quindi disposti, secondo la disposizione tipo, nell'ordine dei loro componenti A. Tutti i sistemi aventi lo stesso componente A verranno trovati, sotto questo componente, nell'ordine dei loro componenti B, etc.

In alcune tavole il piano sara' basato sulla disposizione ℭ in luogo della disposizione tipo. Di cio' verra' sempre fatta menzione.

Indici Per Nome (Inglese)

Le formule chimiche di quasi tutti i composti organici e minerali di cui sono riportate le proprietà nelle T. C. I. si possono trovare con l'aiuto di estesi indici di nomi dati a p. 174, e 280. Se negli indici non si trova il nome bisogna consultare altre opere per trovare la formula. Deve tuttavia notarsi che non è necessaria la formula esatta. Il composto può essere facilmente ritrovato se si conoscono solo gli elementi componenti (nel caso di composti inorganici) o se si conosce solo il numero di atomi di carbonio (nel caso di composti organici) purchè il lettore sia in grado di riconoscerne il nome o la formula quando li vede.

PROPRIETA' FISICHE DELLE SOSTANZE

INTRODUZIONE

Le tabelle seguenti (p. 96 a 314) hanno lo scopo di fornire per una serie di sostanze valori *approssimati* di certe proprietà disposti in modo da essere della più grande utilità. I valori riportati pòs sono essere incerti per una o più unità nelle ultime cifre significative. Le cifre non significative sono indicate in caratteri piccolli. Così 2300 indica che il valore esatto si trova fra 1800 e 2800, e che 2300 è il valore più probabile.

Valori più precisi di queste proprietà quando sono conosciuti, sono riportati nelle sezioni successive delle T. C. I. insieme con le relative indicazioni bibliografiche.

THE PROPERTY-SUBSTANCE TABLES

Following the General Tables will be found (p. 306) the Property-substance Tables, in each of which the substances, identified by Index Number, are arranged in ascending order of the values of the property, the intervals on the scale of values of the property being given in black-face type.

To Identify a Substance by Means of Its Properties.—*Example:* A liquid is found to have the following properties: B. P. = 81.1° at 745 mm, $d = 0.783$, $n_D = 1.347$. What is the substance ? With the aid of Craft's rule, first correct the boiling point to 760 mm. If the general nature of the substance is unknown, put $c = 10^{-4}$ in the Craft's equation, $\Delta t = cT_B(760 - P)$. Thus in the present instance, we should have $\Delta t = 10^{-4} \times (81.1 + 273)\ (760 - 745) = 0.3°$, and $t_B = 81.1 + 0.3° = 81.4°$. Next turn to the special B. P. (p. 310), d (p. 313), and n (p. 276) tables and read off from these tables the index numbers of substances having values of the above properties in the neighborhood of those for the unknown substance. Thus, for the present example, the following index numbers will be obtained: For B. P., 130, 758, 727, 1612, 168, 277, 1535, 506, 792; for d, 208, 168, 395, 506, 3320, 1049, 262, 792, 5156; for n_D, 141, 168, 213. The only index number common to each of these properties is 168; and on turning to this index number in the General ℭ-Table, we can readily identify our substance as acetonitrile. The identification can then be further checked by appropriate chemical tests, if desired.

TABLES DES PROPRIÉTÉS DES SUBSTANCES

On trouvera (p. 306) à la suite des Tables générales, les Tables des Propriétés des Substances, dans chacune desquelles, les substances identifiées par leur Nombre-Index, sont arrangées dans l'ordre ascendant des valeurs de la propriété; les intervalles de l'échelle des valeurs de la propriété sont donnés en caractères gras.

Pour identifier une substance au moyen de ses propriétés.—*Exemple*: On a trouvé qu'un liquide a les propriétés suivantes: P.E. = 81.1° à 745 mm, $d = 0.783$, $n_D = 1{,}344$. Quelle est la substance? Au moyen de la règle de Craft, on corrige premièrement le point d'ébullition à 760 mm. Si la nature générale de la substance est inconnue, on pose $c = 10^{-4}$ dans l'équation de Craft, $\Delta t = cT_E$ $(760 - P)$. Ainsi dans le cas présent, nous aurions $\Delta t = 10^{-4} \times (81.1 + 273)(760 - 745) = 0.3°$, et $t_E = 81.1° + 0.3° = 81.4°$. Ensuite on cherche dans les tables spéciales des P.E. (p. 310), des d (p. 313) et des n (p. 276) et on note les nombres-index des substances ayant les valeurs des propriétés ci-dessus dans le voisinage de celles de la substance inconnue. Ainsi, pour l'exemple présent, les nombres-index suivants seront obtenus; Pour le P.E., 130, 758, 727, 1612, 168, 277, 1535, 506, 792; pour d, 208, 168, 395, 506, 3320, 1049, 262, 792, 5156; pour n_D, 141, 168, 213. Le seul nombre-index commun à chacune de ces propriétés est 168; en revenant à ce nombre-index dans la Table générale ℭ, et en notant les autres propriétés, on peut rapidement identifier notre substance comme étant acétonitrile. L'identification peut être alors poussée plus loin au moyen d'essais chimiques appropriés, si on le désire.

STOFF-EIGENSCHAFTS TAFELN

Den Haupttabellen folgend, findet man Seite 306 Stoff-Eigenschafts Tafeln. In jeder dieser Tafeln, in welcher die Stoffe durch ihre Indexzahlen bezeichnet sind, werden die Stoffe in aufsteigender Ordnung der Werte dieser Eigenschaften dargestellt. Die Intervalle an der Scala der Eigenschaftswerte sind in fettgedruckten Ziffern angegeben.

Die Erkennung eines Stoffes mit Hilfe seiner Eigenschaften.—*Beispiel:* Es ist eine Flüssigkeit gefunden, welche folgende Eigenschaften hat: Siede-Punkt 81.1° bei 745 mm, $d = 0.783$, $n_D = 1.344$. Welcher Stoff ist das? Mit Hilfe der Regel von Craft corrigiere man zuerst den Siede-Punkt auf 760 mm. Ist die allgemeine Natur des Stoffes nicht bekannt, setze man $c = 10^{-4}$ in die Gleichung von Craft ein: $\Delta t = cT_B(760 - P)$. Im gegenwärtigen Falle ist also $\Delta t = 10^{-4} \times (81.1 + 275)(760 - 745) = 0.3°$, wonach dann der Siede-Punkt $t_B = 81.1° + 0.3° = 81.4°$ sich ergibt. Dann verwende man die Sd.P. Tabellen (Seite 310), die *d*-Tabellen (Seite 313) und die *n*-Tabellen (Seite 276), suche in diesen die Indexzahlen jener Stoffe heraus, deren oben genannte Eigenschaften solche Werte haben, die in der Nähe der Eigenschafts Zahlen des unbekannten Stoffes liegen. So erhält man für das gewählte Beispiel, folgende Indexnummern: für Sd. P. 130, 758, 727, 1612, 168, 277, 1535, 506, 792, für *d*, 208, 168, 395, 506, 3320, 1049, 262, 792, 5156; für n_D 141, 168, 213. Die einzige Index-Nummer, die alle drei Eigenschaften vereinigt, ist 168. Diese Index-Nummer wird in der Haupt ℭ-Tabelle aufgesucht; mit Beachtung noch anderer Eigenschaften kann man leicht die Flüssigkeit als Azetonitril erkennen. Die Identifizierung kann dann noch weiter durch

5. Punto di ebollizione. (Alla pressione di 760 mm Hg tranne che non sia altrimenti indicato dalla soprascritta; così 321^{125} = bolle a 321° alla pressione di 125 mm Hg.)
Tabella 𝔅.

6. Densità, g cm^{-3}. (A 20°, tranne che non sia altrimenti indicato dalla soprascritta; così $1.853^{40} = 1.853$ g cm^{-3} a 40°C.)
Tabella 𝔅.

7. Indice di rifrazione e dispersione (n_D e $H_\beta - H_\alpha$) per 20° tranne che non sia altrimenti indicato.

LE TABELLE DELLE PROPRIETA' DELLE SOSTANZE

Seguendo le tabelle generali si troveranno (p. 306) le tabelle delle proprietà in ciascuna delle quali le sostanze, indicate col numero indice, sono disposte secondo l'ordine ascendente dei valori della proprietà. Gli intervalli nella scala dei valori della proprietà sono indicati in grassetto.

Identificazione di una sostanza a mezzo delle sue proprietà.—*Esempio:* si supponga che un liquido abbia le seguenti proprietà: B.P. = 81.1° a 745 mm, $d = 0.783$, $n_D = 1.344$. Che sostanza è?

Con l'aiuto della regola di Craft, bisogna anzitutto ridurre il punto di ebollizione a 760 mm. Se non si conosce la natura della sostanza bisogna mettere, nella equazione di Craft, $c = 10^{-4}$, $t = cT_B(760 - P)$. Così, nel caso nostro, si avrebbe $t = 10^{-4} \times (81.1 + 273)\ (760 - 745) = 0.3°$, e $t_B = 81.1° + 0.3° = 81.4°$. Dopo bisogna guardare alle tabelle speciali per il B. P. (p. 310), per *d* (p. 313) e per *n* (p. 276), e ricavare da queste tabelle i numeri indici delle sostanze aventi valori delle suddette proprietà vicini a quelli della sostanza sconosciuta. Così, per il nostro esempio, si otterranno i seguenti numeri indici: per B.P., 130, 758, 727, 1612, 168, 277, 1535, 506, 792; per *d*, 208, 168, 395, 506, 3320, 1049, 262, 792, 5156; per n_D 141, 168, 213. L'unico numero indice comune a ciascuna di queste proprietà è 168; tornando a questo numero indice nella Tabella Generale ℭ, e osservando le altre proprietà, si può prontamente identificare la sostanza nel acetonitrile.

La identificazione può quindi essere ulteriormente comprovata da appropriati saggi chimici, se si desidera.

LIQUID CRYSTALS

H. W. Foote

The term "transition temperature" refers in the tables to the temperature at which the solid and crystalline-liquid phases are in equilibrium at a pressure of one atmosphere; by "melting point," is meant the corresponding temperature at which the crystalline-liquid and isotropic liquid phases are in equilibrium. In some cases, more than one stable liquid crystal phase exists, giving an additional transition temperature for each additional liquid crystal phase. These transition temperatures between two liquid crystal phases are indicated by *. In most cases, they are only approximate. Melting points which are quite uncertain, usually due to partial decomposition, have "d." written after the value. No attempt has been made to estimate the accuracy of values obtained by a single investigator, as the methods of determination are the same in nearly every case and the result obviously depends on the skill of the investigator and the purity of the compounds.

A series of apparently good determinations by different observers is apt to vary by considerably more than one degree, and it seems unlikely that any transition temperature or melting point of liquid crystals is known with an accuracy much better than one degree. For this reason, the weighted average of a number of different determinations is usually given to the nearest whole degree. When the number of determinations is sufficient, the weighted average deviation, usually to the nearest whole degree, is given also.

The melting points of unstable liquid crystals, in monotropic systems, are not included in the tables, and transition temperatures, in the ordinary sense, do not exist in this case. Many observations on monotropic compounds will be found in nearly all the Halle dissertations and in the publications by Vorländer, which are listed at the end of the tables.

For the effect of pressure on the transition temperature and melting point of liquid crystals, see G. Hulett, *7*, **28**: 629; 99. For approximate data on liquid crystals of alkali salts of higher fatty acids (chiefly) see Vorländer, *25*, **43**: 3120; 10. For similar data regarding compounds which are optically active, see H. Stoltzenberg, Diss., Halle (1911). For qualitative data regarding liquid crystals, see E. Wolferts, Diss., Halle (09), R. Wilke, Diss., Halle (09); K. Mattenklodt, Diss., Halle (11); and Vorländer, *25*, **40**: 1415, 1966; 07.

$HgC_4H_{12}NI_3$	1, 1-Diethylammonium mercuric chloride	R.	Bi.	+	Very large			(16)
$CuC_2H_2O_4.4H_2O$	Cupric formate	M.	Bi.	−	34° 54′	55° 6′	Ax. pl. b(010); $X \wedge c = 23° 35'$ in obtuse $\angle\beta$	(G)
$CuC_{10}H_6O_6S_2.6H_2O$	Copper naphthalene-1, 5-disulfonate	M.	Bi.				Ax. pl.‖(010); $\eta_\alpha \wedge c = 75°$	(14)

VALUE OF AN OLFACTY EXPRESSED AS DEGREE OF SATURATION OF AIR WITH THE ODORIVECTOR

Substance	% Saturation	Substance	% Saturation
Eucalyptol	0.058	Methyl alcohol	1.388
Eugenol	0.144	Toluidine	1.515
Toluene	0.158	Ethyl alcohol	2.5
Benzene	0.169		

VALUE OF AN OLFACTY IN CM OF THE ZWAARDEMAKER OLFACTOMETER

The constants of Zwaardemaker olfactometer are: width of cylinder, 0.8 cm; length, 10 cm; contents, 50 cc; air contact per cc of cylinder, 2.5 cm^2; velocity of air in the air tube, 100 cc per sec (exposure, 0.33 sec).

MINIMUM PERCEPTIBLE IN CM OF OLFACTOMETER SCALE

Saturated solutions (9)

Substance	cm	Substance	cm
Terpineol—H_2O	0.01	Caproic acid—H_2O	0.10
Ethyl propionate—H_2O	0.02	Trinitroisobutyltoluene—H_2O	0.10

RADIOACTIVITY

S. C. LIND, SPECIAL EDITOR

1923 INTERNATIONAL TABLE
RADIOACTIVE ELEMENTS AND THEIR CONSTANTS

λ (*sec*)$^{-1}$ is the *radioactive constant of transformation.*

$$dQ = -\lambda Q dt, \qquad Q = Q_0 e^{-\lambda t}, \qquad \log_{10}\frac{Q_0}{Q} = 0.4343\lambda t,$$

in which Q_0 is the initial quantity and Q the quantity remaining after a time t (seconds).

$\lambda = -\frac{dQ}{Q}\frac{1}{dt}$ represents the fraction of the element transformed, reduced to the unit of time.

In the case of a double transformation, the values between brackets [ ] refer to the constants corresponding with the separate branches; the constant for both branches not being put between brackets.

The sign (?) indicates that the value has been indirectly deduced from the range of the α-rays expelled.

$\theta = \frac{1}{\lambda}$ is the *average life* of the radioactive atoms.

T is *the half period, i.e.,* the time in which the quantity of radioelement is diminished to one half:

$$\lambda T = -\log_e 0.5 = 0.69315 \text{ and } \theta = 1.443T$$

Radiation.—The brackets ( ) indicate that the radiation is relatively feeble.

REMARKS CONCERNING THE NOMENCLATURE

It is desirable that the nomenclature adopted by the international commission should be accepted universally but that now put forward for the present year is provisional, to serve as a basis of discussion with the view to the adoption ultimately of a standard nomenclature.

The most important points are:

1. The three radioactive emanations have been given the names radon, actinon, and thoron, with the symbols Rn, An, Tn, to suggest both their origin and their chemical character as members of the family of the rare gases of which the valency is zero;
2. In the branches which occur at the C members the sign (′) has been used to indicate the products resulting from the emission of β-rays (isotopes of polonium) and the sign (″) to indicate the products resulting from the emission of α-rays (isotopes of thallium);
3. The ultimate products have been indicated by the letter Ω.

EXPLANATION OF THE NOTES

NOTE 1.—*Uranium I.*—The value given for θ is that obtained from the equation:

$$\theta = \frac{1}{\lambda} = 2440 \times 0.97 \times 3 \times 10^6 \times \frac{226}{238} = 6.75 \times 10^9$$

in which the number 2440 represents the average life of radium in years, the number 0.97 the branching coefficient and $3 \times 10^6 \times \frac{226}{238}$ is the ratio between the numbers of atoms of uranium and radium in equilibrium in minerals.

If the actinium series is independent from that of uranium I, λ cannot be calculated by this method.

The value of λ obtained by the direct counting of the α-particles from a compound of uranium is 4.57×10^{-18} from which $\theta = 7 \times 10^9$ years and $T = 4.8 \times 10^9$ years.

NOTE 2.—*Uranium X_2* is also called brevium.

NOTE 3.—Radon replaces the names *radium emanation* and *niton* (the latter of which was proposed by Sir William Ramsay).

NOTE 4.—*Radium C* undergoes a double disintegration: 99.97% of the atoms emit β-rays and produce the substance Ra-C′ which gives α-rays, and 0.03% of the atoms emit α-rays and produce the substance Ra-C″ which gives β-rays.

a_0 is the *range* in cm of the α-rays in air at 0°C and a pressure of 760 mm of mercury.

The range at τ° C. and under p mm of mercury is

$$a = \frac{a_0(273 + \tau)760}{273p}$$

V is the velocity of α or β-rays relatively to that of light.

To convert to cm per sec multiply by 3×10^{10}.

For the α-rays:

$$V = 0.0342\, a^{1/3}$$

$\mu_{\beta Al}$ is the absorption coefficient of the β-rays in aluminium, the thickness being measured in cm.

$\mu_{\gamma Al}$ and $\mu_{\gamma Pb}$ are the absorption coefficients of the γ-rays in aluminium and lead respectively, the thickness being measured in cm; the latter is only given for the most penetrating type of γ-rays.

If I_0 is the initial intensity and I the intensity after the rays have traversed x cm of the absorbent:

$$I = I_0\, e^{-\mu x} \qquad \log_{10}\frac{I_0}{I} = 0.4343\mu x$$

If D is the thickness corresponding with the absorption of one-half of the rays:

$$\mu D = 0.693$$

NOTE 5.—*Radium D* is also called radiolead.

NOTE 6.—*Radium C″* is also called radium C_2.

NOTE 7.—*Uranium Y* is the first known member of the actinium series. It may be derived from Uranium I or Uranium II. In this case, 3% of the atoms of Uranium produce the actinium family, and 97% the radium family.

The hypothesis has also been put forward that the actinium series may be produced independently from a third (hypothetical) isotope of Uranium for which the name actinouranium has been proposed.

NOTE 8.—*Protoactinium* is also called eka-tantalum.

NOTE 9.—A new radioactive substance named uranium Z, and isotopic with protoactinium, accompanies uranium in minute quantity. (*25*, **54B**: 1131; 21). Its period is from 6 to 7 hours. It emits a β-radiation for which D_{AI} varies from: 0.0014 to 0.012. Its parent is an isotope of thorium, but it cannot yet be placed in the series.

NOTE 10.—*Actinon* is also called actinium emanation.

NOTE 11.—*Actinium C.* 0.2% of the α-rays emitted by this substance have a range $a_0 = 6.10$, instead of 5.12. From this it has been concluded that 0.2% of the atoms undergo a transformation by the emission of β-rays as is the case in the radium C and thorium C branches (*3*, **27**: 690; 14. **28**: 818; 14). Confirmatory evidence appears to be desirable.

NOTE 12.—*Actinium C″* is also called actinium D.

NOTE 13.—*Thorium.* The value given for λ is that obtained from the direct counting of the α-particles emitted by a compound of thorium. All the other values are less; the smallest being 0.55 of that given in the table and giving $\theta = 3.45 \times 10^{10}$ years and $T = 2.37 \times 10^{10}$ years (*63*, **19**: 259; 18).

NOTE 14.—*Thoron* is also called thorium emanation.

NOTE 15.—*Thorium C* undergoes a double disintegration: 65% of the atoms emit β-rays and produce the substance Th-C′ which gives α-rays, and 35% emit α-rays and produce the substance Th-C″ which gives β-rays.

NOTE 16.—*Thorium C.* The value $a_0 = 4.69$ is that corresponding with $V = 0.0572$ which has been directly measured.

NOTE 17.—*Thorium C″* is also called thorium D.

NOTE 18.—*Potassium* and *rubidium* emit β-rays but show no other evidence of radioactivity.

ARTIFICIAL DISINTEGRATION OF THE ELEMENTS

G. Rudorf

Disintegration by the splitting off of positively charged hydrogen nuclei by the action of rapidly moving α-particles.

(*a*) Disintegration obtained with B, N, F, Ne, Na, Mg, Al, Si, P, S, Cl, A, K (1, 2, 3, 5).

(*b*) No disintegration obtained with H, He, Li, C, O, Ni, Cu, Zn, Sc, Kr, Mo, Pd, Ag, Sn, X, Au, U (2, 3, 5).

(*c*) Doubtful, Be (4, 5).

Range of Emitted Hydrogen Nuclei (2, 3, 5)

Element	Forward range in cms	Backward range in cms
B	58	38
N	40	18
F	65	48
Na	58	36
Al	90	67
P	65	49
Mg, Si, S, Cl, A, K	18–30	
Ne	16	

The values for B, F, Na, P are possibly somewhat in error (3) but are certainly greater than 40 (2).

ELECTRON EMISSION PRODUCED BY RADIATION FROM RADIOACTIVE SUBSTANCES

Pierre Auger

Relative Ionization of Gases by Po α-Rays Having a 3.8 cm Range (1)

Gas	Air	O_2	N_2	CO_2	Illuminating gas
I	1	1.12	0.97	1.23	0.38

Relative Molecular Ionization of Gases by β and γ Rays (2)

Gas	Air	H_2	O_2	NH_3	N_2O	CO_2	C_2N_2	SO_2	CS_2	C_5H_{12}
$I\beta$	1	0.16	1.17	0.89	1.55	1.60	1.86	2.25	3.62	4.55
$I\gamma$	1	.16	1.16	.90	1.55	1.58	1.71	2.27	3.66	4.53

$I\beta$	3.24	4.41	4.39	5.90	
$I\gamma$	3.19	4.63	4.29	6.47	5.98

Residual Ionization as Dependent on the Pressure

Ionization from the walls (a secondary radiation) in air confined for 10 days. N_I = number of ions per cm^3 per sec (3).

P. atm.	0	10	20	27	40	46	50	60
N_I	0	17	30	38	46	50	50	50

Number of Electrons (δ-rays) Liberated by α-rays

l = thickness of metal traversed. N_E = electrons emitted per incident particle (4).

$10^5\,l$ (g cm^{-2})	In Al							In Ag		In Au	
	81	162	243	324	410	492	570	28.5	591	12.3	1223
N_E	11.9	14.2	15.0	17.2	17.8	18.9	19.4	8.12	13.76	9.82	18.16

Pairs of Ions Produced by α-rays

If R_0 cms is the range of the α-particle in air, it will produce n pairs of ions. $n = n_0 R_0^{2/3}$, where $n_0 = 6.233 \times 10^4$. Direct measurement for Ra-C′ gives $n = 2.20 \times 10^5$ (5).

Energy

Energy of electrons (Sec. β-rays) emitted by metals subjected to the action of γ-rays from Ra(C + E). Three groups of rays (6).

Metal	Pb	Pt	W	U	Ba
Atomic number	82	78	74	92	56
Energy of the secondary rays. Volts × 10^{-5}.	1.49 2.03 2.60	1.58 2.12 2.69	1.66 2.20 2.76	1.22 1.74 2.31	2.53

SECONDARY β-RAY VELOCITIES

Pb subjected to the action of γ-rays from Ra-B has been found to emit the following secondary β-rays:

$RH = \frac{mu^2}{e(1-\beta^2)}$ = 3610, 3250, 2990, 2735, 2225, 2130, 2000, 1935, 1825, 1750, 1620, 1560, 1400, 1240, 1150, 1010, 950, 820, 800 (8).

ABSORPTION

Absorption of the secondary β-rays emitted by metals when subjected to the radiation from Ra(B + C). μ_h for the hard rays, μ_s for the soft rays. Absorbing screen, Al (7).

Metal	Ag	Al	Au	Cu	Fe	Ni	Pb
μ_h, cm^{-1}	69	14	118	35	41	52	118
μ_s, cm^{-1}	207	52.5	345	105	165	165	345

CHEMICAL EFFECTS OF α-PARTICLES

S. C. LIND AND D. C. BARDWELL

M is the total number of molecules reacting (on the left hand of the equation, first column); N is the total number of ion pairs produced in the reactants by α-particles.

$$\frac{M}{N} = \frac{\left(\frac{k_\mu}{\lambda}\right)'\cdot V}{D\cdot F\cdot G\cdot H} \times 1.66 \times 10^3$$

V = volume in cm³ of, and D = diameter in cm of, the reaction sphere.

F = average intensity of ionization (1). G = specific molecular ionization (air = 1).

$H = (\alpha + R)/\alpha$ where α and R are α-ray and recoil atom effects resp. (2).

$$\left(\frac{k\mu}{\lambda}\right)' = \left(ln\frac{P_1}{P_2}\right) \div [E_o(e^{-\lambda_{t_1}} - e^{-\lambda_{t_2}})] \quad (3)$$

where E_o = initial radon (in curies), P = pressure (mm Hg), λ = decay constant of radon (in reciprocal days) and t = time (in days).

Where the quantity of gas in the reaction vessel at atmospheric pressure exceeds the air equivalent of a bulb 2.5 cm in diameter, the ionization is calculated by equations developed by W. Mund (17), slightly modified:[1]

$$I = N_0\,(1-e^{-\lambda t})k\Big[r^{2/3} + \frac{1}{2}r'^{2/3} + \frac{1}{2}r''^{2/3} - \frac{3}{20R}\Big\{3r^{5/3} + r'^{5/3} + r''^{5/3} - 3\,(r-2R)^{5/3} - (r'-2R)^{5/3} - (r''-2R)^{5/3}\Big\} + \frac{81r^{1\,1/3}}{3520R^3} - \frac{27}{160}(r-2R)^{2/3}\Big\{\left(\frac{r-2R}{R}\right)^2 + \frac{3}{22}\left(\frac{r-2R}{R}\right)^3\Big\}\Big]$$

I = Number of ions produced by the three sets of α-particles in the time t.

N_2 = Number of atoms of radon present initially (t = 0) (1 curie = 1.772 × 10¹⁶ atoms Rn)

R = Radius of reaction bulb in cms.

λ = Decay constant of radon (as above)

$k = 6.67 \times 10^4 \frac{\text{ions}}{\text{cm}^{2/3}}$ = ionization constant per α-particle as a function of the range (5); $i = kr^{2/3}$ or $kr'^{2/3}$ or $kr''^{2/3}$ for Rn, Ra-A, and Ra-C, resp. (air at 760 mm and 0°C)

r, r', r'' = ranges of α-particles from Rn, Ra-A, and Ra-C, resp. Wourtzel's (13) M/N values are recalculated by the Mund equation

The values adopted for the number of α-particles per sec per g of radium, and the total ions from one α-particle of Ra-C in its completed path in air are respectively, for column (*a*) 3.72 × 10¹⁰ (4) and 2.37 × 10⁵ (5), and for (*b*) 3.40 × 10¹⁰ (6, 7) and 2.20 × 10⁵ (8). Other combinations of these numbers give intermediate values of M/N.

---

[1] The modified equation is derived by correcting the integration of Mund's function $\varphi(r) = \int_0^{2R}(r-x)^{2/3}x^2dx$ (equation 5, p. 340). In the large bulbs used by Mund no error was introduced by employing his equation since $2R > r$.

Catalytic Effect of Inert Gases (10, 20, 21)

The $-M/N$ values in the table below give the total number of molecules of reactants disappearing for each ion pair of both catalyst and reactants. Example: $\frac{M_{C_2H_2}}{N_{(C_2H_2 + N_2)}} = 18.7$, means that 18.7 molecules of C_2H_2 polymerize to $(C_2H_2)_xs$ for each ion pair whether formed in the reactant or in the catalyst. With the increasing ratio of catalyst to reactant, a decrease in the $-M/N$ is indicated—probably attributable to exhaustion effects. Values by the (a) method only are given.

Reactants	Catalysts: Pure gas	N_2	H	Ne	A	Xe	CO_2	H_2
C_2H_2	19.5	18.7 to 17.8	20.1 to 17.0	19.6 to 16.3	18.2 to 15 0	18.5	17.4	19.6
C_2N_2	7.2	7.2				7.2		reacts
HCN	10.8	10.0				10.0		
$2H_2 + O_2$	5.13	5.0					reacts	
$2CO + O_2$	5.7				3.9		none

SATURATION CURRENT. ABSORPTION IN LIQUIDS AND SOLIDS

Stefan Meyer

SATURATION CURRENT AND NUMBER OF IONS FOR α-RADIATORS

The saturation current is $I_s = Zke$ where Z = number of α-particles per sec per unit mass, k = number of ion-pairs per α-particle and $e = 4.774 \times 10^{-10}$ es.

Number of Ions, k

Based on the values of Ra-C′ and the following alternative Z values for 1 g of Ra: (a) $Z_{\mathrm{Ra}} = 3.72 \times 10^{10}$ (19, 25); (b) $Z_{\mathrm{Ra}} = 3.45 \times 10^{10}$ (12).

$k = \mathrm{A} \times 10^5$ (9, 11, 13, 18, 45, 47)

Element	A (a)	A (b)	Element	A (a)	A (b)
UI	1.16	1.25	An	1.95	2.10
UII	1.27	1.37	Ac-A	2.12	2.28

AcX	1.61	1.74			

* Basic values.

The value of $Z_U = Z_{U_I} + U_{II}$ may be obtained from Z_{Ra} and the basic equilibrium ratio $Z_{Ra}/Z_U = 3.4 \times 10^{-7}$.

The value of Z_{Th} may be calculated from the decay constant of Th. For the following assumed values of the half-life, $T_{½}$, of Th we find for Z_{Th}: 1.25×10^{10} yrs, 4.5×10^3 α sec^{-1}; 1.65×10^{10}, 3.4 α sec^{-1}; and 2.2×10^{10}, 2.6 α sec^{-1}.

Saturation Current

1. (In Electrostatic Units) (**2,3, 4, 5, 6, 7, 8, 20, 26, 31, 32, 34, 43**)

Th-C to Th-D, 15° 1 atm., 0.963 mm in H_2; 0.224 mm in air (**24**).

THE McCOY NUMBER

The McCoy number is the ratio of the total α radiation to the uni-directional radiation per cm² from a U_3O_8 surface of α-saturated thickness. McCoy (**27, 28**) found 793 with $I_s = 1.74 \times 10^{-3}$ es per cm² U_3O_8 and St. Meyer and Paneth (**34**) found 790 with $I_s = 1.73 \times 10^{-3}$. These numbers are smaller than the theoretical.

Lit	(27)	(21)	(21)	(21)	(21)	(21)	(21)	(21)

For range of recoil atoms, *see* p. 368.

Distribution of Ranges.—This follows a probability law. Thus the most probable range for a Ra-F (=Po) α-ray is 3.85 cm at 15° and 1 atm.; 90% lie between 3.75 and 3.95, and 60% between 3.8 and 3.9 (8). For long range particles from Th-C, Ac-C, and Ra-F, *v.* (2). I. Curie (8.5) found for a very narrow beam for Po, the range $R_{15}^{760} = 3.87$ cm, as against the much greater value of H. Geiger, $R_{15}^{760} = 3.925$ cm.

Velocity of α-particles.—The velocity, u, of any α-ray may be computed from the relation $u^3 = aR$ where a is a constant and R the length of the remaining path (11). Taking $u = 1.922 \times 10^9$ cm sec^{-1} (25) as the *initial* velocity of the α-particles from Ra-C′, at 0° and 1 atmosphere in air, this becomes $u = 1.024_6 \times 10^9 R^{1/3}$ where R is the range.

Example: R_0 for Th-C′ in air is 8.168 cm (Table 1, *supra*). Hence $u = 1.024_6 \times 10^9 \times \sqrt[3]{8.168} = 2.064$ cm sec^{-1}, the initial velocity.

The following values of $u \times 10^{-9}$ at 0° and 1 atm. have been directly measured: Ra-A, 1.690 (28); Ra-C′, 1.922 (25); Po, 1.593 (7); Th-C, 1.714 (30); Th-C′, 2.060 (30). S. Rosenblum (22.5) determined directly the ratio of the initial velocities of the α-particles from Th-C—Th-C′ = 1.209.

For velocity of recoil atoms see p. 368.

II. NATURE OF PATH

The path of an α-particle may undergo sudden bends (4, 26, 29). The table gives the number of bends (whose angles lie between the limits $\theta_1 - \theta_2$) for path-lengths (between bends) within the limits $l_1 - l_2$, for 281 Ra-F α-rays in air containing 75% A. The unit of l is $1/126$ cm. 0° and 1 atm. (3).

	$\theta_1-\theta_2 =$	20°–30°	30°–40°	40°–50°	50°–60°	60°–70°	70°–80°	80°–90°	90°–180°
$l_1 - l_2$	3–7	11	20	22	8	13	7	6	8
	7–15	21	17	16	5	7			5
	15–30	12	8	7	2	5			
	$\theta_1 - \theta_2 =$	10°–20°	20°–30°	30°–180°					
	30–100	20	3	3					

The ionization along the path of a β particle varies inversely as the square of the velocity of the particle (28.5). The table gives the number, N_I, of ions produced by a ray per first cm of path (13.5). $e = 4.774 \times 10^{-10}$ es.

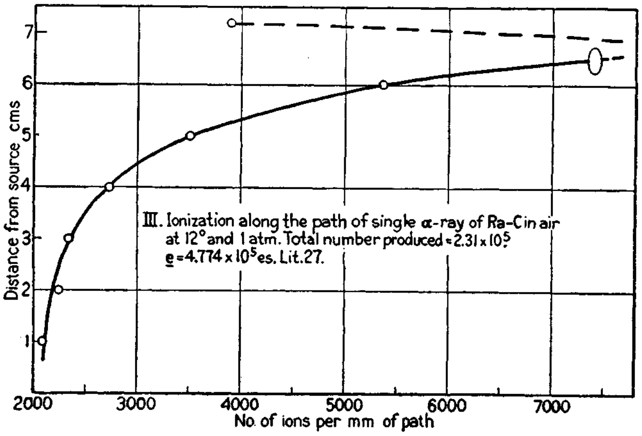
CO_2, λ in (g/cm^2)$^{-1}$	126	101	930	78	

Coefficient of absorption λ in cm^{-1} of γ rays from Ra-C′ in air at 1 atm. and 22° is 0.447×10^{-4} (17.5).



III. Ionization along the path of single α-ray of Ra-C in air at 12° and 1 atm. Total number produced = 2.31×10^5. $e = 4.774 \times 10^5$ es. Lit. 27.

IV. STOPPING POWER OF GASES

$S = \frac{R_{Gas}}{R_{Air}}$ for the same temperature and pressure (6).

1. Ionization method (5). 2. Track-condensation method using Ra-F (21). 3. Scintillation method. α-rays of $R_{15°}$ 6.15 cm (1).

ABSORPTION AND DIFFUSION OF β-RAYS IN LIQUIDS AND SOLIDS

Pierre Auger

Absorption Coefficients.—If I_0 be the initial intensity, and I_x the intensity after screen thickness x is traversed, $I_x = I_0 e^{-x\mu}$ where μ, the absorption coefficient, varies slightly with the thickness traversed. d = density.

Absorption by Al

Velocity Decrease.—R = Radius of curvature of the β-ray in a magnetic field of N units and field force H gauss. ΔRH is the change in RH due to a screen of 0.01 g cm^{-2} and is proportional to the velocity. According to Bohr, $\frac{\Delta RH}{c^3} u^3$ = a constant, K. u = the velocity of the particle, and c that of light (14).

WAVE LENGTHS OF γ-RAYS

E. von Schweidler

GENERAL RELATIONS

A wave length of λ milli-Ångstroms (10^{-3} Å $= 10^{-11}$ cm $= 1$ *X*-unit), corresponds to:

A Frequency (ν) $= 2.9986 \times 10^{21}/\lambda$ sec^{-1}
An Energy ($E = h\nu$) $= 1.9653 \quad 10^{-5}/\lambda$ ergs
A Potential $\left(P = \frac{h\nu}{e}\right) = 1.2344 \quad 10^{7}/\lambda$ volts

The equivalent electron velocity as a fraction of the velocity of light,

$$(\beta) = \sqrt{1 - \frac{1}{\left(1 + \frac{24.288}{\lambda}\right)^2}}$$

$$h\nu = \frac{hc}{\lambda} = E = Pe = c^2 m_0 \left[\frac{1}{\sqrt{1 - \beta^2}} - 1\right].$$

See p. 17 for values of basic constants.

WAVE LENGTHS DETERMINED WITH CRYSTAL GRATINGS

φ = angle of reflexion, d = grating space = 2.814 Å for rock salt = 3.028 Å for calcite. $\lambda = 2d \sin \varphi$. Intensity indicated thus, s = small, m = moderate, g = great, vg = very great.

(*a*) Soft Radiations from Ra-B. Using rock salt (2, 3). Corresponding to L-series of elements of atomic Nos. 82 and 83, according to Swinne (5) and Wagner (6).

WAVE LENGTHS CALCULATED FROM THE ENERGY OF β-RAYS

Primary γ-rays of energy E_γ produce in the disintegrating atom itself, or in other atoms, secondary β-rays of energy $E_\beta = E_\gamma\text{-}A$, where A is the work of removal and depends upon the level from which the β-rays originate. Sometimes it is assumed that the β-rays are primary and produce secondary γ-rays of energy $E_\gamma = E_\beta$. The energy of the β-rays is obtained from their magnetic deflections.

RADIOACTIVE RADIATIONS FROM ORDINARY METALS

R. B. MOORE

1. POTASSIUM AND RUBIDIUM

β-rays only are emitted spontaneously, the emission being an atomic property independent of the temperature.

ACTIVITY OF K IN ARBITRARY UNITS (4)

Salt	K_2SO_4	KI	KBr	KCl	KF	$KClO_3$	KNO_3
%K	44.91	23.58	32.87	52.48	67.32	28.91	28.69
Activity	37.8	21	27.8	42.2	54.0	25.5	30.6
K/Act	118	112	118	124	123	110	126

ABSORPTION OF THE β-RADIATION (6)

λ = absorption coefficient cm^{-1}, d = density of absorbent

λ/d for β-rays from K		λ/d for β-rays from Rb	
By K_2SO_4	11.32	By Rb_2SO_4	96.7
By Sn (90% of the rays)	14	By paper (90% of the rays)	162
By Sn (10% of the rays)	90	By paper (10% of the rays)	950

ABSORPTION OF β-RAYS FROM Rb BY PAPER (5)

W = wt. paper/cm². I_0, intensity of the initial radiation; I_p, that of the emergent radiation.

W	0	0.00153	0.00305	0.00458	0.00764	0.0107	0.0153	0.0198
I_p/I_0	1	0.725	0.545	0.422	0.260	0.159	0.087	0.034

2. CAESIUM, SODIUM, LEAD, IRON AND ZINC

Cs and Na are not radioactive (8, 9, 10). Ordinary Pb shows a slight, very old Pb only a trace of activity. On account of their exceptionally small activity Fe and Zn are recommended for construction of sensitive instruments for radioactive measurements. Ca, Ba, Sr, C, Cl, Br, Cu, Fe, Pb, Mg, Mn, Ni, Ag, Zn. W, Ta, La, Se, As, Sn, Au, Sb, Al and Hg are inactive (10).

3. NOTES

O. Hahn and M. Rothenbach (3) compared Rb salts of various ages but no difference in activity was detected. The Rb rays were found to be more penetrating than the β-rays of UX_1, but not so penetrating as those of Ra. The ratio of the intensity of the Rb rays to those of UX_1 is 1:15. The half-life of rubidium is calculated to be 10^{11} years and that of potassium 3 to 7 times greater. The absorption coefficient in Al of K is from 39.6 to 55.4 as foil thickness increases from 0.0135 to 0.0405 cm. Rb decreases from 593 to 522 as foil increases from 0.0017 to 0.0051 cm.

According to Bergwitz (1) the velocity of the Rb rays is 1.85×10^{-10} cm–sec^{-1}

Ringer (7) states that pure K and Rb give off homogeneous β-rays, the K rays having 10 times the penetrating power of the Rb rays. Harkins and Guy (10) give this figure as from 10 to 15 and state that the radiation from Rb is slightly heterogeneous.

Geiger (2) found that the saturation current from RbCl is the same at room temperature and at liquid-air temperatures.

SELECTED PHYSICAL PROPERTIES OF STARS AND NEBULAE

ALFRED H. JOY

CONTENTS.—(*A*) Classification of stellar and nebular spectra; (*B*) Stellar temperatures, masses, and densities; (*C*) Stellar diameters. (Data pertaining to the solar spectra will be found with other spectroscopic data; consult index.)

A. CLASSIFICATION OF STELLAR AND NEBULAR SPECTRA

The system[1] is that developed at Harvard College Observatory, as used by Miss Cannon in the Henry Draper Catalogue. Except where the exact nature of the spectral changes is not fully understood, decimal sub-classes, representing progressive steps toward the succeeding class, are used. In denoting objects by their catalogue numbers, the following abbreviations are used: B. D. = Bonn Durchmusterung; C. D. M. = Cordoba Durchmusterung; I. C. = Dreyer's Index Catalogue of nebulae and clusters; N. G. C. = New General Catalogue by Dreyer. The number, or numbers, following the abbreviation is the catalogue designation of the object.

Class P includes practically all the gaseous nebulae. Its unique characteristic is the appearance of lines from an unknown origin (nebulium). In addition there are many lines of H, He, C, He+, C+, and N+. All lines are bright and usually sharp. (The order of the Harvard (2) subdivisions should probably be reversed to indicate decreasing intensity of radiation.)

Class	Typical object	Spectral criteria
Pa	I. C. 418	λ5007 and λ4959 faint, λ3869 not seen
Pb	Orion nebula	λ5007 and λ4959 stronger
Pc	I. C. 4997	λ4363 conspicuous
Pd	N. G. C. 6826	λ5007 and λ4959 strong
Pe	N. G. C. 7662	λ4686 present
Pf	N. G. C. 40	λ4686 strong

Wright (11) has divided these spectra into three classes: Class I, having λ4686 present, Class II, with λ4686 absent but λ3869 present, and Class III with both λ4686 and λ3869 absent.

Class O is distinguished by the presence of the Pickering series of ionized helium, upon a strong continuous spectrum with maximum intensity far in the violet. The elements present are H, He, He+, C+, N+, Mg+, O+, CIII, NIII, SiIII, OIII, SiIV. Broad emission bands occur in the earlier subdivisions. Few absorption lines are found in sub-classes Oa, Ob, Oc, which make up the group known as Wolf-Rayet stars. (The Harvard subclasses Od, Oe, and Oe5 which have absorption lines and in some cases narrow emission lines as well, are included in the subclasses O5 to O9 as suggested by H. H. Plaskett (7), the basis of classification being the absorption lines.)

Class	Typical object	Spectral criteria
Oa	B. D. +35° 4013	Band λ4648 stronger than λ4686
Ob	B. D. +35° 4001	λ4686 stronger than λ4648
Oc	C. D. M. −41° 10972	Bands narrower. λ4686 twice λ4638
O5	B. D. +4° 1302	Pickering series very strong. H lines weak, λ4634 and λ4640 (NIII) present
O6	B. D. +44° 3639	Neutral helium appears
O7	9 Sagittae	λ4471 (He), 1.4 × λ4541. λ4089 (SiIV), 0.8 × λ4097 (NIII)
O8	λOrionis	λ4481 (Mg+) appears
O9	10 Lacertae	H stronger, He weak. λ4471, 2.7 × λ4541. λ4089, 1.4 × λ4097

Class B is characterized by the presence of helium, which has its maximum intensity in B2. The principal elements are those of class O, with the addition, in the later sub-classes, of lines of the ionized atom of several of the metals, such as Sr, Ba, and Fe. The H and K lines of calcium are found in increasing strength in this class. The hydrogen lines increase through the sub-classes, reaching a strong maximum at Ao of the following class.

Class	Typical object	Spectral criteria
B0	ζ Orionis	Pickering series weak, λ4649 (OII), λ4116 (SiIV), and λ4089 (SiIV) maximum intensity
B1	β Canis Majoris	He more prominent than O and Si.
B2	γ Orionis	λ4116 not seen. λ4089 and λ4649 faint
B3	η Aurigae	Strongest lines are helium
B5	*q* Tauri	λ4128 and λ4131 (SiII) stronger than λ4121 (He). λ4481, 0.7 × λ4471
B8	β Orionis	λ4481 equal to λ4471
B9	λ Aquilae	H strong. He weak. Several prominent enhanced metallic lines

Classes A, F, G, K and M, which contain the largest numbers of the stars, show a gradual increase in the number and intensity of the lines of neutral metallic elements of the lower atomic weights, and a decrease in the intensity of lines due to ionized elements. Compounds produce bands in the later classes. The sun's spectrum is Go, and is intermediate between that of the white and the red stars.

Class	Typical object	Spectral criteria
Ao	α Lyrae	H maximum strength. Very few other lines except λ4481 (Mg+)
A5	ρ Sagittarii	K (Ca+) stronger than Hδ. λ4290 well marked. λ4481 weaker
Fo	σ Bootis	K 3.0 × Hδ and equal to H + Hε

---

[1] Adopted by International Astronomical Union. It defines a temperature scale which is linear within the present errors of measurement.

Class	Typical object	Spectral criteria
F5	*α* Canis Minoris	Fraunhofer band G first seen. Numerous solar lines
Go	*α* Aurigae	Solar type. H not conspicuous. G band well defined, Hδ = λ4226.
G5	*η* Piscium	Hγ fainter than λ4325
Ko	*α* Bootis	G band conspicuous, λ4226 strong. Hydrogen weaker
K5	*α* Tauri	λ4226 very wide. λ4254 and λ4274 (Cr) strong. Titanium bands very faint
Mo	*β* Andromedae	Titanium bands well marked
M5	*α* Herculis	Titanium bands very stong. Metallic lines fewer

Class R and N stars show the carbon bands in increasing strength. The more advanced stars of class N have very little light in the violet or blue portions of the spectrum. They are the reddest stars known. Typical stars: Class R, B. D. −10° 5057; Class N, 19 Piscium.

Class S spectra resemble those of class K5 except for the presence of bands of zirconium, and other peculiarities in the region near λ4650. The line λ4554 of Ba+ is conspicuous.

Class Q stars are the novae. Near maximum of outburst their spectra are characterized by numerous wide emission bands of hydrogen and helium, and by absorption lines of ionized elements, especially titanium and iron. As the star decreases in light, both absorption and emission lines of N and O become more prominent. In the later stages, bright nebular bands appear; these are ultimately superseded by the bright bands of the Wolf-Rayet spectrum.

B. STELLAR TEMPERATURES, MASSES, AND DENSITIES

Giant stars are characterized by large mass, low density, and great total luminosity. Dwarf stars have smaller mass, higher density, and less total luminosity. Both are found in all classes, but the greatest contrasts between the two are found in the cooler stars of classes K and M. The continuous spectrum of dwarfs has its maximum shifted towards the violet, as compared with that of giants of the same spectral class, indicating that their absolute temperature is about 15% higher than that of the giants. Even with small dispersion, pronounced differences between giants and dwarfs may be noticed in the distribution of intensity in their line spectra. These differences probably arise from differences in the density gradients; they show a correlation with the absolute magnitude and mass of the stars. The low densities of giants favor the enhancement of those lines (absorption) which are produced under conditions of high excitation, such as the spark lines of the metals; the high density of dwarfs favor those produced by low excitation, such as the resonance lines of neutral atoms. The lines λ4077, λ4215 (ionized Sr) are much strengthened in giants, and weakened in dwarfs; the reverse is true of λ4226 (Ca), λ4454 (Ca), λ4607 (Sr).

Stellar Temperatures, Masses and Densities

Units: Temperature, 1000°C abs.; Mass, Mass of Sun; Density, g/cm³.

Class	Effective temperature (giants*)					Mean mass (⁹)		Mean density (⁹)	
	A†	P‡	C§	S‖	F¶	Giants	Dwarfs	Giants	Dwarfs

* Temperatures of dwarfs are 10 % to 20 % higher than giants of same class (indirect methods).

† Abbot (¹). By radiometer.

‡ Potsdam observations. Wilsing *et al.* (¹⁰).

§ Coblentz (³). By thermocouple.

‖ Saha (⁸). Calculated from initial appearance of certain spectral lines under pressure of 0.1 atmosphere. (See note ¶.)

¶ Fowler and Milne (⁴). Calculated from maximum intensity of certain spectral lines under pressure of 1.31 × 10^{-4} atmospheres, assuming 10 000° corresponds to maximum of Balmer lines of H. These temperatures, and those of Saha, are for the reversing layer; true effective temperature is somewhat higher.

Stellar Diameters

Unit: Linear Diameter, 10^6 km.

Star	Class	Parallax	Diameter	
			Angular*	Linear
α Tauri	K5	0.055″	0.022″	60
α Orionis	M2	0.019	0.044	347
α Bootis	Ko	0.088	0.022	37
α Scorpii	M1	0.017	0.040	353

* Measured by means of interferometer (⁵).

DISTRIBUTION OF STARS

Frederick H. Seares

Restriction.—No account is here taken of globular star clusters nor of stars included in spiral nebulae, many of which contain objects whose essentially stellar character can no longer be doubted.

Apparent Distribution and Number.—Statistically considered, the stars are distributed over the face of the sky with a high degree of regularity, their numbers gradually increasing as the Milky Way is approached from either side. The Milky Way defines what is very nearly a plane of symmetry, and for a first approximation, systematic difference between the two hemispheres, progressive changes in galactic longitude, and all local irregularities can be ignored. The resulting mean distribution, as found by Seares and van Rhijn, is shown in Table 1.

To apparent magnitude (see p. 39) $m = 13.5$ the results depend on data covering a large portion of the sky. From $m = 13.5$ to 18.5 they are derived from counts of stars on photographs of the 139 Selected Areas of Kapteyn between the North Pole and declination −15°. For still higher values of m, the values of $\log N_m$ are extrapolated, but the uncertainty consequent to the extrapolation itself is probably small. Excepting in low galactic latitudes, there is little or no systematic uncertainty arising from the particular choice of fields used for the counts. To $m = 16$ the magnitude scale is the mean of several closely accordant determinations made at different observatories, and is probably accurate within a few hundredths of a magnitude. Below this limit the scale depends wholly upon observations made at the Mount Wilson Observatory. Although this part of the scale has not been confirmed by independent measures made elsewhere, it has been established by methods successfully used for the brighter stars.

The indicated total, to the twenty-first photographic magnitude, of all stars in the sky is 890 000 000, and to the twentieth visual magnitude, 1 000 000 000. Barring losses of light by absorption, scattering etc., the increase in $\log N_m$ for a uniform distribution of stars throughout space would be 0.6 per unit of magnitude. The observed increase nowhere attains this value; the stars thin out with increasing distance from the sun, and at great distances they thin out more rapidly than near the sun; these changes are most pronounced in the direction of the poles of the Milky Way. If the law of decreasing space density indicated by the stars accessible to observation holds for those beyond present telescopic reach, the total number of luminous stars in the galactic system must be of the order of 3×10^{10}.

TABLE 1.—LOGARITHMS OF NUMBERS (N_m) OF STARS, OF MAGNITUDES LESS THAN m, PER SQUARE DEGREE IN DIFFERENT GALACTIC LATITUDES (1)

Units: Last column; m = visual magnitude; average $N_m = 1$, if $m = 8$. Other columns; m = international photographic magnitude (2); $N_m = 1$, if $m = 8$, Lat. = 0. Galactic pole: R. A. $12^h41^m20^s$, Dec. +27° 21′ (1875) (Gould).

Distribution of Intrinsic Brightness.—The range in intrinsic brightness among stars is enormous—at least twenty magnitudes, corresponding to an intensity ratio of 100 000 000 to 1. A knowledge of the frequencies of different luminosities among the stars in a given volume of space is essential (unless questionable assumptions are to be introduced) for the calculation of the space distribution of the stars. It is, however, difficult to obtain, and, at present, the frequencies are but imperfectly known. By assuming that the mean parallaxes of stars of apparent magnitude m and proper motion μ can be represented by a linear function of m and $\log \mu$ supposed to be valid for all magnitudes and proper motions, Kapteyn and van Rhijn derived for the distribution of the absolute magnitudes a Gaussian error curve whose ordinates are given in the second column of Table 2. Seares (4) has shown that their adopted mean parallax formula does not represent the distances of the stars of large motion and faint apparent magnitude, all of which are of low luminosity. A revision of the parallax formula, still only provisionally determined, and a recalculation of the luminosity function from about 500 stars of large proper motion leads to the frequencies in the third column of Table 2.

Table 2.—Approximate Luminosity Function

$\phi(M)$ = number of stars, absolute magnitude M, per cubic parsec in the neighborhood of the sun. Unit of distance for M is 10 parsecs. 1 parsec = 3.26 light years = 30.8×10^{12}km.

M	10 + Log$_{10}$ $\phi(M)$		Diff.
	Kapteyn v. Rhijn (3)	Seares (4)	
−4.64	2.61		
−3.64	3.42		
−2.64	4.17		
−1.64	4.85		
−0.64	5.46	5.58	0.12
+0.36	6.00	6.16	0.16
1.36	6.47	6.66	0.19
2.36	6.88	7.05	0.17
3.36	7.21	7.34	0.13
4.36	7.47	7.58	0.11
5.36	7.67	7.74	0.07
6.36	7.80	7.84	0.04
7.36	7.85	7.87	0.02
8.36	7.84	7.86	0.02
9.36	7.76	7.88	0.12
10.36	7.61	7.92	0.31
11.36	7.39	8.06	0.67
12.36	7.10	8.11	1.01
13.36	6.75	8.11	1.36
14.36	6.3	8.13	1.8

For the stars of low luminosity, the departure of Seares' curve from the error curve, shown by the differences in the fourth column, is important and must be accepted as real, although quantitatively the results are still very uncertain. The possibility of a maximum within the range of absolute magnitude considered is not excluded, but any such maximum must be well below the Kapteyn–van Rhijn limit, $M = 7.7$. Since the frequencies of stars of very low luminosity are still unknown, it is impossible at present to express the luminosity function as a true frequency function.

Space Distribution of Stars.—The space distribution is defined by a density function, preferably in a form expressing the total number of stars per unit volume at different distances from the sun. At present, however, we must be content with so expressing the number of stars which are brighter than some limit of absolute magnitude.

Analytically, the problem is to determine the density function, $\Delta(\rho)$, from the integral equation

$$\frac{dN_m}{dm} = \omega \int_0^\infty \phi(M)\Delta(\rho)\rho^2 d\rho$$

where the left hand member can be found from the data in Table 1; ω is a constant, ρ = distance from sun. Since $\phi(M)$, for $M > 8$, is still very uncertain, the general solution cannot be found at present. Values of the density for the neighborhood of the sun (Table 3) can, however, be calculated incidentally in deriving the data in Table 2. Results in the second column of Table 3 (M = 7.86) are in good agreement with similar results by Kapteyn and van Rhijn; the other tabular values indicate what is to be expected for lower limiting values of M. The uncertainty of the luminosity function for $M > 8$ scarcely justifies the effort required to complete the table.

Table 3.—Average Number of Stars, Brighter than Absolute Magnitude M, per Cubic Parsec at Distance ρ from Sun (4)

Unit of ρ is 1 parsec; of distance for M, 10 parsecs. 1 parsec = 3.26 light years = 30.8×10^{12} km.

M Log$_{10}\rho$	7.86	8.86	9.86	10.86	11.86	12.86	13.86	14.86

2.3	.014							
2.5	.011							
2.7	.008							
2.9	.004							

(Values based upon $\phi(M)$ for stars near the sun, and on the assumption that the relative frequencies of M are the same at all distances.)

Average densities for the whole sky give a very imperfect picture of the real distribution in space, as the latter varies greatly with galactic latitude. Broadly speaking, the surfaces of equal space density are concentric, and approximately similar, ellipsoids of revolution, similarly situated, with axes in the ratio of about 5 to 1. See Table 4.

Table 4.—Radii of Equidensity Ellipsoids(6)

$\Delta(\rho)$ = number of stars per cubic parsec at distance ρ from sun. (Values require revision for recent star counts (Table 1) and for error in luminosity function (*cf.* Table 2)).

Unit of radius = 1 parsec. 1 parsec = 3.26 light years = 30.8×10^{12} km. Latitude is galactic.

$\Delta(\rho)$	Latitude	
	90°	0°
1.00	0	0
0.63	118	602
0.40	198	1010
0.25	296	1510
0.16	413	2106
0.100	553	2820
0.063	717	3656
0.040	902	4600

Size of the Galactic System.—At present we have no certain indication as to the distance of the most remote stars belonging to the galactic system; but if ordinary blue stars of absolute magnitude zero occur among the faintest objects listed in Table 1, the diameter of the system cannot be less than a million light years. Such objects are not to be expected in high galactic latitudes, where the stars of very faint apparent magnitude are almost certainly all dwarfs; but their occurrence in the Milky Way is by no means excluded. We have, indeed, strong, though not conclusive, evidence of the existence in the Milky Way of stars of zero absolute magnitude among those of the sixteenth apparent magnitude. The corresponding diameter of the system is a hundred thousand light years. This value may be accepted with some assurance as a lower limit for the size of the system in the plane of the Milky Way, exclusive of such objects as globular star clusters and spiral nebulae, whose relation to the general stellar system about us is not yet clearly defined.

Position of the Sun.—The symmetrical distribution of stars adopted in Table 1 tacitly assumes the sun to be at the center of the system. This is not actually the case, as is shown by systematic deviations from the adopted mean distribution. Shapley's (5) value for the distance of the sun from the galactic plane is about 60 parsecs, to the north, which is certainly of the right order of magnitude. The sun's distance from the center is much less certain, and different estimates range from a few hundred to many thousand parsecs, according to the underlying assumptions and the method of attack. The question is much complicated by the fact that the sun lies within a local cluster whose members form a considerable fraction of the stars of the brighter apparent magnitudes, and a final answer must await the detailed discussion of the distribution of faint stars in galactic longitude.

DISTRIBUTION OF NEBULAE

FREDERICK H. SEARES

The term nebula is applied to objects of such diversity of form, size, distance, and physical characteristics that any study of their distribution presupposes a consideration of the question of classification. The following general classification by Hubble provides for two mutually exclusive divisions, characterized by position in the sky as well as by physical peculiarities, and five sub-classes representing physical differences.

A GENERAL CLASSIFICATION OF NEBULAE

I. Galactic nebulae, characterized by (1) tendency to concentrate about the Milky Way, (2) conspicuous association with individual stars from which they probably derive their luminosity, (3) early-type spectra, either emission or absorption, depending upon the spectral type of the associated stars, and (4) smooth and cloudy or wispy texture. They include

- (*a*) *Planetaries*, distinguished by symmetrical distribution of nebulosity about central stars, sharply defined edges, and emission spectra.
- (*b*) *Diffuse nebulae*, clouds in low galactic latitudes, usually associated with early-type stars. This type ranges from luminous to dark and from semi-transparent to opaque. Subdivided into predominantly luminous, predominantly obscure, and conspicuously mixed.

II. Non-galactic nebulae, characterized by (1) tendency to avoid the Milky Way, (2) no conspicuous association with stars, (3) late-type absorption spectra, and (4) usually a rotational symmetry about dominating non-stellar nuclei. They include

- (*a*) *Elliptical nebulae*, amorphous objects whose forms can be represented as successive stages of an original globular mass flattening under the influence of increasing rotation.
- (*b*) *Spirals of two kinds, logarithmic and barred*, which, once formed, appear to develop along parallel lines, the arms unwinding and the granulation of the material becoming more and more conspicuous.
- (*c*) *Irregular nebulae*, including a few non-galactic objects having no dominating nuclei and, significantly, showing no rotational symmetry.

Physically, the planetaries and diffuse nebulae, Ia and Ib, are distinct and apparently without genetic relationship, except that the planetaries, which, in some cases at least, seem to be late stages in the development of novae, may represent the catastrophic consequences of the penetration of a star within a nebulous cloud of the diffuse sub-class. The spirals IIb, on the other hand, are apparently an evolutionary development from elliptical nebulae, IIa, although it does not follow that all elliptical nebulae will necessarily become spirals. The few irregular nebulae, IIc, present features that might be expected in the case of spirals in the absence of or through the neutralization of dominating dynamical characteristics.

The distribution of the various classes of nebulae is not in general easily shown in tabular form. The following summary for each of the important sub-classes includes, however, references to diagrams which exhibit the main features of the distribution.

Ia. Planetary Nebulae.—In the whole sky only about 150 of these objects are known, many of which are so small as to be recognizable only from their gaseous emission spectra. The smallest objects are closely associated with the Milky Way, and show a marked concentration in the Aquila-Sagittarius region. With increasing size the mean galactic latitude increases, and the largest known objects, to the extent of a dozen or so, are scattered over the sky with some approach to uniformity (3, 6, 11). This suggests that the linear distances of planetaries from the galactic plane are relatively small and that their angular diameters are correlated with their distances from the sun. Very small nebulae thus appear in low galactic latitudes because their distances from the sun are many times their distances from the galactic plane.

The actual distances of planetary nebulae are still very uncertain. Van Maanen (15) has measured the parallaxes of about 20 of these objects and finds distances ranging from 50 to a few hundred parsecs; but, as he points out, these values are in conflict with the fact that the radial velocities average about 30 km/sec, while the proper motions are apparently small, of the order of the parallaxes themselves.

Ib. Diffuse Nebulae.—The distant star clouds of the Milky Way define the galactic circle. A secondary galaxy, inclined some 12° to the galactic circle proper, is outlined by the bright helium stars of the much-flattened local cluster immediately surrounding the sun, most of whose members are within 500 parsecs (14). The diffuse nebulae outside the Magellanic Clouds, some hundreds in all,[1] are closely associated with the primary and secondary galactic circles (7). Since the mean galactic latitude of those following the primary galaxy is only about 2°, and since the space within the two circles is not well filled, the inference is that these nebulae are directly connected either with the Milky Way star clouds or with the local cluster, and that few are to be found in the intervening regions. We thus have a group of diffuse nebulae whose members are within a few hundred parsecs of the sun; the others, forming a widely scattered group associated with the Milky Way, are at distances probably to be counted in thousands of parsecs (10). Both groups include both luminous and dark nebulae; the luminous members of the two groups present somewhat different physical characteristics, most marked in their spectra, which may be either emission, or predominantly continuous or absorption in type. The continuous and absorption spectra occur mostly among the nearer objects connected with the local cluster. The luminous diffuse nebulae are conspicuously associated with stars of high temperature from which they derive their luminosity, either by excitation or reflection.

II. Non-galactic Nebulae.—The members of this class, consisting chiefly of the related sub-classes, elliptical nebulae (IIa) and spirals (IIb), are far more numerous than the galactic nebulae. On the whole, the elliptical nebulae out number the spirals many times; but if only bright objects are considered, the spirals are the more numerous. The distribution in galactic latitude is shown in

---

[1] Less than 200 luminous ones known; no complete list published (*v.* 7, 8). Most complete list of dark nebulae (182 small objects) is given by Barnard (1).

Table 1, which gives to limiting magnitude 18.6 on the international photographic scale the average number per square degree at various latitudes in each hemisphere. The data are compiled from Fath's list (4), based on Mount Wilson photographs (exposure time 1 hour with 60-inch reflector) of the 139 Selected Areas between the North Pole and declination −15°. That part of the northern galactic hemisphere within which nebulae are frequent is wholly covered. About one-half the southern hemisphere is included, but not the south pole itself. Fath's counts have been corrected for losses caused by poor definition in the corners of the negatives (13).

TABLE 1.—NON-GALACTIC NEBULAE: NUMBER PER SQUARE DEGREE(4)

Average number; international photographic magnitude $\leqq 18.6$; *cf.* Table 2 .

Galactic latitude	Hemisphere	
	N	S
5°	0.2	0.0
15	0.8	0.4
25	2.5	5.4
35	13.2	8.2
45	10.3	5.8
55	12.2	7.0
65	22.2	11.9
74	31	
83	(68)	

Fath's list includes all classes of nebulae, but the galactic nebulae are relatively so infrequent that it is practically one of non-galactic nebulae alone. These objects begin to appear at about 20° latitude and increase rapidly in the interval 20° to 35°. From 40° to 70° the numbers increase slowly. The concentration near the north galactic pole is very pronounced. Below latitude 70° the numbers in the southern hemisphere average about three-fourths those of the northern. The assumption of a similar ratio for the regions 70° to 90° leads to integrated totals of 170 000 and 128 000 for the northern and southern hemispheres, a round total of 300 000 for the whole sky (limiting phot. mag. for stars 18.6).

The summary in Table 2 emphasizes the dependence of the distribution on galactic latitude. The uncertainty in the average number per square degree in the region 70°–90° is considerable, and since the number of nebulae in this region is large (29% or 50 000 in the northern hemisphere), the total given for the whole sky is in doubt by many thousand. Curtis (2) has estimated the total (to an undetermined limiting magnitude) to be over 700 000. The difference in the estimates may arise from a difference in magnitude limits or from the fact that the fields counted by Curtis are not certainly representative of the sky as a whole.

TABLE 2.—DISTRIBUTION OF NON-GALACTIC NEBULAE

Lat. = interval in galactic latitude. Sky = % area of sky. Neb. = % number of nebulae. N = northern, S = southern hemisphere.

Lat.	Sky	Neb.	
		N	S
0°–30°	50	7	15
30 –70	44	64	56
70 –90	6	29	29

The distribution of non-galactic nebulae is not, however, simply one of galactic latitude. Data collected by Hardcastle and Hinks (5) and by Reynolds (12) show marked irregularities in longitude, which seem to depend on the angular diameters of the nebulae. Thus objects with diameters >10′ are almost all in the hemisphere including galactic longitudes 50° to 230°. For diameters 5′ to 10′ the northern galactic hemisphere shows high frequencies in longitude 110° and 260°–270°, which become even more marked for diameters 2′ to 5′. For still smaller nebulae, the distribution is again different. Fath's counts, including mostly very small and faint nebulae, show a band of high frequency crossing the northern galactic hemisphere approximately in longitudes 50° and 220°, with other irregularities suggesting a very complicated distribution.

Nothing is known directly of the distances of elliptical nebulae, but their relationship with the spirals is so intimate that the distances of the two sub-classes must be regarded as of the same order. Van Maanen's measures (16) of internal motion in spirals suggest distances of the order of 3000 to 30 000 light years. The application of Shapley's period-luminosity relation by Hubble (9) to numerous typical Cepheid variables discovered by him in the spirals Messier 31 (the Andromeda nebula) and Messier 33 leads to distances of about a million light years for these two objects. The applicability of the period-luminosity relation is assumed, but several lines of corroborative evidence strongly support the larger value of the distance. It is probable, however, that the zero point of the period-luminosity relation requires revision by an amount which would reduce these distances by about 40%.

MOTIONS OF THE STARS AND NEBULAE

GUSTAF STRÖMBERG

The *proper motion* of a star is defined as the angular motion, per year, referred to a certain fundamental system of apparently bright stars distributed uniformly over the sky. The *radial motion* is determined by the Doppler shift for spectral lines of known wave-length. If the distance to a star is known, the three velocity-components of its *space-velocity* can be determined. Proper motions and radial velocities are in general referred to the sun as origin, by correction for the periodic changes due to the earth's motion. The proper motions are in general very small; for the majority of the stars they are below 0.1″ per year. The largest proper motion is that of Barnard's star R. A. 17^{h} 53.0^{m}, Dec. + 4° 28′, (1900.0), which moves 10.27″ per year. The radial velocities are mostly below 40 km/sec, the largest being that of the variable star V X Herculis, which approaches the sun with a velocity of 390 km/sec. The spiral nebulae have even higher velocities, the highest being 1800 km/sec, recession, (N. G. C. 584).

SOLAR MOTION

The sun's motion relative to the stars can be determined either from proper motions, from radial velocities, or from space-velocities. The point in the sky towards which the sun is moving is called the sun's *apex*.

* Preliminary General Catalogue by L. Boss, Washington, 1910.
† Stars brighter than the 6th magnitude (apparent).

Although the agreement between the different determinations is fairly good, a detailed study shows that the sun's motion can not be regarded as a constant vector. The A stars and giant stars in general give a small velocity for the sun; and dwarf stars, a much higher velocity.

AVERAGE PECULIAR MOTIONS OF THE STARS

After the effect of the sun's motion has been removed, the residual or "peculiar" velocities show certain regularities. The average peculiar velocities are different for stars of different spectral types, and vary also with the intrinsic brightness of the stars.

TABLE 2.—AVERAGE RESIDUAL RADIAL VELOCITIES (θ) OF STARS OF DIFFERENT SPECTRAL CLASSES (Sp) AND ABSOLUTE MAGNITUDES (M)

Unit of θ = 1 km/sec

Sp	M*	θ	Lit.	Sp	M*	θ	Lit.
O5 to O9	−3	20.7	(11)	K	+1	18.4	(1)
B	−1	6.5	(3)	K	+6	27.0	(1)
A	+1	11.0	(11)	M	+1	21.6	(1)
F	+2	15.8	(1)	M	+9	29.6	(11)
G	+1	18.0	(1)	Me†	0	40.1	(11)
G	+5	26.3	(1)	P‡	–	28.6	(11)

* The apparent magnitude as observed from a distance of 10 parsecs.
† Contains M stars with bright hydrogen-lines; all are variable stars of long period.
‡ Bright-line nebulae.

PREFERENTIAL MOTION

The peculiar velocities of the stars are not distributed at random. In general the stars show a tendency to move parallel to the galactic plane. To describe the distribution of the peculiar velocities, a distribution-function is adopted, which gives the relative numbers of stars moving in different directions and with different velocities. The simplest distribution-function is the spherical distribution-law,

$$F(xyz) = \frac{N}{(2\pi)^{\frac{3}{2}}\sigma^3}\,e^{-\frac{z^2+y^2+z^2}{2\sigma^2}}$$

where x, y, and z are the velocity-components referred to the "centroid" of the group. N is the number of stars in the group, and σ is the dispersion or the square-root of the mean of the squares of the velocity-components. The number of stars of velocity-components between $x \pm \frac{1}{2}dx, y \pm \frac{1}{2}dy, z \pm \frac{1}{2}dz$ is then given by $F(xyz)\,dxdydz$. In a spherical distribution, the frequency of a velocity is independent of its direction and only dependent upon its size. Spherical velocity-distributions occur for several classes of stars, but in general the distribution in velocity-space is either flattened (B stars) or elongated (A, F, and dwarf stars). Two functions have been used to describe the elongated distribution. Kapteyn and Eddington have used a sum of two spherical functions and have regarded the stars as belonging to two intermingled systems, "two stream hypothesis." Schwarzschild has introduced the ellipsoidal distribution defined by the distribution-function

$$F(xyz) = \frac{N}{(2\pi)^{\frac{3}{2}}abc}\,e^{-\left(\frac{x^2}{2a^2}+\frac{y^2}{2b^2}+\frac{z^2}{2c^2}\right)}$$

with three principal dispersions a, b, and c, which define the three axes of the "velocity-ellipsoid." The velocity-components x, y, and z are here projected on the principal axes of this ellipsoid. The major axis of the velocity-ellipsoid corresponds to the line joining the two centers in the two stream theory. The direction of this fundamental axis, which is common in the two theories, is about R. A. 6^h 6^m, Dec. + 9°, (true vertex). The dwarf stars give a somewhat higher declination for the true vertex.

In the analysis of proper motions, the two stream theory gives two vertices, which correspond to the directions of motion of the two streams relative to the sun. The coordinates of these vertices are R. A. 6^h 14^m, Dec. −13° (first stream) and R. A. 19^h 16^m, Dec. −60° (second stream).

Analyzing stellar motions on the basis of the two stream theory, we find a number of stars which cannot be regarded as belonging to either of the two streams. The B stars and stars of spectral class M, for instance, have a group-motion intermediate between the two streams. For this reason Halm has introduced a third stream (0 stream). But these streams taken together can be fairly well represented by an ellipsoidal distribution using a smaller number of parameters.

Charlier (4) has introduced a generalization of the ellipsoidal theory which makes it possible to take into account deviations from a strictly ellipsoidal distribution, but it is only when these deviations are small that this generalization is practicable.

MOVING CLUSTERS OR GROUPS

Several stars move nearly parallel to one another, the best known example being 5 of the 7 bright stars in the constellation Ursa Major. Another moving group or cluster is the Hyades in the constellation Taurus (Taurus Group). The proper motions of the stars belonging to such a group converge towards a point in the sky, the "convergent point," whose position in the sky gives the direction of motion of the group relative to the sun. The convergent point for 17 stars belonging to the Ursa Major Group is R. A. 20^h 30^m, Dec. −40°; for the Taurus Group (39 stars) R. A. 6^h 7^m, Dec. + 7°. A number of other moving groups are known.

THE GENERAL DISTRIBUTION OF COSMIC VELOCITIES

When the sun's motion is referred to different clases of objects it has been found that this motion is not a constant vector but varies greatly, from about 12 km/sec for the A stars and the Cepheids of long period up to 300 km/sec for the fast moving objects, the globular clusters and the spiral nebulae. A general relationship between group-motion and dispersion exists, which, according to Strömberg (11), holds for all classes of objects, but with a small deviation for the B star system. This variation in group-motion produces an asymmetry in the velocity distribution, in such a way that all fast moving objects move, relative to the sun, towards the same hemisphere. This asymmetry defines an axis along which the group-motion increases with increasing internal velocity-dispersion. The direction of this axis is R. A. 8^h 39^m, Dec. −57°, and the motion of objects with small velocity-dispersion relative to those of high velocity-dispersion is about 300 km/sec in the opposite direction. The group-motion of objects with high velocity-dispersion is approximately the same as that of the globular clusters and spiral nebulae.

The general distribution of cosmic velocities can be approximately represented by a product of two symmetrical distributions S_1 and S_2. The first of these is a sum of concentric and co-axial ellipsoidal distributions, the velocity of the sun relative to the center of the distribution S_1 being 14.8 km/sec in the direction R. A. $17^h\ 43^m$, Dec. +22°. The sun's motion relative to the second distribution, S_2, is 300 km/sec in the direction R. A. $20^h\ 28^m$, Dec. +56°. The first distribution can be regarded as the velocity-distribution in our local system of stars, the second as a velocity-restriction in a universal world-frame of enormous dimensions. Other interpretations, however, may be possible.

*Δ is the amount by which mean time exceeds apparent time when it is noon at Greenwich; it is the excess of the right ascension of the actual sun over that of the mean sun at that instant. It varies continuously with the time, and does not exactly repeat its values in successive years; those given are average values for Greenwich mean noon of an ordinary year, and will seldom differ from the actual values for that time by as much as 0.2 min., except in January and December, when the difference may amount to 0.3 min. In leap years, all dates in the table after February must be reduced by one day.

COMPOSITION OF THE ATMOSPHERE

W. J. HUMPHREYS

TABLE 1.—COMPOSITION OF DRY AIR AT SEA-LEVEL (4, 5)

v = volume of the gas in volume V of dry air

Gas........	N_2	O_2	A	CO_2	H_2*	Ne	He	Kr	Xe
$10^4v/V$.....	7803	2099	94	3	1	0.123	0.04	0.005	0.0006

* Values found by analysis vary; the one here given is that accepted by Hann and the Recueil de Constantes Physiques.

TABLE 2.—COMPOSITION OF ATMOSPHERE AT VARIOUS LEVELS

Computed from data of Table 1 on the assumptions: (1) at surface, H_2O vapor supplies 1.2% of the total number of gas molecules, (2) absolute humidity decreases rapidly to a negligible amount at about 10 km, (3) temperature = 11°C at sea-level, decreases normally (6°C per km) to −55°C at 11 km, remains constant above 11 km, (4) relative proportions of the gases, water vapor excepted, remains constant up to 11 km, (5) above 11 km, distribution is in accordance with their molecular weights (3). The amount of H_2 is in doubt (see note Table 1), especially above 11 km; it may become oxidized to H_2O before reaching the upper atmosphere.

v = volume of the gas contained in volume V of atmosphere. Unit of height = 1 km = 0.621 mi.; of pressure = 1 mm of Hg

Height	$100v/V$							Total pressure
	N_2	O_2	H_2O	A	CO_2	H_2	He

MISCELLANEOUS GEODETIC DATA

W. D. LAMBERT

With certain exceptions which are especially noted, those of the following data which depend upon the dimensions of the earth have been calculated strictly in accordance with the INTERNATIONAL ELLIPSOID OF REFERENCE, adopted by the Section of Geodesy of the International Geodetic and Geophysical Union, meeting at Madrid, October 6 and 7, 1924. This ellipsoid is based upon the results obtained by J. F. Hayford (Supplementary Investigation in 1909 of the Figure of the Earth and Isostasy, Washington, 1910), but is not absolutely identical with Hayford's ellipsoid. (For some of the other spheroids that are used for geographical purposes, see Special Publication #100, U. S. Coast and Geodetic Survey. Recent attempts have been made to show that the actual figure of the earth can be represented more closely by an ellipsoid of three unequal axes, than by one of revolution, systematic departures from the latter being of the order of 100 to 200 meters in elevation and depression.)

If the positions of the two ends of a line are determined geodetically for any assumed spheroid of reference, the uncertainty in the length of the line as measured along the earth depends almost entirely upon the errors in the survey; for geodetic surveys of the highest class, the uncertainty is a little less than one in 100 000 and for an ordinary fair survey it is about four times as great. The proportional error in the straight-line distance is greater, mainly because the geoid does not coincide with the ellipsoid; these additional errors are not serious for a short line, but for two points almost diametrically opposite may amount to 100 or 200 meters.

If the end points are determined astronomically, the principal error in the computed length is due to the difference in the deflection of the plumb-line at the two points; unless the measured line is short, the *average* uncertainty so introduced is of the order of 200 meters, but may be much more, especially in rugged country.

Latitude.—The latitude of a place is defined as the angle which some line of reference makes with the equatorial plane. Four lines of reference, defining four distinct kinds of latitude, are used. Three of these lines pass through the place considered; *viz.*, (1) The plumb-line, defining the *astronomical* latitude, (2) the normal to the spheroid of reference, defining the *geographical* latitude, and (3) the line to the center of the earth, defining the *geocentric* latitude. The fourth line of reference passes through the center of the earth and that point which is upon the circumscribed sphere (radius = equatorial radius of the spheroid) and at the same distance from the axis of rotation as is the point on the spheroid representing the place considered; this defines the *parametric*, or *reduced*, latitude.

Gravity.[1]—If the earth's sea-level surface were accurately represented by the International Ellipsoid of Reference, and if no attracting matter projected above this surface, then the variation of gravity at sea-level (γ_o) would be represented by the equations

$$\begin{aligned}\gamma_o &= \gamma_e(1 + 0.005\ 288 \sin^2\varphi - 0.000\ 006 \sin^2 2\varphi)\\ &= \gamma_{45}(1 - 0.002\ 637 \cos 2\varphi + 0.000\ 006 \cos^2 2\varphi)\end{aligned}$$

---

[1] The resultant acceleration arising from the gravitational attraction and the rotation of the earth.

where φ is the geographic latitude, and γ_e, γ_{45} are the values of γ_o at the equator and at latitude 45°, respectively. These equations differ slightly from that used in computing the table on p. 396; the latter corresponds to an ellipticity of 1/297.4.

TABLE 1.—FORM AND SIZE OF THE EARTH

Based upon International Ellipsoid of Reference; accepted constants, from which the others are computed, are $a = 6\ 378\ 388$ meters, ellipticity $[=(a - b)/a] = 1/297$. The indicated uncertainties are estimates, by Lambert, based upon a consideration of systematic errors as well as of internal discordances.

a = semi-major axis	= 6 378 388(±60)m
b = semi-minor axis	= 6 356 911.946 m
Radius of sphere of same area	= 6 371 227.7 m
Radius of sphere of same volume	= 6 371 221.3 m
Length of equatorial quadrant	= 10 019 148.4 m
Length of meridonal quadrant	= 10 002 288.3 m
f = ellipticity = $\left(\frac{a-b}{a}\right)$	= 0.003 367 0034
$\frac{1}{f}$ = reciprocal of ellipticity	= 297.0(±0.4)
e^2 = (eccentricity)^2 = $f^2\left(\frac{2}{f} - 1\right) = \frac{a^2 - b^2}{a^2}$	= 0.006 722 6700
Area of the ellipsoid	= 510 100 934 km^2
Land area	= 148 847 000 km^2
Ocean area	= 361 254 000 km^2
Volume of the ellipsoid	= 1 083 319.78 × 10^6 km^3
Mass of the ellipsoid* (d = 5.527 g/cm^3, p. 395)	= 5.988 × 10^{24} kg
Principal moments of inertia ($A = B < C$)†:	
A‡ = B‡	= 0.332 35 Ea^2
C‡	= 0.333 44 Ea^2
$C - A$	= 0.001 0921 Ea^2
$\left(\frac{C - A}{C}\right) = \left(\frac{1}{305.12}\right)$§	= 0.003 2774

* For discussion of variation of density with depth below surface, *see* Adams and Williamson, Smithsonian Annual Report, 1923, p. 241.

† E = mass of earth.

‡ Computed values vary but little with any admissible assumption regarding the constitution of the interior of the earth. Values are based upon computations of De Sitter (*64V*, **27**: 233; 24); ellipticity taken as 1/296.92.

§ Deduced from precession of equinoxes; involves no hypothesis regarding constitution of interior of earth.

TABLE 2.—DISTANCES UPON SURFACE OF THE INTERNATIONAL ELLIPSOID OF REFERENCE

M = length of meridian from equator to geographic latitude φ; S_m = length of meridian from latitude $(\varphi - \frac{1}{2}\Delta\varphi)$ to $(\varphi + \frac{1}{2}\Delta\varphi)$; S_p = length of arc of parallel for 1° of longitude at latitude φ. These may be computed by means of the equations: $M = a\varphi - b \sin 2\varphi + c \sin 4\varphi - d \sin 6\varphi$; $S_m = a\Delta\varphi - b \sin \Delta\varphi \cos 2\varphi + c \sin 2\Delta\varphi \cos 4\varphi - d \sin 3\Delta\varphi \cos 6\varphi$; S_m (for $\Delta\varphi = 1°$) $= a - b \cos 2\varphi + c \cos 4\varphi - d \cos 6\varphi$; $S_p = a \cos \varphi - b \cos 3\varphi + c \cos 5\varphi$; where the coefficients and their logarithms have the following values:

Unit of length = 1 meter; of angle = 1°

	M*		S_m*	
	Value	log$_{10}$	Value	log$_{10}$
a	111 136.537	5.045 856 86	111 136.537	5.045 856 86
b	16 107.035	4.207 015 6	32 214.069	4.508 045 6
c	16.976	1.229 84	33.952	1.530 87
d	0.022	$\bar{2}$.348	0.045	$\bar{2}$.649

	S_m* for $\Delta\varphi = 1°$		S_p*	
	Value	log$_{10}$	Value	log$_{10}$
a	111 136.537	5.045 856 86	111 417.657	5.046 954 02
b	562.213	2.749 901	93.904	1.972 686
c	1.185	0.073 7	0.119	$\bar{1}$.074 6
d	0.002	$\bar{3}$.37		

* Owing to uncertainty regarding the actual size of the earth, actual distances upon the earth at sea-level may differ from these computed distances by about 2 in 100 000 near the equator or the poles, by somewhat less in middle latitudes.

TABLE 3.—EXCESS OF GEOGRAPHIC LATITUDE (φ) OVER GEOCENTRIC (φ') AND PARAMETRIC (θ) LATITUDES

$$\begin{aligned}\varphi - \varphi' &= a \sin 2\varphi - b \sin 4\varphi + c \sin 6\varphi \\ &= a \sin 2\varphi' + b \sin 4\varphi' + c \sin 6\varphi' \\ \varphi - \theta &= a' \sin 2\varphi - b' \sin 4\varphi + c' \sin 6\varphi \\ &= a' \sin 2\theta + b' \sin 4\theta + c' \sin 6\theta\end{aligned}$$

where the coefficients and their logarithms have the following values:

Unit of coefficients = 1″

	Value	log$_{10}$		Value	log$_{10}$
a	695.6635	2.842 3992	a'	347.8327	2.541 3704
b	1.1731	0.069 34	b'	0.2933	$\bar{1}$.467 29
c	0.0026	$\bar{3}$.421	c'	0.0003	$\bar{4}$.52

TABLE 4.—MISCELLANEOUS TERRESTRIAL DATA

Angular velocity of rotation	72.921 × 10^{-6} radians/sec*
Rotational energy	2.160 × 10^{36} ergs
Rotational energy lost by tidal friction	1.1 × 10^{19} ergs/sec†
Work required to dissipate the material of the earth to infinity	2.46 × 10^{39} ergs
Mean elevation of land above sea-level	825 m
Mean depth of the oceans	3681 m
Mean effective viscosity is not known, but perhaps between	10^{20} and 10^{25} poises‡

* Mean solar second.

‡ Schweydar, *Veröffentl. des Preuss. Geodät. Inst.*, No. **79**; 19; Jeffreys, *Monthly Notices, Roy. Ast. Soc.*, **75**: 648; 15. **76**: 84; 16. **77**: 449; 17; also *The Earth, its Origin, History, and Physical Constitution*, 222; 1924.

Rigidity (μ). From the yielding of the solid portions (revealed by observations with horizontal pendulums), and on assumption of incompressibility, Schweydar (Zentralbureau Int. Erdmes., Neue Folge No. 38, 1921) deduces $\mu = 30.8\ (1 - 0.90r^2/a^2) \times 10^{11}$ dynes/cm^2, and mean effective rigidity $= 17.6 \times 10^{11}$ dynes/cm^2 (r = distance from center, a = mean radius). To allow for compressibility, these values must be increased by about 20% (Lambert, preliminary, unpublished computations); even then the value computed for the outer shell of half-radius thickness is much less than that deduced from earthquake data. (*See* Adams and Williamson, Smithsonian Annual Report, 1923.) The discrepancy may arise from Schweydar's assumption of high rigidity in the central portions, which may possibly behave as a fluid. (*See* Knott, *68*, **39**: 157; 19; Sieberg, *Geologische, physikalische und angewandte Erdbebenkunde*, 364; 23.)

D. VARIATION OF GRAVITY WITH ELEVATION AND DEPTH

Elevation; Free Air Method.—If there were no matter projecting above the geoid and the geoid were a smooth ellipsoid of revolution, then the value (g_H) of the acceleration of gravity (cm/sec²) at a height H meters above the surface would be related (15, 16) to that (g_0) at the surface, as indicated by equation (1), in which φ is the latitude.

$$g_H = g_0 - (0.000\,308\,55 + 0.000\,000\,22\cos 2\varphi)H + 0.000\,072\left(\frac{H}{1000}\right)^2 \qquad (1)$$

This is known as the free air correction. For most purposes it is sufficient to use the approximate formula (2).

$$g_H = g_0 - 0.000\,3086\,H \qquad (2)$$

If g_0 is taken from Table 2, the value of g_H obtained for any station by the use of equation (1) will agree fairly well with the true acceleration, if the surrounding topography is not too rugged. In a fairly flat country, the difference will be considerably less than 0.1 cm/sec², except in very rare cases; and even in a mountainous country, the difference will ordinarily be less than 0.2 cm/sec². For stations below sea-level, but not below the surface of the earth, the same formulae apply; but for such stations, H is negative.

More Exact Methods.—In mountainous country, the computed value will be practically as close to the true value as in flat country if an additional term is added to the right hand side of equation (1), to take account of the elevation of the place above or below the general level of the topography within a radius of, say, approximately 160 km. For every 10 m the place in question is above the general level, this term amounts to 0.001 cm/sec², and for every 10 m below the general level, it amounts to −0.001 cm/sec². In computing the height of a coast station above the general level, the water must be considered replaced by an equal mass of rock, of average surface density, resting on the bottom of the ocean.

If it is desired to obtain a somewhat better value for the computed gravity at a place, the correction term just mentioned must be replaced by a correction for topography and isostatic compensation, computed by the method of John F. Hayford (12).

A somewhat larger error should be expected in the computed values of gravity on oceanic islands than on the continents. The rocks forming these islands are evidently somewhat heavier than normal in many cases, or the ocean is over-compensated, and the observed values of gravity are therefore usually larger than the computed values. In such cases, an error of 0.3 cm/sec², or possibly even 0.4 cm/sec² in computed values may be expected.

Depth.—As the density of the crust is less than two-thirds the mean density of the earth, the acceleration of gravity increases as we advance into the crust. The mean rate of increase is 0.000 0851 cm/sec² per meter of depth. The actual rate at any place depends upon the density of the crustal material in that locality, and is approximately given by the formula (13, 17)

$$g_d = g_0 + (0.000\,3086 - 0.000\,0837\rho)d \qquad (3)$$

where g_d = acceleration of gravity (cm/sec²) at the depth of d m, and ρ = density (g/cm³).

AERODYNAMICS

L. J. BRIGGS AND H. L. DRYDEN

Problems in aerodynamics cannot be idealized with the same readiness as problems in mechanics. The side of a building may not be regarded as a thin, flat plate for the purpose of computing the force of the wind, and data for a cylinder of a particular length cannot be directly applied for computing the wind force on a cylinder of some other length. Nearby objects exert an influence which cannot be neglected.

Results obtained for a particular object can be applied strictly only to geometrically similar (definition 6) objects in similar surroundings. Many of the apparent discrepancies among the results of different experimenters are to be attributed to departures from geometrical similarity of the models, to the effects of the supports or other nearby objects, and to differences in the fine structure (turbulence) of the approximately steady air streams, rather than to errors in measuring the force or wind speed. It is not possible to discuss these matters in detail here, and there is no complete discussion available for reference.

SYMBOLS

A	Some specified area
A_r	Aspect ratio
C	A coefficient
C_{cp}	Coefficient of center of pressure
C_d	Coefficient of drag
C_l	Coefficient of lift
C_M	Moment coefficient (*see* paragraph on air foils)
C_N	Coefficient of force normal to the plane of reference
C_P	Coefficient of power (input)
C_{P0}	Coefficient of power out-put
C_Q	Coefficient of torque
C_{Q0}	Coefficient of torque load (output)
C_T	Coefficient of force parallel to the plane of reference
C_t	Coefficient of thrust
C. P.	Center of pressure
c	Length of chord of air-foil
D	Diameter
F	Resultant wind force
F_d	Drag = Component of F parallel to wind
F_f	Frictional force
F_l	Lift = Component of F normal to wind and to W
F_N	Component of F normal to the plane of reference
F_T	Component of F parallel to the plane of reference
F_t	Thrust of propeller
F_x	Any component of F
L	Some linear dimension
M	Moment of F about forward (leading) edge
N. A. C. A.	National Advisory Committee for Aeronautics, U. S. A.
n	Number of revolutions per second
P_0	Power developed (output)
P_i	Power input to propeller
P. R.	Pitch ratio
p	Pressure at a point on a surface
p_s	Static pressure of the air
Q	Torque
Q_0	Torque load (output)
q	Dynamic pressure, as indicated by Pitot tube (Fig. 1)
q_0	$\rho V^2/2$ ($= q$ if there is no compression of the air)
R	Reynold's number
S	That dimension of the plane of reference which is at right angles to the wind = Span
T	Temperature
t	Thickness
V	Air speed relative to point considered
V_i	Indicated air speed
W	Width = That dimension of plane of ref-

	ence which is normal to S; *i.e.*, makes least angle with wind
x_c	Distance in the plane of reference, from the leading edge, or its projection to *C. P.*
η	Efficiency
θ_A	Angle of attack
μ	Viscosity
ρ	Density of air when undisturbed by bodies movingrelatively to it.
ρ_0	Conventionally chosen "standard" value of ρ
ϕ	A definite but unspecified mathematical function

DEFINITIONS

1. Angle of Attack (θ_A) is the angle which the direction of the wind makes with the plane of reference; it is positive if the wind strikes what is the under side of this plane when the body is in its usual position.

2. Aspect ratio (A_r) = S/W.

3. Center of pressure (*C. P.*) of a body is that point, in the plane of reference, about which the resultant moment of the pressures is zero.

4. Chord (c). See paragraph on airfoils.

5. Coefficient of center of pressure (C_{cp}).

$$C_{cp} = x_c/W; \text{ for airfoil, } C_{cp} = x_c/c.$$

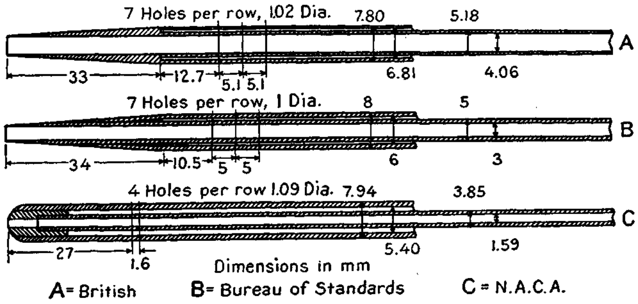

FIG. 1.—Standard Pitot-static tubes.

6. Geometrically similar systems. If two bodies together with their surroundings, are so related geometrically that one system corresponds exactly with a uniformly magnified image of the other, the two systems are said to be geometrically similar.

7. Indicated air speed (V_i) is defined by the relation $q = \rho V^2/2 = \rho_0 V_i^2/2$, where ρ_0 is the "standard" air density.

8. Mean temperature (T_m) of atmospheric air column below Z is that temperature for which the pressure at height Z in an isothermal column of air, pressure at bottom = 760 mm of mercury, would be that actually observed in the atmosphere at Z.

9. Pitch ratio $(P.\ R.)_x$ at any point of the blade of a propeller or of a wind-mill distant x from the axis of revolution is $(P.\ R.)_x = 2\pi x/D \tan \theta_x$, where D is the diameter of propeller or mill wheel, θ_x = angle which face of blade makes with plane of revolution. If $(P.\ R.)_x$ is independent of x, propeller has a constant pitch ratio; if θ_x is independent of x, it has a constant blade angle.

10. Reynold's number (R) = $VL\rho/\mu$, where L is some specified linear dimension. The choice of L depends upon the form of the object, and the problem. R is dimensionless.

CONSTANTS ASSUMED

Standard air density is $\rho_0 = 1.2255$ kg/m³(= 0.002 377 slug/ft.³), which is essentially that of dry air, with normal CO_2 content, at 15°C and one atmosphere.

$$\mu/\rho = 1.427 \times 10^{-5} \text{ m}^2/\text{sec } (= 1.535 \times 10^{-4} \text{ ft.}^2/\text{sec}).$$

For geometrically similar systems $F_x = qL^2\phi(R) = CAq$ (43), where ϕ is independent of the actual size of the system, and q is the value of the dynamic pressure at some specified point. C is a function only of R and of the geometrical form of the system; its value is the same in every self-consistent system of units, and is independent of the actual size of the system. The data in the following tables and graphs apply when all surrounding bodies are so far removed from the one considered that they produce no effect upon F_x.

Reduction of Observations.—To obtain true air speed from speed recorded by cup anemometer, use Table 1. Aerodynamic data are usually reduced to a standard air density (ρ_0). For q, this reduction can be effected by replacing the true air speed (V) by the indicated air speed (V_i) (definition 7), and in most cases the same procedure is amply sufficient for C. *Example:* If V = 100 ft./sec in air at 30°C and 754 mm of mercury, $V/V_i = 1.030$ (Fig. 2); hence V_i = 97.1 ft./sec and q_0 = 11.20 lb./ft.² (Table 2). Owing to isentropic compression of air at this speed, the actual dynamic pressure (q) is 11.20/0.998 (Table 3) = 11.22 lb./ft.² = 54.78 kg/m².

As a basis for the calibration of altimeters, and for use in the comparison of the performances of aircraft, it is assumed that (1) below a certain altitude (Z_i), the rate of decrease (a) of the temperature (T) with the altitude is a constant; (2) above Z_i, $a = 0$; (3) at $Z = 0$, pressure $= p_0$, temperature = T_0. The temperature at $Z_i = T_i$; the mean temperature below Z is T_m. All temperatures are reckoned from absolute zero. Then, if $Z < Z_i$, $T_m = aZ/\log_e(T_0/T)$; if $Z > Z_i$, $T_m = Z/\left(\frac{1}{a}\log_e \frac{T_0}{T_i} + \frac{Z - Z_i}{T_i}\right)$, and for any value of Z, $Z = K \frac{T_m}{T_0} \log_{10}\left(\frac{p_0}{p}\right)$.

The values of these constants define what is called the "standard" atmosphere. There is not entire agreement regarding the values which best represent the average atmospheric condition (28). Those adopted by the governmental aeronautic organizations of the U. S. A. and by many of those of Europe are T_0 = 288°C, T_i = 218°C, p_0 = 760 mm of mercury, a = 6.500 × 10⁻³°C/m (= 1.9812 × 10⁻³°C/ft.), Z_i = 10769 m (= 35332 ft.), K = 19413.3 m (= 63691.8 ft.). These differ slightly from those adopted by the International Commission for Aerial Navigation (see p. 72).

TABLE 1.—ROBINSON CUP ANEMOMETER*

True air speed = V; recorded speed = V_r. If unit is 1 mi./hr, $\log_{10} V = 0.079 + 0.9012 \log_{10} V_r$.

Unit is 1 mi./hr = 1.467 ft./sec = 0.4470 m/sec

V_r	V	V_r	V	V_r	V	V_r	V
1	1.20	26	22.6	51	41.5	76	59.4

* U. S. Weather Bureau type; diameter of cups = 4 in.; centers of cups are 6.72 in. from axis; V_r = 3 times linear speed of centers of cups (3, 82, 83).

TABLE 2.—DYNAMIC PRESSURE ($q = q_0$) FOR INDICATED AIR SPEED V_i

Air compression is negligible, and $q = q_0 = \rho_0 V_i^2/2$ if $V_i < 30$ m/sec (=100 ft./sec); for greater speeds, q exceeds q_0, see Table 3. Metric units are m, kg, sec. English units are ft., lb., sec. 1 lb./ft.² = 4.882 kg/m²; 1 ft./sec = 0.3048 m/sec.

Metric	V_i	English	Metric	V_i	English	English

TABLE 4.—WIND PRESSURE ON STRUCTURES

Reference plane (see below) is normal to wind. $F_N = C_N A q$; A = area of projection of object upon reference plane
Unit of F_N/A = 1 lb./ft.² = 4.88 kg/m²

Object	C_N	F_N/A*
1. Long flat plate	2	30
2. Square flat plate	1.1	16
3. Rectangular prism (1:1:5) (75)	1.6	24
4. Long cylinder	0.8	12
5. Short cylinder	0.7	10

* For V = 76 mi. per hr (=34m /per sec) true speed = 100 mi. per hr recorded by Robinson anemometer.

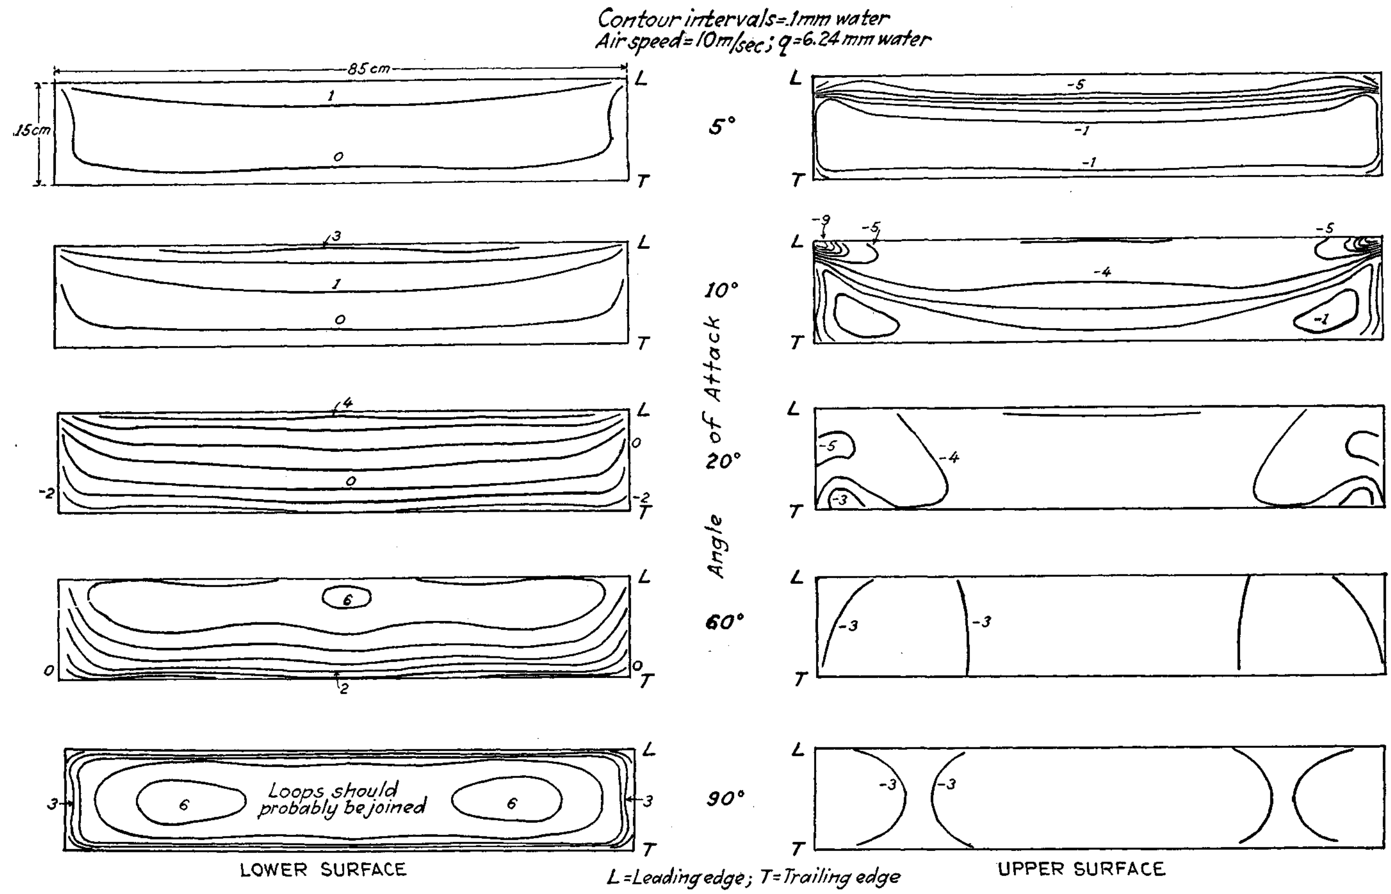

FIG. 4.—Pressure distribution: oblong, rectangular plate, inclined (12, 13).

Wind Pressure on Structures.—One must consider (1) maximum wind speed to which the structure will be subjected, (2) the value of the coefficient C_N, and (3) the effective exposed area. The first and the third depend upon local conditions; in the third, shielding effects are very important. The value of C_N should be determined from observations upon a model of the actual structure, as experiments upon flat plates are of little value for this purpose. Opinions differ regarding whether, in gusty winds, the maximum value of F_N is determined by the average or by the maximum value of V (20, 52). Approximate values of C_N for certain typical cases are given in Table 4, where reference plane for flat plate is surface of plate; for prism, its largest face; for cylinder, the plane through axis and normal to that which contains axis and direction of wind. Object (1) is comparable to such structures as wireless masts and long narrow bridge girders; (2) to thin square signboards; (3) to tall buildings; (4) to chimneys; (5) to cylindrical water tanks.

TABLE 5.—SURFACE FRICTION (F_f) ON THIN FLAT PLATES (Standard density and viscosity)

F_f (= $\int f dA$) = 0.0375 $AqR^{-0.15} = F_0 A K_w K_v$ (5, 61) where A = total area (both sides) exposed to air stream, F_0 is a factor depending upon the density and viscosity of the air and upon the units employed, and K_w and K_v are numerical factors determined, respectively, by the width (W) of the plate in the direction of the stream, and by the speed (V). F_0 is independent of the ratio S/W, provided $0.5 < (S/W) < 2$; if $S/W = 30$, F_0 is 10% less than the value given in the table. For effect of roughness (it is great), and for variation of f from point to point see (22, 24, 32, 53, 54, 55, 62).

English units $F_0 = 0.0420$ lb./ft.^{2} Unit of F_f = 1 lb.; of A = 1 ft.^{2}; of V = 1 ft./sec				Metric units $F_0 = 0.0311$ kg/m^2 Unit of F_f = 1 kg; of A = 1 m^2; of V = 1 m/sec

* TD = tunnel diameter.

† R is dimensionless.

The flow about a sphere is extremely sensitive to slight changes in the method of support, and to the condition of turbulence of the air stream. Changes in C are associated with changes in the locus of the points at which the smooth flow leaves the surface, forming a highly turbulent region to the rear. The location of this locus is determined solely by the irregularities in the air stream, as there are no sharp edges or other geometrical feature which might serve to fix it.

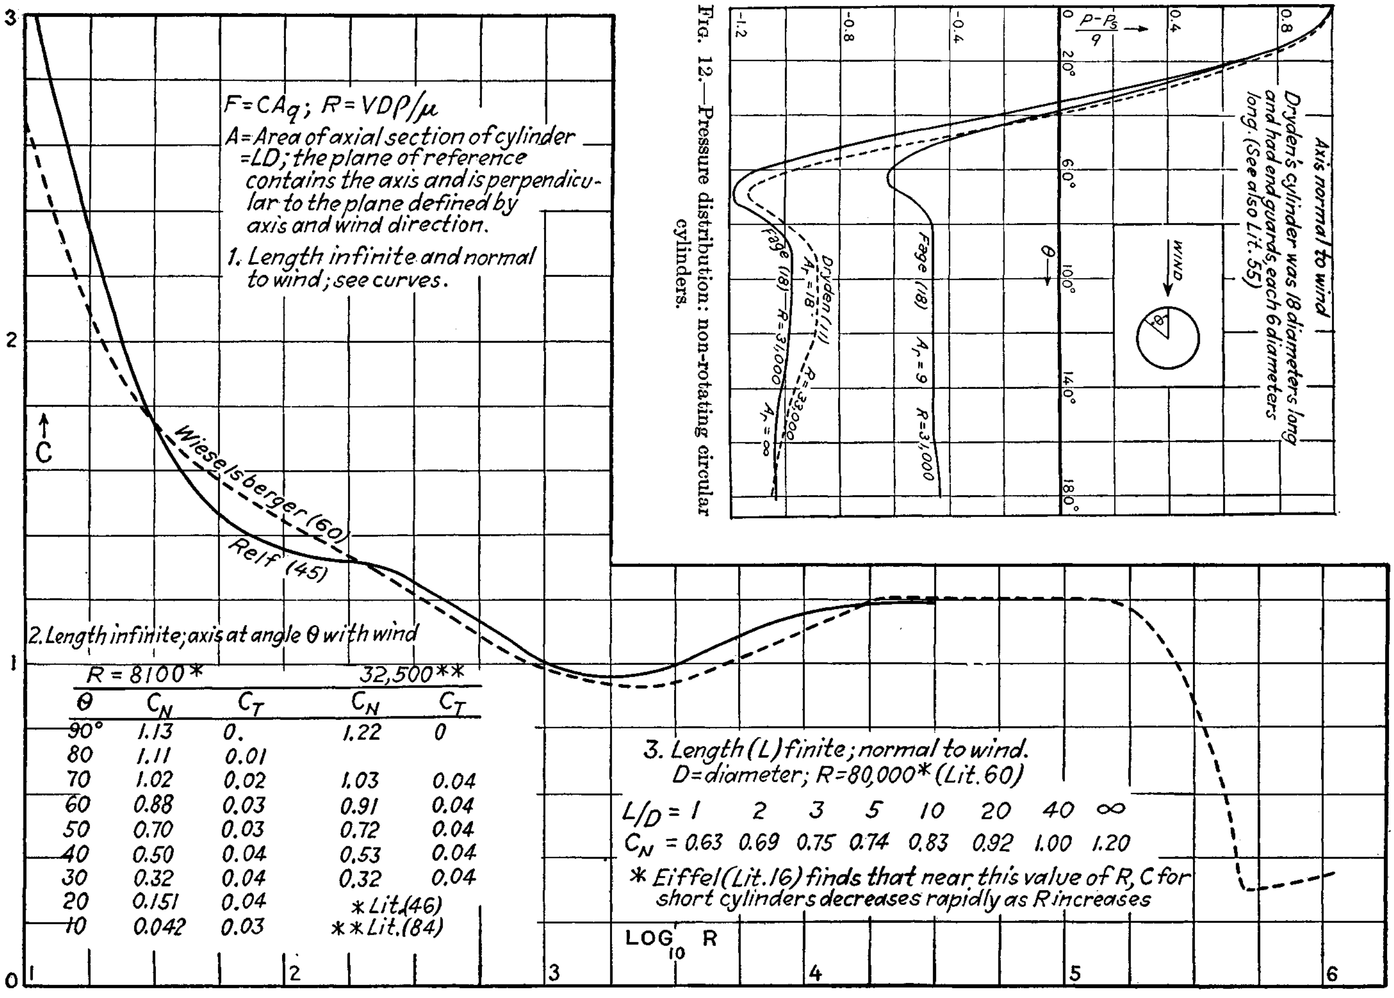
Airfoils.—Aerodynamical characteristics are specified in the same manner as are those of plates. An airfoil's area and angle of attack are conventionally defined with reference to some specified plane. The area of the airfoil is defined as that of its normal projection upon this plane of reference. The length (c) of the projection upon this plane of any fore-and-aft section of the airfoil is called the chord of that section; it is the unit in terms of which all dimensions of that section are expressed. The form of the section is specified by the rectangular coordinates of points upon its boundary; the choice of axes is immaterial, although usually one axis is in the plane of reference. The aspect ratio (A_r) of the airfoil is defined as the ratio of length of span (S) to length of the chord. In addition to the coefficients considered for plates, the moment coefficient $C_M = M/(qAc)$, and the lift-drag ratio (F_l/F_d) are also of importance.

Data are usually given for $A_r = 6$. If $A_r > 3$, then for a given C_l, $\theta_A = \theta'_A + C_l/\pi A_r$ radians, and $C_d = C'_d + C^2_l/\pi A_r$; θ'_A and C'_d are values of θ_A and C_d when $A_r = \infty$; $C_l/\pi A_r$ and $C^2_l/\pi A_r$ are called the induced angle of attack and the induced coefficient of drag, respectively (25, 26, 42, 72).

For airfoils, C_l increases slightly, and C_d decreases very appreciably, as R is increased; C_{cp} remains unchanged. The difference between the values of the coefficients for airfoils of the size used on aircraft and those for models of the size generally employed in laboratory tests, depends upon the form of the airfoil; for a thin, low cambered section (*RAF* 15), it is small; for a highly cambered section, it is large.

For the effects produced by placing one airfoil near another, as in a biplane combination see (26, 27, 36, 42, 74).

For a complete airplane, the drag introduced by the body, and the moment of tail lift, both vary appreciably with the size of the airplane (6, 67, 73).



$F = CAq$; $R = VD\rho/\mu$

A = Area of axial section of cylinder = LD; the plane of reference contains the axis and is perpendicular to the plane defined by axis and wind direction.

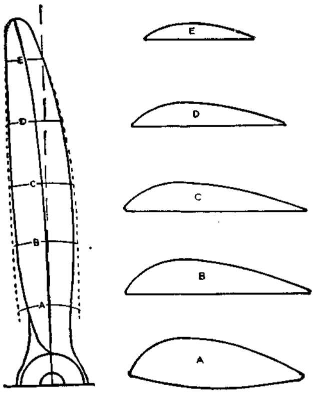

FIG. 18.—Durand's $F_2A_1S_1P_1$ propeller family. Pitch ratio constant. (Members differ only in pitch ratio.)

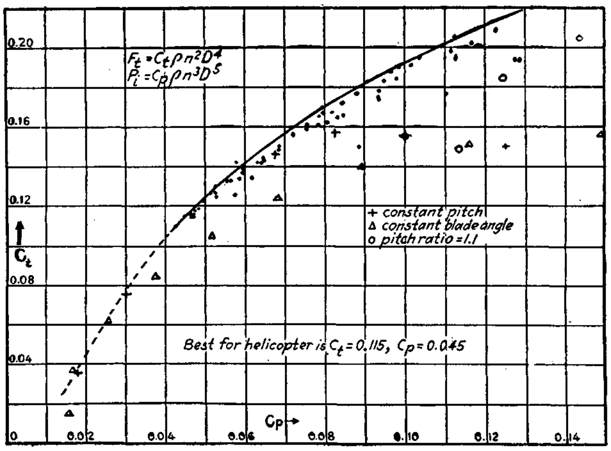

FIG. 19.—Characteristics of Durand propellers at a fixed point (8, 10).

Elongated stream-line solids of revolution have a small resultant drag, which varies greatly with turbulence of air stream, position of neighboring bodies, and slight changes in form. The area entering into the expression $F = CAq$, is generally taken either as the area of maximum section normal to the length, or as $(\text{volume})^{2/3}$. C varies with the Reynold's number. When $A = (\text{volume})^{2/3}$, the minimum value of C for large values of R, and for bodies which are 4 to 5 diameters long, is of the order of 0.014. When A = sectional area, the minimum value of C is of the order 0.03, and is obtained with bodies shorter than 4 diameters. Their equilibrium when parallel to the air stream is unstable; adding fins gives stability and greatly increases their drag (23, 35, 39).

Propellers.—Propellers are usually divided into families in which pitch-ratio and diameter are the only variables. Blade thickness and outline are usually determined largely by structural considerations; if the average thickness and width of blade are fixed, other variations have small effect upon attainable efficiency (**8, 9, 15, 19, 65, 66, 71, 76, 77**).

The characteristics of a propeller working at a fixed point may be expressed by two dimensionless coefficients, C_t and C_P, defined by the equations $F_t = C_t\rho n^2D^4$ and $P_i = C_P\rho n^3D^5$. For most propellers, there is, between C_t and C_P, a functional relation which is nearly independent of the design, provided large blade angles are not used (**33**). In Fig. 19, the curve indicates the most favorable results; marked departures from the curve occur mainly with propellers of high pitch ratio, or of constant blade angle.

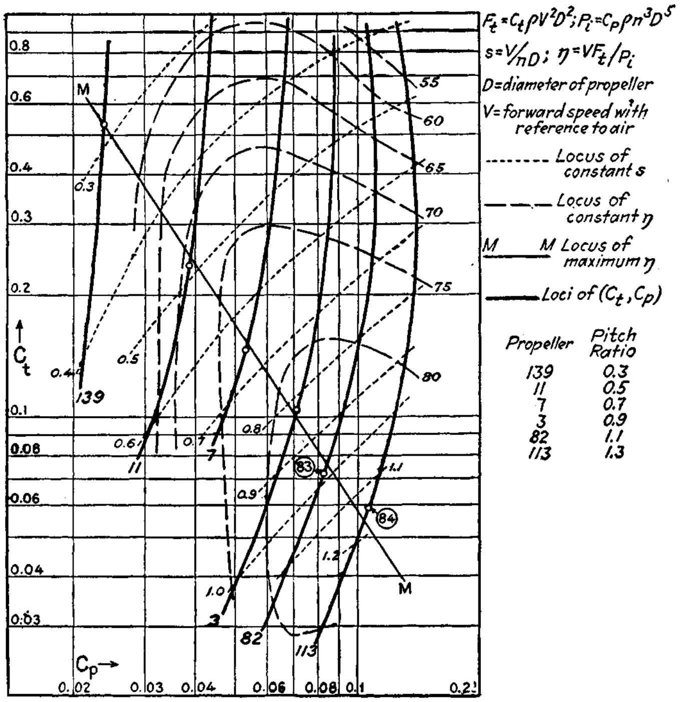

Fig. 20.—Characteristics of advancing Durand $F_2A_1S_1P_1$ propeller family (9).

The characteristics of propellers at various forward speeds (V) and speeds of rotation may be expressed by curves showing the relationships between three parameters. In Fig. 20, the parameters used are C_t, C_P, and s or η, defined by the equation $F_t = C_t\rho V^2D^2$, $P_i = C_P\rho n^3D^5$, $s = V/Dn$; $\eta = C_ts^3/C_P$, and D = diameter of the propeller. Useful range of C_t is 0.05 to 0.25; of C_P is 0.04 to 0.16. Data given are for propellers of two blades; increasing the number of blades, displaces the curves upwards and to the right.

Wind mills.—Quite different principles control the designing of wind mills which derive power from natural winds, and of those (such as the small wind mills used on airplanes for driving fuel pumps, etc.) which derive their power from the motion of a power driven craft. In the former, the controlling factor is the cost per unit of power developed; in the latter, it is the power consumed per unit of power, or torque load, developed.

LITERATURE REFERENCES

LITERATURE REFERENCES

In all literature references cited in International Critical Tables the name of the journal or publication is indicated by means of a *Key Number* corresponding to the list given below. The numbers which follow this key number in a literature citation are, in the order named: (1) the volume, (2) the page, and (3) the last two figures of the year. Thus, 64*V*, **31:** 253; 22, indicates Verslag Koninklijke Akademie van Wettenschappen te Amsterdam, Vol. 31, page 253, 1922. Series numbers are not given. Key Numbers referring to books and other non-serial publications are preceded by the letter *B*, and the volume number is given in Roman numerals. Thus, *B*10, **IV:** 191; 18 indicates Doelter, Handbuch der Mineralchemie, page 191 of Vol. 4 of the 1918 edition. The Key Number *O* is used to indicate "private communication from."

RÉFÉRENCES BIBLIOGRAPHIQUES

Le nom du journal ou de la publication de toutes les références bibliographiques citées dans les Tables critiques internationales est indiqué au moyen d'un nombre-clé correspondant à la liste donnée ci-dessous. Les nombres qui suivent ce nombre-clé dans un renvoi bibliographique indiquent dans l'ordre suivant: (1) le volume, (2) la page, et (3) les deux derniers chiffres de l'année. Ainsi 64*V*, **31:** 253; 22, indique Verslag Koninklijke Akademie van Wettenschappen te Amsterdam, vol. 31, page 253, 1922. Les numeros des séries ne sont pas donnés. Les nombres-clés se rapportant à des livres ou à des publications non périodiques sont précédés de la lettre *B* et le numéro du volume est donné en chiffres romains. Ainsi, *B*10, **IV:** 191; 18 indique Doelter, Handbuch der Mineralchemie, page 191 du volume 4 de l'édition de 1918. Le nombre-clé *O* est employé pour indiquer "communication privée de."

DAS LITERATURVERZEICHNIS

In allen Literaturstellen, die in I. C. T. verzeichnet sind, ist der Name der Zeitschrift oder der Publikation mit Hilfe einer *Schlüsselnummer*, entsprechend der unten folgenden Liste, angegeben. Die Zahlen, welche diesen Schlüsselnummern bei einem Literaturzitat folgen, bedeuten der Reihe nach: (1) der Band, (2) die Seite und (3), die letzten zwei Zahlen des Jahrganges. So bedeutet z. B. 64*V*, **31:** 253; 22, Verslag Koninklijke Akademie van Wettenschappen te Amsterdam, Band 31, Seite 253, 1922. Serien-Nummern werden nicht angegeben. Der Schlüsselzahl wird ein *B* vorausgesetzt, wenn sie Bücher, oder eine andre nicht periodische Veröffentlichung bezeichnet. Die Bandnummer wird durch römische Ziffern angegeben. Es bedeutet z. B. also *B*10, **IV:** 191; 18, Doelter, Handbuch der Mineralchemie, Seite 191, des 4. Bandes, der Auflage des Jahres 1918. Die Schlüsselzahl Null wird gebraucht, um anzuzeigen, dass es eine 'private Mitteilung' ist.

INDICAZIONI BIBLIOGRAFICHE

In tutte le indicazioni bibliografiche che si incontrano nele "Tabelle Critiche Internazionali" il nome del giornale o della pubblicazione è espresso con un *numero chiave* riportato nell'elenco dato più oltre. I numeri che, nella citazione, vengono dopo il numero chiave sono disposti con l'ordine seguente: (1) il volume, (2) la pagina, e (3) le ultime due cifre del millesimo. Cosi 64*V*, **31:** 253; 22, indica la Verslag Koninklijke Akademie van Wettenschappen te Amsterdam, Vol. 31, pagina 253, 1922. I numeri di serie non vengono dati. Quando un numero chiave è preceduto dalla lettera *B* si riferisce a libri o ad altre pubblicazioni non periodiche, e il numero del volume viene allora scritto in cifre romane. Cosi *B*10, **IV:** 191; 18 indica Doelter, Handbuch der Mineralchemie, pagine 191 del IV° volume dell'edizione 1918. Il numero chiave *O* indica "Comunicazione privata da . . ."

KEY TO THE PERIODICALS

Data regarding the libraries which receive many of these periodicals may be found through the following sources:

United States and Canada: "Periodicals Abstracted by Chemical Abstracts, 1926" (Chemical Abstracts, Ohio State Univ., Columbus, Ohio); "Union List of Serials in the Libraries of the United States and Canada, 1925- " (H. W. Wilson & Co., New York City); "A Catalogue of Scientific Periodicals in Canadian Libraries, 1924" (McGill Univ., Montreal, Canada).

IMPORTANT NOTICE

ANNUAL TABLES OF CONSTANTS AND NUMERICAL DATA CHEMICAL, PHYSICAL AND TECHNOLOGICAL

Published by an International Committee, under the authority of the International
Research Council and the International Union of
Pure and Applied Chemistry

THE data given in International Critical Tables are based upon determinations published previous to January 1924.

In order to keep always up to date with future progress in physical measurements, the purchaser of International Critical Tables should become a regular subscriber to *International Annual Tables*, which will bring to his desk each year a volume in which he will find assembled and classified all of the data which has appeared in the world's literature, for the year covered by the volume.

Thus, *Annual Tables*, Volume VI, will contain all the data published in the literature of 1923–1924; Volume VII will contain the data published in the literature of 1925; Volume VIII, the data to be found in the literature of 1926, etc. . . .

The older volumes of Annual Tables go back to 1910 and contain all of the original determinations published during that period and which served as all or part of the basis of selection of the "best" values recorded in International Critical Tables. These older volumes thus constitute a handy and accessible source of reference to the original determinations.

Through special arrangements made with the International Commission in charge of Annual Tables, all purchasers of International Critical Tables will be given special discounts on all purchases of International Annual Tables, as follows:

1. Volumes I, II, III, IV, V (data for 1910–1922), cloth, $52.50 (regular price, $71.00).
2. 25% discount on Volumes VI to X inclusive, covering the period 1923–1928.
3. 25% discount on the index to Volumes I–V, which will be published in 1927.

These discounts apply only on subscriptions addressed to Dr. C. Marie, 9 rue de Bagneux, Paris VI, France.

All subscriptions should be accompanied by draft or money order payable at Paris.

SPECIMEN SECTIONS

Free copies of any of the following specimen sections may be obtained on application to the above address.

Spectroscopy. Electricity, Magnetism, Electrochemistry. Radioactivity. Crystallography, Mineralogy. Biology. Engineering, Metallurgy. Colloids.

The following identification form should be filled out and transmitted with the first subscription.

I. NORTH AMER-

UNITED STATES FOREST

The following data on certain woods of North America are based on an extensive series of tests of small specimens free of defects. All the tests were conducted under a uniform procedure, so that the results are strictly comparable. Analysis of the test figures has made it possible to establish definite density-strength relations, which are represented by the equations given in the first section of the table (Table 1). These equations are all of the parabolic type, the degree being determined to the nearest quarter-unit. By substituting the appropriate specific gravity for a given species (columns 8 and 9) in the equation for any property, the value of the corresponding property may be obtained.

In most species, however, there is a very considerable departure of average test results from the general equation values, although very few species, thus far investigated, are either wholly above or wholly below normal, all properties considered. Since the deviation of a property from the normal value as determined by the equation often indicates the special fitness or unfitness of the species for a particular use, it becomes necessary to supplement the equations with departure factors, for the properties of each species. Such factors, expressed as *percentages* and listed in order below the respective equations, make up the second part of Table 1. By multiplying the value, F, computed by the equation, by the proper correction factor, the actual average value for the property and species in question may be determined.

Example: To find the modulus of rupture of air-dried shagbark hickory. The finding list shows this to be No. 62, *Hicoria ovata.* From the equation of column 15 we find $F = 18.1\ D_d^{1.25}$. For No. 62 we find (column 9) $D_d = 0.724$ and (column 15) correction factor = 119 %, whence

$$F = 1.19 \times 18.1 \times (0.724)^{1.25} = 14.4 \text{ kg/mm}^2 = 14.4 \times 1422 = 20\,500 \text{ lb./in.}^2$$

The test methods that were used conform to Tentative Standard D143-24T of the American Society for Testing Materials, as set forth in *Proc. A. S. T. M.* 939; 24. (General description in U. S. Dept. Agr., *Bull.* No. 556.) The principal data relating to the procedure for each kind of test are summarized as follows:

Shrinkage in Volume.—Specimen 5.08 × 5.08 × 15.24 cm (2 × 2 × 6 in.). Volume determined when green (unseasoned) and after oven-drying to constant weight at 100°C. Specimens thoroughly air-seasoned prior to drying in oven.

Shrinkage, Radial and Tangential.—Specimen 2.54 × 10.16 × 2.54 cm (1 × 4 × 1 in.). Width measured when green (unseasoned) and after oven-drying to constant weight at 100°C. Specimens thoroughly air-seasoned prior to drying in oven.

Static Bending.—Specimen 5.08 × 5.08 × 76.20 cm (2 × 2 × 30 in.). Center loading, 71.12 cm (28 in.) span. Load applied by testing machine head moving 0.254 cm (0.10 in.) per min. Total work is defined as that obtained by continuing the test until either a 15.24 cm (6 in.) deflection is reached or the load falls to 90.7 kg (200 lb.) or less.

Impact Bending.—Specimen and span as above. 22.7 kg (50 lb.) hammer dropped first from 2.54 cm (1 in.) height, next from 5.08 cm (2 in.) height, etc., up to 25.4 cm (10 in.), then from height increments of 5.08 cm (2 in.) until failure.

Compression Parallel to Grain.—Specimen 5.08 × 5.08 × 20.32 cm (2 × 2 × 8 in.). End load, testing machine head moving 0.061 cm (0.024 in.) per min.

Les données indiquées ici, relatives à certains bois de l'Amérique du Nord, sont basées sur une série d'expériences faites sur de petites éprouvettes exemptes de défauts. Tous les essais ayant été effectués suivant une procédure uniforme, les résultats sont donc strictement comparables. L'analyse des chiffres obtenus aux essais a permis d'établir des relations définies entre la densité et la résistance, qui sont représentées par les équations inscrites dans la première section de la table (Table 1). Ces équations sont toutes du type parabolique, le degré étant déterminé au quart d'unité le plus proche. En substituant le poids spécifique approprié pour une espèce donnée (colonnes 8 et 9) dans l'équation relative à une propriété donnée, on peut obtenir la valeur correspondante de la propriété.

Cependant pour la plupart des espèces il y a un écart considérable entre les résultats moyens des essais et les valeurs déduites de l'équation générale; pour autant que les expériences effectuées l'ont démontré, il n'y a qu'un petit nombre d'espèces qui sont, ou en entier au-dessus ou en entier au-dessous de la normale pour toutes les propriétés considérées. Comme l'écart d'une propriété de la valeur normale, ainsi qu'elle est déterminée par l'équation, indique souvent la convenance spéciale de l'espèce pour un usage particulier, ou sa non-convenance, il est nécessaire de compléter les équations par des facteurs de correction pour les propriétés de chaque espèce. Ces facteurs, exprimés en pourcentage et inscrits dans l'ordre au-dessous des équations respectives, constituent la deuxième partie de la Table 1. En multipliant la valeur F calculée au moyen de l'équation par le facteur de correction convenable, on peut déterminer la valeur moyenne de la propriété de l'espèce en question.

Exemple: Soit à déterminer le module de rupture du "shagbark hickory" séché à l'air. La liste de recherches montre qu'il s'agit du No. 62 *Hicoria ovata.* De l'équation de la colonne 15 on trouve $F = 18{,}1\ D_d^{1{,}25}$. On trouve pour le No. 62 (colonne 9) $D_d = 0{,}724$ et (colonne 15) le facteur de correction = 119 %, d'où

$$F = 1{,}19 \times 18{,}1 \times (0{,}724)^{1{,}25} = 14{,}4 \text{ kg/mm}^2 = 14{,}4 \times 1\,422 = 20\,500 \text{ lb./in.}^2$$

Les méthodes d'essais qui ont été utilisées sont conformes à l'examen type D143-24T de la société américaine pour l'essai des matériaux, ainsi qu'elles sont décrites dans *Proc. A. S. T. M.* 939: 24 (*cf.* U. S. Dept. Agr. *Bull.* 556). Les données principales relatives à la procédure pour chaque sorte d'essai sont rassemblées ci-dessous:

Retrait en volume.—Eprouvette 5,08 × 5,08 × 15,24 cm (2 × 2 × 6 pouces). Le volume est déterminé lorsque le bois est vert, puis, après séchage à poids constant au four à 100°C. Avant le séchage au four, les éprouvettes sont complètement séchées à l'air.

Retrait radial et tangentiel.—Eprouvette 2,54 × 10,16 × 2,54 cm (1 × 4 × 1 pouce). La largeur est mesurée sur le bois vert et après séchage à poids constant, au four à 100°C. Avant le séchage au four, les éprouvettes sont complètement séchées à l'air.

Essai de flexion statique.—Eprouvette 5,08 × 5,08 × 76,20 cm (2 × 2 × 30 pouces); charge centrale; portée 71,12 cm (28 pouces). La charge est appliquée par une machine à essai dont la pièce mobile se déplace de 0,254 cm (0,10 pouces) à la minute. Le travail total est défini par celui qu'on obtient en continuant l'essai jusqu'à ce qu'une flèche de 15,25 cm soit obtenue, ou que la charge tombe à 90,7 kg (200 lb.) ou moins.

ICAN WOODS

PRODUCTS LABORATORY

Die hier angegebenen Werte bestimmter nordamerikanischer Hölzer ergeben sich aus einer ausgedehnten Serie von Prüfungen an einer kleinen Zahl von fehlerfreien Arten. Alle Prüfungen sind bei einheitlichem Vorgange ausgeführt worden, so, dass sie direkt vergleichbar sind. Die Analysen der Zahlenwerte der Prüfungsergebnisse machten es möglich gewisse Beziehungen zwischen Dichte und Festigkeit aufzustellen, die durch Gleichungen im ersten Abschnitt der Tafel 1 wiedergegeben sind. Diese Gleichungen sind alle vom parabolischen Typus, der Exponent in der Gleichung ist auf die nächste Viertel-Einheit bestimmt. Durch Einsetzung des entsprechenden spezifischen Gewichtes für eine bestimmte Art (Reihe 8 und 9) in die Gleichung für ihrgend eine Eigenschaft, erhält man den Wert für die entsprechende Eigenschaft.

Bei vielen Arten jedoch ist eine bemerkenswerte Abweichung des durchschnittlichen Wertes des Prüfungsergebnisses von dem Werte, der sich aus der allgemeinen Gleichung ergibt, vorhanden. Es gibt indessen nur sehr wenige Arten, so weit untersucht, deren berücksichtigten Eigenschaften zur Gänze entweder über oder unter dem normalen Werten liegen. Da die Abweichung einer Eigenschaft, von dem durch die Gleichung erhaltenen Wert, häufig die besondere Eignung oder Nichteignung einer Art für eine besondere Verwendung anzeigt, wird es notwendig, für die Eigenschaft jeder einzelnen Art die Gleichung durch einen Abweichungsfaktor zu ergänzen. Solche Faktoren, in *Prozenten* ausgedrückt, befinden sich geordnet unter den entsprechenden Gleichungen und machen den zweiten Teil der Tafel 1 aus. Durch Multiplikation des Wertes F, der nach der Gleichung gefunden ist, mit dem eigenen Korrektionsfaktor, erhält man richtige Mittelwerte für die Eigenschaft des fraglichen Musters.

Beispiel: Es ist die Bruchfestigkeit von lufttrockenem Hykorynussbaum zu finden. Die Nachschlagsliste zeigt, dass dies No. 62 *Hicoria ovata* ist. Aus der Gleichung der Reihe 15 findet man $F = 18{,}1\ D_d^{1{,}25}$. Für No. 62 findet man (Reihe 9) $D_d = 0{,}724$ und (Reihe 15) den Korrektionsfaktor = 119%, mithin

$$F = 1{,}19 \times 18{,}1 \times (0{,}724)^{1{,}25} = 14{,}4\ \text{kg/mm}^2$$

Die angewandten Prüfungsmethoden entsprechen der Standard Prüfung D143-24T der American Society for Testing Materials, wie es in *Proc. A. S. T. M.* 939; 24 (*cf.* U. S. Dep. Agr. *Bull.* 556) mitgeteilt wird. Die hauptsächlichsten Angaben, die den Vorgang bei jeder besonderen Prüfung bezeichnen, sind zusammengestellt, die folgenden:

Volumabnahme (Schwindung).—Muster 5,08 × 5,08 × 15,24 cm. Das Volumen wurde in unausgetrocknetem Zustande und dann nach der Trocknung im Ofen bei 100°C, bis zum konstantem Gewicht bestimmt. Die Proben waren vor der Ofentrocknung vollständig lufttrocken.

Volumabnahme, tangential und radial.—Muster 2,54 × 10,16 × 2,54 cm. Die Masse sind im ungetrocknetem Zustande abgenommen und dann nach der Ofentrocknung bei 100°C, bis zum konstantem Gewicht bestimmt. Die Proben waren vor der Ofentrocknung vollständig lufttrocken.

Statischer Biegeversuch.—Muster 5,08 × 5,08 × 76,20 cm, Mittelbelastung, 71,12 cm Spannweite, Belastung durch eine Festigkeitsmaschine, derart, dass die Durchbiegung 0,254 cm in der Minute beträgt. Die gesammt Arbeit ist diejenige, die bei

I valori qui riportati per certi legni dell'America del Nord sono il risultato di una estesa serie di prove eseguite sopra un piccolo numero di specie senza difetti. Tutti i saggi sono stati condotti con lo stesso metodo, per modo che i risultati sono strettamente confrontabili. L'esame dei valori numerici ha permesso di stabilire alcune relazioni fra densitá e resistenza, le quali sono rappresentate dalle equazioni riprodotte nella prima parte della tabella (Tabella 1). Queste equazioni sono tutte di tipo parabolico, e il grado è determinato con l'approssimazione del quarto dell'unità.

Introducendo nell'equazione per una data proprietà il peso specifico di una determinata specie (colonne 8 e 9) si ottiene il valore della proprietà corrispondente.

In molte specie la media dei risultati dei saggi scarta notevolmente dai valori che si ottengono dall'equazione generale; solo in poche però, tutti i valori sono sempre al di sopra e sempre al di sotto dei normali.

Siccome lo scarto di una proprietà dal valore risultante dall' equazione sta spesso ad indicare se una specie è adatta o no ad uno speciale impiego, è necessario completare le equazioni con dei fattori di correzione per le proprietà di ogni specie. Questi fattori, espressi in percento, sono riportati sotto le equazioni corrispondenti e costituiscono la seconda parte della Tabella 1. Moltiplicando il valore F dato dall'equazione per il rispettivo fattore di correzione, si ottengono valori medi esatti per la proprietà del campione in questione.

Esempio: Si debba trovare la resistenza alla rottura dello "shagbark hickory" seccato all'aria. Dall'elenco di riferimento si ricava che si tratta del No. 62, *Hicoria ovata.* Dall'equazione della colonna 15 si ha $F = 18{,}1\ D_d^{1{,}25}$. Per il No. 62 si trova $D_d = 0{,}724$ (colonna 9) e come fattore di correzione 119% (colonna 15), per modo che si ha

$$F = 1{,}19 \times 18{,}1 \times (0{,}724)^{1{,}25} = 14{,}4\ \text{kg/mm}^2$$

I metodi di prova adoperati corrispondono alle norme D143-24T della American Society for Testing Materials, quali si trovano indicate nei *Proc. A. S. T. M.* 939; 24 (*v.* U. S. Dep. Agr. *Bull.* 556). Le indicazioni principali riferentisi a ogni specie di saggio sono le seguenti:

Contrazione di volume.—Dimensioni della provetta 5,08 × 5,08 × 15,24 cm. Il volume viene determinato su legno non stagionato e su legno seccato in forno a 100°C fino a costanza di peso. I provini vengono seccati completamente all'aria prima che nel forno.

Diminuzione di volume, tangenziale e radiale.—Dimensioni della provetta 2,54 × 10,16 × 2,54 cm. La larghezza viene misurata su legno non stagionato e su legno seccato in forno a 100°C fino a costanza di peso. Le provette vengono seccate completamente all'aria prima che nel forno.

Flessione statica.—Dimensioni della provetta 5,08 × 5,08 × 76,20 cm. Carico centrale, distanza tra gli appoggi 71,12 cm. Il carico viene applicato con una macchina di prova in modo che la freccia di incurvamento cresca con la velocità di 0,254 cm al minuto. Il lavoro totale è quello che si ottiene prolungando il saggio finchè o si raggiunge una freccia di 15,24 cm o il carico si abbassa a 90,7 kg o meno.

Compression Perpendicular to Grain.—Specimen 5.08 × 5.08 × 15.24 cm (2 × 2 × 6 in.). Load applied to side through a steel plate 5.08 cm (2 in.) wide laid across center of piece and at right angles to its length, ⅓ of surface being thus directly subjected to compression; testing machine head moving 0.061 cm (0.024 in.) per min.

Shear Parallel to Grain.—Specimen 5.08 × 5.08 × 6.35 cm (2 × 2 × 2.5 in.). Undercut at one end to permit shear over area 5.08 × 5.08 cm (2 × 2 in.); testing machine head moving 0.038 cm (0.015 in.) per min.

Tension Perpendicular to Grain.—Specimen as above. Transverse recess bored at each end to permit gripping for tension over 5.08 × 2.54 cm (2 × 1 in.) area; testing machine head moving 0.635 cm (0.25 in.) per min.

Hardness.—Specimen 5.08 × 5.08 × 15.24 cm (2 × 2 × 6 in.). Load required to embed a steel ball having a maximum cross-sectional area of 1 cm^2 to ½ its diam.; testing machine head moving 0.635 cm (0.25 in.) per minute.

Cleavage Parallel to Grain.—Specimen 5.08 × 5.08 × 9.525 cm (2 × 2 × 3¾ in.). Transverse recess bored at one end to permit gripping for cleavage of specimen over 5.08 cm (2 in.) width and along a 7.62 cm (3 in.) length; testing machine head moving 0.635 cm (0.25 in.) per min.

WOODS OF THE PHILIPPINE ISLANDS

The Bureau of Forestry and the Bureau of Science of the Philippine Islands

Introduction

Density and strength values for five woods of commerce have been determined. The testing methods used and manner of displaying the results are identical with those used by the U. S. Forest Products Laboratory and the results have therefore been incorporated at the end of Table 1 below.

CANADIAN WOODS

A number of the species listed in Table 1 below have also been tested by the Canadian Forest Products Laboratory, using samples obtained from trees grown in Canada. As far as can be definitely determined, these woods are substantially the same in properties as like species grown in the United States.

Essai de flexion par choc.—Eprouvette et portée comme ci-dessus. Un marteau de 22,7 kg (50 lb.) tombe premièrement d'une hauteur de 2,54 cm (1 pouce), ensuite de 5,08 cm (2 pouces) de haut, etc., jusqu'à 25,4 cm (10 pouces), ensuite par augmentations successives de hauteur de 5,08 cm (2 pouces) jusqu'à rupture.

Compression parallèle à la fibre.—Eprouvette 5,08 × 5,08 × 20,32 cm (2 × 2 × 8 pouces). Charge finale, machine à essai dont la pièce mobile se déplace de 0,061 cm par minute.

Compression perpendiculaire à la fibre.—Eprouvette 5,08 × 5,08 × 15,24 cm (2 × 2 × 6 pouces). Charge appliquée sur le côté par l'intermédiaire d'une plaque d'acier de 5,08 cm de largeur disposée au milieu de la pièce et normalement à sa longueur, de façon que ⅓ de la surface soit soumis à la compression; machine à essai dont la pièce mobile se déplace de 0,061 cm (0,024 pouce) par minute.

Cisaillement parallèle à la fibre.—Eprouvette 5,08 × 5,08 × 6,35 cm (2 × 2 × 2½ pouce). Ecrénée à une extrémité pour permettre le cisaillement sur une surface de 5,08 × 5,08 cm (2 × 2 pouces); machine à essai dont la pièce mobile se déplace de 0,038 cm (0,015 pouce) par minute.

Traction perpendiculaire à la fibre.—Eprouvette comme ci-dessus. Niche transversale découpée à chaque extrémité de façon à permettre la traction sur une surface de 5,08 × 2,54 cm (2 × 1 pouce). Machine à essai dont la pièce mobile se déplace de 0,635 cm (0,25 pouce) par minute.

Dureté.—Eprouvette 5,08 × 5,08 × 15,24 cm (2 × 2 × 6 pouces). Charge nécessaire pour enfoncer une bille d'acier ayant une section maximum de 1 cm^2, de la moitié de son diamètre. Machine à essai dont la pièce mobile se déplace de 0,635 cm (0,25 pouce) par minute.

Clivage parallèle à la fibre.—Eprouvette 5,08 × 5,08 × 9,525 cm (2 × 2 × 3¾ pouces). Niche transversale découpée à une extrémité de façon à permettre le clivage de l'éprouvette sur une largeur de 5,08 cm (2 pouces) et le long de 7,62 cm (3 pouces); machine à essai dont la pièce mobile se déplace de 0,635 cm (0,25 pouce) par minute.

BOIS DES ILES PHILIPPINES

Bureau de Sylviculture et Bureau de Science des Iles Philippines

Introduction

Les valeurs de densité et de résistance ont été déterminées pour cinq bois du commerce. Les méthodes d'essais utilisées, et la façon de disposer les résultats sont identiques à celles utilisées par le U. S. Forest Products Laboratory (voir ci-dessus); c'est pourquoi les résultats ont été incorporés à la fin de la Table 1.

BOIS CANADIENS

Un certain nombre d'espèces mentionnées au bas de la Table 1 ont aussi été essayées par le "Laboratoire des Produits Forestiers Canadiens" qui employa des échantillons provenant d'arbres ayant poussé au Canada. Pour autant qu'on peut le déterminer d'une façon définie, ces bois sont les mêmes, au point de vue de leurs propriétés, que ceux des mêmes espèces croissant aux États-Unis.

fortgesetzter Prüfung entweder eine 15,24 cm Durchbiegung erreicht, oder das Gewicht fällt auf 90,7 kg oder weniger.

Schlagbiegeversuch.—Muster und Grösse wie oben. Ein 22,7 kg Hammer fällt zuerst von 2,54 cm dann von 5,08 cm u. s. w. Höhe herunter, bis 25,4 cm, von hier an, in Höhenzunahmen um 5,08 cm bis zum Bruch.

Druckversuch parallel zur Faserrichtung.—Muster 5,08 × 5,08 × 20,32 cm. Endlast, Festigkeitsmaschine derart, dass Zusammendrückung in der Minute 0,061 cm beträgt.

Druck senkrecht zur Faserrichtung.—Muster 5,08 × 5,08 × 15,24 cm. Das Gewicht an die Seite drückt auf eine Stahlplatte von 5,08 cm Weite, die um die Mitte des Stückes in rechten Winkeln zu seiner Länge angelegt ist, wodurch ⅓ der Oberfläche dem Drucke ausgesetzt wird, derart, dass die Zusammendrückung 0,061 cm in der Minute beträgt.

Scherversuch, parallel zur Faserrichtung.—Muster 5,08 × 5,08 × 6,35 cm. An einem Ende unterschnitten, um eine Scherung über eine Fläche von 5,08 × 5,08 cm zu gestatten; Scherung 0,038 cm in der Minute.

Zugversuch senkrecht zur Faserrichtung.—Muster so wie oben. Kreuzweise an jedem Ende gebohrt um die Zugkraft auf eine Fläche von 5,08 × 2,54 cm wirken zu lassen. Zug der Maschine 0,635 cm in der Minute.

Härte.—Muster 5,08 × 5,08 × 15,24 cm. Das notwendige Gewicht um eine Stahlkugel von einem maximalen Querschnitt von 1 cm bis zur Hälfte seines Durchmessers einzudrücken. Bewegung der Maschine 0,635 cm in der Minute.

Spaltung parallel zur Faserrichtung.—Muster 5,08 × 5,08 × 9,525 cm. Kreuzweise an einem Ende gebohrt für die Fassung des Musters zur Spaltung über eine Weite von 5,08 cm und 7,62 cm der Länge nach. Spaltung 0,635 cm in der Minute.

HÖLZER DER PHILIPPINEN

The Bureau of Forestry and the Bureau of Science of the Philippine Islands

Einleitung

Dichte und Festigkeit von fünf Hölzern des Handels sind bestimmt worden. Die angewendeten Prüfungsmethoden und der Vorgang bei der Darstellung der Ergebnisse sind dieselben, welche von U. S. Forest Products Laboratory angewandt werden und schon oben verzeichnet sind. Es sind daher die Ergebnisse am Ende der Tafel 1 (unten) angegeben.

CANADISCHE HÖLZER

Eine Anzahl der in der Liste Tabelle 1 unten vorhandenen Arten sind ebenso vom Canadian Forest Products Laboratory untersucht worden, indem Proben von in Canada gewachsenen Bäumen, verwendet wurden. Soweit man ein abschliessendes Urteil abgeben kann, sind diese Hölzer im wesentlichen von gleicher Eigenschaft wie diejenigen, die in den Vereinigten Staaten gewachsen sind.

Flessione per urto.—Dimensioni come sopra. Un martello di 22,7 kg cade prima di una altezza di 2,54 cm, poi di 5,08 cm ecc. fino a 25,4 cm; da 25,4 in poi l'aumento di altezza è di 5,08 cm fino a rottura.

Compressione parallela alla fibra.—Dimensioni della provetta, 5,08 × 5,08 × 20,32 cm. Carico finale, spostamento della macchina 0,061 cm al minuto.

Compressione perpendicolare alla fibra.—Dimensioni della provetta 5,08 × 5,08 × 15,24 cm. Il carico è applicato lateralmente a mezzo di una piastra di acciaio di 5,08 cm di larghezza, e questa è disposta nel mezzo del pezzo ad angolo retto rispetto alla lunghezza, per modo che ⅓ della superficie viene sottoposta a pressione. Lo spostamento della macchina deve essere di 0,061 cm al minuto.

Taglio nel senso della fibra.—Dimensioni della provetta 5,08 × 5,08 × 6,35 cm. Adattato ad una estremità in maniera da permettere il taglio sopra un'area di 5,08 × 5,08 cm. Spostamento della macchina 0,038 cm al minuto.

Trazione perpendicolare al senso della fibra.—Dimensioni come sopra. Forato in croce ad ogni estremità per fare agire lo sforzo sopra una superficie di 5,08 × 2,54 cm. Spostamento della macchina 0,635 cm al minuto.

Durezza.—Dimensioni della provetta, 5,08 × 5,08 × 15,24 cm. Carico necessario per far penetrare fino a metà spessore una sfera di acciaio avente una sezione massima di 1 cm.^{2} Spostamento della macchina 0,635 cm al minuto.

Sfaldatura parallela alla fibra.—Dimensioni delle provette 5,08 × 5,08 × 9,525. Forato a croce ad una estremità per sollecitare la provetta allo scorrimento per una larghezza di 5,08 cm e una lunghezza di 7,62 cm. Spostamento della macchina 0,635 cm al minuto.

LEGNI DELLE FILIPPINE

The Bureau of Forestry and the Bureau of Science of the Philippine Islands

Introduzione

Sono state determinate densità e tenacità di cinque legni del commercio. I metodi di saggio adoperati e la rappresentazione dei risultati sono gli stessi impiegati dall' U. S. Forest Products Laboratory (*v.* sopra). I risultati sono stati perciò incorporati nella Tabella 1 e riportati in fondo.

LEGNI DEL CANADÀ

Un certo numero delle specie elencate nella Tabella 1 in basso è stato esaminato dal Canadian Forest Products Laboratory, il quale ha eseguito i saggi su campioni di alberi cresciuti nel Canadà. Questi legni hanno dimostrato di possedere proprietà eguali a quelle delle stesse specie crescente negli Stati Uniti.

TABLE 1.—STRENGTH AND RELATED PROPER-

Index No.	Botanical name: Family	Botanical name: Genus and species	Common name	Place of growth of material tested*	Seasoning condition	Density based on weight when oven-dry and volume: When oven-dry D_o	Density based on weight when oven-dry and volume: When green (D_g)	Density based on weight when oven-dry and volume: When air-dry (D_d)	Moisture content
						g/cm³			% of oven dry-weight

BUILDING STONES

D. W. KESSLER

CONVERSION FACTORS

$1\ \text{kg cm}^{-2} = 14.22\ \text{lb. in.}^{-2} = 1.024\ \text{ton* ft.}^{-2}$

$1\ \text{dyne cm}^{-2} = 1.020 \times 10^{-5}\ \text{kg cm}^{-2} = 1.450 \times 10^{-5}\ \text{lb. in.}^{-2}$
$= 1.044 \times 10^{-6}\ \text{ton* ft.}^{-2}$

$1\ \text{kg}^{-1}\ \text{cm}^{2} = 1.020 \times 10^{6}\ \text{dyne}^{-1}\ \text{cm}^{2} = 0.0703\ \text{lb.}^{-1}\ \text{in.}^{2}$
$= 1.033\ \text{atm}^{-1}$

$1\ \text{g cm}^{-3} = 1000\ \text{kg m}^{-3} = 62.4\ \text{lb. ft.}^{-3} = 0.843\ \text{ton* yd.}^{-3}$

$1\ \text{joule cm}^{-2}\ \text{sec}^{-1}\ (°\text{C, cm}^{-1})^{-1} = 0.239\ \text{g-cal cm}^{-2}\ \text{sec}^{-1}\ (°\text{C, cm}^{-1})^{-1}$
$= 9.48 \times 10^{-4}\ \text{BTU ft.}^{-2}\ \text{sec}^{-1}\ (°\text{F, in.}^{-1})^{-1}$

per deg C = 0.556 per deg F.

* 1 ton = 2000 lb.

COMPRESSIVE STRENGTH

$\text{kg cm}^{-2} \times 10^{-3}$

Example: For basalt from Limburg, 3200 kg per sq. cm (4).

Basalt, Av. Range—2.0 to 3.5

Near Linz a. R.	4.7	(6)
Limburg, Nassau	3.2	(4)
Ortenberg, Hesse	2.7	(4)
Lauterbach, Hesse	2.0	(4)

Phonolite

Rothweil, Baden	3.4	(12)
Aschaffenburg, L. Franconia	3.0	(4)

Porphyry, Av. Range—2.0 to 3.0

Quartz, Beutengrund, Silesia	3.2	(12)
Quartz, Reinsdorf, Silesia	2.2	(12)
Alpirsbach, Black Forest	2.0	(4)

Quartzite, Av. Range—1.0 to 2.0

Kugelberg, Alsace	3.2	(4)
Sierk near Metz	2.9	(4)
Pipestone, Minn	2.0	(45)
White Haven, Pa	1.1	(21)

Felsite

Rohrschweger, Alsace	2.9	(4)
Kerzheim, Alsace	2.0	(4)

Diabase

Ochenkopf, Bavaria	2.7	(4)
Hasselfelde, Harz Mts	2.1	(12)
Taylors Falls, Minn	1.8	(13)

Diorite, Av. Range—1.0 to 2.5

Freiburg, Baden	2.6	(4)
Aschaffenburg, L. Franconia	2.4	(4)
Boulder Canyon, Ariz	2.0	(21)
Quartz mica, Monson, Mass	1.1	(23)

Aplite

Hingham, Mass	2.5	(41)

Syenite, Av. Range—1.0 to 2.0

Fine grained, East St. Cloud, Minn	2.0	(13)
Porphyry, Pulaski Co., Ark	2.0	(34)
Red, Beaver Bay, Minn	1.9	(13)
Gray quartzose, East St. Cloud, Minn	1.9	(13)
Coarse, Watab, Minn	1.8	(13)
Fine grained, Sauk Rapids, Minn	1.5	(13)
Cape Ann, Mass	1.1	(13)
Weinheim, Baden	1.0	(4)

Serpentine, Av. Range—0.9 to 2.0

Hollysprings, Ga	2.0	(21)
Auburn, Calif	1.8	(38)
Roxbury, Vt	1.7	(21)
Einseidel, Bohemia	1.4	(15)
Zoblitz, Saxony	0.8	(16)

Granite, Av. Range—1.0 to 2.8

Quartz-monzonite, Westerly, R. I.	2.0	(41)
Muscovite, Stone Mountain, Ga	1.9	(32)
Hornblende, Mosquito Mt., Maine	1.6	(46)
Gneiss, Branford, Conn	1.6	(41)
Biotite, Milford, Mass	1.6	(41)
Biotite gneiss, Port Deposit, Md	1.6	(21)
Riebeckite-aegirite, Quincy, Mass	1.5	(20)
Hornblende, Rockport, Maine	1.4	(41)

Granite.—(*Continued*)

Coarse biotite, Stony Creek, Conn	1.1	(13)
Gneiss, Monson, Mass	1.1	(41)
Biotite, Aberdeen, Scotland	0.8	(13)

Gabbro

Rice Pt., Duluth, Minn	1.9	(13)
Randauthal, Hanover	1.0	(4)

Lava

Niedermendig, Rhine	1.9	(6)
Fremont Co., Colo	0.7	(18)

Marble, Av. Range—0.8 to 1.5

Hematitic dolomite, Swanton, Vt	1.9	(21)
Coarse dolomite, Pleasantville, N. Y	1.6	(13)
Carbonaceous, Isle LaMotte, Vt	1.5	(21)
Dolomite, South Dover, N. Y	1.4	(21)
Dolomite, Lee, Mass	1.4	(21)

SHEARING STRENGTH

The shearing values given in this table were determined by three types of apparatus, one of which appears to give results which are too low, due to the fact that bending stresses are produced. The values determined by authority No. 41 are probably low for this reason.

RESISTANCE TO ABRASION ("HARDNESS") (19)

The hardness values were determined by subjecting cylindrical specimens 2.5 cm in diameter to the abrasive action of crushed and graded quartz which is fed upon a revolving steel disc. The coefficient of hardness equals $20 - (\frac{1}{3})w$, where w is the weight of specimen worn away by 1000 revolutions of the disc.

Steatite

New London, N. C	4

Impact Hardness ("Toughness") (19)

The toughness values were determined by subjecting cylindrical specimens 2.5 cm high by 2.5 cm diameter to the impact produced by the fall of a 2 kg hammer upon a steel plunger, the lower end of which is spherical and rests on the test piece. The weight is first dropped from a height of 1 cm which is increased 1 cm for each blow until the specimen breaks. The toughness is recorded as the height of the last hammer fall.

Berea grit, Amherst, Ohio	20.0	(21)
Coarse grit, Glenmont, Ohio	22.0	(21)

Gneiss

Two mica, Cresciano, Switzerland	2.5	(39)
Biotite, Castaneda, Switzerland	3.7	(39)
Muscovite, Osogna, Switzerland	4.4	(39)

Gabbro

Randauthal, Hanover	3.0	(12)

Breccia

Quartz, Mels, Switzerland	3.7	(39)

Diorite

Quartz, Pontresina, Switzerland	4.3	(39)

Serpentine

Peridotite, Hospenthal, Switzerland	6.0	(39)

Tuff

Calcareous, Oberdorf, Switzerland	17.0	(39)

Compressibility

$$\frac{1}{v}\frac{dv}{dP},\ \text{kg}^{-1} \times 10^{-6}$$

Example: For granite, the compressibility at a pressure of 2 000 kg cm^{-2} is 0.000 0021 or 0.000 21% per kg.

Granite	at 2 000 kg per sq. cm.	2.1	(44)
	at 10 000 kg per sq. cm.	1.8	(44)
Basalt	at 2 000 kg per sq. cm.	1.8	(44)
	at 10 000 kg per sq. cm.	1.5	(44)
Marble	at 2 000 kg per sq. cm.	1.4	(44)
	at 10 000 kg per sq. cm.	1.4	(44)
Limestone 0 to 12 000 kg per sq. cm			
Lithographic	at 75°C.	1.4	(7)
	at 30°C.	1.3	(7)
Diabase	at 2 000 kg per sq. cm.	1.2	(44)
	at 10 000 kg per sq. cm.	1.2	(44)

Thermal Expansion

$$\frac{1}{l}\frac{\Delta l}{\Delta t},\ \text{deg}^{-1}\ \text{C} \times 10^{-6}$$

Example: For Bedford limestone between 25 and 100°, 0.000 009 or 0.000 9% per °C.

200 to 300	12	(42)

SPECIFIC HEAT

The heat capacity of building stones, irrespective of type, varies within the rather narrow limits of 0.7–0.95 joule per g or 0.18–0.23 cal, per g or BTU per lb. for the dry stone. An occasional higher value, such as 0.28 cal per g for a serpentine from Cornwall, Eng., has been reported (17, 40).

CLAYS

H. RIES

LIST OF CLAYS AND THEIR INDEX NUMBERS

For properties, *v.* Figs. 1, 2, 3

Index No.	Type of clay	Index No.	Type of clay
1	Allophane	40	Laclede Christy raw flint clay
2	Atlas	41	Maryland flint clay
3	American ball clay	42	Ohio flint clay
4	Dorset ball clay	43	Semi-flint clay
5	English blue ball clay	44	Gibbsite
6	English white ball clay	45	Glass pot clay
7	Tennessee ball clay	46	Glenboig fire clay
8	Ayrshire bauxitic clay	47	Halifax clay
9	Bentonite	48	Halloysite
10	Refractory bond clay	49	Helmstadt clay
11	Brazil, Ind., clay	50	Kaolinite
12	Brick clay	51	Kaolin
13	Common brick clay	52	Albsheim kaolin
14	Face brick clay	53	Amberg kaolin
15	Paving brick clay	54	Australian kaolin
16	Plastic clay for No. 1 fire brick, Md.	55	Crude kaolin
17	Plastic clay for No. 2 fire brick, Md.	56	Eger kaolin
18	Bunzlau clay	57	Geisenheim kaolin
19	Cornwall china clay	58	Georgia kaolin
20	English china clay	59	Halle kaolin
21	Crucible clay	60	North Carolina kaolin
22	Czechoslovakia clay	61	St. Yrieix kaolin
23	Diaspore clay	62	Texas kaolin
24	English fire clay	63	Washed kaolin
25	Farnley fire clay	64	White sedimentary kaolin
26	Grossalmerode fire clay	65	Zettlitz kaolin
27	Halle Saxony fire clay	66	Lower Kittanning clay
28	Kittanning No. 2 fire	67	Lower Mercer clay
29	Lischwitz fire	68	Sagger clay
30	Löthian fire	69	Sewer pipe clay
31	Maryland fire	70	Aluminous shale
32	Meissen fire	71	Galesburg, Ill. shale
33	Ohio fire	72	Illinois shale
34	Ohio plastic fire	73	Ohio shale
35	Vallendar fire	74	Stoneware clay
36	Flint clay for No. 1 fire brick, Ky.	75	Cleveland surface clay
37	Flint clay for No. 1 fire brick, Md.	76	Georgia surface clay
		77	Ohio surface clay
38	Flint clay for No. 2 fire brick, Md.	78	Tionesta clay
		79	Velten clay
39	Flint clay for No. 1 fire brick, Md. and Ky.	80	Plastic fire clay
		81	Flint clay

EFFECT OF FIRING ON TRANSVERSE STRENGTH OF CLAY (10)

Clay	*	Modulus of rupture			
		Dried at 110°C, lb. in.$^{-2}$	Fired clay, hundred lb./in.^{2}		
			Cone 6	Cone 8	Cone 10
Tionesta clay: Ellis, Muskingum County, Ohio.	R	390	46	67	38
	W	468	72	83	53
Tionesta clay: Crooksville, Perry County, Ohio.	R	179	20	30	20
	W	315	66	71	37
Lower Kittanning clay (unweathered): Roseville, Muskingum County, Ohio.	R	219	32	34	27
	W	320	86	87	75
Lower Kittanning clay: Toronto, Jefferson Co., Ohio.	R	384	28	23	23
	W	532	79	48	57
New Brighton, Beaver County, Pa.	R	194	29	31	19
	W	191	49	58	34
New Brighton, Beaver County, Pa.	R	195	26	33	15
	W	321	51	52	47
Fire brick, Lawrence County, Ohio.	R	325	41	51	30
	W	499	104	72	62
Nelsonville, Hocking County, Ohio.	R	247	16	35	20
	W	350	47	62	50
Lower Mercer clay: White Cottage, Muskingum County, Ohio.	R	132	30	32	17
	W	251	57	73	47
Mogadore, Summit County, Ohio.	R	143	20	23	22
	W	259	46	48	34
Semi-flint clay: Scioto Furnace, Scioto County, Ohio.	R	94	16	21	20
	W	270	37	74	27

* R indicates run of mine, ground to pass a 20 mesh sieve. W indicates washed clay passing a 150 mesh sieve.

HEAVY CLAY PRODUCTS

H. G. Schurecht

1. CLAY BRICK: SPECIFICATIONS AND PROPERTIES

True specific gravity, 2.4–2.6 (7).
Specific heat, 20–100°C, 0.20–0.25 cal g^{-1} $deg.^{-1}C$ (1)

	Bulk density, g/cm³	Water absorption, %	Compressive strength, kg/cm²	Crossbreaking strength, modulus of rupture, kg/cm²
Vitrified brick	2.0–2.2	<5	281 to 351	56 to 84
Hard brick	1.9–2.1	5–12	175 to 281	28 to 56
Medium brick*	1.8–2.0	12–20	105 to 176	21 to 28
Soft brick	1.7–1.9	>20	56 to 105	14 to 21
Paving brick†	1.7–2.2	0.9–8.0	227 to 592	84 to 178

* Thermal conductivity = 1.6 kg-cal m^{-2} hr^{-1} $(°C, m^{-1})^{-1}$ (7), *see also* p. 314).

† Rattler loss, 22–26 % (1).

2. SAND-LIME BRICK

Compressive Strength of Sand-lime Brick Walls (9)

Walls 1.83 m long and 2.74 m high

Wall No.	Thickness, cm	Mortar	Compressive strength, kg/cm²	
			First crack	Failure
1	21.3	Lime	15.3	22.2
2	33.5	Lime	14.1	20.4
3	21.1	Cement-lime	34.0	47.8
4	33.2	Cement-lime	38.7	39.7
5	21.3	Cement	50.4	67.5

I. ELECTRICAL PORCELAIN

FRANK H. RIDDLE[1]

Classification of Porcelains Based on Their Use

I. Normal porcelains.
  (*A*) Low tension porcelain, porosity, 1%.
    Dry or wet process used under 5000 volts. Flint, clay, feldspar porcelain.
  (*B*) High tension porcelain, porosity, 0%.
    Wet process used above 5000 volts. Flint, clay, feldspar porcelains.
II. Special porcelains.
  (*C*) Spark plug core porcelains, porosity, 0%.
    Usually free from free quartz which has objectionable expansion and alkalis which have an injurious effect upon the insulation at increased temperatures.
  (*D*) Heating element porcelains, porosity, 1%.
    Usually containing over 50% magnesia compounds.
  (*E*) Thermocouple porcelains for protection.
    High in alumina and free from free quartz.

Practically nothing is available in the literature regarding low tension porcelain or heating element porcelain.

Petrographic Character of Insulator Porcelains

A comparative petrographic study of a number of insulator porcelains of American, French and German manufacture leads to the following conclusion.

A good porcelain insulator made from clay, feldspar and flint should consist largely of a glassy matrix with embedded crystals of quartz and mullite ($3Al_2O_3.2SiO_2$) evenly distributed throughout. The quartz should not exceed 20 to 25%, preferably less, and the fragments should have rounded edges and corners, as indicating partial solution by the feldspar glassy matrix. The average grain size of the quartz should not exceed 0.03 to 0.04 mm diameter, and the particles should be evenly distributed. No clay or partially decomposed clay particles should be present. The crystals of mullite should be abundant, well-formed, evenly distributed, and should not exceed *ca.* 0.01 mm length by 0.002 mm thickness.

Owing to the very close resemblance between mullite and sillimanite crystals, the following crystallographic characterization is given (9, 70).

	Mullite $3Al_2O_3.2SiO_2$	Sillimanite $Al_2O_3.SiO_2$
Crystal system	Orthorhombic	Orthorhombic
Prism angle, $110 \wedge 1\bar{1}0$	89° 13′	88° 15′
Cleavage	∥ 010	∥ 010
Optic orientation	$\acute{c} = \gamma$ and $a = \alpha$	$\acute{c} = \gamma$ and $a = \alpha$
Refractive indices γ	1.654	1.677
Refractive indices α	1.642	1.657
Axial angle, $2V$	+45°, −50°	+25°, −30°

BULK DENSITY, SPECIFIC GRAVITY AND POROSITY

1. Typical electrical porcelains for high-tension work

Specific gravity	Bulk density, g/cm³	Open-pore porosity, %	Total porosity, %	Type	Lit.

122	Marquardt	7½ × 2 cm	(53)
98	Insulator	7½ × 2 cm	(45)

* The area of the cross section of the test piece is important, *see* Fig. 5.

† Batch weights and chemical compositions of these bodies are shown under Ref. Nos. 1–7.

ILLUSTRATING THE INFLUENCE OF THE GLAZE

All pieces made of the same body and all burned together (40); *see also* especially (21.1)

kg/cm²	623	720	642	305
Type	No glaze	Best glaze	Good glaze	Crazed glaze

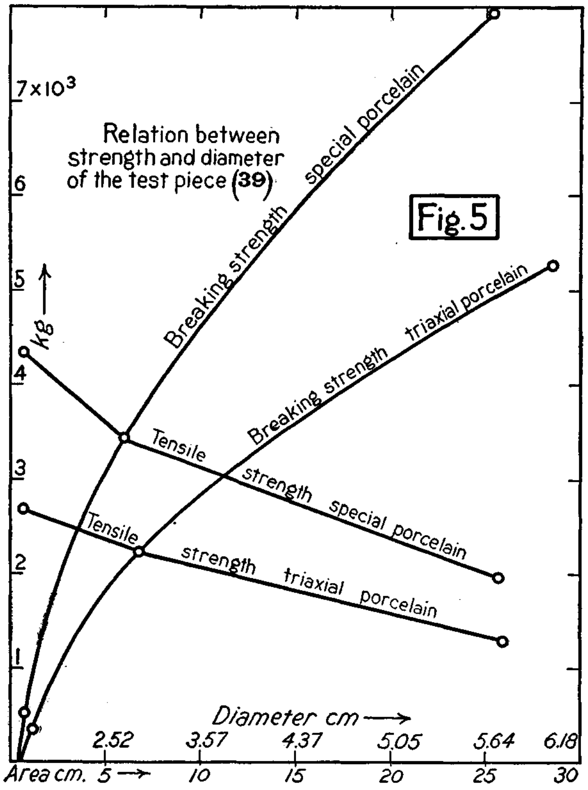
Compare the tensile and crushing strengths of American and German bodies. The German bodies have a greater crushing strength, the American bodies a greater tensile strength.

Modulus of Rupture*

kg/cm²	Type	Lit.	kg/cm²	Type	Lit.
590	Insulator......	(45)	500		(49)
580	DTS sill. Z55..	(53)	490	Hermsdorf.....	(46)
595–469	Average of 7 elec.†........	(38)	416	DTS sill. Z54..	(53)
560–420		(19)	246	Marquardt....	(53)
540	Insulator H...	(46)			

* Extruded cyl. pieces 120 mm long, and 16 mm diam., burned hanging in vertical position and sawed to length. Supported on steel knife edges 10 cm apart and loaded centrally, 1 kg per sec.

† For compositions *see* Ref. Nos. 1–7, inclusive. For effect of glaze *see* (21.1).



Crushing Strength

Unit is 1000 kg/cm²

Strength	Type	Remarks	Lit.
5.8*	DTS sill....................		(53)
≯5.6*	Hermsdorf....................		(53)
≯5.0*	Rosenthal H................	2.11 cm²	(46)
4.8–4.2	Hermsdorf....................	16 × 16 mm	(56)
4.5	Insulator.....................		(45)
4.2	Berlin hard...................	2.5 cm cubes	(42)
4.0	Sill. average of 7.............	4.90 cm²	(39)
4.0†	Insulator.....................		(56)
2.5†	Insulator average of 3.........	2.54 cm diam.	(38)
1.6–1.8‡	....	6 × 3 cm	(8)
1.0	Marquardt....................		(53)
4.2–3.1§	Elec. various..................	Cyl. 3.14 cm²	(44)

* The higher values are probably due to the use of cylindrical test pieces instead of square ones. In 1920 the German committee appointed to arrange standard tests decided on a test piece 16 × 16 mm diameter. According to Demuth (15) test pieces smaller than 50 × 50 mm are too small and the high results obtained are misleading.

† For compositions *see* Ref. Nos. 4, 5 and 7.

‡ The higher value is for glazed, the lower for unglazed.

§ For compositions *see* Ref. Nos. 8–11.

Crushing Strength between Spheres* (53)

kg	982	792	748
Type..........	DTS sill. Z55	DTS sill. Z54	Marquardt

* The Gary press (43) used for this test holds a piece 1 cm thick and 10 cm wide between steel balls 31.7 mm in diameter, through which the pressure is applied. Results calculated to correspond to a disc 1 mm thick.

Modulus of Elasticity (Def. 10)

The unit is 1000 kg/mm²

Modulus	Type	Remarks	Lit.
10.6	"G. E."..................	Bending	(10)
10.2	"G. E."..................	Tensile (*v.* Fig. 1)	(10)

6.3	Hermsdorf 1921...........	End support	(56)
5.2	Westinghouse.............	Bending 19 mm rod	(20)

* With varying loads this value varied from 8.4 to 17.9 with the same test pieces and under uniform conditions. Tests made by Steger's method (59).

The modulus is dependent more upon the conditions of manufacture than upon chemical composition. It is substantially the same for tension and compression. For G. E. porcelain Boyd (10) found the following relations: $D = 0.133L$ for compression; $D = 0.133L$ for bending; $D = 0.143L$ for tension; where D = deformation in 0.00001ths. and L = load in kg-cm⁻².

Rattler Tests (38)

TOUGHNESS AND HARDNESS BY THE "RATTLER" TEST*

Per cent loss of weight by rattler test (38).

15 min	30 min	3 hr	Type
2.2	3.5	10.6	1, Fig. 6
3.2	5.2	14.4	2, Fig. 6
4.4	8.8	21.6	3, Fig. 6
8.0	14.5	27.4	4, Fig. 6
5.1	9.6	23.6	5, Fig. 6
7.8	12.2	29.6	6, Fig. 6
10.2	14.2	33.6	7, Fig. 6

* The 15 min test is an indication of the toughness or resistance to chipping. The 3 hr test is an indication of hardness after edges and corners are gone.
Ratio: Marquardt to DTS sill. Z54, is 2.6, time not stated (53).

With a constant clay content the higher spar and lower flint body is invariably weaker. Increase in clay and decrease in flint decreases strength. The compositions of the bodies are plotted on the triaxial diagram, Fig. 6. Note the relation between loss in wt. and body composition.

Tests were carried out under the following conditions: 13 test pieces 2.25 × 2.25 × 5.0 cm with square edges. Tested in porcelain jar mills 24.75 cm diam. × 33 cm long inside rotating at 40 r.p.m. Besides the test pieces there were 61 pebbles weighing 10 kg. The test pieces were removed and weighed at the time specified.

Resistance to Thermal Shock

The recorded data are not comparable owing to lack of standard methods *v.* (8, 54, 66, 29). The *relative* heat shock strengths of a series of electrical porcelains covering the whole range of compositions is shown in Fig. 4 (22). Substitution of ZrO_2 for SiO_2 improves the resistance to thermal shock (60, 69). "Sillimanite" (mullite) porcelains have a greater resistance than ordinary kinds.

VOLUME RESISTIVITY

Temp., °C	Sp. resist. Megohm-cm	Type	Lit.
613–900	0.068–1.098		(33)
727	0.007	Berlin	(17)
727–1292	0.100–0.0034		(33)

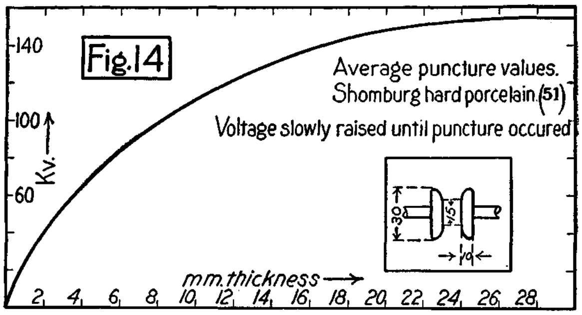

Fig.14

Average puncture values. Shomburg hard porcelain (51)

Voltage slowly raised until puncture occured

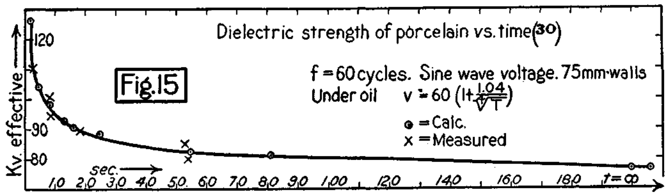

Fig.15

Dielectric strength of porcelain vs. time (30)

f = 60 cycles. Sine wave voltage. 75 mm walls Under oil $v \doteq 60\left(1+\frac{1.04}{\sqrt{T}}\right)$

2. 25°C under oil, 12.7 mm electrodes with rounded edges, voltage increased 1 kv per sec

9 100	Ref. No. 16......	Test piece 6.35 mm to 9.14 mm. 60 cycle sine-wave voltage	(3)
9 400	Ref. No. 17......		(3)
10 600	Ref. No. 18......		(3)
8 400	Ref. No. 19......		(3)

According to Peek (31) the puncture tests on solid insulators vary greatly between different samples of the same material, shape and area of the electrodes, time of application of voltage, etc.; *see* Figs. 12–16.

DIELECTRIC LOSSES

For variation of dielectric losses and power factor with frequency, *see* (25).

FLASH-OVER VOLTAGE

Effect of humidity, Fig. 18.
Effect of length of test piece, Fig. 17.

ELECTROLYSIS OF HOT PORCELAIN

Above 300° porcelain behaves as an electrolytic conductor, the alkali metals migrating toward the cathode. For experimental details, results and conclusions, *v.* Haber (23).

VELOCITY OF SOUND

Velocity km/sec	Type	Lit.	Velocity km/sec	Type	Lit.
5.63	Insulator H	(46)	5.05	Hermsdorf hard	(46)
5.34	Seger 6833	(46)	4.9–5.2	In general	(56)

Velocity of transmission, or vibration of sound, varies with the modulus of elasticity. Porcelains having the highest velocity are the best. Velocity increases with increasing clay content.

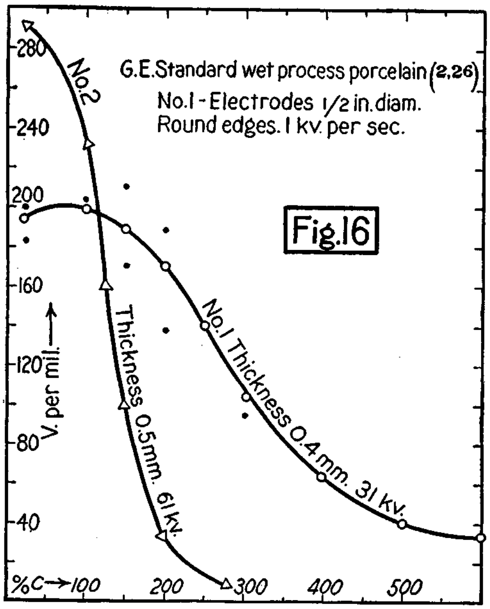

Fig.16

II. LABORATORY PORCELAINS AND WHITEWARES

JAMES A. AUDLEY[1]

A Classification of Porcelains and Whitewares Based on Their Composition and Properties

I. Body vitrified Little or no porosity.
  (*A*) Porcelain. More or less translucent.
    1. Hard porcelain.
      Body and glaze fired up together to a comparatively high temperature, with or without a previous low fire biscuiting. Glaze composition approximating that of the body, but with lime and often zinc oxide added.
    2. Soft porcelain.
      (*a*) Seger porcelain.
      (*b*) Frit porcelain.
      (*c*) Bone porcelain.
      (*d*) Belleek.
      (*e*) Parian (biscuit or figure porcelain).
  (*B*) Stoneware. Not translucent.
II. Body not completely vitrified, porous.
  (*C*) General whiteware (earthenware).
    This includes a variety of wares which pass under different trade names (semi-porcelain, white granite, etc.), but almost imperceptibly grade into one another, and into porcelain at one extreme.

Examples illustrating composition are given further on.

Wall tiles and floor tiles may be of porcelain, stoneware, or earthenware. They are made chiefly by the dry press process.

Electrical porcelain possesses properties which give it a distinct value for certain technical purposes, so that it is impracticable to draw any hard and fast lines between it and some other porcelains. For electrical porcelains proper, *v.* p. 67.

Chemical Composition of Fired Body and Batch Composition of Raw Body

For composition limits assigned to the various types of porcelain and whiteware, *v.* the standard works such as those of Seger, Kerl, Bourry, Granger, etc., and special works such as (**82, 99, 119**).

The actual compositions of some of the bodies whose properties are listed in the following pages are appended hereto, together with the reference numbers by which they are identified in the subsequent pages.

BODY COMPOSITION, WT. %

Petrographic Character of Laboratory Porcelains and Whiteware

The petrographic character of a ceramic body made from clay, feldspar, and flint varies according to the proportions of the component materials and also with the method of preparation (involving physical conditions) and conditions of firing. In porcelains wide variations occur in the relative amounts of glassy matrix, undissolved quartz (or cristobalite), undecomposed or undissolved clay, and mullite ($3Al_2O_3.2SiO_2$). The mullite was for a long time regarded as sillimanite ($Al_2O_3.SiO_2$), discrimination being difficult owing to the close resemblance, *v.* p. 68.

A good porcelain of the kind indicated should consist largely of a feldspathic glassy matrix with embedded crystals of quartz and mullite distributed evenly, but no visible particles of clay. The quartz should not exceed 20, or at most 25 % and the average size of its particles should not exceed 0.03 to 0.04 mm diameter, all edges and corners being rounded off through partial solution in the matrix. The crystals of mullite should be numerous and well formed, and should not exceed *ca.* 0.01 mm in length and 0.002 mm in thickness. Porcelains answering to this description can be produced only at a comparatively high firing temperature. With lower temperatures smaller proportions of glassy matrix and mullite crystals are produced, the proportions diminishing gradually until the crystals cease to be formed and the amount of glassy matrix becomes relatively insignificant, and the product is no longer porcelain but simply white earthenware.

For the microscopic characters of thin sections of porcelains and whitewares, *see* (56, 57, 67, 68, 69, 79, 90, 91, 92, 108, 150, 158, 159).

233	Faience body 135	(119)
416	Fine stoneware, DTS sill. 54	(119)
580	Fine stoneware, DTS sill. 55	(119)
980	Special trial stoneware 6412	(113, 119, 123)

Extruded cylindrical rods 16 mm diameter are fired hanging vertically, and sawn to 120 mm lengths. Loaded centrally, between steel knife edge supports, 1 kg/sec.

* Values for firings at cones 01a and 4a are also given in this paper.

TENSILE STRENGTH (DEF. 4)

kg/cm^2	Type	Cross section,* cm^2	Lit.
1000–2000	Hard porcelain		(29)
280–363	Berlin technical porcelain	2.5 –2.9	(107, 108, 121)
161–265	7 commercial hard porcelains (other than Berlin)	2.8 –3.9	(107, 108, 119)
≯360	Hermsdorf porcelain		(119)
360–420	Hermsdorf porcelain	3.14	(35)
ca. 261	Rosenthal insulator porcelain H		(113, 123)
500	Chinese porcelain		(119)
106–887	American porcelain		(119)
258–396	19 trial porcelains, cone 15, Ref. No. 7–25		(106)
180–240	Soft porcelain, cone 8–9	3.50–3.63	(33)
184–283	Soft porcelain, cone 8–9	2.76–3.40	(33)
84–191†	10 trial porcelains fired to vitrification, cone 7–10, Ref. No. 40–49	*ca.* 3.2	(144)
108–185	6 trial earthenwares fired at cone 8, Ref. No. 166–171‡		(88, 89)
44–80	6 trial earthenwares fired at cone 8–9, Ref. No. 159–164‡		(42)
118	Special hard earthenware 237		(119)
67	Faience body 135		(119)
178	Fine stoneware DTS sill. 54		(119)
163	Fine stoneware DTS sill. 55		(119)

* The area of the cross section of the test piece is important. On comparing the tensile and crushing strengths of German and American porcelains, it may be noted that, in general, the former have greater crushing strength and the latter greater tensile strength.

† The respective values in order of the composition Ref. No. 40–49 are 125.8, 126.5, 126.5, 109.7, 123, 83.7, 92.1, 126.5, 191.2, and 141.3.

‡ Values for firings at cones 01a and 4a are also given in this paper. For other measurements of tensile strengths of trial bodies, *v.* (145). For influence of glaze, *v.* p. 68.

CRUSHING STRENGTH
Unit = 1000 $kg./cm^2$

Strength	Type	Remarks	Lit.
4–5	Hard porcelain		(14, 15, 113, 119)
4.2	Hard porcelain		(112, 123)
ca. 4.2	Berlin technical porcelain	2.5 cm cubes, determined by Rosenthal	(103)
≯5.6	Hermsdorf porcelain		(32, 119, 123)
4.8	Hermsdorf porcelain		(32, 113)
4.5 –5.5	Hermsdorf porcelain	16 mm diam., 16 mm long	(35)
2.8 –4.6	American porcelain		(119)
7.43	Porcelain 152		(119)
2.7 –4.2	8 trial porcelains, cone 16, Ref. No. 26–33*	2 cm diam. cylinders (with 3.14 cm^2 cross section)	(112)
2.7 –4.0	7 trial porcelains, cone 11		(94)
2.8 –4.5	6 American commercial porcelains, cone 11	Cylinders *ca.* 3.1 cm when just formed	(157)
0.04–0.08	6 trial earthenwares, cone 8†, Ref. No. 166–171		(88, 89)
5.8	Fine stoneware, DTS sill. 55		(119)

The higher values (5 and over) are probably due to the use of cylindrical instead of square test pieces. In 1920 the German Committee specified test pieces 16 mm diameter and 16 mm long.

* Highest value given by body with 55 % Zettlitz kaolin and 22.5 % each of quartz sand and feldspar. Only a little inferior were the values for bodies having 15 % feldspar and 30 % quartz, and 30 % feldspar and 15 % quartz, respectively.

† Value for firings at cones 01a and 4a are also given in this paper.

CRUSHING STRENGTH BETWEEN SPHERES*

kg	Type	Lit.
118–152	Berlin technical porcelain	(107, 108, 119)
76–137	7 commercial hard porcelains (other than Berlin)	(107, 108, 119)
50–94	19 trial porcelains fired at cone 15, Ref. No. 7 to 25	(106)
96 (90 – 99)	Trial soft porcelain	(33)
526	Faience body 135	(119)
792	Fine stoneware, DTS sill. 54	(119)
982	Fine stoneware, DTS sill. 55	(119)

* Gary press, *v.* p. 69 (34, 107, 108). The last three values are those of the breaking load—as are some of the others given in (119) and elsewhere—and are about 10 times as large as they should be. Unfortunately, the details are not available.

MODULUS OF ELASTICITY (DEF. 10)
The unit is 1000 kg/mm^2

Modulus	Type	Remarks	Lit.
5.4–7.1	Hermsdorf porcelain		(29, 32, 123)
7–8	Hermsdorf porcelain		(119)
8.7–7.4	Hermsdorf porcelain		(35)
8.2–8.4	Berlin technical porcelain	Bending. Av. of 72 tests	(107, 121, 123, 131)
7.1	Sèvres hard porcelain	Fired at 1370°	(62, 63)
6.7	Sèvres new porcelain	Fired at 1270°	(62, 63)
5.0	Sèvres soft porcelain	Fired at 1100°	(62, 63)
2.5	Sèvres stoneware	Fired at 1270°	(62, 63)
3.7	Fine faience	Fired at 1270°	(62, 63)

MODULUS OF ELASTICITY (DEF. 10).—(*Continued*)

Modulus	Type	Remarks	Lit.
8.4	Rosenthal insulator porcelain G and H	Bending	(123)
7.8	Rosenthal insulator porcelain G and H	Bending	(119)
9.1	Rosenthal table porcelain	Bending	(123)
8.1	Rosenthal table porcelain	Bending	(119)
8.6	Rosenthal trial porcelain 6292	Bending	(123)
14.9	Rosenthal trial stoneware 6412	Bending	(123)
8.9	Rosenthal laboratory porcelain		(119)
6.8	Rosenthal Seger porcelain 6833		(119)
6.5	Chinese porcelain		(119)
2.4	Faience body 135		(119)
5.1	Fine stoneware DTS sill. 54		(119)
6.5	Fine stoneware DTS sill. 55		(119)
151	Trial stoneware 6412		(119)

The value of the modulus changes (usually inversely) with the load. It depends less upon chemical composition than upon conditions of manufacture. It is substantially the same for tension and compression.

MODULUS OF ELASTICITY IN SHEAR (DEF. 11)

kg/cm²	Type	Lit.
430	Trial Seger porcelain Body 6833 (Rosenthal)*	(113)
481	Rosenthal insulator Body G	(113, 119)
500	Rosenthal insulator Body H	(113, 119)
500	Rosenthal laboratory porcelain	(113, 119)
480–600	Hermsdorf porcelain	(119)
226	Fine stoneware 238	(119)
323	Fine stoneware DTS sill. 54	(119)
169	Faience Body 135	(119)
232	Special hard earthenware 237	(119)
246	Special body 240	(119)

* Square cross section.

FIXED IMPACT AND BENDING SHOCK (DEF. 16)

Pendulum-hammer method (34, 108, 119)

cm-kg/cm²	Type	Lit.
2.0	Berlin technical porcelain	(107, 108, 119, 121)
1.75–1.95	7 commercial porcelains (other than Berlin)	(107, 108, 119)
1.9	Hermsdorf porcelain	(119)
1.9–2.3	Hermsdorf porcelain	(35)
0.90	Rosenthal insulator porcelain G	(113, 119, 123)
0.95	Rosenthal insulator porcelain H	(113, 119, 123)
1.36	Rosenthal table porcelain	(113, 119, 123)
1.23	Rosenthal laboratory porcelain	(113, 119, 123)
0.08	Rosenthal trial hard porcelain 6292 (copied from American insulator porcelain body)	(113, 119, 123)
1.0	Rosenthal Seger porcelain 6833	(113, 119, 123)
2.4	Rosenthal trial porcelain 6412	(113, 119, 123)
1.61*	Rosenthal trial porcelain 6048	(113, 123)
1.76–1.95	19 trial porcelains fired at cone 15, Ref. Nos. 7–25	(106)
1.23–1.8	8 trial porcelains, Ref. No. 15 considered the best	(138)
1.68–1.92	Soft porcelain, cone 8–9	(33)
1.6	Faience body 135	(119)
2.0	Hard earthenware 236	(119)
1.5	Hard earthenware 237	(119)
1.7	Earthenware 240	(119)
1.7	Fine stoneware 238	(119)
1.8	Fine stoneware DTS sill. 54	(119)
1.7	Fine stoneware DTS sill. 55	(119)
1.3–1.9	Stonewares Z58, Z59, Z60, Z61	(121)

* In (123) this value is given as 1.38, but the 1.61 occurs twice in (113).

See also (125) for a different impact test.

SUCCESSIVE INCREASING IMPACT SHOCKS

Marten's method

112 cm × kg/cm³ for a table porcelain (113); *see also* p. 70

RESISTANCE TO ABRASION*

Gary sand blast test, 2 min at 3 atm

Type	Loss in cm³	Lit.
Stoneware 6412 (Rosenthal)	1.7	(113, 123)
Faience body 135	7.2	(119)
Special hard earthenware 236	5.8	(119)
Special hard earthenware 237	5.9	(119)
Fine stoneware 238	2.4	(119)

* In (123, p. 57) Singer quotes from (32) results for hardness obtained by Linck with the use of the sclerometer, and the corresponding values according to the hardness scale of Mohs, as follows:

	Sclerometer number	Number in Mohs scale
Easy baked porcelain	10–12	2
Hard baked porcelain	22–25	2.5
Porcelain fired to maturity, unglazed	550–650	7
Surface layer of glaze	950–1000	8
Glaze below the surface	350–400	6.3

TOUGHNESS AND HARDNESS BY THE RATTLER TEST

4.03	7.43	69	(77)				

% loss of weight by rattler test			Type (94)	% loss of weight by rattler test			Type (94)
15 min	30 min	180 min	Ref. No.	15 min	30 min	180 min	Ref. No.
4.67	6.38	11.25	136	3.66	5.20	10.70	140
4.09	5.60	11.40	137	3.60	5.15	9.80	141
4.47	5.98	12.80	138	3.05	4.12	10.30	142
2.95	4.60	9.42	139				

The 15 min test serves to indicate the toughness or resistance to chipping.

The 180 min test indicates hardness after edges and corners have been removed.

These rattler tests were made in a ball mill 9¾ in. diameter and 13 in. long inside, making 40 revolutions per minute. The charge consisted of 61 nearly equal pebbles, weighing 22¾ lb. For each test 13 specimens of porcelain were used, which were weighed at the proper time intervals. For a standard test it is suggested that 10 kg of pebbles might be used along with 12 specimens. The above results of tests are comparable, as the same conditions were maintained throughout.

Further data relating to the rattler test with trial bodies will be found in (53, 65, 128, 145).

Softening Point and Cone Melting Point

°C	Type and remarks	Lit.
1500	Normal	(122)
1700	Special	(122)
1710	Rosenthal porcelain melts	(119, 120, 123)
1390	Japanese table porcelain, Ref. No. 133	(134)
1690	Porcelain, Ref. No. 134 melts	(90)
1670	Porcelain, Ref. No. 135 melts	(90)
	Berlin porcelain	
900–1000	Appreciable softening begins	(103, 123)
ca. 1680	Melting takes place	(103, 119, 123)
ca. 950	Berlin glaze softens	(103, 123)
Cone		
25	Berlin porcelain begins to deform	(72)
25	Ref. No. 58 begins to deform	(72)

Softening point varies with size and shape of test piece and also with time of heating, etc.

In spite of the softening of Berlin porcelain, perceptible far below 1000°C according to Rieke (103, 123), porcelain tubes, crucibles, etc., if suitably protected and not too severely loaded, can be safely used at temperatures up to 1400° or even higher. For Rosenthal porcelain it is claimed that when very strongly heated it can be worked like glass to make laboratory apparatus, *see* (120).

Rosenthal (112) heated one side of thick rods of different hard porcelains in an electric arc-light. He found that bodies rich in feldspar immediately split off in numerous small pieces, bodies rich in quartz and clay substance cracked off more slowly and in larger pieces, whilst specially resistant bodies merely melted at the heated places.

Coefficient of Thermal Expansion

$\frac{10^6\Delta l}{l\Delta t}$	Type	Range °C	Lit.
3.43	Berlin technical porcelain, unglazed.	23–200	(29, 101, 102, 103, 119)
3.53		23–400	(101, 102, 103, 119)

For other values for Berlin porcelain, *v.* (119, p. 428). For expansion coefficients of bodies with calcined clay replaced by sillimanite (mullite) or other special component, *v.* p. 70, and also (93, 127).

[†] Chantepie records results obtained with these two bodies fired at 1370°, and also at 1000° in the case of the former; also with bodies obtained by admixture of considerable percentages of iron oxide, feldspar, or chalk respectively with the former, and of lime or magnesia respectively with the latter. Coefficients for the range 200°–400° are also given in (127). Other thermal expansion coefficients, mainly of trial bodies, will be found in (84, 85, 146, 149). For coefficients of thermal expansion of glazes, *v.* (20, 21, 25, 26, 109).

HEAT CAPACITY (SPECIFIC HEAT)

g-cal/g°C	Range	Type	Cone	Lit.	g-cal/g°C	Range	Type	Cone	Lit.
0.258	15–912	Porcelain		(40)	0.212	20–200	Marquardt body	15	(130)
0.256	15–958	Porcelain		(40)	0.229	20–400	Marquardt body	15	(130)
0.254	15–1075	Porcelain		(40)	0.190		Porcelain, Japanese table		(134)[*]
0.202	20–210	Porcelain, Berlin technical	15	(103, 130)	0.17		Porcelain, hard		(32)
0.221	20–400	Porcelain, Berlin technical	15	(103, 130)	0.25		Porcelain, Rosenthal		(123, 130)[†]
0.212	20–200	Marquardt body	09	(130)	0.2		Porcelain, Hermsdorf		(119)
0.229	20–400	Marquardt body	09	(130)	0.185–0.187	17–100	Stonewares		(121)

[*] A "brown porcelain" (Japanese) used for making bottles with specific heat reported as 0.171, is evidently a stoneware.

[†] According to Dolazalek, the heat capacity per cm^3 is 0.575, the specific gravity being 2.3.

AVERAGE SPECIFIC HEAT IN MEAN CALORIES BETWEEN 20°C AND

5.48	563.2	14.1	278.3
8.08	320.7	19.2	40.30
10.9	150.0	23.8	13.78
15.3	39.40	27.3	3.822
19.0	19.32		

SURFACE RESISTIVITY

This varies enormously with humidity of the atmosphere and with the nature of the surface of the film, *see* (**29, 119**).

DIELECTRIC CONSTANT

Dielectric constant	Type	Remarks	Lit.
5.73	Berlin hard porcelain	Ref. No. 6 for composition, sp. gr., 2.38	(129, 103, 119)
6.61	Berlin Seger porcelain	Ref. No. 34, fired at cone 9, sp. gr., 2.40	(103, 129)
6.84	Berlin figure porcelain	Ref. No. 35, sp. gr., 2.41	(103, 129)
4.5–5.3	Hermsdorf porcelain		(29, 32)
5–6	Hermsdorf porcelain		(119)
5.8	Hard porcelain	Ref. No. 16, same value whether potash feldspar or soda feldspar used	(37, 114)
4.38	Baked porcelain*	"Doit être un peu fort"	(23)
8.95	Hermsdorf porcelain at 20°C		(43, 44)
5.17	Fine stoneware, DTS sill. 55		(119)

---

* Dietrich found no essential difference between glazed and unglazed porcelain.

* The value is low probably because the test piece was "une plaque de porcelaine dégourdie" or product of the low biscuit firing, and therefore would be very porous.

DIELECTRIC STRENGTH

1. Shape of the electrodes not specified (except in (112)). Voltage increased 0.5 kv per sec, starting at 20 kv under oil (138)

Volts per mm	Type	Remarks	Lit.
13 200	Ref. No. 26	Test pieces, 10 cm in diam. and about 2.5 mm thick, with rounded edges, under oil. Fired at cone 16	(112)
13 800	Ref. No. 27		
14 000	Ref. No. 28		
13 200	Ref. No. 29

16 400	100			
6 950	200			
1 310	300			
13 550		Composition 59% mixed clays, 18% flint, 23% feldspar	Fired quickly to cone 10; cooled slowly	(86)
13 470			Fired quickly to cone 13; cooled to cone 02 in. one hour; then slowly	
14 660			Fired quickly to cone 10; then slowly to cone 12; quickly to cone 17; cooled slowly	
12 850			Fired quickly to cone 10; then slowly to cone 13 and fired 20 hr; cooled quickly to cone 2 and then slowly	
13 560		Composition as above but with soda-feldspar instead of potash-feldspar	Fired like the foregoing Other bodies of different compositions gave similar results	(86)
14 820				
14 100				
13 860				

EFFECT OF TEMPERATURE AND OF DIFFERENT FIRING TEMPERATURES.—(*Continued*)

Volts per mm	Temp.	Type	Remarks	Lit.
25 400	14	Ref. No. 42	Test pieces were the cups described above	(144)
18 000	104			
5 030	150			
1 620	213			
1 020	248			
1 040	310*			
520	325*			

* After prolonged application of pressure. Two curves are given (30) showing the current-time effects of the application of a potential of 584 volts (from a storage battery) to porcelain test-pieces heated to 530°. For other tests of dielectric strength of various trial bodies refer to (6, 71, 145).

VELOCITY OF SOUND

Velocity km/sec	Type	Lit.	Velocity km/sec	Type	Lit.
5.93	Rosenthal laboratory porcelain	(113, 123)	4.9–5.2	Porcelain in general	(32, 113, 123)
6.68	Rosenthal special trial porcelain 6048	(113, 123)	3.6	Bad porcelain	(32, 113, 123)
5.05	Hermsdorf hard porcelain	(29, 113)			

The velocity of transmission of sound vibrations depends on the modulus of elasticity of the material. Hence the tone given by porcelain when struck is a function of the velocity of sound, and from such tones may be obtained indications of the quality of the porcelain.

TRANSLUCENCY OF PORCELAIN

For methods and results, *v.* (**65, 74, 77, 81, 133, 151**).

Carbon			1.5–5.5			(84, 48)
Graphite	7.8(40–25°C)					(48)

For mean coefficient between any two temperatures, $\alpha_m = \frac{\alpha_{t_1}(t_1 - 25) - \alpha_{t_2}(t_2 - 25)}{t_1 - t_2}$, where α_{t_1} and α_{t_2} may be taken from a graph.

EXPANSION AND CONTRACTION DURING HEATING

The data given in Figs. 1–4 and in the table below record the % changes in length undergone by 1 × 1 × 9 in. test bars when heated in a gas fired muffle furnace with neutral atmosphere at the rate of 100°C per hour. Specimens marked "brick" are commercial products. For compositions of these and methods of preparing all specimens, *v.* the original (⁸⁸).

† Beginning of shrinkage or expansion.

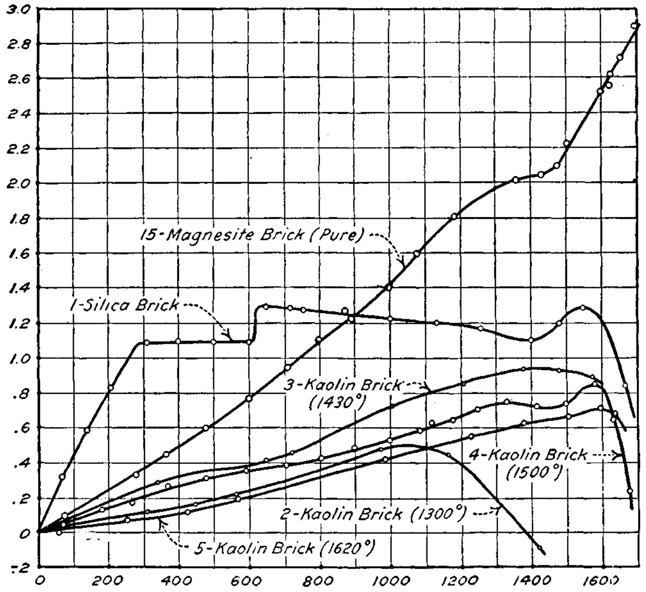

FIG. 1.

Figure 5 shows a comparison of the expansion of German and American silica brick. Curves 1, 2 and 3 are for American silica brick (measurements reported by the National Bureau of Standards); Curves I, II and III, for German silica brick (measurements by Endell and Steger, *Glastech. Ber.*, **4**; May, 1926).

ABRASIVE MATERIALS

M. L. HARTMANN

COMMON AND TRADE NAMES

IND. NO.

1. Aluminium oxide (fused, impure) ("aloxite," "alundum," "lionite," "borolon," "alumo"). Al_2O_3
2. Corundum. Al_2O_3
3. Diatomaceous earth (infusorial earth, kieselguhr, fossil flour, fossil meal, tripolite, diatomite, polerschiefer, desmid earth, molera, white peat, tellurine, randanite, ceyssatite, bergmehl, radiolarian earth). SiO_2
4. Emery.
5. Flint. SiO_2
6. Garnet (almandite, rhodolite).
7. Glass (alkali lime).
8. Pumice (pumicite, santorini, santorine earth).
9. Silicon carbide ("carborundum," "crystolon," "carbolon.") SiC

For diamond, iron oxides, iron alloys and quartz, *see* other sections of I. C. T.

PROPERTIES OF GLASS

GEORGE W. MOREY

CONTENTS.—(*Continued*)

The "Index Nos." of Table 1 are identification numbers by means of which the glasses are identified in the property tables which follow.

TABLE 1.—GLASS COMPOSITIONS

With the exception of those glasses whose index numbers are in italics, all the compositions listed below are calculated from the ingredients melted to produce the glass type (so-called "batch" compositions). The glasses actually measured will therefore differ from the compositions given by unknown amounts; a difference in optical properties between the types of Table 1 and like numbered glasses in subsequent tables indicates such uncontrolled variations. The analyses of similar types shown in Table 1 give an idea of the magnitude of the difference to be expected. In the tables which follow, this uncertainty as to the actual glass composition is usually greater than that introduced by errors in measurement.

The numbers under "Glass Types" in Table 1 represent $(n_D - 1)10^3/10v$; in which $v = \frac{n_D - 1}{n_F - n_C}$. Glasses 1–114 are arranged in the order of increasing n_D; glasses 115–133, in order of decreasing SiO_2 content; glasses 134–146 in order of decreasing n_D.

MATIÈRES.—(*Suite*)

Les nombres index de la Table 1 sont des nombres d'identification au moyen desquels les verres sont identifiés dans les tables des propriétés qui font suite.

TABLE 1.—COMPOSITIONS DES VERRES

A l'exception des verres dont les nombres index sont en italique, toutes les compositions indiquées ci-dessous sont calculées à partir des substances de départ entrant dans la fabrication du verre type. La composition réelle des verres dont on donne les mesures peut donc différer des compositions indiquées par un montant inconnu; une différence dans les propriétés optiques entre les types de la Table 1 et les verres de même numéro dans les tables subséquentes met en évidence ces variations incontrôlées. Les analyses de types similaires indiquées dans la Table 1 donnent une idée de l'ordre de grandeur de la différence à laquelle on peut s'attendre. Dans les tables qui suivent, cette incertitude en ce qui concerne la composition réelle du verre est ordinairement plus grande que celle introduite par des erreurs dans les mesures.

Les nombres dans "Verres types" dans la Table 1 représentent $(n_D - 1)10^3/10v$; dans laquelle $v = \frac{n_D - 1}{n_F - n_C}$. Les verres 1 à 114 sont disposés dans l'ordre de n_D accroissant; les verres 115 à 133 dans l'ordre de la teneur décroissante en SiO_2; les verres 134 à 146 dans l'ordre de n_D décroissant.

INHALTSVERZEICHNIS.—(*Fortsetzung*)

Die Indexnummern der Tafel 1 sind Erkennungszahlen mit Hilfe deren die Gläser in den folgenden Eigenschaftstafeln identifiziert sind.

TAFEL 1.—GLAS-ZUSAMMENSETZUNGEN

Mit Ausnahme bei jenen Gläsern deren Indexnummern kursiv geschrieben sind, ist ihre folgende Zusammensetzung aus den Bestandteilen berechnet, die zur Erschmelzung des Glases verwendet worden sind (Glassatz). Die wirkliche Zusammensetzung des Glases wird deshalb von der angegebenen in unbekanntem Ausmasse abweichen. Ein Unterschied in den optischen Eigenschaften der Glastypen in der Tafel 1 und denen in den folgenden Tabellen, welche ähnlich bezeichnet sind, zeigt solche unkontrollierbare Veränderungen. Die Analyse ähnlicher Glassorten, welche in der Tabelle 1 verzeichnet sind, geben eine Vorstellung von der Grösse der Abweichungen die zu erwarten sind. In den folgenden Tabellen ist die Unsicherheit bezüglich der wirklichen Glaszusammensetzung gewöhnlich grösser, als sie durch Messfehler verursacht werden kann.

Die Zahlen unter "Glass Types" in der Tafel 1 bedeuten $(n_D - 1)10^3/10v$ wobei $v = \frac{n_D - 1}{n_F - n_C}$ ist. Die Gläser 1–114 reihen sich nach aufsteigenden n_D-Werten, Gläser 115–133 nach absteigendem SiO_2-Gehalt und Gläser 134–146 nach absteigenden n_D-Werten.

INDICE.—(*Azione*)

I numeri indici della Tabella 1 sono numeri di identificazione a mezzo dei quali si possono individuare i diversi vetri nelle tabelle delle proprietà.

TABELLA 1.—COMPOSIZIONE DEI VETRI

Fatta eccezione per i vetri con numero indice scritto in corsivo, per tutti gli altri le composizioni riportate sono quelle che si calcolano dalle quantità dei componenti messe a fondere assieme.

Le composizioni effettive differiscono perciò da quelle indicate di una quantità sconosciuta; ed eventuali differenze nelle proprietà ottiche dei vetri della Tabella 1 e di quelli delle tabelle successive contradistinti da uno stesso numero stanno a dimostrare appunto queste incontrollatibili variazioni. Le analisi di tipi simili di vetri riportate nella Tabella 1, danno una idea della grandezza delle differenze che possono aversi. La incertezza intorno alla composizione effettiva del vetro è, in genere, maggiore di quella che può essere dovuta ad errori di misura.

I numeri sotto la dicitura "Glass Types" nella Tabella 1 rappresentano $(n_D - 1)10^3/10v$; dove $v = \frac{n_D - 1}{n_F - n_C}$. I vetri da 1 a 114 sono disposti in ordine accrescente di n_D; i vetri da 115 a 133 in ordine decrescente del contenuto di SiO_2; i vetri da 134 a 146 in ordine decrescente di n_D.

MECHANICAL PROPERTIES OF GLASS

Density

The density of glass is dependent not only on its composition but also on its thermal history; variation in the latter factor may cause differences of ±0.002. Figures 1–5 give the density-composition relations for a number of annealed experimental glasses. The density of four series of glasses of the general formula 100 $SiO_2 \cdot 20$ or 40 Na_2O (or 20 or 40 K_2O) $\cdot xCaO$ can be represented by the equation $d = mx + b$, in which x = weight % CaO. Values of m, b and the range of x are: For 20 Na_2O: 0.0124, 2.368, 3.7 – 23.7 %; for 40 Na_2O: 0.0092, 2.475, 3.2 – 21 %; for 20 K_2O: 0.0097, 2.386, 3 – 22 %; for 40 K_2O: 0.0089, 2.464, 2.7 – 18.6 % (45). The density of multicomponent commercial and experimental glasses is given in Table 2 and of optical glasses in Table 13.

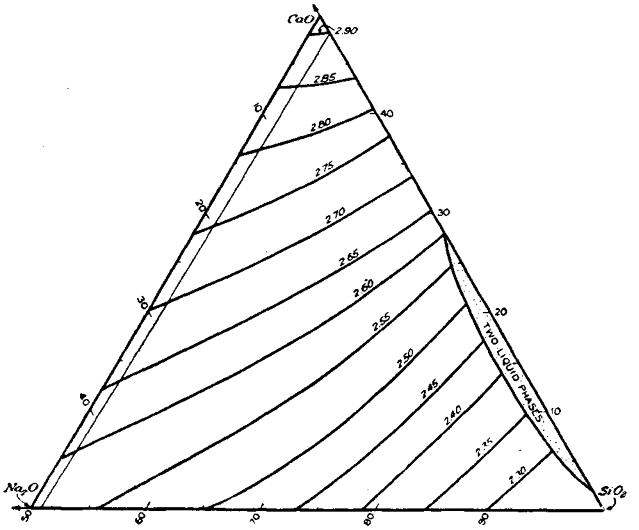

FIG. 1.—Density of the ternary Na_2O-CaO-SiO_2 glasses. Composition in weight % (41).

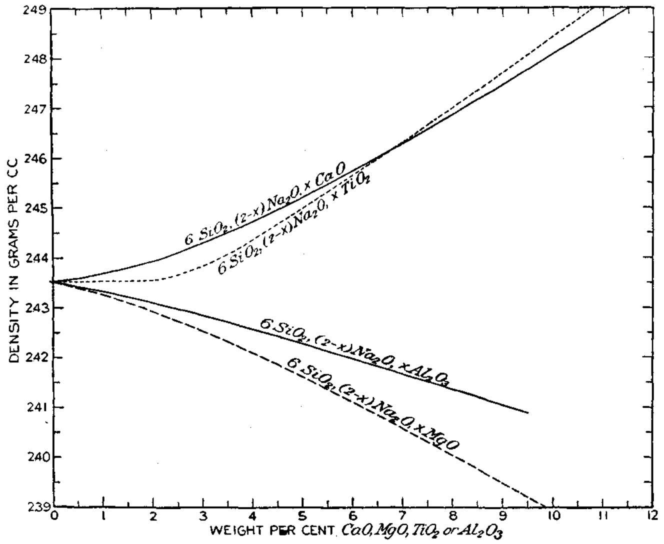

FIG. 2.—Density of some glasses obtained from $Na_2O.3SiO_2$ by substitution of CaO, MgO, Al_2O_3 or TiO_2 for Na_2O. Exact compositions are given in the originals (19, 20, 24, 55).

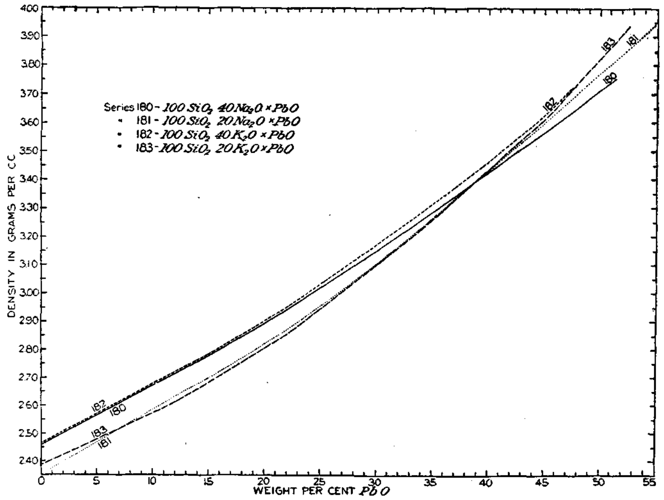

FIG. 3.—Density of some alkali-lead oxide glasses of the approximate composition shown (46).

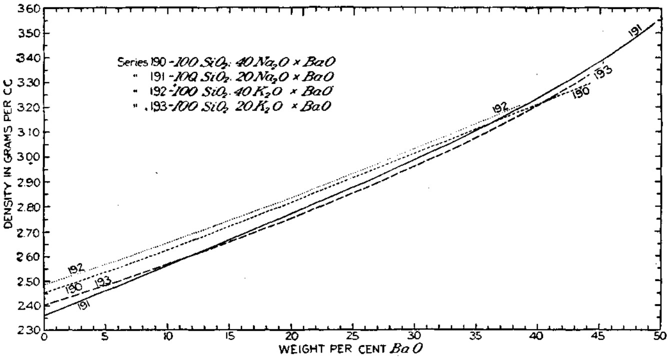

FIG. 4.—Density of some alkali-barium oxide glasses of the approximate composition shown (47).

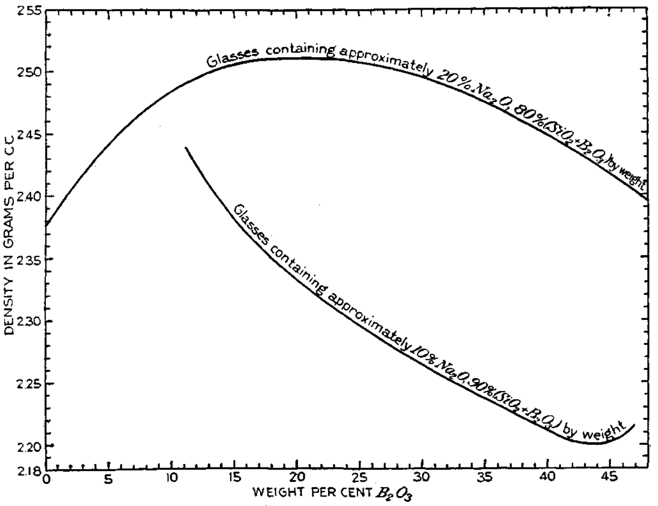

FIG. 5.—Density of some Na_2O-B_2O_3-SiO_2 glasses. Exact compositions are given in the original (28).

Viscosity

For definition of viscosity see vol. 1, p. 42. The variation of viscosity with composition and with temperature in the ternary system Na_2O-CaO-SiO_2 is shown in Figs. 6–12; the effect of replacement of CaO by MgO or by Al_2O_3, in Figs. 13 and 14 respt.; and the temperature-viscosity curves of a number of experimental glasses are shown in Fig. 15 and of optical glasses in Fig. 16.

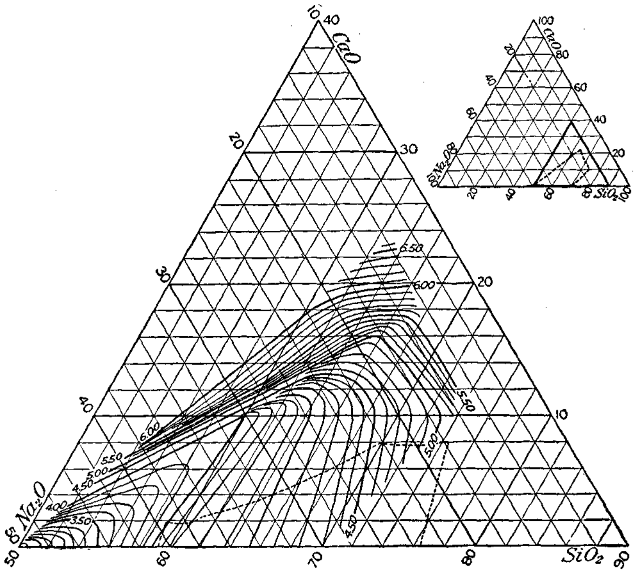

FIG. 6.—Log isokoms (lines of constant viscosity) in the system Na_2O-CaO-SiO_2, at 900°. Viscosity in log poises; composition in weight %. The broken line is the liquidus curve at 900°. *Cf.* Fig. 20 (61).

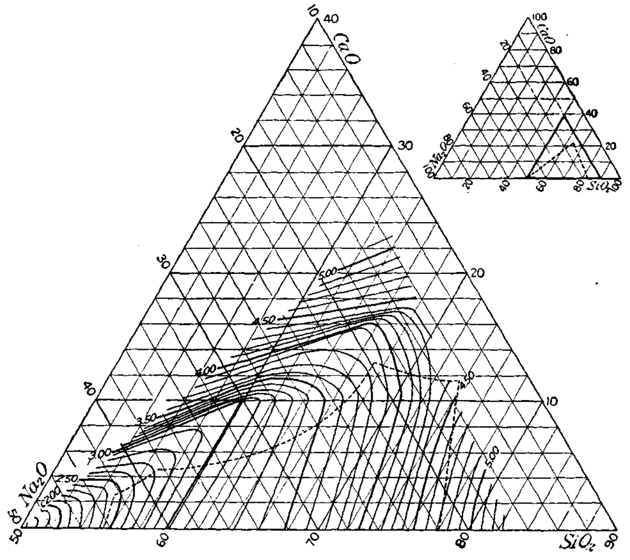

FIG. 7.—Log isokoms in the system Na_2O-CaO-SiO_2 at 1000°. The broken line is the liquidus curve at 1000° (61).

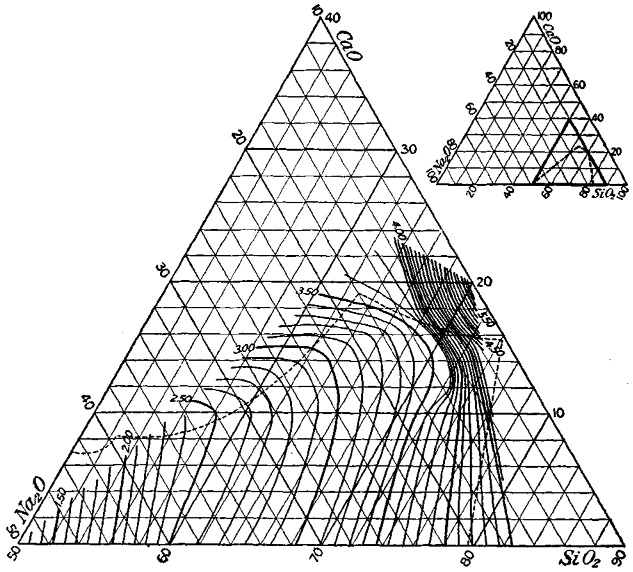

FIG. 8.—Log isokoms in the system Na_2O-CaO-SiO_2 at 1100°. The broken line is the liquidus curve at 1100° (61).

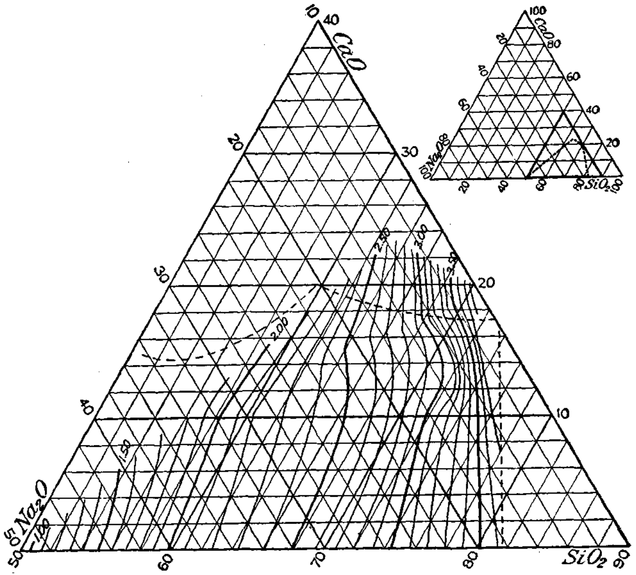

FIG. 9.—Log isokoms in the system Na_2O-CaO-SiO_2 at 1200°. The broken line is the liquidus curve at 1200° (61).

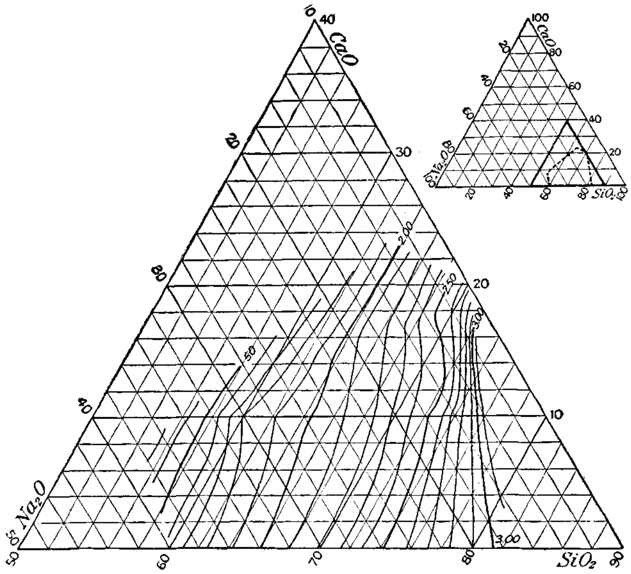

FIG. 10.—Log isokoms in the system Na_2O-CaO-SiO_2 at 1300°. The mixtures at this temperature are all above the liquidus surface, except a few high in SiO_2 (61).

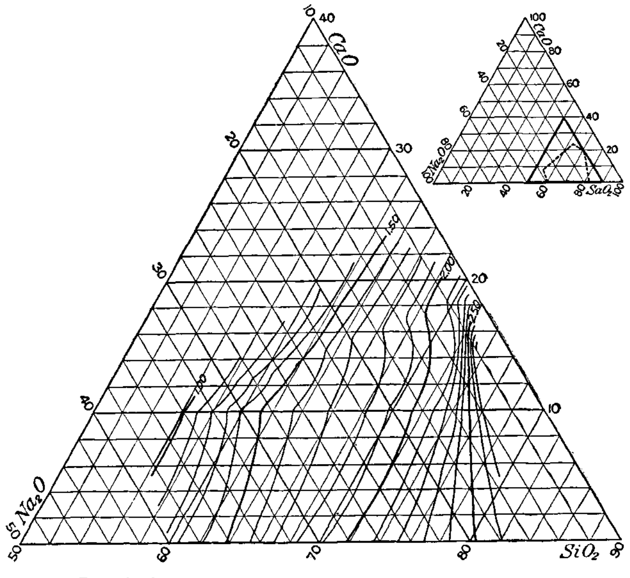

FIG. 11.—Log isokoms in the system Na_2O-CaO-SiO_2 at 1400° (61).

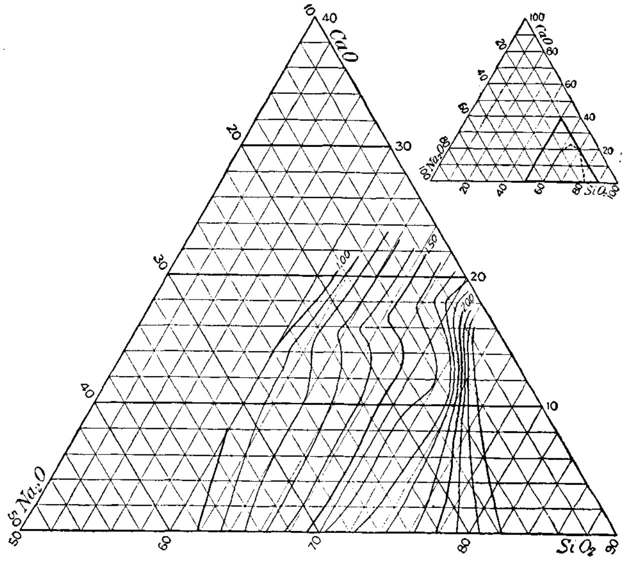

FIG. 12.—Log isokoms in the system Na_2O-CaO-SiO_2 at 1500° (61).

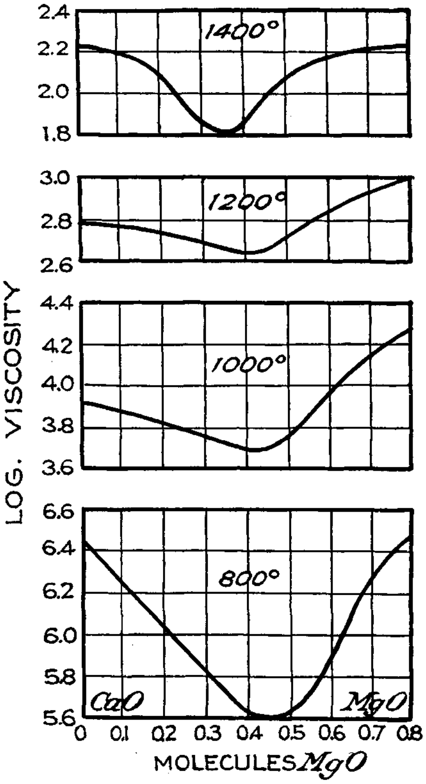

FIG. 13.—Effect on viscosity of replacing CaO by MgO in the mixture $1.2Na_2O \cdot 0.8 CaO \cdot 6SiO_2$, at different temperatures. Viscosity in poises (14.1).

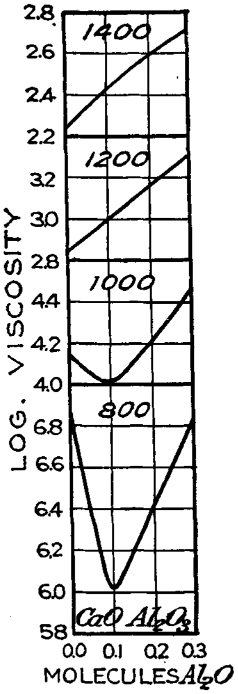

FIG. 14.—Effect on viscosity of replacing CaO by Al_2O_3 in the mixture $1.1Na_2O \cdot 0.9 CaO \cdot 6SiO_2$, at different temperatures (14.1).

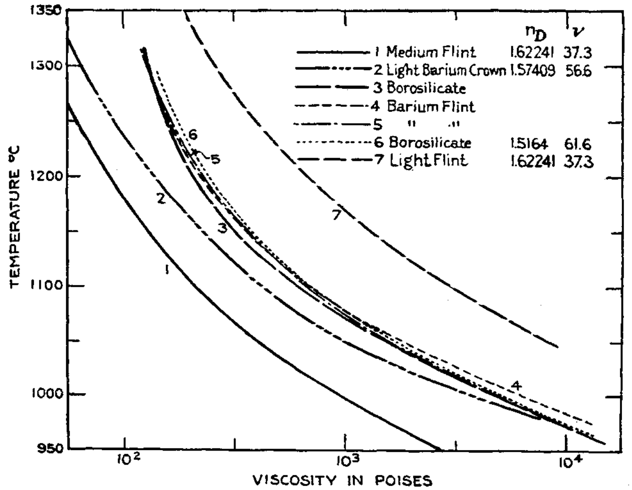

Fig. 16.—Variation of viscosity with temperature in a number of optical glasses (61,1).

Surface Tension

The variation of surface tension with composition in the ternary Na$_2$O-CaO-SiO$_2$ glasses at constant temperature is shown in Figs. 17 and 18; the variation with temperature in Fig. 19.

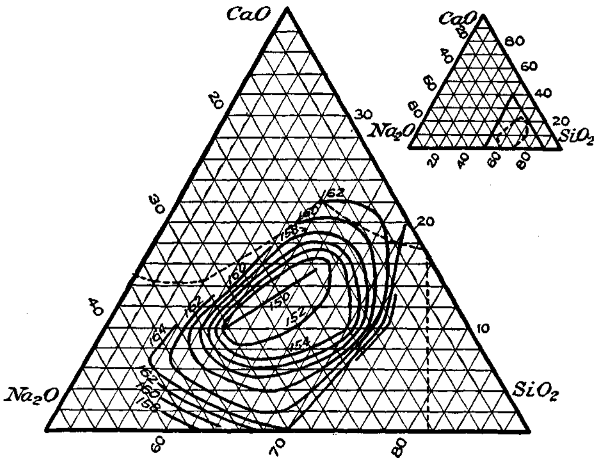

Fig. 17.—Surface tension of Na$_2$O-CaO-SiO$_2$ mixtures at 1206° (61).

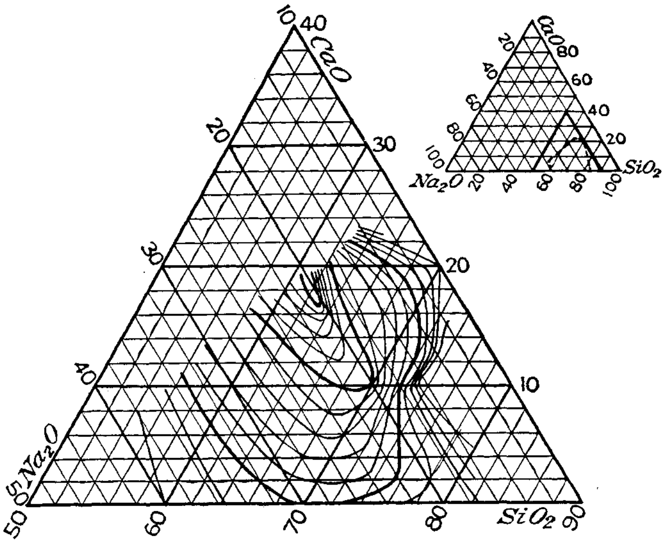

Fig. 18.—Surface tension of Na$_2$O-CaO-SiO$_2$ mixtures at 1454° (61).

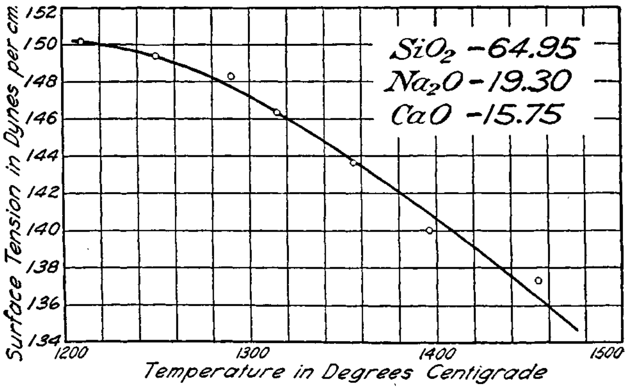

Fig. 19.—Variation of surface tension with temperature (61).

Strength

The strength of glass is so greatly influenced by its thermal history (33) and the condition of its surface (38) that the values given are of uncertain significance and should be used only with an ample factor of safety.

Values of tensile and compressive strength of a number of glasses are given in Table 2. The strength of glass fibers as a function of thickness is given by Griffith (33). The following summarizes the data for tubes, determined on a glass of unknown composition.

TABLE 3.—BURSTING STRENGTH OF GLASS TUBES (44)

Maximum fiber stress, T_m, calculated from the formula

$$T_m = \frac{1}{4}\left[5P_m + 7\left(\frac{P_m - 1}{\left(\frac{R}{R'}\right)^2 - 1}\right) - 1\right] \text{(unit} = 10^6 \text{ barye)}$$

Shape of tubes	Range of radii, R, mm		Number tubes tested	Range of bursting pressures, P_m	Max. fiber stress, T_m	Mean var. from mean, %
	External, R	Internal, R'

Capillary.....	5–7	0.24–1.0	16	420–1200	902	27
Thin walled..	3.8–7.8	3.4–7.3	17	54–377	628	20

Elastic Properties

Young's modulus, E, and Poisson's ratio, σ, for a number of commercial and experimental glasses are given in Table 2; the rigidity and bulk moduli, C and K, are related to these through the equation $C = E/2(1 + \sigma)$ and $K = E/3(1 - 2\sigma)$. The variation of E, in kilo-megabaryes, with weight % of CaO is given by the equation $E = 13.9y + 565.6$, in the range 0–11% CaO (10a). The variation of Young's modulus with temperature is shown in Table 4.

TABLE 4.—THE EFFECT OF TEMPERATURE ON ELASTICITY (66)

THERMAL PROPERTIES OF GLASS

Melting Point Diagrams

The melting point diagrams showing the compositions of the crystalline solid phases which may exist in equilibrium with liquid and the relation between equilibrium temperature and composition of that liquid are not known for most of the glass-forming systems. Figures 20 and 21 give these for the ternary system $Na_2O \cdot SiO_2$-$CaO \cdot SiO_2$-SiO_2 and the binary system PbO-SiO_2.

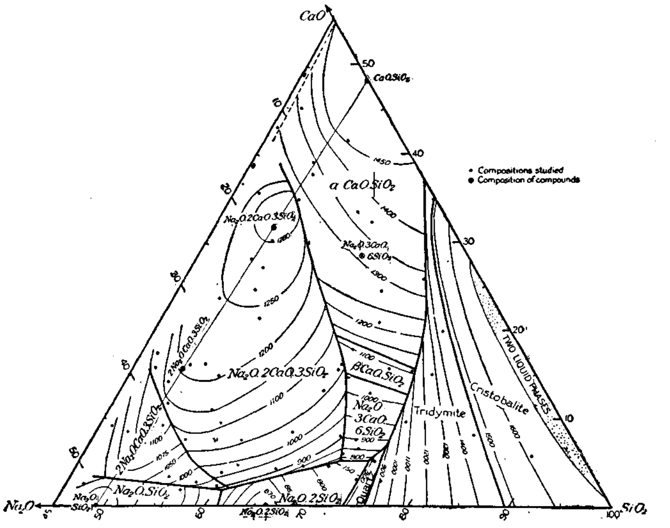

FIG. 20.—Melting point diagram of the system Na_2O-CaO-SiO_2. Composition in weight % (39).

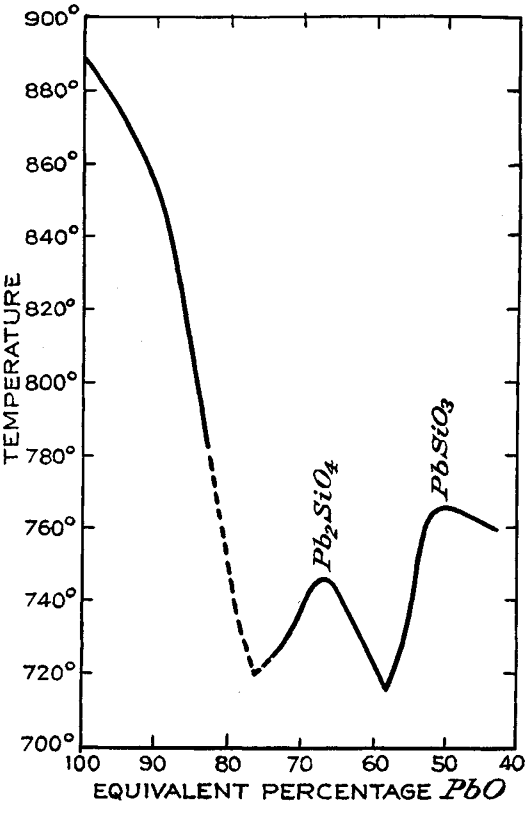

FIG. 21.—Melting point diagram of the system PbO-SiO_2 (11).

Table 5.—Thermal Constants of Representative Glasses

Glasses are undercooled liquids, and hence have no melting points. Following are some of the empirical definitions that have been proposed for characterizing glasses as to their thermal behavior, and the corresponding temperatures for some representative glasses. (*a*) Annealing temperature (62): the temperature at which the ratio of final to initial strain is a minimum, when heating and cooling are carried out in a prescribed manner; *v. also* Table 6 and Figs. 22, 23 and 24. (*b*) Deformation temperature (62): the lowest temperature at which, after 6 hr, one observes a deformation of the polished faces of a 20 mm cube embedded in kieselguhr with a diagonal vertical. (*c*) Cohesion temperature (69): the lowest temperature at which 2 plane polished pieces, 2 mm thick, 10 mm diameter, will coalesce in 30 min. (*d*) Softening temperature, for pyrex (12): the temperature at which a rod 9 in. long and 0.6 mm diameter lengthens under its own weight at the rate of 1 mm per min when heated in an electric furnace throughout its upper 9.5 cm of length. For the rest of the glasses (69), the constant t_o in the empirical 3-constant equation $(t_o - t)(S + S_o) = C$, expressing the relation between the stress, S (measured by birefringence), produced by quickly cooling a cm cube from the temperature t. (*e*) Flow temperature (63): the temperature at which a 25 mm cube embedded in kieselguhr with diagonal vertical flows until the corner cannot be detected, in the given time.

Table 5.—Constantes thermiques des verres représentatifs

Les verres sont des liquides surfondus, et par conséquent ne possèdent pas de point de fusion. Dans ce qui suit, on trouvera quelques-unes des définitions empiriques qui ont été proposées pour caractériser les verres en se basant sur la façon dont ils se comportent au point de vue thermique, et les températures correspondantes pour quelques verres représentatifs. (*a*) Température de recuit (62): c'est la température à laquelle le rapport de la tension finale à la tension initiale devient minimum, lorsque la conduite du chauffage et du refroidissement est effectuée d'une manière prescrite; voir aussi Table 6. (*b*) Température de déformation (62): c'est la température la plus basse à laquelle on observe, après six heures, une déformation des faces polies d'un cube de 20 mm de côté, disposé dans du kieselguhr avec une diagonale verticale. (*c*) Température de cohésion (69): c'est la température la plus basse à laquelle deux pièces polies planes de 2 mm d'épaisseur et de 10 mm de diamètre s'accoleront en trente minutes. (*d*) Température de ramollissement; pour le Pyrex (12): c'est la température à laquelle une baguette de 23 cm de long. et de 0,6 mm de diamètre s'allonge sous son propre poids à raison de 1 mm par min, la baguette étant chauffée dans un four électrique sur une longueur de 9,5 cm. Pour le reste des verres (69), la constante t_o dans l'équation empirique à 3 constantes $(t_o - t)(S + S_o) = C$, exprimant la relation entre la tension, S (mesurée par biréfringence), produite par un refroidissement rapide d'un cube de 1 cm de côté de la température t. (*e*) Température d'écoulement (63): c'est la température à laquelle un cube de 25 mm de côté, disposé dans du kieselguhr, avec une diagonale verticale, s'écoule d'une façon telle que le coin ne peut plus être décelé dans un temps donné.

Tafel 5.—Thermische Konstanten typischer Glassorten

Gläser sind unterkühlte Flüssigkeiten und haben deshalb keinen Schmelzpunkt. Im folgenden sind einige empirische Definitionen angegeben, welche zur Charakterisierung des thermischen Verhaltens von Gläsern herangezogen werden. Auf die entsprechende Temperatur so bezogen, ist das thermische Verhalten einiger typischer Glassorten ebenfalls angegeben. (*a*) Kühltemperatur (62): Die Temperatur bei welcher das Verhältnis der Endspannung zur Anfangsspannung ein Minimum ist, wenn Erwärmung und Kühlung in vorgeschriebener Weise erfolgt. Siehe Tafel 6 und Fig. 22, 23 und 24. (*b*) Deformations-Temperatur (62): Die tiefste Temperatur bei welcher nach 6 Stunden eine Deformation der polierten Flächen eines 20 mm Würfels bemerkt wird, welcher in Kieselgur eingebettet ist (mit vertikaler Diagonale). (*c*) Kohäsions-Temperatur (69): Die tiefste Temperatur bei welcher zwei plan geschliffene Flächen, 2 mm dick, 10 mm Durchmesser in 30 Minuten zusammenschmelzen. (*d*) Erweichungs-Temperatur für Pyrex-Glas (12): Die Temperatur bei welcher ein Stab von 23 cm Länge und 0,6 mm Durchmesser, bei der Erhitzung der ersten obern 9,5 cm seiner Länge, im elektrischen Ofen, unter dem eigenen Gewicht eine minutliche Verlängerung um 1 mm erfährt. Für den Rest der Gläser (69) ist t_o die Konstante der empirischen Gleichung (drei Konstanten) $(t_o - t)(S + S_o) = C$, welche die Beziehung zum Druck S herstellt, der durch eine rasche Kühlung von der Temperatur t herunter in einem 1 cm Würfel erzeugt wird (Druckmessung nach der Doppelbrechung). (*e*) Fluss-Temperatur (63). Ist die Temperatur bei welcher ein 25 mm Würfel in Kieselgur eingebettet (diagonal, vertikal) zerfliesst, so, dass in der gegebenen Zeit die Ecken nicht mehr erkannt werden können.

Tabella 5.—Costanti termiche di vetri tipici

I vetri sono liquidi sopraraffreddati e non hanno perciò punto di fusione.

Qui sono indicate alcune delle proprietà proposte per caratterizzare i vetri dal punto di vista del loro comportamento termico, e sono riportate le temperature corrispondenti per alcuni vetri tipici. (*a*) Temperatura di (ricottura) (62): la temperatura alla quale è minimo il rapporto fra tensione finale e iniziale, quando riscaldamento e raffreddamento vengono eseguiti in una maniera prescritta. Vedi pure Tabella 6, e Fig. 22, 23 e 24. (*b*) Temperatura di deformazione (62): la temperatura più bassa alla quale, dopo sei ore, si osserva deformazione delle facce pulimentate di un cubo di 20 mm immerso nella farina fossile con una diagonale in posizione verticale. (*c*) Temperatura di adesione (69): la temperatura più bassa alla quale aderiscono in 30 minuti due pezzi pulimentati a superficie piana di 2 mm di spessore e 10 di diametro. (*d*) Temperatura di rammollimento. Per il Pyrex (12) è la temperatura alla quale una bacchetta di 23 cm di lunghezza e 0,6 mm di diametro si distende sotto il proprio peso alla velocità di 1 mm per minuto quando sia scaldata in un forno elettrico lungo i 9,5 cm superiori di lunghezza; per gli altri vetri (69) è la costante t_o nella equazione empirica a 3 costanti $(t_o - t)(S + S_o) = C$, esprimente la relazione tra sforzo, S (misurato dalla birifrangenza), prodotto raffreddando rapidamente un cubo di un centimetro dalla temperatura t. (*e*) Temperatura di scorrimento (63): la temperatura alla quale un cubo di 25 mm immerso in farina fossile con una diagonale disposta verticalmente, scorre fino a non potersi più distinguere il vertice nel tempo indicato.

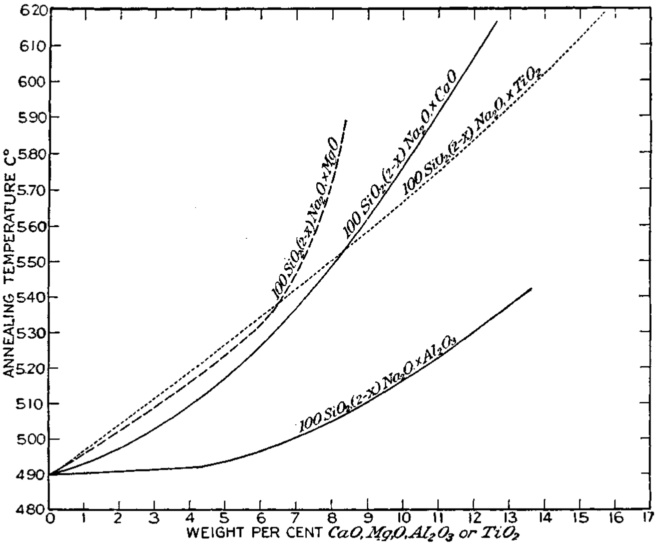

FIG. 23.—Annealing temperatures of glasses derived from $Na_2O \cdot 3SiO_2$, by substitution of CaO, MgO, Al_2O_3 or TiO_2 for Na_2O. Exact compositions are given in the original (15, 17, 21, 55).

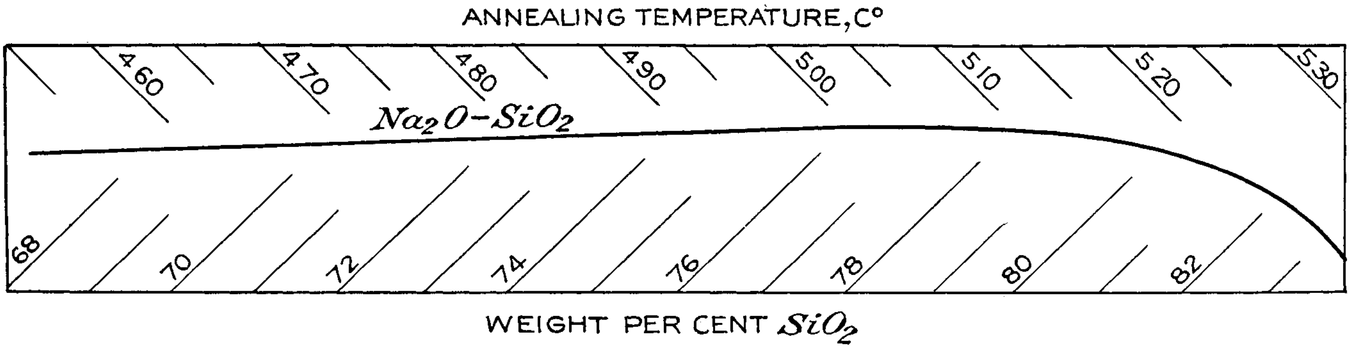

FIG. 22.—Annealing temperature of Na_2O-SiO_2 glasses (14).

Annealing Temperature

Figures 22, 23 and 24 show the relation between annealing temperature and composition of a number of experimental glasses; in these, the annealing temperature is that at which strain disappears rapidly. Table 6 gives the annealing constants of a number of optical glasses.

TABLE 6.—ANNEALING TEMPERATURES

Values of M_1 and M_2 in equation $\log_{10} A = M_1\Theta - M_2$, in which Θ = temp., °C, and M_1 and M_2 are experimental constants, from which may be calculated the annealing constant A. The annealing temperature is defined as that temperature at which the strain will decrease from 50 to 2.5$\mu\mu$ in 2 min, calculated from the formula $At = 1/\Delta n - 1/\Delta n_o$ in which t = time in min, Δn = birefringence in $\mu\mu$.

Ind. No.	Type	M_1	M_2	Annealing temp., °C

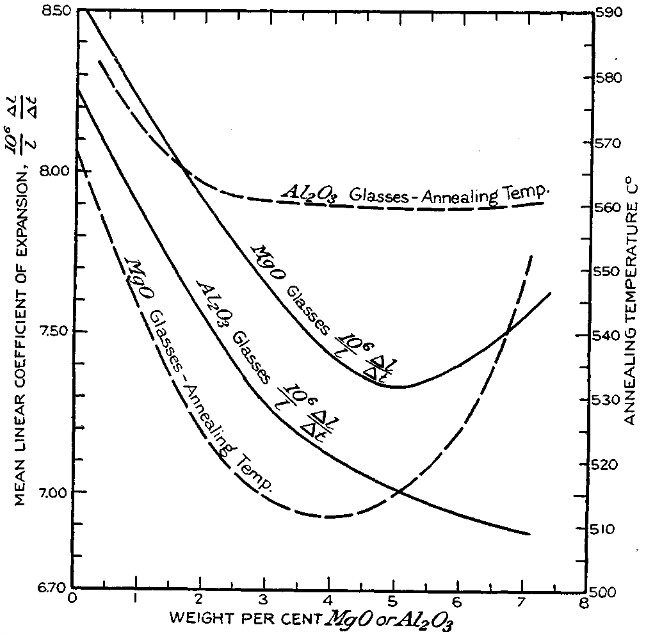

FIG. 24.—Annealing temperatures and thermal expansions of glasses derived from $1.2Na_2O \cdot 0.8CaO \cdot 6SiO_2$ by substitution of CaO by MgO; and from $1.1Na_2O \cdot 0.9CaO \cdot 6SiO_2$ by substitution of CaO by Al_2O_3 (21, 25).

Coefficient of Expansion

The linear coefficient of expansion, $\alpha = 10^6 \Delta l / l \Delta t$, of multicomponent commercial and experimental glasses is given in Tables 2 and 7 and for a systematic series of experimental glasses in Figs. 24–28.

OPTICAL PROPERTIES

The relations between composition and optical properties in several systematic series are shown in Figs. 29–36. The properties of typical optical glasses are shown in Table 13, which, together with the compositions, was furnished by Chance Bros. and Co., Ltd. Table 14 gives the index for the infra-red and ultra-violet; Table 15, the effect of temperature on index; Table 16, the effect of pressure and strain; and Table 17, the absorption of light by various glasses.

TABLE 16.—EFFECT OF PRESSURE ON OPTICAL PROPERTIES

The birefringence produced by a thrust F is measured in terms of the difference in index for white light of the two rays: $n_y - n_z = BF$, in which $B = \frac{n}{2R}\left(\frac{q}{v} - \frac{p}{v}\right)$, in which R = rigidity, $\frac{q}{v}$ and $\frac{p}{v}$, optical coefficients. The effect of uniform pressure, P', can be calculated from the equation $\frac{n_x - n}{n} = \frac{P'}{E}(1 - 2\sigma)\left(\frac{2p}{v} + \frac{q}{v}\right)$, in which E and σ are Young's modulus and Poisson's ratio. Unit of $F = 10^{-13}$ barye.

CHEMICAL DURABILITY OF GLASSES

W. E. S. TURNER

INTRODUCTION

In the measurement of the durability of glasses, results may be duplicated with an accuracy of 5 to 10% only. In a series of glasses of similar composition, the results with the more durable glasses may be reproduced with an accuracy of 5%; the less durable, up to about 10%.

INTRODUCTION

Les résultats ne peuvent être reproduits, dans les mesures de durabilité des verres, qu'avec une précision de 5 à 10% seulement. Dans les séries de verres de composition similaire, les résultats concernant les verres les plus durables peuvent être reproduits avec une précision de 5%; ceux relatifs aux verres les moins durables, jusqu'à environ 10%.

EINLEITUNG

Die Messungsergebnisse über die Dauerhaftigkeit der Gläser lassen sich nur mit einer Genauigkeit von 5 bis 10% angeben. In einer Reihe von Gläsern ähnlicher Zusammensetzung können die Ergebnisse mit dauerhafteren Gläsern auf 5%, mit weniger dauerhaften bis gegen 10% Genauigkeit angegeben werden.

INTRODUZIONE

I risultati ottenuti nelle misure di resistenza chimica dei vetri, sono riproducibili con una approssimazione del 5–10% soltanto. In una serie di vetri di composizione simile, i valori riferentisi ai vetri più resistenti sono riproducibili con l'approssimazione del 5%, e quelli riguardanti i vetri meno resistenti con una approssimazione del 10%.

EFFECT OF COMPOSITION

TABLE 1.—FUSED-QUARTZ GLASS

Milligrams loss in wt. sustained in each test by a 76 cm³ quartz flask, with 89 cm² surface exposed, when subjected in succession to the following reagents under the conditions shown (35); *cf.* (53).

Reagent, time and temperature			Loss mg
H_2O, 18°–100°	Many	Days at 18°	0.0
10% NH_3	2		0.8
10% NaOH	2		0.4
30% NaOH	2		0.0*
30% KOH	4		1.2†
2*N* NaOH	3	Hours at 100°	48
2*N* Na_2CO_3	3		12
2*N* KOH	3		31
2*N* NaOH	3		33
2*N* Na_2CO_3	3		8
2*N* KOH	3		64
2*N* NaOH	3		
N NaOH	14	Hours at 18°	2
N NaOH	14		1.8
N Na_2CO_3	14		0.6
Satd. $Ba(OH)_2$	14		0
Satd. Na_2SO_4	14		0
N H_3PO_4	14		0
10% NH_3	14		0
25% NH_3	60		0
25% NH_3, Fresh flask. Up to 60° with 4 renewals of reagent during experiment, 6 hrs			2.6

* No adsorption of NaOH.

† Adsorbed KOH difficult to remove by washing.

Remarks: $Ba(OH)_2$, 6 mo. at 18°, small crystals of Ba silicate formed. H_3PO_4 at 400°, extensive corrosion with formation of silicyl phosphate. *Dilute acids* in general, and conc. H_2SO_4, 18–100°, no action. Aqueous *methylene blue, congo red,* and *rhodamine;* ethereal *iodoeosin;* and alcoholic *aniline blue;* all slightly adsorbed but removable by hot solvents.

TABLE 2.—CaO · SiO₂ WOLLASTONITE

Milligrams oxides extracted from 2 g by acids (17, 30, 33, 38).

Oxide \ Acid	30 min at 18°	2*N* Acetic	0.1*N* HCl	2*N* HCl	2 hrs at 50°–60°	2*N* HCl	10*N* HCl
mg CaO		0.010	0.017	0.11		0.70	0.76
mg SiO_2		0.000	0.004	0.040		0.26	0.020

SPECIFIC GRAVITY

Ground coat for sheet steel 2.54. White cover enamel for sheet steel 2.66. High lead-tin oxide enamel for cast iron 2.93. Leadless antimony enamel for cast iron 3.32. High lead oxide enamel for jewelry 3.79 (31).

STRENGTH

Ultimate Compressive Strength (Def. 4)

Commercial ground coat for sheet steel, 95 500 lb./in.^{2}. Commercial white cover for sheet steel, 91 740 lb./in.^{2}. Cylindrical test pieces ½ in. diam. × 1 in. long (11).

Cross Bending Strength

See (12, 20).

Impact Resistance

See (11, 17, 29).

HARDNESS

See (2).

THERMAL EXPANSION OF VITREOUS ENAMELS

The coefficient of cubical expansion, $\frac{10^7 dV}{V\,dt}$, can be approximately calculated from the wt. % composition of the melted enamel and the moduli given below.

MODULI

AlF_3	Al_2O_3	As_2O_5	BaO	B_2O_3	BeO	CaO	CaF_2	CeO_2	CoO	Cr_2O_3	Cryo-lite	CuO	FeO
4.4	5.0*	2.0	3.0	0.1*	4.7	5.0* 4.9†	2.5	4.2	4.4	5.1	7.4	2.2	4.0

K_2O	MgO	MnO	NaF	Na_2O	NiO_2	PbO	Sb_2O_5	SiO_2	SnO_2	ThO_2	TiO_2	ZrO_2	ZnO
8.5*	0.1* 1.3_5†	2.2	7.4	10* 13†	4.0	4.2	3.6	0.8* 0.15†	2.0	6.3	4.1	2.1	1.8

* Values from Winkleman and Schott (32).
† Values from English and Turner (13).
All others from Mayer and Havas (18).

The calculation is illustrated in the following example and in the table of Expansion of Enamels.

Composition	Wt.		Moduli		
Silica	25.30	×	0.8	=	20.2
Alumina	7.20	×	5.0	=	36.0
Potassium oxide	6.60	×	8.5	=	56.1
Sodium oxide	8.94	×	10.0	=	89.4
Boric oxide	12.77	×	0.1	=	1.3
Barium oxide	6.21	×	3.0	=	18.6
Zinc oxide	14.00	×	1.8	=	25.2
Calcium oxide	1.68	×	5.0	=	8.4
Calcium fluoride	7.30	×	2.5	=	18.3
Antimony oxide	10.00	×	3.6	=	36.0
	100.00				309.5

The calc. cubical coefficient of expansion for this enamel is therefore 309.5 × 10^{-7} per °C.

Danielson and Souder (10) have shown, however, that values so calculated are only approximate. The following are typical:

Types of enamel	Coeff. of linear expansion × 10^6. Observed values				$\frac{10^6}{l}\frac{\Delta l}{\Delta t}$
	20° to 200°C	20° to 400°C	20° to 450°C	20° to 500°C	Calculated values
Single coat gray ware	9.8	11.6		13.4	11.0
Ground coat for sheet steel	9.4	10.3	11.5		

The determinations made by Mayer and Havas were over the range 0–100°C while those made by Danielson and Souder were carried to the softening points of the enamels, *i.e.*, about 450° to 500°C. It will be noted that the coefficient rapidly increases with increase in temperature as shown by Fig. 1 (10).

The results of these various studies indicate that the factors given by Mayer and Havas place the oxides in approximately their correct order as regards their relative effect on the expansivity of enamels and may thus serve as a valuable guide in the technical control of enamel mixtures.

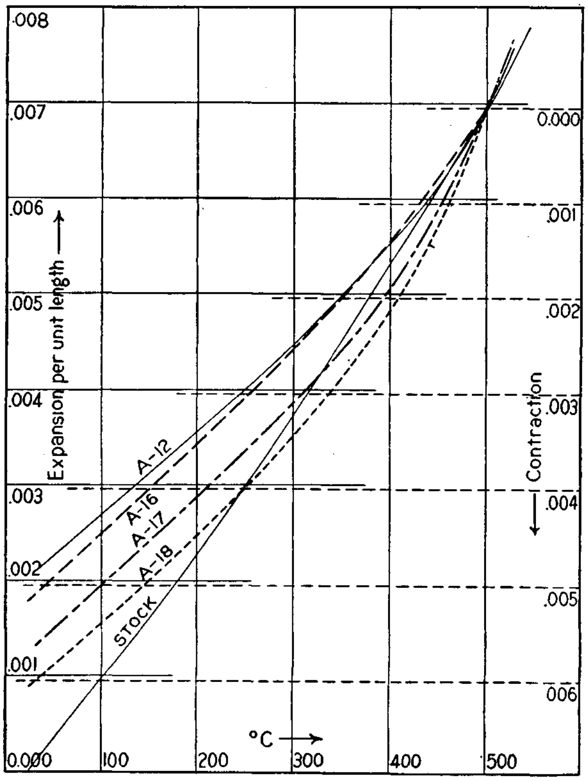

FIG. 1.—Expansion of some typical gray ware enamels and enameling steel.

From the observations of the various investigators it may generally be assumed that the average coefficients of expansion of commercial enamels and enameling metals will be within the following limits:

Type of enamel	$\frac{10^7\,dV}{V\,dt}$
Ground coat for sheet steel	260 to 320
White cover enamel for sheet steel	320 to 400
White enamel for cast iron	290 to 330
White enamel for jewelry	300 to 350
Cast iron	310
Sheet iron and steel	381 to 438

For table of expansion of various enamels *v.* p. 116.

HEAT TRANSFER BY ENAMELED METALS

Observations on a large number of commercial steel enameled units led to the following over-all coefficients of heat transfer under the conditions named (22).

Operating conditions	Over-all coefficient joule m^{-2} hr^{-1} (°C)
Steam, to cold water	1674 to 2929
Hot water, to cold water	1464
Steam, to boiling water	2929
Steam, to thick fruit product	669
Hot water, to cold water or brine	837 to 2510
Hot oil, to cold oil	271 to 586
Hot oil, to boiling water	628 to 837
Steam, to water in tubular heaters	2092 to 3347
Condensing steam to water in tubular condenser jacket	2929

Velocities of liquids over heating surfaces as affected by agitation, differences in mobility, and specific heat were involved in the above experiments.

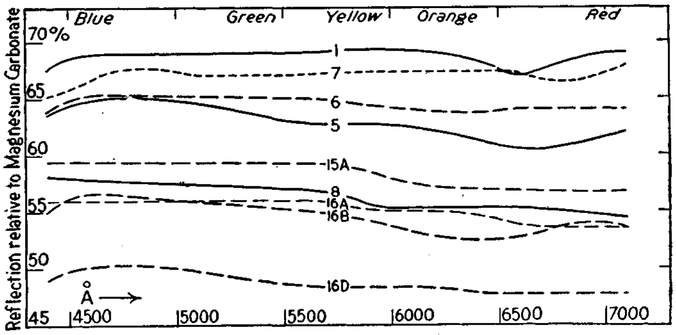

FIG. 2.—Opacifiers for enamels. No. 1. Tin oxide, 7 %. No. 7. Sodium antimonate, 11 %. No. 6. Sodium antimonate, 9 %. No. 5. Sodium antimonate, 7 %. No. 15*A*. Feldspar calcined, 9 %. No. 16*A*. Zinc aluminate calcined, 9 %. No. 8. Zinc aluminate calcined, 7 %. No. 16*B*. Zinc aluminate, 9 %. No. 16*D*. Zinc aluminate, 9 %.

The data on enameled cast-iron units are more limited. Over-all coefficients of heat transfer are given ranging from 1088 to 1464.

The thickness of the enamel coating rather than the thickness of the metal, seems to be the determining factor in the over-all coefficient.

THERMAL EMISSIVITY OF WHITE VITREOUS ENAMELED SURFACES

Very nearly the same as that of white-lead paint (4).

REFLECTIVITY OF SHEET STEEL ENAMELS

A typical white tin oxide enamel for sheet steel has an average reflectivity of 69%, relative to magnesium carbonate (7).

The same frit with other opacifying agents replacing tin oxide has reflectivities varying between 48 and 66% as shown in Figs. 2 and 3 (7).

See (27) for the effect of fineness of grinding on the opacity of enamels.

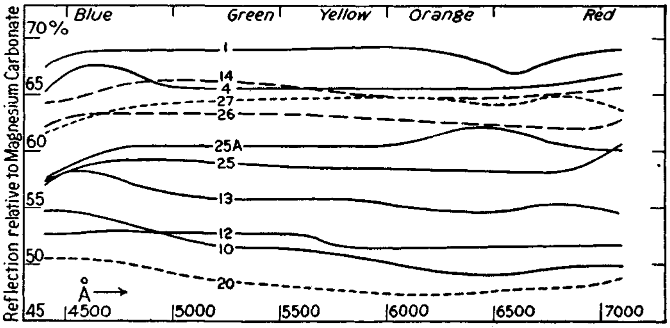

FIG. 3.—Opacifiers for enamels. No. 1. Tin oxide, 7 %. No. 4. Zirconium oxide, 7 %. No. 14. Zirconium oxide, 9 %. No. 10. Zirconium product, 7 %. No. 13. Commercial substitute, 7 %. No. 26. Zirconium silicate B, 9 %. No. 25. Zirconium silicate B, 7 %. No. 25*A*. Zirconium silicate B calcined, 7 %. No. 12. Zirconium silicate A, 7 %. No. 20. Zirconium silicate A, 11 %. No. 27. Zirconium silicate B, 11 %.

STRUCTURAL CEMENTS, LIMES AND PLASTERS

P. H. BATES AND W. E. EMLEY

HYDRAULIC CEMENTS

P. H. BATES

Hydraulic cements have the property of hardening under water and are usually made by burning argillaceous limestones or mixtures of argillaceous and calcareous materials. They include: portland, rosendale, natural, grappier, Eisenportland, Erzportland, Hochofen, trass, tufa, pozzuolana, etc., and hydraulic limes.

The definition and classification of cements is largely a matter of usage, which varies from nation to nation. In the U. S. there is a well-recognized standard for portland cement alone (A. S. T. M., C9–21).

A very infrequently used standard for natural cement differentiates this from portland cement only by its not requiring grinding before calcination, and giving different numerical values for the other properties (A. S. T. M., C10–09).

Rosendale, grappier, and hydraulic limes are natural cements in that the raw material is not ground before calcination. The other classes of cement mentioned above are mixtures of portland cement with various amounts of different slags of natural or of artificial origin. Their use is not very extensive and in general is confined to a few countries.

In France one standard covers the several varieties of hydraulic limes and cements (3).

"Hydraulic limes and cements will be called quick-, medium-, slow-, or extremely slow-setting according as their time of initial set is less than 5 min, 5 to 30 min, 30 min to 6 hr or more than 6 hr respectively.

"Until the time when compression test results can be generalized, the classification by strength shall be made as follows according to minimum strength in tension at 7 and 28 days."

Designation (package to show this designation)	Minimum tensile strength			
	kg cm^{-2}		lb. in.$^{-2}$	
	7 da	28 da	7 da	28 da
1/3 kg	1	3	14.2	42.6
3/5 kg	3	5	42.6	71.0
6/10 kg	6	10	85.0	142.0
10/15 kg	10	15	142.0	213.0
15/20 kg	15	20	213.0	284.0
20/25 kg	20	25	284.0	355.0

The chemical composition of all cements, even of the same class, varies widely. The following table, taken from the file of the U. S. Bureau of Standards, gives the composition of some portland cements of the U. S., wt. %:

SiO_2.....	22.25	25.02	20.75	22.66	20.37	23.40	19.03	19.82	20.80

PORTLAND CEMENT

P. H. Bates

In view of the relatively very small amounts of cements used other than portland, and especially in view of the lack of any critical data on these other types of cements, this section will deal only with portland cements and products made therefrom.

Portland cement is a heterogeneous mixture of several compounds of silica, alumina and lime (being mostly $3CaO.SiO_2$,

$2CaO.SiO_2$, $3CaO.Al_2O_3$, glass and uncombined lime), produced by heating to incipient fusion finely ground mixtures of limestone, marl, or other calcareous compounds with certain argillaceous materials as clay, shale, slag, etc. The cement contains, in addition to the above, compounds or solid solutions of iron, magnesium, sodium, potassium, titanium, etc. The compounds present do not occur in fixed or definite quantities and as a consequence the properties of portland cement vary widely. Furthermore, as it is not stable towards water, moisture, or carbon dioxide in the presence of moisture, its properties are constantly changing (²).

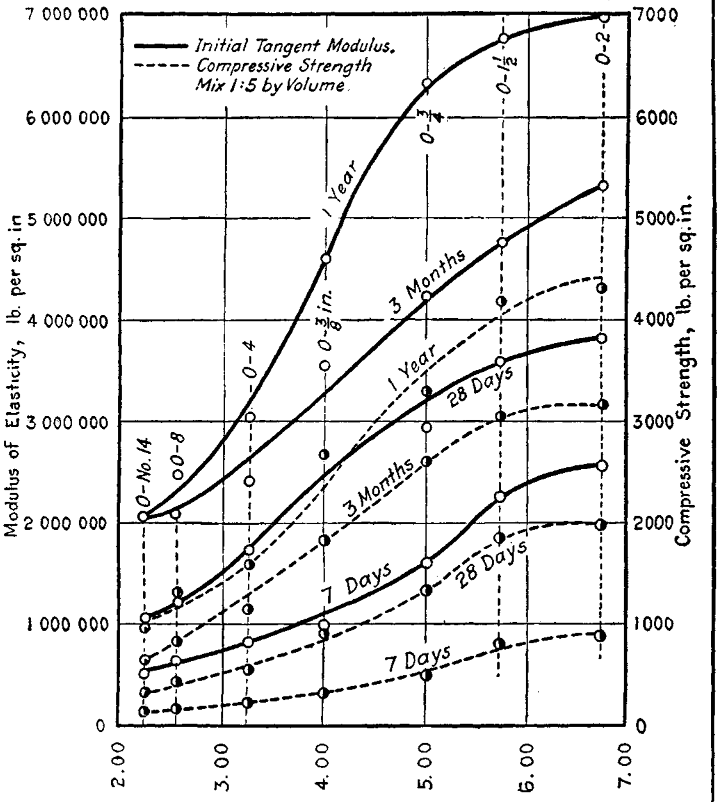

Fig. 1.—Effect of size of aggregate on modulus of elasticity. Compression tests of 6 by 12-in. cylinders. Sand and pebble aggregate. Relative consistency 1.10. Each value is the average of 24 tests from 6 times of mixing.

On mixing portland cement with water certain hydration reactions take place. The character and degree of these reactions depend upon the amount of water used and the presence of dissolved salts. The character and the degree of the reaction determine also the physical properties of the resulting material.

In view of the lack of the use of cement in the neat form (cement and water without the presence of any aggregate, either fine or coarse) no data will be presented referring to the properties when so used. All data will refer to concrete—large particles bonded with cement, or mortar—fine particles, all passing the ⅜ inch sieve, bonded with cement.

Strength of Concrete

The following equations have been suggested for calculating the compressive strength (Def. 4). Feret (²²) states that if values of the expression

$$\left(\frac{V_c}{1 - V_s - V_A}\right)^2$$

[where V_c = absolute volume of cement in unit volume of mortar,

V_s = abs. vol. of sand in unit vol. of mortar,

and V_A = abs. vol. of large aggregate in unit vol. of mortar] be graphed against the compressive strength (Def. 4) of any concrete made of any aggregate of the same consistency, aged under the same condition and for the same period, the points so obtained will lie close to a straight line passing through the origin.

According to Abrams (¹) the compressive strength, S, is expressed by the equation $S = A/B^x$

where x = the $\frac{\text{water}}{\text{cement}}$ vol. ratio in the mixture, and A and B are constants depending upon the quality of cement, age of concrete, curing conditions, etc.

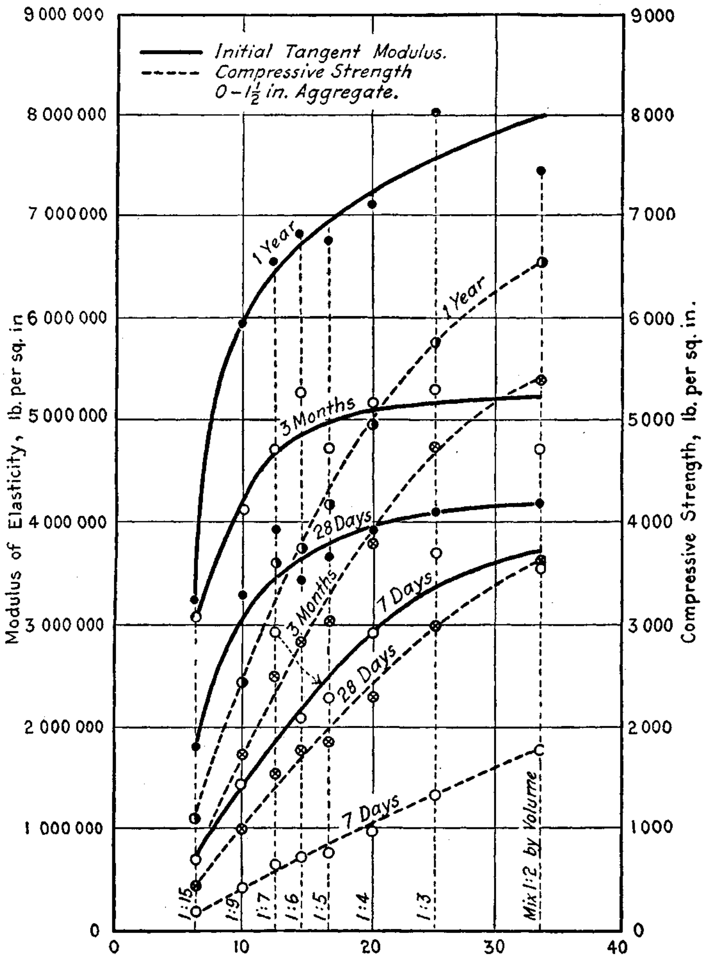

Fig. 2.—Effect of amount of cement on modulus of elasticity. Compression tests of 6 by 12-in. cylinders. Sand and pebble aggregate; graded 0-1½ in. Relative consistency 1.10. Each value is the average of 24 tests from 6 times of mixing.

Talbot (⁴⁰) finds $S = 32\ 000 \left(\frac{C}{V + C}\right)^{2.5}$ lb./in.²,

where C = vol. of cement in unit vol. mixture

and V = voids (air and water) in unit vol. mixture, when the "basic water" content is used. The "basic water" content is the amount of water per unit volume of the mortar that gives the minimum voids. The relation between strength and relative water content is not a straight line function. The strength of the concrete having a water content of 1.5 times that of the basic content would be reduced about one-third.

Modulus of Elasticity

Walker (42) gives $E = CS^m$
where E = modulus of elasticity,
C and m = constants depending upon the conditions of test,
and S = the compressive strength.

"Four different measures of modulus of elasticity of concrete are in more or less common use, as follows:

E_i = the initial tangent modulus;
E_t = tangent modulus at some load;
E_s = secant modulus at some load;
E_d = load modulus between two loads.

The initial tangent modulus for usual concrete mixtures may be represented by the equation $E_i = 33\ 000\ S^{5/8}$. For the tangent modulus at 25% of the compressive strength the equation becomes $E_t = 66\ 000\ S^{1/2}$."

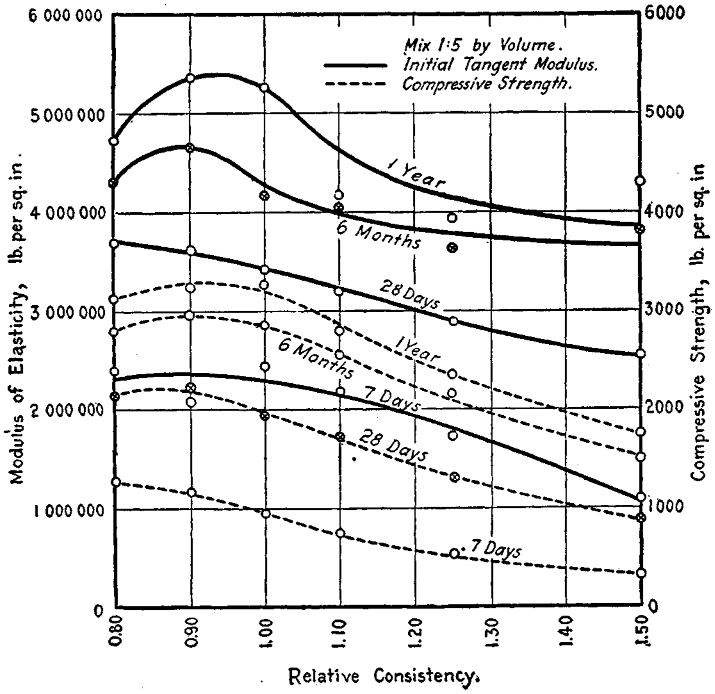

FIG. 3.—Effect of consistency of concrete on modulus of elasticity. Compression tests of 6 by 12-in. cylinders. Each value is the average of 15 tests from 3 sizes of sand and pebble aggregate.

Figures 1–4 illustrate the effect of the several variables mentioned above on the initial tangent modulus. In these graphs certain of the terms used have the same significance as indicated in the tables under "Strengths."

Poisson's Ratio (Def. 9)

Recorded values range from 0.08 to 0.18 (27, 39, 50).

Bulk Density

Varies from 0.68 to 0.90, according to grading and size of particles and is not affected by aging or slight changes in mixing temperature.

Thermal Expansion

Norton (34) found the following values for a "1:2:5 stone concrete." The concrete was permanently deformed by the heat treatment and did not return to its original length. The length on cooling was 75% of the maximum length obtained during heating.

Temperature range	$\frac{10^6 \Delta l}{l\, \Delta t}$
72°– 360°F	4.5 to 6.0
72°– 750°F	5.0 to 6.0
72°–1190°F	4.0 to 5.0
72°–1600°F	3.5 to 4.2

SPECIFIC HEAT (34)

Temperature range	g-cal g^{-1} deg.$^{-1}$C		
	1:2:5 stone	1:2:4 stone	1:2:4 cinder

Setting Time

In the U. S., the standards of the Govt. and Amer. Eng. Stands. Com. require an initial set in not less than 1 hour, and a final set within 10 hours, as determined by a purely empirical test. In other countries cements may be made to meet various specification requirements as to setting (*cf.* p. 117). No method of measuring the set of mortars or concretes has been developed.

Time Rate of Change of Volume

These data have been obtained by linear measurements alone, and are as usual faulty, owing to lack of data that would accurately delimit the concrete under investigation. The change is among other variables a function of the size of specimen, amount of water used, and the humidity of the surrounding atmosphere. The values given indicate a contraction ranging from 0.018 to 0.08% for "reinforced concrete" (33).

Resistance to Weathering and Chemical Action

Mortars and concretes are attacked by acid. If dense and carbonated on the exterior they offer great resistance to weather and other chemical agents.

Tests of Portland Cement

Used in obtaining the data given in Tables 2, 3, 4, and 5.

The cement used in all tests consisted of a mixture of equal parts of four brands purchased in Chicago and gave satisfactory soundness tests (over boiling water).

Tests were made in accordance with the *Standard Specifications and Tests for Portland Cement*, A. S. T. M.

Table 4.—Effect of Size and Grading of Aggregate

Aggregates: sand from Janesville, Wis., and pebbles from Elgin, Ill. Aggregates of different size were obtained by separating sand and pebbles into various sizes and recombining as shown by sieve analyses in Table 2. Different gradings of aggregates were produced by mixing sand (0 to No. 4) and pebbles (No. 4 to 1½ in.) in different proportions.

Mix, 1:5 volume. Relative consistency, 1.10. Specimens tested damp. Each value is the average of 5 tests made on different days.

GYPSUM

(Plaster-of-Paris)

W. E. Emley

Raw Materials and Calcination.—Commercial gypsum should contain $\nless$ 64.5% $CaSO_4.2H_2O$ (A. S. T. M., C22–23T; C23–22). On calcination below 163°C, $CaSO_4.2H_2O$ (gypsum) = $CaSO_4.\frac{1}{2}H_2O + 1\frac{1}{2}H_2O$. Gentle calcination above 163°C, $CaSO_4.\frac{1}{2}H_2O$ = $CaSO_4$ (soluble anhydrite) $+ \frac{1}{2}H_2O$. At higher temperatures $CaSO_4$ (soluble anhydrite) = $CaSO_4$ (natural anhydrite (insol.)) ([29], [44]). For *dissociation pressures*, consult this item in the index of I. C. T. Commercial calcination and product *v.* ([8], [21], [38]).

Properties.—The properties of products made from calcined gypsum are dependent upon the nature of the calcined gypsum (purity, method of calcination, and fineness), upon the quantity of water used in placing it, and upon the kind and amount of other materials (accelerators, retarders, lime, clay, sand) added to it. These facts must be constantly borne in mind when interpreting the figures given below.

Setting Time.—A normal figure is 6 min for no impression by Vicat needle ([24]) (A. S. T. M., C26–33). Doubling the amount of water will give 29 min ([24]). Fine grinding after calcination may lower to 3 min ([49]). The setting reaction is not complete when the Vicat needle indicates that the material is set. Evolution of heat continues and the temp. continues to rise for many min ([18]). If the calcined gypsum is of such a nature that a max. temp. rise of 14°C is attained in 53 min this time can be decreased to 21 min (by 2% sodium chloride) or increased to more than 240 min (by 2% calcium acetate) ([43]).

The commercial accelerator generally recommended is finely ground raw or set gypsum. The accelerating effect of this material is so powerful that especial care must be taken to clean all vessels and tools before mixing a fresh batch of material. 0.5 to 0.6% of this material will decrease the time of set of gypsum plaster about 1 hr (48). Other soluble sulfates, such as are generally found in our water supplies, have similar effects.

Commercial retarder is a mixture made by cooking together soda, lime, and slaughter house refuse; 0.2% of this material will retard the time of set 2.5 to 3 hr (43). Carpenters' glue has a similar effect and is more readily obtainable.

Expansion on Setting.—Calcined gypsum will normally expand when it sets. Heavily retarded material may contract due to settling out of the solid. Calcined gypsum retarded to set in 2 hr and mixed with 35% water expanded 0.15% in length while setting. Increasing the water to 47% increased the expansion to 0.30%. Addition of sand seemed to have little effect.

After the gypsum has set and dried, wetting will cause expansion, drying, contraction. The magnitude of the movement is about 0.04% for the pure material. Addition of sand reduces this expansion, the reduction being proportional to the amount of sand, so that a specimen made of one part calcined gypsum to a little more than two parts of sand shows practically no movement, and leaner mixtures actually contract instead of expanding on being wetted (35).

Strength.—Calcined gypsum, if pure, properly calcined, of such fineness that it will all react, mixed with as little water as possible to bring it to a pouring consistency, molded in the form of a cylinder 2 in. diameter by 4 in. high, not retarded to such an extent that much water can evaporate prior to setting, and stored in a cool place until dry, will develop a compressive strength of at least 1000 lb./in.^{2} (A. S. T. M. C23–22); av. 1665, max. 2285 (21).

Naturally occurring impurities or added materials (except accelerators) will decrease the strength. The average figure for the compressive strength of a mixture of one part calcined gypsum to two parts sand by weight may be taken at 415 lb./in.^{2} (21); for a 1:3 mixture the figure is 335. Lime and clay reduce the strength at early ages, but this is gradually recovered (36). Portland cement reduces the strength in proportion to the cement added until the mixture reaches a minimum at 20% gypsum 80% cement, the strength of which is little more than half that of calcined gypsum (35).

Increased fineness up to 80% through a No. 100 U. S. Stand. sieve (*v.* p. 329), by making the calcined gypsum more reactive, causes increased strength. This size is 50% stronger than material only 40% of which passes a No. 100 sieve. Further increase in fineness is accompanied by a decrease in strength because more water is required to bring the mixture to a workable consistency (45).

The above figures are based on the max. consistency thickness which will allow pouring. Thicker consistencies will give greater strength, clear to the limit of workability of the mixture (9). Thinner consistencies will give lower strengths to zero, for calcined gypsum will not harden under water.

While there is a tendency for accelerators to increase the strength of calcined gypsum and for retarders to reduce it, the action of neither is marked unless retarder is present in sufficient amount to delay the set until the water required for setting has evaporated. Two per cent calcium acetate, for example, will retard calcined gypsum so far as to destroy completely its strength (43).

Castings made of calcined gypsum are strongest when completely dry. Moisture, or more particularly percolating water, seems to dissolve the bond between the crystals, resulting in permanent loss of strength or eventual disintegration. On account of the comparatively high dissociation pressure of gypsum at ordinary temperatures (100 mm Hg at 62°C) (41), it is dangerous to resort to artificial drying. The strength reaches very nearly its maximum as soon as the casting is dry, so that the age of a test specimen is of little importance (A. S. T. M. C26–23).

The ratio compressive strength/tensile strength = *ca.* 4.62 (21).

Thermal Conductivity and Fire Resistance.—(25). (*See also* p. 315.)

Heat of Dehydration.—*See* I. C. T. Section on Thermochemistry.

Porosity, Solubility and Weather Resistance.—Calcined gypsum will not harden under water. When hardened in air and immersed in running water, castings made of calcined gypsum will eventually disintegrate. Calcined gypsum should not be used in situations where it will be exposed to the weather unless special precautions are taken.

These characteristics are usually attributed to the fact that gypsum is "quite soluble," but it is now believed that they are dependent more upon porosity than solubility.

The solubility of gypsum in pure water varies from 0.18% at 0°C to a maximum of 0.21% at 40°C, but it is much more soluble in water containing certain common salts (23). Taking the weight of set gypsum at 77 lb./ft.^{3} (32) and the specific gravity of the solid material at 2.35, the pores must occupy 47.5% of the total volume. (This figure may vary within wide limits, depending upon the fineness of the calcined gypsum and the quantity of mixing water used.) Owing to the crystalline nature of the material, these pores are comparatively large and afford passages for circulation of water, thereby rendering material assistance in the solution of the gypsum.

It has been found that if calcined gypsum is heavily retarded so that it can be trowelled frequently while setting, the dense surface thus produced is quite effective in improving the weather resistance of the finished product (46).

LIME MORTAR AND MASONRY

W. E. Emley

Commercial limes and mortars are made by mixing properly calcined limestone with water, or water and sand. Their properties depend on many variables, lack of control of which render most of the published quantitative data valueless. For the available qualitative information, reference should be made to the literature cited.

Raw Materials

Nature of Raw Materials, Commercial Definitions and Specifications (12).—(A. S. T. M. C51–22T; C5–22T).

Density.—*v.* p. 53.

Porosity.—Limestone usually less than 1 vol. % (*v.* p. 53).

Dissociation Pressure and Rate of Dissociation.—The dissociation pressure reaches 1 atm at 898°C for $CaCO_3$ and 756.5°C for $MgCO_3$. For further data, *v.* "Dissociation pressure" in the index of I. C. T. Commercial calcination is *ca.* 6 hr at *ca.* 1400°C (6, 15).

Other Properties.—*See* the pure materials in the various tables of I. C. T. *See also* p. 47.

Hydrated Lime and Lime Putty

Manufacture.—When CaO is properly mixed with an excess of water sufficient to keep the temp. below 100°C "lime putty" is obtained. With less excess, the resultant product is dry "hydrated lime." With still less water, the temperature may rise above 375°C and an "oxyhydrate" is obtained (17, 26).

"Plasticity."—(20, 25, 26, 28).

Lime Mortars

Decrease in Volume on "Setting."—From 9% for non-plastic to 27% for plastic lime putty (28). This contraction is in practice reduced to *ca.* 5% by admixture of 80–90% of sand (5, 40).

Setting Time.—No agreement as to definition of term. The following laboratory test has been proposed (37):

Setting shall be assumed to be attained when an electrical resistance of 30 000 ohms is reached between two 5 mm brass plugs imbedded 8 mm in the plaster with their centers 10 cm apart.

Under this definition, neat lime putty will set in 40–50 hr, and this may be reduced 5–10 hr by admixture of sand (37).

Rate of Carbonation.—As ordinarily mixed and placed, lime mortar will carbonate from the surface inwards at *ca.* ⅛ in. per month (16). This is subject to change, within narrow limits, by variations of the factors enumerated above. A 2-in. cube exposed on 5 sides will carbonate completely in *ca.* 8 months; an 8-in. mortar joint exposed on one side will require more than 5 years.

Soundness.—(20, 31, 47).

Strength.—For purposes of intercomparison only, the following figures may be quoted as the strength of a mortar made of high calcium hydrate with three parts by weight of run-of-mine Ottawa sand and enough water to bring the mixture to "Standard" consistency (19) on the plunger viscometer, the mortar being molded in the form of 2-in. cubes for compression, the usual type of briquette for tension, and 12 × 1 × 1 in. bars for transverse and shear, and the specimens stored in the laboratory, with 5 sides exposed, for 90 days: Compressive, 403; Tensile, 69; Shearing, 82; Transverse, 146 lb./in.^{2}

Expansion after Setting.—No published data. Humidity and thermal coefficients at room temperature approximately equal to those of concrete. Thermal coefficient much greater at higher temperatures (9).

Strength of Masonry (7, 13).—Common brick masonry (1 to 4 pt. by vol. lime mortar) should withstand a compression of 125 lb./in.^{2} (14). *See also* p. 66.

Thermal Conductivity and Fire Resistance.—(25).

MAGNESIA CEMENTS AND CONCRETES

LEROY C. STEWART

BULK DENSITY (7)

Grams per cm^3: Stucco, 3.0 to 3.4. Flooring, 1.55 to 1.8. Special mixes with wood flour, cork dust, etc., 1.0 to 2.0.

ULTIMATE TENSILE STRENGTH (DEF. 4) AND MODULUS OF RUPTURE (DEF. 5) OF CEMENTS MADE WITH SPECIALLY CALCINED DOLOMITES

Wt. %: Calcined dolomite 31, ground flint 12.5, Ottowa sand 56.5. 1.179 sp. gr. $MgCl_2$ soln., kg/cm^2 (22).

Dolomite	Tensile strength			Modulus of rupture*		
	1 day	3 days	7 days	Not sprayed	Wet	Recovered
A			32.6	112.2	54.0	68.0
B	18.1	30.2	34.4	133.0	69.6	102.6

* Bars sprayed 24 hr at 14, 16 and 18 days' age. "Wet" bars broken at 19 days' age and "Recovered" at 21 days' age. "Not Sprayed" bars broken at 20 days' age.

ELASTIC PROPERTIES

Elastic limit (Def. 2), modulus of elasticity (Def. 10*a*) and ultimate compressive strength (Def. 4) of cement mortar and concrete.

1.23 sp. gr. $MgCl_2$ soln. used. Aged 80–85 days. Unit kg/cm^2 (1).

Magnesite-sand-rock by wt.	Elas. lim.	Mod. elas.	Compr. str.
1- 4-0	253	194 000	319
1- 6-0	150	192 000	240
1- 8-0	127	146 000	185
1-10-0	53-114	96 400	143
1- 2-4	234	269 000	359
1- 3-6	234	194 000	305

Under this definition, neat lime putty will set in 40–50 hr, and this may be reduced 5–10 hr by admixture of sand (37).

Rate of Carbonation.—As ordinarily mixed and placed, lime mortar will carbonate from the surface inwards at *ca.* ⅛ in. per month (16). This is subject to change, within narrow limits, by variations of the factors enumerated above. A 2-in. cube exposed on 5 sides will carbonate completely in *ca.* 8 months; an 8-in. mortar joint exposed on one side will require more than 5 years.

Soundness.—(20, 31, 47).

Strength.—For purposes of intercomparison only, the following figures may be quoted as the strength of a mortar made of high calcium hydrate with three parts by weight of run-of-mine Ottawa sand and enough water to bring the mixture to "Standard" consistency (19) on the plunger viscometer, the mortar being molded in the form of 2-in. cubes for compression, the usual type of briquette for tension, and 12 × 1 × 1 in. bars for transverse and shear, and the specimens stored in the laboratory, with 5 sides exposed, for 90 days: Compressive, 403; Tensile, 69; Shearing, 82; Transverse, 146 lb./in.^{2}

Expansion after Setting.—No published data. Humidity and thermal coefficients at room temperature approximately equal to those of concrete. Thermal coefficient much greater at higher temperatures (9).

Strength of Masonry (7, 13).—Common brick masonry (1 to 4 pt. by vol. lime mortar) should withstand a compression of 125 lb./in.^{2} (14). *See also* p. 66.

Thermal Conductivity and Fire Resistance.—(25).

SOLID FUELS

S. W. PARR

1. CLASSIFICATION

For the purpose of displaying typical values of their properties and compositions, solid fuels will be assigned to classes on the basis of two characteristics which will be called unit-heat-value (*UHV*) and unit-volatile-matter (*UVM*), respectively, and which are defined by the following equations ([17, 21]).

$$UHV = \frac{H - 5000S}{F}\ \text{BTU/lb.} = \frac{H - 2778S}{F}\ \text{g-cal/g}, \qquad (1)$$

where H is the total calorific value of the fuel (BTU/lb., g-cal/g, respectively); and

$$UVM = 100\left(\frac{V - (0.08 + 0.4S)}{F}\right)\%, \qquad (2)$$

where V = the volatile matter per unit mass of fuel.

In both equations the factor, $F = 1 - (W + 1.08A + 0.55S)$, where W, A and S are, respectively, the water, ash and sulfur content of the unit mass of fuel as determined by chemical analysis.

The numerical factors in equations (1) and (2) are such that the quantities UHV and UVM represent, respectively, the heating value and the volatile matter per unit mass of fuel-substance contained in the solid fuel; *see also* ([17, 21]).

By means of these two characteristics, every solid fuel can be represented as a point on a plane and the location of this point with respect to the areas which have been selected for delimiting the various classes of solid fuels, identifies the class to which the fuel belongs and its relative location in that class. This is illustrated by the diagram in Fig. 1. The circles represent the loci of certain selected samples, representative of each class, and whose compositions are shown in Table *A*. The crosses represent the loci of a series of coals corresponding to the composition averages of Tables 2–10.

Another method for classifying coals, based upon limits for carbon, hydrogen, oxygen plus nitrogen, and volatile matter has been proposed by Seyler ([27, 28, 29, 30]). The classes which he proposes are, however, in close agreement with those defined in Fig. 1 [*cf.* ([24])] and a comparison of the proposed nomenclatures is shown in the following table. All proposed nomenclatures are provisional, since no agreement has as yet been reached.

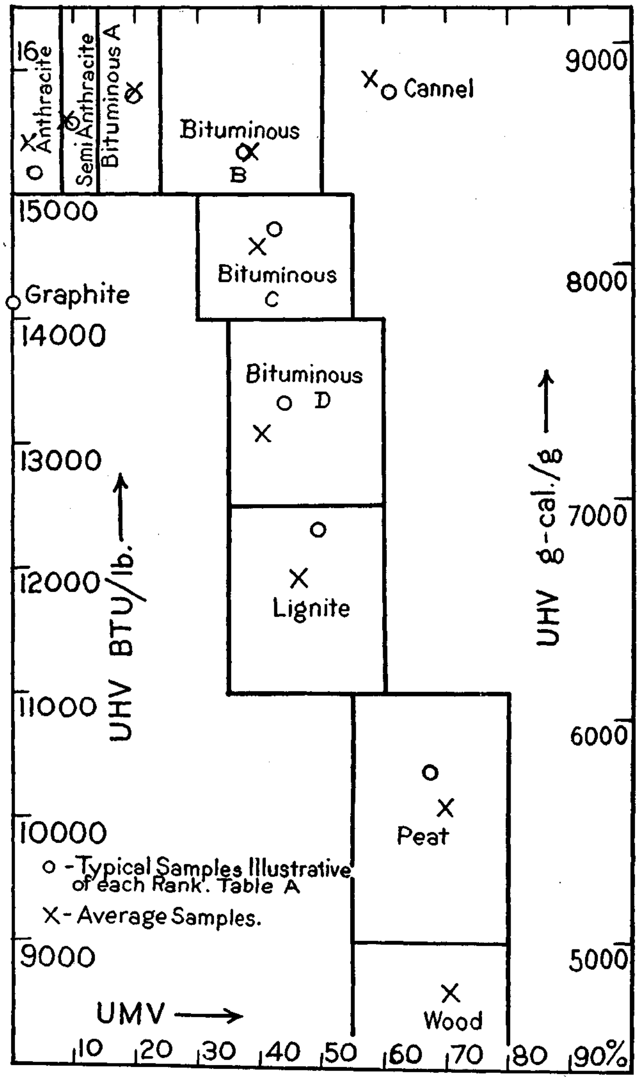

FIG. 1.—Classification of solid fuels.

CALORIFIC VALUE

The values characteristic of the different classes of solid fuels are evident from Fig. 1. The calorific value of a solid fuel of the fossil fuel type may be computed (1 to 2%) by means of the Du Long formula, $H = 8080C + 34\,500\left(H - \frac{O}{H}\right) + 2250S$, g-cal, where C = total carbon, $\left(H - \frac{O}{H}\right)$ = combustible hydrogen, and S = sulfur; *cf.* (34).

It may also be computed from equation (1) since the value of *UHV* is constant for a given mine or region and needs to be determined only once. For standard calorimetric methods, *v.* (5).

SULFUR CONTENT

For methods of differentiating between organic and inorganic *S*, *v.* (23). Distribution of the different forms, *v.* (19, 39, 40).

ASH FUSIBILITY

Methods (14, 26). Results for 2000 coals (26). Fusibility of coal ash by states and seams (41). Bibliography (7); *see also* (8, 25). Values range from 1040° to 1700°C.

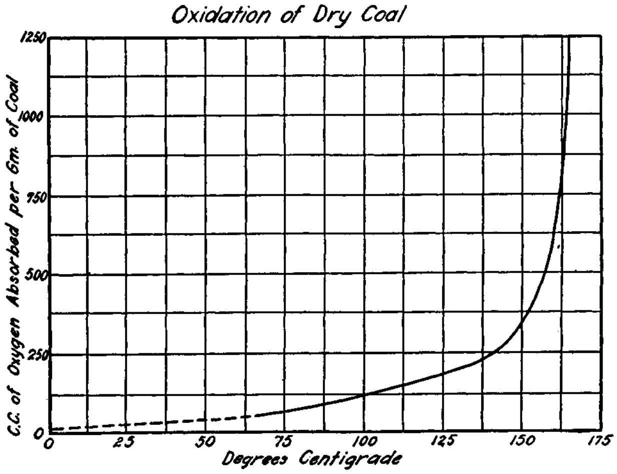

FIG. 2.—(*Courtesy Industrial and Engineering Chemistry.*)

DENSITY

True density, g/cm³; anthracite, 1.4–1.8; bituminous, 1.2–1.5; lignite, 1.1–1.4 (15). Coke, 1.45–2.0(35).

BULK DENSITY IN BIN OR PILE, ±10 TO 15% (9)

Anthracite

Size	lb./ft.³	kg/m³
Buckwheat	55	888

POROSITY

Methods (3). Coal—no data. Coke—29–59% (3); *v.* Table 11.

SPECIFIC HEAT

0.26 to 0.37 g-cal/g (22).

SPONTANEOUS COMBUSTION, WEATHERING AND DETERIORATION

Absorption of oxygen by powdered bituminous coal: Fig. 2 (18). Effect of storage on calorific power: Fig. 3 (20).

COKING BEHAVIOR

See (6, 10, 13, 14, 16, 32, 33, 37).

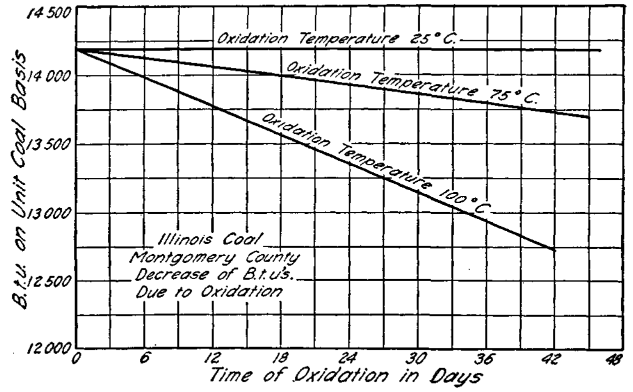

FIG. 3.—(*Courtesy Industrial and Engineering Chemistry.*)

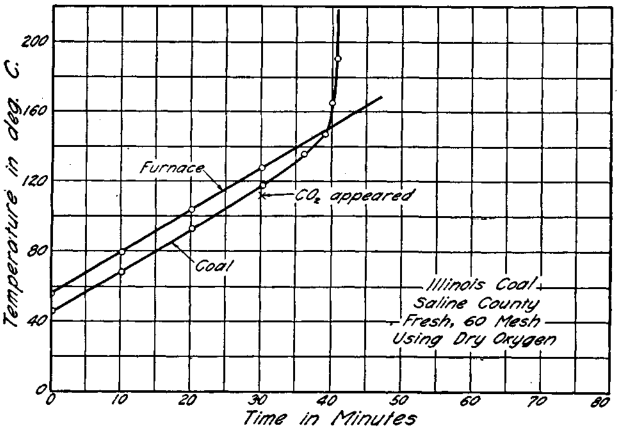

FIG. 4.—(*Courtesy Industrial and Engineering Chemistry.*)

IGNITION TEMPERATURES

The ignition temperature of a mass of coal is the temperature at which oxidation within the mass proceeds autogenously under the conditions of the experiment. Curves showing typical progress of heating within and without a 10 g sample of bituminous coal are shown in Figs. 4 and 5 (38). The following table (36) gives the ignition temperatures of various types of coal, using dry oxygen and 60 mesh "as-received" coal.

COMBUSTIBILITY OF COKE

A combustibility test is designed to show "the speed at which the carbon molecules in the coke combine with oxygen under given conditions" and is especially important in determining the value of a blast furnace coke. For method and results, *v.* (31).

COMPOSITION AND DENSITY OF CRUDE PETROLEUMS

North America

CANADA

Low boiling constituents are of the C_nH_{2n+2} series up to C_{10}. The C_nH_{2n} series starts at C_{11} and includes both straight-chain olefins and saturated naphthenes. The series poorer in hydrogen occur in the high boiling fractions. More aromatics present than in Pennsylvania or Ohio oils. Sulfur as thiophanes, $C_nH_{2n}S$ (**121, 127, 135, 136, 172**).

California.—Proportion of distillates below 225°C small to moderate and composed of methylenes similar in B. P. and sp. gr. to those in Russian oil, except for the compounds $C_{11}H_{22}$, $C_{12}H_{24}$ and $C_{13}H_{26}$. Proportion of aromatics large. Members of the C_nH_{2n+2} series absent (133). Organic bases mainly mixture of alkylated quinolines with small side chains (139). Oxygen usually as naphthenic acids with some phenolic compounds. Sulfur as $C_nH_{2n}S$.

* Mixed-base oil with small amount naphthenic acid. Low-boiling distillate contains aromatics.

† No solid paraffins and little asphalt. Empirical composition $C_nH_{1.47n}$.

‡ Mixed-base petroleum containing solid paraffins and asphalt. Aromatics and small amounts of naphthenic acids in the lighter distillates.

§ $C_{20}H_{26}$, $C_{22}H_{22}$, $C_{24}H_{24}$, $C_{26}H_{26}$, xylene and isocumene isolated (205).

JAPAN (138)

Chiefly the C_nH_{2n} series. Aromatics much smaller than in California.

PROXIMATE COMPOSITION

For comprehensive tables covering the chief producing fields of the world *see* (39, 53.1); for extensive tables of data on North and South American crudes, *see* (108).

Below are given the data for the oil fields of the United States as collected from the reports of the U. S. Bureau of Mines, Reports of Investigations, Nos. 2293, 2595, 2608, 2235, 2364, 2322, 2202, 2416.

The various fractions ("cuts") used in these tables are defined by their distilling ranges or by their Saybolt viscosities (η) at 100°F as follows:

1. Gasolene and naphtha. Below 200°C at 1 atm.
2. Kerosene. Between 200° and 275°C at 1 atm.
3. Gas oil. All vacuum fractions (p = 40 mm) with $\eta < 50$ sec.
4. Light lubricating distillate. All vacuum fractions (p = 40 mm) with η between 50 and 99 sec.
5. Medium lubricating distillate. All vacuum fractions (p = 40 mm) with η between 100 and 199 sec.
6. Viscous lubricating distillate. All vacuum fractions (p = 40 mm) with $\eta > 199$ sec.

Specific gravities (d) are at 60/60F = 15.5/15.5C. % S = % sulfur.

Field	County	Crude		Gasolene and naphtha		Kerosene		Gas oil		Lubricating distillates

SPECIFIC GRAVITY AND THERMAL EXPANSION

In this section, S will be used to represent $d_{15.56}^{15.56°}\text{C} = d_{60}^{60°}\text{F}$.

CONVERSION FORMULAE

All weights in vacuo

$$°\text{API} = \frac{141.5}{S} - 131.5. \quad °\text{Bé (American)} = \frac{140}{S} - 130$$

$$\text{Lb. per gal. (U. S.)} = 8.328 \times S$$

$$\text{Lb. per gal. (Brit.)} = 10.00 \times S$$

$$\text{Gal. (U. S.) per lb.} = 0.1201 \times S$$

$$\text{Gal. (Brit.) per lb.} = 0.1000 \times S$$

For other conversion factors, *v.* vol. I, p. 23. For elaborate computed conversion tables convenient for interpolation, *v.* (10).

Crude Petroleums

The specific gravity of crudes varies with locality between the extreme limits 0.65 to 1.07. Below are given only those crudes for which values above 0.95 or below 0.75 have been recorded. The recorded data for all other crudes lie between the above values. For these *v.* (26, 39, 53.1, 87, 120, 169).

Blending Chart.—For use in determining % of naphtha to be added to gasolene to obtain blend of given density, *v.* (8).

LUBRICATING OIL AT LOW TEMPERATURES

This sample had the following properties: $S_{15.5}^{15.5} = 0.9427$; Fl. P., 224°C; η at 98.9°C, 92 sec Saybolt; Pour point, −18°C. The density data were $d_4^t = 0.9740$, (−35° to −40°C); and $d_4^t = 0.9523 - 0.000665t$, (−30° to +20°C) (76).

PARAFFINS

Solid.—$d_{15}^{15} = 0.87 - 0.94$; $d_{15}^{50} = 0.84 - 0.89$. Recorded data on thermal expansion very conflicting, possibly due to enclosed air (19, 158, 166, 211). Between −190° and 17°C Dewar found $\frac{1}{V}\frac{\Delta V}{\Delta t} = 0.000357$ per deg (43).

Liquid.—$d_{15}^{50} = 0.777 - 0.785$; $d_{15}^{80} = 0.755 - 0.780$. $d_{15}^t =$ const. $(= 53 \text{ to } 85) \times 10^{-5}t$ (between *ca.* 50° and 100°C) (19, 158, 166, 211).

MISCELLANEOUS

Petrolatum ("Vaseline").—$d_4^t = 0.873$, 23°; 0.868, 32°; 0.862, 42°C (206).

Petroleum Ether.—$V_t = V_0(1 + 146 \times 10^{-5}t + 16.0 \times 10^{-7}t^2)$, −190° to 0°C (90).

THERMAL EXPANSION

$$d_t = d_s - \alpha(t - t_s) + \beta(t - t_s)^2$$

$$\alpha = (66 \pm 5) \times 10^{-5};\ \text{for } S \nless 0.84$$

$$\alpha = [(189.4 - 146.5S) \pm 3] \times 10^{-5};\ \text{for } S \ngtr 0.84$$

$$\beta = [(-15.4 + 19S) \pm 2] \times 10^{-7}$$

$$d_t = d_4^t \text{ or } d_{15.5}^t$$

$$d_s = d_4^{t_s} \text{ resp. } d_{15.5}^{t_s} \text{ when } 15^\circ < t_s < 35^\circ$$

S = the density or specific gravity (two decimal places sufficient) at any temperature between *ca.* 15° and 35°.

Example: Given $d_{15.5}^{17} = 0.6935$, to find $d_{15.5}^{60}$

$$d_{60} = 0.6935 - (189.4 - 146.5 \times 0.69) \times 10^{-5} \times (60 - 17) + (-15.4 + 19 \times 0.69) \times 10^{-7}(60 - 17)^2 = 0.6551 \pm ca.\ 0.0003.$$

For all practical purposes, the above relations appear to be applicable to all petroleum oils, both crude and refined, between 0° and 50°C (and probably to 100°C) as long as they continue to remain homogeneous liquids sufficiently fluid to be measured with a hydrometer (18). For elaborate computed tables convenient for temperature conversions and based substantially on the above relations *v.* (10, 41).

Additional Literature on Thermal Expansion.—Crudes (51, 94, 148, 182, 183, 197). Derivatives (94, 102, 117, 181).

Expansion above 100°C.—A recent investigation (225) of California petroleum products yields the equations:

$$v_t = v_{15.56}[1 + \alpha(t - 15.56^\circ) + \beta(t - 15.56^\circ)^2] \quad \text{(Range, 15° to 260°C)}$$

and

$$v_t = v_{260}[1 + \alpha'(t - 260^\circ) + \beta'(t - 260^\circ)^2] \quad \text{(Range, 260° to 400°C)}$$

$$\alpha = [2.32 - 1.7S] \times 10^{-3};\ \text{for } S \nless 0.82$$

$$\alpha = [4.36 - 4.2S] \times 10^{-3};\ \text{for } 0.82 < S < 0.75$$

$$\beta = [4.86 - 4.5S] \times 10^{-6}$$

For S =	1.0	0.95	0.90	0.89
$10^3 \alpha'$ =	0.75	0.83	1.05	1.20

$$\beta' = [20.29 - 19.45\,S] \times 10^{-6}$$

where v_t is the volume (cm³) at t°C, and S is the specific gravity at 15°C.

COMPRESSIBILITY

The mean coefficient of compressibility between P_1 and P_2 is defined by the equation

$$\beta = \frac{V_{P_1} - V_{P_2}}{V_{P_1}(P_2 - P_1)}$$

Kerosene and Lubricating Oils.—Within the accuracy of the measurements, all available data are correctly expressed by the equation

$$\frac{10^{-6}}{\beta} = \mathrm{a} + \mathrm{b}P - \mathrm{c}P^2 + \mathrm{d}P^3,$$

in which $\beta = \dfrac{V_0 - V_P}{V_0 P}$ is the mean coefficient between 0 and P.

Conversion Factors.—To convert a pressure, in any of the following units, into atmospheres, multiply it by the factor given.

Megabarye	kg cm^{-2}	Lb. in. $^{-2}$
0.98692	0.96784	0.068047

Kerosene.—Between 1 and 11 atmospheres and 0–100°C, β in atm.$^{-1}$ is expressed by the equation $\beta = (67.5 + 0.458t) \times 10^{-6}$ (161).

VISCOSITY

See also Lubricants and Lubrication, p. 164.

Viscosity Units and Their Interconversion. *See* vol. I, p. 25.

Viscosity at Room Temperatures.—Typical values in poises are:

(*a*) Gasolenes, 0.003–0.006;
(*b*) Kerosene, 0.02;
(*c*) Light lubricating oils, 0.025–1.5;
(*d*) Medium lubricating oils, 1.5–3.5;
(*e*) Heavy lubricating oils, 3.5–20;
(*f*) Petrolatum (M. P., 85°–95°F), 1.3 at 130°, 0.24 at 210°F.

Variation of Viscosity with Temperature.—If the viscosity of an oil is known at two temperatures, its viscosity at a third temperature may be obtained graphically with the aid of Fig. 1. When the viscosity temperature values for any oil are graphed on this chart a straight line will be obtained for all portions of the temperature range within which the oil remains a homogeneous liquid of constant composition (11). Copies of this chart may be obtained by addressing The Texas Company, New York City.

SURFACE TENSION

Below are summarized the reported data on the surface tension (γ, in dynes per cm) of various products.

Crudes.—24–38 at 20°C (63, 84, 160, 176). The lower values, 24–26, are reported for crudes from Pennsylvania and California (176); the higher values, 35–38, for crudes from California fields at Montebello, Sunset, and Kern (84).

Petroleum Distillates.—For distillates up to 300°C, γ = 19–29 at 20° and is approximately a linear function of the density. *See* Fig. 12 (p. 157). $d\gamma/dt$ = *ca.* −0.1 per °C between 0° and 50° (63, 64, 140, 176).

Naphthas.—(B. P. up to 150°C). γ = 19–23 at 20° (176).

Kerosenes.—(B. P. 150°–300°C). γ = 23–32 at 20° (77, 176).

Gas Oils.—γ = 28–29 (175).

"Gas Oil Distillates."—(150°–300°C). γ = 21–28 (175).

"Tar Oils."—γ = 34–37.6 (175).

"Tar Oil Distillates."—(150°–300°C). γ = 27–36 (175).

Lubricating Oils.—Oklahoma and California. γ = 36–37.5 at 30°C (63, 78).

"Wax Distillates."—γ = 34–36 at 30°C (63).

Paraffin.—γ = 30.6 at 54°C (162).

INTERFACIAL TENSIONS

Oil-Water Interface.—Dyne cm^{-1}. Gasolenes and naphthas, 39–51: kerosene, 47–49: mineral seal, 47–50: lubricating oils, 33–54: cylinder oils, petrolatum, paraffin at higher temperatures, 35–50, increasing after filtration. Several days' exposure to light produces decreases up to 30% (70, 99). $d\gamma/dt$ = *ca.* −0.1 between 4° and 8°C.

Addition of fatty acids lowers the interfacial tension against both H_2O and Hg (20, 213).

PENETRATIVITY (1)

The penetrativity, z, of a liquid is measured by the ratio $\gamma/2\eta$ where η is the viscosity (206). If z for H_2O is taken as 1 at room temperature, z for kerosene is 0.05 at 20°C; z for paraffin is 0.092 at 65°, 0.39 at 185° and 0.45 at 215°C. z for petrolatum ("vaseline") in absolute units is $0.063(t - 30)^2$ cm sec^{-1}, where t is the temperature in °C between 100 and 200.

MELTING POINT

The petroleum products of commerce are all mixtures, and consequently possess no sharp melting or freezing point; but exhibit instead a *melting range.* It is, of course, possible by suitable blending to obtain a product with almost any initial melting or freezing point between the extreme limits of −150°C (0.70 specific gravity gasolene) and +60°C (the high melting waxes).

Typical Values.—The limiting values recorded below show the regions of the temperature scale within which the melting or freezing ranges of some typical commercial products may be expected to lie (For "pour test" *see* p. 156).

Material	Typical melting or freezing range, °C
Gasolene 0.704 sp. gr. 15.5/15.5	−122 to −150
.719 sp. gr. 15.5/15.5	−120 to −147
Petroleum jelly—pale	39 to 51
Paraffin waxes:	
Match wax	40.5 to 46
White crude scale (Pa.)	50 to 52.2
Semi-refined (Pa.)	50 to 51
Fully refined (Pa.)	49 to 50
Fully refined (Calif.)	59 to 60
Ceresins:	
General range	60 to 80
Normal wax	65 to 66
Pure	79 to 80

Melting Point of Paraffins

Variation of melting point with oil content (221)

Material	% of pressed oil	Refractive index at 25°C	Melting point °C
"Parowax"	0.16	1.4481	51.7
Refined wax	0.28	1.4487	50.0
Refined wax	0.25	1.4485	50.0
Refined wax	0.17	1.4481	51.7
Refined wax	0.16	1.4479	51.7
Refined wax	0.09	1.4476	54.4
Refined wax	0.08	1.4475	54.4
Scale wax	2.58	1.4570	48.3
Scale wax	2.56	1.4568	48.3

Variation of Melting Point of Paraffin with Pressure

$t_P = t_0 + 0.029776 \quad (P - 1) - 0.0000523 \quad (P - 1)^2$, between 1 and 200 atm.

t_P (resp. t_0) = melting point of paraffin under pressure P (resp. 1 atm.).

SOLUBILITY OF PARAFFIN

For solubility of various kinds of paraffin in gasolenes, kerosene, lubricating oil, paraffin oil, fuel oil, benzene, alcohols, and acetic acid *see* (184).

VAPOR PRESSURE AND BOILING POINTS

The few available data when graphed (log p against $1/T$) are found empirically to give approximately straight lines. p = the vapor pressures at T°K. In the table below are given, (1) typical or limiting values of the B. P. (at 1 atm.) for the class, (or, in parentheses, the B. P. at 1 atm. as obtained by extrapolation of the vapor pressure curve); (2) the range covered by the available vapor pressure data; (3) the value of d $\log_{10} p/\text{d}(1/T)$, the slope of the vapor pressure curve; and (4) the source of the experimental data.

Correction of B. P. for Barometric Pressure.—In the present state of our knowledge, it is necessary to know the slope of the log p, $1/T$ curve for the particular type of product under examination (*i.e.*, the B. P. must be determined at two pressures), in order to be able to make this correction with any degree of certainty for pressures not close to 760 mm.

DEW POINTS

Definitions and Abbreviations.—The temperature at which condensation begins, when a mixture of air and motor fuel is cooled, is called the *dew point*, t_D. The *dew-point index*, I_D, is the sum of the °C boiling points at the 10, 20, 50, 70, 90, and 100% points of the 100 cc standard Engler distillation procedure. For °F it is one-half this sum. The 85% *point*, t_{85}, is the boiling point corresponding to the 85% point of the Engler distillation.

The following generalizations have been put forward.

Thirteen commercial gasolenes with I_D values ranging from 612 to 1025 give, when mixed with 15 parts of air by weight, values of t_D ranging from 10° to 88°C, the relation being

FLASH POINTS OF SATURATED VAPORS OF COMBUSTIBLE LIQUIDS

E. H. Leslie and J. C. Geniesse

1. Pure Substances.—The flash point of the vapor above a liquid is the temperature at which ignition will occur. The observed value is materially dependent upon the type of apparatus used (*v.* p. 150 for comparison of values with different types of apparatus). The lower limit of the flash point of a pure liquid is approximately the temperature at which its vapor pressure is equal to B/kN where B is the barometric pressure, N is the number of moles of O_2 required for complete combustion of one mole of the liquid, and k is a constant varying with the type of apparatus employed *cf.* (4). The flash point varies with the barometric pressure at the same rate as the boiling point.

In the accompanying table are shown for a number of liquids; (*a*) the value of N, (*b*) the observed flash point as recorded in the literature and (*c*) the flash point as calculated from the above relation, assuming $k = 8$. A better agreement between observed and calculated flash point might perhaps be obtained by using different values of k for different types of apparatus but the recorded flash points vary greatly and a careful and comprehensive investigation is needed.

Formula	Name	N	Flash point		Lit.
			Observed	Calculated, min.	
CS_2	Carbon disulfide	3	−25.5 to −20	−27	(4)

QUANTITATIVE EFFECTS OF SOME COMPOUNDS UPON DETONATION IN INTERNAL COMBUSTION ENGINES

T. A. BOYD

The detonation or "knock" that characterizes combustion in gasoline engines under certain conditions is influenced primarily by the chemical composition or structure of the fuel, and secondarily by the compression to which the combustion mixture is subjected, by its temperature, and by the point in the cycle at which ignition occurs, as well as by some more minor factors, such as the shape of the combustion chamber and the location of the spark plug (1, 8). The principal types of compounds that may be used as fuels in the gasoline engine arrange themselves in the order of decreasing tendency to knock as follows (2, 8): ethers, paraffins, olefins, naphthenes, aromatics, alcohols. The tendency of any given fuel to detonate may either be increased or decreased as desired by the addition of a suitable compound to the combustion mixture, the amount required being very small in some cases.

La détonation ou le "cognage" qui caractérise la combustion dans les moteurs à benzine sous certaines conditions, est influencée premièrement par la composition chimique ou la structure du carburant et secondairement par la compression à laquelle le mélange combustible est soumis, par sa température, et par le point du cycle auquel l'allumage se produit, de même que par quelques autres facteurs de moindre importance, tels que la forme de la chambre de combustion et la situation de la bougie d'allumage (1, 8). Les principaux types de composés qui peuvent être utilisés comme carburants dans les moteurs à essence peuvent être classés dans l'ordre de leur tendance décroissante à détoner, comme suit (2, 8): Ethers, Paraffines, Oléfines, Naphthènes, Aromatiques et Alcools. La tendance de chaque carburant à détoner peut être augmentée ou diminuée suivant le désir, par l'addition d'un composé convenable au mélange de combustion, la quantité requise pour produire l'effet étant dans certains cas très faible.

Die Detonation oder das Klopfen (knock), welche die Verbrennung in Benzinmotoren unter gewissen Bedingungen kennzeichnet, ist zunächst von der chemischen Zusammensetzung oder Struktur des Brennstoffes beeinflusst, in zweiter Linie von der Kompression, dem das Verbrennungsgemisch ausgesetzt ist, von seiner Temperatur und von der Lage des Zündpunktes im Kreisprozess. In gleicher Weise hängt es noch von kleineren Faktoren ab, wie der Form des Verbrennungsraumes und der Lage der Zündkerze (1, 8). Die hauptsächlichsten Arten die als Motorbetriebsstoffe in Frage kommen, ordnen sich selbst in abnehmender Ordnung ihrer Fähigkeit zu klopfen, in folgender Weise (2, 8): Äther-Arten, Paraffine, Olefine, Naphtene, Stoffe der aromatischen Reihe und Alkohole. Die Neigung irgend eines gegebenen Betriebsstoffes zu detonieren, kann nach Bedarf erhöht oder erniedrigt werden, durch Hinzufügung einer passenden Verbindung zum Betriebsstoff. Die dazu notwendige Menge ist in manchen Fällen sehr gering.

La detonazione (Knock) che, in certe condizioni, caratterizza la combustione nei motori a essenza, è influenzata anzitutto dalla composizione chimica o struttura del carburante, e in secondo luogo dal grado di compressione della miscela, dalla sua temperatura, e dal momento in cui l'accensione avviene durante il ciclo. Essa dipende pure da altri fattori secondari, come la forma della camera di combustione e la posizione della candela (1, 8). I principali tipi di composti che possono adoperarsi come carburanti nei motori a essenza si possono disporre nell'ordine seguente graduandoli secondo la tendenza decrescente a detonare (2, 8): eteri, paraffine, olefine, nafteni, sostanze aromatiche, alcoli. La tendenza di un dato combustibile a detonare può essere accresciuta o diminuita a piacere aggiungendo alla miscela combustibile un adatto composto. La quantità di sostanza a ciò necessaria è in alcuni casi molto piccola.

Die Neigung irgend eines gegebenen Betriebsstoffes zu detonieren, kann nach Bedarf erhöht oder erniedrigt werden, durch Hinzufügung einer passenden Verbindung zum Betriebsstoff. Die dazu notwendige Menge ist in manchen Fällen sehr gering.

La détonation ou le "cognage" qui caractérise la combustion dans les moteurs à benzine sous certaines conditions, est influencée premièrement par la composition chimique ou la structure du carburant et secondairement par la compression à laquelle le mélange combustible est soumis, par sa température, et par le point du cycle auquel l'allumage se produit, de même que par quelques autres facteurs de moindre importance, tels que la forme de la chambre de combustion et la situation de la bougie d'allumage (1, 8). Les principaux types de composés qui peuvent être utilisés comme carburants dans les moteurs à essence peuvent être classés dans l'ordre de leur tendance décroissante à détoner, comme suit (2, 8): Ethers, Paraffines, Oléfines, Naphthènes, Aromatiques et Alcools. La tendance de chaque carburant à détoner peut être augmentée ou diminuée suivant le désir, par l'addition d'un composé convenable au mélange de combustion, la quantité requise pour produire l'effet étant dans certains cas très faible.

La detonazione (Knock) che, in certe condizioni, caratterizza la combustione nei motori a essenza, è influenzata anzitutto dalla composizione chimica o struttura del carburante, e in secondo luogo dal grado di compressione della miscela, dalla sua temperatura, e dal momento in cui l'accensione avviene durante il ciclo. Essa dipende pure da altri fattori secondari, come la forma della camera di combustione e la posizione della candela (1, 8). I principali tipi di composti che possono adoperarsi come carburanti nei motori a essenza si possono disporre nell'ordine seguente graduandoli secondo la tendenza decrescente a detonare (2, 8): eteri, paraffine, olefine, nafteni, sostanze aromatiche, alcoli. La tendenza di un dato combustibile a detonare può essere accresciuta o diminuita a piacere aggiungendo alla miscela combustibile un adatto composto. La quantità di sostanza a ciò necessaria è in alcuni casi molto piccola.

RELATIVE EFFECTS OF SOME MISCELLANEOUS COMPOUNDS FOR SUPPRESSING DETONATION IN ENGINES

Aniline in concentration of 2% of the fuel by volume taken as standard of effect. All measurements made with bouncing-pin apparatus, using kerosene as fuel (1, 3, 4). The values given below are, respectively, (*a*) amount in grams required to give an "anti-knock" effect equivalent to 1 g of aniline, and (*b*) reciprocal of the number of mols required to give an "anti-knock" effect equivalent to 1 mol of aniline.

Compound	Formula	(*a*) Wt. for given effect	(*b*) Rel. mol. effectiveness	Lit.
Aniline	$C_6H_5NH_2$	1	1	
Benzene	C_6H_6	9.8	0.085	(1)
Toluene	$C_6H_5CH_3$	8.8	0.112	(1)
Xylene	$C_6H_4(CH_3)_2$	8.0	0.142	(1)
Alcohol	C_2H_5OH	4.75	0.104	(5)
Ethyl iodide	C_2H_5I	1.55	1.09	(6)
Diethyl selenide	$(C_2H_5)_2Se$	0.214	6.9	(6)
Diphenyl selenide	$(C_6H_5)_2Se$	0.49	5.2	(6)
Diethyl telluride	$(C_2H_5)_2Te$	0.075	26.6	(6)
Diphenyl telluride	$(C_6H_5)_2Te$	0.139	22.0	(6)
Triphenylphosphine	$(C_6H_5)_3P$	3.08	0.91	(7)
Triphenylarsine	$(C_6H_5)_3As$	2.44	1.35	(7)
Triphenylstibine	$(C_6H_5)_3Sb$	1.56	2.42	(7)
Tetraethyl tin	$(C_2H_5)_4Sn$	0.66*	3.8*	(7)

Tetraphenyl lead	$(C_6H_5)_4Pb$	0.080†	69.5†	(9)
Diphenyl diethyl lead	$(C_6H_5)_2$-$(C_2H_5)_2Pb$	0.041†	110†	(9)
Triethylbismuthine	$(C_2H_5)_3Bi$	0.135†	23.8†	(9)
Triphenylbismuthine	$(C_6H_5)_3Bi$	0.22†	21.5†	(9)
Nickel carbonyl	$Ni(CO)_4$	0.053†	35†	(9)
Dimethyl cadmium	$(CH_3)_2Cd$	1.23†	1.25†	(9)
Titanium tetrachloride	$TiCl_4$	0.64†	3.2†	(9)

* Values for tetraethyl tin in doubt because of preignition induced by the compound.

† These figures computed from the data of the original article, and converted to the aniline scale used for the other values in the table, on which tetraethyl lead is 118, instead of 100 as it is in the system of comparison used by the authors.

RELATIVE EFFECTS OF SOME COMPOUNDS OF NITROGEN FOR SUPPRESSING DETONATION IN ENGINES

Aniline in concentrations up to 3% of the fuel by volume taken as standard of effect. All measurements made with bouncing-pin apparatus, using kerosene as fuel (4). The values given below are, respectively, (*a*) amount in grams required to give an "anti-knock" effect equivalent to 1 g of aniline, and (*b*) reciprocal of the number of mols required to give an "anti-knock" effect equivalent to 1 mol of aniline. Negative values are marked (−).

Compound	Formula	(*a*) Wt. for given effect	(*b*) Rel. mol. effectiveness
Aniline	$C_6H_5NH_2$	1	1
Cumidine	$(CH_3)_3C_6H_2NH_2$	0.96	1.51
Diphenylamine	$(C_6H_5)_2NH$	1.21	1.5
m-Xylidine	$(CH_3)_2C_6H_3NH_2$	0.92	1.4
Monomethylaniline	$C_6H_5NHCH_3$	0.83	1.4
Toluidine	$CH_3C_6H_4NH_2$	0.94*	1.22*
Amylaminobenzene	$C_5H_{11}C_6H_4NH_2$	1.53	1.15
Ethylaminobenzene	$C_2H_5C_6H_4NH_2$	1.14	1.14
Aminodiphenyl	$C_6H_5C_6H_4NH_2$	1.6	1.14
Methyl-*o*-toluidine(7)	$CH_3C_6H_4NHCH_3$	1.15	1.13
n-Butylaminobenzene	$C_4H_9C_6H_4NH_2$	1.44	1.11
n-Propylaminobenzene	$C_3H_7C_6H_4NH_2$	1.32	1.10
Monoethylaniline	$C_6H_5NHC_2H_5$	1.27	1.02
Mono-*n*-propylaniline	$C_6H_5NHC_3H_7$	1.95	0.75
Ethyldiphenylamine	$C_2H_5N(C_6H_5)_2$	3.65	0.58
Mono-*n*-butylaniline	$C_6H_5NHC_4H_9$	3.1	0.52

LUBRICANTS AND LUBRICATION

J. H. HYDE

For density, viscosity and other physical properties of lubricants, *see* p. 136.

JOURNAL BEARING FRICTION

In the following tables the value of the coefficient of friction of a journal bearing is given for different values of the quantity:

$$\frac{60\eta N}{P} = 60 \times \frac{\text{Absolute viscosity of lubricant at bearing temperature} \times \text{r. p. s.}}{\text{Pressure on bearing}},$$ where pressure on bearing = $$\frac{\text{Total load on bearing}}{\text{Length of bearing} \times \text{diameter of journal}}.$$

LUBRICATING VALUE OF OILS UNDER CONDITIONS OF HEAVY LOADS AND TEMPERATURES UP TO 100°

Tests made on the Daimler-Lanchester Worm Gear Testing Machine at the National Physical Laboratory, England, show that the value of a straight mineral oil as a lubricant, when the load is great, diminishes rapidly above a certain critical temperature. It has been found by a very large number of tests under the same conditions of speed, load and supply of lubricant at a given temperature, that the efficiency of the worm gear in the testing machine remains remarkably constant at the load selected for the tests, and, as differences of efficiency could be determined to 0.1 % (absolute efficiency to 0.2 %), the efficiency-temperature values obtained give a valuable indication of the quality of the lubricant.

Effect of Temperature on Gear Efficiency

Variation of efficiency of power transmission by worm gear, with temperature of lubricant, for a straight mineral oil (Bayonne oil). This example is typical of all mineral oils (⁵).

°C	15 to 42	45	50	55	60	65	70
Gear efficiency, %	95.0	94.7	94.2	93.8	93.4	93.1	92.9

°C	75	80	85	90	95	100
Gear efficiency, %	92.8	92.7	92.6	92.5	92.5	92.4

The following critical temperatures were observed: Bayonne, 42°; FFF cylinder, 71°; Victory red oil, 50°; Mobiloil "A," 56°; Mobiloil "BB," 62°; lard, rape, castor and sperm, none observed. A small addition of fatty oil, fatty acid or graphite raises the critical temperature 10 to 20°.

TYPICAL ANALYSES AND PROPERTIES OF GASEOUS FUELS

E. R. Weaver

The hydrocarbons in natural gases and the hydrogen and saturated hydrocarbons in manufactured gases are usually determined by combustion, and the actual compounds present are not determined. The properties which affect the use of the gas as a fuel (heating value, specific gravity, air required for combustion and products formed by combustion) would be the same for a mixture of the composition stated by the analysis as for the mixture analyzed. For example, a mixture of one volume of hydrogen and one of ethane has the same values for these properties as two volumes of methane; and in an analysis of manufactured gas they would appear as methane. The "illuminants" of manufactured gas generally include all hydrocarbons present except those of the paraffin series. The first table gives the actual compositions of some typical gases; the second table gives analyses stated in the conventional manner. The same index letter in the two tables refers to the same gas.

Actual Composition

ASPHALTS AND MINERAL WAXES

HERBERT ABRAHAM

Under this heading will be considered the following groups of substances: (1) Mineral waxes; (2) native asphalts; (3) asphaltites; (4) asphaltic pyrobitumens; and (5) pyrogenous asphalts. These five groups are members of the class "Bituminous substances," the first three falling within the group "Bitumens," the fourth within the group "Pyrobitumens," and the fifth within the group "Pyrogenous residues."

NOMENCLATURE

The definitions which follow show the relationship between these respective groups of substances.

Bituminous Substances.—A class of native and pyrogenous substances containing bitumens or pyrobitumens, or resembling them in their physical properties. [This definition includes bitumens, pyrobitumens, pyrogenous distillates (pyrogenous waxes and tars) and pyrogenous residues (pitches and pyrogenous asphalts).]

Bitumen.—A generic term applied to native substances of variable color, hardness and volatility; composed of hydrocarbons substantially free from oxygenated bodies; sometimes associated with mineral matter, the non-mineral constituents being *fusible* and largely *soluble* in carbon disulfide; the distillates, fractionated between 300 and 350°C, yield *considerable sulfonation residue.* [This definition includes petroleums, native asphalts, native mineral waxes and asphaltites.]

Pyrobitumen.—A generic term applied to native substances of dark color; comparatively hard and non-volatile; composed of hydrocarbons, which may or may not contain oxygenated bodies; sometimes associated with mineral matter, the non-mineral constituents being *infusible,* and relatively *insoluble* in carbon disulfide. [This definition includes the asphaltic and non-asphaltic pyrobitumens and their respective shales.]

Mineral Wax.—A term applied to a species of bitumen, also to certain pyrogenous substances; of variable color, viscous to solid consistency; having a *characteristic luster* and *unctuous feel;* comparatively non-volatile; composed of hydrocarbons, substantially free from oxygenated bodies; containing *considerable crystallizable paraffins;* sometimes associated with mineral matter, the non-mineral constituents being easily fusible and soluble in carbon disulfide. [This definition is applied to crude and refined native mineral waxes, also to pyrogenous waxes. Crude native mineral waxes include ozokerite, etc. Refined native mineral waxes include ceresine (refined ozokerite) and montan wax (extracted from lignite or pyropissite by means of solvents). Pyrogenous waxes include the solid paraffins separated from non-asphaltic and mixed-base petroleums, peat, tar, lignite tar and shale tar].

Asphalt.—A term applied to a species of bitumen, also to certain pyrogenous substances of *dark color,* variable hardness, comparatively non-volatile; composed of hydrocarbons, substantially free from oxygenated bodies; containing relatively little to no crystallizable paraffins; sometimes associated with mineral matter, the non-mineral constituents being *fusible,* and largely soluble in carbon disulfide; the distillate, fractionated between 300 and 350°C, yields *considerable sulfonation residue.* [This definition is applied to native asphalts and pyrogenous asphalts. Native asphalts include asphalts occurring naturally in a pure or fairly pure state, also asphalts associated naturally with a substantial proportion of mineral matter, sometimes termed "rock asphalts." The associated mineral matter may be sand, sandstone, limestone, clay, shale, etc. Pyrogenous asphalts include residues obtained from the distillation, blowing, etc., of petroleums (*e.g., residual oil,* produced by the dry distillation of non-asphaltic petroleum, the dry or steam distillation of mixed-base petroleum and the steam distillation of asphaltic petroleum, *blown asphalt,* produced by blowing air through heated residual oils, *residual asphalts,* produced by the steam distillation of mixed-base and asphaltic petroleum, *sludge asphalt,* produced from the acid sludge obtained in the purification of petroleum distillates with sulfuric acid, etc., also from the pyrogenous treatment of wurtzilite (*e.g., wurtzilite asphalt,* produced by depolymerizing wurtzilite in closed retorts).]

Asphaltite.—A species of bitumen, including dark colored, comparatively hard and non-volatile solids; composed of hydrocarbons, substantially free from oxygenated bodies and crystallizable paraffins; sometimes associated with mineral matter, the non-mineral constituents being *difficultly fusible* and largely soluble in carbon disulfide; the distillation residue, fractionated between 300 and 350°C, yields *considerable sulfonation residue.* [This definition includes *gilsonite* (conchoidal fracture and characteristic brown streak on porcelain), *glance pitch* (conchoidal to hackly fracture and black streak) and *grahamite* (conchoidal to hackly fracture and black streak).]

Asphaltic Pyrobitumens.—A species of pyrobitumen, including dark colored, comparatively hard and non-volatile solids; composed of hydrocarbons, *substantially free from oxygenated bodies;* sometimes associated with mineral matter, the non-mineral constituents being *infusible* and largely *insoluble* in carbon disulfide. [This definition includes *elaterite* (characteristic rubbery nature and brown streak), *wurtzilite* (conchoidal to hackly fracture; brown streak; depolymerizes on heating, becoming fusible and soluble), *albertite* (conchoidal to hackly fracture; brownish black streak; depolymerizes partially on heating), *impsonite* (hackly fracture; black streak; does not depolymerize on heating) and the *asphaltic pyrobituminous shales.*]

CHARACTERISTICS

The distinguishing physical and chemical characteristics of the substances enumerated above are given in the following table.

THERMAL PROPERTIES

An asphalt of 2.1_2 specific gravity gave the following values for the *thermal conductivity* in joule $cm^2\ sec^{-1}\ (°C,\ cm^{-1})^{-1}$: 0°, 0.0061; 10°, 0.0065; 20°, 0.0070; 30°, 0.0074 (Poensgen, *98,* **56:** 1653; 12. **60:** 27; 16).

According to Kinoshita (*380,* **39:** 497; 16) the *specific heat* of asphalt is 0.22 g-cal per g per °C.

BITUMINOUS MATERIALS

JOHN M. WEISS AND CHARLES R. DOWNS

TARS, PITCHES AND DISTILLATES

This section deals with those species of pyrogenous residues known as "tars," together with the products of tar distillation, *i.e.*, "residuals" or "pitches," and "distillates" or "tar oils." These are highly complex materials formed by the pyrogenetic decomposition of various organic materials, so that a particular member or sub-member may vary widely in its physical characteristics.

In the first section are given certain so-called constants in terms of ranges for the various materials. These give general information as to the nature of the various materials. The results are expressed in terms of arbitrary tests which depend upon rigid adherence to details of manipulation; the test methods are those generally used in the United States. The ranges given have been taken partly from the literature, but for the most part from private communications from various commercial concerns dealing with the products (2, 5, 6, 11, 16, 18, 19), and certain U. S. Government laboratories (4, 10). Freak results caused by some unusual procedure in the production of a given material have been eliminated so as to make the ranges representative of the materials as they are ordinarily encountered in industry.

In addition, there are reported the available more or less absolute constants that have been determined. As the materials in a given narrow class vary in ordinary tests, so they also vary in these "absolute" constants between samples in the same class; the accuracy of the figures is only moderate, but, in general, adequate to the commercial need which caused the determinations to be made. Blanks indicate that no authentic results are available. Single figures mean that the test of a single sample only could be obtained.

TABLE 1.—TARS

The figures in Table 1 apply to water-free tar. In attempting to identify tars, it is advisable to distill them and test the oils (*See* Table 3.) Methods of testing are given by Weiss (22). η is Engler viscosity, sec for 100 cm³; % insol. is the % organic insoluble in C_6H_6 and C_7H_8.

Genus	Species	Member	Sub-member	$d_{15.5}^{15.5}$	η	% insol.	% fixed carbon	% ash	% tar acids

EXPLOSIONS AND GASEOUS EXPLOSIVES

WILLIAM A. BONE AND DONALD T. A. TOWNEND

IGNITION TEMPERATURE

The ignition temperature of a gaseous mixture is the temperature at which the heat lost by conduction, etc., is more than counterbalanced by the rate at which it is developed by the reaction, the combustion thus becoming self-propellant. This temperature is a function not only of the gaseous mixture employed but also of the means used for heating it. Also, there is often a short "pre-flame" period, during which the combustion is autogenous, but without any actual appearance of flame.

Experimental Methods

A. Mixture passed through tube held at known temperature.

B. Mixture rapidly admitted to hot bulb at known temperature. Pre-flame "lag" sometimes determined by this method.

C. Bulb containing mixture heated rapidly to definite temperature.

D. Mixture passed through small reservoir while temperature was raised until flame at exit tube ran back into it.

E. Constituent gases heated separately in concentric tubes, gas from inner tube being then passed into gas in outer tube. In most recent methods pre-flame "lag" has been controlled.

F. Constituent gases heated separately and mixed in open away from surface contact.

G. Mixture adiabatically compressed and temperature calculated from final volume.

H. Mixture adiabatically compressed and temperature calculation based on final pressure experimentally determined. Correct temperature lies between the values calculated by methods G and H.

I. Glass vessel within an iron one, each containing a constituent gas. Glass vessel broken at definite temperature.

J. Small drop of inflammable liquid dropped into air or oxygen maintained at a known temperature.

K. Soap bubble blown with mixture touched by hot wire at known temperature.

Pressure = 1 atm. unless otherwise noted.

COEFFICIENTS OF CUBICAL EXPANSION

$\alpha = \frac{10^6(V_2 - V_1)}{V_1(t_2 - t_1)}$. In each case an average figure for use is suggested, with figures showing the maximum deviation of individual samples from the average suggested. For special cases, reference to the original articles is recommended (**3, 8, 13, 21, 23**). For effect of solids in creosote oil, *see* (**8, 13**).

EXPLOSIONS AND GASEOUS EXPLOSIVES

WILLIAM A. BONE AND DONALD T. A. TOWNEND

IGNITION TEMPERATURE

The ignition temperature of a gaseous mixture is the temperature at which the heat lost by conduction, etc., is more than counterbalanced by the rate at which it is developed by the reaction, the combustion thus becoming self-propellant. This temperature is a function not only of the gaseous mixture employed but also of the means used for heating it. Also, there is often a short "pre-flame" period, during which the combustion is autogenous, but without any actual appearance of flame.

Experimental Methods

A. Mixture passed through tube held at known temperature.

B. Mixture rapidly admitted to hot bulb at known temperature. Pre-flame "lag" sometimes determined by this method.

C. Bulb containing mixture heated rapidly to definite temperature.

D. Mixture passed through small reservoir while temperature was raised until flame at exit tube ran back into it.

E. Constituent gases heated separately in concentric tubes, gas from inner tube being then passed into gas in outer tube. In most recent methods pre-flame "lag" has been controlled.

F. Constituent gases heated separately and mixed in open away from surface contact.

G. Mixture adiabatically compressed and temperature calculated from final volume.

H. Mixture adiabatically compressed and temperature calculation based on final pressure experimentally determined. Correct temperature lies between the values calculated by methods G and H.

I. Glass vessel within an iron one, each containing a constituent gas. Glass vessel broken at definite temperature.

J. Small drop of inflammable liquid dropped into air or oxygen maintained at a known temperature.

K. Soap bubble blown with mixture touched by hot wire at known temperature.

Pressure = 1 atm. unless otherwise noted.

H_2

468	ca. $3O_2 + 16N_2$				

* Calc. using γ = 1.4.

† Calc. using γ = 1.32 to allow for cooling losses during compression.

$H_2 + Cl_2$

For $Cl_2 + H_2$ by method A (9), 430°–440°; method C (9), 240°–270°; in dark, 190° (11).

H_2S

For $2H_2S + 3O_2$ by method A (9), 315°–320°; method C (9), 250°–270°. For H_2S, by method E (21), in O_2, 220°–235°; in air, 346°–379°.

NH_3

By method E (21), in O_2, 700°–860°. By method not stated (22), in air, 780°.

CO

Method B (4): M = $2CO + O_2$				
t°C	M+	t°C	M+	Method E (43); cf. (21) For CO in O_2, 665° with $\frac{1}{2}$ sec lag; 624° with 10 sec lag For CO in air, 725° with $\frac{1}{2}$ sec lag; 685° with 10 sec lag Method B (24) 20–70% in air, 610°
645–650	CO	650–657	$4N_2$	
630–650	4CO	695–715	$3CO_2$	
650–680	O_2			
For method A and C cf. (9); for method D (13); for method G (19); for method K (31)				

CH_4 Methane

$CH_4 + 2O_2$, by method A (9), 650°–730°; by method C (9), 606°–650°. By method D (13), 656°–678°.

By method B (4), $CH_4 + 2O_2$ at 600°–650°; $5CH_4 + 2O_2$ at 640°–660°; 10% CH_4 by vol. in air at 730°–790°. (First observation of lags prior to explosion.) Method B* (23, 24, 40). % = % CH_4 in air; V_{15} = temp. in 15 cm^3 vessel, V_{275} in 275 cm^3 vessel and V_{81} in 81 cm^3 vessel.

%	V_{15}	V_{275}	%	V_{15}	V_{275}	%	V_{81}	%	V_{81}
3	737	680	10	750	710	2	711	8.8	707
6.5	736	675	12	765	710	3	700	10	714
8.0	735	680	16	807	750	5.9	695	11.8	724
						7.0	697	14.4	742

* The explosion occurs after certain definite time lags.

Method E (43), cf. (21). For CH_4 in O_2, $\frac{1}{2}$ sec lag, 665°; 10 sec lag, 624°. For CH_4 in air, $\frac{1}{2}$ sec lag, 725°; 10 sec lag, 685°. Method E (50, 52, 58). For CH_4 in air. P = mm pressure; L = lag in sec.

P / L	100	200	400	600	760	1520	2280	3800	5320
0.5							705	675	653
0.6	815	788	765	753	746	722			
1	804	768	747	737	728	711	695	666	644
2	782	733	717	712	715	690	680	652	633
3	—	715	702	696	694	676	667	640	624

Method E (58). For CH_4 in O_2. P = mm pressure; L = lag in sec.

P / L	75	100	200	400	600	760
0.5	727	728	732	720	696	670
0.6	715	716	721	715	688	666
1	694	695	697	692	675	657
2	667	665	660	652	645	641
3		651	643	636	631	629
10		633	621	611	604	602

By method G (58), $CH_4 + 3O_2$, 340°; $CH_4 + 5O_2$, 345°; $CH_4 + 15O_2$, 377°; $7\frac{1}{2}$% CH_4 in air, 428°.

C_2H_2 Acetylene

By method E (21), in O_2, 400°–440°; in air, 406°–440°. By method B (24), for 45–55% C_2H_2 in air, 335°; 20% in air, 400°; 10% in air, 500°.

C_2H_4 Ethylene

For $C_2H_4 + 3O_2$, method C (9), 530°–606°. By method B (24), for 4.5–6.5% C_2H_4 in air (vol. vessel = 275 cm^3), 487°. By method E (21), for C_2H_4 in O_2, 500°–519°; in air, 542°–547°. *Cf.* (9), method A; (13), method D; (31), method K.

C_2H_6 Ethane

By method B (47). % = % C_2H_6 in air (vol. vessel = 85 cm³)

%	1.9	2.3	4.05	4.85	5.7	8.15	10.60
t°C	594	571	560	555	550	540	534

For C_2H_6, method A, *cf.* (9); method D (13). By method C (9), for $C_2H_6 + 3.5O_2$, 530°–606°. By method B (24), for 4–8% C_2H_6 in air (275 cm³ vessel), 560°.

C_3H_8 Propane

By method D (13), in O_2, 545°–548°. By method E (21), in O_2, 490°–570°. Method B (47), vol. of vessel = 85 cm³

% C_3H_8 in air	1.25	2.50	3.05	4.90	6.50	7.85
t°C	588	552	544	525	516	514

C_4H_{10} *n*-Butane

Method B (47), vol. of vessel = 85 cm³

% *n*-C_4H_{10} in air	1.25	2.00	2.60	3.65	4.85	7.65
t°C	569	545	531	515	502	489

C_4H_{10} Isobutane

For *iso*-C_4H_{10} by method D (13), in O_2, 545°–550°.

C_5H_{12} *n*-Pentane

For 2–3% C_5H_{12} in air, 512° by method B (24). For 6.7% in air, 320°–336° by method H (37). Method B (47), vol. of vessel = 85 cm³.

% C_5H_{12} in air	1.5	2.15	2.75	3.75	5.30	7.65

ELECTRICAL IGNITION

In the case of electrical ignition and probably also in contact with direct flame or with an incandescent wire, ionization of the gas is an important factor. In the case of electric spark ignition, attempts have been made to determine experimentally the minimum igniting current or spark energy. Unfortunately, however, quantitative values are not easily determined owing to experimental difficulties. Consequently, much of the experimental evidence is of a contradictory nature, so that the part played by ionization in determining the least energy required to inflame a given explosive mixture remains an unknown factor. Representative curves showing least igniting currents are given in Figs. 1 to 4.

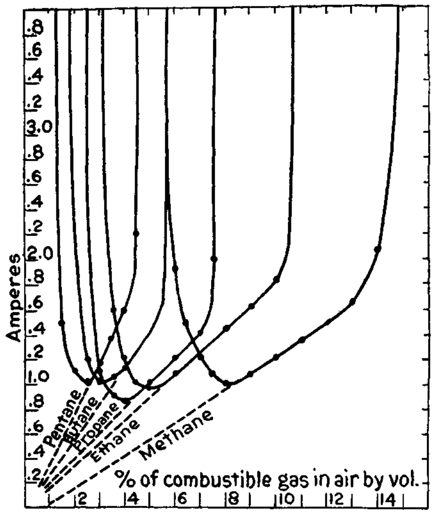

FIG. 1.—Least igniting currents for mixtures in air of members of the paraffin series, using break-sparks. Iron poles. 100 volts (5).

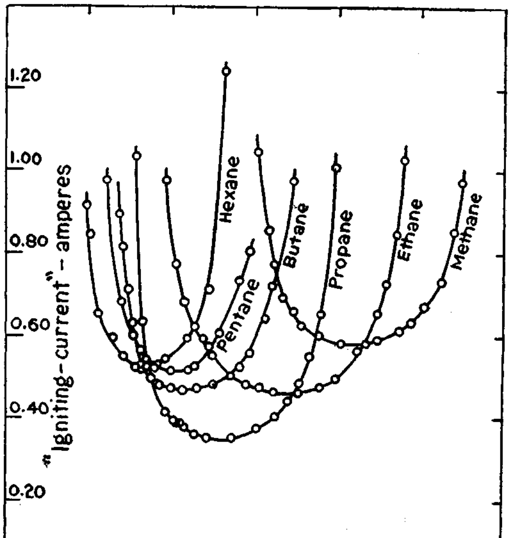

FIG. 2.—Least igniting currents for mixtures in air of members of the paraffin series, using impulsive electrical discharges (33).

LIMITS OF INFLAMMABILITY

The limits are given in volume % and apply to atmospheric conditions of temperature and pressure unless otherwise stated. The first value in the limits column is the lowest lower limit, and the second the highest higher limit of the experimentally found values, which usually agree within a few tenths of 1%.

Abbreviations

E_v	Explosion in closed vessel of volume v, cm³ generally stated.
Fl_D	Downward propagation of flame.
Fl_H	Horizontal propagation of flame.
Fl_U	Upward propagation of flame.
Atm.	Nature of atmosphere.
Exper. condn.	Experimental conditions.
Tb_x	Tube whose diameter = x cm.
$Sat._x$	Gases saturated with H_2O vapor at x°.
$P_{xat.}$	Pressure, x atmospheres.
P_{xmm}	Pressure, x mm Hg.

All temperatures are in °C.

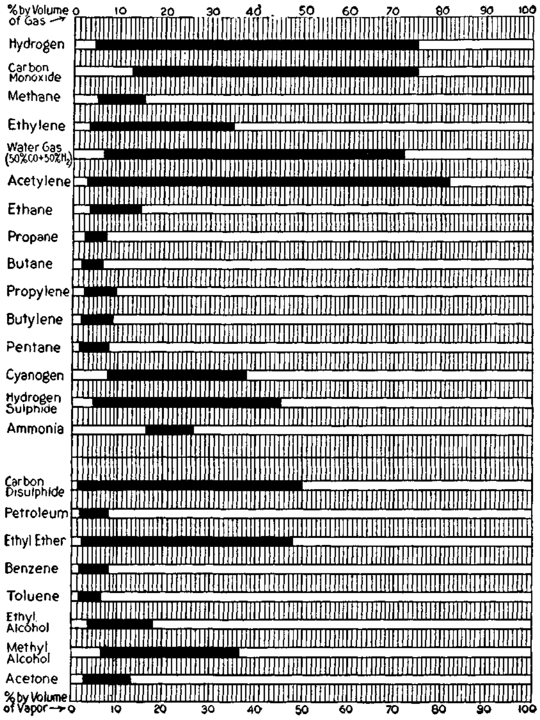

FIG. 4*a*.—Limits of inflammability of mixtures of gases and vapors with air.

PROPAGATION OF FLAME

The "Uniform Movement" and Attendant Phenomena

Given certain conditions, an initial "slow uniform flame movement" can usually be effected in a gaseous explosive medium; its velocity is, however, dependent upon (1) the composition of the mixture, (2) its temperature and pressure, (3) the nature and dimensions of the containing vessel (in case of a tube, the diameter being the important dimension) and (4) the source and character of ignition. It is usually determined experimentally by igniting each explosive mixture with the same type of flame at the open end of a tube which is closed at the other end.

The flame movement so initiated usually proceeds at uniform velocity for a certain short distance, and its termination is marked by a period of accelerated vibrational flame movement, which may in some cases give rise to detonation. In other cases, however, it seems to be succeeded abruptly by detonation.

Recently attempts have been made to establish a so-called "law of flame speeds" for complex combustible gaseous mixtures, *e.g.*, coal-gas and air, on the supposition that in such cases the observed flame speed is caused by the oxygen or combustible gas (whichever of the two is in defect) dividing itself during the combustion so as to form a series of explosive mixtures (of each single component combustible gas with oxygen) giving the same flame speed. This, however, seems a fundamentally wrong view of things.

Abbreviations and Units

Tb_x. A tube of diameter x cm was used in experiment. The values given in the tables are the velocities of propagation of flame in cm/sec for the mixtures noted. All gas percentages are in volume %.

DETONATION

The phenomenon of detonation, or "l'onde explosive" as it was originally known, in gaseous explosions was discovered by Berthelot and Vieille and by Mallard and Le Chatelier in the year 1881. It is set up when a sufficiently explosive mixture is ignited by means of a detonator (such as fulminate) or under circumstances such that the burning gases are exposed to the repeated effects of reflected compression waves. In the last named circumstance the initial uniform slow velocity is rapidly accelerated up to the point of detonation.

When once established its velocity is constant and within wide limits unaffected by the material and diameter of the tube employed, being solely dependent on the nature of the explosive mixture and on its temperature and pressure.

In the explosion wave the explosive mixture is fired adiabatically by compression so that the chemical reaction is more intense and of much shorter duration than in the case of normal combustion. In addition the pressure in the wave is much greater than in ordinary explosions, this being the cause of its shattering effect.

Abbreviations

Values not otherwise designated are detonation velocities in meters per second.

Composition of gas mixtures when given in percentages are in volume %.

The initial conditions of the detonating mixture are ordinary temperature and pressure unless otherwise stated.

20.190	0.007620	2649.0	2710
40.430	0.015100	2679.0	2706

Distance in inches from spark at which detonation occurs = D_0 for spark at end of tube and D_3 for spark 3 in. from end (16).

Mixture	D_0	D_3
$2H_2 + O_2$	48	12
$2H_2 + 2\frac{1}{2}O_2$		48
$6H_2 + O_2$		192
$C_2N_2 + O_2$	$8\frac{1}{2}$	4
$C_2N_2 + 2O_2$	12	10
$2C_2H_2 + 3O_2$	$4\frac{1}{2}$	$2\frac{1}{2}$
$C_2H_4 + 2O_2$	9	5

Distance before detonation wave is established = *D* cm (13). Glass tube, 10 mm diam. Spark at end of tube

Mixture	*D*
$2C_2H_2 + O_2$	100
$C_2H_2 + O_2$	5
$C_2H_2 + 6O_2$	15
$C_2H_2 + 10O_2$	80
$C_2H_2 + 2NO$	20
$C_2H_2 + 6NO$	50
$C_2H_2 + 2N_2O$	100
$C_2H_2 + 6N_2O$	10

Influence of tube diameter on the distance from the firing source at which detonation occurs (25). Mixture = $CS_2 + 3O_2$. Spark at end of tube. D_{cm} = cm travelled by flame before detonation.

Tube diam., mm	D_{cm}
6.5–7	48
10	50
24–25	58
34–35	84
43–44	103
53–54	131

Distance required for the re-establishment of detonation waves after they are damped out by passing from one tube to another of larger diameter (26). Diam. of first tube = 7 mm. Distance in cm travelled by flame in second tube prior to detonation = *D*.

Diam. mm second tube......	13	16	23–24	33–34	44–45
D ($CS_2 + 3O_2$)..............	8	10	15	50	100
D ($2H_2 + O_2$)..............			3	62	

WAVE VELOCITIES (14)

	$C_2H_2 + O_2$	$C_2H_2 + 2NO$	$2CO + O_2$
L'onde explosive (détonation wave)..........	2990	2850	1900
L'onde rétrograde (retonation wave)*.........	2300	1140	
L'onde réfléchie (reflexion wave)†...........	2250	1350	1000
L'onde prolongée (collision wave)‡..........	2050		

* A "retonation" wave is thrown back into the burnt gases when the detonation wave is set up.

† The wave reflected through the burnt gases after a detonation wave has reached the walls of the vessel in which the explosion occurs.

‡ Collision waves occur when two detonation waves meet.

REFLECTED WAVES IN A $C_2H_2 + O_2$ MIXTURE

Initial speed...........	2300	After first crossing......	1080
After reflection.........	1350	After second crossing...	980

Ratio of Wave Velocities ([16])

Mixture	Detonation wave velocity	Reflection wave velocity	Ratio of velocities
$2H_2 + O_2$	2820	1538	1.83
$H_2 + N_2O$	2305	1383	1.67
$2CO + O_2$	1676	1078	1.56
$C_2N_2 + O_2$	2728	1230	2.22
$C_2N_2 + 2O_2$	2321	1129	2.06
$2C_2N_2 + 5O_2$	2391	1133	2.11

Two equations of importance have been deduced whereby velocities of detonation agreeing closely with experimental values may be calculated ([34, 35]).

$$V^2 = \frac{2RJ}{\mu C_v^2}[\{(m-n)C_p + mC_v\}C_pT_o + (C_p + C_v)h] \text{ where}$$

V	Velocity of wave.
R	Gas constant.
J	Dynamical equivalent of heat (42 × 10^6 ergs).
μ	Gram equivalents of the mixture exploded.
n and m	Number of molecules before and after the chemical change in the wave.
C_p and C_v	Mean specific heats of the products at constant pressure and volume, respectively.
h	Total heat generated in the wave.
T_o	Initial temperature (abs.) of the mixture exploded.

$$\left(\frac{dP}{dl}\right)^2 = \mu^2\frac{Rk_2T_2}{M}\left(1 + \frac{k_2R}{MC_2}\right), \text{ where}$$

$\left(\frac{dP}{dt}\right)$	Velocity of the wave.
R	Gas constant.
M	Molecular mass of the gas taken.
T_2	Temperature of the flame.
μ	$\frac{d_2}{d_1}$ (ratio of the final and initial densities).
C_2	Mean specific heat at constant volume of the explosion products.
k_2	Number of molecules in the explosion products.

EXPLOSIONS IN CLOSED VESSELS

Much of the experimental determination of explosion times and pressures using gaseous mixtures has been carried out with coal gas—air mixtures. Owing to the variable composition and heat of combustion of the samples of coal gas so employed, it has not been found possible to tabulate such data except in so far as they may have a general bearing on the subject of gaseous explosions—and more particularly where data relative to the simpler combustible gases are lacking.

All maximum pressures have been expressed as a ratio, $\frac{\text{maximum pressure}}{\text{initial pressure}}$, thus giving a better basis of comparison. In most cases the published figures for initial pressures refer to room temperatures. Where this has been found to be otherwise, the initial pressures have been adjusted to correspond to a temperature of 15°C, and a corresponding correction applied to maximum pressures.

No attempt has been made to tabulate investigators' estimates of their explosion temperatures because (*a*) an arbitrary correction must necessarily be applied for cooling loss during the explosion period—this being dependent on the explosion vessel employed and (*b*) allowances must be made for dissociation. An approximate value of the temperature attained may be calculated from the formula

$$T_{(\text{max.})\text{ abs.}} = \frac{P_{\text{max.}}}{P_{\text{init.}}} \times T_{(\text{init.})\text{ abs.}} \times \frac{m}{n}$$

where m/n represents the molecular change.

Few direct determinations of explosion temperatures have been possible owing to the very high temperatures developed.

In comparing explosion times, consideration must be given to the dimensions of the explosion vessels concerned—on which they are solely dependent.

In the following tables all results may be considered to refer to explosions of gaseous mixtures at atmospheric pressure and temperature unless specially stated otherwise.

Abbreviations

$\frac{P_{\text{max.}}}{P_{\text{init.}}}$	Ratio of maximum pressure developed to initial pressure.
$P_{\text{init.}}$	Initial pressure in atmospheres.
$T_{\text{init.}}$	Initial temperature in °C.
V_x	Vessel whose capacity is x cm^3, unless otherwise stated.
Cyl.	Cylindrical.
Con.	Conical.
Sphere	Spherical.
Exper. condn.	Experimental conditions.
Milli-sec	Time in milli-seconds to attain maximum pressure.

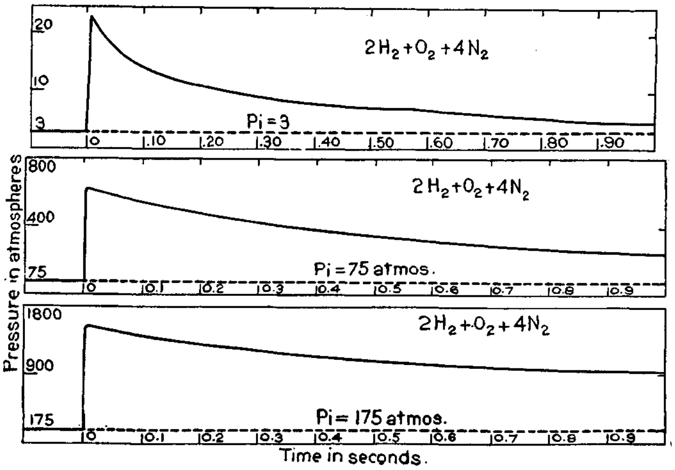

FIG. 11.—Time-pressure curves of $2H_2 + O_2 + 4N_2$ explosions at initial pressures of 3, 75 and 175 atm. (73, 79). Spherical vessel, 2400 cc capacity.

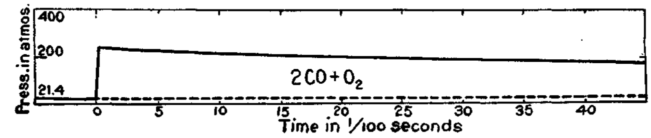

FIG. 12.—Time-pressure curve of $2CO + O_2$ explosion at an initial pressure of 21.4 atm. (69). Spherical vessel, 240 cc capacity.

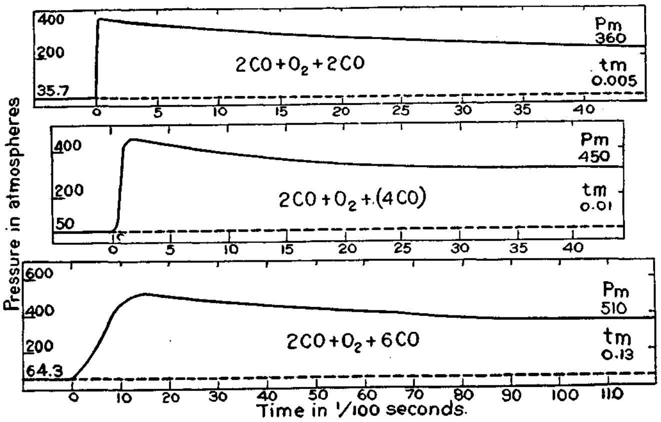

FIG. 13.—Time-pressure curves of $2CO + O_2 + (2CO, 4CO, 6CO)$ explosions at initial pressures of 35.7, 50 and 64.3 atm. respt. (69).

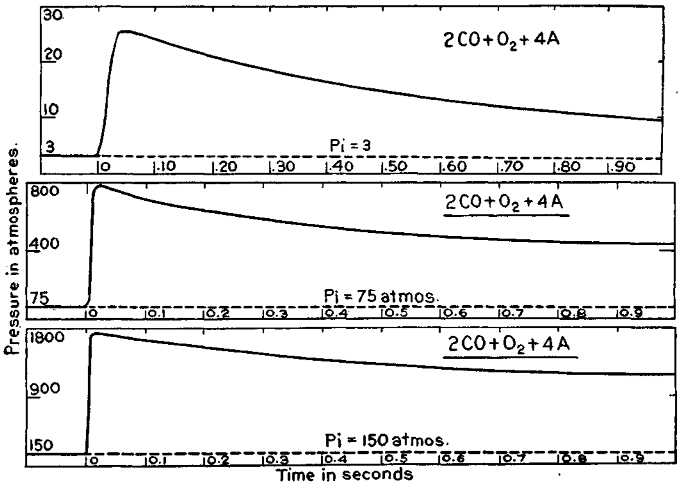

FIG. 15.—Time pressure curves of $2CO + O_2 + 4A$ explosions at initial pressures of 3.75 (73) and 175 atm. (79). Spherical vessel, 240 cc capacity.

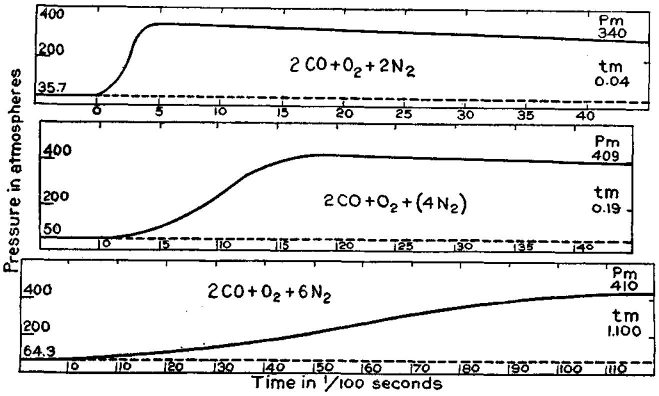

FIG. 14.—Time-pressure curves of $2CO + O_2 + (2N_2, 4N_2, 6N_2)$ explosions at initial pressures of 35.7, 50, and 64.3 atm. respt. (69).

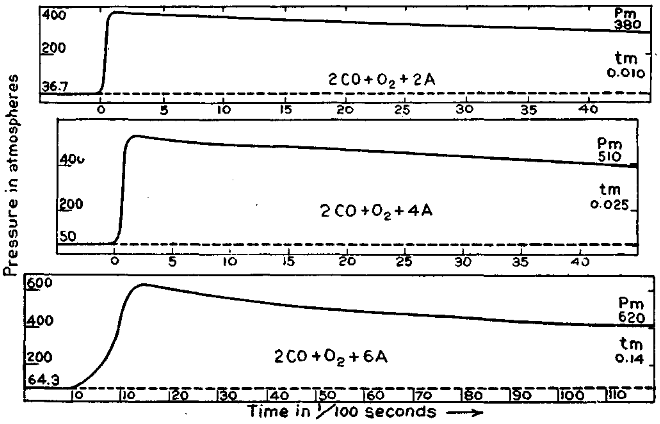

FIG. 16.—Time-pressure curves of $2CO + O_2 + (2A, 4A, 6A)$ explosions at initial pressures of 35.7, 50 and 64.3 atm. (69).

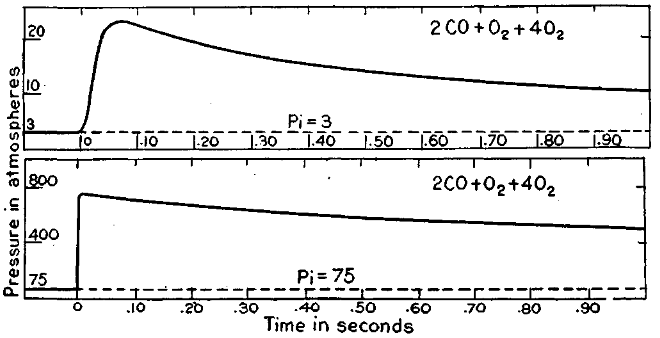

FIG. 17.—Time-temperature curves of $2CO + O_2 + 4O_2$ explosions at initial pressures of 3 and 75 atm. (73). Spherical vessel, 240 cc capacity.

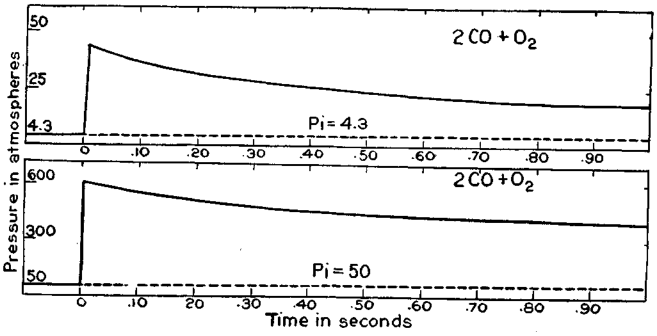

FIG. 18.—Time-pressure curves of $2CO + O_2$ explosions at initial pressures of 4 and 50 atm. (73). Spherical vessel, 240 cc capacity.

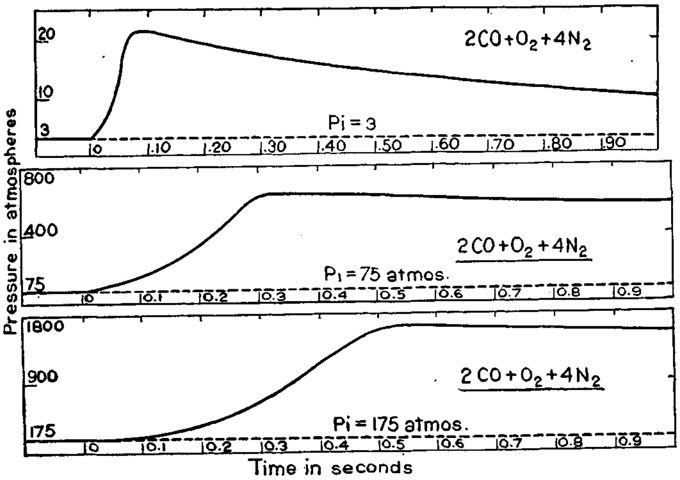

FIG. 19.—Time-pressure curves of $2CO + O_2 + 4N_2$ explosions at initial pressures of 3 (79), 75 and 175 atm. (73). Spherical vessel, 240 cc capacity.

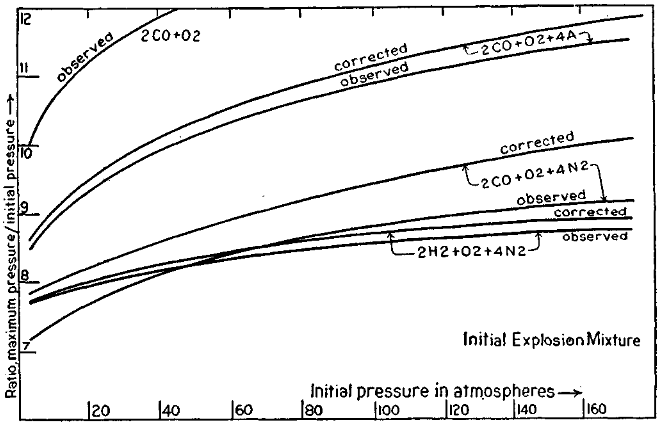

FIG. 20.—Influence of initial pressure on the ratio maximum pressure/initial pressure (79). Spherical bomb, capacity 240 cc. The corrected curve gives maximum pressure (corrected for cooling loss during combustion period)/initial pressure (corrected for deviation from Boyle's law).

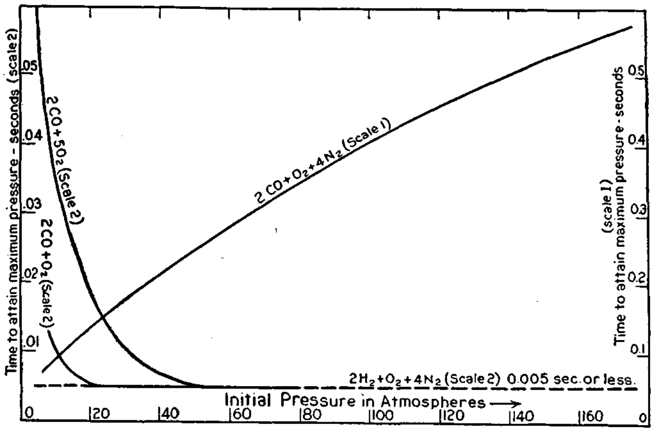

FIG. 21.—Influence of initial pressure on the time taken for the attainment of maximum pressure (79). Spherical bomb. capacity 240 cc.

Various Formulae for Approximate Estimation of Cooling Losses in Explosions of Coal Gas—Air Mixtures

General formula for radiation loss in coal gas—air explosions (59)

$$R_T = 0.0001\ (T_{\text{max.}} - 700\sqrt{D \times L})$$

where

R_T = Total radiation registered
$T_{\text{max.}}$ = Maximum temperature (mean, °K)
D = Density of the gaseous mixture in atmospheres
L = Length of the explosion cylinder in cm

Rate of loss of heat by radiation, cm² of wall surface/sec (R_L) (64)

$$R_L = 1.75 \times 10^{-14}\theta^4$$

where

θ = mean absolute temperature.

For a cylindrical vessel (h cm diam. × h cm deep):

$$R_L = 0.32 \times 10^{-14}\theta^4\sqrt{h}.$$

Rate of loss of heat by conduction, cm² of wall surface/sec (R_L) (64):

$$R_c = 4 \times 10^{-13}\ (t - t_w)^4$$

for temperatures above 2000°K;

$$R_c = 7 \times 10^{-10}\ (t - t_w)^3$$

for temperatures below 2000°K where $(t - t_w)$ is the temperature difference, °C, between the hot gases and the walls of the explosion vessel.

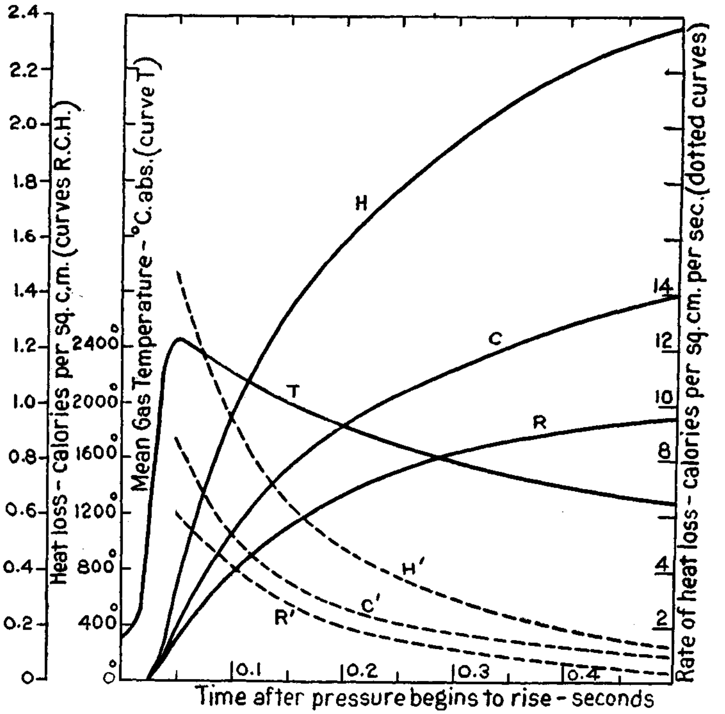

FIG. 29.—Heat loss from 15 % mixture of coal gas and air (64, 74). R = mean loss of heat by radiator per cm² of wall surface. C = mean loss of heat by conductor per cm² of wall surface. H = total heat loss. R′, C′ and H′ give the *rate* of heat loss by radiation, conduction and total loss, respectively. T = mean gas temperature (deduced from the pressure).

Rate of total heat loss, cm² of wall surface/sec (H_T) in a cylinder (h cm diam. × h cm deep) (64):

$$H_T = 4 \times 10^{-13}\ (T - T_w)^4 + 0.32 \times 10^{-14}\ T^4\sqrt{h}$$

for temperatures above 2000°K;

$$H_T = 7 \times 10^{-10}\ (T - T_u)^3 + 0.32 \times 10^{-14}\ T^1\sqrt{h}$$

for temperatures below 2000°K.

Total heat loss to walls of cylindrical explosion vessel (30 cm × 30 cm up to moment of maximum pressure (64) (coal gas—air explosions) at atmospheric density:

$$H_{\text{max.}} = 2.15 \times 10^{-8}\theta^{2\cdot5}_{\text{max.}} \times t_e$$

or expressed as a proportion of the heat of combustion

$$H_{c\ \text{max.}} = 1.43 \times 10^{-5}\theta^{1\cdot5}_{\text{max.}} \times t_e$$

where t_e is the explosion time.

Total heat loss per unit area in similar engines working under similar conditions may be given by the equation (74):

$$H = C + R\sqrt{d}$$

where

C = conduction loss per unit area
$R\sqrt{d}$ = radiation loss per unit area in an engine of diameter d.

INFLUENCE OF TURBULENCE

Explosions of coal gas—air mixtures in conical vessel, capacity 115 in.^{3} (ignition at vertex) (68); *cf.* (**7, 31, 39, 56, 75**)

Distribution of Energy at the Moment of Maximum Pressure

Coal gas—air explosions (64)

Internal Thermal Energy.—From 72% of the heat of combustion in a 9.7% coal gas—air mixture to 80% in a 15% mixture.

Available Chemical Energy.—About 10% in each case.

Heat Loss to Walls of Vessel.—From about 10% in a 15% mixture to about 18% in a 9.7% mixture.

ANIMAL AND VEGETABLE OILS, FATS AND WAXES

C. Ainsworth Mitchell

INTRODUCTION

The General Property Table.—In Table 2, the oils and fats are first classified according to the Alder Wright system. Under each class, the individuals are arranged in alphabetical order of their generic names; and each individual is given a *General Index No.* by means of which it is identified in all subsequent tables. Where only one series of values is given, the data are usually those recorded for a single specimen of the particular oil. Table 2 serves therefore as a general finding table based upon the scientific names. If the scientific name is not known to the reader, he should first consult Table 1 and obtain the General Index No.

Supplementary Tables.—Properties not covered by Table 2 are set forth in Tables 3 to 17 inclusive.

Property-Substance Tables.—In these tables (Tables 18 to 27, inclusive) the individuals are arranged by index number in ascending order of the value of the property, the intervals on the scale of property values being indicated in bold-face type. These property-substance tables may be used (1) to select an individual having any desired value of a given property, or (2) to identify (in some cases at least) an individual by means of its properties. For the latter purpose, the properties cited in the following example are most useful.

Example; An oil is found by test to have the following properties: Congealing point, 0°; saponification, 190; iodine, 82; acetyl,

INTRODUCTION

Table des propriétés générales.—Dans la Table 2, les huiles et les graisses sont d'abord classées suivant le système d'Alder Wright. Dans chaque classe, les huiles et graisses sont rangées suivant l'ordre alphabétique de leurs noms génériques et on leur a attribué un "numéro index général" au moyen duquel elles seront identifiées dans toutes les tables suivantes. Où on a donné seulement une serie de valeurs, les données sont généralement ceux d'un seul échantillon de l'huile particulière. La Table 2 est donc une table de recherche générale, basée sur les noms scientifiques. Si le nom scientifique n'est pas connu du lecteur, il devra d'abord consulter la Table 1 afin d'obtenir le "numéro index général."

Tables supplémentaires.—Les propriétés qui ne sont pas mentionnées dans la Table 2 sont contenues dans les Tables 3 à 17 inclusivement.

Tables des propriétés des substances.—Dans ces tables (Tables 18 à 27 inclusivement), les huiles et graisses représentées par leur nombre index sont arrangées suivant l'ordre ascendant de la valeur de la propriété, les intervalles de l'échelle des valeurs de la propriété étant indiqués en caractères gras. Ces tables des propriétés des substances peuvent être utilisées: 1) pour choisir une huile ou graisse possédant une valeur désirée d'une propriété donnée, ou 2) pour identifier (au moins dans quelques cas) une huile ou graisse au moyen de ses propriétés. On se servira alors de

11; unsaponifiables, 0.6; fatty acids, M. P., 28°; "titer," 21°; n_D^{25}, 1.466. From each of Tables 20, 23, 22, 21, 26, 27 and 16*B*, write down a list of the General Index Nos. lying in the neighborhood of the experimental value and arrange each list in ascending order of these numbers. Determine the number of times each Index No. occurs in this set of lists. For the present example, this gives the following result: 8 times, No. 8; 7 times, No. 31; 4 times, Nos. 3, 5, 26, 47, 62, 91; 3 times, Nos. 13, 20, 29, 33, 54, 61, 67, 83, 84, 92.

By turning to Table 2 and examining the properties there recorded for these oils, all but Nos. 8 and 31 are definitely eliminated. The oil under examination must, therefore, be either olive oil or neat's foot oil, or some oil closely resembling these but not included in Table 2. A further comparison of Nos. 8 and 31 results in the elimination of No. 31 on the basis of the acetyl and iodine values, but additional confirmatory tests are necessary.

Definitions.—*v.* p. viii.

EINLEITUNG

Die Haupteigenschafts Tafel.—In der Tafel 2 werden die Öle und Fette zuerst entsprechend dem Alder Wright System klassifiziert. In jeder Klasse sind die einzelnen Fette und Öle in alphabetischer Ordnung mit deren Gattungsnamen angeordnet, wobei jedem eine "General Index No." zu geordnet ist mit der es in den folgenden Tafeln erkannt werden kann. Ist nur eine Serie von Werten angegeben, so beziehen sich diese gewöhnlich auf eine einzelne Probe des bezeichneten Öles. Tafel 2 dient daher allgemein zum Nachschlagen, mit den wissenschaftlichen Namen als Grundlage. Ist dem Leser der wissenschaftliche Name nicht bekannt, so wäre zuerst die Tafel 1 heranzuziehen, wo die General Index No. erhalten wird.

Ergänzende Tafeln.—Eigenschaften die sich nicht in der Tafel 2 vorfinden, sind in den Tafeln 3 bis einschliesslich 17 enthalten.

Eigenschafts Tafeln.—In diesen (Tafel 18 bis einschliesslich 27) sind die einzelnen Öle und Fette nach ihren Index Nummern in aufsteigender Ordnung ihrer Eigenschaftswerte gereiht, wobei die Intervalle an der Skale der Eigenschaftswerte durch hervorgehobene Schrift angezeigt werden. Diese Eigenschafts Tafeln wären zu benützen:1) Um ein besonderes Öl oder Fett heranzuziehen, welches ihrgend einen gewünschten Wert einer gegebenen Eigenschaft hat. 2) Zur Erkennung (wenigstens in einigen Fällen) eines besonderen Öles oder Fettes auf Grund seiner Eigenschaften. In diesem zweiten Falle ist es am nützlichsten die Eigenschaften in der Art des folgenden Beispieles festzulegen.

Beispiel: Von einem Öl wurden durch Untersuchung folgende Eigenschaften gefunden: Erstarrungspunkt 0°; Verseifungszahl 190; Jodzahl 82; Azetylzahl 11; Unverseifbares 0,6; Fettsäure: Sm. P. 28°; Erstarrungs-Punkt 21°; $n_D^{25} = 1{,}466$. Aus jeder der Tafeln, 20, 23, 22, 21, 26, 27; und 16*B* schreibe man eine Liste der General Index Nummern heraus, welche in der Nähe der experimentell bestimmten Grösse liegen, wobei in der Liste die Nummern in aufsteigender Reihenfolge anzuordnen sind. Dann bestimmt man wie oft jede einzelne Index Nummer in der Liste anzutreffen ist. Für das vorliegende Beispiel bekommt man als Ergebnis: 8 mal No. 8, 7 mal No. 31, 4 mal No. 3, 5, 26, 47, 62, 91, 3 mal No. 13, 20, 29, 33, 54, 61, 67, 83, 84, 92.

Verwendet man die Tafel 2 und prüft die für diese Öle hier angegebenen Eigenschaften, so findet man, dass bis auf No. 8 und No. 31, alle anderen ausscheiden. Das gesuchte Öl ist daher entweder Olivenöl oder Klauenöl, oder ihrgend ein Öl, welches den genannten zwei sehr eng verwandt sein muss und nicht in der Tafel 2 enthalten ist. Ein weiterer Vergleich von No. 8 und No. 31 gibt, dass No. 31 auf Grund der Azetyl- und Jodzahl wegfällt. Besondere bestätigende Untersuchungen sind jedoch notwendig.

Definitionen.—*v.* p. viii.

préférence des propriétés citées dans l'exemple suivant, qui sont les plus utiles pour atteindre ce but.

Exemple: On a trouvé expérimentalement qu'une huile possède les propriétés suivantes: point de congélation 0°; indice de saponification, 190; indice d'iode, 82; indice d'acétyle, 11; insaponifiable 0,6; acides gras Pt. F., 28°, Pt. S., 21°;n_D^{25}, 1,466. On consulte alors les Tables 20, 23, 22, 21, 26, 27 et 16*B* et on dresse pour chacune des tables la liste des "numéros index général" qui se trouvent dans le voisinage de la valeur expérimentale, en disposant dans chaque liste ces numéros dans l'ordre ascendant. Ensuite on détermine combien de fois chaque numéro index se trouve dans l'ensemble des différentes listes. Pour l'exemple indiqué, on obtient les résultats suivants: 8 fois le No. 8; 7 fois le No. 31; 4 fois les Nos. 3, 5, 26, 47, 62, 91; 3 fois les numéros 13, 20, 29, 33, 54, 61, 67, 83, 84 et 92.

En se référant à la Table 2 et en examinant les propriétés qui y sont mentionnées relativement à ces huiles, on peut éliminer tous les numéros à l'exception des Nos. 8 et 31. L'huile à déterminer doit donc être ou de l'huile d'olive, ou de l'huile de pied de boeuf, ou une huile présentant une ressemblance étroite avec celles-ci, mais non mentionnée dans la Table 2. D'une comparaison ultérieure des Nos. 8 et 31, il résulte l'élimination du No. 31, sur la base les indices d'acétyle et d'iode, mais des essais supplémentaires confirmant la chose sont nécessaires.

INTRODUZIONE

Tabella delle proprietà principali.—Nella Tabella 2 gli olii ed i grassi sono anzitutto classificati secondo il sistema di Alder Wright. In ogni classe essi sono disposti in ordine alfabetico in base al nome comune, e ad ognuno è assegnato un numero indice che serve a riconoscerlo nelle tabell successive. Data una sola serie di valori, questi sono in generale quelli di uno solo campione del olio particolare. La Tabella 2 serve perciò come tabella generale di riscontri in base ai nomi scientifici. Se il lettore non conosce il nome scientifico, deve consultare prima la Tabella 1 dove trova il numero indice.

Tabelle supplementari.—Le proprietà che non si trovano nella Tabella 2, sono contenute nelle tabelle da 3 a 17 inclusa.

Tabelle delle proprietà.—In queste (da 18 a 27 inclusa) i singoli olii e grassi sono disposti nell'ordine crescente delle loro proprietà in base ai numeri indici: gli intervalli nella scala dei valori delle proprietà sono indicati con caratteri in grassetto.

Queste tabelle di proprietà possono servire: 1) per scegliere una sostanza che abbia un determinato valore di una certa proprietà, oppure, 2) per identificare (in alcuni casi almeno) una sostanza in base alle sue proprietà. A questo ultimo scopo sono sopratutto utili le proprietà citate nel seguente esempio.

Esempio.—Si sia trovato che un olio ha le seguenti proprietà: Punto di congelamento 0°; numero di saponificazione 190; numero di iodio 82; numero di acetile 11; insaponificabile 0,6; punto di fusione degli acidi grassi 28°, punto di solidificazione 21°; n_D^{25}, 1,466.

Da ognuna delle Tabelle 20, 23, 22, 21, 26, 27 e 16*B* si ricava allora una lista di numeri indici con valori delle proprietà vicini a quelli sperimentali e si dispone ogni lista con questi valori in ordine crescente. Si osserva quindi quante volte ogni numero indice figura in questa serie di elenchi. Nel caso presente si ha: 8 volte il numero 8; 7 volte il numero 31; 4 volte i numeri 3, 5, 26, 47, 62, 91; 3 volte i numeri 13, 20, 29, 33, 54, 61, 67, 83, 84, 92.

Se ora si considera la Tabella 2 e si esaminano le proprietà ivi riportate per questi olii, essi vengono ad essere tutti scartati tranne i numeri 8 e 31. L'olio in esame perciò deve essere olio di oliva, oppure olio di piede di bue, o un olio che rassomiglia molto a questi due, ma che non è compreso nella Tabella 2.

Confrontando ancora i numeri 8 e 31, si scarta pure il 31 in base ai numeri di acetile e di iodio.

E' necessario però confermare ulteriormente questo risultato.

1. INDEX OF COMMON NAMES

English

(In the following index the word "oil" has been omitted. The various entries are oils unless specifically classified as "fats," "waxes," etc.)

French

(Dans la table suivante, le mot "huile" n'est pas mentionné. Les diverses références sont des huiles à moins qu'elles ne soient spécifiées comm "graisses" "cires," etc.)

German

(In dem folgenden Index wird das Wort "Öl" meistens ausgelassen. Die verschiedenen Bezeichnungen gelten Ölen, wenn sie nicht besonders mit den Namen "Fette," "Wachse," etc. bezeichnet sind)

Italian

(Nell'indice seguente è stata omessa la parola "olio." I diversi prodotti sono olii, tranne che non sia esplicitamente dichiarato che si tratta di "grassi," "cere," ecc.)

2. SCIENTIFIC NAMES AND COMMON PROPERTIES

3. COMPOSITION TABLE

(In weight %)

General Index Number

Class 1. Non-drying Oils of Almond and Olive Oil Type

Glycerides principally of oleic acid. Linolic acid present in small proportion

0.5. *v.* (98.5).

1. Similar to No. 13.

2. Oil from kernels is non-drying. Olein, 80.4; stearin, 17.3 (48). The oil from the pericarp is black and has high iodine value (294) (202).

3. Palmitin, stearin, arachidin, lignocerin, olein, linolin and possibly hypogaein. The mixed lignoceric and arachidic acids (Renard's "arachidic acid") vary from 4.3 to 5.4 (av. 4.8); stearic acid *ca.* 5. Unsaturated acids *ca.* 30, of which *ca.* 60% is linolic (63). Hypogaeic acid not found (164) but occurrence considered probable (78). For variations in constants *v.* (100). "Unsaturated" fatty acids 75–79.5, with iodine value, 109–126 (100).

3.5. Similar to No. 17 (185).

4. Non-drying glycerides.

5. Oleic acid, 85; palmitic, 9.4; stearic, 1; glycerol, 10.4; phytosterol, 0.5 (76).

5.5. *v.* (19, 28.5, 150).

7. Glycerides of oleic, stearic and palmitic acids, and, according to Völker, behenic acid.

8. *Ca.* 25 solid and 75 liquid glycerides, mainly olein. Linolic acid, 7; oleic, 93 (80). No stearic acid (83). A mixed glyceride (1–2%, M. P. 53–55°), probably stearic, palmitic and oleic, has been isolated (92). Ultimate composition: C, 77.2; H, 11.3; O, 11.5 (163). Highly unsaturated acids, 78–93.5, with iodine value, 89–98 (100).

9. Similar to No. 8. Solid acids, 9.7 (of which stearic, 40; palmitic, 60); liquid acids, oleic and linolic; no arachidic (110).

10. Oil from commercial rice meal contains free fatty acids, 43–77 (168). Impure fat from polishings *v.* (68).

11. The constants indicate presence of oleic and volatile insoluble fatty acids. On the border-line between oils and solid fats.

12. Largely oleic glycerides.

13. Fatty acids, mainly oleic, with *ca.* 6 linolic (63). No linolenic. Little, if any, stearic (84).

14. Similar to No. 13 *cf.* (160).

15. Resembles No. 13, but has higher iodine value (110–114), indicating larger amount linolic acid. HCN present (141).

16. Similar to No. 13, but contains more linolic acid.

16.5. *v.* (32, 200).

16.6. *v.* (21.1).

16.7. *v.* (72).

17. Very similar to No. 8. 88–93 liquid acids with iodine value 99.6–104.4 (118). This commercial oil is distinct from tea oil (*Thea sinensis*) *v.* (184).

Class 2. Non-drying Oils of Rape Oil Class

19. Greater proportion unsaturated fatty acids than No. 20.

20. Mainly glycerides of rapic and erucic acids (159.5); linolenic acid present (63); arachidic and lignoceric acids *ca.* 1.43 (11). Yields *ca.* 1% insoluble bromide of mixed glyceride (84). "Unsaturated" acids 94–95, with iodine value, 100.5–105 (100).

21. Larger amount less saturated glycerides than No. 20.

22. Similar to No. 24.

23. Resembles No. 20, but has less drying capacity.

24. Resembles No. 20. Contains *ca.* 1.3 arachidic and lignoceric acids (11). Yields *ca.* 1.5 insoluble bromide (84).

25. Similar to No. 24. "Unsaturated" acids, 91.5–94.5, with iodine value, 103–120 (100).

Class 3. Non-drying Oils: Castor Oil Type

26. Glycerides of hydroxylated fatty acid, not identical with ricinoleic. Liquid fatty acids, consist of equal proportions oleic and linolic (111). Solid fatty acids, *ca.* 10, of which palmitic, 80, and stearic, 20. No linolenic.

27. Largely glycerides of ricinoleic and isoricinoleic acids (79), with small amount saturated acids.

28. Palmitic, stearic, oleic and linolic acids, and hydroxy acids (*ca.* 25), not identical with ricinoleic (5).

Class 4. Animal Oils Largely Glycerides of Oleic Acid

29. Mainly olein, with small amount linolin, palmitin, and stearin. Practically free from volatile fatty acids.

30. Glycerides of oleic with very little solid acids.

31. Resembles No. 30, but contains more saturated glycerides. Stearic 2–3; palmitic, 17–18; oleic, 74.5–76.5; glycerol, 5–10; unsaponifiables, 0.1–0.5 (54).

Class 5. Semi-drying Oils

Glycerides of linolic acid are characteristic constituents

32. Resembles No. 51 (146).

33. Glycerides of oleic and linolic acids. Does not yield insoluble bromide.

34. Glycerides of oleic, linolic and palmitic acids, with small amount of erucic acid (141).

35. Similar to No. 47, but does not give Baudouin reaction (27).

35.5. *v.* (52, 91.5).

37. Glycerides of stearic, palmitic, myristic, lauric, caproic, butyric, and acetic acids; also tiglic and higher homologues of oleic acid, but no oleic (163).

38. Glycerides of oleic and linolic acids.

39. Glycerides of oleic and linolic acids. Slight reaction in Becchi's test and Halphen's test.

40. Olein, linolin, with small amount palmitin and stearin.

41. C, 76.4; H, 11.4; O, 12.2 (163). Glycerides of oleic and linolic acid in approx. proportion 3 to 4.5 (224). Linolic acid, 17–18 (63). Stearic acid present. Fatty acids liberated by hydrolysis in practically same proportion as in original oil (101). Unsaturated acids, 69.7–73.9, with iodine value, 144.2–148 (100).

42. Contains hydnocarpic acid, a cyclic fatty acid of general formula $C_nH_{2n-4}O_2$ (154); with neutralization value, 222.7; specific rotation +67.70°; iodine value, 100 (33). Method of separation from chaulmoogric acid, *v.* (51).

43.5. *v.* (48).

44. Glycerides of oleic, linolic, stearic and myristic acids, with 2.3 lecithin (16). Arachidic acid at least 0.4 (223).

45. Glycerides of oleic, linolic, stearic and palmitic acids.

45.2. *v.* (59.5).

47. C, 75.22; H, 11.13; O, 13.65 (163). Glycerides of oleic, and linolic acids, with small amount stearic, palmitic and myristic acids. Solid fatty acids, 12–14; linolic acid, *ca.* 16 (63). Glycerides of oleic, 48.1; linolic, 36.8; palmitic, 7.7; stearic, 4.6; arachidic, 0.4; unsaponifiables, 1.7. Unsaturated acids, 80.6%, with iodine value, 129.7 (104).

48. Saturated acids, *ca.* 12 (mainly stearic and palmitic); unsaturated, *ca.* 80 (linolic and oleic, with *ca.* 50 of isomer of linolic (109)). Insoluble fatty acids: palmitic, 10; stearic, 2; arachidic, 1; lignoceric, linolenic, linolic and oleic, 88 (199); *cf.* (18).

49. Glycerides of chaulmoogric, hydnocarpic, linolic and myristic acids (45). Chaulmoogric acid: neutralization value, 200–202; specific rotation, +58° to +59°; iodine value, 89.5–90.7 (33). For constants of oils from 8 authentic species of

seeds allied to chaulmoogra, *v.* (147). Also *v.* references for No. 42.

50. Contains glycerides of oleic and linolic acids.
51. Mainly glycerides of oleic and linolic acids, with small amounts palmitic, stearic, and arachidic acids (195). Saturated acids, 4.5; olein, 44.8; linolin, 48. 2 (95). Unsaturated acids, 84.6–86.4, with iodine value, 140.8–142.9 (102).

Class 6. Drying Oils

Usually characterized by linolenic and isolinolenic acids and linolic and isomeric acids

52. Glycerides of oleic (*ca.* 25) and elaeostearic acids (isomer of linolic acid). For constants of oils from different species *v.* (138).
53. Glycerides of α-elaeostearic and oleic acids [(1), p. 207].
54. Glycerides of oleic (56.9), linolic (33.4), stearic, palmitic, myristic and linolenic acids (6.5) (204). Yields *ca.* 8% insoluble bromide.
55. Glycerides of β-elaeostearic, oleic, and probably linolic acids (144).
56. Oleic, 57; linolic, 33.5; linolenic, 6.5; oxidised glycerides, 2.8 (203).
57. For general characteristics, *v.* (10).
58. Glycerides of linolic, 70; linolenic and isolinolenic, 15; oleic acid, 15 (224).
59. Glycerides of solid fatty acids (palmitic and stearic) *ca.* 10; liquid acids (oleic and linolic) *ca.* 90 (122).
60. For characteristics, *v.* (30).
61. Yields only small amount insoluble bromide (84).
62. Glycerides of oleic acid, 33.4; linolic, 57.5; palmitic, 3.5; stearic, 2.9; arachidic, 0.6; and lignoceric, 0.4 (99).
63. For characteristics, *v.* (29).
64. For characteristics, *v.* (108). Cross between *J. nigra* and *J. cinere* contains *ca.* 70 linolic acid glycerides, with those of stearic, oleic, and linolenic acids (65).
65. Glycerides of myristic, lauric, oleic, linolic, and linolenic acids. Liquid acids: linolic, 80; linolenic, and isolinolenic, 13; oleic, 7 (224).
66. Elaidin test indicates large proportion olein.
67. C, 78.11; H, 10.96; O, 10.93 (163). Glycerides of solid fatty acids, 10–15. Liquid acids: oleic, 15–20; linolic, 30; linolenic, 38 (62). Saturated acids: stearic, 64.4; palmitic, 20 (140). On bromination, liquid acids yield 20–25 linolenic hexabromide (84). Yields 2 insoluble mixed glycerides on bromination: (1) linolic-dilinolenic bromoglyceride, 22–25; (2) trilinolic bromoglyceride, or oleic-linolic-linolenic bromoglyceride (182). Oil contained: α-linolenic acid, 21.1; isomeric linolenic, 2.7; α-linolic, 17.0; hydoxy-acids, 0.5; saturated acids, 8.0; glyceryl radical, 4.1; phytosterol, 1.0; undetermined, 46.2 (55).
69. Glycerides of oleic (20); linolic (65); linolenic acids (5) (224).
70. *v.* Nos. 52, 53, 55.
71. Glycerides of oleic, linolic, linolenic, palmitic and stearic acids. Fatty acids yield 45–51 linolenic hexabromide (66). Linolenic acid yields hexabromide identical with that from No. 67 (17).
72. Unsaturated acids, 82.8, with iodine value, 157.9 (53).

73–80. For characteristics *v.* (73).

81. *v.* (74, 170).
82. For characteristics *v.* (52).

Class 7. Fish and Marine Animal Oils

Characterized by presence of highly unsaturated glycerides. These oils yield insoluble bromoglycerides, which blacken when heated

83. Glycerides of palmitic, 22.7; myristic, 9.2; stearic, 1.8; unsaturated acids with 18 carbon atoms, 24.9; 20 carbon atoms, 22.2; 22 carbon atoms, 20.2 (190).
84. Glycerides of fatty acids with: C_{14}, 4.5; C_{16} (palmitic), 11.5; palmitoleic, 17; C_{18} (stearic), 2.5; unsaturated (mainly oleic), 36.5; C_{20} (unsaturated), 16; C_{22} (unsaturated), 10; C_{24} (unsaturated), 1.5; unsaponifiables, 1.7 (136). Oil yields *ca.* 25% insoluble bromoglyceride (84). Clupanodonic octobromide (8.39%) from fatty acids.
85. Glycerides of highly unsaturated fatty acids (iodine value, 296–317) (40). Yields clupanodonic octobromide (3.8–6.5%) (183).
86. Glycerides of highly unsaturated acids. Jecoric acid, $C_{18}H_{30}O_2$ (isomeric with linolenic) and palmitic (13.6) (61). For characteristics of pilchard oil *v.* (119).
87. Glycerides of highly unsaturated acids 13% with iodine value 319.5 (40). From 13–14 of clupanodonic acid, $C_{18}H_{28}O_2$ (iodine value 344.4) in mixed fatty acids (183). Glycerides yielded 23.6 insoluble bromide (183).
88. High proportion glycerides of volatile fatty acids (139). Also esters of other alcohols. Deposits spermaceti. Isopropylacetic acid (Chevreul's "phocoenic" acid) in volatile acids (6).
89. Glycerides of highly unsaturated acids (14.3 with iodine value 285.4) (40). Valeric acid, 19.9–24 in jaw oil; 2.71 in body oil (139).
90. For characteristics *v.* (180, 181).
91. Glycerides of myristic, palmitic, stearic, oleic, erucic and unsaturated acids $C_{16}H_{30}O_2$ and $C_{20}H_{38}O_2$ (39, 40, 41). From 17–21 of highly unsaturated acids with iodine value, 324 (189). Clupanodonic acid present (189). Acid of general formula $C_nH_{2n-8}O_2$ (clupanodonic acid) isolated. Oil yields *ca.* 34–42 insoluble bromide (84).
92. Glycerides of saturated acids, 17; liquid acids (oleic and physetoleic) 83 (128); linolic (225); highly unsaturated acids (iodine value 330), 11.96 (40). Mixed fatty acids yield 13.9–14 insoluble bromides.
93. Glycerides of highly unsaturated acids (8.57 with iodine value 312.5) (40). Yields *ca.* 22 insoluble bromide (83). Oil from certain species contains large proportion of $C_{30}H_{50}$, spinacene (43) and squalene (186). For characteristics of liver oils (Jap. sharks) *v.* (187, 188). The liver of *Cetorhinus maximus*, 41.9–55.5 unsaponifiables, mainly squalene.
94. For characteristics *v.* (180). A shark oil.

Class 8. Insect Oil

95. Glycerides of oleic, linolic (4.38), solid fatty acids (mainly palmitic), phytosterol (not cholesterol); glycerol, 9.42 (185). Also *v.* (127).

Class 9. Vegetable Fats

96. *v.* (28).
97. *v.* (131).
98. Much stearic, little palmitic acid. Mixed glyceride, oleodistearin, isolated (86, 89).
99. *v.* (179).
100. *v.* (28).
101. *v.* (29).
102. *v.* (28).
103. *v.* (9).

104–106. *v.* (31).

107. *v.* (31, 34).
108. *v.* (31).
109. *v.* (94).
110. *v.* (48).
111. *v.* (31).
112. *v.* (52).
113. *v.* (64, 72). The crude oil contains *ca.* 3.5% resin, on removal of which a semi-drying oil containing a large amount of linolic acid is obtained. Cong. pt. *ca.* −2°, iodine value, 96.8 (169).

114. *v.* (145).

115. Glycerides of oleic acid, 59.6; palmitic, 38.2; and stearic, 1.8; unsaponifiables, 0.2 (201).

116. Solid fatty acids, mainly palmitic; liquid acids, oleic (124); *v.* (28).

117. Glycerides of fatty acids in approximately proportions given: caproic, 2; caprylic, 9; capric, 10; lauric, 45; myristic, 20; palmitic, 7; stearic, 5; oleic, 2 (57). For criticisms on method of alcoholysis, *v.* (59, 174). Glycerides of kernel oil: caprylic, 9.5; capric, 4.5; lauric, 51; myristic, 18.5; palmitic, 7.5; stearic, 3 (?); oleic, 5; linolic acid glycerides, 1.0 (13). Mixed glycerides isolated (24).

118. *v.* (28).

119. Palmitin, free palmitic acid, olein and small amount linolin (84).

120. Glycerides of caproic acid, 2; caprylic, 9; capric, 10; lauric, 45; myristic, 20; palmitic, 7; stearic, 5; oleic, 2 (58). *v.* No. 117. Mixed glycerides (5) isolated (26).

121–122. *v.* (28).

123. Mainly oleo-distearin (87); *v.* (48).

124. Mainly palmitin, with glycerides of oleic and linolic acids. Stearic acid, 3.3 (83).

125. Glycerides of stearic, palmitic and oleic acids. Oleo-distearin and oleo-dipalmitin isolated (115). For characteristics of fats from different varieties of pontianak nuts, *v.* (71). For relationship of constants, *v.* (178).

126. Largely laurin with glycerides of oleic and probably linolic acid; *v.* (60).

127–129. *v.* (192).

131. Solid acids, 71.4; liquid acid (oleic), 23 (141).

132. Glycerides of lauric, myristic and palmitic acids (121).

133. *v.* (28).

134. *v.* (126).

135. Glycerides of myristic, palmitic, stearic, and oleic acids. Glycerol, 13.4 (1).

136. Glycerides of myristic acid, 73–74; oleic, 20; butyric, 1; essential oil, 2–3 (1).

137. Glycerides of lauric acid, 15.1; myristic, 52.2; palmitic, 0.2; oleic, 3.9. Unsaponifiables, 20.4 (20).

138. Glycerides of myristic and oleic acids and an essential oil.

139. *v.* (28).

140. *v.* (72).

141. *v.* (196, 200).

142. *v.* (197).

143. *v.* (126).

144. Largely palmitic acid and its glycerides. Mixed glyceride isolated (69).

145. Insoluble fatty acids, including lauric and arachidic, 91 (163). Volatile acids contain butyric and acetic acids. Liquid acids, 55; unsaponifiables, 3.12 (207).

146. Glycerides of palmitic and oleic acids. No stearic acid (83). Oleo-dipalmitin isolated (114).

147. Glycerides of stearic, palmitic, oleic, and linolic acids. Stearic acid in fatty acids, 40 (83). Saturated acids, 59.7; oleic, 31.2; other acids, 6.3 (63). Mixed glycerides (113, 116). Oleic, 43–45; palmitic, 23–25; stearic, 31–33. Five mixed glycerides isolated (3).

149. *Ca.* 75 solid (palmitic) and 25 liquid acids (oleic) (121).

Class 10. Animal Fats

150. Mainly glycerides of palmitic, stearic and oleic acids, with small amounts linolic. Palmito-distearin and stearo-dipalmitin isolated (23). Stearic acid, 7–13 (83).

151. Mainly glycerides of palmitic, stearic, and oleic acids, with traces of linolic and linolenic acids (63). Mixed glycerides isolated include oleo-dipalmitin, stearo-dipalmitin, oleo-palmito-stearin and palmito-distearin (23). These crystallize in different form from lard glycerides.

152. Glycerides of palmitic, stearic and oleic acids. Stearic, 0–36 (83).

153. Mainly triolein, with small amounts stearo-dipalmitin, palmito-diolein, and oleo-dipalmitin (4). Fatty acids contain stearic, 3.8; palmitic, 21.2; and oleic, 72.3 (25.5).

154. For characteristics, *v.* (117).

155. Glycerides of palmitic, stearic and oleic acids.

156. Glycerides of oleic and linolic acids, 9.9 (63). Stearic acid sometimes present (1). No linolenic (63).

159. *v.* Nos. 151, 152.

160. Glycerides of stearic acid, 19–21; palmitic, 20–21; oleic, 53–59; glycerol, 5–10; unsaponifiables, *ca.* 0.5 (54).

161. Glycerides of butyric, caproic, caprylic, and capric acids, 8.35; oleic, 32.5; stearic, 1.83; palmitic, 38.61; myristic, 9.89; and lauric, 2.59, with 1.83 dihydroxystearic acid (35). Stearic acid, 0–22 (137). Mixed glycerides include butyro-diolein, butyro-palmito-olein and oleo-dipalmitin (2). For particulars of *ghee*, *v.* (29.1, 29.2, 109.5, 193.5).

Class 11. Liquid Animal Waxes

162. Mainly various alcohols (iodine value, 64.8–65.2) in combination with fatty acids of oleic series (1).

163. Mainly alcohols, chiefly of ethylene series, in combination with fatty acids of oleic series. Iodine value of alcohols, 63.9–74.1 (22).

Class 12. Vegetable Non-glyceridic Waxes

164. Contains a hydrocarbon (M. P. 59°), an alcohol, $C_{27}H_{56}O$; myricyl alcohol, carnaubic acid, cerotic acid, and a hydroxy acid (175).

165. From 50–52 hydrocarbons (37).

166. Esters of montanic acid and unsaponifiable matter (157, 162, 212).

Class 13. Animal Non-glyceridic Waxes

167. Complex mixture of esters of higher alcohols; also glycerides (50, 112, 165).

168. Free cerotic acid and esters of alcohols (36).

169. Free cerotic acid, myricin, with smaller amounts free melissic acid, unsaturated fatty acids, and ceryl and other alcohols (81, 96). Free hydrocarbons, 11.0–17.5 (38).

170. *v.* (36).

171. Chiefly ceryl cerotate with small amounts of other esters.

172. Mainly cetin or cetyl palmitate with very small amounts of similar esters or glycerides.

Influence of Temperature on Viscosity under Pressure

400 kg cm^{-2} (6000 lb. in.$^{-2}$) produces approx. the following % increase in viscosity: Lard (No. 150) 75% at 25°, 34% at 100°; sperm (No. 163) 72% at 25°, 29% at 100°.

For lard oil (No. 150) the solidifying pressure at 21° is *ca.* 155 kg cm^{-2} (22 800 lb. in.$^{-2}$) and at 100° the viscosity is increased 240% by 1500 kg cm^{-2} and 600% by 3000 kg cm^{-2} (44 000 lb. in.$^{-2}$) [*Report of Research Sub-committee on Lubrication, Amer. Soc. Mechan. Engineers*, No. **1833** (Dec. 1921)].

Drying oils heated in contact with air acquire greater conductivity; also oils that have become rancid. If a definite temperature has not been reached (about 260°) the original conductivity is restored on cooling. Of the oils tested, linseed oil showed the greatest conductivity.

For castor, olive, and linseed oils *see* (222).

16. REFRACTIVE INDEX AND BUTYROREFRACTOMETER READING

In preparing Table 16*B* below, butyrorefractometer values have first been converted into values of n_D by means of the *conversion factors* given in Table 16*A*. Values of n_D below 25° and above 40°C have then been converted to 25° and 40°, respectively, by means of the convenient approximate relation,

$$\frac{\Delta n_D}{\Delta t} = -0.00037\ (106).$$

16*A*. Table for Converting Butyrorefractometer Readings into Refractive Indices

Scale divisions	n_D	Scale divisions	n_D	Scale divisions	n_D	Scale divisions	n_D

19.1	1.4370	44.4	1.4555	71.9	1.4735		

For more extensive data *v.* (106). For specific refraction (Lorenz) *v.* (156).

The following empirical relations have been proposed:

$$\frac{n^2-1}{n^2+2} \times \frac{100}{d_4^t} = 33.07 + 0.00075(I) - 0.01375\ (S) + 0.002(t - 15)$$

where d = density, S = saponification value, and I = iodine value, all at t°C. When hydroxy acids are present, the first constant of the equation is lower (14).

$$n_D^{40} = 1.4643 - 0.000046\ (S) - 0.0096\left(\frac{A}{S}\right) + 0.0001171\ (I),$$

where A = acid value.

An observed refractive index higher than that calculated from this formula indicates oxidation of the oil (149).

In the case of hydrogenated cottonseed, linseed, arachis, sesame and sardine oils, and bassia tallow,

$$n_D^{60} = [1.4468 + 1.03 \times 10^{-4}\ (I) + 7.3 \times 10^{-3}(I^2)] \pm 0.0005.$$

The refractive indices of hydrogenated castor oil are lower than those of other oils with similar iodine values, owing to reduction of the hydroxyl groups by the catalyst (178).

* At 56°.

(93) describes a method based on the inversion of the spectrum colors shown by tung oil.

17. OPTICAL ROTATION OF OILS

Values expressed in reading on Laurent's saccharimeter (200 mm at 20°) unless otherwise stated (148)

General index No.	Oil or fat	Optical rotation
69	Poppy oil	0.0
3	Arachis oil	−0.1 to −0.4
14	Apricot kernel oil	−0.2
65	Walnut oil	−0.3
13	Almond oil	−0.7
20	Rape oil	−1.6 to −2.1
82	Stillingia oil	−18.6
8	Olive oil	+0.2 to +0.6
47	Sesame oil	+0.8 to +2.4
27	Castor oil	+7.6 to +9
37	Croton oil	+14.5 to +16.4
42	Hydnocarpus oil α_D^{20}	+49.50 to +51.5
49	Chaulmoogra oil α_D^{20}	+50.8 to +58.2

PROPERTY-SUBSTANCE TABLES

The bold-faced numbers are intervals on the scale of property values. The other numbers are General Index Numbers in the order of the value of the property.

18. DENSITY

Oils.—15/15: **0.861**: 163, 162, 6, 88, 94.5. **0.91**: 88, and all others except 60. **0.95**: 49, 27, 60, 42.2. **0.97.**

Fats.—100/15.5: **0.852**: 148, 138, 141, 149, 125, 116, 119, 147, 131, 108, 115, 109, 111, 99, 130, 146, 117. **0.86**: 141, 146, 117, and all others except 155. **0.90**: 155. **0.91.**

Waxes.—100/15.5: **0.805**: 172, 171, 169, 167, 164. **0.85.**

19. MELTING POINT

Fats.—**4°**: 141. **10°**: 141, 130, 114, 156, 96. **20°**: 130, 114, 156, 117, 145, 101, 103, 105, 120, 96. **25°**: 114, 156, 117, 145, 105, 120, 109, 102, 140, 147, 119, 133, 153, 125, 107, 161, 100, 118, 116, 124, 150. **30°**: 156, 109, 147, 119, 153, 125, 107, 161, 116, 124, 150, 121, 148, 142, 126, 110, 157. **35°**: 156, 119, 161, 116, 150, 126, 157, 158, 131, 146, 113, 111, 149, 137, 97, 132, 136, 167, 138. **40°**: 119, 150, 158, 146, 111, 149, 132, 136, 167, 138, 98, 135, 123, 159, 106, 172, 151, 160. **45°**: 150, 158, 146, 136, 135, 159, 172, 151, 152, 155, 144. **50°**: 136, 159, 155, 144. **60°**: 169, 170, 168, 165. **70°**: 166. **80°**: 171, 164. **90°**: 166, 164.

20. CONGELATION TEMPERATURE

Oils.—**−30°**: 66, 59, 51, 80, 65, 79, 58, 73, 67, 77, 13. **−20°**: 51, 65, 58, 77, 13, 81, 54, 66, 59, 51, 80, 65, 79, 58, 73, 67, 77, 13, 81, 54, 52, 53, 15, 74, 14, 1, 45, 34, 69, 5, 27, 37, 28, 75, 40, 25, 68, 62, 24, 88, 38. **−15°**: 51, 65, 77, 13, 14, 45, 27, 37, 28, 48, 23, 43, 41, 61, 64, 17. **−10°**: 37, 39, 12, 16, 10, 46, 20, 21, 3, 36, 8. **−5°**: 20, 3, 8, 47, 83, 99, 91, 84, 29, 31, 30, 92, 82. **0°**: 41, 99, 29, 31, 53, 30, 7, 95, 33, 26, 6. **5°**: 41, 31, 30, 4, 45.3. **10°**: 41, 30, 4, 11, 42.4, 42.5. **20°**: 30, 42.3, 42.2, 42.1, 41.5. **75°.**

21. ACETYL VALUE

0: 91, 161, 117, 172, 150, 147, 3. **3**: 3, 5, 163, 13. **5**: 163, 13, 51, 116, 26, 120, 58, 31, 159, 54. **10**: 51, 26, 54, 8, 65, 125, 84, 44, 69, 160, 36, 20, 41, 28. **15**: 26, 84, 37.5, 44, 41, 169, 92, 119, 59, 153, 28, 144, 37. **20**: 26, 84, 44, 41, 144, 68, 141, 63, 82, 28. **30**: 141, 37, 28, 113. **40**: 28, 2. **50**: 164. **55. 149**: 27. **150.**

22. IODINE VALUE

Oils.—**50**: 11, 30, 31, 4. **60**: 30, 31, 4, 29, 42.5. **70**: 31, 29, 16.5, 6, 5.5, 39, 2, 8, 45.3. **80**: 16.5, 39, 8, 42.1, 18, 12, 27, 42, 5, 9, 3, 42.2. **90**: 42.3, 39, 42, 3, 33, 17, 1, 13, 24, 20, 41.5, 28, 10, 22, 49, 113,[1] 40, 42.4, 26, 88, 25. **100**: 33, 13, 20, 28, 22, 49, 40, 26, 25, 16, 46, 14, 73–80, 19, 35.5, 41, 47, 36, 44, 37, 7, 21. **110**: 28, 49, 40, 73–80, 41, 47, 44, 7, 21, 35, 15, 51, 93, 84. **120**: 44, 21, 51, 93, 84, 57, 87, 45, 38, 48, 59, 61, 37.5, 89, 62, 81. **130**: 93, 48, 59, 61, 56.5, 62, 63, 34, 72, 68, 91, 56, 65. **140**: 59, 34, 72, 68, 82, 91, 56, 65, 58, 83, 82, 55, 70. **150**: 34, 52, 91, 58, 83, 52, 53, 55, 70, 74, 82. **160**: 53, 55, 91, 58, 83, 54. **170**: 83, 86, 67, 60, 68.5. **180**: 83, 86, 67, 71. **190**: 86, 67, 71. **200**: 67, 71. **205**: 71. **260**: 92. **344.**

Fats and Waxes.—**4**: 135, 167, 144, 172, 103, 168–170, 117, 138. **10**: 167, 144, 168–170, 120, 101, 129, 100, 118, 133, 164, 102, 166, 96, 167, 140, 161. **20**: 96, 167, 137, 127, 146, 155, 161, 122, 132. **30**: 167, 137, 146, 155, 161, 122, 132, 125, 147, 123, 159, 151, 148, 98. **40**: 167, 137, 146, 161, 147, 159, 151, 98, 104, 131, 142, 100, 150, 152, 145, 109, 116. **50**: 167, 137, 150, 152, 145, 160, 105, 111, 110, 115, 99, 108, 153. **60**: 150, 152, 105, 111, 99, 108, 153, 106, 107, 128, 157, 126, 158, 130. **70**: 99, 157, 126, 158, 130, 134, 156, 96, 139, 121, 97. **80**: 158, 156, 121, 124. **90**: 158, 124, 113, 139.5. **100.**

23. SAPONIFICATION VALUE

50: 165, 166, 164, 167, 168, 169, 170. **100**: 167, 168, 170, 163, 162, 172. **150**: 136, 93, 84, 20, 94, 85, 72, 91, 24, 28, 19, 25, 6, 23, 27, 21, 90, 146, 143, 111. **180**: 84, 85, 91, 28, 19, 27, 21, 90, 143, 111, 146, 43, 108, 76, 16.7, 130, 9, 141, 50, 13, 66, 134, 7, 8, 137, 142, 51, 3, 88, 60, 123, 98, 44, 92, 34, 36, 148, 68, 106, 104, 38, 47, 62, 71, 4, 67, 86, 59, 96, 61, 87, 107, 149, 48, 83, 39, 54, 49. **190**: 84, 85, 28, 146, 130, 13, 8, 42.3, 68.5, 137, 142, 51, 139.5, 3, 123, 98, 44, 42.5, 92, 68, 104, 38, 47, 62, 71, 4, 67, 86, 59, 61, 87, 107, 149, 37.5, 48, 83, 39, 54, 49, 35, 80, 32, 99, 64, 17, 95, 81, 58, 160, 65, 63, 12, 78, 75, 18, 1, 16, 79, 153, 40, 5, 14, 73, 74, 125, 139, 110, 10, 26, 33, 57, 45, 69, 147, 15, 70, 29, 159, 30, 31, 105, 114, 157, 37, 113, 41, 52, 53, 55, 2. **195**: 84, 13, 8, 137, 142, 92, 86, 59, 49, 160, 65, 63, 40, 5, 14, 10, 26, 70, 29, 159, 30, 31, 105, 114, 157, 37, 41, 52, 53, 55, 2, 109, 152, 155, 156, 150, 112, 151, 115, 121, 126, 46, 116, 158, 131, 119, 56, 89, 135, 42, 144, 82, 42, 45.3, 41.5, 42.2,

HYDROGENATED OILS

Hydrogenation reduces the iodine value, and refractive index, (56) but has little influence upon the acid value, saponification value and unsaponifiable matter.

In oils, such as castor oil, containing hydroxyl groups, the hydroxyl value is lowered (143). The amount of insoluble bromides is reduced. The stearic acid formed on hydrogenation is identical with normal stearic acid (120).

A method of differentiating hydrogenated and natural oils has been based on the ratio between the amounts of stearic acid and palmitic acid (135). Hydrogenated oil may be recognized by a determination of the iso-oleic acid formed in the process (208).

PARTLY HYDROGENATED OILS (218)

General index No.	Oil	M. P., °C	Congelation point, °C	Butyrorefractometer reading (40°)	Acid value	Saponification value	Iodine value
117	Coconut	44.5	27.7	35.9	0.4	254.1	1.0
47	Sesame (techn.)	62.1	45.3	38.4	4.7	188.9	25.4
84	Whale	45.1	33.9	49.1	1.2	192.3	45.2

ADHESIVES AND GELATINS

JEROME ALEXANDER

INTRODUCTION

Most practical adhesives are mixtures of several ingredients, with or without some kind of salt, and may be classified as:

(*A*) Animal adhesives: *e.g.*, glues, gelatins, casein, albumin;

(*B*) Vegetable adhesives: *e.g.*, flours, starches, dextrins, gums, gum resins, oils, and proteins;

(*C*) Mineral adhesives: *e.g.*, silicate of soda, cements, limes, plasters, clays, pitches, tars, artificial resins, solders, and such mixtures as iron + sulfur and litharge + glycerin.

In using an adhesive to join two surfaces, the surfaces concerned are the ultimate exterior ones and the adhesive must either take hold of these exterior surfaces or must remove them and take hold on the surface below. Thus, if the articles to be joined are not cleaned, the exterior surface is frequently a layer of grease. Setting and drying are promoted by any agency which increases the concentration of the adhesive; for example, by removing the solvent. Joint strength is influenced by quantity of adhesive used, by speed of set and drying, and by the application of pressure.

Animal Glues

Use.—(1) Keep dry and from excessive heat; (2) use definite weights of glue and water; (3) soak glue in cold water until softened; (4) melt on water bath and keep temperature as low as work permits (usually below 65°C); melt small batches successively to avoid prolonged heating which injures strength; (5) supply evaporation losses; (6) use clean vessels, and, if necessary, a preservative.

ADHESIVES AND GELATINS

JEROME ALEXANDER

INTRODUCTION

Most practical adhesives are mixtures of several ingredients, with or without some kind of salt, and may be classified as:

(*A*) Animal adhesives: *e.g.*, glues, gelatins, casein, albumin;

(*B*) Vegetable adhesives: *e.g.*, flours, starches, dextrins, gums, gum resins, oils, and proteins;

(*C*) Mineral adhesives: *e.g.*, silicate of soda, cements, limes, plasters, clays, pitches, tars, artificial resins, solders, and such mixtures as iron + sulfur and litharge + glycerin.

In using an adhesive to join two surfaces, the surfaces concerned are the ultimate exterior ones and the adhesive must either take hold of these exterior surfaces or must remove them and take hold on the surface below. Thus, if the articles to be joined are not cleaned, the exterior surface is frequently a layer of grease.

Setting and drying are promoted by any agency which increases the concentration of the adhesive; for example, by removing the solvent. Joint strength is influenced by quantity of adhesive used, by speed of set and drying, and by the application of pressure.

Animal Glues

Use.—(1) Keep dry and from excessive heat; (2) use definite weights of glue and water; (3) soak glue in cold water until softened; (4) melt on water bath and keep temperature as low as work permits (usually below 65°C); melt small batches successively to avoid prolonged heating which injures strength; (5) supply evaporation losses; (6) use clean vessels, and, if necessary, a preservative.

SELECTION

Wood Joints.—Hide-stock glues, grades 70–130.[1] Joining pressure before setting increases joint strength rapidly up to 200, and then more slowly up to 1000 lb./in.^{2}. Surfaces must be well joined, dry, and preferably warm. Good joints are stronger than the wood, and may show shearing strength of 2000 to 3000 lb./in.^{2}

Veneers.—Bone and hide stock mixtures between 50 and 70. Avoid foam.

Paper Boxes.—For hand setting-up, 70 to 90 test; for machine, 100 to 160 test. For covering or stripping, 30 to 60 test.

Book Binding.—For rounding and backing, grades above 90 are best (usually mixed with some glycerin). For hand pasting, grades about 50. For case-making machines, grades 60 to 100.

Leather Belting, Printer's Rollers, Plaster Molds.—Hide glues above 120; usually with addition of glycerin, etc.

Gelatins

Photographic Gelatin (1).—Jelly strength, 130 or above. pH, 5–6 (limit 4–7). Ash <3%. Fe and Cu <50–60, Pb <50, parts per million. Al_2O_3 <0.2%, SO_2 <0.1%, of dry gelatin. Mucin, grease, and ammonia$\ngtr$traces. Traces of thiocarbimides are essential(55).

Food Gelatin.—U. S. Dept. of Agriculture, Bureau of Chemistry, tolerance limits (parts per million): As_2O_3, 1.4; Zn, 100; Cu, 30; Pb, 20; SO_2 must be declared on label.

Joint Strength

The strength of joints made with an adhesive depends upon the kind of material joined and the condition of its surface, upon the thickness of the adhesive film, and upon such conditions as temperature, humidity, time of drying, and pressure used in forming the joint.

TENSILE STRENGTH (DEF. 4): OAK TO OAK (32)

Unit: kg/cm^2

* Reduced to about 30 if the joint be heated to 100° for 4 days while clamped.

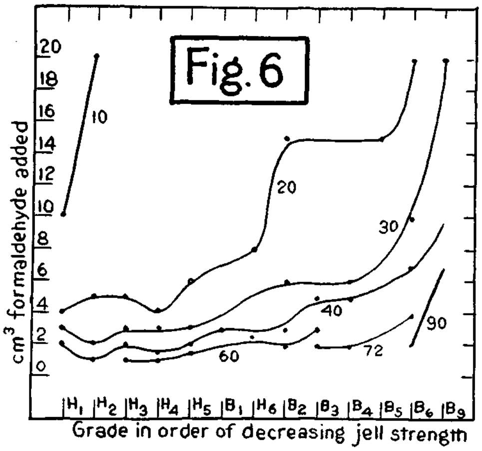
† Film not complete. Three coatings raise value to 112; values have been measured as high as 600. Additional data are given in Figs. 1–5.

TENSILE STRENGTH OF SOME COMMON ADHESIVES
Unit: kg/cm²

Glue (calculated)	700–2000
Collagen	1300
Gelatin	960
Viscose	2100

Jelly Strength

The jelly strength of a glue is usually measured by the force required to cause a definite compression of the jelly. The addition of formaldehyde to glues decreases the jelly strength in direct proportion to the amount of HCHO added, until the glue becomes insoluble. Figure 6 shows the number of cm³ of 10% HCHO required to produce insolubility in various glues, the numbers on the curve giving the grams of glue to 180 g total weight of solution (⁷).



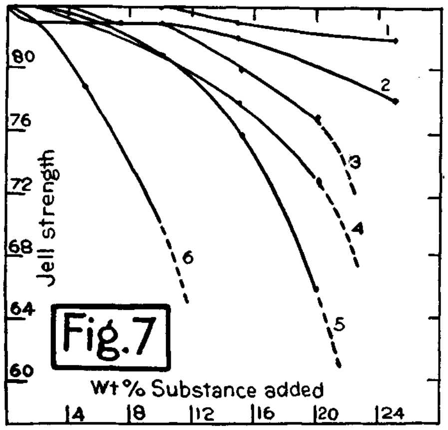


Figure 7 shows the effect of added substances upon the jelly strength. 1 H_2SO_4; 2 NaOH; 3 $MgCl_2$; 4 Acetic acid; 5 Chloral hydrate; 6 KI. 1 and 2 in cm³ of 0.5*N* soln. added instead of wt. % (⁷).

The relation between the nitrogenous constituents and the jelly strengths of hide (H) and bone (B) glues is shown in Figs. 8 and 9 (⁹).

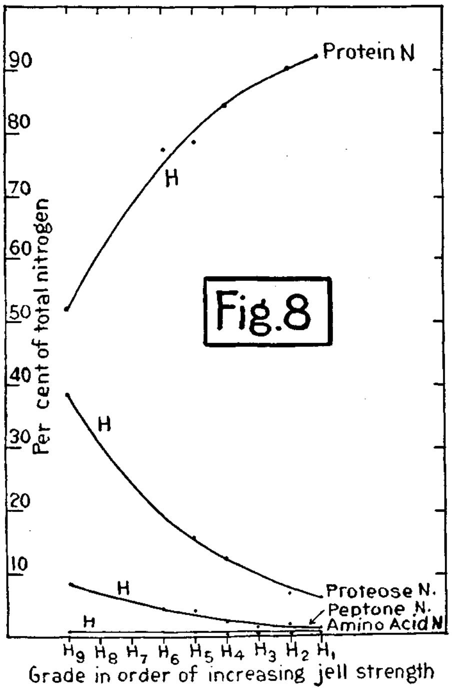
Viscosity; η

The viscosity of 20% solutions of hide and bone glues at 15.5°C (60°F) is constant for at least 90 minutes after preparation. Vigorous agitation lowers η slightly (2% after 2 minutes beating) (⁷).

The increase in η produced in dilute solutions of glues by formaldehyde is slight, but rises rapidly with increasing glue content. Agitation increases η of HCHO treated glues slightly and after drying such glues exhibit increased η on re-solution or become insoluble with increasing HCHO content (⁷).

The amount of protein precipitated by 24–30% $MgSO_4$ solution from liquid glue varies directly as η for glue solutions having the same jelly strength (⁹).

The amount of material absorbable from glue solutions decreases as η decreases (³⁴).



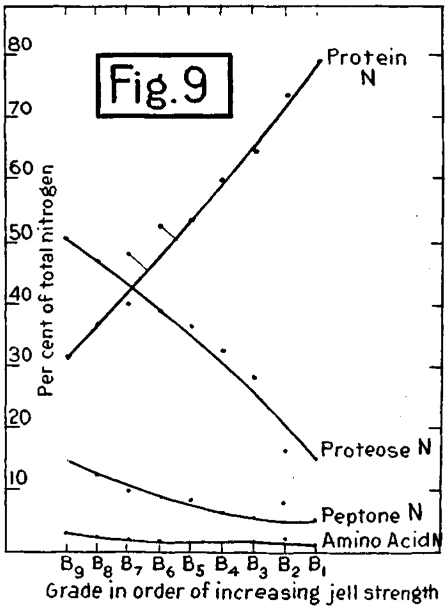


Figure 10 shows the effect of time on η (in seconds, H_2O = 42) of HCHO treated glues and Fig. 11 the effect of temperature. (Numbers on curve = cm³; 10% HCHO added.) (⁷).

Figure 12 shows the effect of alums on η of glue solutions; Fig. 13 the effect of time, and Fig. 14 the effect of temperature on the η of alum-treated glues (⁷).

Figure 15 shows the variation of η (in seconds, H_2O = 42) of glue solutions with temperature, the melting point of the glue solution being taken as temperature at which the slope of the curve approaches infinity (⁸).

Figure 16 shows the effect of temperature on the η of hide glues, and Fig. 17 on the η of bone glues (η in MacMichael degrees) (8).

Figure 18 shows the relation of η to jelly strength of hide glues (11).

The flow of starch pastes, under pressure, through a capillary tube is shown in Fig. 19 and of dextrin pastes in Fig. 20. The numbers on the curves give the wt. % of dry solids in the pastes (16).

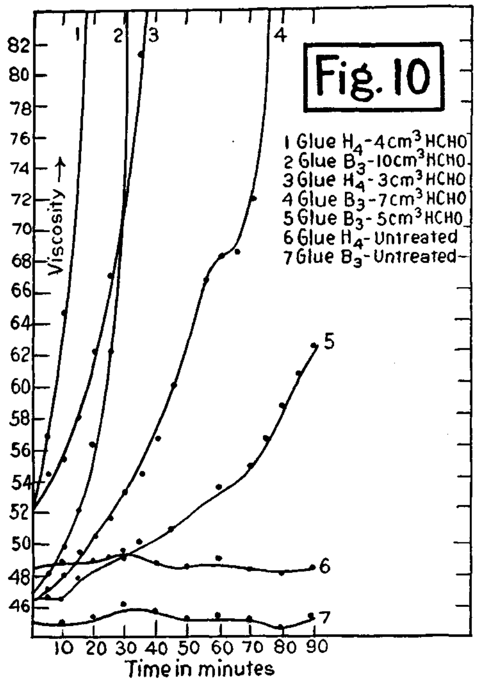

Fig. 10

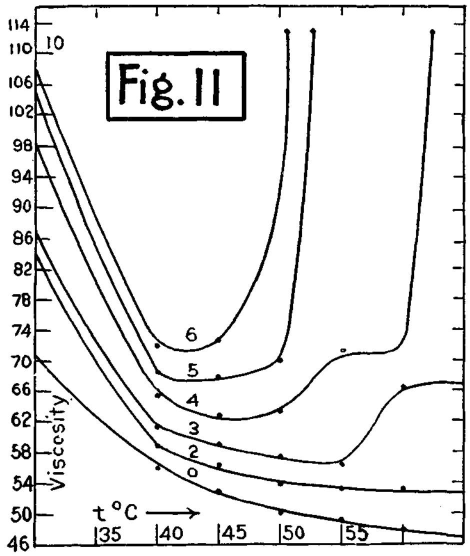

Fig. 11

The η of 10% hide and glue solutions, measured at 35°C, is decreased considerably by heating under pressure up to 5 atm. for 1 to 5 hr. (23).

Addition of anhydrous chrome alum in small percentages has little or no effect on the η of glue solutions (33).

Gelling point

The gelling point of a glue is the temperature at which appreciable flow under the action of gravity ceases.

Chrome alum (anhydrous salt = 0.8% wt. of dry glue) raises the setting or gelling point *ca.* 2°C with 20% glue solutions and *ca.* 10° with 50% glue solutions. The gelling points (in °F on curves) of glue solutions as affected by addition of chrome alum are shown in Fig. 21 (33).

Drying Behavior

High grade liquid glues lose water much more slowly than low grade glues when dried at room temperatures (2).

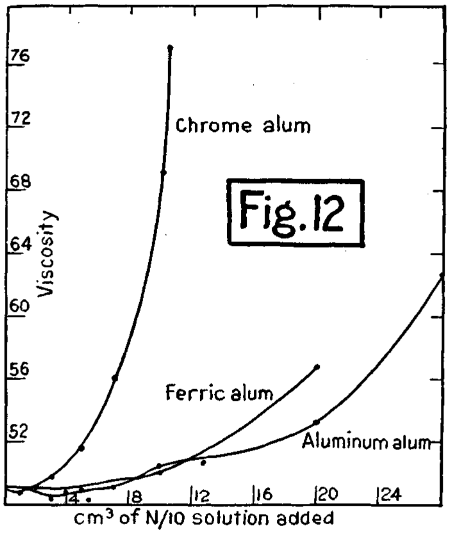

Fig. 12

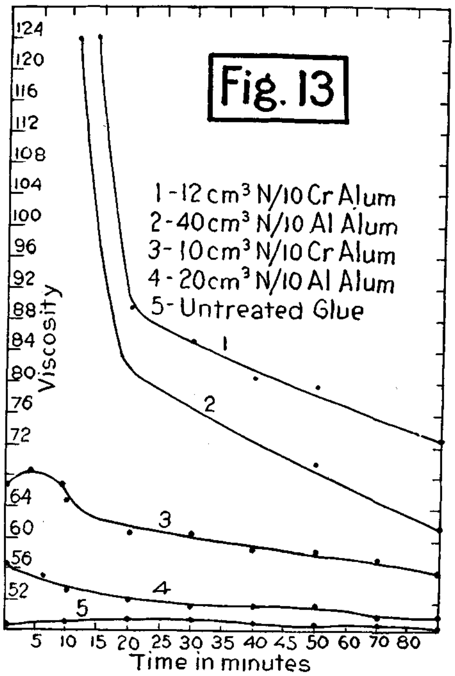

Fig. 13

2. GELATINS

Jelly Strength

Alcohol up to *ca.* 25 vol. % tends to increase the rigidity of 10% gelatin gels; larger amounts cause a decrease. Acetone acts similarly (20).

According to Bogue (15) the maximum jelly strength occurs at pH = *ca.* 4, and minimum at pH = *ca.* 5, near the isoelectric point. Sheppard and Sweet (27) find the maximum at the isoelectric point, pH = 4.7, with a minimum at pH = *ca.* 5.5 and a second maximum at pH = 7.8.

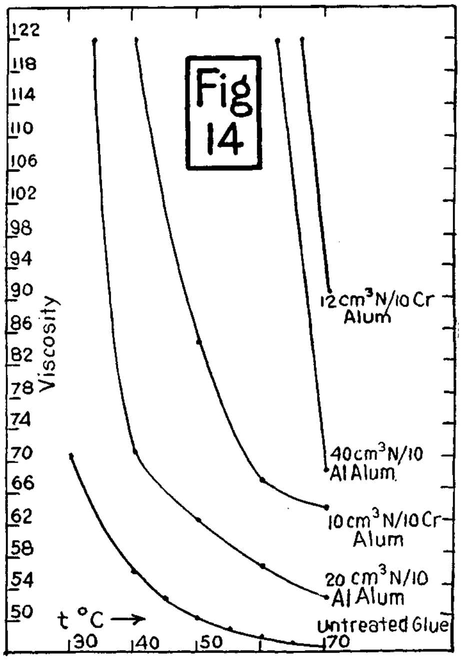

Fig 14

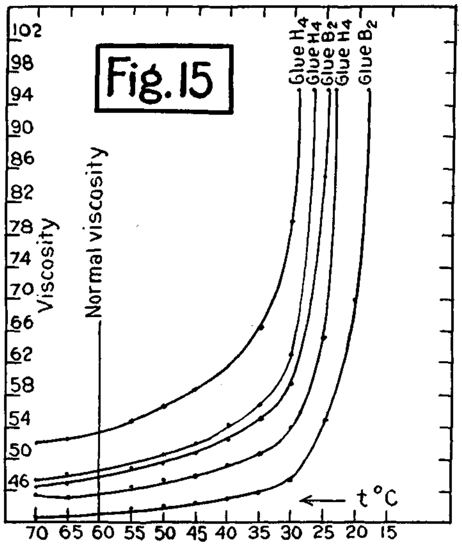

Fig. 15

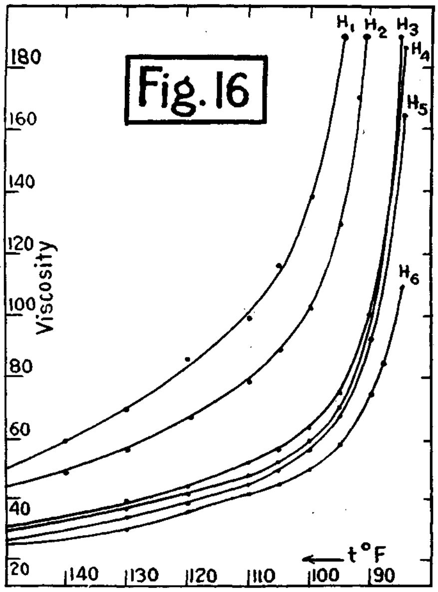

Fig. 16

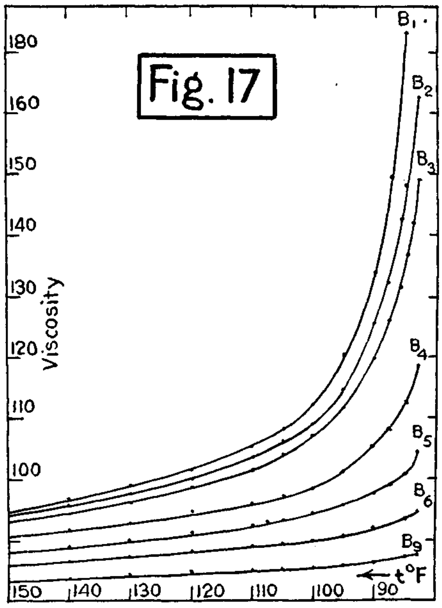

Fig. 17

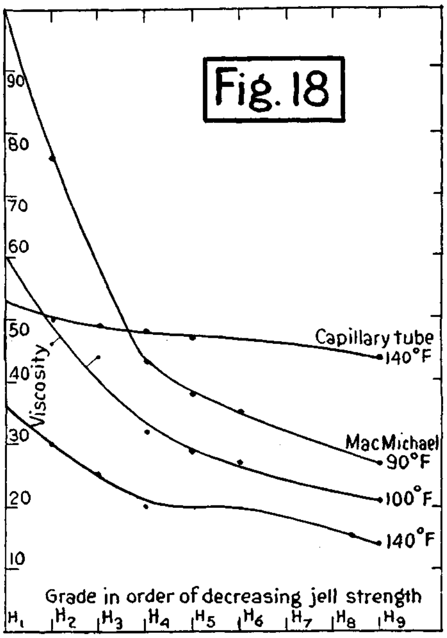

Fig. 18

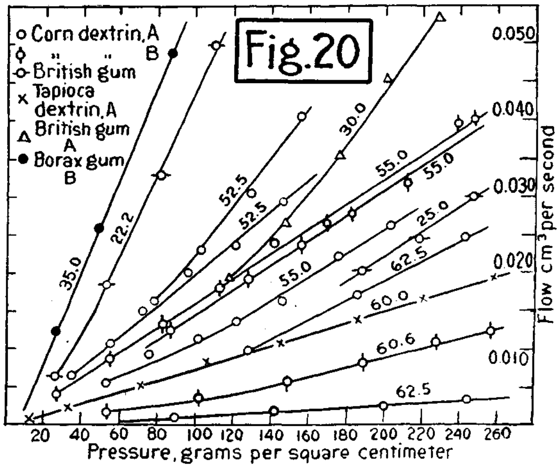

Fig. 20

Figure 22 shows the influence of traces of Al salts on the rigidity of a 7% gelatin jelly (28).

For the effect of sulfuric, phosphoric and lactic acids on jelly strength, *see* (4).

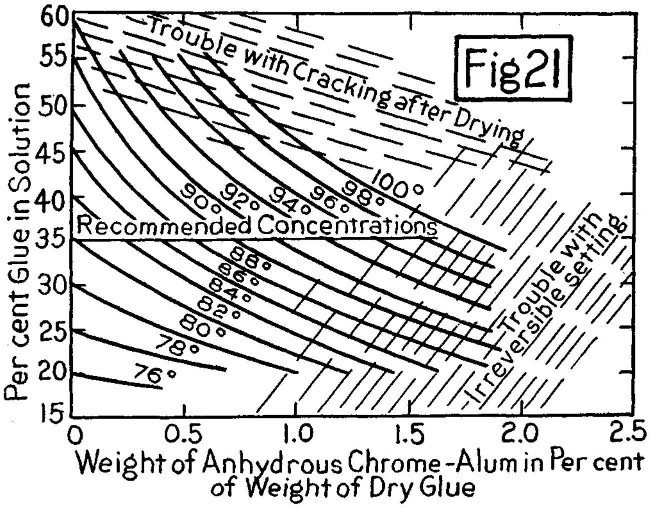

Fig 21

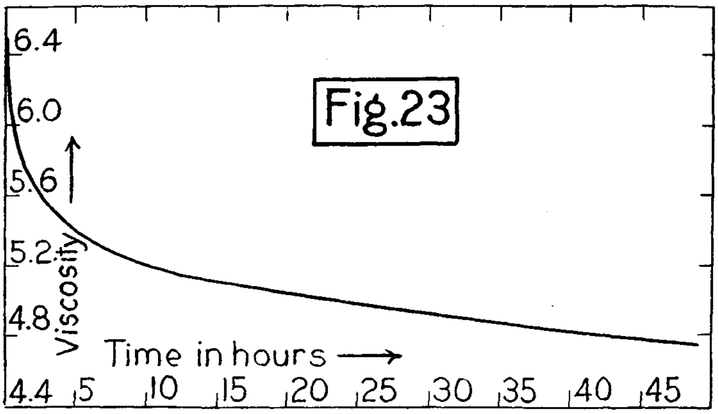

Fig.23

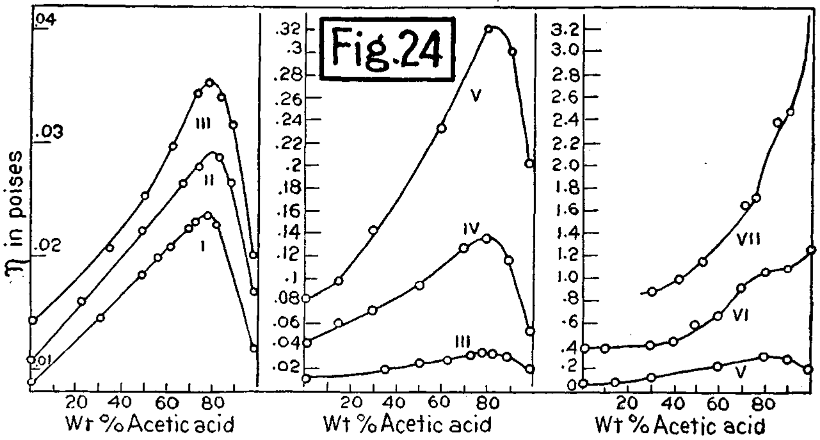

Fig.24

Adhesive Strength

Slight hydrolysis increases the adhesive strength of high-grade gelatin, while continued hydrolysis decreases it (13).

Viscosity

Gelatin in aqueous solution, as measured by the MacMichael viscometer, follows the laws of viscous flow at temperatures above *ca.* 40°C, but exhibits the properties of plastic flow below the solidification point. The sol-gel transformation occurs over a range rather than at a point. At 35°C, time rate of change of η varies with the pH of the solution, the concentration and nature of inorganic ions, and the amount of hydrolyzed protein present (3).

Figure 23 shows the variation of η at 35°C (in arbitrary units) with time for a 5% purified photographic gelatin, pH = 4.9 (18).

The η at 25°C of solutions of gelatin in aqueous acetic acid is given in Fig. 24. Curve (1) is for the two liquids alone, (2) for 0.2 g gelatin per 100 cm^3 of solution, (3) for 0.6 g, (4) for 5 g, (5) for 10 g, (6) for 15 g, (7) for 20 g per 100 cm^3 (20).

The η at 25°C of solutions of gelatin (10 g per 100 cm^3) in formamide + water and formamide + acetic acid is given in Fig. 25. The dotted curves are the η of the mixtures without the gelatin (20).

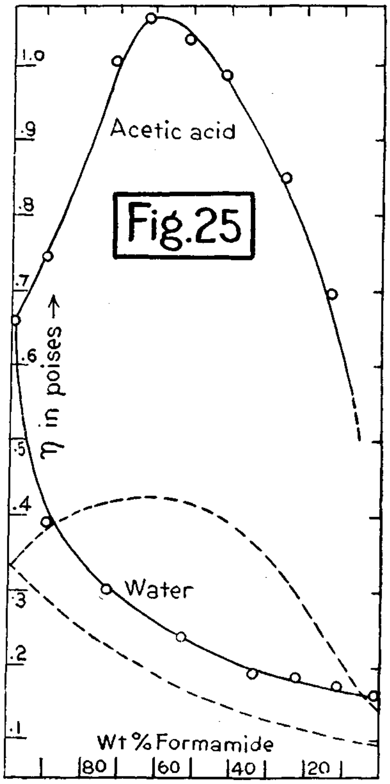

Fig.25

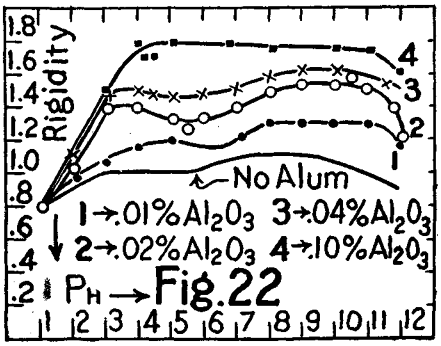

Fig.22

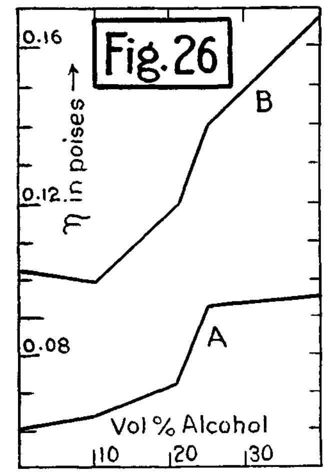
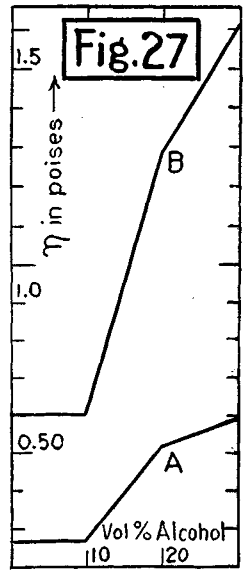
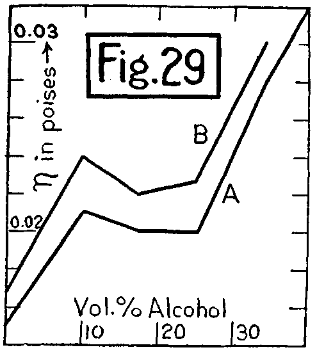
Figure 26 shows the η at 28°C of solutions of gelatin (5 g per 100 cm^3) in methyl alcohol-water mixtures. A = η of fresh solution; B = η after 30 min (20).

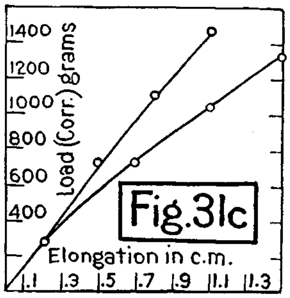
Figure 27 shows η at 30°C of solutions of gelatin (15 g per 100 cm^3) in methyl alcohol-water mixtures. A = freshly prepared; B = after 15 min (20).

Figure 28 gives η at 25°C of solutions of gelatin (2 g per 100 cm^3) in ethyl alcohol-water mixtures. A = freshly prepared; B = after 30 min (20).









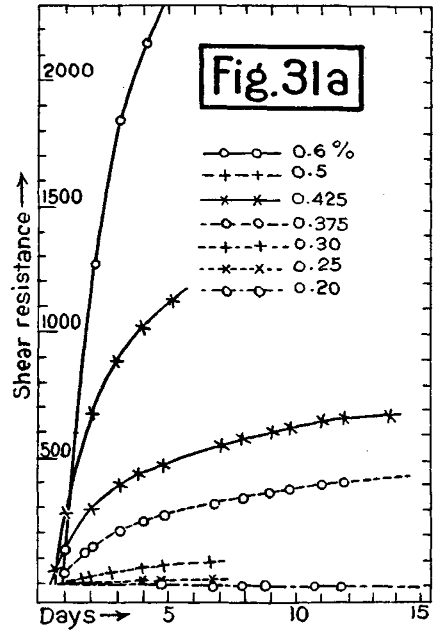


Figure 29 gives η at 30°C of solutions of gelatin (10 g per 100 cm³) in ethyl alcohol-water mixtures. A = freshly prepared; B = after 30 min (20).

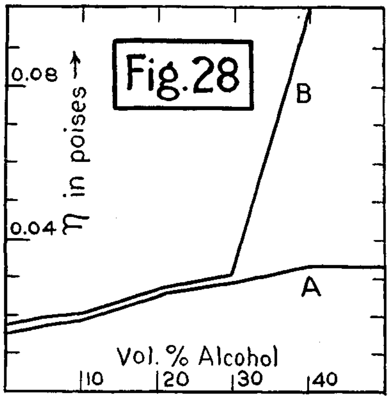
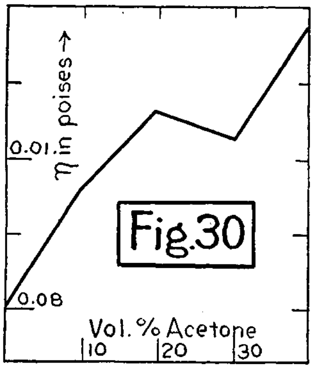
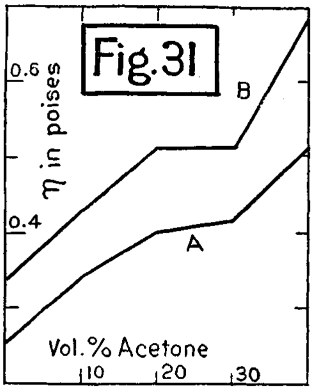
Figure 30 gives η at 35°C of solutions of gelatin (10 g per 100 cm³) in acetone-water mixtures (20).







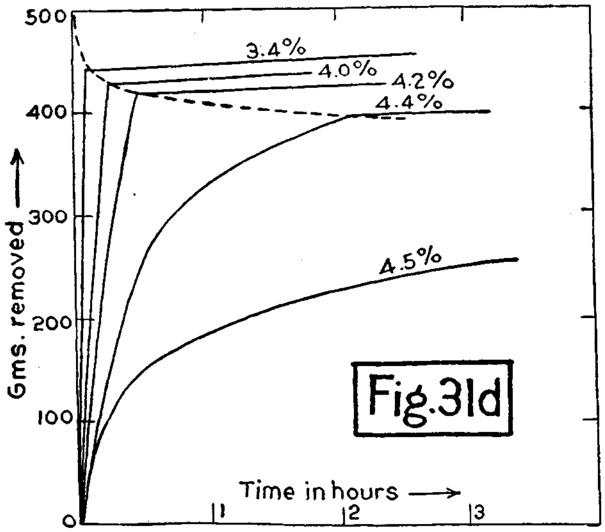


Figure 31 gives η at 30° of solutions of gelatin (15 g per 100 cm³) in acetone-water mixtures. A = freshly prepared; B = after 15 min (20).

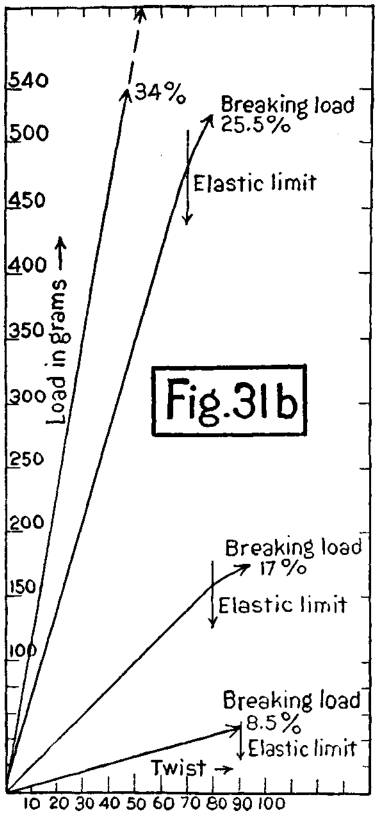
The addition of pyridine to solutions of gelatin in water increases η, while addition of dimethylamine and diethylamine up to *ca.* 25 wt. % of solution decreases, and over 30% again increases η (20) *cf.* (45, 46, 47).

Plasticity and Elasticity

The temperature at which plasticity appears in gelatin solutions depends both on the concentration and on the way in which the solution is prepared (49).

Figure 31*a* gives the change with time of the elastic resistance to shear of dilute gelatin solutions (0.2–0.6%) at 8°C (50).

Figures 31*b* and 31*c* show the behavior of gelatin jellies under torsion and stretch, respectively. The gelatin content of the jellies is given in wt. % (51).



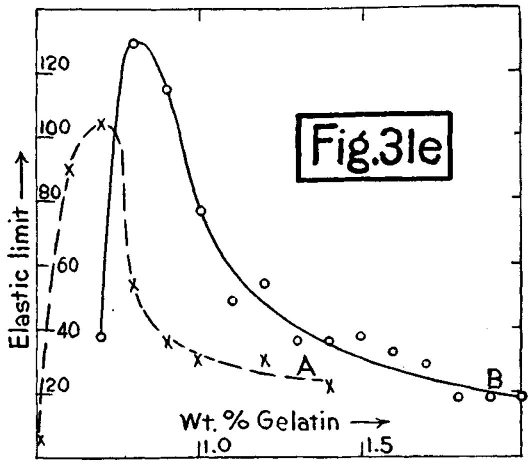


Figure 31*d* shows the behavior of gelatin jellies (3.4–4.5 wt. % gelatin) which have been under a load of 500 g at 16.5°F. The portion of the load removed in order to keep the deformation constant is given as a function of time (52).

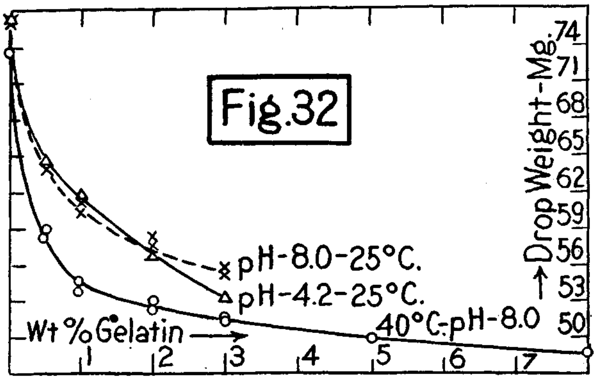
Figure 31*e* shows the relation between the elastic limit of gelatin solutions and the concentration of the gelatin in the solution. A = purified gelatin; B = a commercial gelatin.

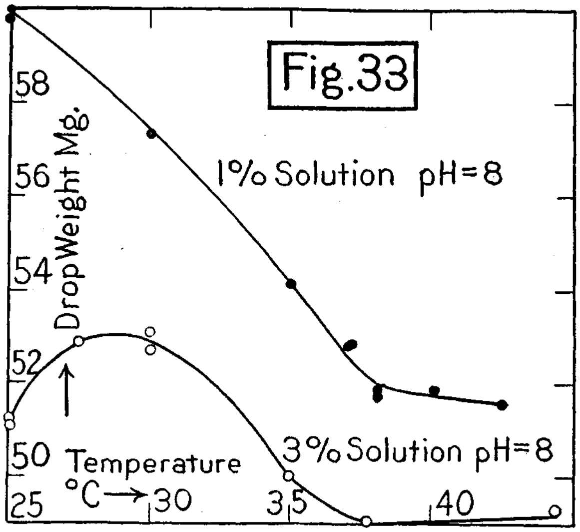
Surface Tension; γ

Figure 32 shows the variation in the drop-weight of water solutions of ossein gelatin with varying concentrations of gelatin (13).

Figure 33 shows the variation of drop weight of gelatin-water solutions with temperature, and Fig. 34 with pH (13).

Figure 35 shows the effect of pH on the drop weight of various gelatin-water solutions containing 0.5% gelatin (13).





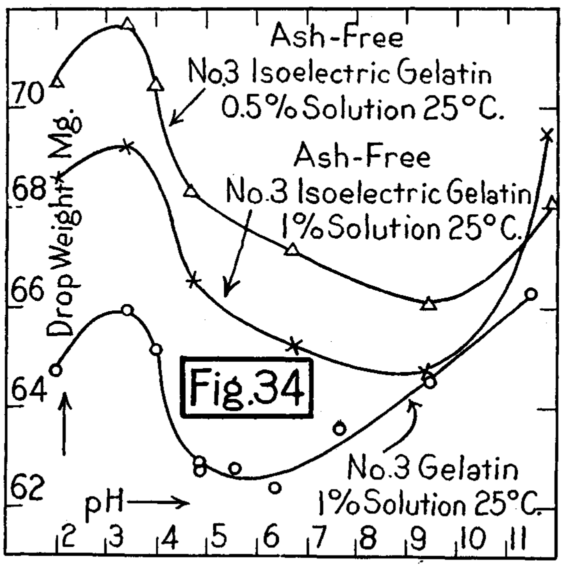


Figure 36 shows the effect of pH on a hide gelatin (0.5 and 1 wt. % of gelatin) solution in water at 25° and 40°C (13).

Figure 37 gives the variation in drop weight of 1 and 2% gelatin in water solutions with time (13).

Figure 38 (20) shows the variation of γ with temperature for various gelatin solutions. A_1 = pure H_2O. A_2 = 5 g gelatin per 100 cc water solution. B = pure formamide (same for 5 g gelatin per 100 cc formamide solution). C = phenol-acetic acid mixture (dotted line gives values of γ after addition of gelatin, 5 g per 100 cm³ of mixture). D = *o*-cresol-acetic acid mixture (dotted line after addition of 5 g gelatin per 100 cm³ of mixture). E_1 = pure acetic acid. E_2 = pure acetic acid + 5 g gelatin per 100 cm³. The inset gives γ for water-alcohol solutions of gelatin against temperature. Solid curve for mixtures of alcohol-water. Dotted curve for mixtures with 10 g gelatin per 100 cm³ solution.

Two per cent gelatin solutions at 30°C by stalagmometer show a rise in γ to a maximum at pH = 8–9, falling to a minimum at pH = 4.5 and rising to a lower maximum at pH = 3 (12).

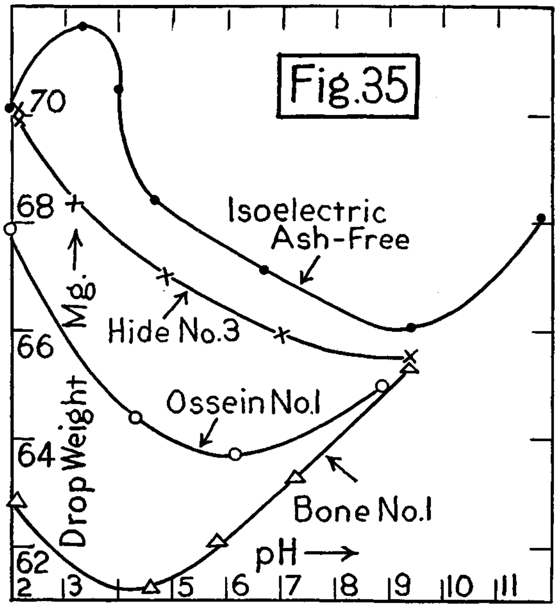

Fig.35

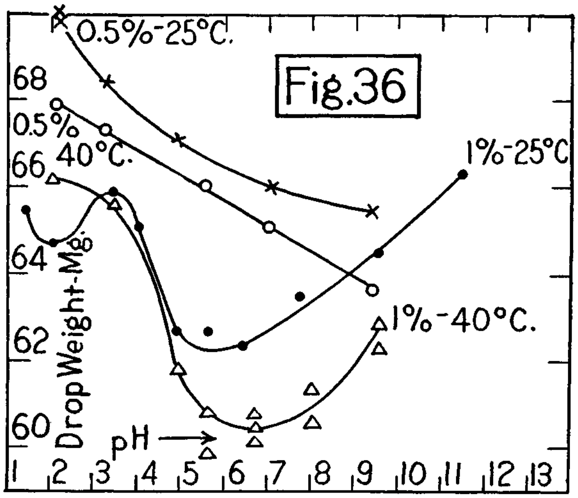

Fig.36

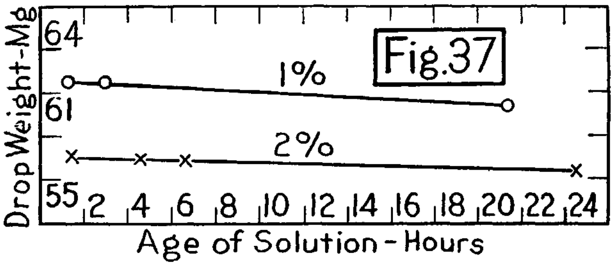

Fig.37

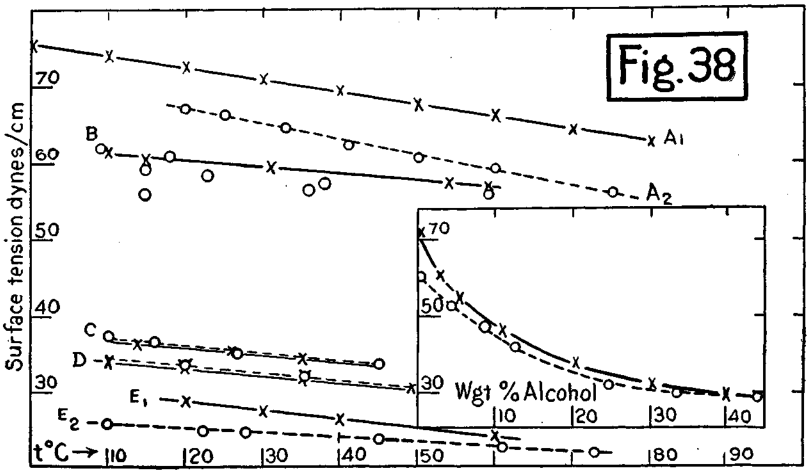

Fig.38

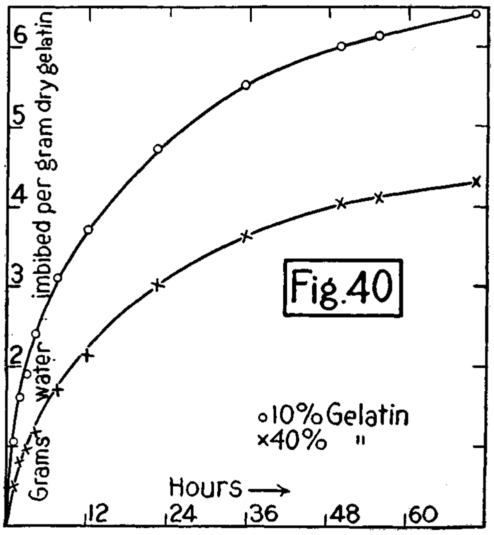

Fig.40

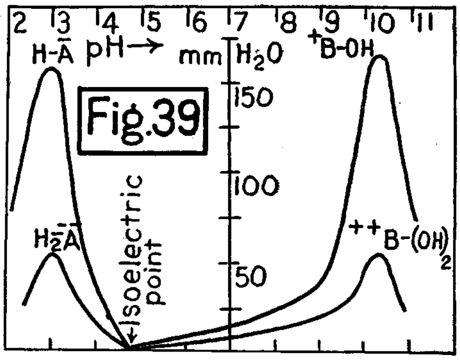

Fig.39

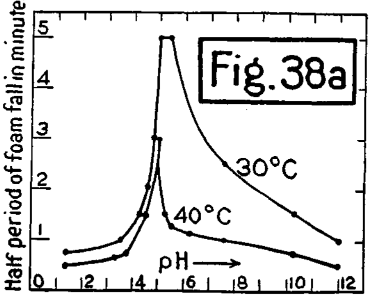

Fig.38a

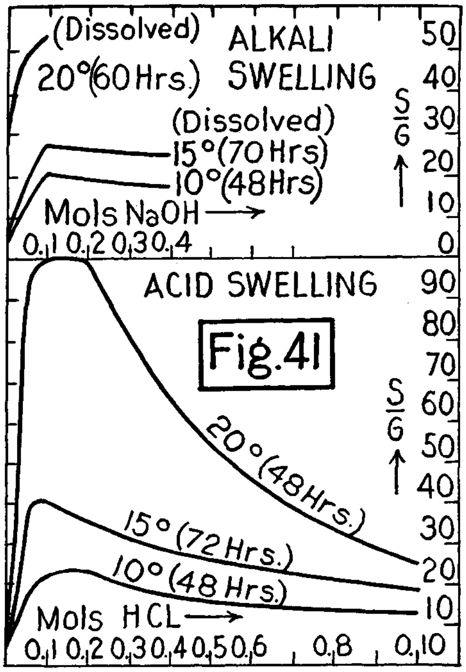
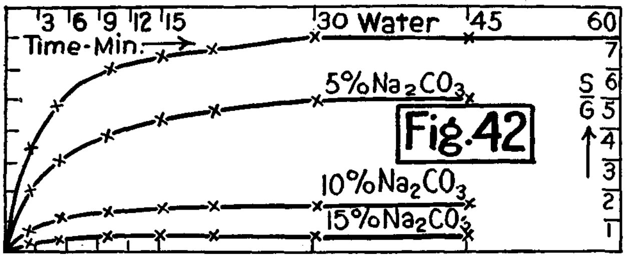
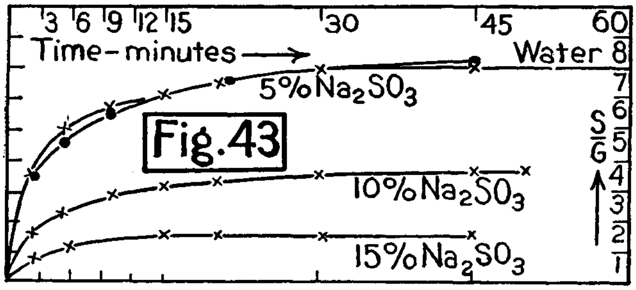
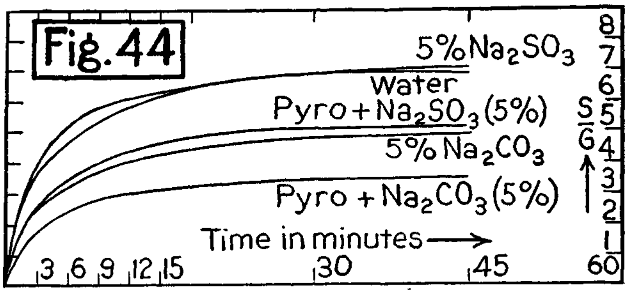








See (54) for γ between toluene and gelatin solutions.

Figure 38*a* shows the relation between pH and foam on aqueous gelatin solutions, γ for the solution being smallest at the isoelectric point where the foam is most stable.

THERMAL EXPANSION

Aqueous solutions of gelatin (37)

Wt. % gelatin	0.0	2.02	5.04	8.9	10.4	16.5	24.8
$\frac{10^6}{V}\frac{\Delta V}{\Delta t}$ (15°–32°C)	241	249	267	289	300	341	386

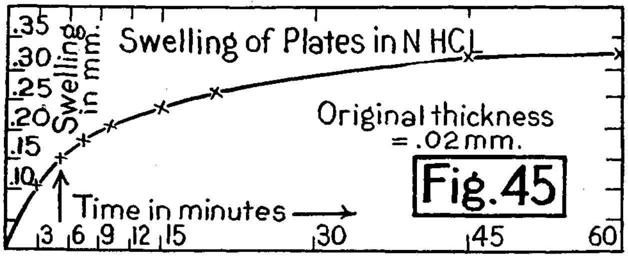
Wt. % gelatin	0.0	3.60	7.05	13.00
Temp. of max. density	+4.0°	+2.5°	+1.3°	−1.2°

Osmotic Pressure

Figure 39 gives the osmotic pressure at 10°C of 0.5 g gelatin per 100 cm³ water solution against solutions of acids and bases of pH value indicated (29).

Swelling and Contractility

Figure 40 shows the swelling behavior of dry gelatins when immersed in pure H_2O for the times indicated. The 10% gel was prepared by drying a solution made from 90 g H_2O + 10 g gelatin and the 40% gel from a solution of 60 g H_2O + 40 g gelatin, the dried pieces being of the same area and thickness (15).



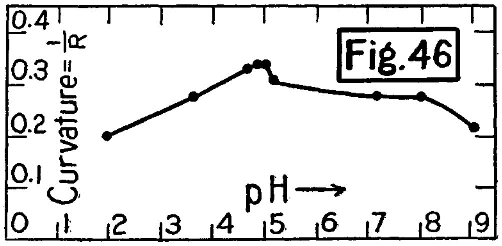


Figure 41 shows the influence of temperature, S/G = grams H_2O imbibed per gram gelatin (25).

Figures 42, 43, 44, and 45. Silver bromide emulsion gelatin on plates when immersed in the solutions indicated for varying times (25).

The following table and Fig. 46 show the contractility of gelatin films as measured by the curvature produced in thin Al discs coated on one side with 10% gelatin solution and dried under uniform conditions. In Fig. 46, the gelatin films were prepared from de-ashed material, in solutions of the pH indicated (26).

CONTRACTILITY

Gelatin	Radius in cm	Curvature 1/R	Remarks
Commercial hard A	24	0.041	Good grade
Commercial hard B	24.5	0.0405	photographic gelatins
Ossein gelatin	26	0.038	Photographic quality
Hide gelatin No. 6902	31	0.032	Good grade hide gelatin
Same, de-ashed	31	0.032	Ash less than 0.01%
Sizing gelatin	34	0.029	Poor grade

There is no definite relation between the contractility of gelatins and their swelling on immersion in H_2O, indicating that there are individual structural differences in gelatins, depending not simply on physico-chemical conditions but on origin and previous history (26).

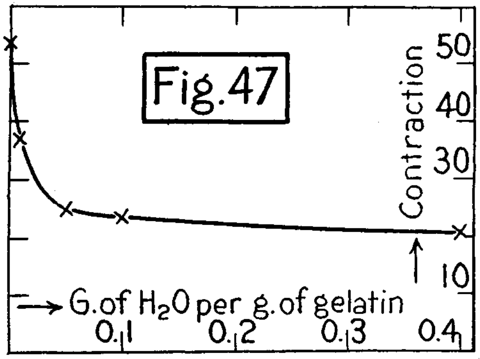

Fig. 47

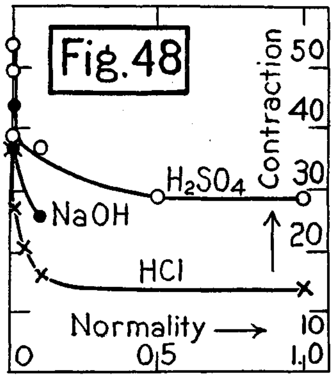

Fig. 48

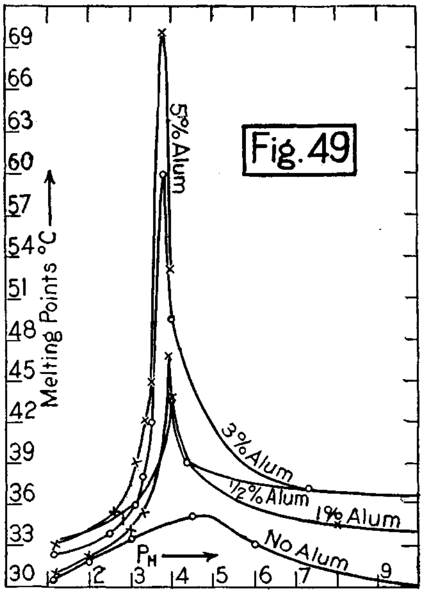

Fig. 49

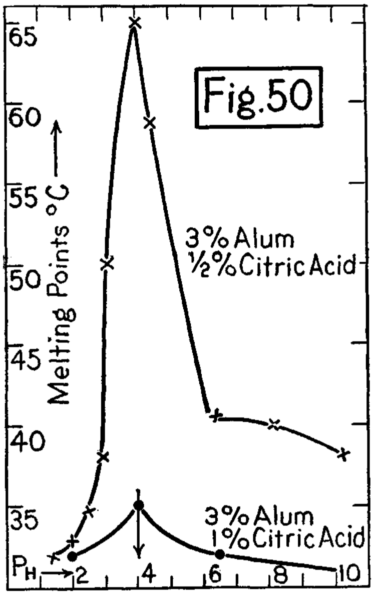

Fig. 50

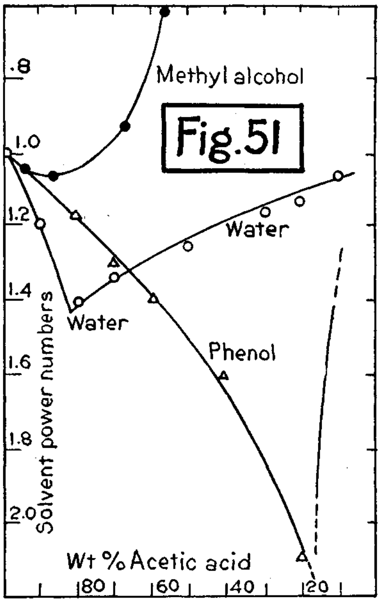

Fig. 51

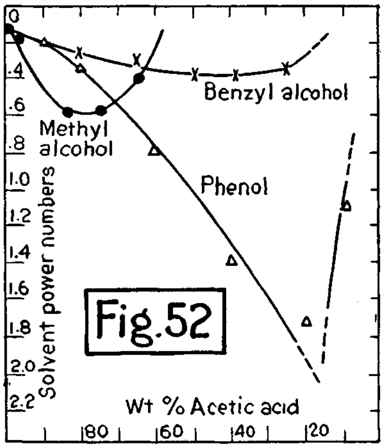

Fig. 52

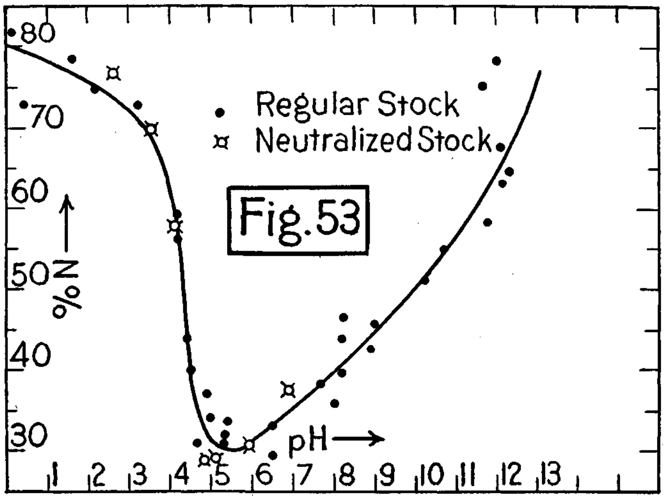

Fig. 53

Gelatin shows two points of minimum swelling with change in pH, one at pH = 4.7 and the other at pH = 7.7 (41).

For the swelling of gelatin in solutions of polybasic acids and their salts, *see* (42).

Figure 47 shows the contraction in mm³ per g of gelatin on dissolving in 100 cm³ of H_2O as a function of the H_2O content of the gelatin before dissolving, and Fig. 48 shows the contraction on dissolving a gelatin of constant H_2O content in 100 cm³ of acid or alkali of varying normality (31).

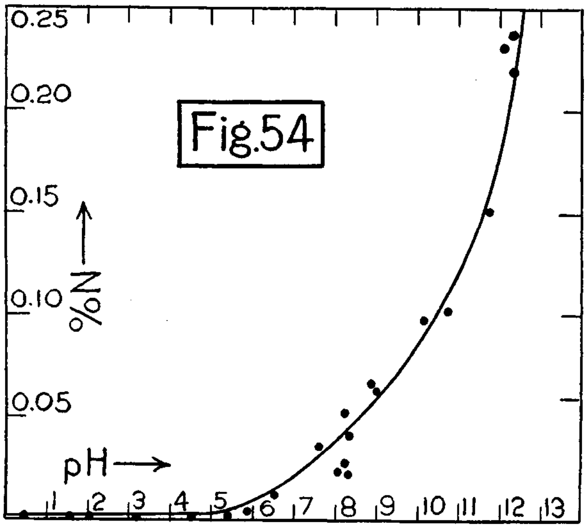

Fig. 54

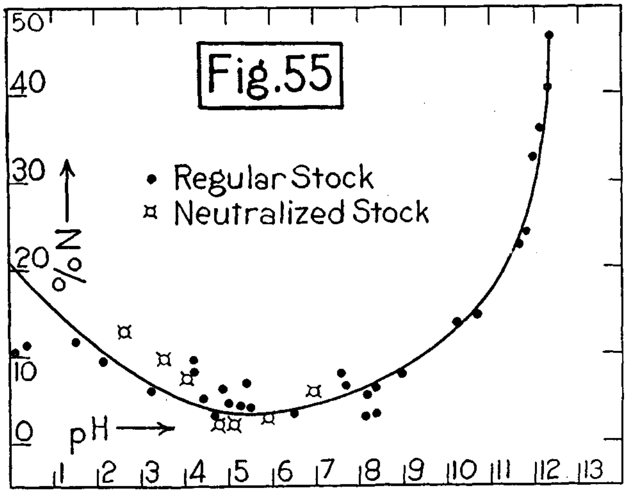
The swelling of gelatin gels shows a maximum at pH = 3–3.5 and a minimum at pH = 5 (4). For effects of certain solutes in increasing swelling *v.* (36).

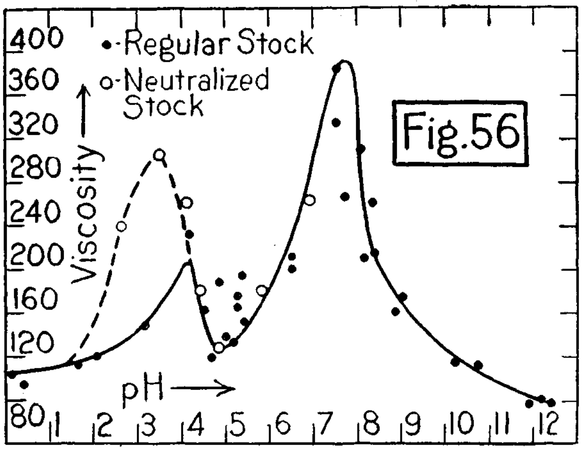
Gelatin gels show a minimum resistance to stretch at pH = 4.7 and a maximum at pH = 3 and 11 (24).

Melting Point

Figure 49 shows the "M. P." of gelatins, prepared with different pH values, as determined after immersion for a constant time in alum solutions of the concentrations indicated (25).

Figure 50 shows the "M. P." of gelatins, prepared with different pH values, as determined after immersion for a constant time in alum solutions with 0.5 and 1.0% of citric acid (25).





Solubility in H_2O

<0.01 wt. % at room temp. (17, 18).

Parts ‰. 22°C, 1; 18.3°, 0.7; 15–17°, 0.5; 0°, 0.2 (35).

Solvent Power Numbers

The solvent power number is the relative volume of a liquid required to start the precipitation of gelatin from a solution containing 15 g gelatin per 100 cm³, upon mixing at 25°C.

Figure 51 shows the solvent power numbers for acetone on solutions of gelatin in acetic acid mixtures and Fig. 52 the same values for xylene (20).

Hydrolysis of Collagen to Gelatin (6)

The experiments covered by the following figs. were carried out on well limed hide pieces for periods of 8 hr unless otherwise indicated and exhibit the effect of the pH during hydrolyzing on the factors named:

Fig. 53. On the % of total N recovered in the solution.

Fig. 54. On the % of N evolved as NH_3.

Fig. 55. On the % of amino acid N recovered in the solution.

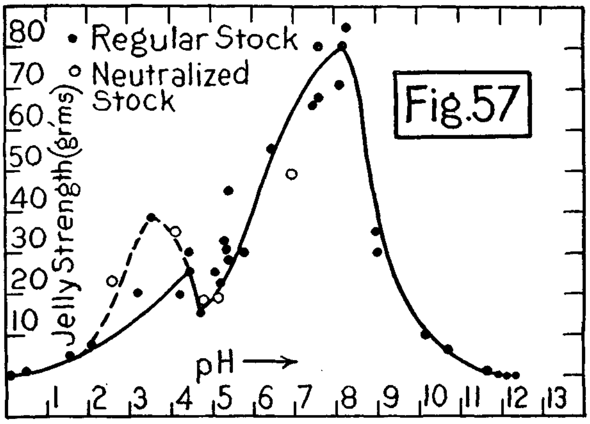
Fig. 56. On the viscosity (in arbitrary units) of the product at 35°C.

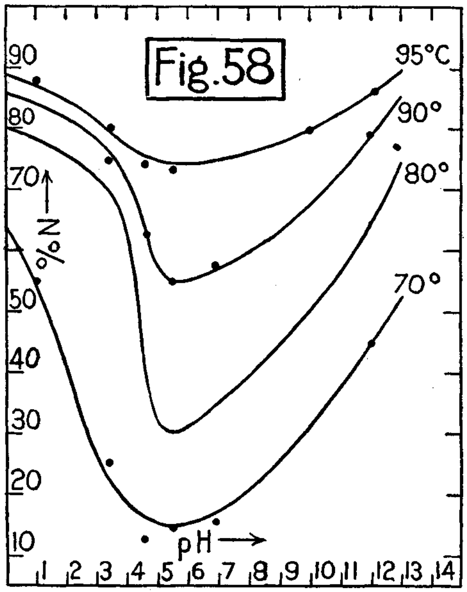
Fig. 57. On the jelly strength of the product at 10°C.

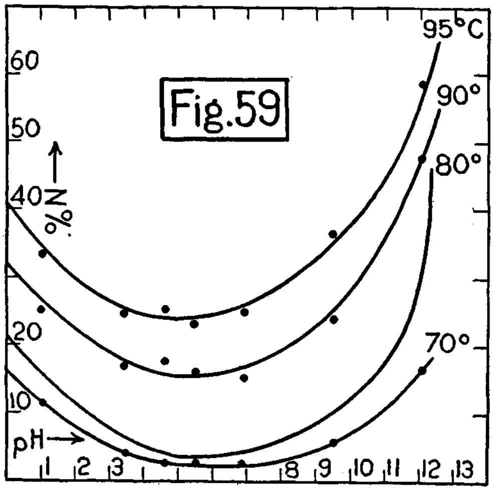
Fig. 58. On total N recovered in the solution after hydrolyzing at temperatures indicated.

Fig. 59. On amino acid N in the solution after hydrolyzing at temperatures indicated.

Fig. 60. On the total N recovered and Fig. 61 on the amino acid N, in the solution after hydrolyzing at 80°C for times indicated.







Mutarotation

The change in specific rotation (mutarotation) of gelatin solutions of constant concentration, upon reducing the temperature from 35° to 15°C, decreases very rapidly with decreasing jelly consistency of the gelatin or glue (4). *See also* (17, 35, 48).

Electrical Conductivity

The conductivity of gelatin solutions in water is a useful criterion of the purity of the gelatin. The purest solutions which have been prepared have the same conductivity as pure water (38). *See* (39) for the conductivity of some gelatin and glutin solutions.

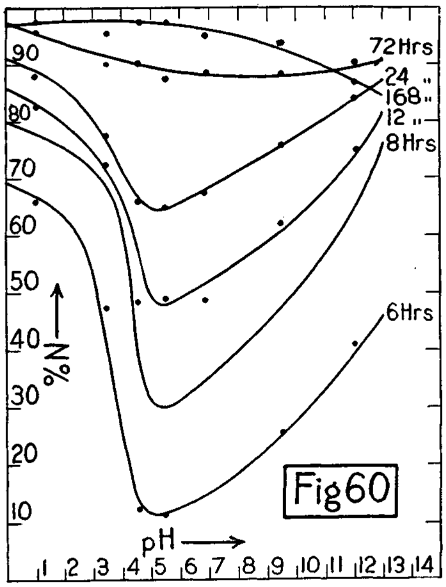


Fig60

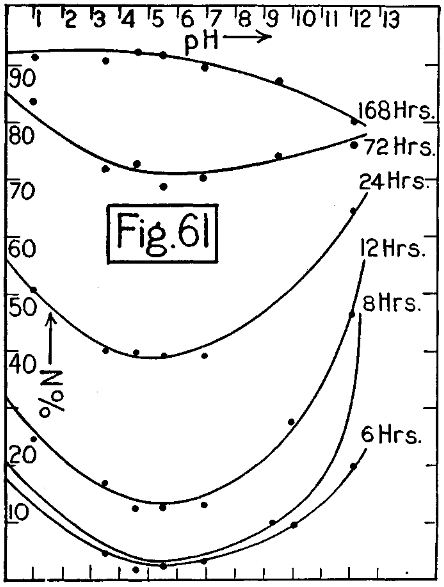

Fig.61

Miscellaneous

For the extraction of gelatin from bones as a function of temperature and time, *see* (19).

Figure 62 shows the influence of pH on the alcohol number, turbidity, and foam of gelatin solutions (4).

A method of determining the gelling power of gelatins is given in (43).

For the liquefaction of gelatins by salt solutions, *see* (44).

TEXTILE FIBERS

J. MERRITT MATTHEWS

BOTANICAL CLASSIFICATION OF IMPORTANT VEGETABLE FIBERS

(*A*) Vegetable hairs.
  1. Cotton (seed-hairs of *Gossypium* sp.).
  2. Bombax cotton (fruit-hairs of *Bombaceæ*).
  3. Vegetable silks (seed-hairs of various *Asclepiadaceæ* and *Apocynaceæ*).

(*B*) Bast fibers from the stalks and stems of dicotyledonous plants.
  (*a*) Flax-like fibers.
    4. Flax (*Linum usitatissimum*).
    5. Hemp (*Cannabis sativa*).
    6. Gambo hemp (*Hibiscus cannabinus*).
    7. Sunn hemp (*Crotalaria juncea*).
    8. Queensland hemp (*Sida retusa*).
    9. Yercum fiber (*Calotropis gigantea*).
  (*b*) Bœhmeria fibers.
    10. Ramie or China grass (*Bœhmeria nivea*).
  (*c*) Jute-like fibers.
    11. Jute (*Corchorus capsularis* and *C. olitorius*).
    12. Raibhenda (*Abelmoschus tetraphyllos*).
    13. Pseudo-jute (*Urena sinuata*).
  (*d*) Coarse bast fibers.
    14. Bast fibers from *Bauhinia racemosa*.
    15. Bast fibers from *Thespesia lampas*.
    16. Bast fibers from *Cordia latifolia*.
  (*e*) Basts.
    17. Linden bast (*Tilia* sp.).
    18. Bast from *Sterculia villosa*.
    19. Bast from *Holoptelea integrifolia*.
    20. Bast from *Kydia calycina*.
    21. Bast from *Lasiosyphon speciosus*.
    22. Bast from *Sponia Wightii*.

(*C*) Vascular bundles from monocotyledonous plants.
  (*a*) Leaf fibers.
    23. Manila hemp or abaca (*Musa textilis* and others of this kind).
    24. Pita (*Agave americana* and *A. mexicana*).
    25. Sisal (*Agave rigida*).
    26. Mauritius hemp (*Agave fœtida*).
    27. New Zealand flax (*Phormium tenax*).
    28. Aloe fibers (*Aloë* sp.).
    29. Bromelia fibers (*Bromelia* sp.).
    30. Pandanus fibers (*Pandanus* sp.).
    31. Sansevieria fibers (*Sansevieria* sp.).
    32. Esparto fibers (*Stipa tenacissima*).
    33. Piassave (*Attalea funifera*, *Raphia vinifera*, etc.).
  (*b*) Stem fibers.
    34. Tillandsia fibers, southern moss (*Tillandsia usneoides*).
  (*c*) Fruit fibers.
    35. Coir or coconut fiber (*Cocos nucifera*).
    36. Peat fibers.
  (*d*) Paper fibers.
    37. Straw fibers (rye, wheat, oat, rice).
    38. Esparto fibers (leaf fibers of *Stipa tenacissima*).
    39. Bamboo fibers (*Bambusa* sp.).
    40. Wood fiber (pine, fir, aspen, etc.).
    41. Bast fiber from paper mulberry (*Broussonetia papyrifera*).
    42. Bast fiber from *Edgeworthia papyrifera*.
    43. Peat fibers.

(Wiesner, *Die Rohstoffe des Pflanzenreiches*)

MICROSCOPICAL CHARACTERISTICS OF IMPORTANT VEGETABLE FIBERS

Fiber	Microscopical appearance
Cotton	Appears as a flat, ribbon-like band, more or less twisted on its longitudinal axis. Twist of fiber not continuous in one direction; cell-walls thick; lumen breadth much thicker than cell-wall; between thickened edges fiber shows finely granulated surface. Diameter uniform for ¾ length, then tapers to a point where it is cylindrical and solid
Flax	Cylindrical tapering to sharp point; cell-wall so thick that lumen appears as thread; fine cross-lines at intervals give appearance of joints or nodes, sometimes intersecting like letter X
Hemp	Lumen is broad, equaling or exceeding the thickness of the walls. Pronounced longitudinal striations. Ends of fibers blunt and thick-walled, often with lateral branches. Dislocations or folds; also swellings and cross-fissures. Fibers less transparent than flax and canal more difficult to distinguish
Jute	Lumen irregular, at times as wide as or wider than cell-wall; at ends of fiber lumen broadens out; end round. Longitudinal striations, no transverse markings, no jointed ridges
Manila hemp (abaca)	Lumen broad, distinct and uniform; cell-wall thin; ends narrow and sharp; no markings; diameter uniform
Manila hemp, sisal or Domingo hemp.	Fibers usually very stiff, and become very broad toward middle; have broad lumen, broad, blunt, thick ends, which are seldom forked. Short thick-walled cells are abundant, and show a narrow lumen and distinct surface pores. Peculiar spiral and parenchyma cells are often present
Straw	Bast cells are long thin fibers of regular structure with small canal; very slender and taper to fine point. Epidermal cells are thick-walled, short, broad, serrated. Parenchyma cells thin-walled and shaped like coffee bean
Esparto	Cells smaller than, but very similar to, straw cellulose. Esparto does not have the thin-walled bean-shaped cells, but has very small characteristic pear-shaped cells. Bast cells have numerous cross-markings
Ramie	Bast cells very long and broad, diameter very irregular; base very irregular; lumen, sometimes quite distinct, and sometimes disappearing entirely; fibers show numerous joints and transverse fissures; ends of fibers form a thick-walled, rounded point, and the lumen is reduced to a line
New Zealand flax.	Fiber elements, or cells, are usually very regular and uniform, surface is smooth in general. Lumen is usually narrower than cell-wall and very uniform in width. Ends are sharply pointed, and not divided. Fragments of parenchyma and epidermis can often be seen on the fibers
Pita fiber	Fiber is stiff and short, has a rather thin wall. Fiber has a distinctive wavy appearance and is very elastic. Very similar to sisal hemp in microscopical appearance
Pineapple leaf fiber.	Fiber very fine and has great durability. Lumen narrow and appears like a line. This fiber is distinguished from all other leaf fibers by its extreme fineness
Coniferous wood fibers.	Fibers from coniferous trees have a characteristic flat ribbon-like appearance, and numerous circular spots or pores are to be seen on many of them. The circular markings are more prominent in hard, strong sulfites or sulfates, but are often less distinct in well-boiled pulps. Occasionally the cells are twisted something like cotton fibers. The shape and distribution of the pores in the fibers give some indication of the tree used
Broad-leaf hardwood fibers.	The fibers from broad-leaf trees are shorter and more cylindrical in shape, and are always pointed at each end, and occasionally exhibit cross-markings. In addition to the true fibers, there are always a number of vessels, tubular in shape, short and of very large diameter, which show numerous pits; these establish the presence of fibers from broad-leaf trees

DIMENSIONS OF FIBER ELEMENTS

Name	Length, mm			Breadth, microns			Source
	Min.	Max.	Mean	Min.	Max.	Mean	
Abelmoschus tetraphyllos	0.1	1.6		8	29	13	W

Physical Properties of Individual Cotton Fibers

Variety	Length, cm	Rigidity, dynes cm^2	Weight, 10^{-6} g
Sea-island	4.2–5	0.010–0.021	5.9–6.7
Egyptian nubarri	3.6	0.024	6.3
Egyptian affifi	3.1	0.032	5.6
Peruvian hybrid	2.9	0.063	7.7
Trinidad native	2.6	0.045	4.9
Upland Memphis	2.6	0.039	5.3
American FGM	2.4	0.061	5.6
Upland cross	2.3	0.045	5.0
Pernams	2.2	0.071	6.7
Indian Bharat	1.7	0.111	5.8

The rigidity of the fiber is the torque, or twisting force, in the fiber when 1 cm is given one complete twist.

Pierce[1] furnishes the following physical factors for the cotton fiber, that may be calculated approximately from the staple length:

Staple length	L (in cm)
Fiber mass	5.8×10^{-6} g
Mass per centimeter	$(5.8/L) \times 10^{-6}$ g
Wall cross section	$(3.9/L) \times 10^{-6}$ cm^2
Rigidity	$0.3/L^2$ dynes cm^2
Breaking load	$20/L$ g
Fibers in yarn section	$1000L/N$ or $(L''/4N) \times 10^4$
Initial couple in yarn	$300t/LN = 300p/L\sqrt{N}$

The density of the cotton fiber is assumed as 1.51; N is the count of the yarn, L'' is the staple length in inches, t is the twist, and p the spinning factor $t/\sqrt{N}$.

Breaking Strengths of Different Varieties of Cotton

Cotton	Mean breaking strain	
	Grains	Grams
Sea-island (Edisto)	83.9	5.45
Queensland	147.6	9.59
Egyptian	127.2	7.26
Maranham	107.1	6.96

85	18.92

HEAT CONDUCTIVITY

HEAT CONDUCTING POWERS OF TEXTILE MATERIALS

	Relative values
Slag wool	100
Hair felt	117
Cotton felt	122
Sheep's wool	126
Air space	280

Comparative Values of Fibers as Non-Conductors of Heat[1]

A mass of the non-conducting material 1 in. thick was placed on a flat surface of iron kept heated to 310°F; the amount of heat transmitted per hr through the non-conductor was measured in lb. of water heated 10°F, the unit of area being 1 sq. ft. of covering:

Substance	Lb. water heated 10°F	Solid matter in 1 sq. ft., 1 in. thick, parts in 1000	Air occluded, parts in 1000
Loose wool	8.1	56	944
Goose feathers	9.6	50	950
Carded cotton	10.4	20	980
Hair felt	10.3	185	815
Fine asbestos	49.0	81	919
Air alone	48.0	0	1000

[1] Ordway, Eng. Min. J., **1890**, 650.

Heat Retaining Value of Clothing Materials

Count Rumford heated a large thermometer to 70°R and then ascertained the length of time required for the thermometer to fall to 10°R when surrounded with various textile materials, as follows:

	Sec
Air	576
Raw silk	1284
Sheep's wool	118
Cotton	1046
Fine lint (linen?)	1032
Beaver's fur	1296
Hare's fur	1315
Eiderdown	1305

In another series of experiments, however, using the same materials differently arranged, different results were obtained, as follows:

	Sec
Sheep's wool, loosely arranged	1118
Woolen thread, wound round bulb	934
Cotton, loose	1046
Cotton thread, wound round bulb	852
Lint, loose	1032
Linen thread, wound round bulb	873
Linen cloth, wound round bulb	786

From these experiments, Rumford showed that the heat-retaining value of clothing depends more on its texture than on its actual material.

FIREPROOFING

Minimum Quantity of Chemical Substances Required to Render 100 Parts of Cotton Non-inflammable (Duhem)

Reagent	Parts by weight
Tungstate of ammonium	12
Sulfate of ammonium	4½
Phosphate of sodium	30
Chloride of sodium (common salt)	35

LITERATURE

(For a key to the periodicals see end of volume)

For much additional material on textile fibers and a fairly complete bibliography, *see* Matthews, *The Textile Fibers.* 4th ed., New York, Wiley, 1924.

TANNINS AND VEGETABLE TANNING MATERIALS

John Arthur Wilson

and

Arthur W. Thomas

The tabulation of the properties of tanning substances of vegetable origin is complicated by the facts that the chemistry of these exceedingly complex substances is still in its infancy, the literature is not always clear, due to confusion in terminology, and the authenticity of the specimen studied is often uncertain. Formulas, especially those reported in the literature before 1910, are of little value, except as they indicate the relative percentages of C, H and O.

CLASSIFICATION

The earlier classification, based upon color reactions with ferric salts, is of no present value. Two systems are now used: Perkin (34) and Freudenberg (13).

Perkin's classification: α, Gallotannins (Depsides); β, Ellagitannins (Diphenylmethylolids); γ, Catecholtannins (Phlobatannins). These are characterized by the following reactions: *$FeCl_3$:* α, blue; γ, green. *Boiling dilute H_2SO_4:* α, gallic acid is formed; β, ellagic acid ppts.; γ, phlobaphenes or "reds" ppt. *Br:* γ give a ppt. *HCl and pine wood:* γ give phloroglucinol reaction, while α and β do not. *$C_6H_5N{:}NCl$:* γ give a ppt., indicating the presence of phloroglucinol or resorcinol groups, while α and β do not. *Fusion with alkali:* α yield gallic acid and a little pyrogallol; γ yield protocatechuic acid. *Heating in glycerol:* α form pyrogallol; γ form catechol. *HCHO and HCl:* γ give complete precipitation, the others do not. *Lead acetate in CH_3CO_2H:* α are pptd., γ are not.

Freudenberg's classification: A. Hydrolyzable tannins in which the benzene nucleus is united to a larger complex through the O atoms. **A1.** Mutual esters of phenolcarboxylic acids or with other hydroxy-acids (Depsides). **A2.** Esters of phenolcarboxylic acids with polyatomic alcohols and sugars. **A3.** Glucosides. In this group gallic acid predominates as the phenolic component. There is also the extraordinary distribution of combined caffeic acid and the presence of a new phenolcarboxylic acid in chebulinic acid. The ellagic acid glucosides also belong here. The most important criterion for the inclusion in this group is the splitting into simple components by hydrolyzing enzymes, especially tannase and emulsin.

B. Condensed tannins in which C linkages hold the nuclei together. These are not decomposed into simple components by enzymes. They are generally, not always, precipitated by bromine and under the influence of oxidizing agents or strong acids condense to high molecular weight tannins or "reds." By drastic treatment, preferably by alkalis, the C skeleton is broken up and phloroglucinol, if present, is dissolved out while the remainder of the molecule is transformed mainly into phenolcarboxylic acids. **B1.** Simple ketones such as hydroxybenzophenones and hydroxyphenylstyryl ketones. The phloroglucinol and benzene nuclei are present in equimolecular proportions. **B2.** This group is more complicated. The phloroglucinol and benzene nuclei are present in equimolecular proportions. This class embraces the catechols with their corresponding tannins and "reds." This is the most important class of technically used tannins. **B3.** There is practically nothing that can be said about this class of condensed tannins. It is even impossible to state whether they are really jointly condensed systems. In common with the first class of the condensed tannin group, they are precipitated by bromine and are transformed into "reds." On the other hand, they contain no phloroglucinol nucleus. It is possible that the hydroxycinnamic acids are characteristic components of this class; caffeic acid itself is readily transformed into condensation products of the nature of "reds."

In the following tables, the information is given in the following order: Name; classification (Perkin's being indicated by Greek letters, Freudenberg's by the above combinations of letters and figures); (1), source; (2) color and form in which it is isolated; (3) formula; (4) solvents; (5) specific rotatory power; (6) color with ferric salts; (7) remarks as to constitution, etc.

TANNINS AND VEGETABLE TANNING MATERIALS

JOHN ARTHUR WILSON

AND

ARTHUR W. THOMAS

The tabulation of the properties of tanning substances of vegetable origin is complicated by the facts that the chemistry of these exceedingly complex substances is still in its infancy, the literature is not always clear, due to confusion in terminology, and the authenticity of the specimen studied is often uncertain. Formulas, especially those reported in the literature before 1910, are of little value, except as they indicate the relative percentages of C, H and O.

CLASSIFICATION

The earlier classification, based upon color reactions with ferric salts, is of no present value. Two systems are now used: Perkin (34) and Freudenberg (13).

Perkin's classification: α, Gallotannins (Depsides); β, Ellagitannins (Diphenylmethylolids); γ, Catecholtannins (Phlobatannins). These are characterized by the following reactions: *$FeCl_3$:* α, blue; γ, green. *Boiling dilute H_2SO_4:* α, gallic acid is formed; β, ellagic acid ppts.; γ, phlobaphenes or "reds" ppt. *Br:* γ give a ppt. *HCl and pine wood:* γ give phloroglucinol reaction, while α and β do not. *$C_6H_5N{:}NCl$:* γ give a ppt., indicating the presence of phloroglucinol or resorcinol groups, while α and β do not. *Fusion with alkali:* α yield gallic acid and a little pyrogallol; γ yield protocatechuic acid. *Heating in glycerol:* α form pyrogallol; γ form catechol. *HCHO and HCl*: γ give complete precipitation, the others do not. *Lead acetate in CH_3CO_2H:* α are pptd., γ are not.

Freudenberg's classification: **A.** Hydrolyzable tannins in which the benzene nucleus is united to a larger complex through the O atoms. **A1.** Mutual esters of phenolcarboxylic acids or with other hydroxy-acids (Depsides). **A2.** Esters of phenolcarboxylic acids with polyatomic alcohols and sugars. **A3.** Glucosides. In this group gallic acid predominates as the phenolic component. There is also the extraordinary distribution of combined caffeic acid and the presence of a new phenolcarboxylic acid in chebulinic acid. The ellagic acid glucosides also belong here. The most important criterion for the inclusion in this group is the splitting into simple components by hydrolyzing enzymes, especially tannase and emulsin.

B. Condensed tannins in which C linkages hold the nuclei together. These are not decomposed into simple components by enzymes. They are generally, not always, precipitated by bromine and under the influence of oxidizing agents or strong acids condense to high molecular weight tannins or "reds." By drastic treatment, preferably by alkalis, the C skeleton is broken up and phloroglucinol, if present, is dissolved out while the remainder of the molecule is transformed mainly into phenolcarboxylic acids. **B1.** Simple ketones such as hydroxybenzophenones and hydroxyphenylstyryl ketones. The phloroglucinol and benzene nuclei are present in equimolecular proportions. **B2.** This group is more complicated. The phloroglucinol and benzene nuclei are present in equimolecular proportions. This class embraces the catechols with their corresponding tannins and "reds." This is the most important class of technically used tannins. **B3.** There is practically nothing that can be said about this class of condensed tannins. It is even impossible to state whether they are really jointly condensed systems. In common with the first class of the condensed tannin group, they are precipitated by bromine and are transformed into "reds." On the other hand, they contain no phloroglucinol nucleus. It is possible that the hydroxycinnamic acids are characteristic components of this class; caffeic acid itself is readily transformed into condensation products of the nature of "reds."

In the following tables, the information is given in the following order: Name; classification (Perkin's being indicated by Greek letters, Freudenberg's by the above combinations of letters and figures); (1), source; (2) color and form in which it is isolated; (3) formula; (4) solvents; (5) specific rotatory power; (6) color with ferric salts; (7) remarks as to constitution, etc.

I. Natural Tannins

Beech tannin. γ. (1) Bark of red beech. (3) $C_{20}H_{22}O_9$ (34).

Caffetannic acid. γ. (1) Coffee berries as Ca and Mg salts; cainia root, *Chiococca brachiata; Nux vomica;* St. Ignatius beans; Paraguay tea, *Ilex paraguensis.* (2) Amorphous powder. (4) H_2O, C_2H_5OH. (6) Dark green (34).

Callutannic acid. γ. (1) Heather, *Calluna vulgaris.* (2) Amber colored powder. (6) Dark green (34).

Canaigre tannin. γ. **B3.** (1) Tuberous roots of the sorrel, *Rumex hymenosepalus.* (2) Bright yellow powder. (3) C, 58.10; H, 5.33 (34). (4) H_2O, C_2H_5OH. (6) Green (13, 34).

Catechol. γ. **B2.** (6) Green. *See* Table 3.

Chebulinic acid, Eutannin. α. **A2.** (1) Myrobalans, fruit of the *Terminalia chebula.* (2) Rhombic prisms, also colorless needles (34). (3) C, 50.60; H, 3.65. Probably $C_{34}H_{30}O_{23}$ (16). Air-dry substance contains 16.5% H_2O of crystn., which is lost at 100° (2). Mol. wt. by titration and by boiling point elevation in acetone, 806 (16). (4) Hot H_2O, C_2H_5OH, acetone, ethyl acetate (13). (5) α_D, +61.7° to 66.9° (H_2O) (5). α_D^{18}, +85° ±4° (abs. C_2H_5OH) (11); α_D^{22}, −60 (acetone, 1%) (2). α_D +59° to 67° (C_2H_5OH, 1–2%)(13). (6) Blue-black. (7) Apparently union between di-gallolyl-glucose and the dibasic acid, $C_{14}H_{14}O_{11}$ with elimination of $2H_2O$ (11, 16). D. at 234° (34).

Cherry bark tannin. γ. (1) Bark of *Prunus cerasus.* (3) $C_{21}H_{20}O_{10}.0.5H_2O$. (6) Green (34).

Chestnut tannin. α. **A3.** (1) Leaves, bark and wood of Spanish chestnut, *Castanea vesca.* (3) Purified tannin, C, 50.79; H, 3.32. Mol. wt. 400 or multiple as detd. by titration (24). (4) H_2O. (6) Dark green to blue. (7) Tannin from leaves, wood and bark identical. Raw tannin is mixture containing quercetin, sugar, ellagic and gallic acids. Contains no phloroglucinol. Probably similar to tannin of German native oak (24).

Chinese tannin. *See* Gallotannin.

Chlorogenic acid. **A1.** (1) Monopotassium salt combined with one molecule of caffein in coffee beans. (2) Cryst. (3) $C_{16}H_{18}O_9.0.5H_2O$. (4) Hot H_2O, C_2H_5OH, acetone, ethyl acetate. (5) α_D, −33.1° (H_2O, 1–3%). (6) Green ppt. (7) 3, 4-Dihydroxy-cinnamoyl-quinic acid (13).

Cinchona tannin, quinotannic acid. γ. **B3.** (1) Cinchona bark. (2) Light yellow powder. (3) $C_{14}H_{16}O_9$(?) (34). (4) H_2O, C_2H_5OH (13). (6) Green ppt. (7) Very hygroscopic.

Cocatannic acid. γ. (1) Leaves of *Erythroxylon coca.* (2) Yellow micro. cryst. (3) $C_{17}H_{22}O_{10}.2H_2O$(?) (6) Green (34).

Colatein. γ. **B2.** (1) Cola nuts, *Cola acuminata.* (4) Hot H_2O, C_2H_5OH, acetone. (6) Green. (7) M. P. 257°–288° (13).

Colatin, Colatannin. γ. **B2.** (1) Cola nuts, *Cola acuminata.* (2) Cryst. (13). Light red amorphous powder (34). (3) $C_{16}H_{20}O_8$ (34). (4) C_2H_5OH, acetone, ethyl acetate. (5) Inactive. (6) Green. (7) M. P. 148° (13).

Cortepinitannic acid. γ. (1) Bark of Scotch fir, *Pinus sylvestris.* (2) Bright red powder. (3) $C_{32}H_{34}O_{17}$. (6) Intense green (34).

Cyanomaclurin. **B2.** (1) Wood of *Artocarpus integrifolia.* (2) Cryst. (3) $C_{15}H_{12}O_6$. (6) Violet. (7) M. P. above 290° (13).

***m*-Digallic acid.** α. **A1.** (1) Esterified with glucose in Chinese tannin; also synthetic. *See* Table 2.

Ellagic acid. β. (1) From many tannins containing ellagitannin by boiling with dilute H_2SO_4. Divi-divi, myrobalans and valonia best sources; also synthetic. *See* Table 2.

Filitannin. γ. **B2.** (1) Fern-root, *Aspidium filix-mas.* (2) Red-brown powder (34). (3) $C_{41}H_{36}NO_{18}$(?) (29, 34). (4) C_2H_5OH, H_2O (29). (5) Inactive (13). (6) Olive-green. (7) Heated at 125°, loses water and becomes insoluble (13).

Fraxitannic acid. γ. (1) Leaves of ash tree, *Fraxinus excelsior.* (2) Brownish-yellow deliquescent powder. (3) $C_{26}H_{32}O_{14}$ (?) (29, 34). (4) H_2O, C_2H_5OH (29, 34). (6) Dark green ppt. (7) Heated at 100°, loses water and becomes practically insoluble. Yields quinone upon oxidation by permanganate (29, 34).

Galitannic acid. γ. (1) Bark of *Galium verum.* (3) $C_{14}H_{16}O_{10}.H_2O$. (6) Green (34).

Gallotannin, Gallotannic acid, Tannin, Tannic acid. α. **A2.** (1) From galls on leaves and buds of various species of oak, especially *Quercus infectoria* and *Q. lusitania* ("Turkish tannin") due to puncture by insects of the genus *Cynips.* From galls on leaves and buds of a species of sumach, *Rhus semialata* ("Chinese tannin") due to puncture of insect, *Aphis chinensis.* (2) Light yellow-brown powder. (3) Average of several specimens, C, 52.59 to 53.70; H, 3.24 to 3.40 (6). $C_{76}H_{52}O_{46}$ (E. Fischer). Mol. wt., 1247–1636 by boiling point elevation in acetone. (4) H_2O, C_2H_5OH, ethyl acetate. (5) α_D^{20}, +58° to +70° (different specimens, H_2O); α_D^{20}, +18° (one specimen, C_2H_5OH) (1, 6); α_D^{22}, +12.9° (acetone); α_D^{22}, +17.6° (purified specimen, C_2H_5OH) (1, 3). (6) Bluish-black. (7) Hydrolysis of purified specimen by dil. H_2SO_4 yields 93.6% gallic acid and 6.8% glucose (1, 3). Undoubtedly a mixture of at least two individuals (34). The tannin, according to E. Fischer, is penta-*m*-digalloylglucose. Nierenstein objects, asserting that gallotannin is probably a glucoside of polydigalloyl-leucodigallic acid anhydride or of its free acid (31).

Gallotannin, Chinese Tannin. α. **A2.** (1) *See* Gallotannin above. (2) Amorphous yellow to light brown powder. (3) Penta-*m*-digallolyglucose. Mol wt., 1700 (13). (4) *See* Gallotannin above. (5) α_D^{26}, +73° (purified specimen, H_2O, 1%) (1, 7); α_D, +45° to +53° (H_2O, 20%), rising rapidly on dilution to +135° to +140° (H_2O, 1.2%) (13); α_D in formamide, +13°; acetone, +14°; C_2H_5OH, +18°, glacial acetic acid, +25°; pyridine, +40°. These all showed high and low α_D fractions in water; were alike in organic solvents. Colloidal forms and impurities markedly affect α_D in water (23). Two fractions—(a) α_D, +30° to +40° (H_2O); +40° to +41° (pyridine); (b) α_D, +150° to +158° (H_2O); +50° to +51° (pyridine) (27). Purified tannin, after removing part difficultly soluble in water, α_D, +13.9° (C_2H_5OH, 3%); +14.9° (C_2H_5OH, 10%); +13.1° (acetone, 10%) (1, 4). Potassium salt, containing 10.2% K, α_D^{18}, +46.3° (H_2O, 1%) (1, 4). (6) Bluish-black. (7) Upon hydrolysis with dil. H_2SO_4 there is produced 88.6% gallic acid and 11.4% glucose (13). This tannin is a mixture of deka-, nona-, and octa-gallolyl-glucoses averaging 8 to 9 gallic acid radicals to 1 molecule glucose. The fractions of lower α_D contain more depside-like gallic acid (27). *See also* gallotannin above.

Gallotannin, Turkish Tannin. α. **A2.** (1) *See* Gallotannin above. Aleppo galls. (2) Amorphous yellow to light brown powder. (3) C, 52.5; H, 3.5 (13). (4) *See* Gallotannin above. (5) α_D^{17}, 2.5° (H_2O, 7%); α_D, +5° (H_2O, 7% and less); α_D^{14} +23.2° to +24.2° (acetone, 10%) (1, 8). (6) Bluish-black. (7) Hydrolysis of purified specimens with dil. H_2SO_4: 81.8 to 84.8% gallic acid; 2.7 to 3.8% ellagic acid; 11.5 to 13.8% glucose; 2.0 to 4.1% tannin residue (1, 8). Hydrolysis and fractionation give a series of fractions of increasing α_D in alcohol from 15.7° to 43.7°. Concomitantly there is a decrease in ellagic and increase in gallic acid content. The ellagic acid is a part of the tannin molecule. At least 25% of the gallic acid is in depside form, partly directly bound in ester form to the sugar hydroxyl groups (28).

Gallnut Tannin. α. **A2.** (1) Galls on acorn cups of *Quercus robur* and *Q. pedunculata.* (3) C, 52.0; H, 3.3 (13). (7) Undoubtedly identical with gallotannin.

Hamamelitannin. α. **A2.** (1) Bark of *Hamamelis virginica.* (2) Fine white needles (13). (3) C, 49.9; H, 4.0; H_2O of crystn. 17.9%, approximating $C_{20}H_{20}O_{14}.6H_2O$ (10, 18). (4) Hot H_2O, C_2H_5OH, acetone, ethyl acetate (13). (5) α_D^{23}, +29° (H_2O, 2.35%); α_D^{23}, +33° (H_2O, 1.24%); α_D^{20}, +35.6° (another specimen, H_2O, 1.2%) (10). (7) Contains no free carboxyl group. Acidity, equal to that of pyrogallol, is due to phenolic hydroxyls (10, 18). Upon hydrolysis with dil. H_2SO_4: gallic acid, 70%; sugar, 30%. Upon hydrolysis with tannase: gallic acid, 66%; sugar, 34% (13). M. P., 115°–117° (air-dry); 203° (dried at 100°) (34).

Hemlock tannin. γ. (1) Hemlock bark, *Tsuga* (*Abies*) *canadensis.* (3) $C_{20}H_{18}O_{10}$ (?). (7) Probably related to quercitannic acid of the oak (29, 34).

Horsechestnut tannin. γ. (1) Nearly all parts of the *Aesculus hippocastanum* and in root bark of apple tree. (2) Nearly colorless powder. (3) $C_{26}H_{24}O_{12}$. (6) Green (34).

Ipecacuanhic acid. γ. (1) Roots of *Psychotria ipecacuanha.* (2) Reddish-brown hygroscopic substance. (3) $C_{14}H_{18}O_7$. (6) Green (34).

Larch tannin. γ. (1) Bark of the larch, *Larix europea.* (6) Green (34).

Maclurin. B1. (1) Wood of "old fustic," *Chlorophora tinctoria;* also synthetic. (2) Yellow crystals (13). Colorless needles when pure (34). (3) $C_{13}H_{10}O_6$. (4) 14°, 1 part in 190 parts H_2O (13). (6) Green. (7) 2, 4, 6, 3′, 4′-Pentahydroxybenzophenone, M. P. 200° (anhydrous form) (34).

Maletto tannin. γ. **B2.** Bark of *Eucalyptus occidentalis* and other species of *Eucalyptus.* (2) Brown powder. (3) $(C_{19}H_{20}O_9)_n$ (29, 34). (4) H_2O, abs. C_2H_5OH (from which it is precipitated by ether) (13). (7) Similar to quebracho tannin (13, 34).

Mangrove tannin. γ. **B2.** (1) *Rhizophora mangle*, *R. mucronata*, *Ceriops candolleana*, *C. roxburghiana.* (2) Amorphous red powder. (3) $C_{24}H_{26}O_{12}$ (29). (6) Green. (7) Closely resembles catechutannic acid (34).

Mimosa tannin. γ. (1) Various species of *Mimoseae* such as *Acacia arabica* of Egypt and the "wattles" of Australia. (6) Bluish-violet. (7) With the exception of the reaction with ferric salts, gives all the ordinary reactions of the phlobatannins (34).

Oak tannin. B3 (36). (1) Leaves and buds of German oak, *Quercus pedunculata.* (2) Amorphous reddish-yellow powder (22). (3) C, 49.9; H, 4.2. (4) H_2O, C_2H_5OH, acetone (22, 36). (4) $\alpha_{\mathrm{Hg\ yellow}}$, −39° ± 10° ($H_2O$); −30° ± 4° ($CH_3OH$) (21). (7) Tannin from leaves of *Quercus sessiflora* identical (21). Molecule contains 18–25% bound ellagic acid; 3–7% bound glucose; and the rest is an amorphous acid, "Quercus acid," C, 50.2; H, 3.6. Titration equivalent about 400 (21, 22).

Oak tannin, Quercitannic acid. γ. **B2.** (1) Bark of various species of *Quercus* (34); Bark of *Quercus robur* (13). (2) Reddish-white powder (34). Light brown powder (13). (3) $C_{20}H_{20}O_4$ (?): C, 59.79; H, 5.0 (34). C, 56.8; H, 4.4. C, 55.4; H, 4.1 (13). (6) Green (34). Black-blue (13).

Oak tannin, Quercin, Quercic acid, Quercinic acid. γ. **B2.** (1) Wood of various species of *Quercus.* (2) Light brownish-yellow (34). (3) $C_{15}H_{12}O_9.2H_2O$ (29, 34). C, 48.3; H, 4.5 (13). (6) Blue.

Paullinio tannin, Guarana tannin. γ. **B2.** (1) "Guarana paste" from seeds of *Paullinia cupana.* (2) Small colorless crystals (34). Gray needles (30). (3) $C_{37}H_{35}O_{18}.COOH.2H_2O$ (30). (4) H_2O, C_2H_5OH, ethyl acetate, glacial acetic acid (30). (5) α_D^{20}, −74.4° (H_2O, 10%); α_D^{18}, −39.1° (C_2H_5OH, 8%); −48.1° (acetone, 6%); α_D^{20}, −56.8° (initial rotation in pyridine, 8%. By mutarotation falls to constant value of −8.6°) (30). (7) M. P. 199°–201° with evolution of CO_2. Loses two mol. H_2O of crystn. at 130°. M. P. of anhydrous form 259°–261° with evolution of CO_2 (30). Paullinia catechol isolated from paullinia tannin is identical with "acacatechin" in crystal form and chemical properties. Chemically it is identical with gambier-catechin (13).

Pinicortannic acid. γ. (1) Bark of Scotch fir, *Pinus sylvestris.* (2) Reddish-brown powder. (3) $(C_{16}H_{18}O_{11})_2.H_2O$. (6) Green (34).

Pistachio tannin. γ. **B2.** (1) Leaves of mastic tree, *Pistachia lentiscus.* (2) Pale brown brittle mass (34). (4) H_2O, C_2H_5OH, ethyl acetate (13). (6) Blue-black. (7) Often sold for sumach (34).

Pomegranate tannin, Ellagitannin. β. **A3.** (1) Root bark of *Punica granatum.* (2) Amorphous greenish-yellow powder. (3) $C_{20}H_{16}O_{13}$ (34). Two fractions: A (sol. in H_2O), C, 50.9; H, 3.4. B (insol. in H_2O), C, 52.4; H, 3.4 (13). (4) Fraction A: H_2O, C_2H_5OH, ethyl acetate (13). (6) Blue-black. (7) Glucoside of ellagic acid and hexose (13).

Quebracho tannin. γ. **B2.** (1) Wood of *Quebracho colorado*, *Schinopsis lorentzii* and *Balsanae.* (2) Red powder. (3) C, 62.5; H, 5.4. (4) Hot H_2O, C_2H_5OH, ethyl acetate, acetone (13). (6) Green. (7) Tannin is mixture of products insol. in H_2O and sparingly sol. in cold H_2O. A benzoyl derivative, C, 73.0; H, 4.2, showed a mol. wt. in benzene of about 2300.

Rhatany tannin. γ. Bark of root of rhatany, *Krameria triandra.* (2) Light yellow powder. (4) H_2O. (6) Green (34).

Rheotannic acid, Rhubarb tannin. γ. **B2.** (1) Rhubarb. (2) Yellowish-brown powder. (3) $C_{26}H_{26}O_{14}$ (34). (4) H_2O. (6) Black-green ppt. (7) Contains two glucosides, glucogallin ($C_{13}H_{16}O_{10}$) and tetrarin ($C_{32}H_{32}O_{10}$) (34). Catechin also present which is probably identical with gambier-catechin (13).

Rubitannic acid. γ. (1) Leaves of *Rubia tinctorum.* (3) $C_{14}H_{22}O_{12}.0.5H_2O$. (6) Green (34).

Sequiatannic acid. γ. (1) Cones of *Sequoia gigantea.* (2) Reddish-brown powder. (3) $C_{21}H_{20}O_{10}$ (29, 34). (4) H_2O, C_2H_5OH. (6) Brown-black ppt.

Spruce bark tannin. γ. (1) Bark of spruce. (3) $C_{21}H_{20}O_{10}$ (?) (34).

Sumach tannin. α. **A2.** (1) From leaves of many species of *Rhus.* Also *Coriaria myrtifolia* (French), *Colpoon compressum* (Cape), *Arctostaphylos* (Russian). (2) Yellow powder. (3) C, 52.3; H, 3.5. (*Rhus coriaria*) (13). (4) H_2O, C_2H_5OH, ethyl acetate. (7) Similar to Turkish tannin.

Tannecortepinic acid. γ. (1) Bark of young Scotch firs in spring time. (3) $C_{28}H_{26}O_{12}$. (6) Green (34).

Tannic acid. *See* Gallotannin.

Tea tannin. γ. **A2.** (1) Leaves of black tea. (4) H_2O, ethyl acetate. (5) α_D, −177.3° (29). (7) Probably identical with quercitannic acid (29, 34). A gallotannin (13).

Tormentilla tannin. γ. (1) Root of *Potentilla tormentilla.* (2) Amorphous reddish powder. (3) $C_{26}H_{22}O_{11}$. (6) Blue-green (34).

Turkish tannin. *See* Gallotannin.

Willow bark tannin. γ. (1) Bark of *Salix triandra.* (6) Green. (7) Glucoside tannin (34).

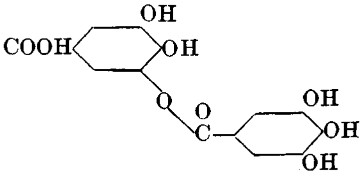
II. SYNTHESIZED TANNINS

***m*-Digallic acid.** α. A1. (2) Fine needles. (3) I (13). (4) CH_3OH, C_2H_5OH, $C_5H_{11}OH$. 23°, 1 part in 950 parts H_2O; 1 part in 350 parts ethyl acetate; 1 part in 2000 parts ether (1, 5). 25°, 1 part in 1900 parts H_2O. 100°, 1 part in 50–60 parts H_2O (13). (5) Inactive. (6) Blue-black. (7) Found esterified with glucose in Chinese tannin. When hot aq. solution is chilled, it jellifies (13). M. P., 275° (282° corr.) with foaming and decomposition (1, 5).

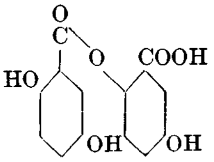
Digalloyl-levoglucosan. A2. (2) Micro-needles. (3) $C_{20}H_{18}O_{13}$. (4) H_2O, C_2H_5OH, acetone. (5) α_D^{18}, −27.9° (C_2H_5OH, 1.8%). (6) $FeCl_3$ gives blue-black ppt. in C_2H_5OH solution. (7) Decomposes 220°, carbonizes 270° (26).

Digentisic acid. α. (2) Fine needles. (3) II. (4) 0°, 1 part in 900 parts H_2O. (5) Inactive. (6) Fugitive blue and ppt. (1, 5). (7) Dry form melts 204°–205° (208°–209° corr.) with sintering.

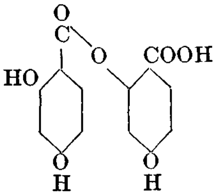
Diprotocatechuic acid. α. (2) Fine needles. (3) $(OH)_2C_6H_3$-$CO.O.C_6H_3(OH)COOH$. (4) Acetone, CH_3OH. 1 part in 2500 parts H_2O. (5) Inactive. (6) Blue-green. (7) M. P., 237°–239° (corr.) (1, 5).



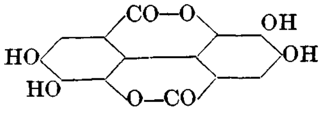
I. *m*-Digallic acid



II. Digentisic acid



III. Di-β-resorcylic acid



IV. Ellagic acid

Di-β-resorcylic acid. α. (2) Micro-needles. (3) III. Isomeric with digentisic acid. (4) C_2H_5OH, acetone, ethyl acetate, hot H_2O, ether. (5) Inactive. (6) Violet red. (7) Foams and decomposes at about 210° (215° corr.) (1, 5).

Ellagic acid. β. (2) Cryst. from pyridine in prismatic needles which are converted by C_2H_5OH to a pale yellow cryst. powder. (3) $C_{14}H_6O_8.2H_2O$. IV. (5) Inactive. (7) Above 360° sublimes with carbonization (34). Not a true tannin. *See* Table 1.

Hexagalloyl mannite. **A2.** (2) Amorphous brown powder. (3) $C_6H_8O_6[CO.C_6H_2(OH)_3]_6$. (4) H_2O, C_2H_5OH, acetone, ethyl acetate. (5) α_D^{18}, +27.0° (C_2H_5OH, 2%). (6) Dark blue (1, 4).

Maclurin. **B1.** *See* Table 1.

Penta-*m*-digalloyl-α-glucose. **A2.** (2) Light brown amorphous mass. (3) $C_{76}H_{52}O_{46}$. (4) 18°, 1 part in 200 parts H_2O. (5) Prepared by alkaline hydrolysis of acetates: α_D^{18}, +36°(C_2H_5OH, 10%); +40° to 41° (acetone, 10%); 43.8° (H_2O, 1%) (1, 3). Prepared from acetates by CH_3OH and HCl: α_D^{18}, +41.3° (C_2H_5OH, 5%); +44.6° (acetone, 5%); +51° (H_2O, 0.5%) (1, 4). (6) Blue-black. (7) Potassium salt containing 10.3% K, α_D^{18} +56.6° (H_2O, 5%) (1, 4).

Penta-*m*-digalloyl-β-glucose. **A2.** (2) Light brown amorphous mass. (3) $C_{76}H_{52}O_{46}$. (4) 20°, 1 part in 1000 parts H_2O. (5) Prepared by alkaline hydrolysis of acetates: α_D^{18}, +14.9° (C_2H_5OH, 10%); +13.1° (acetone, 10%); +42.3° (H_2O, 1%) (1, 3). Prepared from acetates by CH_3OH and HCl: α_D^{18}, +10.8° (C_2H_5OH, 5%); +10.8° (acetone, 5%); +21° (H_2O, 0.1%) (1, 4). (6) Blue-black. (7) Apparently identical with Chinese tannin. Potassium salt containing 10.3% K, α_D^{18}, +33.7° (H_2O, 0.5%) (1, 4).

Pentagalloyl-α-glucose. **A2.** (2) Yellow mass. (3) $[(OH)_3C_6H_2CO]_5C_6H_7O_6$. (4) H_2O, C_2H_5OH, ether (1, 3). (5) α_D^{18}, +66.5° (H_2O, 1%). α_D^{23}, 65.4° (H_2O, 1%). α_D^{20}, +77.0° (C_2H_5OH, 3%). α_D^{18}, 76.4° (C_2H_5OH, 2%) (1, 3). α_D^{16}, +60° (H_2O, 1%); +81.5° (C_2H_5OH, 2%) (1, 4). (6) Blue-black.

Pentagalloyl-β-glucose. **A2.** (2) Yellow mass. (3) $[(OH)_3C_6H_2CO]_5C_6H_7O_6$. (4) H_2O, C_2H_5OH (1, 3). (5) α_D^{18}, +13.1° (H_2O, 1%); +13.6° (H_2O, 10%); +23.3° (C_2H_5OH, 2%) (1, 3). α_D^{18}, +15° (H_2O, 1%); +24° (C_2H_5OH, 2%). (6) Blue-black. (7) Potassium salt contains 10.1% K.

Pentapyrogallol-carboyl-glucose. **A2.** (2) Amorphous powder. (3) $[(OH)_3C_6H_2CO]_5C_6H_7O_6$. (4) Hot H_2O, C_2H_5OH, acetone. (5) α_D^{18}, +69° (H_2O, 2.5%). (6) Dark blue (1, 9). (7) Sinters at 160° and melts at about 200° with decomposition.

Tetragalloyl-erythrite. **A2.** (2) Cryst. (3) $[(OH)_3C_6H_2CO]_4C_4H_6O_4$. (4) Hot H_2O, C_2H_5OH, acetone, mixtures of H_2O and C_2H_5OH. (7) Decomposes at about 308° (1, 4).

Tetragalloyl-α-methylglucoside. **A2.** (3) $C_{35}H_{30}O_{22}$. (4) Identical with pentagalloyl-glucoses. (5) α_D^{20}, +26.4° (H_2O, 4%). (6) Identical with pentagalloyl-glucoses in reactions. (7) M. P. 130°–140° with decomposition (1, 6).

Trigalloyl-acetone-glucose. **A2.** (2) Amorphous light brown mass. (3) $[C_6H_2(OH)_3CO]_3C_6H_7O_6(C_3H_6)$. (4) Warm H_2O, CH_3OH, C_2H_5OH, acetone, ethyl acetate. (5) α_D^{20}, −93° (dry acetone, 4%). (6) Blue-violet (1, 2).

Trigalloyl-glucose. **A2.** (2) Amorphous yellowish brown mass. (3) $[C_6H_2(OH)_3CO]_2C_6H_9O_6$. (4) Cold H_2O, CH_3OH, C_2H_5OH, acetone, ethyl acetate, pyridine. (5) α_D^{20}, −118° (dry acetone, 2.5%). (6) Deep violet (1, 2).

Trigalloyl-glycerol. **A2.** (2) Amorphous yellowish brown mass. (3) $[(OH)_3C_6H_2CO]_3C_3H_5O_3$. (4) H_2O, acetone, ethyl acetate, warm ether. (6) Deep blue (1, 4).

α-Trigalloyl-levoglucosan. A2. (2) Micro. hexagonal crystals. (3) $C_{27}H_{22}O_{17}$. (4) Hot acetone. (5) α_D^{18}, −18.0° (C_2H_5OH, 19%). (6) $FeCl_3$ gives blue-black ppt. in C_2H_5OH solution. (7) Decomposes 250°–300°, carbonizes 320° (26).

β-Trigalloyl-levoglucosan. **A2.** (2) Micro-needles. (3) $C_{27}H_{22}O_{17}$. (5) α_D^{18}, −21.0° (C_2H_5OH, 1%). (6) $FeCl_3$ gives blue-violet ppt. in C_2H_5OH solution. (7) Decomposes 270°, carbonizes 320° (26).

III. Catechols or Catechins

d-**Catechol.** (1) Acacia and gambier catechus. (2) Thin needles. (3) $C_{15}H_{14}O_6.4H_2O$ (20). (4) C_2H_5OH, ethyl acetate, pure ether. Anhydrous form almost insoluble in latter two. (5) α_{578}, +17° (50% acetone, 9%) (14, 15, 19, 20). α_{578}, ±0° (C_2H_5OH) (20). α_D, −2° (C_2H_5OH) (20). α_D^{18}, −0.47° ±0.03° (C_2H_5OH, 9%); +3.7° ± 0.5° (50% C_2H_5OH, 9%). α_D^{20}, +18.4° ± 0.9° (H_2O, 0.9%, increasing markedly with temperature decrease) (14). (7) For discussion of structural formula *see* (20, 29, 33). M. P. 93°–95°; anhyd., 174–5°.

l-**Catechol.** (1) Isolated from acacia and gambier catechus. (2) Thin needles. (3) $C_{15}H_{14}O_6.4H_2O$. (5) α_{578}, ±0° (C_2H_5OH); α_{578}, −16.8° (50% acetone, 3%) (20). (7) M. P. 93°–95°; anhyd., 174°–175° (19, 20).

dl-**Catechol.** (1) Principal constituent of catechol separated from acacia catechu. (2) Thin needles. (3) $C_{15}H_{14}O_6.3H_2O$. (7) Is "acacatechin" (19). Sinters at 100°, melts 214°–216° with decomposition (19, 20).

Catechol-a. (1) Acacia catechu (33, 35). (3) $C_{15}H_{14}O_6.3H_2O$ (35). (7) Is *dl*-catechol (14). Methylated "acacatechin" has same melting point and crystal form as synthetic methyl compound (14). M. P. 204°–205° (35).

Catechol-b, Gambier catechol. (1) Gambier catechu (33, 35). (7) Identical with *d*-catechol in crystal form, melting point, solubility, and constitution.

Catechol-c. (1) Gambier catechu. (2) Small pale yellow prisms (35). (3) $C_{15}H_{14}O_6$. (7) Identified as *d*-epicatechol (20). M. P. 235°–237° (35).

Chinese rhubarb catechol. (5) α_{578}, +18° (50% acetone) (15).

Mahogany catechol. (5) α_D, +23° (50% acetone). α_{578}, +16° (50% acetone); +15° (C_2H_5OH) (15).

Paullinia catechol. (5) Inactive in C_2H_5OH. α_D, +3.7° (50% acetone) (15).

d-**Epicatechol.** (2) Thick prisms. (3) $C_{15}H_{14}O_6.4H_2O$. (5) α_{578}, +68.9° (C_2H_5OH, 7%); +59.9° (50% acetone, 4%). (7) M. P. 245° (20).

l-**Epicatechol.** (1) Gambier and acacia catechus (19). (2) Thick prisms. (3) $C_{15}H_{14}O_6.4H_2O$ (19, 20). (5) α_{578}, −68.2° (C_2H_5OH, 6%): −59.0° (50% acetone, 4%) (19, 20). (7) M. P. 245°.

***dl*-Epicatechol.** (1) Gambier and acacia catechus (19). (2) Exists both as prisms and needles. (3) $C_{15}H_{14}O_6.4H_2O$. (7) M. P. of prisms, 224°–226° (20).

***d*-β-Gambier catechol-carboxylic acid.** (2) Micro-needles. (3) $C_{16}H_{14}O_8$. (5) α_D^{20}, +12.6° (H_2O, 5%); +17.6° (C_2H_5OH, 7%). (7) M. P. 249°–251° with evolution of CO_2 (30).

***l*-β-Gambier catechol-carboxylic acid.** (2) Large needles. (3) $C_{16}H_{14}O_8$. (5) α_D^{18}, −22.4° (H_2O, 5%). α_D^{17}, −31.6° (C_2H_5OH, 6%). (7) M. P. 258°–261° with evolution of CO_2 (30).

***dl*-β-Gambier catechol-carboxylic acid.** (3) $C_{16}H_{14}O_8$. (7) M. P. 252°–253° with evolution of CO_2 (30).

The relationship between the catechols and epicatechols is shown as follows:

M = mixing; Ra = racemizing; Re = rearrangement (20).

SOURCE AND TANNIN CONTENT OF VEGETABLE TANNING MATERIALS

The names and tannin contents listed were taken from the literature at large for what they may be worth; in some cases the information given may be considerably in error. The place grown may indicate either the place where the sample analyzed was grown or the place where the material grows in abundance. In the majority of cases, at least, the tannin contents are supposedly those of the air-dried material.

In using the tannin figures, it should be recognized that they are not true tannin contents, but merely figures obtained by methods open to very serious question. A number of slightly different methods were used, but all conformed roughly to the following general scheme. A solution of the tanning material of concentration confined to certain limits was treated with lightly chrome-tanned hide powder until no tannin was left in solution; *i.e.*, the solution no longer gave a precipitate with gelatin solution. The decrease in concentration of all matters in solution was then taken as the measure of the tannin content. Obviously all substances of a slightly acid nature would be removed to some extent by the hide powder and hence all figures must be high where these are present.

The probable magnitude of the error was shown by Wilson and Kern for a number of the commoner tanning extracts. By first freeing the tannin solution of tannin by shaking with hide powder and then freeing the hide powder from nontannin by washing, they were able to estimate the tannin by the increase in weight of the dried hide powder. The tannin contents so obtained differed in many cases by startling amounts from those obtained by the methods generally accepted as official.

The comparison is with the official method of the American Leather Chemists' Association, which is similar in principle to the methods employed in other countries.[1]

Tanning material	Per cent tannin found	
	A. L. C. A. method	Wilson-Kern method
Chestnut wood extract	25.80	11.90
Gambier extract	24.95	7.79
Hemlock bark	10.06	6.17
Hemlock bark extract	26.68	23.38
Oak bark extract	24.20	12.88
Osage orange extract	39.87	13.37
Quebracho extract	68.01	47.41
Spruce bark extract	22.14	11.71
Sumac extract	25.51	16.29
Sumac leaves	25.56	9.61
Wattle bark extract	33.55	24.16

Many of the tanning materials are leached on a large scale by extract manufacturers and the concentrated extracts are available on the market showing a tannin content by the A. L. C. A. and similar methods of from 20 to 35% for liquid extracts and from 45 to 70% for solid extracts.

It may be assumed that nearly every form of plant life contains some tannin. The following list is not complete but is intended to serve as a guide to those whose interests might be directed into these fields of work.

---

[1] For a detailed comparison of the methods and their interpretation, see J. A Wilson, *The Chemistry of Leather Manufacture*, p. 215–31 (The Chemical Catalog Co., New York, 1923).

SOURCE AND TANNIN CONTENT OF VEGETABLE TANNING MATERIALS

Botanical name	Common name	Place grown	Per cent tannin
Abies alba	White spruce	Northern America	Bark 7–13
Abies canadensis	Hemlock fir	Northern America	Bark 8–15
Abies dumosa	Hemlock spruce	Northern America	Bark 10
Abies excelsa	Norway spruce	Northern Europe	Bark 7–13
Abies grandis	Lowland fir	California	Bark 9
Abies pectinata	Silver fir	Europe	Bark 6–15
Acacia acuminata	Raspberry jam wood	Australia	Bark 7–15
Acacia angica	Angica	Brazil	Bark 20–25
Acacia anema	Mulga	New South Wales	Bark 5–9
Acacia arabica	Babul	India	Bark 12–20 Pods 20–42
Acacia binervata	Black wattle	Australia	Bark 30
Acacia catechu	Cutch	India	Wood ext. 60
Acacia cavenia	Espinillo	South America	Pods 18–21 Bark 6
Acacia cebil	Red cebil	Argentina	Bark 10–15 Leaves 6–7
Acacia cunninghamii		Queensland	Bark 9
Acacia curupi	Curupy	South America	Bark 18
Acacia dealbata	Wattle	Africa and Asia	Bark 17–23
Acacia decurrens	Wattle	Australia	Bark 18–51
Acacia granulosa		New Caledonia	Bark 12
Acacia homalophylla	Yarran	New South Wales	Bark 9
Acacia horrida	Doornbosch	Cape Good Hope	Bark 8–18
Acacia koa	Koa tree	Hawaii	Bark 18
Acacia leptocarpa		Queensland	Bark 10
Acacia longifolia		Cyprus	Bark 15
Acacia melanoxylon	Blackwood	New South Wales	Bark 11 Leaves 3
Acacia microbotrya	Manna wattle	Australia	Bark 18–27 Leaves and twigs 20
Acacia mollissima	Green wattle	Australia	Bark 12–47
Acacia neriifolia		Australia	Bark 14
Acacia oswaldi	Miljie	Australia	Bark 10
Acacia penninervis	Hickory	Europe	Bark 14–38
Acacia podalyriaefolia		Queensland	Bark 12
Acacia polystachya		Queensland	Bark 18
Acacia pycnantha	Golden wattle	Australia	Bark 40–50
Acacia salicina		Australia	Bark 6–8
Acacia sentis		New South Wales	Bark 6
Acacia seyal	Talh	Sudan	Bark 18
Acacia sp.	Gallol	Somaliland	Bark 24
Acacia spiralis	Guaic	New Caledonia	Bark 17
Acer campbellii	Himalayan maple	India	Bark 3
Acer campestre	Field maple	Europe	Bark 4
Alchornea triplinervia	Tapia gwazu-ih	Paraguay	Bark 12
Allophylus edulis	Koku	Paraguay	Bark 10
Alnus firma	Minibari	Japan	Fruits 25
Alnus glutinosa	Alder	Europe	Bark 16–20
Alnus incana	Grey alder	Europe	Bark 10
Alnus maritima	Hannoki	Japan	Fruits 25
Alnus oregona	Red alder	Pacific states	Bark 9
Anacardium occidentale	Kashew nut	India	Bark 9
Anogeissus acuminata	Yon	India	Bark 10
Anogeissus latifolia	Dhawa	India	Bark 16 Leaves 10–18 Shoots 20–30 Red tips 54
Anogeissus pendula		India	Bark 9
Apuleia praecox	Yhvihra-pere	Paraguay	Bark 11
Arctostaphylos uva-ursi	Bearberry	Russia	Leaves and twigs 14
Areca catechu	Betelnut palm	India	Fruits 10–15
Aspidiosperma polyneuron	Palo rosa	Paraguay	Bark 3

SOURCE AND TANNIN CONTENT OF VEGETABLE TANNING MATERIALS.—(*Continued*)

Botanical name	Common name	Place grown	Per cent tannin
Aspidiosperma quebracho-blanco	White quebracho	Argentina	Leaves 27–28 Bark 4 Wood 3
Banksia integrifolia	Coast honeysuckle	Queensland	Bark 11
Banksia serrata	Heath honeysuckle	Australia	Bark 11–23
Bauhinia vahlii	Muhurain bark	India	Bark 9
Betula alba	White birch	Northern Europe	Bark 2–18
Betula lenta	Black birch	Northern America	Bark 3–18
Boswellia serrata	Salai bark	India	Bark 13
Bruguiera gymnorrhiza	Mangrove	East Africa	Bark 22–52
Bruguiera parviflora	Hagalay	Philippines	Bark 7–13
Bruguiera rhumphii	Mangrove	New Caledonia	Bark 27–42 Root bark 6 Root wood 9
Bumelia obtusifolia	Pihkasurembiu	Paraguay	Bark 8
Byrsonima cydoniaefolia	Mureci	Bolivia	Bark 20
Byrsonima spicata	Tamwood	South America	Bark 44
Cabralea sp	Cancharana	Paraguay	Bark 5
Caesalpinia brevifolia	Algarobilla	Chile	Pods 43–67
Caesalpinia cacolaco	Cascalote	Mexico	Pods 40–55
Caesalpinia coriaria	Divi-divi	Central America	Pods 30–50
Caesalpinia digyna	Tari	India and Burma	Pod cases 40–60
Caesalpinia melanocarpa	Guyacan	Argentina	Pods 15–23 Wood 8
Caesalpinia tinctoria	Celavinia	Central America	Pods 30–32
Callitris calcarata	Australian fir	Australia	Bark 17–31
Callitris glauca	Australian fir	Australia	Bark 12–15
Camellia thea	Tea	Asia and Africa	Leaves 5–10
Carissa spinarum		India	Leaves 8–12
Cassia auriculata	Tarwar	India	Bark 16–22
Cassia fistula	Amaltas	South India	Bark 11–15 Pod husk 17
Castanea pubinervis	Japanese chestnut	Japan	Bark 6 Wood 7
Castanea cesva	Spanish chestnut	Southern Europe Southern U. S.	Bark 6–8 Wood 7–11
Castanopsis chrysophylla	Western chinquapin	Pacific states	Bark 8
Castanopsis sinensis	Gie-gay	Indo-China	Bark 12
Casuarina	Ironwood	New Caledonia	Bark 10
Casuarina equisetifolia	Casagha pine	Southern Asia	Bark 11–18
Casuarina glauca	Bull oak	New South Wales	Bark 12
Ceanothus velutina	Snow bush	Western U. S.	Leaves 17
Ceriops candolleana	Bahau	India and Africa	Bark 24–42
Ceriops roxburghiana	Goran	India	Bark 13
Ceriops tagal	Tangal	Philippines	Bark 24–37
Cleistanthus collinus	Kodarsi		Bark 33
Cocos romanzoffiana	Pindo	Paraguay	Bark 7
Copaifera lansdorfii	Kupaih	Paraguay	Bark 17
Coriaria myrtifolia	French sumac	France	Leaves 15
Coriaria nepalensis		India	Leaves 20
Coriaria ruscifolia	Tutu	New Zealand	Bark 16–17
Corylus avellana	Hazel	Europe	Bark 5
Coulteria tinctoria	Tara	Algeria and Peru	Pods 43–51
Crossostylis multiflora	Bush mangrove	New Caledonia	Wood 21 Bark 3
Cryptomeria japonica	Japanese cedar	Japan	Bark 6
Cupania sp	Cedrillo	Paraguay	Bark 16
Cupania uraguensis	Kambuata	Paraguay	Bark 18
Cupania vernalis	Yaguarataih	Paraguay	Bark 15
Dalbergia sp	Yhsapih-ih	Paraguay	Bark 6
Dioscorea atropurpurea	Cu-nao	Indo-China	Tubers 20
Elaeocarpus grandis	Blue fig bark	New South Wales	Bark 10
Elephantorrhiza burchellii	Elephant roots	Africa	Root 6–22
Enterolobium timbouva	Timbo	Paraguay	Bark 22

SOURCE AND TANNIN CONTENT OF VEGETABLE TANNING MATERIALS.—(*Continued*)

Botanical name	Common name	Place grown	Per cent tannin
Eremophila longifolia	Emu bush	New South Wales	Bark 5 Leaves 10
Eucalyptus accedens	Spotted gum	Australia	Bark 18
Eucalyptus alba	Mountain gum	Australia	Bark 30–32
Eucalyptus amygdalina	Ribbon gum	New South Wales	Gum 58–65
Eucalyptus corymbosa	Bloodwood	New South Wales	Gum 28 Leaves 18 Bark 6
Eucalyptus diversicolor	Karri	Australia	Bark 16–20
Eucalyptus erythronema	White mallet	Australia	Bark 30
Eucalyptus falcata	Silver mallet	Australia	Bark 5–32
Eucalyptus globulus	Eucalyptus	Australia	Sap 28
Eucalyptus gunnii	Red gum	New South Wales	Leaves 17 Bark 11
Eucalyptus longifolia	Woolly-butt	Australia	Bark 8
Eucalyptus maculata	Spotted gum	New South Wales	Gum 45 Bark 10 Leaves 5
Eucalyptus loxophleba	York gum	Australia	Bark 5–10
Eucalyptus obliqua	Stringy bark	New South Wales	Bark 17
Eucalyptus occidentalis	Black mallet	Australia	Bark 20–26
Eucalyptus occidentalis astringens	Red mallet	Australia	Bark 40–50
Eucalyptus odorata	White box	New South Wales	Leaves 7
Eucalyptus piperita	Messmate	New South Wales	Gum 32–62 Leaves 13
Eucalyptus platypus	Round leaf moort	Australia	Bark 25
Eucalyptus redunca	Wandoo	Australia	Bark 16–20
Eucalyptus redunca oxymitra	Blue leaf mallet	Australia	Bark 22–30
Eucalyptus robusta	Mahogany	Florida	Leaves 12–17
Eucalyptus rostrata	Blue gum	Australia	Bark 16
Eucalyptus salmonophloia	Salmon gum	Australia	Bark 8–13
Eucalyptus salubris	Gimlet	Australia	Bark 16–19
Eucalyptus siderophloia	Red iron bark	New South Wales	Gum 35–73 Bark 10 Leaves 6
Eucalyptus sieberiana	Cabbage gum	New South Wales	Bark 37
Eucalyptus spathulata	Swamp mallet	Australia	Bark 26
Eucalyptus stellulata	Black gum	New South Wales	Bark 13 Leaves 17
Eucalyptus stuartiana	Apple	New South Wales	Bark 5 Leaves 10
Eucalyptus torquata	Flowering gum	Australia	Bark 17
Eucalyptus viminalis	Manna gum	New South Wales	Bark 8 Leaves 4
Eugenia braziliensis	Yhva-poroitih	Paraguay	Bark 43 Leaves 17 Wood 12
Eugenia jambolana	Java plum	India	Bark 19
Eugenia jambos		Brazil	Bark 12
Eugenia maire		New Zealand	Bark 16–17
Eugenia michellii	Nangapirih gwazu	Paraguay	Bark 29
Eugenia pungens	Yhva viyu	Paraguay	Bark 11
Eugenia smithii		Australia	Bark 17
Eugenia sp	Yhvajhay puihta gwazu	Paraguay	Bark 16–29
Exocarpus cupressiformis	Native cherry	Australia	Bark 15–16
Fiscus sp	Kili bark	Sudan	Bark 19
Fusanus acuminatus	Quandony	Australia	Bark 19
Garicinia mangostana	Mangoustan	Cochin-China	Fruit shells 14
Grevillia striata	Beefwood	Australia	Bark 18
Guarea sp	Guare	Paraguay	Bark 10
Hakea glabella		Australia	Bark 18
Hakea leucoptera	Needle bark	New South Wales	Bark 11
Heritiera fomes	Sundri bark	India	Bark 7

SOURCE AND TANNIN CONTENT OF VEGETABLE TANNING MATERIALS.—(*Continued*)

Botanical name	Common name	Place grown	Per cent tannin
Hopea odorata		India	Bark 14–15 Leaves 11 Wood 10
Hopea parviflora	Ironwood	India	Bark 17–22
Hydnora longicollis	Ganib	Africa	Roots 32
Inga affinis	Inga gwazu	Paraguay	Bark 26
Inga feuillei	Paypay	Peru	Pods 12–15
Juniperus recurva	Weeping blue	Japan	Bark 8
Krameria triandria	Rhatany	Peru	Root bark 20
Larix dahurica	Larch	Japan	Bark 9
Larix europaea	Larch	Europe	Bark 9–10
Larix occidentalis	Western larch	N. W. United States	Bark 11 Wood 7
Laurus lingue		Chile	Bark 17–19
Leuceadendron argenteum	Silver tree	Cape Good Hope	Bark 9–16
Leucospermum conocarpum	Knotted tree	Cape Good Hope	Bark 10–22
Ludwigia caparossa	Caparossa	Brazil	Bark 20–25
Lysiloma candida	Palo blanco	Lower California	Bark 26
Maclura pomifera	Osage orange	Texas	Wood 11
Malpighia faginea	Nance	Mexico	Bark 26
Malpighia punicifolia	Mangrutta	Nicaragua	Bark 20–30
Mimosa farinosa	Mimosa	Argentina	Bark 4
Mimosa pudica	Mimosa	India	Roots 10
Mimosa sp	Yukeri gwazu	Paraguay	Bark 11
Myrica asplenifolia	Sweet fern	Michigan	Leaves 4–5 Roots 4–6
Myrica nagi	Box myrtle	India	Bark 13–27
Nauclea gambir	Gambier	East Indies	Leaves and twigs 5–6
Ocotea bullata		South Africa	Bark 6
Ocotea sp	Yhva-iha	Paraguay	Bark 11
Osyris abyssinica		Transvaal	Leaves and twigs 13–25
Osyris arborea		Northern India	Leaves 20
Osyris compressa	Cape sumac	Cape Good Hope	Leaves 17–23
Oxalis gigantea		Chile	Bark 25
Paullinia sorbilis	Guara	Brazil	Fruit 43–55
Peltophorium dubium	Yhvihra puihta	Paraguay	Bark 31
Pentacme suavis		India	Leaves 12–24 Bark 7–13 Wood 4
Phyllanthus emblica	Amla	India	Stoned fruit 26–35 Leaves 23–28 Bark 15–24
Phyllocladus asplenifolia	Celery-topped pine	Tasmania	Bark 23
Phyllocladus rhomboidalis		Tasmania	Bark 21
Phyllocladus trichomanoides		New Zealand	Bark 28–30
Picea glehni	Red yezomatsu	Japan	Bark 19
Picea sitchensis	Sitka spruce	Pacific states	Bark 12–18
Pinus cembra	Pine	Alpine Europe	Bark 3–5
Pinus densiflora	Red pine	Japan	Bark 6
Pinus halepensis	Aleppo pine	Mediterranean coasts	Bark 10–15
Pinus Khasya	Pine	Burma	Bark 7–10
Pinus longifolia	Long-leaved pine	India	Bark 11–14
Pinus muricata	Swamp pine	California	Bark 13
Pinus radiata	Monterey pine	California	Bark 14
Pinus sylvestris	Scotch fir	Northern Europe	Bark 4–5
Pinus thunbergii	Black pine	Japan	Bark 6
Piptadenia cebil		Argentina	Bark 15
Piptadenia rigida	Kurupaih-ra puihta	Paraguay	Bark 28
Pistacia lentiscus	Pistacio	Mediterranean	Leaves 12–19
Pistacia orientalis	Pistacio	India	Galls 30–40
Pithecolobium dulce	Camanchile	Mexico	Bark 15–25
Polygonum amphibium		Missouri	Roots 22 Branches 17
Polygonum bistorta	Snakeweed	England	Roots 16–21

SOURCE AND TANNIN CONTENT OF VEGETABLE TANNING MATERIALS.—(*Continued*)

Botanical name	Common name	Place grown	Per cent tannin
Populus tremula	Poplar	Europe	Bark 3
Prosopis oblonga	Abu-surug	Sudan	Bark 14
Protea grandiflora		Cape Good Hope	Bark 15–16
Protea mellifera	Sugarbush	Cape Good Hope	Bark 18–25
Pseudotsuga taxifolia	Douglas fir	Pacific states	Bark 7
Punica granatum	Pomegranate	India	Fruit rind 27–30 Kernel 32 Bark 18–22
Quebrachia lorentzii	Quebracho	South America	Wood 20–30 Bark 6–8
Quercus aegilops	Valonia	Mediterranean	Acorns 17–40
Quercus agrifolia	Live oak	California	Bark 19
Quercus alba	White oak	Northern America	Bark 7
Quercus californica	Black oak	California	Bark 10
Quercus cerris	Turkey oak	Southern Europe	Galls 35
Quercus chrysolepis	Maul oak	Pacific states	Bark 7–12
Quercus coccifera	Kermes oak	Mediterranean	Bark 10–18
Quercus coccinea	Scarlet oak	United States	Bark 8
Quercus densiflora	Tanbark oak	California	Bark 10–29
Quercus dentata	Japanese oak	Japan	Bark 11 Wood 7
Quercus fenestrata		Northern India	Bark 10–16
Quercus garryana	Pacific post oak	Pacific states	Bark 6–7
Quercus grosseserrata	Water oak	Japan	Bark 9 Wood 2
Quercus ilex	Evergreen oak	Southern Europe	Bark 5–11
Quercus incana		India	Bark 22
Quercus infectoria	Aleppo	Turkey	Galls 24–60
Quercus lamellosa		Northern India	Bark 8–10
Quercus lineata		Northern India	Bark 11
Quercus lobata	White oak	California	Bark 12
Quercus mirbechi		Algeria	Bark 8
Quercus pachyphylla	Sungra katus	Northern India	Acorn cups 13–15 Bark 12–13 Leaves 10
Quercus prinus	Chestnut oak	United States	Bark 9–12
Quercus pseudocornea	Gie-quang	Indo-China	Bark 16
Quercus robur	Common oak	Europe and U. S.	Bark 9–12 Wood 2–4
Quercus rubra	Red oak	Northern America	Twig galls 35 Bark 4–6
Quercus spp	Gie-bob	Indo-China	Bark 11
Quercus suber	Cork oak	Europe	Bark 12–19
Quercus tozae		Southern France	Bark 14
Quercus velutina	Black oak	United States	Bark 6–12
Quercus wislizeni	Highland oak	California	Bark 7–8
Rheedia braziliensis	Pakuri	Paraguay	Bark 22
Rhizophora conjugata	Mangrove	Philippines	Bark 26–32
Rhizophora mangle	Mangrove	Tropical coasts	Bark 15–42 Leaves 22
Rhizophora mucronata	Mangrove	Asia and Africa	Bark 21–48
Rhus copallina	Sumac	United States	Leaves 17–38
Rhus coriaria	Sicilian sumac	Sicily	Leaves 25–32
Rhus cotinus	Venetian sumac	Italy	Leaves 17
Rhus cotinoides	Sumac	United States	Leaves 21
Rhus glabra	White sumac	United States	Leaves 15–25
Rhus metopium	Sumac	United States	Leaves 8
Rhus mysorensis		Southern India	Bark 20
Rhus pentaphylla	Tizra sumac	Morocco	Roots 29 Wood 23
Rhus rhodanthema	Deep yellow wood	New South Wales	Bark 23
Rhus semialata	Sumac	America and Asia	Leaves 5 Chinese galls 70

Source and Tannin Content of Vegetable Tanning Materials.—(*Continued*)

Botanical name	Common name	Place grown	Per cent tannin
Rhus succedanea	Sumac	India	Leaves 20
Rhus thunbergii		Cape Good Hope	Bark 28
Rhus typhina	Virginian sumac	Virginia	Leaves 10–18
Robinia pseudacacia	Black locust	Europe	Bark 2–7 Wood 3–4
Rollinia sp	Aratiku gwazu	Paraguay	Bark 4
Rumex hymenosepalum	Canaigre	Mexico	Roots 25–30
Rumex maritima	Docks	Europe	Roots 22
Sabal palmetto	Cabbage palmetto	Florida	Roots 10–18
Sabal serrulata	Saw palmetto	Florida	Leaves 13
Salix alba	White willow		Bark 9
Salix arenaria	Willow	Russia	Bark 13
Salix caproea	Willow	Japan	Bark 8–12
Salix fragilis	Willow		Bark 9–12
Salix lasiandra	Yellow willow	California	Bark 2
Salix purpurea	Willow	Japan	Bark 8
Salix viminalis	Willow	Russia	Bark 7–10
Schinus molle	Molle	Argentina	Leaves 19
Sequoia sempervirens	Redwood	Pacific states	Heartwood 4–12 Sapwood 1–2 Bark 1–3
Shorea obtusa		India	Bark 9 Wood 6–7
Shorea robusta	Sal bark	India	Bark 6–15
Sonneratia pagatpat	Pagatpat	Philippines	Bark 11–12
Spermolepsis gummifera	Oak gum	New Caledonia	Bark 17 Resin 43–80
Statice coriaria	Marsh rosemary	Southern Russia	Roots 20–22
Stryphnodendron barbatimao	Barbatimao	Brazil	Bark 18–27
Tamarix africana	Tamarisk	Mediterranean	Galls 26–56 Twigs 9 Leaves 9
Tamarix articulata	Tamarisk	Morocco	Galls 43–56
Tamarix dioica	Jhao	India	Bark 10
Taxus cuspidata	Yew	Japan	Bark 10
Terminalia arjuna	Kahua	India	Bark 18–24
Terminalia belerica	Bedda	India	Nuts 12
Terminalia catappa	Badamier	India	Bark 12–25
Terminalia chebula	Myrobalan	India	Nuts 30–40
Terminalia glabra	Kumbuk	Ceylon	Bark 27–32
Terminalia mauritiana	Jamrosa	India	Bark 30
Terminalia oliveri	Thann	Malay	Bark 31 Leaves 14
Tormentilla erecta		Europe	Roots 20–46
Trichilia catigua	Kaatigua puihta	Paraguay	Bark 21
Trichilia hieronymi	Kaatigua moroti	Paraguay	Bark 23
Tsuga canadensis	Hemlock	Northern America	Bark 7–12
Tsuga heterophylla	Western hemlock	Pacific states	Bark 9–16
Umbellularia californica	California laurel	California	Bark 16
Vateria indica		India	Fruit 25
Weimannia glabra	Curtidor	Venezuela	Bark 10–13
Woodfordia floribunda	Itcha	India	Bark 27 Leaves 15
Ximenia americana	Alimu	Sudan	Bark 17
Xylia dolabriformis	Jamba	Burma and India	Bark 9–19 Wood 4
Xylocarpus granatum	Piagao	Africa and Asia	Bark 21–48
Xylocarpus obovatus	Tabique	Philippines	Bark 22–25
Zizyphus nummularia	Ber	India	Bark 10
Zizyphus xylopyra	Gothar	India	Fruit flesh 23

18. Chrome-tanned steer hide (sole leather).	Cuir de génisse, tanné au chrôme (cuir de semelles).	Chromgares Rindleder (Sohlenleder).	Pelle di giovenco al cromo (cuoio da suola).

Each analysis was made on one representative skin of each type. The same 18 skins were used to make all measurements listed in this section, thus making all properties of any one type directly comparable and related to chemical composition.

Chaque analyse a été effectuée sur une peau représentative de chaque genre de cuir. On a utilisé les mêmes 18 peaux pour faire toutes les mesures mentionnées dans cette section. De la sorte, toutes les propriétés de chaque genre de cuir sont directement comparables et en relation avec la composition chimique.

Jede Analyse wurde an einem besonderem Vertreter einer Hauttype gemacht. Dieselben 18 Häute sind für alle Messungen die in diesem Abschnitt angeführt werden, verwendet worden. Es werden dadurch alle Eigenschaften jeder einzelnen Type direkt vergleichbar und in Beziehung zur chemischen Zusammensetzung gebracht.

Ogni analisi fu fatta sopra un campione rappresentante ciascun tipo di pelle. Gli stessi 18 campioni furono usati per eseguire tutte le misure indicate in questa sezione, risultando così tutte le proprietà di ogni singolo tipo direttamente paragonabili ed in rapporto alla composizione chimica.

TENSILE STRENGTH, STRETCH AND STITCH TEAR (¹)

Each value recorded is the average of 3 determinations. The strips for strength and stretch were cut with a die 2.54 × 15.24 cm and the jaws of the testing machine were initially 10.16 cm apart. The 3 strips from each skin were cut with their lengths parallel to the backbone and spaced equally between head and tail end along a line midway between backbone and belly edge. The leather was in equilibrium with an atmosphere of 50% relative humidity. The stitch tear was made with Irish flax shoe thread No. 6 slipped through a hole 2 mm from the leather edge.

l = average thickness; TS = tensile strength in kg per cm² of original cross section; S = stretch (*a*) at 13.6 kg per 2.54 cm width, (*b*) at 225 kg per cm²; ST = stitch tear.

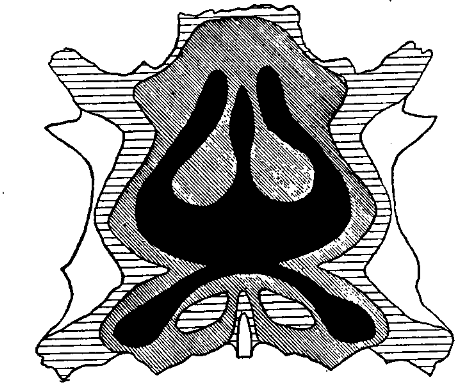

FIG. 1.—Variations in strength and resistance to stretch for calf leather from different parts of the skin (³).

Tensile strength given in kg per cm².
Percentage stretch measured under load of 225 kg per cm².

☐ Tensile strength less than 170 kg. Stretch greater than 60 %.

▤ Tensile strength 170 to 260 kg. Stretch 60 to 26 %.

▨ Tensile strength 260 to 350 kg. Stretch 26 to 20 %.

■ Tensile strength greater than 350 kg. Stretch less than 20 %.

Water Content at Different Relative Humidities (¹, ²)

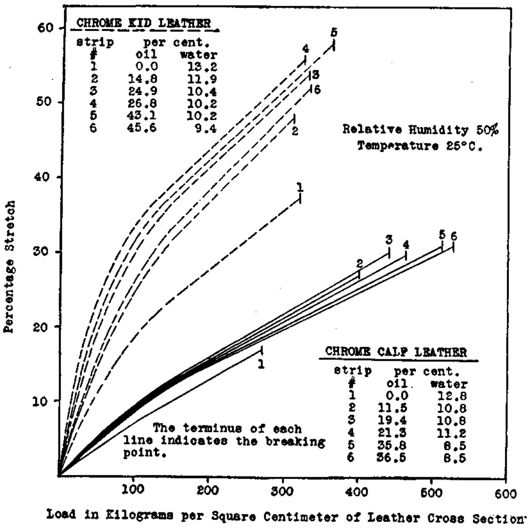

FIG. 2.—Effect of oil content (⁴).

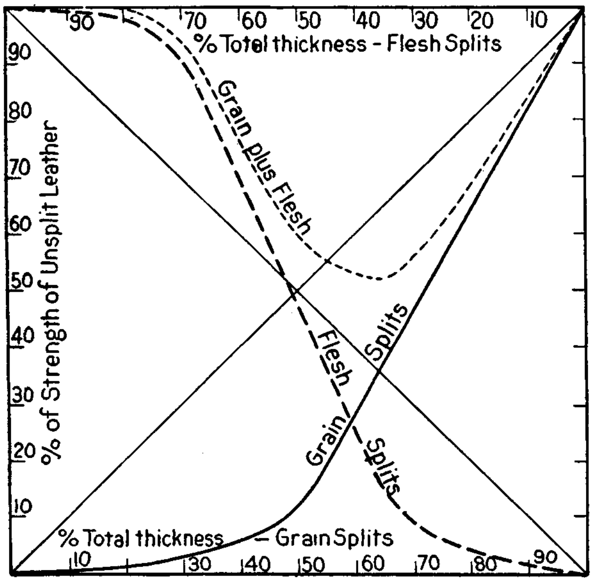

FIG. 3.—Relative strengths of splits of vegetable-tanned calf leather compared with unsplit leather. Average tensile strength of skin 324 kg/cm²; average thickness 0.91 mm. Strengths in chart are given per unit width, not cross section (⁵).

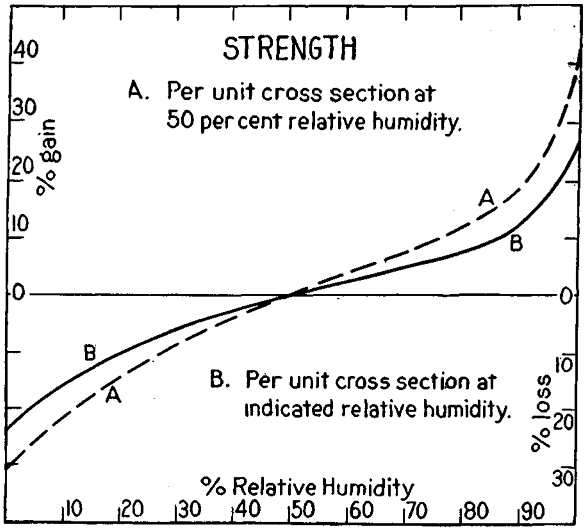

Fig. 4.—Percentage gain or loss in strength per unit cross section of chrome calf leather with change of relative humidity. The difference between the two curves reflects the volume change in the leather with relative humidity. Leather with high fat content shows much less change in strength with relative humidity (8).

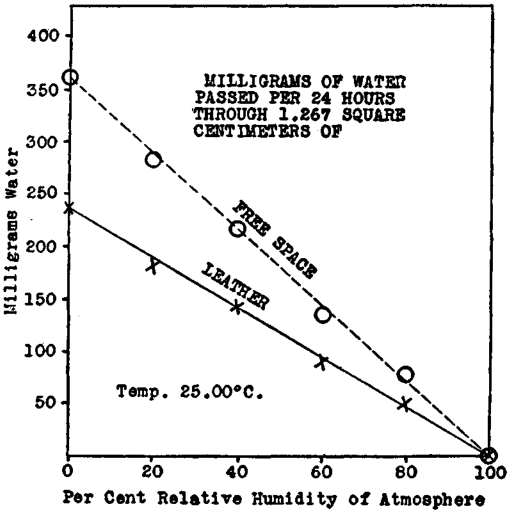

Fig. 5.—Effect of relative humidity of 1 atmosphere upon passage of water into it from an atmosphere kept at 100 % relative humidity through vegetable-tanned calf leather and through free space (6).

Ventilating Properties

Effect of kind of skin and tannage (1)

Ind. No.	1	2	3	4	5	6	7	8	9
1 mm	1.08	1.00	0.73	0.53	1.15	0.88	1.22	0.60	0.88
P_W*, %	70	70	70	65	54	95	74	97	79
P_A†	197	67	249	185	41	1183	369	1820	246

Ind. No.	10	11	12	13	14	15	16	17	18
1 mm	0.88	0.89	1.01	0.99	1.37	2.59	2.31	6.28	4.80
P_W*, %	78	89	6	9	5	38	49	34	4
P_A†	251	1416	0	0	0	45	179	43	0

* P_W, % permeability to water vapor, is defined as 100 times the ratio of the rate of passage of water from an atmosphere of 100% relative humidity to one of zero humidity through a given area of the leather sample, of thickness, 1, to the rate of a similar passage of water through an equal area of free space at the same temperature. In these measurements, the area chosen was 1.267 cm² and the temperature 25°C.

† P_A, permeability to air, is defined as the rate of flow of air (cm³/min per cm² of leather) through thickness 1, under the pressure difference, atmospheric to 35 mm Hg.

Effect of temperature, Fig. 6; effect of relative humidity, Fig. 5.

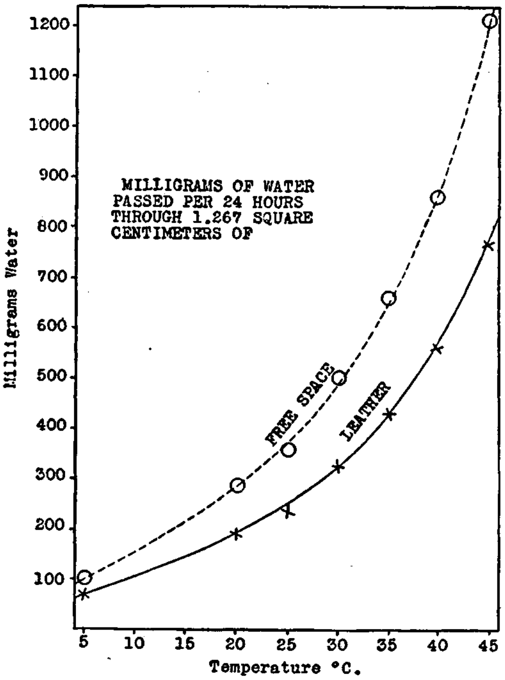

Fig. 6.—Effect of temperature upon passage of water from an atmosphere of 100 % relative humidity to one of zero relative humidity through vegetable-tanned calf leather and through free space (6).

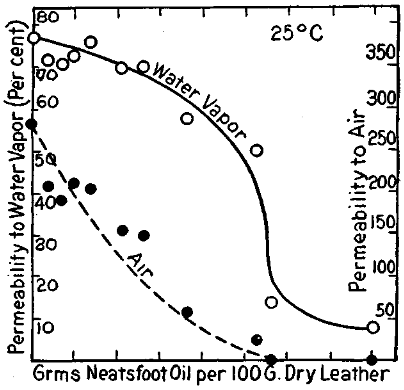

Fig. 7.—Effect of oil content of leather (6).

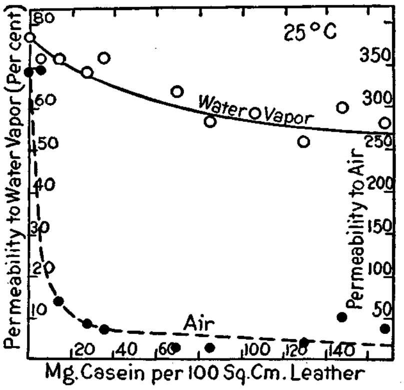

Fig. 8.—Effect of quantity of casein used as finishing material (6).

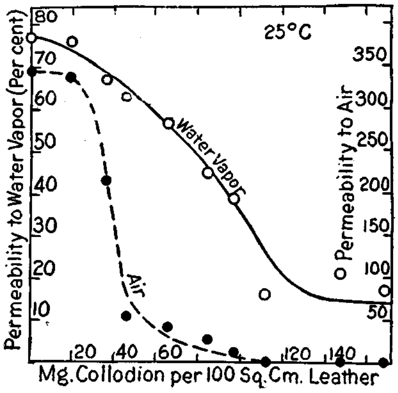

Fig. 9.—Effect of quantity of collodion used as finishing material (6).

Relative resilience is defined as the percentage rebound of a brass plunger (weighing 48.5 g and having a contact area of 0.70 cm^2) when dropped from a height of 60 cm upon a thickness of 3 mm of leather backed by a solid maple block. Relative humidity 50%.

The relative resilience is decreased by an increasing content of either water or oil.

ABBREVIATIONS

T_B	Breaking load expressed unless otherwise stated as kg per cm^2 unstrained cross section
E_B	Ultimate elongation (percentage of unstrained length)
T_x	Stiffness, expressed as the load (kg/cm^2 unstrained cross section) required to produce an increase in length x times the unstrained length
E_T	Stiffness, expressed as the percentage elongation produced by a load T kg/cm^2 unstrained cross section
V. C.	Vulcanization coefficient
D_{30}	Plasticity expressed as the thickness of a disc (0.4 g) after 30 min in a Williams' plastometer at 100° under a load of 5 kg
ΔD	Plasticity expressed as D_{25}–D_{35}
Cure	Unless otherwise indicated, the period of vulcanization required to give an optimum or standard "cure."
η	Viscosity, expressed unless otherwise indicated as the time of flow of a 1% solution in benzene relative to the time of flow of the pure solvent.

Relative resilience is defined as the percentage rebound of a brass plunger (weighing 48.5 g and having a contact area of 0.70 cm²) when dropped from a height of 60 cm upon a thickness of 3 mm of leather backed by a solid maple block. Relative humidity 50%.

The relative resilience is decreased by an increasing content of either water or oil.

Vulcanization of Latex

TABLE 15.—INFLUENCE OF PERIOD OF VULCANIZATION AND OF CHARACTER OF THE S ON THE COMBINED S (43)

Composition of mixture: 100 cm³ latex; 50 cm³ H_2O; 2 g S (rubber coagulated by acetone). Latex No. 1: rubber, 32.9%; NH_3, 0.6%. Latex No. 2: rubber, 30.15%; NH_3, 0.43%. Vulcanizing conditions: rise to 141°, 10 min; blow-off, 20 min.

Time at 141°, min	Combined sulfur, %			
	Latex No. 1	Latex No. 2		
	Flowers	Flowers	Pptd.	Colloidal
0	0.18	0.13	0.23	0.47
20	0.59		0.85	1.56
30		0.46	1.04	1.87
60	0.91	0.55	1.47	2.44
120	1.07			2.64

TABLE 16.—INFLUENCE OF CONCENTRATION OF S (43)

Composition of mixture: 100 cm³ latex (30.7% rubber; 0.43% NH_3); 50 cm³ H_2O; 1% S (calculated on rubber + S). Vulcanizing conditions: 10 min rise; 30 min at 141°; 20 min at blow-off.

S		Comb. S, %	E_{60} (films)
g	% on rubber		
1	3.26	0.64	1000
2	6.51	1.02	954
4	13.02	1.42	951
6	19.53	1.65	886

TABLE 17.—VULCANIZATION WITH SODIUM POLYSULFIDE (43)

Composition of mixture: 120 cm³ latex (32.9% rubber, 0.6% NH_3); 10 cm³ sodium polysulfide (21.0% S on pptn.). Vulcanizing conditions: 10 min rise to 141°; 20 min blow-off.

Period at 141°, min	0	20	30	60	120
Combined S, %	0.31	0.85	1.02	1.42	1.88

Coagulation

Acidity Necessary for Coagulation.—By addition of acid, pH = 4.3 to 4.8 (10, 20). By addition of acid to ammoniated latex (dialyzed or undialyzed), pH *ca.* 5.5 (103). For spontaneous coagulation, pH = 4.8 to 5.6 (20).

CH_3CO_2H, ACETIC ACID

TABLE 18.—PROPORTION OF CH_3CO_2H USED IN PLANTATION PRACTICE (189)

Rubber	15%		25%	
For coagulation on	Same day	Next day	Same day	Next day
CH_3CO_2H(g/l)	1–1.25	0.75	1.5	1

TABLE 19.—CONCENTRATION OF CH_3CO_2H REQUIRED TO COAGULATE LATEX DILUTED TO DIFFERENT EXTENTS (189), *cf.* (188)

% rubber content	Ratio, acid: rubber	% rubber content	Ratio, acid: rubber
30	1:303	6	1:83.5
24	1:190	3	1:91
18	1:115	1.5	1:125
15	1:100	0.75	1:83.5
12	1:89		

Influence of excess CH_3CO_2H on properties of crepe: Double the minimum quantity increases time of cure 0 to 5 min; decreases viscosity 0 to 4. Four times minimum quantity increases time of cure 5 to 10 min for the stock: rubber, 92.5; S, 7.5, at 148°; decreases viscosity 2 to 7 (176).

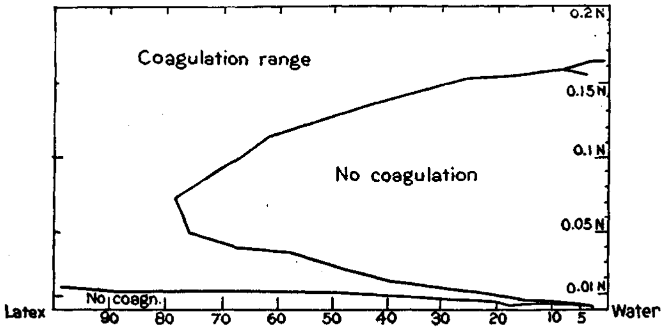

FIG. 1.—Concentrations of hydrochloric acid producing coagulation in latex (31.8 % rubber, *ca.* 35 % total solids) diluted to different extents (188).

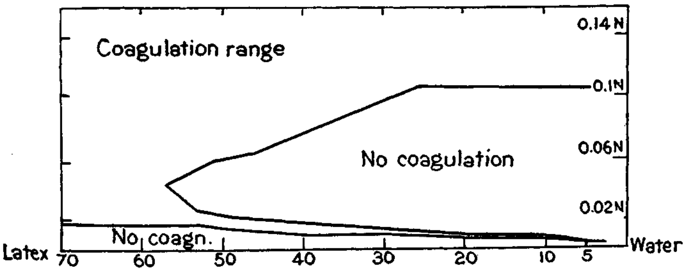

FIG. 2.—Concentrations of nitric acid producing coagulation in latex (28 % rubber) diluted to different extents (188).

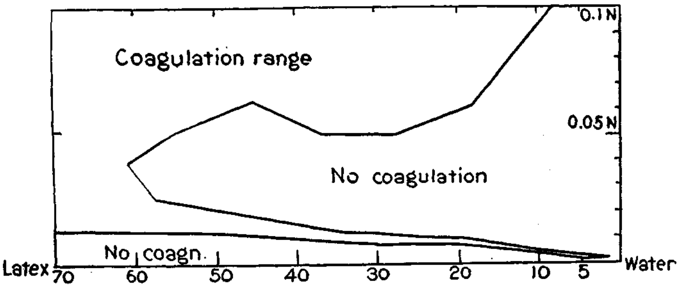

FIG. 3.—Concentrations of sulfuric acid producing coagulation in latex (28 % rubber) diluted to different extents (188).

H_2SO_4, SULFURIC ACID

Proportion H_2SO_4 Used in Practice.—0.45 to 0.6 g/l latex (15% rubber).

TABLE 20.—VULCANIZING PROPERTIES OF CREPE RUBBER PREPARED BY H_2SO_4 (182)
Stock: rubber, 92.5; S, 7.5; vulcanized at 148° (ring-shaped test pieces)

Normal proportion				Double the normal proportion			
Cure, min	T_B	Slope	η	Cure, min	T_B	Slope	η
125	140	38	35	150	136	38.5	27

ALUM

Minimum Effective Proportions.—3 to 4 g/l.

TABLE 21.—EFFECT OF ALUM (COMPARED WITH CH_3CO_2H) ON PROPERTIES OF CREPE (182)

Load-Strain Curves for Vulcanized Rubber

Independently of state of cure, the load-strain curve for rubber-S stock is a conchoid expressed by

$$y = a - b \sin \alpha \qquad (1)$$
$$x = n\,(a \cot \alpha - b \cos \alpha)$$

where x = load; y = strain; a = distance between pole and asymptote; b = distance between origin and asymptote; and n =

a constant fraction of corresponding abscissae of parent conchoid (137).

$$y = cx + a \sin^2 bx \tag{2}$$

where y = strain; x = load; c, a, b = constants for the rubber specimen in question, characterizing respectively the initial, the middle, and the ultimate elongations (39).

$$x = A\left\{1 - \frac{2}{l - b}\right\} e^{h(p-l)^2} \tag{3}$$

where x = load; l = length; b = breadth $\left(\text{taken as } \frac{1}{\sqrt{l}}\right)$; h, p = constants for the rubber specimen in question (118).

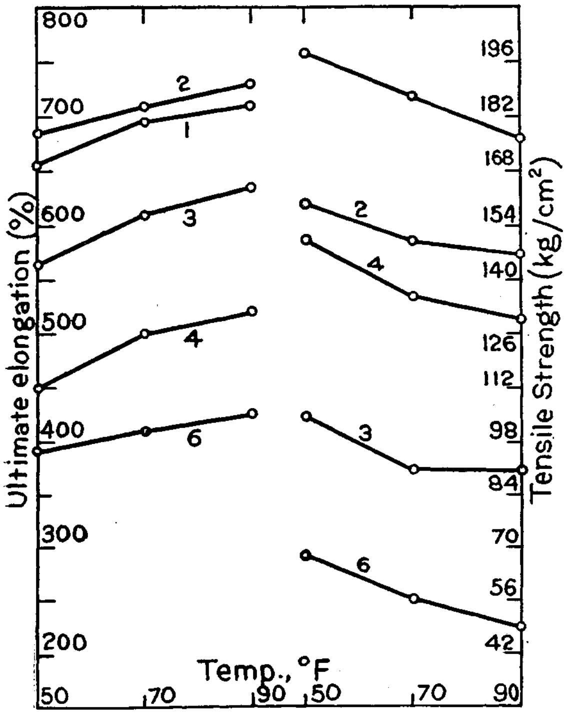

FIG. 20.—Influence of temperature on the tensile strength and ultimate elongation of five samples (32).

Stress-Strain Curve for Vulcanized Rubber

$$y = \frac{ax}{b + x} \tag{1}$$

where y = strain; x = load referred to unstrained cross section; a = distance of asymptote from axis; b = intercept cut off by tangent at origin on the asymptote.

The curve is a rectangular hyperbola, with asymptotes parallel to the axes, with the equations

$$y = a,\ x = -b.$$

Making the asymptotes the axes

$$x'y' = -ab \ (82)$$

$$\text{Stress} = Ee + e/B^{\frac{l}{k}} \tag{2}$$

where e = elongation; l = original length; E = Young's modulus; B and k = constants (146).

Mechanical Hysteresis

TABLE 80

Extension and sub-permanent set in a succession of cycles of extension and retraction (24). Pure gum rubber, sp. gr. 0.985, loaded at rate of 0.8 kg/cm² per 27 sec.

Cycle No.	1	2	3	4	5	6	7	8
Extension produced, %	516	568	590	604	617	627	636	643
Sub-permanent set, %	20	23	25	28	28	28	28	28

Extension, sub-permanent set, energy absorption, energy of hysteresis in succession of cycles of various amplitudes (80).

Extension in a series of cycles. Extension = $a + b \log$ (No. of cycle) where a = extension in second cycle; b = increment of extension in subsequent cycles (140).

Influence of amount of extension on amount of hysteresis. In general, the shorter the cycle, the smaller the energy of hysteresis (*cf.* Fig. 23).

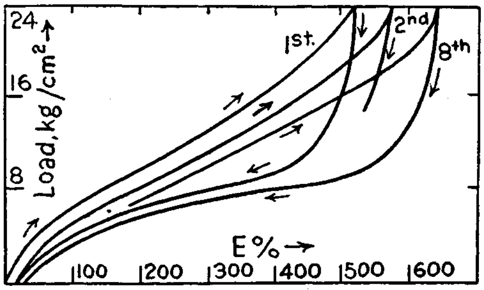

FIG. 21.—Load-strain curve for cycles Nos. 1 and 8 and part of cycle No. 2 (Table 80) (24).

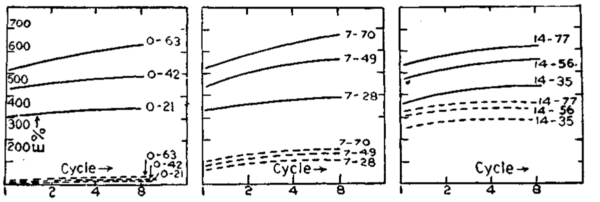

FIG. 22.—Relation between cycle number and max. (solid lines) and min. (dotted lines) extension for cycles between various loads. Stock: rubber (smoked sheet), 94 vols.; S, 3 vols.; MgO, 1 vol.; carbon black, 2 vols.; vulcanized 60 min at 149°. Load expressed in kg/cm² (80).

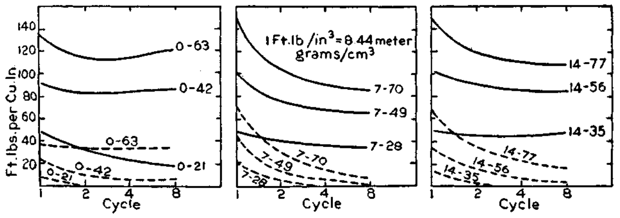

FIG. 23.—Relation between the cycle number and energy absorption (solid lines) and energy of hysteresis (dotted lines) for cycles between various loads. Load expressed in kg/cm² (80).

TABLE 81

Pure gum rubber subjected to a succession of cycles of different lengths, each cycle being repeated until the course of the load-strain curves was constant (24).

Cycle No.	Amplitude kg/cm²	Difference between elongation at same load during extension and retraction, %
1	0–4	61
2	0–8	167
3	0–12	286
4	0–16	533

Influence of rate of loading and unloading. The higher the rate of loading and of unloading, the smaller the extension and the greater the hysteresis (24).

Influence of state of cure and of the presence of a filler on energy absorption (Figs. 26 and 27) and energy of hysteresis (Figs. 28 and 29) in a succession of cycles of extension and retraction (80).

Stock A (by volume): rubber, 94; S, 3; MgO, 1; carbon black, 2.

Stock B (by volume): rubber, 63; S, 2; MgO, 1; carbon black, 2; whiting, 32.

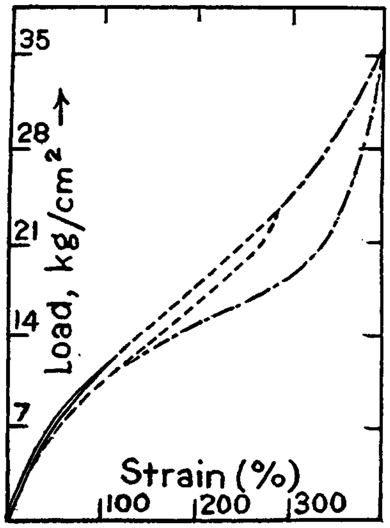

FIG. 24.—Pure gum rubber subjected to hysteresis cycles of different lengths (141).

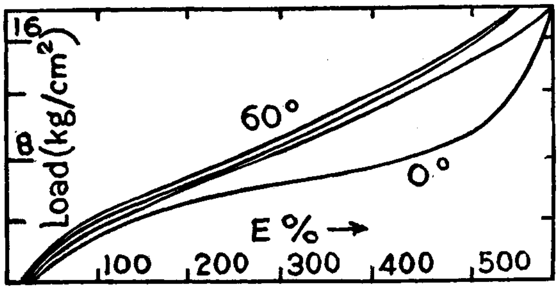

FIG. 25.—Influence of temperature on extension (24). Pure gum rubber, sp. gr. 0.985, loaded to 18.4 kg/cm² at 0° and 60°.

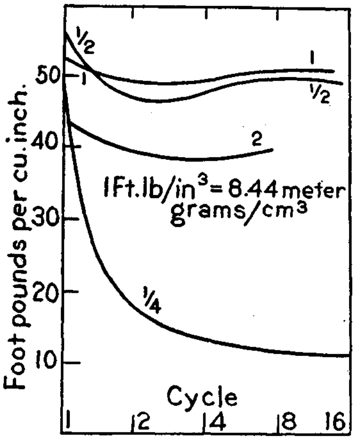

FIG. 26.—Stock A vulcanized for periods from 0.25 to 2 hr at 149° (80).

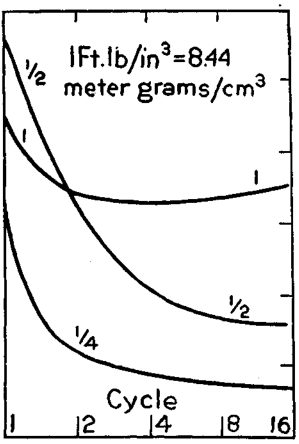

FIG. 27.—Stock B vulcanized for periods from 0.25 to 1 hr at 149° (80).

Influence of compounding ingredients on Poisson's ratio for rubber (174). (P_v, P_t, P_w: Poisson's ratio from measurements of volume, thickness, width, respectively.)

1. $P_t = P_w = P_v$ at elongations up to 200: carbon black, ZnO.
2. P_t does not equal P_w; $P_v = 0.5$.

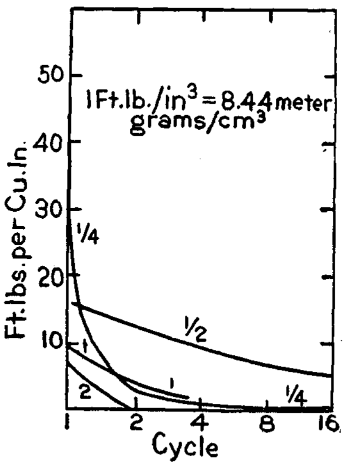

FIG. 28.—Stock A vulcanized for periods from 0.25 to 2 hr at 149° (80).

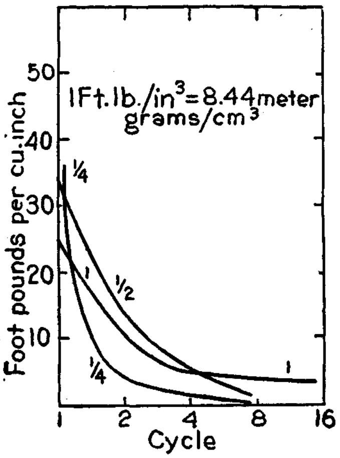

FIG. 29.—Stock B vulcanized for periods from 0.25 to 1 hr at 149° (80).

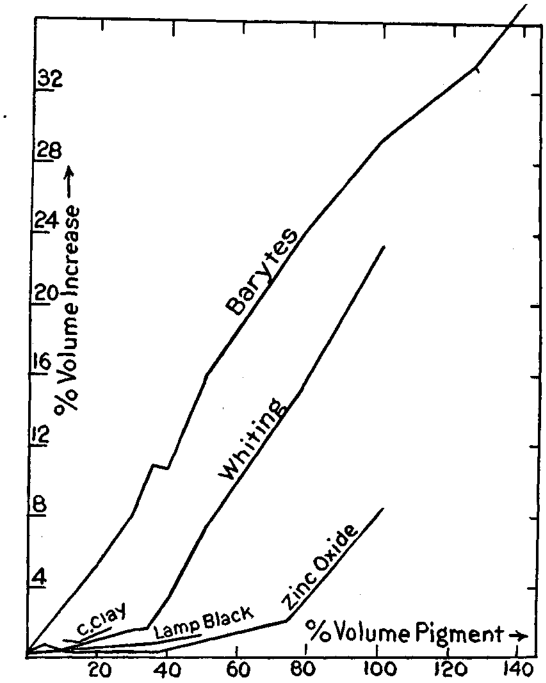

FIG. 30.—Increase in volume produced by straining to 100 % elongation stocks containing various volumes of barytes, china clay, lampblack, whiting and ZnO. Basal stock: rubber, 100; S, 5; litharge, 30 (139).

3. $P_w = P_t$; $P_v < 0.5$ at 300%: barytes, lithopone.
4. P_w does not equal P_t; $P_v < 0.5$: tripoli at high elongations (*cf.* Fig. 32).

	At 25 % elongation		
	P_t	P_w	P_v
Magnesium carbonate	0.72	0.31	0.51
Clay	0.69	0.32	0.505
Tripoli	0.61	0.39	0.50

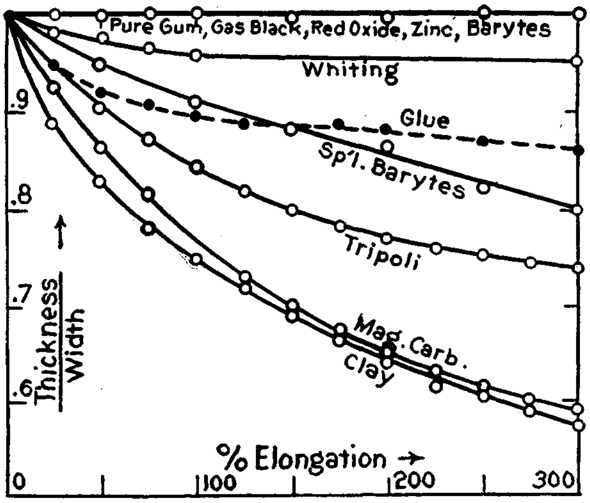

FIG. 31.—Effect of strain on the ratio thickness: width as influenced by various compounding ingredients (20 vols. per 100 vols. rubber) (174).

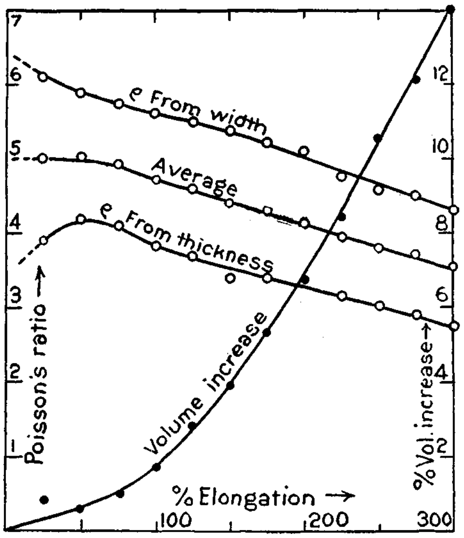

FIG. 32.—Effect of tripoli on Poisson's ratio and on increase in volume at various extensions (174). Stock contains 20 vols. tripoli per 100 vols. rubber.

Load-Compression Relations. Pure Gum Rubber

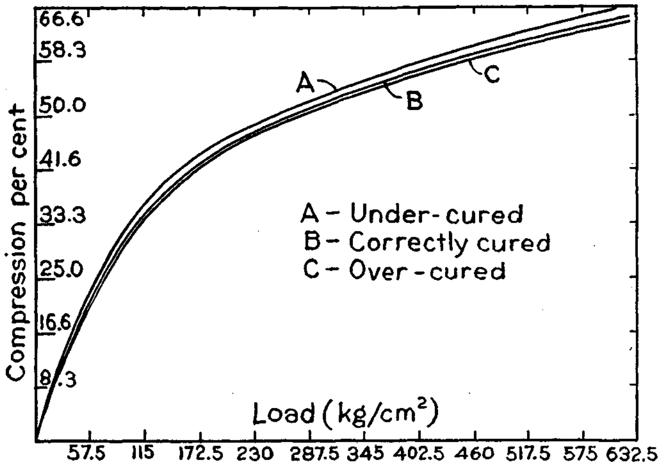

FIG. 33.—Load-compression curves for the stock: rubber, 100; S, 10; in various states of cure (17).

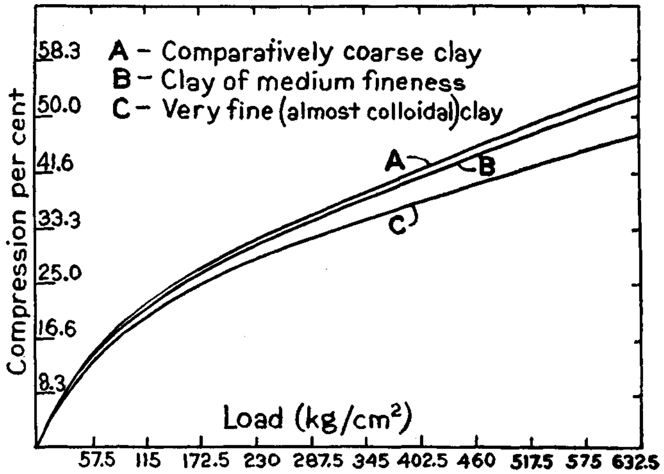

FIG. 34.—Load-compression curves for the stock: rubber, 100; china clay, 20; S, 10; ZnO, 5; diphenylguanidine, 1; using clay of different degrees of fineness (17).

Hardness

Definitions.—Plastometer number: the depression in hundredths mm produced by a steel sphere when the force against a surface of the rubber is increased from 85 to 1085 g, and then maintained for 60 sec (79).

Modulus of hardness: the force in dynes producing a depression of 1 cm^3 (79).

See p. 270 for Figs. 35–39, giving illustrative values.

Resistance to Tearing

TABLE 82.—INFLUENCE OF STATE OF CURE ON RESISTANCE TO TEAR (231)

Stock: rubber, 92.5; S, 7.5; vulcanized at 145°

Time of cure, min.	30	45	60	75	90	105	120	135	150
Resistance to tear, kg/cm^2	5.6	7.7	9.8	11.6	13.3	16.8	13.3	11.9	11.2

Compressibility

Compressibility.—92.95 × 10^{-6} of the original volume per kg/cm^2 (40). Equal to that of bronze (2), *cf.* (105).

Volume Elasticity (107).—Soft, gray rubber (sp. gr., 1.289; T_B, 58; E_B, 890): 14 000 kg/cm^2. Red rubber (sp. gr., 1.407; T_B, *ca.* 58; E_B, 630): 8000 kg/cm^2. Gray rubber (sp. gr., 2.340; T_B, 58; E_B, 340): 66 000 kg/cm^2.

Thermal Properties

Expansion.—Coefficient of cubical expansion of:

(*a*) Sample of vulcanized rubber (sp. gr., 0.996), 2.25° above to 2.25° below its maximum density: 0.000526 (88).

(*b*) Sample of black vulcanized rubber (sp. gr., 0.90166 at 17.4°; S content, 2.5 to 3 %) at 0–60.7°: 0.000763 (105).

(*c*) Gray rubber: 0.000562 (105).

Specific Heat.—Above mentioned sample (*a*): 0.415 (88).

Conductivity.—Vulcanized rubber, crepe, smoked sheet, etc. (45–100°): 0.00032 cal/sec/cm^3 (227).

Absorption

ABSORPTION OF ORGANIC VAPORS

TABLE 84.—ABSORPTION (g/g RUBBER) BY RAW RUBBER AND A RUBBER STOCK (RUBBER, 100; S, 12.5) VULCANIZED TO VARIOUS DEGREES (93)

V. C.	0.0	1.2	2.0	3.5	4.4	6.4
Carbon tetrachloride	0.99	0.975	0.99	0.98	0.99	1.05
Benzene	0.98	0.895	0.87	0.86	0.86	0.85
Carbon disulfide		0.64	0.65	0.63	0.64	0.67

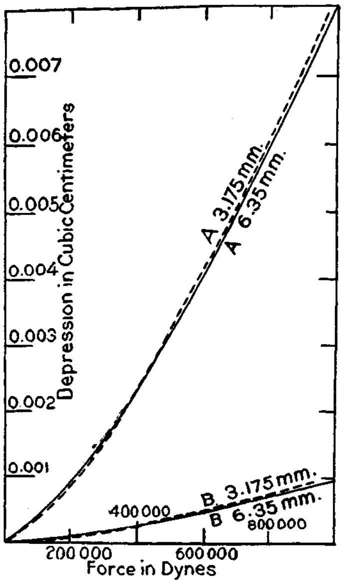

FIG. 35.—Force-volume depression curves for 2 samples of vulcanized rubber (steel balls 3.175 and 6.35 mm in diameter) (79).

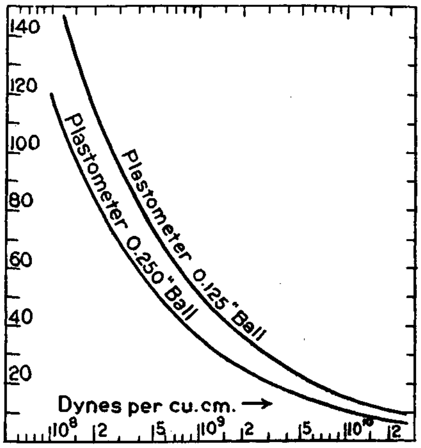

FIG. 36.—Relation between plastometer number and modulus of hardness (79).

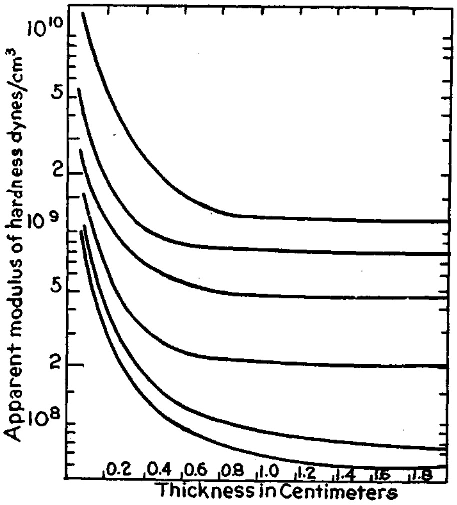

FIG. 38.—Influence of thickness of thin specimens on apparent hardness as determined by the plastometer (6 samples) (79).

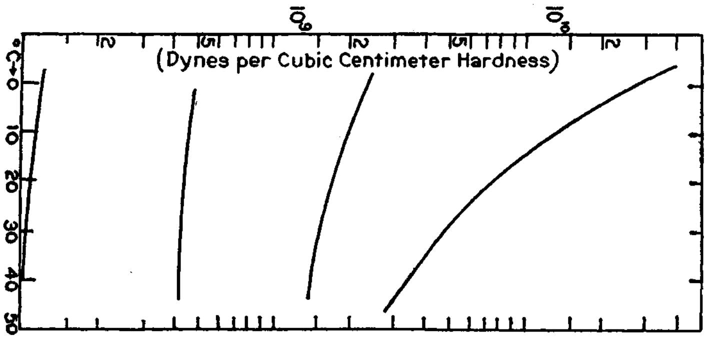

FIG. 37.—Change of modulus of hardness with temperature (4 samples) (79).

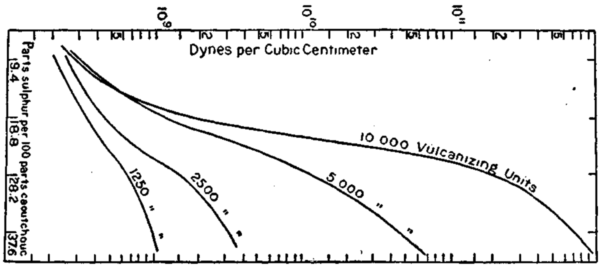

FIG. 39.—Modulus of hardness and degree of vulcanization (vulcanizing unit = (time of vulcanization at t°) × 1.1^{150-t} (79).

ABSORPTION OF WATER

TABLE 85.—ABSORPTION BY RAW RUBBER OF WATER FROM MOIST AIR (130), *cf.* (210)

Relative humidity, %		100	89	79	49	100	89	79	49
Type	Resin %	% absorption at 16°				% absorption at 30°

SELENIUM (228)

In raw rubber: <0.05 % at 80°C.

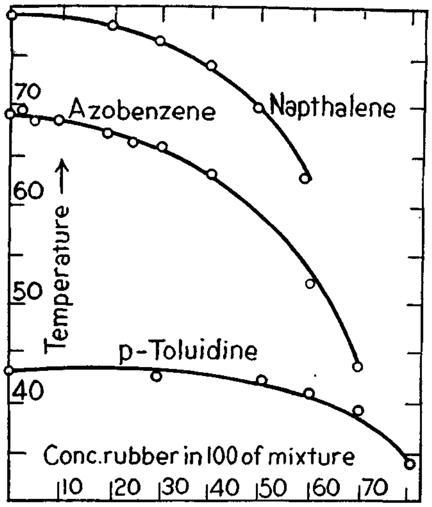

FIG. 42.—Solubility of naphthalene, azobenzene and p-toluidine in raw rubber (27).

Permeability to Gases and Vapors

Permeability is proportional to the partial pressure of the gas and to the thickness of the rubber (44, 59, 89, 229).

SPECIFIC PERMEABILITY

Unit.—cm³ gas/min/cm² area/cm thickness.

Hydrogen.—20.4 × 10^{-6} at 25° (vulcanized rubber on balloon fabric) (59). $(5.520 + 0.876t) \times 10^{-6}$, range 12.8 to 30.7° (sp. gr., 0.9455 at 18 to 20°) (89).

Carbon Dioxide.—$(-5.084 + 2.928t) \times 10^{-6}$, range 9 to 33° (sp. gr., 0.9455 at 18 to 20°) (89).

TABLE 94.—PERMEABILITY RELATIVE TO HYDROGEN AT SAME TEMPERATURE

In (59) samples are vulcanized rubber on balloon fabric. In (44) samples are vulcanized, probably by sulfur chloride

INFLUENCE OF COMPOUNDING INGREDIENTS

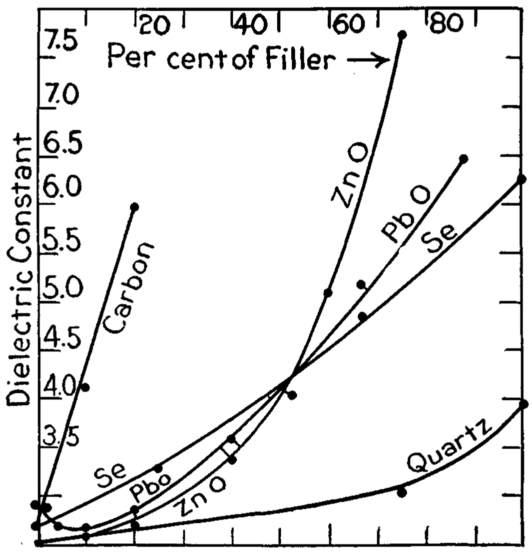

FIG. 49.—Influence of carbon black, ZnO, litharge, Se and quartz on dielectric strength (42).

In the case of ZnO, quartz, and Se, "% of filler" means the parts of filler by weight added to the following basal mixtures:

	Rubber	S	ZnO	Palm oil	Tetramethylthiuram disulfide
Zinc oxide	93.75	2		4	0.25
Quartz	92.75	2	1	4	0.25
Selenium	90.75	4	5		0.25

In the case of litharge " % filler" means the percentage present in the following series of mixtures:

Litharge	0	4	10	20	40	66	88
Rubber	96	88	82	74	52	22	9
Sulfur	4	4	4	6	8	11	1
Ozokerite		4	4				
Palm oil						1	2

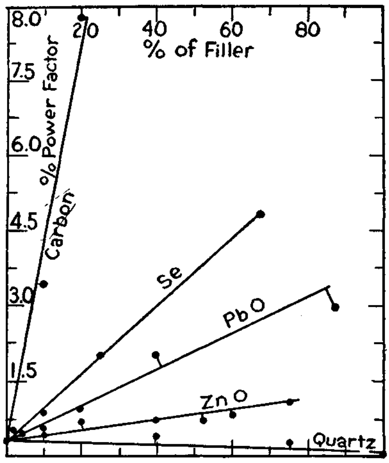

FIG. 50.—Influence of filler on the power factor at optimum cure (42); *cf.* note to Fig. 49.

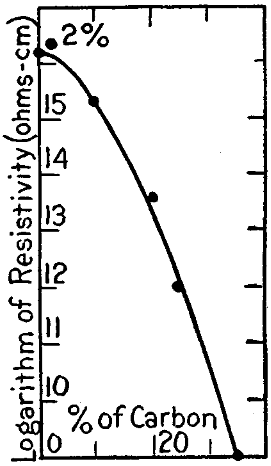

FIG. 51.—Influence of carbon black on the resistivity (42).

TABLE 104.—INFLUENCE OF BARYTES, "TITANOX," IRON OXIDE, TELLURIUM, CHINA CLAY AND ASBESTINE (42)

Stock No. 1: smoked sheet, 90.75; S, 5; ZnO, 4; tetramethylthiuram disulfide, 0.25%. Stock No. 2: smoked sheet, 90.75; S, 5; ZnO, 4; diphenylguanidine, 1%

Rubber mixture, %	Dielectric constant, 1000 ~	Power factor, %	Resistivity (10^8 megohm-cm)

No. 1 + tellurium, 25	3.20	0.50	85
No. 2	2.62	0.75	190
No. 2 + china clay, 49	3.27	1.13	170
Rubber, 41; S, 2; ozokerite, 5.4; tetramethylthiuram disulfide, 0.1; asbestine, 50	4.24	2.1	14

* Approximate composition: titanium dioxide, 25; barium sulfate, 75%.

INFLUENCE OF SOFTENERS

In a stock cured by the aid of tetramethylthiuram disulfide, the following softeners have little effect on the dielectric constant: ozokerite, 10; vaseline, 10; beeswax, 10; stearic acid, 10; palm oil, 5 parts.

The following increased the dielectric constant from 2.67 to the figures noted: *p*-coumarone resin, 10, to 2.80; mineral rubber, 33, to 2.88 (42).

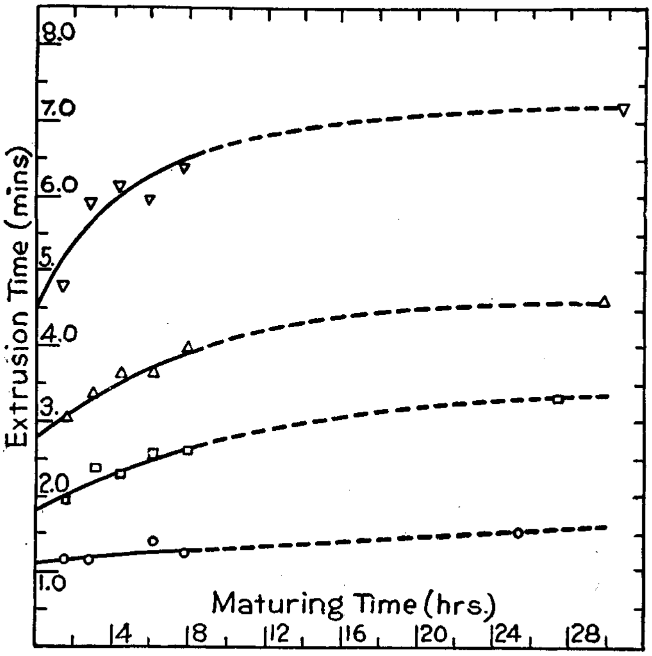

FIG. 54.

Recovery from Milling

Figure 54 shows the recovery from milling (expressed as maturing time/plasticity) of the same batch of typical pale crepe rubber milled to different degrees of plasticity and then allowed to remain at room temp. in the form of rolls 25 cm long × 7.5 cm diam. (78); the plasticity is expressed as the extrusion time in a Griffiths' plastometer (*cf.* Table 111).

Figure 55 shows the recovery of rubber (2 samples) from milling as shown by the viscosity of solutions (2 g in 97 cm³ CS_2) after storage for various periods (123).

FACTITIOUS PLASTICS

A. NITROCELLULOSE ("PYROXYLIN") PLASTICS[1]

Made by the application of heat and pressure to colloidal mixtures of pyroxylin with relatively non-volatile solvent (camphor or substitute for camphor) and volatile solvent (usually ethyl alcohol), followed by evaporation of the volatile solvent; ordinarily containing sufficient non-volatile solvent to insure "plasticity" at 75–90°C—*e.g.*, celluloid, fiberloid, pyralin, pyradiolin, viscoloid, xylonite.

Except as otherwise noted, the data given are for the freshly manufactured, commercial type of camphor product. Photographic film is not covered.

1. *Composition.*—Varies according to manufacturer. The following are illustrations:

PYRALIN (7)

Pyroxylin 11% N	Camphor	Stabilizer	Residual volatile solvent	Additions: dyes, pigments, etc.
68–75%	23–27%	0.5–1%	1–5%	0–14%

VARIOUS FOREIGN AND DOMESTIC SAMPLES (21)

Nitrocellulose	Camphor + solvent	Ash
58–78%	17–31%	0.7–28%

Mechanical

2. *Density.*—g cm^{-3}. 1.35 (transparent) to 1.60 (commercial pigmented material)(7). $d = 1.37 + 0.0125p$, where $p = \%$ ZnO between 1 and 15 (14). For influence of stretching *v.* (16).

3. *Permeability.*—Transparent material of thickness 0.030 in., exposed on one surface to atmosphere dried by $CaCl_2$ and on other side to summer atmosphere, transmitted moisture at rate of 0.013 g per in.^{2} per week (7).

Pyralin, from saturated air to air dried by $CaCl_2$, 0.0046 resp. 0.063 in. thick, transmitted moisture at the rate of 0.029 resp. 0.004 g in.$^{-2}$ day^{-1} in three days (7).

4. *Modulus of Elasticity* (Def. 10*a*).—Young's modulus = $(2.0 \text{ to } 3.9) \times 10^5$ lb. in.$^{-2}$ (**5, 7, 11, 12, 16, 17**). Exhibits hysteresis (13).

5. *Elastic Limit.*—Yield point = $(3.9 \text{ to } 7.4) \times 10^3$ lb. in.$^{-2}$. Varies with thickness and pigment content (**5, 7, 12, 16**).

6. *Poisson's Ratio.*—0.36 to 0.43 (**5, 11**).

7. *Tensile Strength* (Def. 4).—Varies with thickness, nature of nitrocellulose, camphor content, and pigment content. $(4.9 \text{ to } 8.5) \times 10^3$ lb. in.$^{-2}$ (**7, 11, 12**); 6 kg mm^{-2} (5). Variation with temp. °C; 20°, 7.5; 70°, 4.5; 90°, 1.0; $\times 10^3$ lb. in.$^{-2}$ (7).

8. *Ultimate Elongation at Failure.*—From 10% for 0.005 in. thick up to 40% for 0.2 in. thick; for 0.015 in. thick, from 20 to 30% for 0 pigment, to 15 to 25% for 16% pigment (7), *cf.* (**4, 5**).

9. *Resistance to Bending.*—Schopper's folding endurance tester. Sample $0.5 \times 4.0 \times 0.015$ in., double bends of 100° required to break $(B_D) = 8$ to 22. $B_D = k \times (\text{thickness})^{-1.35}$ (7).

---

[1] Acknowledgment is made to Mr. A. F. Randolph, du Pont Viscoloid Company, for a critical examination of this section.

10. *Hardness.*—Brinell, 10.7 to 11.7 ([20]). $H = \text{const.} - (0.05 \times \%\ \text{ZnO})$, approx. between 1 and 15%. Method of penetration by loaded sphere ([14]).

11. *Coefficient of Friction.*—Static, of polished material on self, glass, paper, or planed wood, 0.25 to 0.35 ([7]).

12. *Viscosity.*—Solutions in camphor-alcohol ([15]).

Thermal

13. *Thermal Expansion.*—$\frac{1}{l}\frac{dl}{dt}$ (20–50°C) = $(12 \text{ to } 16) \times 10^{-5}$ ([19, 20]).

14. *Heat Capacity (Specific Heat).*—0.34 to 0.38 cal g^{-1} °C^{-1} ([20]).

15. *Thermal Conductivity.*—Cal $\text{cm}^{-2}\ \text{sec}^{-1}\ (°\text{C}, \text{cm}^{-1})^{-1}$. 3.1×10^{-4} ([20]). 5.14×10^{-4} ([22, 27]).

16. *Working Range for Molding.*—85 to 120°C ([7]).

17. *Permanent Shrinkage on Heating.*—1.4% after two heatings to 100° in air ([18]); 0.5–1% ([7]). Variable, depends on amount of internal strain.

18. *Flash Point.*—141 to 185°C for 0.3 g of powder heated 3° per min ([15]). 160 to 200°, for material of good quality ([7, 9]). 550 to 640° for edge contact with hot porcelain rod ([21]).

19. *Loss in Weight at 110°.*—Very variable ([7, 9]), *cf.* ([21]).

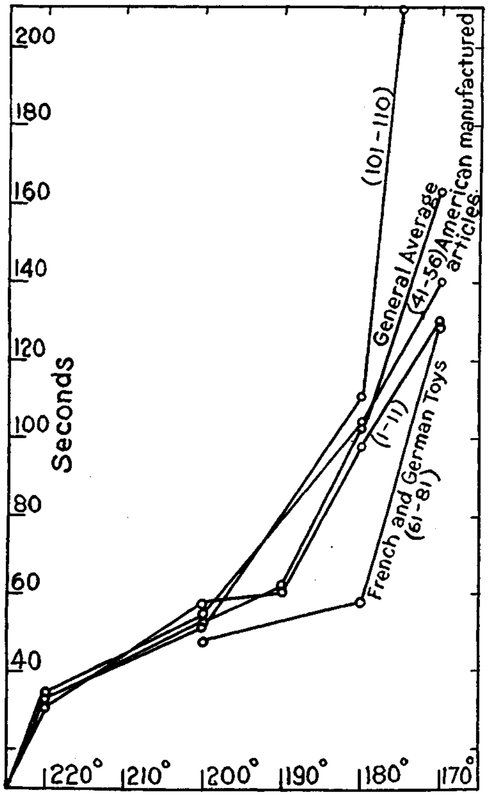

FIG. 1.—Average explosion times.

20. *Explosion Times.*—([21]). For improved method of test, *v.* ([24]).

Time in seconds	Temperature of metal, °C	Transparent pyralin		Pyradiolin	
		A	B	A	B
(A) to the start, (B) to the finish, of fuming-off or burning of 0.5 × 0.5 × 0.06 in. samples thrown on surface of molten metal ([7]).	215	63	65	300	330
	225	59	61	58	85
	235	39	42	50	65

Yellow transparent	64	635
Pyradiolin	59	780
Pyradiolin	60	750

Optical

26. *Refractive Index.*—$n_D = 1.46 \pm 0.03$ (7).

27. *Birefringence.*—Celluloid under tension exhibits birefringence. The *specific birefringence*, $\frac{N_E - N_O}{\%E}$, for Na light (where E is the elongation and N_E, resp. N_O, the refractive indices for the extraordinary and ordinary ray resp.), is 0.046 for 0% camphor and decreases to 0.005 for 50% camphor. For constant tension it increases with time. Data *in re* the after effects of tension on birefringence, density, and dispersion are also given in (5, 10, 11, 16).

28. *Coefficient of Absorption.*—$I = I_0 l^{-kt} = 1.81$ and 1.95, two samples (Na light) (11). Cellulose acetate transmits the ultraviolet down to 230$\mu\mu$ (13).

Chemical

29. *Chemical and Solvent Action of Various Reagents.*—A, Little or no effect at room temperature. B, Superficial attack, blistering or softening. C, Gelatinization. D, Solution with decomposition. E, Good solvent. F, Not solvent, but becomes good solvent on addition of small amounts of camphor. G, Not solvent, but becomes good solvent on addition of large amounts of camphor. H, Can be used as diluent for E. I, Causes precipitation if used as diluent. Not solvent and does not become solvent on addition of camphor (4, 7, 23, 26).

H_2SO_4. <40%, A; 45%, B; 60%, D.

HNO_3. 14%, A; 25%, B; conc. D.

HCl. 13%, A; 25%, B after several days; 35%, B and D.

Acetic acid (CH_3COOH). Dilute, B; glacial, E.

Alkaline solutions. Weak at room temp., B; with increasing strength or temp., D.

Ketones, diacetone alcohol, wood spirit, methyl, ethyl, propyl, butyl or amyl acetate, nitrobenzene, E.

The lower aliphatic alcohols, C, F.

The ethers and the lower aromatic hydrocarbons, G, H.

$CHCl_3$, $C_2H_2Cl_4$, CCl_4, gasolene, turpentine, water, I.

Oils and fats, A, except for castor oil which has slight solvent action.

$SeOCl_2$, E.

Pyridine, D.

30. *Absorption of Water.*—(7).

TESTS ON STANDARD TRANSPARENT MATERIAL

	Symbol	Thickness 0.015 in.	Thickness 0.860 in.
Net gain in weight of seasoned material, resulting from immersion in water,* %	A	1.3 to 2.1	1.6 to 2.3
Hours required to reach approximately maximum wt. and length		24	100 to 200
Net increase in length of seasoned material, resulting from immersion in water,* %	M	0.4 to 0.7	0.5 to 0.7
Loss of weight due to extraction of camphor in 2 months,† %	B	0.6 to 1.0	0.5 to 2.1
Total water absorbed by seasoned material,† %	A+B	2.3 to 2.6	2.8 to 3.2
Loss in weight of seasoned material in atmosphere dried by $CaCl_2$, ultimate, %	C	1.1 to 1.2	1.4 to 1.6
Hours required to reach approximately minimum wt. and length		100 to 200	700 to 1000
Decrease in length over $CaCl_2$, %	N	0.5	0.5 to 0.7
Maximum capacity for moisture, %	A+B+C	3.4 to 3.8	4 to 4.1
Change in length between extremes, %	M+N	1 to 1.2	1.2

* *I.e.*, net effect of absorption of water; extraction of camphor; replacement of alcohol by water (probably negligible).

† Neglecting replacement of alcohol by water.

31. *Molecular Complexity.*—"Films of celluloid have been made on water by evaporation of a dilute solution. The thinnest stable films are 10 Å thick, indicating that the molecular complex of celluloid is not over 10 Å in diameter" (2).

B. PHENOL RESINS AND THEIR PRODUCTS

("Bakelite," "Redmanol," "Condensite," Etc.)

L. V. REDMAN

Commercial Phenol Resins are phenol-formaldehyde condensation products, prepared under conditions that produce a resin capable of becoming hard, strong, insoluble and infusible with application of heat and pressure. Phenol Resin Products include: (1) Pure Resin; (2) Molded Products (employing as fillers wood flour, asbestos or other fibrous materials); and (3) Laminated

Products (prepared from paper or cloth which has been previously impregnated with the uncured resin).

The information given below is based upon data from (1, 2).

Type of Material

Type	Molded, and filled with			Laminated and filled with			Pure resin
	Wood flour	Asbestos	Mica	Paper	Canvas	Cloth	
Symbol	M_W	M_A	M_M	L_P	L_C	L_{Cl}	P

Tensile Strength.—One-half inch figure-8 shaped test pieces for M and P materials (A. S. T. M. [D-48-24]). For L materials, values are parallel to laminations; *v.* (3) for shape of test piece.

Tensile strength = A $\times 10^3$ lb. in.$^{-2}$ = A′ $\times 10^7$ dyne cm^{-2}.

Type	M_M, M_W and M_A	L_P	L_C	P
A......	3.5– 6.0	8.7– 25	8.5–12	5–11
A′.....	24 –40	60 –175	62 –80	35–75

Compressive Strength.—Inch-cube test-piece. (A. S. T. M. [D-48-24].) Compressive strength = A $\times 10^3$ lb. in.$^{-2}$ = A′ $\times$ 10^7 dyne cm^{-2}; at 20° unless otherwise noted; parallel or perpendicular to laminations as indicated.

Type	M_W	M_W, 100°	M_A	$L_P \parallel$	$L_C \parallel$	$L_C \perp$	P
A...	25– 36	12	18– 36	20– 45	20– 25	35– 47	26– 33
A′..	175–250	80	125–250	140–275	140–175	245–330	180–230

Modulus of Elasticity in Tension, Young's Modulus.—M = 1.5–2.5 $\times 10^6$ lb. in.$^{-2}$ = 1.1–1.75 $\times 10^{11}$ dyne cm^{-2} for the L_P material parallel to laminations; *v.* (3) for sample used.

Modulus of Elasticity in Bending.—Samples 12 in. long by 1 in. wide, with 10 in. span. M = load $\times$ span^3 ÷ 4 $\times$ width $\times$ thickness^3 $\times$ deflection at center = 1.1–2.1 $\times 10^6$ lb. in.$^{-2}$ = 75–175 $\times 10^9$ dyne cm^{-2} for the L_P material ⊥ to laminations.

Modulus of Rupture.—Samples 12 in. by 1 in. by 0.25 in.; 10 in. span. M = 3 $\times$ load $\times$ span ÷ 2 $\times$ width $\times$ thickness^2 =, for L_P material, 15 000–30 000, and for P material, 12 500–20 000 lb. in.$^{-2}$ = for L_P, 1.05–2.10 $\times 10^9$ and for P, 0.85–1.40 $\times 10^9$ dyne cm^{-2}.

Impact Behavior.—(*a*) Olsen impact machine. Test piece 2½ in. × 1 in. × ½ in. with edges and corners rounded, 2 in. span. Drop increments of ½ in. between blows, from zero up to the breaking point. The values given below are the sums of the corresponding mass-height products.

Type		M_W	M_A	L_P	$L_C \perp$	P
Σ mh	lb. in.	500–1200	200–540	400–2000	3500–5300	500–1750
	kg cm	575–1380	230–620	460–2300	4000–6000	575–2000

(*b*) Pendulum method. Energy of blow to break a ½ in. square sample. L_P, ∥ 0.3–1.5 lb. ft.; 0.04–0.20 kg m; L_C, ∥ 2–3 lb. ft.; 0.25–0.40 kg m.

Bulk Density and Hardness.—Brinell test by application of 500 kg wt. for 30 sec. Scleroscope test with hard hammer.

Type		M_W	M_A	L_P	L_C	P
d, g cm^{-3}		1.33–1.40	1.78–2.00	1.32–1.40	1.36–1.40	1.20–1.29
Hardness	Brin...	30–38	38–42	35–45	33–38	30–45
	Scler...	78–92	75–95	84–94	60–67	75–110

Water Absorption.—Per cent gain in weight of sample (5 × 10 × 1¼ cm) after 24 hr immersion in water at 20°.

Type	M_W	M_A	L_P	L_{Cl}	P
Per cent gain.....	0.05–0.20	0.05–0.10	0.20–1.0	0.20–2.0	0.05–0.07

Softening Point Under Load.—A. S. T. M. method [D-17-T-1919]. M_W, 125–130; M_A, 130–150; L_P, 125–150; P, 75–100; deg. C. Do not flow under pressure of screw heads and similar forces at ordinary temperatures.

Thermal Expansion and Specific Heat.—Mean coefficient of linear expansion = A $\times 10^{-6}$ per °C between 20 and 70°. Specific heat, c_1 in joules g^{-1} per °C, c_2 in cal g^{-1} per °C or BTU lb.$^{-1}$ per °F.

Type		M_W	M_A	L_P	L_C	P
	A	25–45	20–45	20–30	20–30	50–110
Sp. ht.	c_1, joules....	1.2–1.5	1.5–1.7	1.2–1.7		1.4–1.5
	c_2, cal or BTU.....	0.30–0.36	0.35–0.40	0.30–0.40		0.33–0.37

Electrical Resistivity.—At 20°C and 50% atmospheric humidity the total resistivity (in ohm) is of the order of 10^{10}–10^{11} for most types, that for the M_A material being somewhat lower, 10^8–10^9, and that for the pure resin sometimes higher, 10^{10}–10^{12}. The surface resistivity for L_P (in 10^9 ohm) is 10–90 000 for 24%, 0.9–660 for 50% and 0.1–15 for 84% relative humidity. Exposure to light, especially ultra-violet, decreases surface resistivity.

Dielectric Constant (ε) *and Power Factor.*—At radio frequencies. Phase difference = power factor (P. F.) × 0.57.

Type	M_W	M_M	L_P	L_{Cl}	P
ε.........	4.5–7.5	4–5	4.5–6.0	4.5–6.0	4.5–7.0
P. F., %..	1.5–7	0.5–1.5	1.5–5	2–7	0.2–3

Dielectric Strength.—A. S. T. M. low frequency test. L and P materials in 1/32 in. sheets.

Type	M_W	M_A	L_P	L_C	P
Volts mil^{-1}..........	250–700	150–500	750–1300	250–500	250–700
Kilovolts cm^{-1}......	100–280	60–200	300– 500	100–200	100–280

Flash-over Voltage.—Between two 2 cm skirted brass studs 2 cm apart. Radio frequencies, L_P, 18–28; L_C, 18–25 kilovolts.

Optical Properties.—For the pure resins, n_D^{20} = 1.62–1.70. Quite transparent in the infra-red. Darkening occurs on long exposure to sunlight.

Miscellaneous Effects.—Exposure to (1) steam, does not affect mechanical properties but increases water absorption; (2) weak acids, no effect; (3) strong acids, charring of the organic fillers; (4) strong oxidizing acids, disintegration of the resin; (5) mild alkalis, softening; (6) strong alkalis, disintegration; (7) organic solvents, no effect; (8) aging, no effect.

C. COMPARISON OF PROPERTIES OF HARD RUBBER, VULCANIZED FIBER, LAMINATED AND MOLDED PHENOLIC INSULATING MATERIALS[1]

Hard rubber is composed of crude rubber, sulfur, and usually some mineral filling compound. The relatively high cost of crude rubber had induced some makers of hard rubber to use reclaimed rubber or else load the new rubber with a high percentage of mineral filler. The lack of a proper understanding of this fact between the maker and the user has often resulted in unjust censure of hard rubber as an insulator. The better grades of hard rubber are made of new rubber containing no mineral filler

---

[1] Dellinger and Preston, *32*, **216**: 619; 22.

and are free from excess sulfur. With these points in mind it is evident that the values assigned to a particular property or the effect of a certain test must necessarily be broad. Neither the best nor the poorest grade of hard rubber is considered in the data and opinions given in the following table.

Vulcanized fiber is made of parchmentized paper. For the better grades of fiber, rag base paper is used. The paper is run slowly through a warm concentrated solution of sulfuric acid or zinc chloride, the one solution being used in making fiber sheets one-eighth inch thick or less, the other solution being used for thicknesses greater than one-eighth inch. The purpose of the acid or zinc chloride is to soften the walls of the cellulose (cotton) fibers, so that when several sheets of treated paper are pressed together the fibers tend to mat and cohere. The treated paper is wound on a drum until the cylindrical tube of the desired thickness is obtained, the cylindrical tube being then cut so as to form a sheet whose width is equal to the width of the paper and whose length is equal to the circumference of the drum. The composite sheet of treated paper is then soaked in water to remove the acid or zinc chloride, dried, and pressed. The term "vulcanized" is somewhat misleading. Fiber does not depend upon heat and pressure to cure it as does hard rubber.

Vulcanized fiber varies much in both mechanical and electrical properties. The properties depend somewhat on the quality of rags used, the amount of residual sulfuric acid or zinc chloride, and upon the density of the finished product. Since the various processes of fiber making are difficult to control, the following statements relative to fiber must be taken as general and the recorded numerical data as average data.

The several makes and many grades of *laminated phenolic insulating material* are discussed quite fully in the paper. Any numerical value or statement given in the following summary table is an approximation.

The *molded phenolic insulating materials* are subject to as many variations as hard rubber. There is probably not as much variation in the phenolic resin binder in the molded phenolic materials as there is in the crude or reclaimed rubber binder of hard rubber. There are many other chances for variation in the press pressure and temperature, length of curing in the presses, and kind and quality of filler. Some of the fillers used are wood flour, pulverized mica, and asbestos. The kind and amount of filler will affect both the mechanical and electrical properties. All these possible variations make the data only approximate and require rather general statements in the summary table.

Most of the numerical data given in the table below are from tests made at the Bureau of Standards. The statements concerning the effects of various things on the different insulating materials are based on the experience of various members of the Bureau of Standards staff and upon the experience of the manufacturers of these materials. The manufacturers' experience on hard rubber and vulcanized fiber extends over many years, while the experience on the phenolic insulating materials is much more limited.

While it is possible to make up insulating materials which would give results different from those recorded for any particular property, yet it is believed that this table gives information in a condensed form which will serve to show some of the limitations as well as some of the possibilities of these various materials as now obtainable commercially.

Comparison of Properties of Hard Rubber, Vulcanized Fiber, Laminated and Molded Phenolic Insulating Materials

Properties	Hard rubber	Vulcanized fiber	Phenolic insulating materials	
			Laminated	Molded
Surface resistivity at 50% relative humidity, ohm	10^{12} to $>10^{15}$		10^{11}	10^{11}
Phase differences (ψ) at radio frequencies, deg	0.5*	3.0†	1.5 to 4.0	1.5 to 4.0
Dielectric constant (ϵ) at radio frequencies	3.0*	5.0†	4.5 to 6.0	5.0 to 7.5
Dielectric strength, volt/mm	10 000 to 38 000‡§	9 000 to 16 000‡§	27 000 to 45 000‡§	9 000 to 40 000‡§
Tensile strength, lb./in.^{2}	3 500 to 6 500	9 000 to 20 000	10 000 to 25 000	3 500 to 7 000
Water absorbed in 24 hr, percentage by weight	0.02	26 to 45‖	0.2 to 1.0¶	0.05 to 0.2**
Density, g/cm^3	1.12 to 1.40††	1.3 to 1.5	1.3 to 1.4	1.3 to 1.4
Thermal expansivity (at 20 to 60°C)	60 to 80 $\times 10^{-6}$	27 $\times 10^{-6}$	20 to 30 $\times 10^{-6}$	25 to 45 $\times 10^{-6}$
Effects of various agents				
Age	Deteriorates slowly, but if properly vulcanized and protected from the light it is not affected	Improves in quality by seasoning‡‡	Improves§§	No depreciation in physical or chemical properties; slight increase in hardness§§
Heat	At 65.5°C (150°F) pure hard rubber softens perceptibly; at 100°C (212°F) it is so soft it may be bent easily; at 115.5°C (240°F) it becomes leathery and may readily be cut with a knife; melts at 200°C (392°F)‡	Will not melt under any circumstances; not readily inflammable; at very high temperature chars and becomes brittle; active combustion begins at about 343°C (650°F)	Not readily inflammable; will withstand continuously a temperature of 149°C (300°F); heat tends to complete the reaction and volatile substances are driven off. Hence, when cooled it shrinks considerably and may split; shrinks and loses in weight above 60°C‖‖	See statement for laminated materials for cellulose-filled molded materials. Asbestos-filled and mica-filled materials are much more resistant to heat¶¶

Comparison of Properties of Hard Rubber, Vulcanized Fiber, Laminated and Molded Phenolic Insulating Materials.—(*Continued*)

	Hard rubber	Vulcanized fiber	Phenolic insulating materials	
			Laminated	Molded
Sunlight	Discolors and disintegrates after a few months; the sulfur of the hard rubber is oxidized, forming the equivalent of sulfuric acid; this may take up ammonia from the air or may attack the filling materials and form various sulfates upon the surface; the surface resistivity is greatly reduced***	No effect‡	No visible effect†††	After two and one-half years some materials show a slight change, such as discoloration or very fine cracks; other materials show no such change‡†††
Ultra-violet light for 20 hr	Discolors and disintegrates; the action is as pronounced for a few hours' exposure to ultra-violet light as for many months' exposure to sunlight; the surface resistivity is greatly reduced***	No data	Appreciable lowering of surface resistivity	Appreciable lowering of surface resistivity***
Moist air	Hard-rubber compounds excepting those containing organic substances other than rubber are practically moisture proof	Absorbs water freely, but without permanent injury; while saturated it becomes soft and flexible and swells; warps and twists upon drying	Absorbs slight amount of water, reducing dielectric properties‡‡‡	Absorbs slight amount of water, reducing dielectric properties
Steam	The only effect is that due to the high temperature	Same as above, except absorption is more rapid	Best grades not affected beyond slight absorption of moisture; after a few days in steam the cheaper grades will swell appreciably and split; superheated steam tends to warp and blister all grades of the material	Absorbs a slight amount of moisture; if steam is superheated, the high temperature will cause decomposition of cellulose-filled materials. The mineral-filled materials are much more resistant to heat
Solvents:				
Acetone	Attacks, dissolving oils and free sulfur‡	No permanent effect‡	No effect‡§§§	No effect‡§§§
Alcohol	Attacks to a slight degree‡	No permanent effect‡	No effect‡§§§	No effect‡§§§
Ammonia	No effect‡	No permanent effect‡	Strong solutions may cause material to swell‡	No effect other than slight absorption of moisture‡
Aniline	Softens at ordinary temperature‡	Not known	Probably no effect‡	Probably no effect‡
Benzene	Softens at ordinary temperature‡	No permanent effect‡	Probably no effect‡§§§	Probably no effect‡§§§
Carbon bisulfide	Dissolves small amount of hard rubber and any free sulfur‡	No permanent effect‡	Probably no effect‡§§§	Probably no effect‡§§§
Ether	Dissolves small amount of hard rubber and any free sulfur‡	No permanent effect‡	No effect‡	Probably no effect‡§§§
Naphtha	Softens and swells to slight extent‡	No permanent effect‡	Probably no effect‡	Probably no effect‡§§§
Oil of turpentine	Dissolves in boiling oil‡	No permanent effect‡	Probably no effect‡	Probably no effect‡§§§

Comparison of Properties of Hard Rubber, Vulcanized Fiber, Laminated and Molded Phenolic Insulating Materials.—(*Continued*)

	Hard rubber	Vulcanized fiber	Phenolic insulating materials	
			Laminated	Molded
Oil:				
Mineral	Slight softening[‡]	Slight absorption[‡]	Practically impervious[‡]	Practically impervious[‡]
Organic	Unaffected[‡]	Slight absorption[‡]	Practically impervious[‡]	Practically impervious[‡]
Weak acids	Unaffected[‡]	Swells due to absorbed water; may be attacked after some time[‡]	Practically unaffected except for absorption of water[‖‖]	Practically unaffected[¶¶¶]
Weak caustic alkalis	Unaffected[‡]	Swells due to absorbed water; may be attacked after some time[‡]	Does not successfully resist the action of alkali unless very dilute	Does not successfully resist the action of alkali unless very dilute
Stronger acids (HNO_3, HCl, H_2SO_4)	Not attacked by concentrated hydrochloric, hydrofluoric, acetic acids; not attacked by sulfuric acid of less than 1.50 specific gravity or nitric acid of less than 1.12 specific gravity[‡]	Cellulose fiber attacked; soon decomposes	Decomposes; rapidity depends on specific gravity and temperature of acid	Cellulose-filled materials decompose; rapidity depends on specific gravity and temperature of acid. Molding materials made with acid-resistant fillers, such as mica, offer much greater resistance[****]
Stronger caustic alkalis	No effect	Cellulose fiber attacked; soon decomposes	Binder and filler decompose[¶¶¶]	Completely destroyed; speed of the reaction depends on the strength of the solution
Ozone	Oxidizes and soon ruins for electrical purposes	No effect[‡]	Not known	Not known
Metallic inserts	Rapidly deteriorated by contact with iron or copper, the metals themselves being corroded; the inserts should be coated with tin, paper, unvulcanized rubber, or other mutually protecting medium	No effect[‡]	No effect	No effect
Miscellaneous				
Machining qualities	Admits of a high polish; machines less accurately than would be supposed, due to great resiliency; the better the grade the more readily it is machined; quality may be judged roughly by color and texture, toughness, color, and grain of a shaving; has tendency to warp; can be molded but not accurately to size	Admits of a fine finish; may be sawed, punched, drilled, stamped, embossed, turned, planed, bent, tapped; tough, resists shock; can not be molded[††††]	Admits of a good polish; can be sawed, punched, drilled, stamped, turned, planed, knurled, embossed, milled, tapped either with or against the grain, though not as easily as hard rubber and vulcanized fiber; tough, resists shock; cannot be molded[††††]	Admits of a fine lasting polish; can be machined, cut, filed, sawed with difficulty; can be molded accurately to size; quite brittle
Cost (1922)	About $2 per pound in sheet form	50–80 cents per pound up to 1 inch in thickness; about $5 per pound for 2 inches in thickness	About $1 per pound	Cost varies with complexity of steel molds

---

[*] These values were obtained at frequencies between 750 000 and 75 000 cycles per second (400 to 4000 meters wave length), there being very little change throughout this range. The grade of the sample tested is unknown, so values differing somewhat from these might be expected on other samples using different quantities and kinds of filler.

[†] Values of ψ and K may be somewhat lower or much higher, depending on amount of moisture present in the fiber.

‡ Information obtained from sources other than the Bureau of Standards.

§ Values vary with the thickness of sample, kind of filler, shape of electrodes used, rate of increase of voltage, as well as atmospheric conditions under which tests are made.

‖ The Railway Signal Association specifications require an absorption when immersed in water at 70°F for 24 hours, not to exceed 45% by weight for one-eighth inch fiber, 30% for three-sixteenth inch fiber, and 26% for one-fourth inch fiber.

¶ Dependent upon nature of surface, surface area, and kind and amount of filler.

** Varies with polish of mold, press pressure, and temperature, length of curing, ratio of resin to filler, kind of filler, and size of sample.

†† The density depends on the amount of sulfur present and increases with the increase in amount of filler. Pure hard rubber ranges from 1.12 to 1.25. A fair commercial quality ranges from 1.25 to 1.40.

‡‡ This means seasoning or aging in a protected place, such as a storage house.

§§ These materials are of comparatively recent development, and hence no information has been gained covering very long periods. Theoretically, under certain conditions the chemical reactions would tend to continue, which would age and improve the material. One manufacturer claims a slight improvement in dielectric properties and a marked improvement in machining qualities when the aging takes place under ordinary atmospheric and temperature conditions. If the aging takes place in a moist atmosphere, the dielectric properties are subject to deterioration.

‖‖ *See* pages 580 to 583 of Technologic Paper, U. S. Bureau of Standards, No. 216.

¶¶ When subjected to temperatures above 60°C (140°F) some of the volatile matter is driven off, resulting in the shrinking and loss in weight of the material. This can be carried out many times with the same result, the material becoming more brittle. Tests made on these materials show that they are very erratic in behavior and do not expand or contract in a uniform way. It seems altogether probable that a point would be reached after all volatile matters had been driven off, when further subjection to a moderate temperature and subsequent cooling would not result in further shrinkage. This has not been proved experimentally. High temperature will produce decomposition. Further information regarding these tests will be found in Scientific Paper of the Bureau of Standards No. 352. (*See also* pages 580 to 583 of Technologic Paper, U. S. Bureau of Standards, No. 216.)

*** A further discussion of the tests at the Bureau of Standards may be found in Scientific Paper of the Bureau of Standards, No. 234.

††† *See* effect of ultra-violet light.

‡‡‡ *See* discussion on pages 599 and 600 of Technologic Paper, U. S. Bureau of Standards, No. 216.

§§§ Strong solvents affect the phenolic binder of the material to a limited extent unless the chemical reaction has been carried to the point where it is in the insoluble state. This condition would render the sheet material too brittle for general use. When water is present, the material will absorb it in various amounts.

‖‖‖ The effects vary with the materials, different molding mixtures, and acids. Nitric acid is harmful. In general weak acids will mar the surface and attack the edge of a sample soon after they come in contact with the sample, but there is little or no further change.

¶¶¶ *See* page 608 of Technologic Paper No. 216.

**** The action differs for various materials and grades. Some materials resist the action of a 30% solution of H_2SO_4 for several months and will withstand hydrochloric acid without any visible sign of attack. On other materials of this class sulfuric and nitric acids attack the surface of the sample and form a protective coating. This ruins the sample as far as further electrical use is concerned, but on removing the sample from the acid and cutting it open it is found that the acid has not penetrated more than one-sixteenth inch after several months' exposure to the acid.

†††† Thin sheets can be pressed to simple shapes when warm.

COMMERCIAL CARBONS FOR ELECTRICAL USES

N. K. Chaney

Manufactured carbon articles in the form of rods, plates, blocks, tubes, etc. in a wide variety of shapes are made by molding or extruding specially prepared mixtures of pulverized carbon "flours" with binding materials of tar or pitch, and subsequently carbonizing the binder at high temperatures. The resulting products always consist of a porous mass of carbon particles knit together by the residual carbon resulting from the decomposition of the binding materials. Because of the variations inherent in all manufacturing processes the physical properties of commercial carbons are subject to characteristic variations, the allowable range of which is determined by the service and cost requirements of the consumer. A high degree of precision in the individual determinations is therefore valueless, the typical range of variation being alone significant. Individual values where given must be regarded merely as representative.

Characteristic Range in Physical Properties of Typical Grades of Commercial Carbons (5)

	Resistance milliohm-cm	Density, g/cm³		Scleroscope hardness
		True*	Bulk	
Coke electrodes	3.5 –5.0	2.00–2.10	1.53–1.64

A high degree of precision in the individual determinations is therefore valueless, the typical range of variation being alone significant. Individual values where given must be regarded merely as representative.

Characteristic Range in Physical Properties of Typical Grades of Commercial Carbons (5)

	Resistance milliohm-cm	Density, g/cm³		Scleroscope hardness
		True*	Bulk	
Coke electrodes	3.5 –5.0	2.00–2.10	1.53–1.64	
Coal electrodes	3.3 –6.3	1.95–2.10	1.50–1.67	
Brushes:

INSULATING OILS

J. B. WHITEHEAD AND J. H. LAMPE

Only oils commonly used in industrial electrical apparatus are considered in this section. For data on other oils which might possibly meet industrial requirements, reference must be made to other sections of this volume. Among the following data are some for 7 distinct samples of domestic (U. S. A.) oil; these oils are here designated by the letters A to F, inclusive.

On n'utilise dans les appareils électriques que les huiles minérales de paraffine; on n'a considéré que de telles huiles dans cette section. Pour les données relatives á d'autres huiles qui peuvent présenter, éventuellement, une utilisation industrielle, il faut s'adresser á d'autres sections de ce volume. Parmi les données suivantes, il s'en trouve pour 7 échantillons distincts d'huiles indigènes (U. S. A.); ces huiles sont désignées par les lettres A à F, inclusivement.

Es werden nur Mineralöle paraffinischen Ursprunges in den elektrischen Apparaten benützt, nur solche sind deshalb Gegenstand des Abschnittes. Für Zahlenwerte weiterer Öle, welche vielleicht industrielle Beachtung verdienen, muss an anderer Stelle dieses Bandes nachgesehen werden. Unter den folgenden Werten sind 7 von heimischen (U. S. A.) Ölproben vorhanden. Diese Öle sind hier vom Buchstaben A bis einschliesslich F angeführt.

Solo gli olii minerali di paraffina sono adoperati negli apparecchi elettrici, e solo essi perciò sono qui presi in considerazione. Per le caratteristiche di altri olii che potrebbero eventualmente soddisfare alle richieste vedi altri capitoli di questo stesso volume. Tra i valori che seguono sono riportati quelli di 7 campioni di olii degli S. U. A. Questi olii sono indicati con le lettere da A a F inclusa.

TABLE 1.—GENERAL PROPERTIES OF VARIOUS INSULATING OILS

For dielectric strength, *see* Table 2. Bracketed numbers indicate the range of variation; *e.g.*, first entry indicates that *d* varies from 0.846 to 0.915.

Unit of $\rho = 10^{12}$ ohm-cm; of $\epsilon = 1$ cgse; of *P. F.* = 1%; of temperature = 1°C.

	0.20					72.5			72.5

* This is the standard gap recommended by American Society for Testing Materials (1)—1 in. flat disks with square shoulders, spaced 0.1 in. apart. For this gap, the B. D. value for transformer oils should lie in the range 26.4 to 33.4 kilovolt.

TABLE 5.—RELATIVE BREAKDOWN VOLTAGES FOR THREE COMMERCIAL TEST GAPS (1)

(Voltage, gap E_1)/(voltage, gap E_2)

Unit of D and G = 1 in. = 2.54 cm.

E_1	A	B	C
A	1.00	1.80	2.05
B	0.55	1.00	1.20
C	0.50	0.85	1.00
	Disk	Disk	Sphere
D	1	0.5	0.5
G	0.1	0.2	0.15

TABLE 6.—ERROR IN THE AVERAGE OF n TESTS OF DIELECTRIC STRENGTH OF AN OIL

Based on 3000 tests (6, 7)

Unit of error = 1 %.

n	Error	Sphere long*	Sphere short*	Point, sphere
1	Av.	7.8	7.8	8.4
1	Max.	48.5	34.1	44.8
3	Av.	5.2	4.9	4.9
3	Max.	22.4	19.7	19.1
6	Av.	2.7	3.5	4.1
6	Max.	17.5	15.0	14.3

* Average: Long = 27 mm; short = 2 mm.

TABLE 7.—SPARKOVER VOLTAGE BETWEEN CONCENTRIC CYLINDERS (14)

For $\frac{R}{r} > 3.5$ corona appears in transformer oils before sparkover occurs; for $\frac{R}{r} < 3.5$, the sparkover and corona voltages are the same and obey the relation: $g = 36\left(1 + \frac{1.2}{\sqrt{r}}\right)$. g = maximum voltage gradient at surface of electrode, in kilovolt/cm; R, r = radius of outer, inner, cylinder in cm; g_o, $g_c = g_x$ observed, g computed. The * denotes where R/r becomes less than 3.5.

Unit of r = 1 cm; of P. D. = 1000 volt; of g = 1000 volt/cm (R = 3.81 cm).

r	P. D., max.	g_o	g_c
0.238	84.0	127.7	123.8
0.317	85.5	108.1	112.7
0.635	98.3	86.3	90.3
0.794	106.1	85.5	84.6
0.952	103.2	78.1	80.2
1.111*	108.5	79.4	76.9
1.270	107.5	77.0	74.3
1.587	104.3	75.1	70.4
1.905	93.7	70.7	67.2
2.540	64.3	62.4	63.1

TABLE 8.—INFLUENCE OF MOISTURE ON DIELECTRIC STRENGTH

Kilovolt (kv) for breakdown; disks, D = 0.5 in., G = 0.2 in.; temp. 25°C; U. S. A. Oil F (13, 14)

Water, volume in 10 000	0	0.5	1.0	2.0	5.0	10.0
Kv, 60 cycles, maximum	62.3	33.5	33.4	31.7	27.3	25.4
Kv, constant voltage	61.5	34.7	34.3	30.2	24.7	23.0

Ryan (17), Tobey (23), Peek (13, 14, 15), and others (11, 16, 2) show that moisture in very small quantities decreases the dielectric strength of insulating oil.

Hirobe (8), McLaughlin (9), Stern (22), Spath (21), and Schroter (19) agree experimentally that moisture has little effect on the dielectric strength of the purest oils. The potent causes of low dielectric strength are fibers and dust particles in the oil.

Their effect is increased by the presence of moisture (*cf.* Table 9). For methods and effect of cleaning electrodes, *see* (8).

TABLE 9.—DIELECTRIC STRENGTH: EFFECT OF CLEANING AND DRYING THE OIL (19)

F = effective field strength at which breakdown occurs

Unit of F = 1000 volt/cm; of $\%\Delta = 1\%$.

Condition of oil*	F	$\%\Delta$
As delivered	48.5	75
Filtered through 4 mm clay wall	115.0	50
Centrifuged	124.0	30
Filtered through ordinary filter paper	163.0	35
After prolonged drying by heat	184.0	40
Prolonged drying by heat and filtered once through celloid filter	232.0	8
As in preceding, but filtered twice	332.0	7

* Each line of the table is complete in itself; tests were not successive.

TABLE 10.—RESISTIVITY (R) AND DIELECTRIC STRENGTH (S) OF DRY OIL: VARIATION WITH TEMPERATURE (23)

R is expressed in terms of the resistance between disks, D = 4 in., G = 0.44 in.; S in terms of the effective breakdown P. D. between spheres, D = 0.5 in., G = 0.15 in. Approximately $S = S_{25} - 0.13\ (t - 25°)$ kilovolt (1); t = temperature, °C; S_{25} = value of S at 25°C.

Unit of S = 1000 volt; of $R = 10^6$ ohm; of t = 1°C.

Temperature (t)	30	40	50	60	70	80	90°C
Strength (S)	33	35	36	37	38	39	41
Resistivity (R)			1225	960	570	360	250

INSULATING SOLIDS

F. MALCOLM FARMER

Because of inherent variations in composition and physical condition of both manufactured and natural products, no single value can be assigned to any of the various properties of solid electrical insulators. Furthermore, the value obtained in the measurement of many electrical properties depends upon the method employed and the conditions under which the test was made. For example, in determinations of either the volume or the surface resistivity, the result will depend upon the voltage employed, the duration of its application, temperature, humidity, etc. No standard procedure has yet been established for determining the various quantities. The available data have been obtained under a great variety of conditions and with many different procedures (which, in most cases, are not fully stated) so that the selection of values for these tables has been a matter of judgment, the aim being to select those values which it is believed are most typical and, consequently, the most reliable for general application. Some of the principal sources from which data have been obtained are named on p. 311. Discussions of some of these variable factors will be found in (1, 3, 9); for bibliographies, *see* (2, 18, 19).

Par suite des variations inhérentes à la composition et aux conditions physiques des produits manufacturés et naturels, il n'est possible d'assigner une valeur unique à aucune des propriétés variées des isolants électriques solides. De plus, les valeurs obtenues par les mesures de plusieurs propriétés électriques dépendent de la méthode employée et des conditions dans lesquelles l'essai a été effectué. Par exemple, dans les déterminations de la résistivité du volume et de la résistivité superficielle, le résultat dépend du voltage employé, de la durée de l'application, de la température, de l'humidité, etc. Aucune procédure type n'a encore été établie pour déterminer les quantités variées. Les données disponibles ont été obtenues suivant une grande variété de conditions et avec des procédures différentes (qui, dans la plupart des cas, ne sont pas complètement spécifiées); de sorte que la sélection des valeurs pour ces tables a été une question de jugement, l'objectif étant de choisir celles des valeurs qui étaient présumées les plus typiques et par conséquent les plus dignes de confiance pour l'application générale. Quelques unes des sources principales dont ont été tirées les valeurs sont indiquées à la page 311. On trouvera les discussions relatives à quelques uns des facteurs variables à (1, 3, 9); en ce qui concerne la bibliographie, *voir* (2, 18, 19).

Entsprechend der eigenartigen Änderung in der Zusammensetzung und des physikalischen Zustandes der festen Isolatoren, kann man sowohl den künstlichen als auch den natürlichen Produkten keinen einzelnen Wert ihrgend welcher der verschiedenen Eigenschaften zu ordnen. Es hängt ferner der gemessene Wert vieler elektrischer Eigenschaften von der angewandten Methode und den Bedingungen unter welchen die Probe ausgeführt worden ist, ab. Z. B. bei der Bestimmung des Oberflächen Widerstandes wird das Ergebnis von der angewandten Volt-Zahl, der Dauer der Einwirkung, der Temperatur, der Feuchtigkeit u. s. w. abhängen. Bis jetzt ist keine diesbezügliche Standardmethode zur Messung der verschiedenen Grössen aufgestellt. Die erreichbaren Daten sind unter den verschiedenen Bedingungen und sehr verschiedenen Prüfungsvorgängen (die in vielen Fällen auch nicht ganz angegeben sind) erhalten. Es ist deshalb diese Auswahl nach besonderem Urteil gemacht worden, mit dem Ziel im Auge, diejenigen Werte herauszugreifen, die man als die typischesten ansieht und demzufolge allgemein am zuverlässlichsten sein werden. Einige der hauptsächlichsten Quellen aus denen die Werte geschöpft wurden sind Seite 311 angegeben. Zur Diskussion einiger der veränderlichen Faktoren, (1, 3, 9), Literatur dazu, *siehe* (2, 18, 19).

A causa di alterazioni nella composizione e nello stato fisico sia dei prodotti artificiali che naturali, non si può assegnare un valore determinato alle varie proprietà degli isolanti elettrici solidi. Inoltre, il valore ottenuto nella misura di molte proprietà elettriche dipende dal metodo impiegato e dalle condizioni nelle quali la prova è stata fatta. Per espempio, quando si determina la resistività di volume o di superficie, il risultato dipende dal voltaggio adoperato, dalla durata di applicazione, dalla temperatura, dalla umidità, ecc. Non è stata ancora stabilita una procedura uniforme per determinare le varie grandezze.

I dati disponibili sono stati ottenuti in condizioni molto diverse e con metodi differenti (il più delle volte neppure completamente indicati); per modo che la scelta dei valori per queste tabelle è stata fatta con un certo arbitrio e con lo scopo di raccogliere i valori ritenuti più tipici e quindi suscettibili di una più generale applicazione.

Alcune delle fonti principali dalle quali i dati sono stati tratti sono indicate a pag. 311. Per la discussione di alcuni dei fattori variabili si veda (1, 3, 9) e per le indicazioni bibliografiche si veda (2, 18, 19).

Manufacturers Mentioned in this Section

M1	Alberene Stone Company, New York, N. Y.
M2	Chicago Mica Company, Chicago, Ill.
M3	Continental Fibre Company, Newark, Del.
M4	Electrose Manufacturing Co., Brooklyn, N. Y.
M5	Garfield Manufacturing Co., Garfield, N. J.
M6	General Electric Co., Schenectady, N. Y.
M7	General Insulate Co., Brooklyn, N. Y.
M8	Hemming Manufacturing Co., Garfield, N. J.
M9	Irvington Varnish and Insulator Co., Irvington, N. J.
M10	Mica Insulator Co., Schenectady, N. Y.
M11	Minerallac Electric Co., Chicago, Ill.
M12	Mitchell-Rand Mfg. Co., New York, N. Y.
M13	National Vulcanized Fibre Co., Wilmington, Del.
M14	Spaulding Fibre Co., Inc., Tonawanda, N. Y.
M15	D. M. Stewart Manufacturing Co., Chattanooga, Tenn.
M16	Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa.

TABLE 1.—INDEX AND DESCRIPTION OF MATERIALS

Glass, *v.* p. 87, porcelain, *v.* p. 66, rubber and rubber products, *v.* p. 254, phenol condensation products, *v.* p. 296

I. Bituminous, Wax and Molded Materials

INDEX No.

1. Ambrion.—A molded product (German). Asbestos, impregnated with a pitch or rosin binder. Several grades—some fireproof, some limited to 80 to 100°C.

2. Asphalt.—Various grades known as bitumen, byerlite, elaterite, gilsonite, manjak, and mineral pitch. A black, natural product found in various parts of the world. Used extensively as base for insulating varnishes, for impregnating insulating materials, and (in Europe) for insulating wires and cables (instead of rubber). Hard at ordinary temperatures, plastic at 40–60°C, melts at 100–200°C, depending upon purity.

3. Beeswax.—The secreted substances of which the bee's honeycomb is constructed; yellow; agreeable odor and taste. Solid at ordinary temperatures, plastic when warm, melts at 62–64°C.

4. Ceresin.—A yellow or white wax made by purifying and bleaching ozokerite (*see* 10). Used extensively in manufacture of insulating compounds.

5. Electrose.—Trade name for a product manufactured and molded by M4; working temperature limit, about 90°C.

6. Gummon.—Trade name for a coal tar and asbestos product manufactured and molded in desired shape by M5. Black, hard, dense, not easily drilled or sawed, can be highly polished, and will withstand 200°C indefinitely.

7. Hemit.—Trade name for a coal tar and asbestos product manufactured and molded in desired shape by M5. Hard, dense, not easily drilled or sawed; withstands temperature of 600 to 800°C. Grade "B" is gray and hygroscopic; grade "A" is impregnated, making it black and more nearly waterproof.

8. Insulate.—Trade name for a mineral product manufactured and molded in desired shape by M7. Non-hygroscopic; maximum working temperature, 70°C.

9. Minerallac.—Trade name for asphaltic base insulating material manufactured by M11 in various grades for different applications (principally cable joints, cable terminals, etc.). Some grades semi-liquid, others semi-solid at 25°C. Moisture-proof.

10. Ozokerite (*See* Ceresin).—A natural, mineral wax material, usually associated with rock salt or gypsum; found throughout the world, but principally in Galicia. Is probably paraffin resulting from natural decomposition of petroleum. Natural color brown or black, but white when purified; melts at 110°C.

11. Paraffin.—Translucent, more or less colorless wax material obtained in the distillation of petroleum. Various commercial grades; melts at 45 to 80°C, depending upon grade; unaffected by ordinary acids and alkalies.

11(*a*). Petrolatum.—A neutral and purified residue derived by distillation of petroleum. Three forms—liquid, soft, and hard. The soft form is a grease similar to vaseline and is used extensively as an impregnating material for paper insulated cables; melts about 50–55°C; electrical properties vary greatly with the purity.

12. Rosin.—A variety of resin. Product of distillation of oil of turpentine from crude turpentine.

13. Tegit.—Trade name for a coal tar and asbestos product manufactured and molded in desired shape by M8. Uses limited to 200°C.

II. Fibrous Materials and Fiber Products

14. Cellulak.—Trade name for laminated paper insulation manufactured by M9. Processed under heat and pressure. Hard, tough, readily machined.

15. Cellulose.—A carbohydrate similar in chemical composition to starch. When pure, is amorphous and white; is basis of practically all fibrous insulating materials. Unsized, well bleached linen paper is practically pure cellulose.

16. Conite.—(*See* 18.) Trade name for a thin, hard, vulcanized fiber prepared by M3 with special care to insure its freedom from acid.

17. Empire Cloth.—Trade name of M10 for various varnished cloths having coatings of linseed-oil base (*see* 29).

18. Fiber, Vulcanized.—Also known as fiber, horn fiber, hard fiber, indurated fiber, leatheroid, etc. Made by treating layers of paper stock made from pure cotton cellulose (old cotton rags free from dirt, oil, and grease) with concentrated acids or zinc chloride. Compressed under great pressure to desired thickness; soaked and washed in water for long periods to remove acid or chloride; air dried, pressed in steam-heated presses and calendered to final thickness. Hard, tough, bone-like, hygroscopic, absorbs water readily, disintegrates with strong acids, unaffected by organic solvents and oils, becomes brittle at 80 to 100°C sustained temperature, readily machined, various colors. Manufactured by M3, M13, M14, and others.

19. Fish Paper.—Also known as tarpon paper, leather paper, leatheroid, and fiberoid. Prepared in similar manner to vulcanized fiber using cotton rag stock. Flexible; dark gray; thickness about 0.1 to 1.2 mm.

20. Kobak Cloth.—Trade name (M10) for black varnished cambric (*see* 28).

21. Kraft Paper (For cables).—Unsized paper made from wood pulp stock by sulfate process (21*a*). Hygroscopic. Used extensively in Europe in high tension power cables where it is impregnated with an insulating material (21*b*) after application to conductors.

22. Manila Paper (For cables) (*See* 26).—Unsized paper made from old manila rope (22*a*). Used extensively in America on high tension power cables where it is impregnated with an insulating material (22*b*) after application to conductors.

23. Paraffined Paper.—Bond paper coated or saturated with hot paraffin. Used extensively in low voltage electric condensers.

24. Pressboard.—Also known as fullerboard and presspan (in Europe). A high grade cardboard paper made from cotton rag and paper clipping stock. Hygroscopic.

25. Pressboard, Treated.—Pressboard dried (sometimes in vacuum) and varnished (25*a*) or boiled in mineral oil (25*b*) to make it moisture-proof and to increase dielectric strength.

26. Rope Paper (*See* 22).—Paper made from old rope stock (hemp and jute). Compressed but unsized. Hygroscopic.

27. Varnished Cloth (*See* 17, 20, 28, 29, 30, 31 and 33).—Also known as treated cloth. Thin cotton, linen, or silk cloth dried and coated with various thicknesses of various kinds of liquid insulating materials so applied and treated as to produce a smooth, sheet insulating material which is flexible, tough, and uniform in thickness. Great variety manufactured (some under trade names) by M6, M9, M10, M12, M16, and others.

28. Varnished Cambric, Black (*See* 27).—Coated with an asphaltic material and an oxidizing oil. Black, oil-proof, but not moisture-proof; is more flexible, and remains flexible longer, than the yellow cambric; is, also, more resistant to action of corona discharge (*i.e.*, ozone and nitric acid). Thickness, 0.1 to 0.4 mm.

29. Varnished Cambric, Yellow (*See* 27).—Also known as varnished muslin, oiled cambric and oiled muslin. Coated with linseed oil and a resin; filler is yellow and translucent; absorbs moisture, but is oil-proof. Thickness, 0.1 to 0.4 mm.

30. Varnished Duck or Canvas, Black.—Same as black varnished cambric except that the base is duck or canvas. Thickness, 0.4 to 0.8 mm.

31. Varnished Duck or Canvas, Yellow.—Same as yellow varnished cambric except that the base is duck or canvas. Thickness, 0.4 to 0.8 mm.

32. Varnished Paper.—Paper [cotton (bond), linen, and hemp (manila) stock papers, also fish paper] treated like varnished cloth. Treatment greatly increases resistance to moisture absorption and increases dielectric strength (*ca.* 25%).

33. Varnished Silk.—Same as yellow varnished cambric except that base is silk. Thickness, 0.05 to 0.2 mm.

34. Woods, Hard.—Maple, hickory, cherry, ash, and yellow pine principally used. Dried (34*a*) and impregnated with oil (34*b*), paraffin (34*c*) or rosin, either by boiling until evolution of gas ceases or by impregnation under pressure after drying *in vacuo*.

III. Mineral Materials

35. Alberene (*See* soapstone, 47).—A fine grade of natural soapstone uniformly gray in color, free from metallic veins. Marketed by M1. Does not split or shale under intense local heating, such as electric arc. Stated to be capable of withstanding 1300 to 1600°C. Soft, easily machined, sawed, and drilled.

36. Asbestos Paper.—Soft, flexible sheet material made from fibrous asbestos with 15 to 20% cotton. Very hygroscopic.

37. "Lava."—A form of talc (hydrated magnesium silicate), similar to pumice, which, while in its natural state, is formed or machined to desired shape and then baked at 1100°C, making it very hard. It is then not affected by any lower temperature; very porous, but dimensions not affected by absorption of water; slightly affected by HCl, but not by other ordinary acids and alkalis; very light yellow.

38. Lavite.—Trade name for patented product manufactured by M15. Similar to "lava." Compares with glass in hardness; unaffected by temperatures up to 1000°C, or by ordinary acids or alkalis; porous; very light yellow.

39. Marble.—Crystalline limestone which takes a high polish. Pure marble is white; colored marbles contain impurities, such as iron oxide. Much used for electrical switchboards where, because of porosity, it is frequently impregnated with insulating material to increase dielectric strength; often stained black (called marine finish) to prevent discoloration due to oil staining, etc.

40. Mica.—A laminated mineral composed of crystallized anhydrous silicate of aluminum and potash, or soda. Pure mica is transparent, but frequently colored by salts deposited between laminations. Laminations easily separated so that mica can be split down to 0.005 mm. In natural state it is not uniform in quality, is not flexible, and largest pieces are relatively small; hence it is reconstructed, by splitting into thin laminations and cementing together the small pieces, with suitable binders, to form continuous sheets of various thicknesses, which are marketed under trade names (*see* 41 to 45 inc.). Powdered and flaked mica is used in conjunction with suitable binders to make molded insulations (a substitute for hard rubber, etc.). Properties vary considerably with impurity content, and with sources from which obtained, the principal of which are India, Africa, Canada, and United States. The clear variety has highest dielectric strength.

41. Mica Cloth.—Reconstructed mica (*see* 40) with special binder and backed with cloth. Flexible (to various degrees); thickness, 0.1 to 3 mm.

42. Mica Bond.—Trade name for mica cloth, mica paper, and mica plate products manufactured by M2 (*see* 41, 43 and 44).

43. Mica Paper.—Reconstructed mica (*see* 40) with special binder and backed with Japanese paper. Flexible; thickness, 0.25 to 0.5 mm.

44. Mica Plate.—Reconstructed mica (*see* 40) with shellac binder. Not flexible; thickness, 0.25 to 3 mm.

45. Micanite.—Trade name for mica cloth, mica paper, and mica plate products manufactured by M10 (*see* 41, 43, 44).

46. Slate.—Natural rock of clay or mica composition with natural cleavage. Formed by geological processes involving high temperature and pressure. Principal components are silica and alumina with some iron oxides, lime, magnesia, potash, and soda. Slate for electrical purposes is principally the mica variety from Vermont (purple to green), Maine, and Pennsylvania; the last two are dark gray (called black slate). Is hygroscopic and contains relatively large amount of water of composition, hence thorough drying followed by oil treatment or coating with insulating varnish or enamel greatly improves insulating value. Easily machined; takes good polish.

47. Soapstone (*See* Alberene, 35).—A natural, soft stone; a variety of talc. (Also called steatite.) Slightly soapy or oily to touch. Easily machined, drilled, and sawed. Hygroscopic. Withstands temperatures of the order of 1500°C.

IV. Gum Materials

48. Amberite.—(Ambroid.) Compressed scrap amber (fossilized vegetable resin). Equal to native amber in volume resistivity, but surface must be kept clean for high surface resistivity.

49. Copal.—A resinous substance which, when dissolved in alcohol, oil of turpentine, or linseed oil, makes a colorless varnish. Very inflammable; brittle when cold.

50. Shellac.—A crude form of lac, a resinous gum exuded by an East Indian insect, also obtained from sap of certain trees. Shellac dissolved in alcohol is extensively used as an insulating varnish which on drying forms hard, protective coating. Brittle, brown, hygroscopic.

V. Miscellaneous Materials

51. Enamel.—A hard, smooth, and flexible coating baked on magnet wire as substitute for cotton and silk, or in addition thereto. Composition more or less a manufacturing secret, but stated in some cases to be stearin pitch, cellulose acetate, or cellulose nitrate. Applied by running wire through thin bath and rapidly drying each coat by passing through hot oven. Occupies less space than cotton and silk, has greater thermal conductivity; moisture-proof and mineral oil-proof, but more or less soluble in vegetable oil, animal oil, alcohol, turpentine, and coal tar solvents; withstands 100°C indefinitely; breaks down electrically at 300°C.

52. Galalith.—German product manufactured from skim-milk heated with caustic soda and precipitated with acid. The precipitate, in sheet and plate form, is dried, saturated with formaldehyde, and again dried and pressed. Used as substitute for ivory. Translucent and yellowish white; readily shaped, after softening in hot water; rather hygroscopic.

53. Ivory.—Tusks of the elephant, walrus, etc. Hard and white.

TABLE 2.—ELECTRICAL PROPERTIES

Volume resistivity (*see* Vol. I, p. 41) = $R_v \times 10^n$. Surface resistivity (*see* Vol. I, p. 41) = $R_s \times 10^n$. Power factor = cos φ. Temperature = 18 to 25°C except as indicated. Unit of: R_v = 1 ohm-cm; R_s = 1 ohm; frequency = 1 cycle/sec; dielectric constant = 1 cgse (essentially, air = 1); thickness = 1 mm.

Index No.	Material	Resistivity				Dielectric constant		Dielectric strength		Power factor	
		R_v	n	R_s	n	Frequency	Constant	Thickness	Kv/mm	Frequency	cos φ

* For Nos. 38, 39, 46 data are for transverse strength, as noted.

† In machine direction (*i.e.*, lengthwise of majority of fibers). Strength crosswise about half as great.

‡ Modulus of rupture (transverse strength)—probably somewhat higher than tensile strength.

§ Kg per cm of width. Stress in direction of warp. About half as strong when stress is in direction of filler.

THERMAL INSULATING MATERIALS FOR MODERATE AND LOW TEMPERATURES

F. H. Schofield and J. A. Hall

This section covers the various types of commercial insulating materials, associated structural materials and some miscellaneous materials. For the second group of materials reference should also be made to the sections of I. C. T. dealing with these classes of materials.

In the tables below the various materials are assembled in groups which are arranged approximately in the ascending order of the lowest thermal conductivity of any material of the group.

The thermal conductivity, k, is given in 10^{-3} joule cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$, one unit of which = 0.239×10^{-3} g-cal cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$, = 0.192×10^{-3} BTU ft.$^{-2}$ sec^{-1} (°F, in.$^{-1}$)$^{-1}$. *See also* vol. I, p. 25 for other conversion factors.

Cette section comprend les types variés des matières isolantes du commerce, les matériaux de construction associés, et quelques matières diverses. En ce qui concerne le deuxième groupe de matières, il faut aussi consulter les sections des I. C. T. qui traitent de ces classes de matières.

Dans les tables ci dessous, les matières variées sont arrangés en groupes approximativement dans l'ordre ascendant de la conductibilité thermiqué la plus basse du groupe.

La conductibilité thermique, k, est donnée en 10^{-3} joule cm^{-2} sec^{-1}(°C, cm^{-1})$^{-1}$, une unité de celle-ci = $0{,}239 \times 10^{-3}$ g-cal cm^{-2} sec^{-1}(°C, cm^{-1})$^{-1}$, = $0{,}192 \times 10^{-3}$ BTU ft.$^{-2}$ sec^{-1}(°F, in.$^{-1}$)$^{-1}$. Voir vol. I, p. 25 pour d'autres facteurs de conversion.

Dieser Abschnitt behandelt die verschiedenen Typen von handelsüblichen Isoliermaterial, damit zusammenhängendem Material und einigem verschiedenen anderen. Für die zweite Gruppe der Materialien soll auch in dem Teil der I. C. T. nachgeschlagen werden, die diese Klasse von Materialien behandeln.

In der unteren Tafel sind die verschiedenen Materialien in Gruppen angeordnet und zwar ansteigend von dem kleinsten Wert der Gruppe für die thermische Leitfähigkeit.

Die thermische Leitfähigkeit, k, ist gegeben in 10^{-3} Joule cm^{-2} sec^{-1}(°C cm^{-1})$^{-1}$, deren Einheit = $0{,}239 \times 10^{-3}$ g-cal cm^{-2} sec^{-1}(°C, cm^{-1})$^{-1}$, = $0{,}192 \times 10^{-3}$ BTU ft.$^{-2}$ sec^{-1} (°F, in.$^{-1}$)$^{-1}$. Umrechnungsfaktoren, Bd. I, p. 25.

Questa sezione comprende i diversi tipi di materiali isolanti che si trovano in commercio, i prodotti analoghi per costruzioni e materiali varii. Per il secondo gruppo di materiali, si consultino anche le sezioni della I. C. T., che trattano di queste classe di materiali.

Nelle tabelle seguenti, i diversi materiali sono disposti in gruppi approssimativamente secondo l'ordine della conduttività termica, crescente dalla più bassa del gruppo in su.

La conduttività termica, k, e data in 10^{-3} joule cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$, di cui una unità = $0{,}239 \times 10^{-3}$ g-cal cm^{-2} sec^{-1} (°C, cm^{-1})$^{-1}$, = $0{,}192 \times 10^{-3}$ BTU ft.$^{-2}$ sec^{-1} (°F, in.$^{-1}$)$^{-1}$. Vedi inoltre tomo I, p. 25, per altri fattori di conversione.

THERMAL CONDUCTIVITY OF POWDERS UNDER REDUCED AIR PRESSURES

For granular powders, Smoluchowski gives the following formula connecting the thermal conductivity k with the pressure p of the gas in the interstices:

$$k = A \log (1 + ep)$$

where, for a given gas A is a constant depending on the arrangement of the grains and e on the material of which they are composed. For spongy powders this law does not hold. In the following table the conductivity of various powders (having the indicated average grain diameters in mm) is given in hectoerg ($=10^{-5}$ joule) per cm² per sec per (deg. C per cm). Smoluchowski, *Acad. Sci. Crac. Bull.* **5b**: 129; 10 and **8a**: 548; 11.

THERMAL INSULATING MATERIALS FOR HIGH TEMPERATURE

GORDON B. WILKES

	Bulk density, g/cm^{-3}	Max. safe temperature for continuous use, °C	Mean coefficient of thermal conductivity* 600 to 25°C
Insulating blocks composed chiefly of			
1. Diatomaceous earth and asbestos	0.32–0.40	700– 900	0.00072–0.00096
2. Rock and slag wool mixtures	0.26–0.40	700– 900	0.00090–0.00120
Insulating bricks			
1. Diatomaceous earth (natural)	0.48	850–1000	0.00066–0.00108
2. Clay, diatomaceous earth and cork (fired)	0.43	850–1000	0.00096–0.00120
3. Diatomaceous earth and clay (fired)	0.64–0.96	1100–1300	0.00150–0.00360

* Joule, cm^{-2} sec^{-1} (°C, cm^{-1}).

Values taken from U. S. Bur. Stand., trade catalogs of The Celite Products Co., Armstrong Cork and Insulation Co., and mainly from determinations in Heat Measurement Laboratory, Mass. Inst. Tech.

RAW MATERIALS OF THE PAINT AND VARNISH INDUSTRIES

AVERAGE BULKING VALUES AND SPECIFIC GRAVITIES OF THE MORE COMMON DRY PIGMENTS USED IN THE PAINT INDUSTRY

HENRY A. GARDNER AND H. C. PARKS

	Specific gravity	Wt. per solid gal., lb.	1 lb. bulks, gal.
Basic carbonate white lead	6.81	56.73	0.01763
Basic sulfate white lead	6.41	53.40	0.01873
Zinc oxide	5.66	47.15	0.02121
Zinc oxide, leaded (contains 35% basic lead sulfate)	5.95	49.56	0.02018
Lithopone (*ca.* 28% ZnS, 72% $BaSO_4$)	4.30	35.82	0.02792
Titanox (25% TiO_2, 75% $BaSO_4$)	4.30	35.82	0.02792
Talc (contains *ca.* 5% $CaCO_3$)	2.85	23.74	0.04212
Barytes	4.45	37.07	0.02698
China clay	2.62	21.82	0.04583
Silica	2.65	22.07	0.04531
Whiting ($CaCO_3$)	2.71	22.57	0.04431
Venetian red (20% Fe_2O_3)*	3.05	25.41	0.03935
Red oxide (40% Fe_2O_3)	3.45	28.74	0.03479
Red oxide (95% Fe_2O_3)	4.95	41.23	0.02425
Indian red (90% Fe_2O_3)	4.92	40.98	0.02440
Ferric oxide (98% Fe_2O_3)	5.15	42.90	0.02331
Tuscan red	3.95	32.90	0.03040
Ochre	2.80	23.32	0.04288
Sienna, raw	3.27	27.24	0.03671
Sienna, burnt	3.95	32.90	0.03040
Umber, raw	2.68	22.32	0.04480
Umber, burnt	3.80	31.65	0.03160
Brown oxide (50% Fe_2O_3)	3.35	27.91	0.03583
Mineral brown (45% Fe_2O_3)	3.34	27.82	0.03595

	Specific gravity	Wt. per solid gal., lb.	1 lb. bulks, gal.
Chromium oxide	4.95	41.23	0.02425
Litharge	9.40	78.30	0.01277
Orange mineral	8.80	73.30	0.01364
Red lead	8.80	73.30	0.01364
Pure paranitraniline toner	1.50	12.50	0.08000
Para red 10% (on lime and barium base)	2.65	22.07	0.04531
Pure toluidine red toner	1.49	12.41	0.08058
Chrome green, C. P.	3.90* 5.08*		
American blue (iron cyanide blue)	1.85	15.41	0.06489
Ultramarine blue	2.35	19.58	0.05107
Chrome yellow, C. P*	6.00*		
Lampblack	1.78	14.83	0.05743
Carbon black	1.81	15.08	0.06631
Drop black	2.64	21.99	0.04548
Graphite	2.36	19.66	0.05086
Mineral black filler (clay base with from 15 to 30% carbon)	2.71	22.57	0.04431
Zinc dust	7.06	58.81	0.01700
Aluminum dust	2.64	21.99	0.04548
Lead dust	11.09	92.38	0.01082

* These will vary widely according to composition required for shade or tone and character of base.

Red and brown oxides of variable composition. Matter other than iron oxide may be clay, silica, etc.

AVERAGE CONSTANTS OF OILS USED IN PAINT AND VARNISH INDUSTRY

HENRY A. GARDNER AND L. L. STEELE

Oil	Species	Specific gravity $\frac{15.5°C}{15.5°C}$	Iodine (Hanus) No.	Saponification No.	Acid No.	Refractive index 25°C
	Vegetable and seed oils					
Chia	*Salvia hispanica*	0.934	196	192	0.6	1.486
Corn	*Zea mays*	0.921	125	190	4.0	1.480
Cottonseed	*Gossypium herbaceum*	0.924	112	194	0.9	1.472
Hempseed	*Cannabis sativa*	0.927	149	191	4.0	1.482
Kapok seed	*Eriodendron anfractuosum*	0.924	119	196		
Linseed (boiled)	*Linum usitatissimum*	0.941	172	187	2.7	1.490
Linseed (heavy bodied)	*Linum usitatissimum*	0.968	133	189	2.8	1.497
Linseed (lithographic)	*Linum usitatissimum*	0.970	102	199	2.7	1.498
Linseed (raw)	*Linum usitatissimum*	0.934	186	191	2.0	1.480
Oticia	*Conepia grandifolia*	0.969	180	189	8.0	
Palo maria	*Calophyllum inophyllum*	0.934	97	193	46.0	1.474
Perilla	*Perilla ocimoides*	0.934	200	188	2.0	1.487
Poppyseed	*Papaver somniferum*	0.926	134	192		
Raisinseed (grapeseed)	*Vites*, spp.	0.926	133	193	4.5	1.471
Rosin oil	*Pinus palustris*	0.964	69	36	32	
Rubberseed	*Hevea brasiliensis*	0.924	137	193	57	
Sesame	*Sesamum orientale & indicum*	0.924	110	190	1.5	
Soya bean	*Soja hispida*	0.924	129	189	2.3	1.481
Sunflower	*Helianthus annuus*	0.924	125	189	7.5	1.480

Oil	Species	Specific gravity $\frac{15.5°C}{15.5°C}$	Iodine (Hanus) No.	Saponification No.	Acid No.	Refractive index 25°C
		Nut oils				
Lumbang (candlenut)	*Aleurites moluccana*	0.927	152	192	1.0	1.477
Lumbang (soft)	*Aleurites trisperma*	0.938	164	194	4.4	1.493
Peanut	*Arachis hypogaea*		102	193	2.2	1.479
Tung (American)	*Aleurites fordii*	0.941	166	195	0.2	1.517
Tung (Chinese)	*Aleurites fordii*	0.944	165	192	4.8	1.517
Walnut	*Juglans regia*	0.926	143	193		1.477
Wood (Japanese)	*Aleurites cordata*	0.934	154	193	0.9	1.508
		Marine animal oils				
Channel catfish		0.923	123	192	11	1.474

Menhaden	*Alosa menhaden (Brevoortia tyrannis)*	0.932	158	187	4	1.485
Salmon	*Salmo salar*	0.927	159	183	10	1.479
Sardine	*Clupea sardinus*	0.919	135	177	10	1.480
Shark		0.910	133	160	5	1.482
Shark liver	*Borealis scymnus*	0.922	136	62	1.5	1.471
Skate liver	*Squatina vulgaris*	0.932	152	180	2	1.471
Tuna fish		0.933	184	190	0.5	
Whale	*Balæna*	0.924	148		9	1.482
Yellow tail fish	*Seriola dorsalis*	0.932	180	190	0.6	

TOXICOLOGY OF GASES AND VAPORS

R. R. Sayers

EFFECTIVE CONCENTRATIONS AND PROPERTIES

In the following paragraphs the numbers in bold face have the following significance:

1. Boiling point.
2. Percentage fatal in 30 minutes or less.
3. Percentage causing dangerous illness in 0.5 to 1 hour.
4. Percentage that can be borne without severe effects for 0.5 to 1 hour.
5. Maximum safe concentration.
6. Properties (1).
7. Portal of entry (1).
8. Symptoms (1).
9. Occupations (1).

Acrolein, $CH_2{:}CHCHO$.—**1.** 52°. **2.** 0.001 (2). **5.** 0.00033 (2). **6.** Colorless, pungent fluid, of fiery taste. **7.** As vapor, through organs of respiration and mucous membranes. **8.** Itching in the throat; irritation of eyes, exciting lachrymation; conjunctivitis, irritation of the air passages, bronchial catarrh. **9.** Manufacture of lard, linoleum, stearic acid; bone and fat rendering, galvanizing, tallow refining, tinsmithing, varnish boiling.

Ammonia, NH_3.—**1.** −35.5°. **3.** 0.25–0.45 (3). **4.** 0.03 (3). **6.** Colorless gas of sharply penetrating odor. **7.** As gas, through organs of respiration. Seldom pure, mostly in combination with other gases. Immediate effects on the conjunctiva and the cornea. **8.** Acute inflammation of the respiratory organs, cough, edema of the lungs, chronic bronchial catarrh, redness of the eyes, increased secretion of saliva, retention of urine. **9.** Manufacture of acetylene, ammonium salts, artificial ice, artificial silk, bone-black, dyes, shellac, soda, varnish; work around coke-ovens, refrigerating plants, sewers; bronzing, dyeing, galvanizing, gas purifying, mercerizing, shoe finishing, sugar refining, tinsmithing; work with glue, illuminating gas.

Aniline, $C_6H_5NH_2$.—**1.** 184.4°. **4.** 0.00004–0.00006 (3). **6.** Colorless oil acquiring tint on exposure to air and light. **7.** Absorption through skin, directly or by saturation of clothing; absorption through respiratory organs as volatile particles and impalpable dust; through digestive organs. **8.** Pallor of skin, vertigo, unsteady gait, loss of appetite, increased frequency of respiration, anemia, slowing of the pulse, eczematous eruptions, bloody urine, spasmodic muscular pains, cyanosis. **9.** Manufacture of aniline, artificial leather, calico, explosives, coal-tar products, dyes, paint, colored pencils; vulcanizing, tanning, printing, typesetting, photography, painting, lithography; work with feathers; compounding, mixing, reclaiming rubber, and work in press rooms.

Arsine, AsH_3.—**1.** −54.8°. **2.** 0.05 (2). **5.** 0.001 (2). **6.** Colorless, extremely offensive gas, with the odor of garlic. **7.** As gas, through respiratory organs, generally mixed with hydrogen. **8.** General malaise, difficult breathing, fainting fits, gastric disturbances, jaundice, bluish discoloration of the mucous membrane, pain in the region of spleen and kidney, darkened urine, fetor of the mouth resembling garlic. **9.** Manufacture of dry batteries, dimethyl sulfate, dyes, fertilizer, nitroglycerin, shoddy, zinc chloride; acid dipping, filling toy balloons, bronzing, enamelling, galvanizing, lead and lime burning, pickling, metal refining, tinsmithing; work with aniline, sulfuric acid, submarine storage batteries; ferro-silicon work.

Benzene, C_6H_6.—**1.** 80.2°. **4.** 0.001–0.0015 (3). **5.** 0.0005 (3). **6.** Unstable, extremely volatile, colorless fluid, burning with a bright sooty flame. A coal tar product. **7.** As vapor, through the respiratory organs; re-absorption through the skin. **8.** Headache, vertigo, anemia, muscular tremor, scarlet lips, spots of extravasated blood in the skin, irritant cough, fatty degeneration of liver, kidneys and heart. **9.** Manufacture of aniline, artificial leather, dry batteries, carbolic acid, colors, dyes, explosives, fertilizer, lacquer, paint, rubber tires, shellac, shoes,

Aniline, $C_6H_5NH_2$.—**1.** 184.4°. **4.** 0.00004–0.00006 (3). **6.** Colorless oil acquiring tint on exposure to air and light. **7.** Absorption through skin, directly or by saturation of clothing; absorption through respiratory organs as volatile particles and impalpable dust; through digestive organs. **8.** Pallor of skin, vertigo, unsteady gait, loss of appetite, increased frequency of respiration, anemia, slowing of the pulse, eczematous eruptions, bloody urine, spasmodic muscular pains, cyanosis. **9.** Manufacture of aniline, artificial leather, calico, explosives, coal-tar products, dyes, paint, colored pencils; vulcanizing, tanning, printing, typesetting, photography, painting, lithography; work with feathers; compounding, mixing, reclaiming rubber, and work in press rooms.

Arsine, AsH_3.—**1.** −54.8°. **2.** 0.05 (2). **5.** 0.001 (2). **6.** Colorless, extremely offensive gas, with the odor of garlic. **7.** As gas, through respiratory organs, generally mixed with hydrogen. **8.** General malaise, difficult breathing, fainting fits, gastric disturbances, jaundice, bluish discoloration of the mucous membrane, pain in the region of spleen and kidney, darkened urine, fetor of the mouth resembling garlic. **9.** Manufacture of dry batteries, dimethyl sulfate, dyes, fertilizer, nitroglycerin, shoddy, zinc chloride; acid dipping, filling toy balloons, bronzing, enamelling, galvanizing, lead and lime burning, pickling, metal refining, tinsmithing; work with aniline, sulfuric acid, submarine storage batteries; ferro-silicon work.

Benzene, C_6H_6.—**1.** 80.2°. **4.** 0.001–0.0015 (3). **5.** 0.0005 (3). **6.** Unstable, extremely volatile, colorless fluid, burning with a bright sooty flame. A coal tar product. **7.** As vapor, through the respiratory organs; re-absorption through the skin. **8.** Headache, vertigo, anemia, muscular tremor, scarlet lips, spots of extravasated blood in the skin, irritant cough, fatty degeneration of liver, kidneys and heart. **9.** Manufacture of aniline, artificial leather, dry batteries, carbolic acid, colors, dyes, explosives, fertilizer, lacquer, paint, rubber tires, shellac, shoes, smokeless powder, varnish; vulcanizing, coal-tar still cleaning, photography, photoengraving, painting, lithography, gilding, electroplating, dry cleaning, leather and fertilizer degreasing, pottery decorating, case scrubbing, bronzing; compounding, drying, mixing, washing, reclaiming, treading rubber; mixing rubber cement, cementing rubber shoes; work with benzol stills, coke ovens, coal tar, feathers, illuminating gas, glue, mordants.

Bromine, Br_2.—**1.** 58.6°. **2.** 0.1 (3). **3.** 0.004–0.006 (3). **4.** 0.0004 (3). **5.** 0.0001 (3). **6.** Fuming liquid with an extremely disagreeable odor. **7.** As gas, through the respiratory organs. **8.** Pallid countenance, emaciation, decayed teeth, bronchial irritation and asthma, gastric disturbances, irritation of the skin. **9.** Manufacture of dyes; chemical and pharmaceutical industries.

Carbon Disulfide, CS_2.—**1.** 46.2°. **3.** 0.001 (3). **4.** 0.0002–0.0003 (3). **5.** 0.0001 (3). **6.** When pure, a limpid, highly refractive, volatile fluid, having an odor like chloroform; imperfectly refined, it is pale yellow, with an offensive odor. **7.** As vapor, through respiration; as fluid, through the skin. **8.** Headache, pain in the extremities, trembling, deafness, reduction of the reflexes, accelerated heart action, nausea, digestive trouble, emaciation, disturbance of sense of vision, excitement and violent temper followed by depression, hyperstimulation of the sexual instinct, later its abnormal decline, chronic dementia. **9.** Manufacture of ammonium salt, artificial silk, carbon disulfide, celluloid, insecticide, matches, paint, putty, smokeless powder; asphalt testing, cementing rubber shoes, rubber cement mixing, dry cleaning, enamelling, oil extracting, tallow refining, sulfur extracting, vulcanizing, rubber drying and reclaiming, work with paraffin and glue.

Carbon Dioxide, CO_2.—**1.** −78.2°. **2.** 30.0 (3). **3.** 6.0–8.0 (3). **4.** 4.0–6.0 (3). **5.** 2.0–3.0 (3). **6.** Specifically dense, odorless, colorless gas, collecting near the ground or floor. **7.** As gas, by inhalation. **8.** Anemia, cyanosis, headache, drowsiness, vertigo, tinnitus, and general nervousness. **9.** Manufacture of alkali salts, carbon dioxide, fertilizer, pottery, soda, starch, wine, white lead, yeast; blacksmithing, brass founding, brewing, brick, charcoal and lime burning, lime kiln charging, mining, sugar refining; work in boiler rooms, caissons, drying rooms, silos; work around furnaces, sewers.

Carbon Monoxide, CO.—**1.** −190°. **2.** 0.5–1.0 (7). **3.** 0.2–0.3 (3). **4.** 0.05–0.10 (3). **5.** 0.04 (7). **6.** Colorless, tasteless gas, odorless in diffused state, burning with a blue flame in air. **7.** As gas, through the respiratory organs. **8.** Stage 1 (7): Tightness across forehead, dilatation of cutaneous vessels, headache (frontal and basal), throbbing in temples, weariness, weakness, dizziness, nausea and vomiting, loss of strength and muscular control, increased pulse and respiration rates, collapse. Stage 2: Increased pulse and respiration, fall of blood pressure, loss of muscular control, especially sphincters, loss of reflexes, coma usually with intermittent convulsions, Cheyne-Stokes' respiration, slowing of pulse, respiration slow and shallow, cessation of respiration, death. **9.** Manufacture of acetylene, carbide, celluloid, cores (founding), felt hats, incandescent lamp filaments; baking, blacksmithing, brass founding, cable splicing, calico printing, charcoal burning, charging (zinc smelting), chimney sweeping, copper smelting, enamelling, incandescent lamp finishing; work with bisque kilns, coke ovens, coal tar; work in drying and boiler rooms.

Carbon Tetrachloride, CCl_4.—**1.** 76.74°. **2.** 0.03–0.04 (3). **3.** 0.015–0.02 (3). **4.** 0.0025–0.004 (3). **5.** 0.001 (3). **6.** Colorless liquid with pleasant odor, having a narcotic action somewhat similar to chloroform (11). **7.** As vapor, through the respiratory organs. **8.** Nausea, vomiting, abdominal pain, stupor deepening into coma, absence of reflexes, clonic convulsions, weak pulse, increased temperature and death (11). **9.** Used in industry as a rubber solvent, an ingredient of certain types of paint, a fire extinguisher, and a shampooing agent.

Chlorine, Cl_2.—**1.** −33.6°. **2.** 0.10 (3). **3.** 0.004–0.006 (3). **4.** 0.0004 (3). **5.** 0.0001 (3). **6.** Yellowish-green, suffocating gas of penetrating odor, whose water solution is a greenish-yellow. **7.** As gas, through the respiratory organs. **8.** Pallid countenance, emaciation, decayed teeth, bronchial irritation and asthma, gastric disturbances, irritation of the skin, chloracne. **9.** Manufacture of alkali salts, brooms, chloride of lime, chlorine, disinfectants, dyes, phosgene, sulfur and zinc chloride; pulp beating, bleaching, calico printing, laundry work, photography.

Chloroform, $CHCl_3$.—**1.** 61.2°. **2.** 0.03–0.04 (3). **3.** 0.007 (3). **4.** 0.0025–0.003 (3). **5.** 0.001 (3). **6.** Heavy colorless liquid, with characteristic odor and sweet taste; used as an anesthetic (11). **7.** As vapor, through the respiratory organs. **8.** In anesthesia the untoward symptoms are shallow or irregular respiration, sudden cessation of respiration, pulse either very slow or very rapid, dilatation of the pupils, cyanosis, asphyxia leading to dilatation of the heart, vagus stimulation, and finally failure of heart due to asphyxial condition. In delayed poisoning there is great prostration, delirium, coma, death (11). **9.** Chloroform manufacture, but the principal hazard is in its use as an anesthetic.

Chloropicrin, CCl_3NO_2.—**1.** 112°. **2.** 0.05 (2). **3.** 0.002 (2). **4.** 0.0001 (2). **6.** Colorless oil, insoluble in water. Sufficiently volatile to keep the strata of air above it thoroughly poisonous, and persistent enough to be dangerous after 5 or 6 hours. **7.** As gas, through the respiratory organs. **8.** Lachrymatory and respiratory irritant, with specific action on the vomiting center. Causes coughing, nausea, vomiting, and in large quantities unconsciousness. Secondary effects are bronchitis, shortness of breath. **9.** Warfare.

Dichlorodiethyl Sulfide, $(CH_2ClCH_2)_2S$.—**1.** 215–217°. **5.** 0.002 (2). **6.** Oily fluid with sharp odor. Its peculiar property of blistering the skin, combined with its high persistency, makes it the most valuable war gas known. **7.** As vapor, through the respiratory passages, and through the skin. **8.** Conjunctivitis and superficial necrosis of the cornea; hyperemia, edema and, later, necrosis of the skin, leading to skin lesion of great chronicity; congestion and necrosis of the epithelial lining of the trachea and bronchi. Systemic effects due to the absorption of the substance into the blood stream and its distribution to the various tissues of the body (4). **9.** Warfare.

Hydrogen Chloride, HCl.—**1.** −82.9°. **2.** 0.5 (2). **3.** 0.15–0.2 (3). **4.** 0.005–0.01 (3). **5.** 0.005 (2). **6.** Pure HCl is a colorless gas that fumes when open to the air, forming a dense, acid, white mist. The crude commercial acid is, for the most part, impure, containing arsenic among other mixtures. **7.** Action on skin and nasal mucous membrane; seldom as vapor affecting the respiratory organs. **8.** Irritation of mucous membranes, conjunctivitis, coryza; pharyngeal, laryngeal, and bronchial catarrh; dental caries. **9.** Manufacture of alkali salts, ammonium salts, aniline, dry batteries, camphor, carbolic acid, dyes; dipping, mixing, recovering, transporting acid; cartridge dipping, shoddy carbonizing, calico printing, acid finishing (glass).

Hydrogen Cyanide, HCN.—**1.** 26.5°. **2.** 0.048 (9). **3.** 0.012–0.024 (9). **4.** 0.005–0.006 (3). **5.** 0.002–0.004 (3) **6.** Colorless, highly volatile fluid, of penetrating, pungent, and irritating odor. **7.** As gas, through the respiratory organs; also through the epidermis. **8.** Headache, vertigo, unsteadiness of gait, nausea, loss of appetite, disturbance of gastric and intestinal functions, slowing of the pulse, albuminuria. **9.** Manufacture of ammonium salts, celluloid, dyes; acid dipping, blacksmithing, browning (gun barrels), calico printing, case hardening, electroplating, fulminate mixing, gas purifying, gold refining, photography, pickling, silver refining, tanning, tempering; work around blast furnaces, and with illuminating gas.

Hydrogen Sulfide, H_2S (10).—**1.** −60.2°. **2.** 0.06–0.1 (10). **3.** 0.05–0.07 (3). **4.** 0.02–0.03 (3). **5.** 0.01–0.02 (10). **6.** Colorless gas with odor of rotten eggs in low concentration; burns with bluish flame forming SO_2 and water; mixed with 7 parts air, explodes with violence when ignited. **7.** As gas, through the respiratory organs. **8.** Poisoning is of two types—acute and subacute—causing asphyxiation and irritation (conjunctivitis, bronchitis, pharyngitis, and depression of the central nervous system), respectively. In low concentration the symptoms are headache, sleeplessness, dullness, dizziness, and weariness; pain in the eyes, followed by conjunctivitis, is fairly constant; bronchitis and pains in the chest are frequent. Further poisoning produces depression, stupor, unconsciousness and death. Spasms—clonic and tonic—are present. Death from asphyxia is caused by paralysis of respiratory center, while death from subacute poisoning is associated with edema of the lungs. **9.** Manufacture of alkali salts, celluloid, dyes, fertilizer, matches, soda, sodium sulfide, starch, artificial silk; bronzing, cable splicing, flax retting, gas purifying, petroleum refining, pyrites burning, sugar refining, tanning; work around blast furnaces; work with glue, illuminating gas, sewers.

Iodine, I_2 (11).—**1.** 184.35°. **4.** 0.0003 (3). **5.** 0.00005–0.0001 (3). **6.** At ordinary temperatures gives off invisible vapor very irritating to the nose and eyes (1). **7.** As vapor. **8.** Inflammation of the lungs and pulmonary edema. **9.** Manufacture of iodine.

Mercury, Hg.—**1.** 357.33°. **5.** Less than 0.000125 causes symptoms of poisoning after daily exposure for 2 or 3 months (5). **6.** Silver-white, shining metal, unchangeable in air, but evaporating at house temperature (6). **7.** Through the uninjured skin, and the respiratory organs in the form of vapor and dust (amalgam dust, dust of the compounds of mercury) (6). **8.** Industrial mercurial poisoning is a chronic poisoning occasioned by work in this metal for a long period. The first symptom is generally increased ptyalism, with swelling and inflammation of the gums and of the buccal mucous membrane, often with the formation of rodent ulcers; frequently disturbances of digestion, lassitude and pallor. With further absorption of the metal, "erethism" supervenes—a peculiar psychic excitability (timorousness, bewilderment, irritability), tremor. Death may result in the worst cases in consequence of the violent tremor and spasms affecting the entire body; in other cases increasing weakness (6). **9.** Mining and smelting of quicksilver; mirror plating, amalgam gilding and silvering; manufacture of thermometers, barometers, manometers, incandescent electric lamps, Roentgen and Hittorf tubes, mercurial vapor lamps, salts of mercury, amalgams, colors, pharmaceutic products, antiseptic dyes, inflammable materials, explosives; use of mercury salts, especially in the hare's fur business and felt hat manufacture; photography, steel engraving (6).

Nitrogen Oxides (Expressed in Percentages as Nitric Acid) NO.—**1.** −153°. **2.** 0.07 (12). **3.** 0.01 (12). **4.** 0.007 (12). **5.** 0.0033 (12). **6.** NO is colorless gas readily transformed into brown NO_2 by atmospheric oxygen. **7.** As gas, through respiratory organs. **8.** Local cauterization of the respiratory tract, leading to laryngitis, bronchitis, hyperemia, hemorrhages and severe edema in addition to vicarious emphysema of the lungs. In men the real illness generally appears only 4 to 6 hours or more after inhalation of the gas; in animals lung edema and a condition threatening to be dangerous ensue promptly (12). **9.** Manufacture of aniline, artificial leather, celluloid, dimethyl sulfate, explosives, felt hats, fertilizer, imitation pearls, incandescent lamps, picric acid, soda; dipping, mixing, recovering, transporting acid; bleaching, cartridge dipping, dipping and wringing gun-cotton, enamelling, etching, fur preparing, galvanizing, lithography, mining, nitrating, photo-engraving, pickling, metal refining, steel engraving; work with glue, jewelry, mordants, nitric acid, nitroglycerin, sulfuric acid.

Nitrobenzene, $C_6H_5NO_2$.—**1.** 210.9°. **4.** 0.0001 (3). **5.** 0.00002 (3). **6.** Colorless, highly refractive fluid having an odor like that of bitter almonds. (All nitro-compounds of benzene have similar properties). **7.** As gas, through the respiratory organs. **8.** Methemoglobin formation, general debility, anemia, presence of free hematoporphyrin, albumin, and sometimes free poison in the urine; jaundice, gradually becoming cyanosis; skin eruptions, visual disturbances, dyspnea, odor of bitter almonds in breath. **9.** Manufacture of aniline, dyes, explosives, perfumes, smokeless powder, soap.

Phosgene, $COCl_2$.—**1.** 8.2°. **2.** 0.02–0.05 (2). **3.** 0.0025 (2). **5.** 0.0001 (2). **6.** Colorless gas of suffocating odor. **7.** As vapor, through the respiratory organs. **8.** Destruction of lung tissue, emphysema and edema, myocardial insufficiency due to the emphysema, pleural thickening and adhesions, chronic bronchitis, mild diffuse bronchiectasis, nocturnal dyspnea, polycythemia. **9.** Manufacture of dyes, phosgene.

Phosphorus Trichloride, PCl_3.—**1.** 76°. **2.** 0.00035 (3). **3.** 0.00003–0.00005 (3). **4.** 0.000001–0.000002 (3). **5.** 0.0000004 (3). **6.** Liquid with sharp smell, fuming in air, and decomposing into phosphorous acid and hydrochloric acid (13). **7.** As vapor, through the respiratory organs. **8.** Sensation of suffocation, difficulty of breathing, lachrymation, bronchitis, edema and inflammation of the lungs, with frothy, blood-stained expectoration. **9.** Manufacture of phosphorus trichloride and organic compounds; use of phosphorus trichloride as chlorinating agent and as solvent of phosphorus.

Phosphine, PH_3.—**1.** −85°. **2.** 0.2 (14). **3.** 0.04–0.06 (3). **4.** 0.01–0.02 (3). **6.** Colorless gas of nauseating odor. **7.** As gas, through the respiratory organs. **8.** Oppressed feeling in the chest, headache, vertigo, tinnitus aurium, general debility, loss of appetite, great thirst. **9.** Manufacture of acetylene, red phosphorus; phosphorus extracting, work with ferro-silicon.

Sulfur Dioxide, SO_2.—**1.** −10°. **2.** 0.2 (2). **5.** 0.01 (2) **6.** Gas with pungent odor and suffocating effect. **7.** As gas, through the respiratory organs. **8.** Irritation of the mucous membrane of the respiratory organs and eyes, spasmodic cough, bronchial catarrh, digestive disturbances, blood-tinged mucus. **9.** Manufacture of alkali salts, bricks, brooms, carbolic acid; work around blast furnaces, brass foundries, sulfuric acid towers; bleaching, zinc charging.

Sulfur Trioxide, SO_3.—**2.** 0.001 (2). **5.** 0.0002 (2). **6.** White solid, which evolves dense white fumes on exposure to the air. **7.** As gas, through the respiratory organs. **8.** Irritation of the respiratory organs, bronchitis. **9.** Manufacture of sulfuric acid.

Toluidine, $CH_3C_6H_4NH_2$.—**1.** 200°. **4.** 0.00025 (3). **5.** 0.0001–0.00025 (3). **6.** Reddish brown liquid. **7.** As vapor, through the respiratory organs. **8.** Headache, weakness, difficulty in breathing, cyanosis, convulsions, psychical disturbances, air hunger, marked irritation of the renal organs (13). **9.** Manufacture of aniline, coal-tar dyes; tank and still work (13).

PREVENTION AND EMERGENCY TREATMENT OF GAS POISONING

I. Prevention of poisoning

A. For all gases

1. Prevention of escape of vapor or fumes into the air of working places.
2. Good ventilation.
3. Testing before entering air suspected of containing poisonous gases.
4. Never entering or working alone in places where the air is known to be contaminated by poisonous gases.
5. Wearing of respirators, gas masks, hose masks, or oxygen breathing apparatus—the latter especially if the air is low in oxygen.
6. Education of workmen regarding the danger of poisoning and methods of prevention.

B. For special gases

1. Protection of the skin by suitable clothing and by the application of oils, etc.

   In the case of dichlorodiethyl sulfide (mustard gas), ordinary clothing affords no protection, but cloth painted with linseed oil is adequate. Oiling the skin gives some protection from short exposure to low concentrations of this gas and in high concentrations increases the efficiency of removal-treatment; for long exposure, oils give practically no protection.
2. Abstinence from alcohol, at least during and immediately after labor, especially when exposed to such gases as aniline, toluidine, and nitrobenzene.
3. Scrupulous cleanliness of working places and personally on the part of the workmen.
4. Physical examination of prospective employees to see that they are not suffering from any disease that would make them more susceptible to certain poisonous gases; reexamination of employees at stated intervals (every 30 days for workers in aniline) to detect beginning of poisoning, especially where exposed to fumes of aniline, mercury, and other gases, the action of which is cumulative and danger of acute poisoning is not so great.

II. Emergency treatment

A. For all gases

1. Immediate removal from poisonous atmosphere to fresh air.
2. Immediate administration of artificial respiration (preferably by the Schaefer prone pressure method) if breathing has ceased.
3. Calling a physician.
4. Keeping the patient at rest, lying down (very important).
5. Keeping the patient warm and stimulating circulation by rubbing limbs of patient.

B. For special gases

1. Administration of pure oxygen, especially in case of carbon monoxide poisoning.[1]
2. Administration of stimulants: Black coffee, caffein, camphor, or ether in case of poisoning by aniline, hydrogen cyanide, hydrogen sulfide, phosphine, and toluidine; subcutaneous administration of atropine in poisoning by hydrogen chloride, hydrogen sulfide, and phosphine; hypodermic administration of morphine in poisoning by hydrogen cyanide; inhalation of chloroform in poisoning by phosgene; inhalation of ammonia vapor or soda spray in poisoning by hydrogen chloride, phosgene, phosphorus trichloride, and chloropicrin; infusion of alkaline solution in poisoning by arsine, bromine, iodine, and sulfur dioxide.
3. Venesection is recommended in treatment of poisoning by bromine, chlorine, iodine, nitrogen oxides, phosgene, and chloropicrin, but must not be used after collapse has started.
4. In the case of dichlorodiethyl sulfide (mustard gas) prevention is especially important as palliative measures are not very successful. The respiratory lesions may be treated by frequent spraying or instillation of a few drops of 1 % sodium bicarbonate, followed by liquid petrolatum and gargling of the throat with a weak Dakin's solution. The eyes should be kept clean by frequent irrigation with a saturated solution of boric acid or with 1 % sodium bicarbonate, followed by a few drops of oil. All clothing should be removed to the skin. Burns of the skin from the vapor should be treated with antiseptics and protected from any irritation. Irritant drugs, such as picric acid or mercuric chloride solutions, should not be applied.

---

[1] Five per cent carbon dioxide in oxygen, if available, may be administered in carbon monoxide poisoning.

AIR CONDITIONING

A. HYGROSCOPIC PROPERTIES OF INDUSTRIAL MATERIALS

D. C. Lindsay

Hygroscopic Moisture.—The moisture contained in a hygroscopic material in equilibrium with the relative humidity of the surrounding atmosphere. The moisture content of a hygroscopic material when in equilibrium depends upon the relative humidity of the surrounding atmosphere but varies widely with different materials. The moisture content also varies to a slight extent with different temperatures at the same humidity. Hygroscopic moisture in materials is in most industries termed "*regain*," and is expressed in parts of water per 100 parts of dry material.

Hygroscopic Properties of Materials.—The hygroscopic properties of materials vary widely from one another and even in the same material a wide variation is frequently observed, and is dependent upon the prior history of the material. The curves given below are based upon a critical study of available data. Qualitatively, they are correct and can be used where extreme accuracy is not required. Consistency in form will be noted in all cases. For the accurate determination of hygroscopic characteristics of materials, the use of insulated cabinets provided with air circulation and automatic instruments (10) for controlling temperature and humidity are recommended as being superior to the taking of such data, within a stagnant atmosphere, the moisture equilibrium of which is maintained by hygroscopic solutions such as sulfuric acid.

Electrostatic Condition of the Atmosphere—Electrical charges are dissipated at normal temperatures (18 to 30°C) at a relative humidity of 50 % or above.

AIR CONDITIONING

A. HYGROSCOPIC PROPERTIES OF INDUSTRIAL MATERIALS

D. C. Lindsay

Hygroscopic Moisture.—The moisture contained in a hygroscopic material in equilibrium with the relative humidity of the surrounding atmosphere. The moisture content of a hygroscopic material when in equilibrium depends upon the relative humidity of the surrounding atmosphere but varies widely with different materials. The moisture content also varies to a slight extent with different temperatures at the same humidity. Hygroscopic moisture in materials is in most industries termed "*regain*," and is expressed in parts of water per 100 parts of dry material.

Hygroscopic Properties of Materials.—The hygroscopic properties of materials vary widely from one another and even in the same material a wide variation is frequently observed, and is dependent upon the prior history of the material. The curves given below are based upon a critical study of available data. Qualitatively, they are correct and can be used where extreme accuracy is not required. Consistency in form will be noted in all cases. For the accurate determination of hygroscopic characteristics of materials, the use of insulated cabinets provided with air circulation and automatic instruments (10) for controlling temperature and humidity are recommended as being superior to the taking of such data, within a stagnant atmosphere, the moisture equilibrium of which is maintained by hygroscopic solutions such as sulfuric acid.

Electrostatic Condition of the Atmosphere—Electrical charges are dissipated at normal temperatures (18 to 30°C) at a relative humidity of 50 % or above.

This is of extreme importance in textile mills and printing plants where the charged atmosphere prevalent during the winter causes bristling of the fibers and hampers operations.

The elimination of static by humidification has been successfully applied to reduce explosion hazards in munition plants and other explosive atmospheres.

Mildew Fungi.—These will thrive in relatively still atmosphere only at relative humidities above 75%.

FAVORABLE CONDITIONS OF TEMPERATURE AND HUMIDITY ARTIFICIALLY CREATED AND MAINTAINED IN MANUFACTURING PROCESSES

11	Rope manila..................	1.6	1.5			25	75	(6)

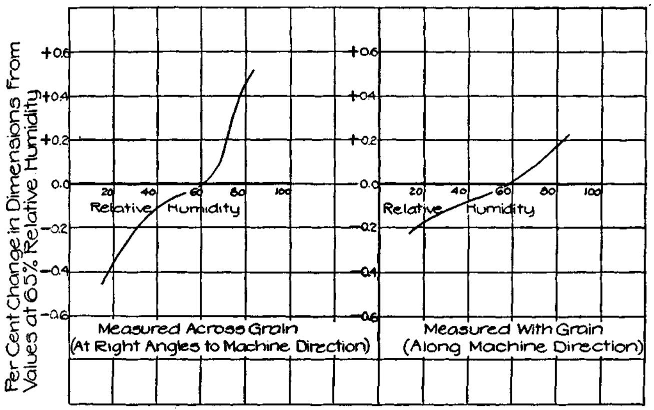

FIG. 2.—Composite curves for all papers in Fig. 1. Variation in dimensions with variation in relative humidity.

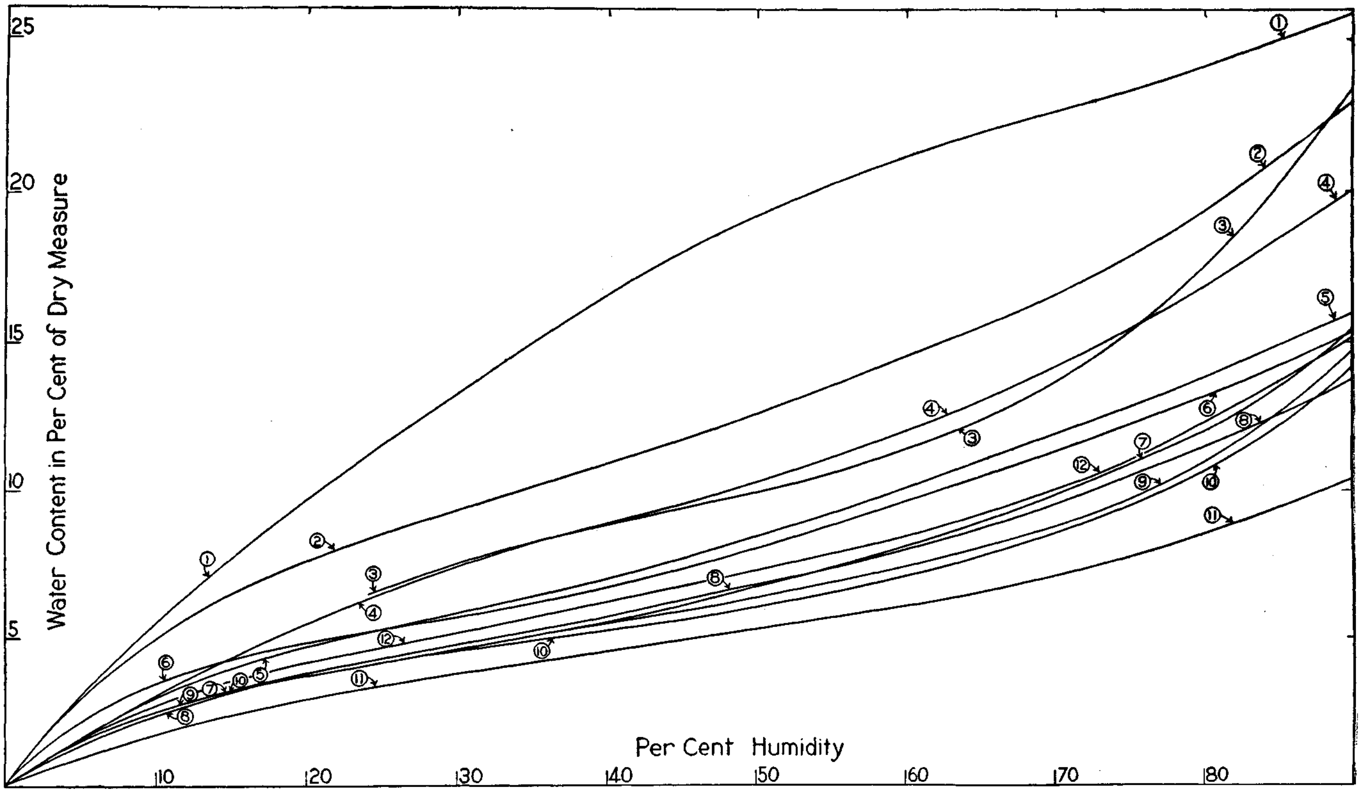

Fig. 3.—Hygroscopic moisture of natural fiber textile materials [3, 5, 12, 14]).

Curve No.	Material	Curve No.	Material	Curve No.	Material	Curve No.	Material
1	Absorbent cotton	7	Indian cotton	4	Jute	10	American cotton
2	Wool, worsted	8	Cotton cloth	5	Manila hemp	11	Linen
3	Silk, new yellow	9	Egyptian cotton	6	Sisal hemp	12	Flax

All observations at approx. 25°C.

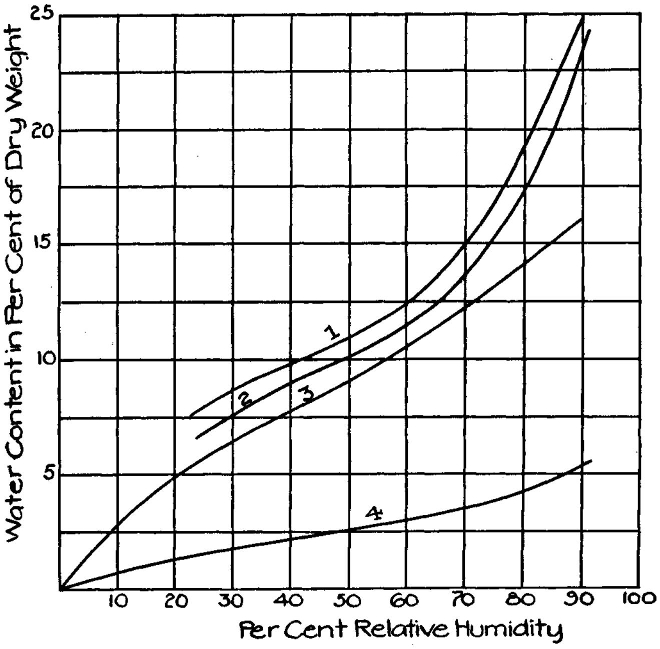

Fig. 4.—Hygroscopic moisture of artificial textile fibers compared with crude constituents and natural silk (3, 14).

Curve No.	Material
1	Viscose rayon (artificial silk)
2	Natural silk, new yellow
3	Nitrocellulose
4	Cellulose acetate

All observations at approx. 25°C.

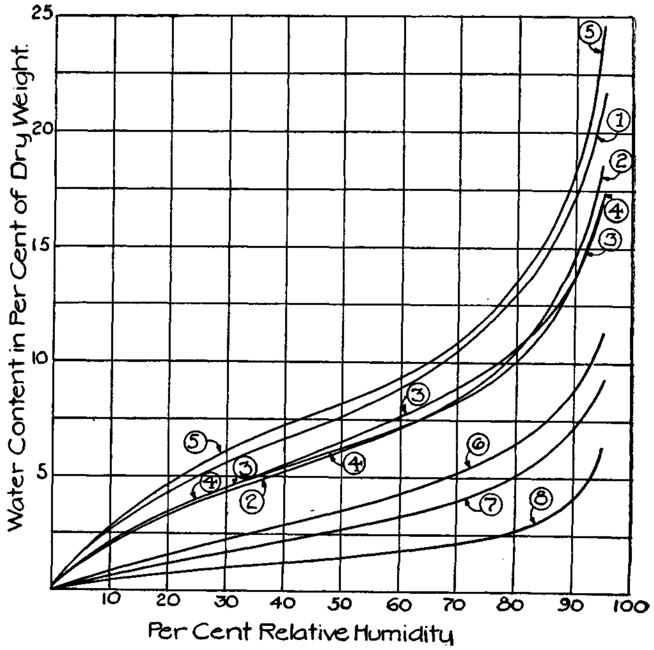

Fig. 6.—Hygroscopic moisture of various fibrous materials prepared for electrical insulation (8, 9).

Curve No.	Material
1	Manila paper
2	Red rope paper
3	Press board
4	Leatheroid paper
5	Silk
6	Red rope paper (varnished)
7	Empire cloth
8	Asbestos paper

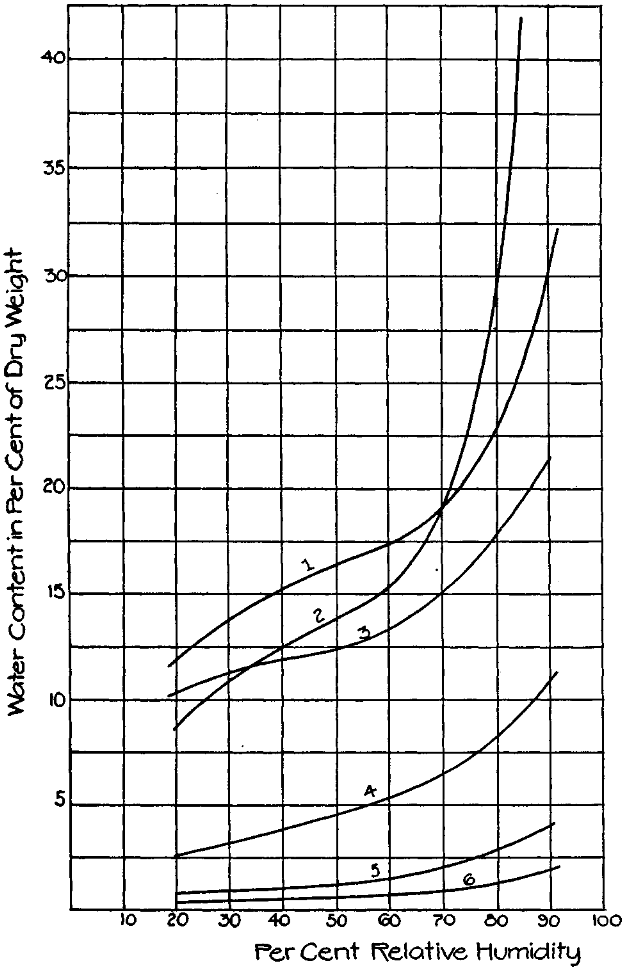

FIG. 5.—Hygroscopic moisture of leather and rubber (³).

Curve No.	Material
1	Leather (sole oak tanned)
2	Sheepskin
3	Gold beater skin
4	Latex, dipped cord
5	Reclaimed rubber
6	Smoked, crepe sheet

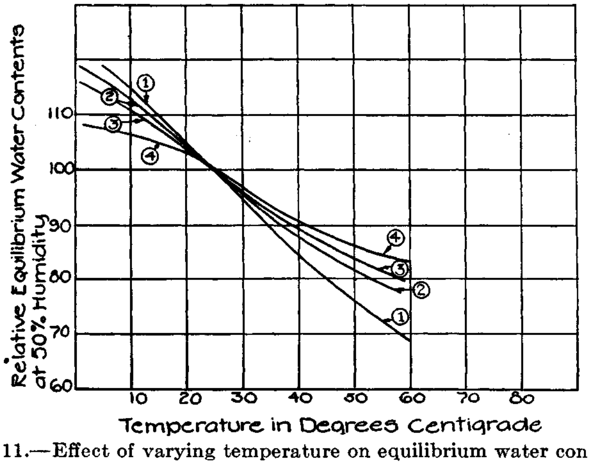

FIG. 11.—Effect of varying temperature on equilibrium water content at constant relative humidity of 50 % (¹⁴).

Curve No.	Material
1	Wood
2	Silk
3	Wool
4	Cotton

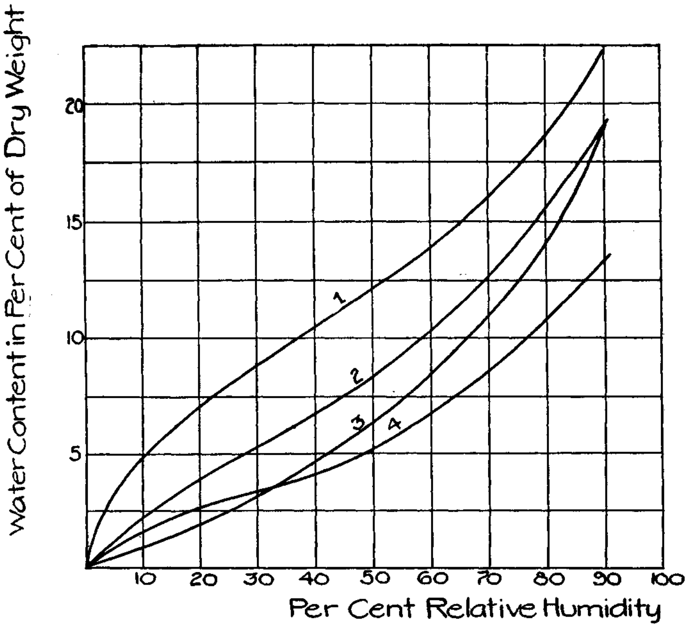

FIG. 7.—Hygroscopic moisture of cereal foods (¹, ³, ¹⁴).

Curve No.	Material
1	Macaroni
2	Flour (patent)
3	Bread
4	Crackers

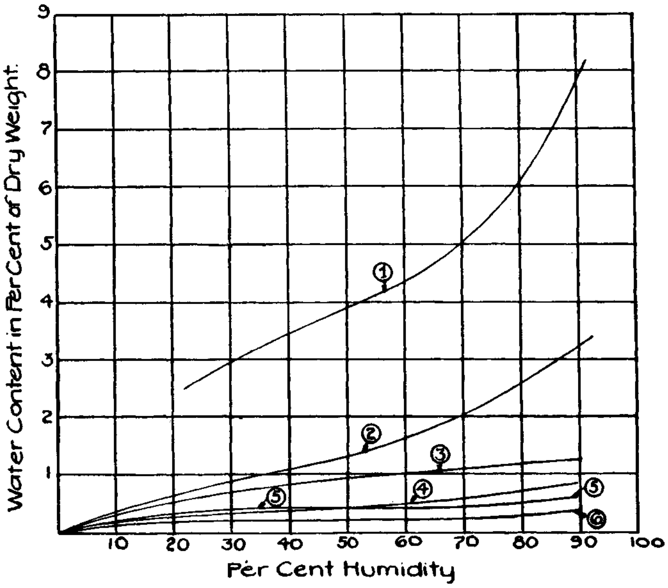

FIG. 8.—Hygroscopic moisture of some inorganic substances (¹⁰, ¹⁴).

Curve No.	Material
1	English ball clay
2	Kieselguhr
3	Kaolin
4	Asbestos fiber
5	Zinc oxide
6	Glass wool

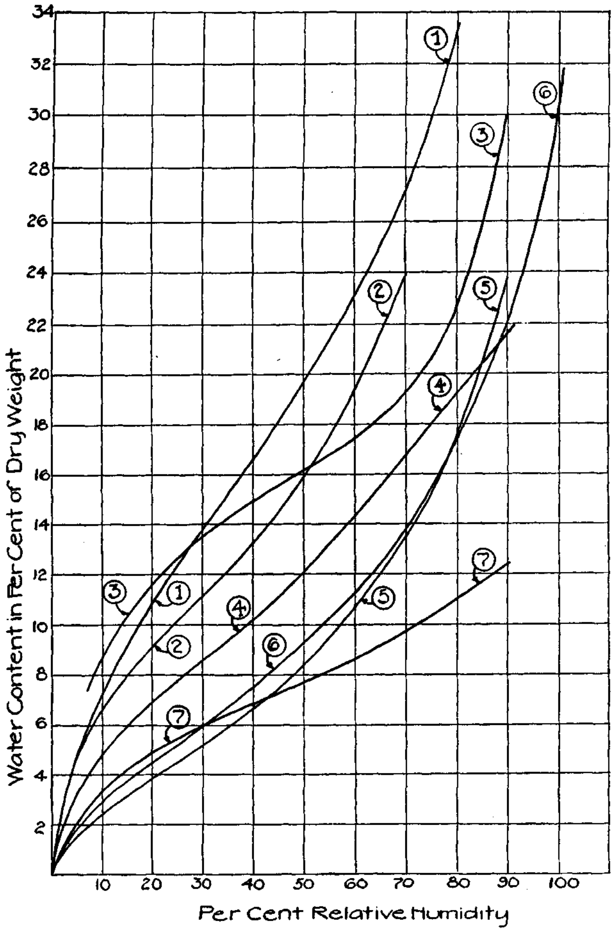

FIG. 9.—Hygroscopic moisture of some organic substances.

Curve No.	Material	Lit.
1	North Carolina leaf tobacco	(3)
2	Cigarette tobacco (Fatima)	(14)
3	Sole leather (oak tanned)	(3)
4	Catgut	(14)
5	Soap (Ivory)	(14)
6	Lumber*	(4)
7	Glue (hide, first grade)	(14)

* All species of timber have been found to have approximately the same values at given relative humidities. Rate of absorption or evaporation from timbers varies according to the density of the species.

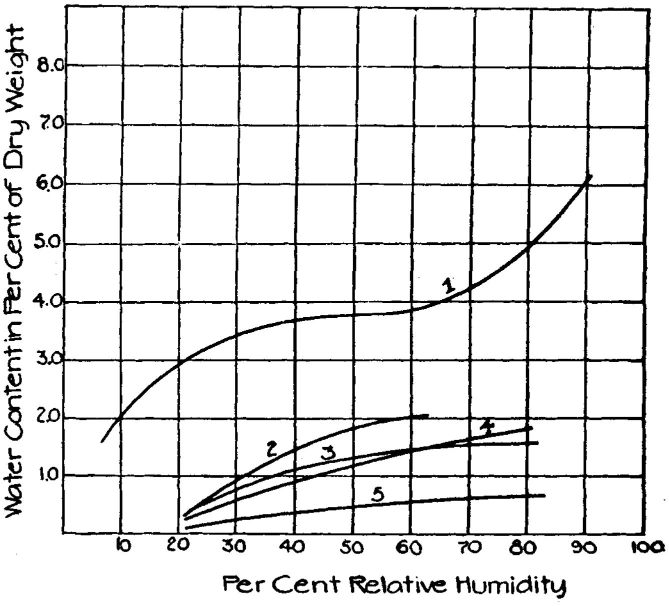

FIG. 10.—Hygroscopic moisture of carbon products (13, 14).

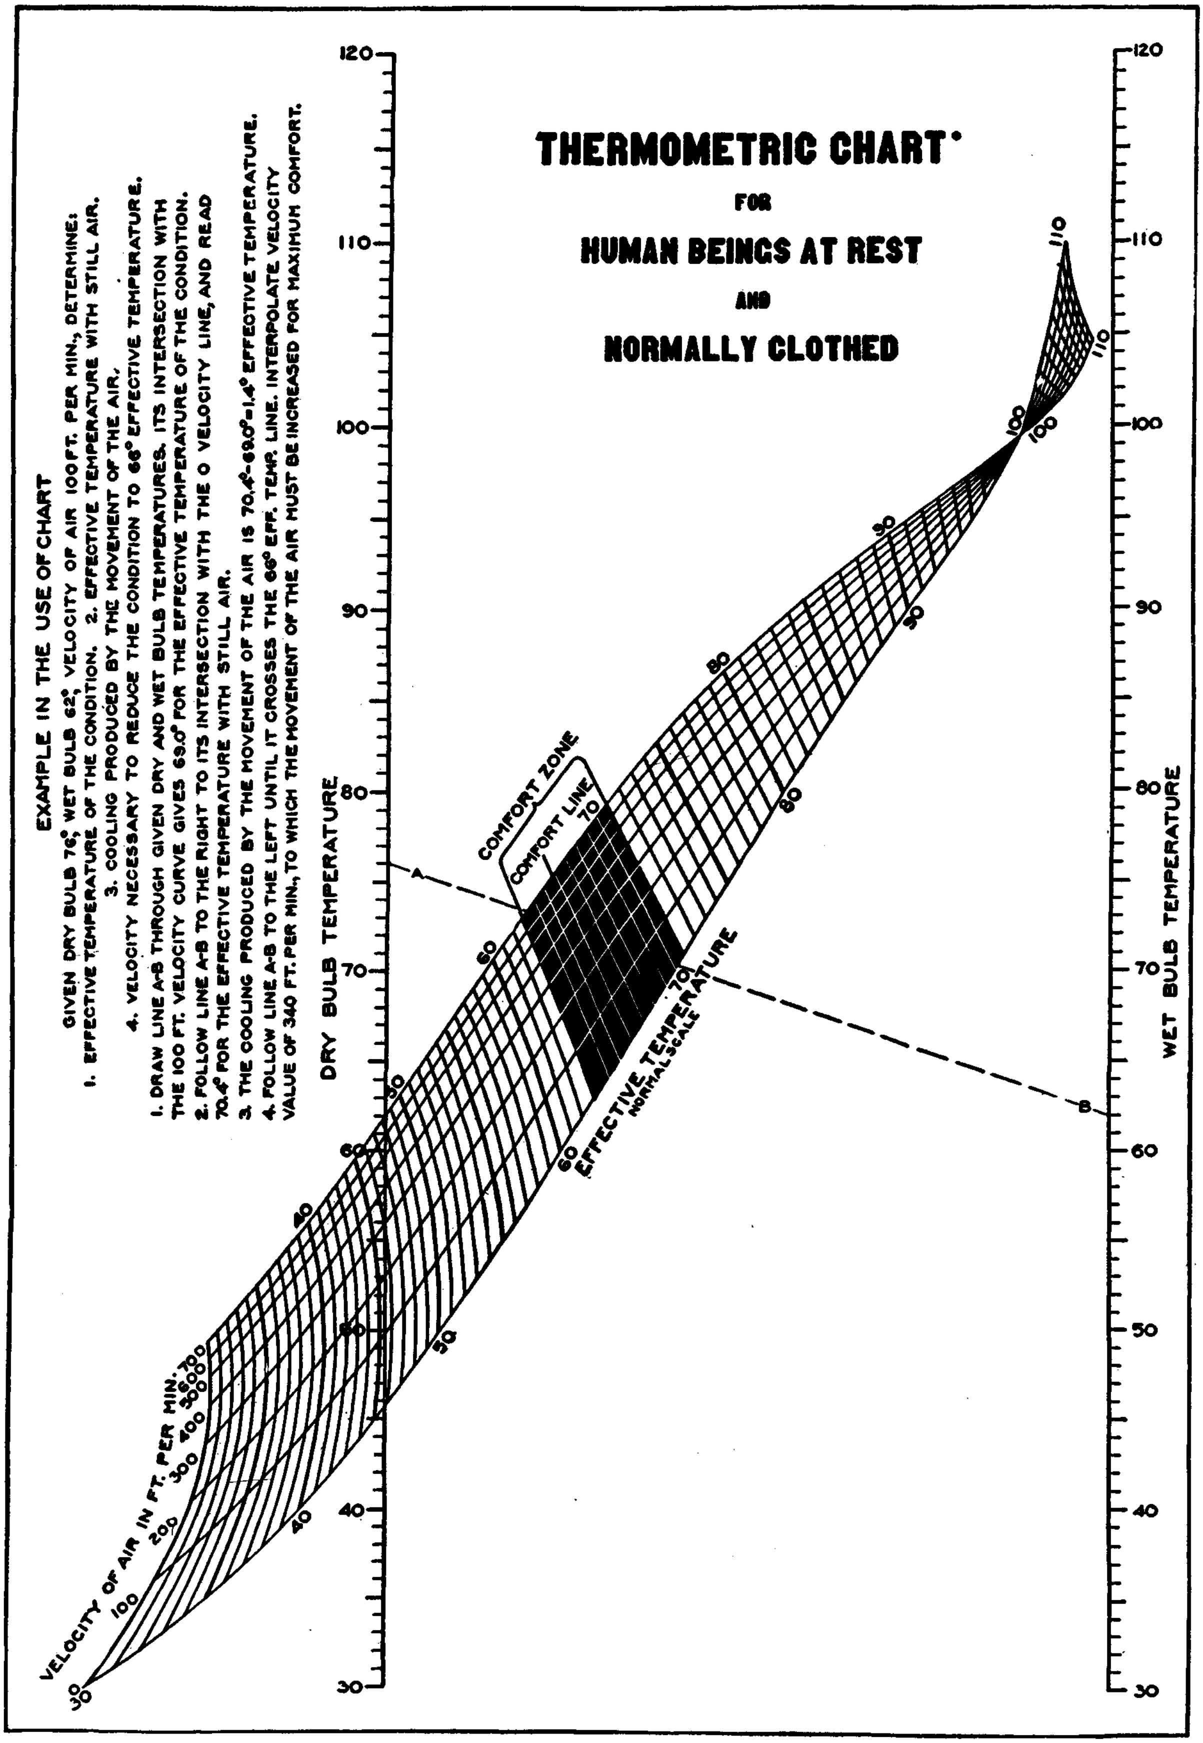
Curve No.	Material
1	Carbon black for rubber trade
2	By-product furnace coke (Franklin Co., Ill., coal)
3	By-product coke, domestic size (Pittsburgh bed coal)
4	By-product coke (domestic size)
5	Connellsville, 72 hour bee-hive foundry coke

B. SPACES OCCUPIED BY HUMAN BEINGS

R. R. SAYERS

EFFECTS OF TEMPERATURE AND HUMIDITY ON HUMAN BEINGS IN STILL AIR

Temperature of air, relative humidity 100 %	Effects when at rest				Effects when at moderate work		
	Pulse rate	Body temperature	Metabolism	Remarks	Pulse rate	Body temperature	Remarks
°F 98	Greatly increased	Marked increase	Marked increase	Very hot, even with little clothing	Very rapid	Marked increase	Very hot
95	Marked increase	Increased	Increased	Hot, even when little clothing worn	Very rapid	Marked increase	Very hot
90	Increased	Increased	Increased	Very warm	Rapid	Increased	Hot
85	No change	No change	Slight increase	Warm	Increased	Slight increase	Very warm
75–80	Slight decrease	Slight decrease	Minimum metabolism	Comfortable	Slight increase	Slight increase	Comfortable or warm
65–70	Decrease	Slight decrease	Slight increase	Slightly cool to comfortable	Slight increase	Slight increase	Comfortable
55–60	Decrease	Slight decrease	Slight increase	Cool, clothing needed for comfort	Slight increase	Slight increase	Comfortable to cool
45–50	Decrease	Slight decrease	Increased	Cool, clothing needed for comfort	Slight increase	Slight increase	Cool



THERMOMETRIC CHART*
FOR
HUMAN BEINGS AT REST
AND
NORMALLY CLOTHED

EXAMPLE IN THE USE OF CHART

GIVEN DRY BULB 76°, WET BULB 62°, VELOCITY OF AIR 100 FT. PER MIN., DETERMINE:

1. EFFECTIVE TEMPERATURE OF THE CONDITION. 2. EFFECTIVE TEMPERATURE WITH STILL AIR.
3. COOLING PRODUCED BY THE MOVEMENT OF THE AIR.
4. VELOCITY NECESSARY TO REDUCE THE CONDITION TO 66° EFFECTIVE TEMPERATURE.

1. DRAW LINE A-B THROUGH GIVEN DRY AND WET BULB TEMPERATURES. ITS INTERSECTION WITH THE 100 FT. VELOCITY CURVE GIVES 69.0° FOR THE EFFECTIVE TEMPERATURE OF THE CONDITION.
2. FOLLOW LINE A-B TO THE RIGHT TO ITS INTERSECTION WITH THE 0 VELOCITY LINE, AND READ 70.4° FOR THE EFFECTIVE TEMPERATURE WITH STILL AIR.
3. THE COOLING PRODUCED BY THE MOVEMENT OF THE AIR IS 70.4°-69.0°=1.4° EFFECTIVE TEMPERATURE.
4. FOLLOW LINE A-B TO THE LEFT UNTIL IT CROSSES THE 66° EFF. TEMP. LINE. INTERPOLATE VELOCITY VALUE OF 340 FT. PER MIN., TO WHICH THE MOVEMENT OF THE AIR MUST BE INCREASED FOR MAXIMUM COMFORT.

VISCOSITY

Data for low temperatures, very meager. The information available is expressed by the following equations and tables: (*cf.* I. C. T. sections on viscosity of H_2O and salt solutions).

NaCl, $\eta = [(\eta_w + ap + bp^2) \pm 0.5\%]$. Range, 0–30° and 5–20% (18, 19, 32, 37).

CaCl₂, $\log \eta = [(\log \eta_w + ap + bp^2) \pm 3\%]$. Range 10–30°, 5–30% (37).

For $p = 30.89\%$, $\eta = [(0.139_2 + 0.00481_5 t + 47.2_7 \times 10^{-6}t^2) \pm 5\text{–}10\%?]$. Range, −50 to 30° (39).

MgCl₂, $\eta_{25°} = 0.895 + 0.0339p + 900 \times 10^{-6}p^2 + 82.14 \times 10^{-6}p^3$. Range 0–22%. Precision ±0.5%. Accuracy ? (18, 41).

SIEVES AND SCREENS

LEWIS V. JUDSON

INTRODUCTION

The accuracy of woven metal sieves is often very high. An idea of the accuracy which may reasonably be expected in precision testing sieves may be obtained from the data in Table 2. For many purposes, such a narrow tolerance is not necessary and should not be required. An abnormally wide separation between two adjacent parallel wires may cause a serious error, especially in sieves with narrow openings. In bolting cloth, the diameters of the threads and the widths of the openings vary, not only from brand to brand, but even from bolt to bolt of the same brand. When accuracy is required, it is necessary to select particular portions of selected bolts of the cloth. Sieves are commonly designated either by the mesh per unit of length, or by the mesh per unit of area. Several different units of length (and of area) are employed. For U. S. A. grain sieves, *see* following publications of the U. S. Department of Agriculture: *Handbook of Official Grain Standards for Wheat, Shelled Corn, Oats, and Rye* (U. S. G. S. A. Form No. 90); *Handbook of United States Grades for Grain Sorghum* (U. S. G. S. A.-GI-Form No. 142); *United States Grades for Milled Rice* (Dept. Agriculture Circular 291); *Proposed Revision of United States Grades for Rough Rice* (Mimeograph U. S. G. S. A.-GI-No. 26).

INTRODUCTION

La précision des tamis métalliques tissés est souvent très grande. On peut se faire une idée de la précision qui peut être raisonablement attendue des tamis pour essais de précision, en consultant les données de la Table 2. Pour beaucoup de buts, une tolérance aussi étroite n'est pas nécessaire et ne doit pas être exigée. Une séparation anormalement large entre deux fils adjacents parallèles peut occasionner une sérieuse erreur spécialement dans les tamis à réseaux fins. Dans les étamines, les diamètres des fils et la largeur des ouvertures varient, non seulement de marques à marques, mais aussi souvent d'étamines à étamines de la même marque. Lorsqu'on exige de la précision, il est nécessaire de choisir des portions particulières d'étamines choisies. Les tamis sont communément désignés ou par le nombre de mailles par unité de longueur, ou par le nombre de mailles par unité de surface. On emploie plusieurs unités de longueur (et de surface) differentes. Pour les tamis de grains des États Unis, voir les publications suivantes du Département d'Agriculture des États Unis: *Handbook of Official Grain Standards for Wheat, Shelled Corn, Oats, and Rye* (U. S. G. S. A. Form No. 90) *Handbook of United States Grades for Grain Sorghum* (U. S. G. S. A.-Form No. 142); *United States Grades for Milled Rice* (Dept. Agriculture Circular 291) *Proposed Revision of United States Grades for Rough Rice* (Mimeograph U. S. G. S A.-GI-No. 26).

EINLEITUNG

Gewebte Metallsiebe haben häufig einen hohen Grad von Genauigkeit. Eine Vorstellung davon, wieweit sich diese bei der Präzision der Prüfung treiben lässt, erhält man aus den Angaben der Tafel 2. Für viele Zwecke ist eine so kleine Toleranz nicht notwendig und soll auch nicht gefordert werden. Eine abnormal grosse Entfernung zwischen zwei benachbarten parallelen Drähten, kann Ursache grösserer Fehler werden, besonders bei Sieben mit engen Öffnungen. Bei Siebtüchern ändert sich der Durchmesser der Fäden und die Öffnungsweite nicht nur von Marke zu Marke, sondern sogar in den Tüchern derselben Marke. Ist hier Genauigkeit gefordert, so ist es notwendig, gewisse Teile der gewählten Tücher auszusondern. Siebe sind im allgemeinen entweder durch die Zahl der Maschen pro Längen- oder pro Flächeneinheit gekennzeichnet. Es sind einige verschiedene Längen- und Flächenmasse üblich. Für die Siebe (Korn, etc.) der Vereinigten Staaten siehe die folgenden Abhandlungen des U. S. Department of Agriculture: *Handbook of Official Grain Standards for Wheat, Shelled Corn, Oats, and Rye* (U. S. G. S. A. Form No. 90) (Korn Standard); *Handbook of United States Grades for Grain Sorghum* (U. S. G. S. A.-GI-No. 142) (Sandzucker); *United States Grades for Milled Rice* (Dept. Agriculture Circular 291) (Mühlen Reis); *Proposed Revision of United States Grades for Rough Rice* (Mimeograph U. S. G. S. A.-GI-No. 26).

INTRODUZIONE

Gli stacci di tessuto metallico hanno spesso un alto grado di esattezza. Una idea della approssimazione che può ragionevolmente attendersi con stacci per saggi di precisione, può dedursi dai dati della Tabella 2. Per molti scopi una tolleranza così stretta non è necessaria, e non potrebbe pretendersi. Una distanza anormalmente grande fra due fili paralleli adiacenti può essere causa di gravi errori, specialmente negli stacci a fori piccoli. Nelle tele da buratti, il diametro dei fili e l'ampiezza dei fori variano non solo da marca a marca, ma anche nei tessuti di una stessa marca. Se si richiede grande esattezza è necessario scegliere particolari porzioni di tessuti scelti. Gli stacci sono in genere designati in base al numero di maglie per unità di lunghezza o di superficie. Le unità adoperate sono differenti.

Per gli stacci da granaglie degli S. U. A. vedi le pubblicazioni seguenti del U. S. Department of Agriculture: *Handbook of Official Grain Standards for Wheat, Shelled Corn, Oats, and Rye* (U. S. G. S. A. Form No. 90); *Handbook of United States Grades for Grain Sorghum* (U. S. G. S. A.-GI-Form No. 142); *United States Grades for Milled Rice* (Dept. Agriculture Circular 291); *Proposed Revision of United States Grades for Rough Rice* (Mimeograph U. S. G. S. A.-GI-No. 26).

TABLE 1.—SERIES OF WOVEN SIEVES

For pharmaceutical sieves, *see* Table 3

D = diameter of wire (mm); O = width of opening (mm).

Sieve designation[a]	United States of America					Great Britain	France			Switzerland
	U. S. Standard[b]		Tyler[c, d] Standard screen scale	Howard[d, e] and Morse sieve series (old)	Newark[d, e] "Market Grade" testing sieves	Institute[d, f] Mining and Metallurgy; Standard screens	Suter-Strehler[g] sieve series	Weiller and Cie.	Franck and Cie.	Market[h] Grade testing sieve cloth
N	D	O	O	O	O	O	O			O
			*26.67					Designated by number of meshes per 27.777 mm; *cf.* preceding column. Sieves of the same designation are woven with wires of various sizes, and O varies accordingly: for example, the catalogue lists No. 20 sieve in 14 different sizes of wire.	Designated by number of meshes per 27 mm; for approximate size of openings, *see* following column.

---

[a] Sieve designation is number of meshes per linear unit. For U. S. and Great Britain the unit is the inch (=25.4 mm), excepting for the U. S. Standard, for which the unit varies slightly but always approximates closely to the inch; for the Suter-Strehler series it is 27.8 mm: and for Switzerland it is 27 mm.

[b] Specifications require a frame 8 in. in diameter (3 in. for paint pigments), and either 5 cm or 2.5 cm high (above cloth). For tolerances, *see* Table 2. This series has been tentatively adopted, as standard, by the American Society for Testing Materials, using a preferred designation of width of opening in microns. Sieves of this series now used by most A. S. T. M. committees, and specifications requiring other series, are in process of revision.

[c] Widths of openings in successive sieves are related as 1 to $\sqrt[4]{2}(=1.189)$: those starred (*), as 1 to $\sqrt{2}(=1.414)$. The scale is based upon the No. 200 sieve with openings 0.0029 in. wide. Successive sieves finer than No. 4 nominally correspond, within limits of tolerance, with successive sieves of the U. S. Standard series, but there are notable differences in the designations of the two series.

[d] $D + O = 25.4/N$.

[e] U. S. Standard is now regular with Howard and Morse, Inc., but the Old Howard and Morse Standard is obtainable.

[f] This series is the standard of British Engineering Standards Committee. [g] $D + O = 27.8/N$. [h] $D + O = 27/N$.

TABLE 2.—TOLERANCES FOR U. S. STANDARD SIEVES*

D = diameter of wire; O = width of opening; min. = minimum; max. = maximum; av. = average. Unit: 1% of specified value.

Sieves	O		D_{av}	
	Av.	Max.	Min.	Max.
4 to 18	±3	10	−15	+30
20 to 45	±5	25	−15	+30
50 to 120	±6	40	−15	+35
140 to 200	±8	60	−15	+35
230 to 325	±8	90	−15	+35

* *See* Table 1.

Example: For sieve No. 30 of U. S. Standard, the average diameter of the wire must be not more than 15 % smaller or 30 % greater than 0.33 mm (Table 1); the width of the average opening must not differ from 0.59 mm by more than ±5 % (= ±0.01 mm), and the width of the largest opening must not exceed 0.59 mm by more than 25 % (=0.15 mm).

TABLE 3.—PHARMACEUTICAL SIEVES

In the body of the table are indicated the sieves composing a complete set, and the customary designations of the several sieves: * indicates that the sieve is designated by the number of meshes per cm as given in first column (Italy is an exception: *see* note). "Width" = width of opening.

Meshes per cm	Width (mm)	Austria	Belgium	Denmark	Finland	France		Germany	Great Britain	Hungary	Italy[2]	Japan	Mexico	Netherlands[3, 4]	Norway	Russia	Sweden[6]	Switzerland[3]	U. S. A.

[1] Numbers in this column are the number of meshes per "pouce" (=2.7 cm), and are the customary commercial designations of the sieves.

[2] Sieves designated by number of openings per cm² = square of number of meshes per cm.

[3] Also sieves with round holes; diameters, 1.5 mm, 3 mm, and 5 mm.

[4] Manufacturers commonly designate sieves by meshes per 26 mm.

[5] Material which passes a sieve of 9 or 10 meshes per cm is considered a "powder," and powders are graded, depending upon the country, in accordance with one of the following systems:

(*a*) Coarse, fine, very fine; (*b*) "farines," medium fine, fine, very fine; (*c*) coarse, medium, fine; (*d*) coarse, medium fine, fine, very fine; (*e*) coarse, medium fine, fine; (*f*) coarse, medium, fine, very fine; (*g*) coarse, medium coarse, medium fine, fine; (*h*) 20 to 30 mesh = coarse powder, 40 to 60 = powder, 80 to 120 = fine powder; (*i*) No. 12 = very coarse, No. 20 = coarse, No. 40 = moderately coarse, No. 50 = moderately fine; No. 60 = fine, No. 80 = very fine; No. 6, No. 30, and No. 100 also used.

[6] Silk sieves.

* The "quality" of the cloth is determined by the coarseness of the thread used. The figures given apply to the Standard, the Extra (X), and the Double Extra (XX) qualities. For the Triple Extra Heavy (XXX) quality the number of meshes per inch is in each case one less than the number given in the table. Diameter of threads is not specified. *Grit gauze* is designated by number of meshes per inch (= 25.4 mm) and is obtainable from No. 14 to No. 86.

Table 5.—Woven Sieves for Special Purposes (Metric Designation)

Sand and cement sieves, except as indicated for pharmaceutical sieves, *see* Table 3

In the body of the table are given the widths of the openings (O) in mm. If D = diameter of wire (mm) and N = number of meshes per cm, $D = 10/N - O$. Sieves are woven, except as noted. * indicates that neither D nor O is specified.

---

[a] Also copper plates with round holes 1.5 mm and 1.0 mm in diameter.

[b] Also, for cement sand, plate 0.25 mm thick with round holes 1.350 mm and 0.775 mm in diameter.

[c] For sand and pebbles, plates with round holes 60, 30, 15, 10, 5, 2, and 0.5 mm in diameter.

[d] Also plates with round holes 2, 1.5, 1, and 0.5 mm in diameter. For other woven sieves *see* Table 1.

[e] Commercial designations recognized: meshes per inch (25.4 mm), meshes per old French inch (=pouce = 27 mm), meshes per Rhenish in. (=Zoll = 26.15 mm) and meshes per cm, as well as meshes per cm^2.

[f] Sieves commonly designated by meshes per inch of 26 mm.

[g] French sieves are used in flour industry: British sieves, in mining industry.

[h] Sieves in common use are designated by meshes per linear inch, meshes per linear verchoc (44.45 mm), and meshes per cm^2.

[i] Tidbeck sieves are designated by meshes per inch of 25 mm.

[j] For other woven sieves, *see* Tables 1, 3, 4. For *Grit Gauze see* Table 4, footnote.

[k] Tolerance in mean value of $O = \pm 5\%$; max. deviation for N = 1 to 7 is ±10 %, 8 to 20 is ±20 %; 20 to 100 is ±30 %. Tolerance in mean value of D for N = 1 to 4 is ±3 %, 5 to 70 is ±4 %, 80 to 100 is ±5 %; max. deviation for same limits of N are ±6 %, ±8 %, ±10 %, respectively. Series consists of N = 1, 2, 3, 4, 5, 6, 8, 10, 11, 12, 14, 16, 20, 24, 30, 40, 50, 60, 70, 80, 100.

TABLE 6.—WOVEN WIRE SIEVES FOR SPECIAL PURPOSES* (INCH DESIGNATION)

American and British; for pharmaceutical sieves, *see* Table 3

D = diameter of wire; δD = amount by which the average D of all the wires in one direction may depart ($\pm$) from value specified for D: δn = allowable variation ($\pm$) in n per whole cm; max. [min.] = maximum [minimum] allowable value; N = approximate number of meshes per in.; n = number of meshes per cm; O = width of opening; S = specified value.

* Round holes, specified by their diameters in inches. For sizing gypsum rings 76, 38, and 25 mm in diameter are used.

† Gages are of sheet metal at least 5 mm thick and contain both circular holes and slots.

SACCHARIMETRY, THE PROPERTIES OF COMMERCIAL SUGARS AND THEIR SOLUTIONS

Frederick Bates, F. P. Phelps, C. F. Snyder

Properties.—Under each sugar the various properties of the sugar and its solutions are given in the following order: optical rotation, refractive index, density, solubility, mutarotation, hydrolysis and decomposition.

Propriétés.—Sous chaque sucre on trouvera les propriétés variées du sucre et de ses solutions disposées dans l'ordre suivant: rotation optique, indice de réfraction, densité, solubilité, mutarotation, hydrolyse et décomposition.

Eigenschaften.—Unter jedem Zucker werden die verschiedenen Eigenschaften und die seiner Lösungen in folgender Ordung angegeben: Rotation, Refraktions-Index, Dichte, Löslichkeit, Multirotation, Hydrolyse und Zersetzung.

Proprietà.—Per ogni zucchero, le sue proprietà e quelle delle soluzioni sono riportate nell'ordine seguente: rotazione ottica, indice di rifrazione, densità, solubilità, mutarotazione idrolisi e scomposizione.

INTRODUCTION

Saccharimetric Methods and Standards

Specific Rotation.—The specific rotation $[\alpha]$ of any substance in the dissolved state is represented and defined by the equation

$$[\alpha]_X^{t^\circ} = \frac{\alpha}{lC} = \frac{\alpha}{lpd}$$

where t designates the temperature of measurement, X is a character used to identify the wave length of the light source used, α is the observed rotation in circ. deg., l the length of the solution in dm, C its concentration in g per ml at $t°$, p its concentration in wt. %, and d its density in g/ml at $t°$. $[\alpha]$ varies with X, and to a less extent with t and C (or p). Wherever possible the values of the specific rotations of the more important sugars are given at definite intervals of concentration. $[\alpha]$ for all intermediate concentrations may be found by interpolation.

Saccharimetric Method.—Since monochromatic light sources are difficult to obtain, it is frequently more convenient to use a white-light source and a quartz-wedge saccharimeter. This saccharimeter is particularly applicable to the sugar group because the rotatory dispersions of quartz and the common sugars are very similar. The conditions for accurate observing are improved if the violet end of the spectrum is absorbed by the potassium bichromate cell. The saccharimetric scale is defined by the rotation of sucrose, its hundred point being the rotation of 26 g (in air, $d = 0.0012$, brass weights) in 100 ml of solution. Therefore in order to determine a sugar having a different rotatory power, the weight used must be adjusted to the sucrose scale, *i.e.*, the saccharimetric normal weight of the sugar in question is that weight which, dissolved in 100 ml of solution, will give a rotation of 100° on the sucrose scale. To compute this weight use, whenever the data are available, the results of direct determinations of the values of the rotations on the sucrose scale.

In the case of the first four sugars of the following table, determinations have been made of the relation between the rotation in sucrose deg. (°*S*) and circ. deg. of sodium light for the same solution. If this relation is known, the saccharimetric normal weight for the saccharimeter can be computed from the known specific rotation.

In the case of many sugars no direct determinations of the relative values of the sugar deg. and circ. deg. are available, and in these instances the saccharimetric normal weight must be computed from the relative specific rotations of sucrose and of the sugar in question on the assumption that the rotation dispersion of all the sugars is the same as that of sucrose, which is not strictly true. Saccharimetric normal weights so computed must therefore be considered only as the nearest approximation at present available. The computation depends upon the assumption that the saccharimetric normal weights of the sugars vary inversely as their specific rotations.

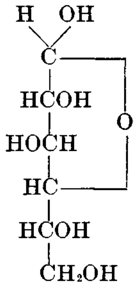
SACCHARIMETRIC NORMAL WEIGHTS, W_N

In air, $d = 0.0012$, brass weights

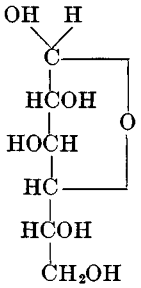
Sugar	1°*S* =	W_N
Dextrose	0.3448	32.24$_8$
Lactose	.3452	32.85$_7$
Maltose	.3449	12.47$_4$
Raffinose ($5H_2O$)	.3450	16.50$_7$
Levulose	calc.	18.59$_2$
Invert sugar	calc.	86.45$_0$

Thus in the determination of these sugars it is merely necessary to weigh out the appropriate normal weight of the sugar and proceed exactly as in the analysis of sucrose. The specific rotation is in general not exactly proportional to the concentration of the sugar, and for accurate work a correction should be applied for readings which vary much from the 100° point. Many experimenters advise using a variable saccharimetric normal weight according to the concentration of the sugar taken, but this requires a previous knowledge of the quantity of sugar present or a preliminary assay of the material. It is more convenient to use a uniform saccharimetric normal weight and to apply a correction for the various parts of the sugar scale.

Mutarotation.—In a very large class of sugars a considerable lapse of time is required for the dissolved sugar to exhibit a stable rotatory power. The rotation of the freshly prepared solution in general steadily changes according to the laws of unimolecular reactions, to a steady state, where no further change occurs. This phenomenon is called "mutarotation." The specific rotation of the sugar is commonly expressed in terms of this equilibrium condition. Mutarotation has been satisfactorily explained by the discovery of two modifications of each of the sugars in which the phenomenon exists. These two modifications have been designated the α- and β-forms. When the sugar crystallizes, but one of these forms separates from solution, usually on account of a considerable difference in solubility, and, consequently, when a fresh solution is prepared the rotatory power of this form is exhibited. The most plausible explanation of the isomerism of the α- and β-forms is connected with the end carbon atom which is capable of changing its relation to the rest of the molecule. For example, in the case of dextrose the mutarotation reaction is regarded as a balanced reaction between the two forms:—



α-*d*-Glucose
$[\alpha]_D^{20} = 113.4°$



β-*d*-Glucose
$[\alpha]_D^{20} = +19.0°$

The steady state is, under this hypothesis, a state in which the reaction velocities $\alpha \rightarrow \beta$ and $\beta \rightarrow \alpha$ are equal.

As the change of one form into the other obeys the laws of mass action and appears to be a unimolecular reaction, the mutarotation constant is expressed by the formula

$$k_1 + k_2 = \frac{1}{t} \log_{10} \frac{r_0 - r_\infty}{r_t - r_\infty},$$

r_0 and r_∞ being the initial and final rotations, and r_t the rotation at the time, t, from the start.

International Sugar Scale.—The Ventzke sugar scale, although in general use for many years, has never been fully understood by polariscopists generally. This has led to much confusion and to the use of 100 ml flasks on instruments standardized for use with the Mohr flask. In addition, 17.5°C is well below the temperature of the average laboratory. Because of these and other considerations the International Sugar Commission at the Paris meeting in 1900 recommended the use of a new definition of the 100° point based upon true ml and a standard temperature of 20°C. In order to divorce it as completely as possible from confusion with the Ventzke scale, the new scale is referred to as the international sugar scale because of its origin. The change to 20°C necessitated a change in the saccharimetric normal weight in order to keep the new scale comparable with the Ventzke. Correcting for the change in the specific rotation (−0.000184), the expansion of a glass tube (+0.000008), quartz wedge (−0.000130), and metal scale (−0.000018), the new weight becomes 26.000+ g. The *international sugar scale* was then defined at the Paris meeting as follows: The graduation of the saccharimeter and all readings shall be made at 20°C; 26 g (in air, $d = 0.0012$, brass weights) of sucrose are dissolved in water and the volume made up to 100 ml at 20°C. This will determine the 100° point.

Standardization of International Sugar Scale.—The 100°*S* point on the international sugar scale was determined by Herzfeld and Schönrock in 1900–1904 (33, 82), with the result that 100°*S* = 34.657° (λ = 589.25mμ). In 1916 Bates and Jackson (9) of the Bureau of Standards, as the result of an elaborate investigation, found that 100°*S* = 34.620 (λ = 589.25mμ). They found that the saccharimetric normal sucrose solution as defined by the International Sugar Commission did not read 100°*S* on saccharimeters standardized on the Herzfeld-Schönrock basis. Subsequently additional investigations were carried out at the Institut für Zucker-Industrie (52) and at the Research Institute for the Czechoslovakian Sugar Industry (87). The readings of the saccharimetric normal sucrose solution on the original Herzfeld-Schönrock scale are given in the following table:

Original Herzfeld-Schönrock determination	1900–1904	100.00°*S* (33, 82)
Bates and Jackson	1916	99.895 (99.870–99.91) (9)
Stanek	1921	(99.81–99.90) (87)
Kraisy and Traegel	1924	99.834 (99.775–99.895) (52)

Saccharimetric Scale Conversion Factors.—Comparisons may be made between the readings of different scales by means of the following conversion factors: 1° International sugar scale = 0.34620° angular rotation *D;* 1° French sugar scale = 0.21666° angular rotation *D;* 1° Wild sugar scale = 0.13284° angular rotation *D.* (Saccharimetric normal weight = 26.00 g International scale = 16.29 g French scale = 10.00 g Wild scale.)

Quartz Control Plates.—The accuracy of the readings on the quartz wedge saccharimeter is checked by means of quartz control plates accurately standardized for the mercury line, λ = 546.1mμ. In order to obtain a quartz rotation for λ = 589.25, use the equation

$$\frac{\phi_{\lambda=589.25}}{\phi_{\lambda=546.1}} = 0.85085 \ (^{6,\,9})$$

where ϕ is the rotation in circ. deg. By this method the errors due to the character of the sodium source of light are eliminated and the measurements of one observer may be readily compared with those of another. The rotation of quartz in circ. deg. at a temperature t is given by:

$$\phi_t = \phi_0\,(1 + 0.000144t), \text{ between 4 and 50°C}$$

THICKNESS OF THE NORMAL QUARTZ PLATE (^{9})

Wave length of light source, Å	Rotation of normal plate (Bates and Jackson)	Rotation of 1 mm of quartz at 20°C; light parallel to optic axis	Thickness of normal plate, mm
5892.5	34.620°	21.7182° (Gumlich)	1.5940
5892.5	34.620°	21.7283° (Lowry)	1.5934
5461	40.690°	25.5371° (Lowry)	1.5934

Rotation of Normal Quartz Plate (^{9}). Normal quartz plate = 100°*S* = 34.620° (λ = 5892.5 Å) at 20°C; 1° (λ = 5892.5 Å) = 2.8885°*S*. Normal quartz plate = 100°*S* = 40.690° (λ = 5461 Å) at 20°C; 1° (λ = 5461 Å) = 2.4576°*S*.

Absolute Rotation of Saccharimetric Normal Sucrose Solutions (^{9}).—The rotation of the saccharimetric normal sucrose solution for λ = 5461 Å by direct measurement is: 100° sucrose = 40.763° of arc. Since the rotation ratio for the saccharimetric normal solution for λ = 5892.5 Å and λ = 5461 Å is 0.84922° the rotation of the saccharimetric normal solution for λ = 5892.5 Å is 34.617°.

Rotation Ratios for Quartz and for Sucrose Solutions (^{9}).—The ratios of the rotations in circ. deg. of quartz and of sucrose solutions for two wave lengths are as follows: For quartz $\frac{\phi^{20}_{\lambda=5892.5\text{Å}}}{\phi^{20}_{\lambda=5461\text{Å}}}$ = 0.85085 and for sucrose $\frac{\phi^{20}_{=5892.5\text{Å}}}{\phi^{20}_{=5461\text{Å}}} = 0.84922$.

Rotatory Dispersion Curves of Quartz and of Sucrose Solution (^{9}).—The difference between the rotations of the normal quartz plate and the saccharimetric normal sucrose solution for λ = 589.25mμ is 0.003° and for λ = 546.1mμ, 0.073°. The values indicate that the rotatory dispersion curves of plate and solution cross at about λ = 585mμ. The reading of the saccharimetric normal solution on the true saccharimeter scale with the source λ = 589.25mμ has been calculated to be 99.99°*S*.

Rotation Difference, in Sucrose Degrees, for Saccharimetric Normal Sucrose Solution between λ = 5461 Å *and* λ = 5892.5 Å.—Saccharimeter reading (λ = 5461 Å) − saccharimeter reading (λ = 5892.5 Å) = 0.19_2°*S* (^{9}).

$C_{12}H_{22}O_{11}$, SUCROSE

(Composition: Levulose < > Dextrose)

Optical Rotation

IN H_2O

(p = wt. % sucrose; C = g sucrose per 100 ml solution). $[\alpha]^{20}_{\mathrm{D}} = 66.386° + 0.01503_5 p - 0.0003986 p^2$ [Tollens (^{88})]. $[\alpha]^{20}_{\mathrm{D}} = 66.438° + 0.01031_2 p - 0.0003545 p^2$ [Nasini and Villavecchia (^{67})]. Landolt (^{55}) has combined the above giving: $[\alpha]^{20}_{\mathrm{D}} = 66.435° + 0.00870C - 0.00023C^2$, ($C$ from 0 to 65) or, $[\alpha]^{20}_{\mathrm{D}} = 66.412° + 0.01267_3 p - 0.0003765 p^2$ between p = 0 and 50 wt. %; all weights *in vacuo.*

EFFECT OF SALTS ON THE ROTATION OF SUCROSE IN H_2O AT 20°C

The rotation in deg. *S* of a saccharimetric normal sucrose solution containing *m* grams of salt per 100 ml of solution is expressed by the equation $R = 100 - am$, where a has the following values:

Salt	NaCl	NH_4Cl	$K_2C_2O_4$	$CaCl_2$	Pb $(C_2H_3O_2)_2$; *v.* Fig. 1			
a	0.265	0.169	0.234	0.339	m	1.0	2.0	5.0
m_{max}	3.7	6.8	4.0	3.3	$R - 100$	0.03	0.04	0.11

$[\alpha]_D^{25}$ for a 9.60% sucrose solution containing NaCl is expressed by the equation $[\alpha]_D^{25} = 66.410 - 1.456r$ for values of r up to 1.3; r = ratio, g NaCl to g sugar (91, 92, 93).

Density of Aqueous Sucrose Solutions at 20°C, g/ml

All weights *in vacuo*. For hydrometer conversion formulae *see* vol. I, p. 31 and for computed conversion tables and temperature corrections *v.* (17.5, 61.5, 75). For conversion table giving deg. Brix, d_4^{20}, d_{20}^{20} and deg. Baumé, based upon the formula, °Bé = 145 − 145/sp. gr., d_{20}^{20} *v.* (7).

Density of Aqueous Sucrose Solutions at 20°C, g/ml.

g sucrose per 100 cm³ solution	0.3	1.6	3.8

Hydrolysis

HYDROLYSIS (INVERSION) OF SUCROSE

Sucrose	Acid	°C	*k*	Lit.
17.1%	0.099*N* HCl	35	0.00161	(72)

1000 g H_2O + 0.25 g-mole of sucrose + 1 g-mole of acid, 25°C

HNO_3	HCl	H_2SO_4	Lit.
k = 0.00464	0.00500	0.00549	(1)

TIME NECESSARY FOR VARYING PERCENTAGES OF HYDROLYSIS (INVERSION) OF SUCROSE WITH HCL (0.01*N* AT 20°C) AS THE CATALYZER (50)

°C	*k*	50% inversion, min	90% inversion, min	99.9% inversion, hr
50	0.001145	262.9	873.4	43.5
60	0.003806	79.1	262.9	13.1
70	0.01182	25.5	84.6	4.2
80	0.03303	9.11	30.3	1.5
90	0.08922	3.37	11.21	33.4*
100	0.26797	1.12	3.73	11.2*

* Minutes.

The reaction velocities for lower acidities may be computed without appreciable error by considering the velocity proportional to the concentration of acid. Thus, the velocities at 0.005*N* HCl will be very closely half those at 0.01*N* and the time of reaction twice as great.

REACTION VELOCITIES AT VARIOUS TEMPERATURES

$$k = \frac{1}{t}\log_{10}\frac{r_0 - r}{r_t - r},\ t \text{ in min}$$

$$k_{T_2} = k_{T_1}e^x, \text{ where } x = \frac{Q}{R}\,\frac{T_2 - T_1}{T_2T_1}$$

Sucrose, 50%; HCl, 0.1*N* at 20°C. Q/R = 12 925.2 (48)

30.093	0.01001	40.088	0.03791

INVERSION OF SUCROSE WITH INVERTASE (69)

$$t = \frac{1}{n}\log_{10}\frac{100}{100 - p} + 0.002642p - 0.000008860p^2 - 0.0000001034\,p^3;$$

t = minutes; p = % inversion; n is proportional to the amount of active invertase and depends upon the temperature.

Range of invertase concentration from 12 to 1; temperature from 15 to 35°; H-ion concentration 4×10^{-5} to 3.2×10^{-7}.

At any given temperature *n* may be used to measure the activity of an invertase solution.

LENGTH OF TIME REQUIRED TO FORM CARAMEL EQUIVALENT TO 0.01 % INVERT SUGAR (9)

The time, in hours, required to form caramel equivalent to 0.01% invert sugar at any temperature *t* (°C) between 39 and 100° may be computed from the equation:

$$\log_{10} \text{hr} = 5.0026 - 0.0595t.$$

LACTOSE

$C_{12}H_{22}O_{11}$ (Galactose < Dextrose <)

TRANSITION TEMPERATURES AND MELTING POINTS (85)

α-hydrate → β-anhydrous, 93.5°. α-anhydrous → liquid, 222.8°. β-anhydrous → liquid, 252.2°. α-anhydrous is metastable below its melting point. α-hydrate → liquid, 201.6°.

	99.0	.0676 HCl	.0353
	99.0	.0773 HCl	.0707
	99.0	.1041 HCl	.3172

The "apparent" acidities are those which would have been produced in pure water. A portion of the acid in each instance was rendered ineffective by inorganic impurities.

Velocity of Conversion of Inulin in the Presence of Varying Concentrations of Hydrochloric Acid at 100°C

Normality of HCl	Velocity constant, k	k (ash-free) in 0.01N HCl
0.0095	0.00641	$\frac{k(3-2)}{N(3-2)} = 0.0184$
0.0199	.0394	$\frac{k(4-3)}{N(4-3)} = 0.0212$
0.0545	.1022	$\frac{k(4-2)}{N(4-2)} = 0.0199$
0.1034	.2057	
Mean		0.020

By taking the differences in velocity at the higher acidities the neutralizing action of inorganic impurities is arithmetically eliminated.

Decomposition of Levulose in the Presence of Sulfuric Acid (51)

Clerget Analysis for Sucrose (48)

The estimation of sucrose in the presence of other optically active substances by the Clerget Method depends upon the change of rotation which the sugar undergoes upon inversion. The difference in saccharimeter deg. between the rotation of 26 g of pure sucrose in 100 ml of solution observed in a 200 mm column and the rotation of invert sugar calculated to a concentration of 26 g of inverted sucrose in 100 ml is known as the Clerget Divisor. Two general methods of inversion are employed:

(*a*) Inversion by the enzyme, invertase.[1]
(*b*) Inversion by hydrochloric acid.[2]

Values of Clerget Divisor

(m_s, resp. m_A, resp. m_N, resp. m_{Na} = g inverted sucrose, resp. HCl, resp. NH_4Cl, resp. NaCl in 100 ml of solution. t = °C.)

(*a*) Invertase inversion.

Positive constituent	Negative constituent
+100	$-42.1 - 0.0676\,(m_s - 13) + t/2$

(*b*) HCl inversion, 2.312 g anhyd. HCl in 100 ml of inverted solution, equivalent to 10 ml of HCl ($d_4^{20} = 1.1029$).

Positive constituent	Negative constituent
+100	$-43.25 - 0.0676\,(m_s - 13) + t/2$

(*c*) HCl inversion and subsequent neutralization with NH_4OH equivalent to 10 ml HCl ($d_4^{20} = 1.1029$) in 100 ml of inverted solution.

Positive constituent	Negative constituent
+100	$-43.91 - 0.0676\,(m_s - 13) + t/2$

(*d*) HCl inversion with 10 ml of HCl ($d_4^{20} = 1.1029$) in 100 ml of inverted solution; 2.315 g NaCl contained in 100 ml of solution for direct polarization (in order to equalize the effect of HCl upon invert sugar when present as an impurity).

Positive constituent	Negative constituent
+99.38	$-42.1 - 0.0676\,(m_s - 13) + t/2$

(*e*) HCl inversion with 10 ml HCl ($d_4^{20} = 1.1029$) in 100 ml of inverted solution and subsequent neutralization with NH_4OH; 3.392 g NH_4Cl contained in 100 ml of solution for direct polarization.

Positive constituent	Negative constituent
+99.43	$-43.91 - 0.0676\,(m_s - 13) + t/2$

Generalized Formulae

Positive constituent: $R = 100 - 0.265\,m_{Na} = 100 - 0.169\,m_N$.

Negative constituent: $R_{HCl} = -41.12 - 0.5407m_A - 0.0676\,m_s + 0.5\,t$. $R_{NH_4Cl} = -41.12 - 0.563m_N - 0.0676m_s + 0.5t$.

Reducing Powers toward Fehling's Solution

For Munson and Walker's table for calculating dextrose, invert sugar, in mixtures containing sucrose, lactose and maltose *v.* (18, 65). For Allihn's tables *v.* (14, 20).

X-RAY DIFFRACTION DATA—
MISCELLANEOUS NATURAL AND INDUSTRIAL MATERIALS

RALPH W. G. WYCKOFF

The following bibliography contains references to qualitative and quantitative studies by means of X-rays on various natural and industrial materials, and supplements the quantitative data on pure metals, alloys, soaps, etc., presented in vol. I, p. 338–353. The following classes of materials are covered: I. Structure of Alloys. II. Non-ferrous Metals and Alloys. III. Iron and Steel. IV. Worked Metals and Alloys. V. Orientation of Crystals in Electrodeposited Metals. VI. Fibrous or Deformed Substances. VII. Cellulose and Related Compounds. VIII. Rubber and Related Compounds. IX. Ceramic Materials and Products. X. Glass and Silica. XI. Catalysts. XII. Amorphous and Colloidal Materials. XIII. Application to the Identification of Compounds.

I. STRUCTURE OF ALLOYS

(1) Hadfield, Main and Brooksbank, *83*, **15 II**: 72; 20 (steels). (2) Bain, *33*, **25**: 657; 21 (crystal structure). (3) Bain, *80*, **68**: 625; 23 (crystal structure of solid solutions). (4) Wever, *Bericht No.* 24 *des Werkstoffausschusses der Ver. deutscher Eisenhüttenleute*, Oct. 5, 1922 (structure of metals). (5) Jeffries and Archer, *33*, **29**: 923, 966; 23 (solid solutions). (6) Rosenhain, *58*, **112**: 832; 23 (solid solutions and inter-metallic compounds). (7) Rosenhain, *115*, **115**: 591; 23 (inner structure of alloys). (8) St. John, *430*, **112**: 890, 908; 23 (X-rays in the steel industry). (9) Bain, *45*, **16**: 692; 24 (X-ray crystal analysis in metallurgy).

(10) Becker, *Metallbörse*, **14**: 297, 346, 395, 442; 24 (X-rays in chemical research). (11) Andrew, *J. Roy. Tech. Coll. Glasgow*, No. **2**: 63; 25 (crystalline structure of metals). (12) Czochralski, *218*, **13**: 425, 455; 25. *95*, **17**: 1; 25 (metallography and physical research). (13) Glöcker, *95*, **16**: 180; 24 (testing of materials). (14) Jeffries, *66*, **25 I**: 444; 25 (X-ray metallography). (15) Rosenhain, *325*, **24**: 361; 25 (inner structure of alloys). (16) Weiss, *198*, **36**: 397; 25. *74*, **22**: 333, 450; 25 (X-ray spectrography and the study of metals). (17) Weiss, *5*, **108**: 643; 25 (X-rays and the study of alloys). (18) Westgren and Phragmén, *55*, Special No., April 1, 1925, p. 86 (structure of alloys). (19) Westgren, *Sartryck ur Teknisk Tidsk.*, 1925, häft 22 (solid solutions).

(20) Aborn and Burgmann, *The Tech Engineering News*, April, 1926, p. 2 (ultimate structure of metals). (21) Rinne, *95*, **18**: 37, 81; 26 (models for the mechanics of metals). (22) Tammann, *8*, **79**: 81; 26 (distribution of two kinds of atoms in mixed crystals). (23) Westgren and Phragmén, *95*, **18**: 279; 26 (metallic systems). (24) Westgren and Phragmén, *20*, **19B**: No. 12; 26 (structure analogies of alloys).

II. STRUCTURES OF NON-FERROUS METALS AND ALLOYS

(1) Imai, *159*, **11**: 313; 22 (Cu-Zn). (2) McKeehan, *Ann. Postes, Télég. Téléph*, **12**: 1303; 23. *47*, **32**: 564; 24 (K, Be, BeO, and Ag-Pd and Au-Ag alloys). (3) Davey, *2*, **26**: 736; 25 (W). (4) Johansson and Linde, *8*, **78**: 439; 25 (Au-Cu and Pd-Cu). (5) Krüger and Sacklowski, *8*, **78**: 72; 25 (Pd-Ag alloys containing H). (6) Anderson, *143*, **201**: 465; 26 (duralumin and its crystal structure). (7) Bradley and Ollard, *58*, **117**: 122; 26 (Cr). (8) Freeman and Brandt, *31A*, **20**: 661, 695; 26 (Zn). (9) Friauf, *1*, **48**: 1906; 26 (magnesium plumbide).

(10) Harang, *63*, **27**: 204; 26 (Heusler alloys). (11) Holgersson, *8*, **79**: 35; 26 (Au-Ag and Ni-Cu). (12) Sillers, *31A*, **20**: 686; 26. *Cf.* Pierce, Anderson and Van Dyck, *143*, **200**: 363; 25 (Zn). (13) Westgren and Phragmén, *468*, **2**; 1926 (Cr-C). (14) Westgren and Phragmén, *93*, **156**: 27; 26 (W-C and Mo-C).

III. CRYSTAL STRUCTURE OF IRON AND STEEL

Cf. vol. I, p. 349

(1) Iokibe, *159*, **9**: 275; 20 (graphite and temper-carbon from cast iron). (2) Westgren, *220*, **105**: 401; 21 (steel). (3) Westgren, *140*, **103**: 303; 21. *115*, **111**: 727, 757; 21 (iron and steel). (4) Westgren and Lindh, *7*, **98**: 181; 21 (iron and steel). (5) Wever, *226*, **3**: 45; 21 (arrangement of iron atoms in austenitic steel). (6) Bain, *33*, **26**: 543; 22 (martensite formed spontaneously from austenite). (7) Tammann, *77*, **42**: 772; 22 (transformation of cementite at 210°). (8) Westgren and Phragmén, *140*, **105**: 241; 22 (steel). (9) Westgren and Phragmén, *7*, **102**: 1; 22 (iron and steel).

(10) Wever, *226*, **4**: 67; 22 (iron carbide). (11) Wever, *226*, **4**: 81; 22 (graphite and temper-carbon). (12) Bain and Jeffries, *430*, **112**: 805; 23 (red hardness in high-speed steel). (13) Heaps, *2*, **22**: 486; 23 (crystal structure and magneto-striction). (14) Okochi, *469*, **2**: 13; 23 (brittleness in electrolytic iron). (15) Westgren and Phragmén, *220*, **1923**: 449 (steel). (16) Zorning, *471*, **4**: 77; 23 (examination of steel by X-ray spectrometer). (17) Bain, *80*, advance copy, Feb., 1924 (martensite). (18) Greene, *430*, **114**: 615, 670; 24 (troostite and sorbite). (19) Heindlhofer, *2*, **24**: 426; 24 (martensite).

(20) Heindlhofer and Wright, *212*, **7**: 34; 24 (hardened ball steel). (21) Honda, *212*, **6**: 187; 24 (transformation in pure Fe). (22) Lucas, *212*, **6**: 669; 24 (austenite and martensite). (23) Westgren and Phragmén, *58*, **114**: 94; 24. *140*, **109**: 159; 24 (steel). (24) Wever, *9*, **30**: 376; 24 (technical iron). (25) Wever and Rütten, *226*, **6**: 1; 24 (solid solution γ-Fe-C). (26) Williams, *417*, **13**: 175; 24 (hardened steel). (27) Benedicks, *58*, **115**: 230; 25 (hardness of Mn-steel). (28) Foley, *80*, **73**: 850; 26 (amorphous cement and the formation of ferrite). (29) Honda, *159*, **14**: 165; 25 (formation of martensite in C-steels).

(30) Wever, *77*, **45**: 1208; 25 (Fe). (31) Davey, *120*, **29**: 440; 26 (iron and steel). (32) Fink and Campbell, *212*, **9**: 717; 26 (influence of heat treatment and carbon content on pure Fe-C alloys). (33) Osawa, *140*, **113**: 447; 26 (lattice-constant and density of Fe-Ni alloys). (34) Phragmén, *140*, **1926**, advance paper (Fe-Si alloys).

IV. X-RAY DIFFRACTION OF WORKED METALS AND ALLOYS

(1) Owen and Blake, *58*, **92**: 686; 14 (metallic crystals). (2) Schmidt, *63*, **17**: 554; 16 (metals). (3) Gross and Blassmann, *190B*, **42**: 728; 19 (wire-forming W crystals). (4) Nishikawa and Asahara, *2*, **15**: 38; 20 (metals). (5) Bain and Jeffries, *33*, **25**: 775; 21 (mixed orientation in crystals of ductile metals). (6) Ettisch, Polanyi and Weissenberg, *63*, **22**: 646; 21 (metals). (7) Ettisch, Polanyi and Weissenberg, *96*, **7**: 181; 21 (fibre-structure of Cu and W-wires). (8) Ettisch, Polanyi and Weissenberg, *7*, **99**: 332; 21 (fibrous structure of hard-drawn metals). (9) Kirchner, *8*, **69**: 59; 22 (experiments on structure).

(10) Mark, Polanyi and Schmid, *96*, **12**: 58, 78, 111; 22 (drawing Zn crystals). (11) Niwa and Matûra, *338*, **122**: 1; 22 (cold rolling of sheet steel). (12) Ono, *470*, **2**: 261; 22 (inner structure of strained metals). (13) Ono, *470*, **2**: 241; 22 (inner structure of strained Cu-wire). (14) Polanyi, *218*, **10**: 411; 22 (crystal arrangement). (15) Polanyi, *9*, **28**: 16; 22 (fixing single crystals). (16) van Arkel, *208*, **3**: 76; 23 (uni-crystalline W). (17) Bain, *33*, **28**: 65; 23 (cored crystals and metallic compounds). (18) Czochralski, *95*, **15**: 60, 126; 23 (structure hypotheses). (19) Kakinuma, *219*, **5** 90; 23 (atomistic mechanism of metal rolling).

(20) Mark and Polanyi, *96*, **18**: 75; 23 (space-lattice, gliding directions and gliding planes in white Sn). (21) Mark, Polanyi and Schmid, *218*, **11**: 256; 23 (uni-crystalline Sn-wires). (22) Mark and Weissenberg, *96*, **16**: 314; 23 (rolled metal foils). (23) Mark and Weissenberg, *96*, **14**: 328; 23 (rolled metal foils). (24) Müller, *5*, **105**: 500; 24 (crystal axes in "single-crystal" Al-bars). (25) Polanyi, *96*, **17**: 42; 23 (structure changes through cold working). (26) Polanyi and Weissenberg, *97*, **4**: 199; 23 (worked metals). (27) Thomassen, *95*, **15**: 306; 23 (surface layer of worked metals). (28) Bragg, *58*, **113**: 639; 24 (metal film). (29) Research Staff of General Electric Co., *3*, **48**: 800; 24 (deformation of W single crystals).

(30) Glöcker and Kaupp, *95*, **16**: 377; 24 (recrystallization of Ag). (31) Gross, *95*, **16**: 18; 24. *47*, **31**: 385; 24 (deformed crystals and the process of work-hardening). (32) Kakinuma, *219*, **5**: 150; 24 (atomistic mechanism of metal rolling). (33) Lester, *471*, **5**: 455; 24 (crystal deformation in cold-worked steel). (34) Polanyi, *97*, **5**: 580; 24 (worked metals). (35) Schiebold, *95*, **16**: 417, 462; 24 (hardening phenomena in metals). (36) Wever, *96*, **28**: 69; 24 (cubically crystallizing metals after rolling). (37) Anderson and Norton, *80*, **71**: 720; 25 (evidence versus the amorphous-metal hypothesis). (38) van Arkel, *208*, **5**: 208; 25. *218*, **13**: 662; 25 (deformation of lattice of metals). (39) Clark, Brugmann and Heath, *45*, **17**: 1142; 25 (ultimate structures of commercial metals).

(40) Davey, *50*, **29**: 1211; 25 (plasticity of single crystals). (41) Elam, *115*, **120**: 368; 25 (orientation of crystals produced by heating strained Fe). (42) Fujiwara, *429*, **8A**: 339; 25 (arrangement of micro-crystals in Al-wire). (43) Glöcker, *96*, **31**: 386; 25 (deformation and recrystallization structures). (44) Glöcker, Kaupp and Widmann, *95*, **17**: 353; 25 (recrystallization of rolled plate Ag). (45) Leonhardt, *94*, **61**: 100; 25 (Laue diagrams of deformed crystals). (46) Lester and Abron, *471*, **6**:120, 200; 25 (Fe-crystals in steel under stress). (47) Mark, *94*, **61**: 75; 25 (growth and deformation structures). (48) Norton and Anderson, *2*, **25**: 582; 25 (cold-worked and burnished metals). (49) Ono, *470*, **3**: 195; 25 (Cu and Al under extension, compression and torsion).

(50) Ono, *470*, **3**: 267; 25 (α-Fe plastically strained in extension, compression and torsion). (51) Ono, *470*, **3**: 287; 25 (crystal rearrangement and the cause of strain-hardening). (52) Polanyi, *95*, **17**: 94; 25 (crystal deformation

and hardening). (53) Polanyi, *94*, **61:** 49; 25 (deformation of single crystals). (54) Polanyi and Schmid, *96*, **32:** 684; 25 (solidification and melting of Sn). (55) Sachs and Schiebold, *98*, **69:** 1557, 1601; 25 (volume compression of Al). (56) Sachs and Schiebold, *218*, **13:** 964; 25 (lattice lengths of deformed single crystals and crystal aggregates). (57) Seidl and Schiebold, *95*, **17:** 221, 320, 365; 25 (inhomogeneous Al-castings on cold rolling). (58) Tanaka, *429*, **8A:** 319; 25 (rolled Pt-plate). (59) Taylor and Elam, *5*, **108:** 28; 25 (plastic extension and fracture of Al-crystals).

(60) Carpenter, *440*, **28:** 543, 575; 26. **29:** 31, 26 (single crystals). (61) Elam, *5*, **112:** 289; 26 (tensile tests of large Au, Ag and Cu-crystals). (62) Frölich, Clark and Aborn, *Mass. Inst. Tech. Publications*, **61:** 239; 26. *78*, **49:** preprint; 26 (lead deposits). (63) Owen and Preston, *67*, **38:** 132; 26 (effect of rolling on crystal structure of Al). (64) Schiebold and Sachs, *94*, **63:** 34; 26 (growth of Al-crystals during recrystallization). (65) Smithells, Rooksby and Pitkin, *47*, **1926:** advance paper (deformation of W-crystals).

V. ORIENTATION OF CRYSTALS IN ELECTRODEPOSITED METALS

(1) Glöcker and Kaupp, *96*, **24:** 121; 24 (fibrous structure). (2) Clark and Frölich, *9*, **31:** 655; 25 (electrolytic Ni). (3) Bozorth, *2*, **26:** 390; 25 (orientation of crystals in electrodeposited metals).

VI. FIBROUS OR DEFORMED SUBSTANCES

(1) Friedrich, *63*, **14:** 317; 13 (X-ray interference in non-crystalline bodies). (2) Nishikawa and Ono, *219*, **7:** 131; 13 (transmission of X-rays through fibrous, lamellar and granular substances). (3) Nishikawa, *219*, **7:** 296; 14 (spectrum of X-rays obtained by lamellar or fibrous substances). (4) Becker, Herzog, Jancke and Polanyi, *96*, **5:** 61; 21 (arrangement of crystal elements). (5) Herzog, *218*, **12:** 955; 24 (fine structure of fibrous materials). (6) Rinne, *94*, **59:** 230; 24 (rearrangement and decomposition of crystal structures). (7) Rinne, *189*, No. **17:** 513; 24 (permanent structural deformation of graphite). (8) Schmid, *96*, **22:** 328; 24 (plastic deformation of crystals). (9) Rinne, *189*, **1925:** 225 (optical anomalies).

(10) Rinne, *218*, **13:** 690; 25 (paracrystalline and stressed substances). (11) Rinne, *94*, **61:** 389; 25 (flow of natural salts). (12) Sachs and Schiebold, *95*, **17:** 400; 25 (melting and recrystallization). (13) Herzog, *472*, **24:** 137; 26 (fibrous substances). (14) Levitskii, *96*, **35:** 850; 26 (bending of rock-salt in air and water). (15) Ranzi, *59*, **3,** No. **3:** 135; 26 (changes in reticular distances of rock-salt and calcite).

VII. CELLULOSE AND RELATED COMPOUNDS

(1) Herzog and Jancke, *96*, **3:** 196; 20 (cellulose). (2) Herzog, Jancke and Polanyi, *96*, **3:** 343; 20 (cellulose). (3) Herzog, *473*, **2:** 101; 21 (cellulose). (4) Herzog and Jancke, *92*, **34:** 385; 21 (cellulose). (5) Herzog, *472*, **21:** 388; 23 (deformation of cellulose). (6) Hess, Weltzien and Messmer, *13*, **435:** 1; 23 (cellulose). (7) Sponsler, *223*, **5:** 757; 23 (structural units of starch). (8) Gonell, *96*, **25:** 118; 24 (cellulose). (9) Katz, *63*, **25:** 659; 24 (X-ray spectroscopy and swelling).

(10) Katz, *63*, **25:** 321; 24 (swelling of substances giving fibrous diagram). (11) Katz, *63*, **25:** 659; 24 (X-ray methods and imbibition). (12) Katz and Mark, *64V*, **33:** 294; 24 (swelling). (13) Sponsler, *2*, **23:** 662; 24 (X-ray reflection from very thin crystals). (14) Vieweg, *25*, **57B:** 1917; 24 (aqueous and dilute alcoholic NaOH and cellulose). (15) Herzog, *473*, **6:** 39; 25 (constitution of cellulose). (16) Herzog, *472*, **23:** 121; 25 (significance of fine structure of cellulose fiber in purification process). (17) Katz, *473*, **6:** 37; 25 (celluloses of different degrees of polymerization). (18) Katz, *473*, **6:** 35; 25 (X-ray data and alkali adsorption of cellulose). (19) Katz and Mark, *9*, **31:** 105; 25 (X-ray diffraction patterns of cellulose hydrate and its reversion products).

(20) Katz and Mark, *7*, **115:** 385; 25 (changes in powder pattern of cellulose due to swelling). (21) Katz and Vieweg, *9*, **31:** 157; 25 (X-ray diffraction patterns and the alkali content during swelling of cellulose). (22) Herzog, *37*, **9:** 631; 26 (acetyl- and nitro-cellulose). (23) Herzog, *Pulp Paper Mag. Can.*, **24:** 699; 26 (colloidal characters of cellulose). (24) Herzog, *55*, **39:** 98; 26 (swelling of cellulose). (25) Herzog, *Pulp Paper Mag. Can.*, **24:** 694; 26. *Paper Trade J.*, **83,** No. **1:** 51; 26 (cellulose). (26) Herzog, *50*, **30:** 457; 26 (significance of structure of cellulose in chemical transformation). (27) Herzog and Gonell, *92*, **39:** 380; 26 (weighting of silk). (28) Katz, *9*, **32:** 269; 26 (inflation and mercerization of cellulose). (29) Ott, *37*, **9:** 378; 26 (crystalline character of acetyl-cellulose).

VIII. RUBBER AND RELATED COMPOUNDS

(1) Davey, *2*, **21:** 719; 23 (ZnO in vulcanized rubber). (2) Pummerer, Koch and Gross, *13*, **438:** 294; 24 (crystalline rubber and hydrorubber). (3) Hauser and Mark, *Kautschuk*, Dec., 1925 (elongated samples of rubber). (4) Katz, *55*, **36:** 300: 25. **37:** 19; 25. *218*, **30:** 410; 25 (changing of X-ray spectrum of rubber on stretching). (5) Katz, *136*, **49:** 353; 25 (rubber under different degrees of elongation). (6) Katz and Bing, *92*, **38:** 439; 25 (Is raw rubber partially crystallized?). (7) Katz and Bing, *92*, **38:** 545; 25 (rubbers containing inorganic ingredients). (8) Clark, *45*, **18:** 1131; 26 (rubber and allied materials). (9) Hauser, *456*, **40:** 2090; 26 (origin of interference in stretching of rubber).

(10) Hauser and Mark, *287*, **Ambronn-Festschrift:** 64: 26 (stretched rubber). (11) Hauser and Mark, *287*, **22:** 63; 26 (stretched rubber). (12) Ott, *218*, **14:** 320; 26 (size of rubber and gutta-percha molecules).

IX. CERAMIC MATERIALS AND PRODUCTS

(1) Hadding, *Lunds Universitets Årsskrift*, **14:** No. 23; 18. *Mineral. Abstr.*, **2:** 205 (feldspar). (2) Hadding, *Lunds Universitets Årsskrift*, **17:** No. 6; 20 (feldspar). (3) Kozu and Endö, *159*, **1 III:** 1; 21 (andularia and moonstone). (4) Bragg, Shearer and Mellor, *82*, **22:** 105; 23 (china clays). (5) Schwarz and Brenner, *25*, **56B:** 1433; 23 (synthetic aluminum silicate). (6) Rinne, *218*, **12:** 244; 24 (lead-pencil marks). (7) Schwarz, *105*, **8:** 298; 24. *103*, **32:** 538; 24 (formation of kaolin). (8) Shearer, *82*, **23:** 314; 24 (china clays). (9) Sielakov, *74E*, **21:** 527; 24 (clays).

(10) Hadding, *82*, **24:** 27; 25 (clays). (11) Research Staff of General Electric Co., *82*, **24:** 402; 25 (constitutional changes occurring in clays on heating). (12) Navias, *38*, **8:** 296; 25 (development of mullite in fired clays). (13) Navias and Davey, *38*, **8:** 640; 25 (mullite and sillimanite). (14) Norton, *38*, **8:** 401; 25 (natural and artificial sillimanite). (15) Norton, *38*, **8:** 636; 25 (cyanite and andalusite). (16) Rinne, *103*, **33:** 427, 459, 525; 25 (X-ray and ceramics). (17) Rinne, *94*, **61:** 113; 25 (calcined calcite, dolomite, kaolinite and mica). (18) Bowen and Wyckoff, *128*, **16:** 178; 26 (thermal dissociation of dumortierite). (19) Greig, *38*, **8:** 465; 25. *12*, **11:** 1; 26 (mullite from cyanite, andalusite and sillimanite).

(20) Mark and Rosbaud, *190B*, **54:** 127; 26 (Al_2SiO_5 and pseudobrookite). (21) Rosbaud, *9*, **32:** 317; 26 (aluminum silicate). (22) Wyckoff, Greig and Bowen, *12*, **11:** 459; 26 (mullite and sillimanite).

X. GLASS AND SILICA

(1) Kyropoulos, *93*, **99:** 197, 249; 17 (various kinds of silica). (2) Miller, *5*, **101:** 515; 22 (vitreous silica). (3) Washburn and Navias, *197*, **8:** 1; 22 (chalcedony and other forms of silica). (4) Selyakov and Strutinskii, *Mitt. wiss.-tech. Arbeiten in der Republik* (*Russ.*), **13:** 18; 24 (structure of glass). (5) Selyakov, Strutinskii and Krasnikov, *96*, **33:** 53; 25 (structure of glass). (6) Wyckoff and Morey, *105*, **9:** 256; 25 (soda-lime-silica glasses).

XI. X-RAY DATA APPLIED TO PROBLEMS OF CATALYSIS

(1) Clark, Asbury and Wick, *1*, **47:** 2661; 25 (structure of nickel catalysts). (2) Levi, *22*, **2:** 419; 25 (thorium oxide and the dehydration of alcohol). (3) Wyckoff and Crittenden, *1*, **47:** 2866; 25 (ammonia catalysts). (4) Levi and Haardt, *36*, **56:** 424; 26 (catalytic action considered as that of surfaces). (5) Levi and Haardt, *22*, **3:** 91; 26 (catalytic action of metals of the Pt group). (6) Levi and Haardt, *22*, **3:** 215; 26 (catalytic action of metals of the Pt group).

XII. AMORPHOUS AND COLLOIDAL MATERIALS

(1) Asahara, *210*, **1:** 23; 22. *209*, **1:** 35; 22 (graphite and amorphous C). (2) Haber, *25*, **55B:** 1717; 22 (amorphous precipitates and crystallized sols). (3) Kustner, *96*, **10:** 41; 22 (decomposition and rebuilding of gadolinites). (4) Mulligan, *50*, **26:** 247; 22 (dehydration of crystalline aluminum hydroxide). (5) Böhm and Niclassen, *93*, **132:** 1; 23 (amorphous precipitates and crystallized sols). (6) Fricke and Wever, *93*, **136:** 321; 24 (aging of precipitated metal hydroxides). (7) Rinne, *94*, **60:** 55; 24 (finely divided minerals, artificial products and dense rocks). (8) Baudisch and Welo, *141*, **64:** 753; 25 (aging of ferrous hydroxide and ferrous carbonate). (9) Böhm, *93*, **149:** 203; 25 (aluminum hydroxide and iron hydroxide).

(10) Böhm, *93*, **149:** 217; 25 (glowing of oxides of certain metals). (11) Herzog, *55*, **37:** 355; 25 (colloid systems). (12) Herzog and Gonell, *25*, **58B:** 2228; 25 (collagen). (13) Katz and Gerngross, *218*, **13:** 900; 25 (gelatin and collagen). (14) Levi, *216*, **7:** 410; 25 (new chemical studies). (15) Ruff, Schmidt and Olbrich, *93*, **148:** 313; 25 (amorphous C and graphite). (16) Welo and Baudisch, *141*, **65:** 215; 25 (catalytically active and inactive forms of Fe_2O_3). (17) Welo and Baudisch, *166*, **62:** 311; 25 (oxides of iron in new catalytic actions). (18) Gutbier, Hüttig and Dobling, *25*, **59B:** 1232; 26 (stannic oxide-water). (19) Herzog and Krüger, *218*, **14:** 599; 26 (dispersibility of organic colloids).

(20) Posnjak, *50*, **30:** 1073; 26 (stannic acids).

XIII. APPLICATION TO THE IDENTIFICATION OF COMPOUNDS

(1) Posnjak and Merwin, *1*, **44:** 1965; 22 (Fe_2O_3-SO_3-H_2O). (2) Schleede and Gruhl, *9*, **29:** 411; 23 (luminescent zinc silicate). (3) Kohlschütter and Scherrer, *37*, **7:** 337; 24 (polymorphism in lead oxide). (4) Levi and Quilico, *36*, **54:** 598; 24 (non-existence of Ag suboxide). (5) Shaxby, *34*, **179:** 1602; 24 (monochromatic X-rays in production of Laue diagrams and structure of mother-of-pearl). (6) Volmer, *13*, **440:** 200; 24 ($HClO_4.H_2O$ and NH_4ClO_4). (7) Jung, *93*, **142:** 73; 25 (dehydration products of gypsum). (8) Levi, *216*, **7:** 410; 25 (new chemical studies). (9) Levi and Tacchini, *36*, **55:** 28; 25 (non-existence of Ni suboxide).

(10) Linck and Jung, *93*, **147:** 288; 25 (black metallic P). (11) Shaxby, *3*, **49:** 1201; 25 (monochromatic X-rays in production of Laue diagrams and structure of mother-of-pearl). (12) Sosman and Posnjak, *128*, **15:** 329; 25 (ferromagnetic ferric oxide). (13) Ewles, *Proc. Leeds Phil. Lit. Soc.*, **1:** 6; 26 (luminescence of solids). (14) Frebold, *187*, **23:** 115; 26 (iron hydroxide ores).

PROPERTIES OF METALS AND ALLOYS

W. ROSENHAIN, SPECIAL EDITOR

F. P. UPTON, EDITORIAL ASSISTANT

INTRODUCTION

The very condensed form in which it has been necessary to present the metallurgical data in the tables, requires some explanation in regard to their use. The abbreviations and special symbols used are explained on p. 392 and some examples illustrating their interpretation in particular cases are given below.

A table of "Critical Values" of the mechanical properties of metals and alloys necessarily differs in certain important respects from the "Critical Values" given in other connections. The reason is that metallurgical products, particularly of the more complex sort, are subject to certain unavoidable variations even when produced under the best conditions. In regard to

INTRODUCTION

Etant donné la forme très condensée dans laquelle il a été nécessaire de présenter les données métallurgiques dans les tables, il est indispensable de donner quelques explications pour leur emploi. Les abréviations et les symboles spéciaux utilisés sont expliqués à la p. 392, et quelques exemples illustrant leur interprétation dans des cas particuliers sont donnés ci-dessous.

Une table de "valeurs critiques" des propriétés mécaniques des métaux et alliages diffère nécessairement sous certains rapports importants des "valeurs critiques" données pour d'autres sujets. La raison en est que les produits métallurgiques, et plus particulièrement ceux qui sont les plus complexes, sont sujets à certaines varia-

EINLEITUNG

Die äusserst knappe Form in welcher die Metallurgie notwendigerweise in den Tafeln dargelegt ist, erfordert für ihren Gebrauch einige Erklärungen. Die vorkommenden Abkürzungen und besondere Symbole sind Seite 392 erklärt. Einige Beispiele zu ihrer Verständnis in besonderen Fällen sind weiter unten angegeben.

Eine Tafel der "Kritischen Werte" der mechanischen Eigenschaften von Metallen und Legierungen, weicht in gewissen wichtigen Beziehungen von den "Kritischen Werten" anderer Arten ab. Dies ruht daher dass metallurgische Produkte, besonders solche komplexerer Art, gewissen unvermeidlichen Eigenschaftsschwank-

INTRODUZIONE

La forma molto condensata in cui è stato necessario esporre i dati metallurgici richiede alcune spiegazioni circa l'uso delle tabelle. A pag. 392 sono spiegate le abbreviazioni e i simboli speciali adoperati, e più avanti sono riportati alcuni esempi illustranti la loro interpretazione in casi particolari.

Una tabella di "valori critici" delle proprietà meccaniche di metalli e leghe differisce necessariamente sotto alcuni punti di vista importanti dai "valori critici" di altre proprietà, e ciò per il fatto che i prodotti metallurgici, specie quelli più complessi, sono soggetti a variazioni inevitabili, anche se ottenuti nelle migliori condizioni. Per molti metalli e leghe i valori riportati many of the metals and alloys mentioned in the tables the origin of the data varies widely, some being derived from numerous tests on industrial products, while others represent the results of laboratory investigation. In making use of the tables, therefore, it is necessary to ascertain the nature of the data given. This can always be done by reference to the literature quoted. While laboratory results are generally accurately determined, it must be borne in mind that they may be either higher or lower than the figures to be anticipated from a corresponding industrial product. In some instances large-scale production makes it possible to secure better results than can be obtained in relatively small laboratory experiments, while in other cases the special conditions which can be used in laboratory work cannot readily be reproduced in industrial production.

If it is desired to form an opinion of the value of a given material for constructional purposes the nature of the material must be considered. In the case of castings, wide variations in mechanical properties occur as between different parts of the same casting, as between a large and small casting, and as between actual castings and test bars prepared either at the same time or otherwise. Even in a casting of given shape and material, variations in casting conditions, such as pouring temperature, rate of pouring and mold temperature, may cause considerable differences in mechanical properties. The figures quoted in the tables must therefore be regarded as indicating the values found for cast materials under conditions specified in the corresponding literature, and cannot be used, without further consideration, for the purpose of calculating the reliable strength of a particular casting. In wrought material, variations are likely to be much smaller than in cast. However, complete uniformity cannot be relied upon, particularly as between the products of different makers. In regard to some materials which are extensively produced industrially, the data given in the tables sometimes represent the values obtained from very numerous tests. In other cases the data may represent only isolated experiments. In compiling the tables, care has been taken to incorporate as far as possible only the most reliable data of both kinds.

Another cause of considerable variation in the mechanical properties of metals and alloys, in the wrought state, arises from the effect of mass. Material in large sections is in almost every case weaker than the same material produced in small sections. This is particularly marked where heat treatment of any kind has been given. Where the data in the tables include values corresponding to materials of different sections, it will obviously be desirable to attach the greatest importance to those figures relating to materials which have a cross section similar to that which it is proposed to use, or whose properties it is desired to ascertain. It should also be borne in mind that there is a steady improvement in foundry, rolling mill, forging and heat-treating practice, so that, as a rule, the more modern methods yield values superior to those of older materials.

In the use of the tables three possibilities will arise: (I) The properties of an alloy whose composition is known are desired. (II) The properties of some commercial alloy whose composition is not known are desired. (III) An alloy having certain properties is desired.

I. Composition of Alloy Known. Properties Desired

1. Turn to the Table of Contents (p. 358), and ascertain the section in which this type of alloy is treated.
2. Turn to the section at the page number given.
3. With the aid of the Table of Contents at the beginning of the section, ascertain the table containing the desired type of information and turn to it.
4. In each table (unless otherwise indicated) the alloys are arranged in the order of their "type formulae." The type formula

tions inévitables, même lorsqu'ils ont été fabriqués dans les meilleures conditions. L'origine des données se rapportant a plusieurs des métaux et alliages mentionnées dans les tables varie dans une large mesure; certaines données proviennent de nombreux essais sur des produits industriels alors que les autres représentent les résultats d'expériences de laboratoire. C'est pourquoi il est nécessaire pour l'emploi des tables de s'assurer de la nature des valeurs données. Ceci peut toujours être réalisé en se référant à la source bibliographique citée. Les résultats de laboratoire sont généralement déterminée avec précision; il ne faut pas cependant perdre de vue qu'ils peuvent être ou supérieurs ou inférieurs aux chiffres qu'on peut attendre d'un produit industriel correspondant. Dans certains cas une production sur une large échelle permet l'obtention de meilleurs résultats que ceux qui peuvent être obtenus dans des expériences effectuées dans le laboratoire, alors que dans d'autres cas, les conditions spéciales qui peuvent être utilisées dans le travail de laboratoire ne sont pas reproductibles facilement dans une production industrielle.

Si l'on désire se faire une opinion de la valeur d'une matière donnée et cela pour des buts de construction, il faut considérer la nature de la matière. Dans le cas des pièces fondues, il existe de grandes variations dans les propriétés mécaniques aussi bien entre les différentes parties d'une pièce donnée qu'entre une grande ou une petite pièce ou qu'entre une pièce donnée et des éprouvettes préparées au même moment ou plus tard. Même pour une pièce de dimension et d'une matière données, les variations dans les conditions de coulée, telle que la température de coulée, la vitesse de coulée et la température du moule, peuvent occasionner des différences considérables dans les propriétés mécaniques. Les chiffres cités dans les tables doivent donc être regardés comme indiquant les valeurs trouvées pour des matières coulées dans des conditions spécifiées dans la littérature correspondante, et ils ne peuvent être utilisés sans autres considérations, dans le but de calculer une valeur de résistance digne de confiance d'une pièce coulée particulière. Dans les matières travaillées, les variations sont ordinairement plus petites que dans les matières fondues. Cependant, on ne peut pas tabler sur une complète uniformité, surtout entre des produits de différents fabricants. En ce qui concerne certaines matières qui sont produites industriellement en grand, les valeurs données dans les tables représentent quelquefois les valeurs obtenues dans de très nombreux essais. Dans d'autres cas, les valeurs peuvent ne représenter que des expériences isolées. En établissant les tables, il a été pris soin de n'incorporer autant que possible que les valeurs des deux sortes les plus dignes de confiance.

Une autre cause, occasionnant une variation considérable dans les propriétés mécaniques des métaux et alliages à l'état travaillé, est produite par l'effet de la masse. Une matière de grande section est dans presque chaque cas plus faible que la même matière produite en petites sections. Ce fait est particulièrement marqué lorsqu'un traitement thermique quel qu'il soit a été effectué. Lorsque les données dans les tables comportent des valeurs correspondant à des matières de différentes sections, il sera évidemment préférable d'attacher la plus grande importance aux chiffres se rapportant aux matières ayant une section similaire à celle qu'on se propose d'utiliser, ou dont on désire connaître les propriétés. Il ne faut pas oublier non plus qu'il se produit une amélioration certaine dans les opérations de fonderie, de laminage, de forgeage et par les traitements thermiques de sorte qu'en règle générale, les méthodes les plus modernes conduisent à des valeurs supérieures à celles obtenues avec des matières fabriquées moins récemment.

Trois possibilités se présentent dans l'usage des tables: (I) On désire connaître les propriétés d'un alliage, dont la composition est connue. (II) On désire connaître les propriétés d'un alliage commercial dont la composition n'est pas connue. (III) On ungen unterworfen sind, selbst wenn die Herstellungsbedingungen die besten waren. Bezüglich der vielen in den Tabellen angeführten Metallen und Legierungen, sind die Quellen aus welchen die Daten entnommen worden sind, sehr verschieden. Einige Daten sind von vielen Materialsprüfungen an Industrieprodukten abgeleitet, andere wieder, stellen das Ergebnis von Laboratoriumsuntersuchungen dar. Beim Gebrauche der Tafeln ist daher die Feststellung der Natur der Daten notwendig, was immer an Hand der angegebenen Literatur geschehen kann. Während im allgemeinen die Laboratoriumsergebnisse genau sind, muss man bedenken, das die Zahlenwerte bald höher bald niedriger sein können als die, welche an einem Industrie-Produkt zu erwarten sind. In mancher Hinsicht gestattet die Herstellung im Grossen, ein besseres Ergebnis als es in dem verhältnismässig kleinem Masstab des Laboratoriums möglich ist. In anderen Fällen wieder können die Bedingungen im Laboratorium nicht leicht bei der industriellen Herstellung eingehalten werden.

Ist es wünschenswert, dass man sich ein Bild über die Zahlenwerte eines gegebenen Materials für Konstruktionszwecke macht, so ist es notwendig die Natur des Materials zu berücksichtigen. Beim Guss weichen die mechanischen Eigenschaften sehr weitgehend an verschiedenen Stellen desselben Gusstückes von einander ab. Unterschiede sind sowohl zwischen einem in grossen oder kleinem Gusstuck als auch zwischen dem Hauptguss und dem Probestück vorhanden, wenn beide zugleich oder auf andere Weise hergestellt wurden. Sogar beim Giessen einer gegebenen Form und gegebenen Material, zeigen sich bemerkenswerte Differenzen der mechanischen Eigenschaften, wenn die Bedingungen beim Gusse, wie Gusstemperatur, Gussgeschwindigkeit, die Temperatur der Form, u. s. w., verändert werden. Es gelten daher die in den Tafeln angegebenen Zahlenwerte für ein gegossen hergestelltes Material nur unter den Bedingungen, welche in der entsprechenden Literatur angegeben sind. Die Zahlenwerte können jedoch nicht ohne weiteres zu dem Zwecke benützt werden, um einen zuverlässlichen Eigenschaftswert eines bestimmten Gusses zu berechnen. In bearbeitetem Material sind die Unterschiede häufiger viel kleiner als im gegossenen. Auf eine vollkommene Gleichheit ist nie zu rechnen, ganz besonders bei Materialien verschiedenen Ursprunges. In Bezug auf gewisse Materialien, welche ausgedehnt industriell hergestellt werden, stellen die angegebenen Werte manchmal die Ergebnisse sehr zahlreicher Prüfungen dar. In manchen anderen Fällen beziehen sich die Daten nur auf einzelne Untersuchungen. Bei der Zusammenstellung der Tafeln wurden soweit als möglich sorgfältig nur die verlässlichsten Daten, beider Typen aufgenommen.

Ein anderer Grund zur Änderung der mechanischen Eigenschaften von Metall und Legierung im bearbeiteten Zustand, kommt vom Einfluss der Masse her. Ein Material in grossen Stücken ist fast in allen Fällen weicher, als wenn dasselbe in kleineren Stücken hergestellt wird. Dies ist besonders bei einer Wärmebehandlung irgend welcher Art hervortretend. Wo in den Tafeln Werte vorhanden sind die sich auf Material-Stücke verschiedener Grösse beziehen, so wird es natürlich wünschenswert sein die grösste Wichtigkeit den Zahlen beizulegen, die sich auf ein herausgearbeitetes Stück beziehen, welches gleich dem Stück ist, welches benützt werden soll, oder dem Stück dessen Eigenschaften man kennen lernen will.

Man bedenke, dass in den Giessereien, Walzwerken, bei der Schmiedung und Wärmebehandlung ständig Fortschritte zu verzeichnen sind, so dass in der Regel die modernere Methoden ein Material liefern, dessen Eigenschafts-Werte den nach älteren Methoden hergestellten überlegen sind.

Beim Gebrauch der Tabellen können drei Möglichkeiten vorliegen: (I) Man sucht Eigenschaften einer Legierung bekannter Zusammensetzung. (II) Man sucht Eigenschaften einer

provengono da fonti notevolmente diverse: alcuni sono ricavati da numerosi saggi su prodotti industriali, mentre altri sono dedotti da ricerche di laboratorio. Nel servirsi delle tabelle è perciò necessario tener conto della natura dei dati, cosa che può sempre farsi riferendosi alla letteratura citata. I risultati di prove di laboratorio sono in genere accurati, e perciò essi possono essere più bassi o più alti dei valori prevedibili per un prodotto industriale corrispondente. In alcuni casi la produzione su larga scala rende possibile migliori risultati di quelli ottenibili in piccole prove di laboratorio, mentre in altri casi le condizioni speciali che si possono realizzare in laboratorio non si possono facilmente riprodurre nell'industria.

Per farsi una idea di un dato materiale a scopi costruttivi, se ne deve prendere in considerazione la natura. Nel caso di getti, ad es., si hanno ampie oscillazioni nelle proprietà meccaniche tra le diverse parti di uno stesso getto, come pure tra un getto grande e uno piccolo ed anche tra getti e provini, sia che questi vengano preparati assieme al getto sia che vengano ottenuti diversamente. Anche in un getto di forma e materiale determinati, eventuali differenze nelle condizioni di colata, come temperatura e velocità di colata, e temperatura della forma, possono produrre differenze notevoli nelle proprietà meccaniche. Perciò i valori delle tabelle indicano le proprietà del materiale quando questo sia ottenuto nelle condizioni specificate nella letteratura corrispondente ed essi non possono servire per calcolare senz'altro la resistenza probabile di un particolare getto. Nei materiali lavorati le variazioni sono spesso molto più piccole che in quelli ottenuti di getto; tuttavia non si può fare affidamento sopra una completa uniformità specie se si tratta di prodotti che hanno provenienza diversa. Per certi materiali che sono prodotti largamente nell' industria, i valori delle tabelle sono alcune volte ricavati da numerosissimi saggi; in altri casi invece essi rappresentano soltanto esperienze isolate. Nel compilare le tabelle si è avuto cura di servirsi il più che possibile solo dei valori dei due tipi che più sono degni di fiducia.

Considerevoli differenze nelle proprietà meccaniche dei metalli o leghe allo stato lavorato possono essere prodotti da effetto di massa. Un materiale in sezioni grandi è quasi sempre più debole che in sezioni piccole, e questo è particolarmente evidente nei casi in cui si è ricorso ad un trattamento termico qualunque. Quando nelle tabelle sono riportati valori corrispondenti a sezioni differenti, bisogna evidentemente attribuire la massima importanza ai numeri che si riferiscono a materiali con sezione simile a quella che si ha in animo di usare o di cui si vogliono stabilire le proprietà. Deve pure tenersi presente che vi è un continuo miglioramento nella pratica di fonderia di laminatoio, di fucina, e dei trattamenti termici per modo che, di regola, i metodi più moderni danno valori superiori a quelli dei materiali più antichi.

Nel servirsi delle tabelle tre casi si possono presentare: (I) Si può desiderare di conoscere le proprietà di una lega di cui è nota la composizione. (II) Si può desiderare di conoscere le proprietà di una lega commerciale di cui non è nota la composizione. (III) Si può desiderare di conoscere una lega che abbia determinate proprietà.

I. La composizione della lega è nota e si desidera conoscerne le proprietà

1. Si consulta l'indice a p. 358 e si vede quale è il capitolo in cui si parla di questo tipo di leghe.
2. Si consulta il capitolo alla pagina indicata.
3. Dall'indice che si trova al principio del capitolo si ricava la tabella che contiene il tipo di informazione che si desidera.
4. In ogni tabella (tranne che non sia indicato diversamente) le leghe sono disposte nell'ordine delle loro formule tipo. La formula tipo di una lega è costituita da dei simboli chimici dei suoi costituenti essenziali scritti in ordine decrescente della proporzione

of an alloy consists of the chemical symbols of its essential constituents written in descending order of their amounts in the alloy except in the case of steels, where C is written last. (*N. B.*—An element once thought merely incidental or an impurity in an alloy may later be found to have an important effect on its properties; *cf.* the case of silicon in duralumin.) Thus Pb-Sb-Cu is the type formula of alloys whose largest constituent (by weight) is Pb, the next largest Sb, and the next Cu; while a vanadium steel has the type formula Fe-V-C, although C is generally present in larger amounts than V. The different alloys are arranged in alphabetical order according to their type formulae.

Under a given type formula the alloys are arranged in descending order of the amounts of the principal constituent in the alloy, where this is given by analysis, and, where it is not given, then in ascending order of amounts of the second largest constituent in the alloy. Under each composition the data follow approximately in order of the extent of treatment given the alloy. Thus the properties of castings (symbol = G) appear first, then those of hot-worked material, and finally those of cold-worked material. The properties of heat-treated material follow immediately after those of the material before heat treatment.

Example 1: It is desired to compare the mechanical properties of a sand-cast 10% aluminum bronze with those of the same alloy in which 3% of the Al is replaced by Fe. It is desired to ascertain the properties of the alloys at high temperatures. The first alloy, call it "A," has the type formula Cu-Al; the second, call it "B," has the type formula Cu-Al-Fe. Turning to the Table of Contents (p. 359), we find that the section containing the mechanical properties of Al bronzes, begins on p. 572. Turning here we find a Table of Contents for the section in which are listed 15 tables of properties of the type Cu-Al and 6 tables of properties of the type Cu-Al-Fe.

Let us first consider the Ultimate Tensile Strength (*UTS*) in kg/mm², % Elongation (*El*) and Brinell Hardness Number (*BHN*) of our alloy "A" in the sand-cast (G$_s$) condition. From the tables we find as follows:

t, °C / Table	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	500	
1	46–53		20		90–100		(13)
2	49.9		21.7				(3)
3	29.1	18.2	9.4	3.1			(2, 15)
4					76.7	<50	(12)
13	42.2		28.5		118		(26)
13	52.0		19.5		100		(7)

The values in Table 1 represent the average properties of alloy "A" and agree fairly well with those in the other tables excepting those in Table 3, which probably are for material cast under unsatisfactory conditions, a thing easily possible with aluminum bronze.

Considering alloy "B" in the same manner we have:

t, °C / Table	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	500	
17	52.4		38.0		80		(10)
20	(Contains 7.6% Al, 2% Fe)				125	70	(12)

Although fewer data are available, alloy "B" seems to be as strong as and more ductile than "A" at 20°C, while the presence of 2% Fe has increased the hardness of the alloy at 500°C. Hardness figures of (12), however, are inconsistent with those from other sources. On the basis of the tables then, alloy "B" is somewhat the better alloy.

The index (p. 370) shows whether any commercial alloys of the composition of "B" are included. Index numbers of aluminum bronzes are listed in one of the tables of Alloy Classes following

désire un alliage ayant certaines propriétés. Les trois cas seront considérés dans l'ordre indiqué.

I. Composition de l'alliage connue. Propriétés désirées

1. Consulter la table des matières p. 358 et s'informer de la section dans laquelle il est traité de ce type d'alliage.

2. Consulter cette section à la page indiquée.

3. Au moyen de la table des matières se trouvant au commencement de la section, s'informer qu'elle est la table contenant le type d'information désiré et s'y porter.

4. Dans chaque table (à moins d'une autre indication) les alliages sont arrangés dans l'ordre de leur "formule type." La formule type d'un alliage se compose des symboles chimiques de ses constituants essentiels écrits dans l'ordre descendant de leurs proportions dans l'alliage, excepté pour le cas des aciers, où C est écrit en dernier. (*N. B.* Il peut se trouver qu'un élément dont la présence peut être considérée accidentelle ou une impureté dans un alliage peuvent avoir un effet important sur ses propriétés: par ex. cas du silicium dans duralumin). Ainsi Pb-Sb-Cu est la formule type des alliages dont le constituant le plus important (en poids) est Pb, celui qui vient ensuite dans le même ordre d'idée est Sb, et finalement vient Cu; un acier au vanadium aura la formule type Fe-V-C, quoique C soit généralement présent en plus grande quantité que V. Les différents alliages sont arrangés dans l'ordre alphabétique en accord avec leurs formules types.

Sous une formule type donnée, les alliages sont arrangés, lorsque ce résultat est fourni par l'analyse, dans l'ordre descendant des proportions de leur constituant principal dans l'alliage; lorsque l'analyse n'a pas été effectué, dans l'ordre ascendant des proportions du deuxième constituant en importance de l'alliage. Sous chaque composition, les données suivent approximativement dans l'ordre de la succession des traitements subis par l'alliage. Ainsi les propriétés des pièces fondues (symbole = G), sont mentionnées en premier. Ensuite viennent les propriétés de la matière travaillée à chaud et finalement celles de la matière travaillée à froid. Les propriétés de la matière traitée thermiquement suivent immédiatement celles de la matière avant le traitement thermique.

Exemple 1: On désire comparer les propriétés mécaniques d'un bronze d'aluminium à 10% Al coulé en sable avec celles du même alliage dans lequel 3% de l'Al ont été remplacés par Fe. On désire connaître les propriétés des alliages à hautes températures. Le premier alliage, désignons-le par "A," a la formule type Cu-Al; le second, désignons-le par "B" a la formule type Cu-Al-Fe. Consultant la table des matières (p. 359) on trouve que la section contenant les propriétés mécaniques des bronzes d'Al commence à p. 572. À cette page nous trouvons une table des matières pour la section, dans laquelle sont disposées en liste 15 tables des propriétés du type d'alliage Cu-Al et 6 tables des propriétés du type d'alliage Cu-Al-Fe.

Considérons d'abord: la charge de rupture (*UTS*) en kg/mm², l'allongement en % (*El*) et le nombre de dureté Brinell (*BHN*) de notre alliage "A" dans la condition "coulé en sable" (G$_s$). Des tables, on trouve:

t, °C / Table	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	500	
1	46–53		20		90–100		(13)
2	49,9		21,7				(3)
3	29,1	18,2	9,4	3,1			(2, 15)
4					76,7	<50	(12)
13	42,2		28,5		118		(26)
13	52,0		19,5		100		(7)

Les valeurs dans la Table 1 représentent les propriétés moyennes de l'alliage "A;" elles s'accordent assez bien avec celles des autres

Legierung des Handels, unbekannter Zusammensetzung. (III) Man sucht eine Legierung von bestimmten Eigenschaften.

I. Die Zusammensetzung der Legierung ist bekannt. Eigenschaften gesucht

1. Man sehe im Inhaltsverzeichnis (S. 358) nach und stelle den Abschnitt fest in welchem diese Legierungstype behandelt wird.
2. Man schlage den Abschnitt an der gegebenen Seitenzahl auf.
3. Mit Hilfe des Inhaltsverzeichnisses am Anfang dieses Abschnittes, stelle man die Tafel fest, welche die gewünschte Type der Eigenschaften enthält und schlage diese Tafel dann auf.
4. In jeder Tafel (wenn nichts anderes angegeben ist) sind die Legierungen in der Reihenfolge ihrer "Typen-Formel" angeordnet. Diese "Typen-Formel" einer Legierung besteht in der Nebeneinandersetzung der chemischen Zeichen ihrer wesentlichen Bestandteile in absteigender Ordnung ihrer Prozentgehalte Eine Ausnahme ist bei den Stählen vorhanden, wo am Ende C steht. (*N. B.*—Ein Element, das zuweilen nur zufällig oder als Verunreinigung in den Legierungen vorhanden angesehen wurde, kann später als ein solches von besonderem Einfluss auf die Eigenschaft derselben erkannt werden, z. B. Si in Duralumin.) So ist Pb-Sb-Cu die Typenformel von Legierungen, in welchen Pb den höchsten Prozentgehalt darstellt, den nächst niedrigeren Sb, dann folgt Cu. Ein Vanadium-Stahl hat hingegen die Typenformel Fe-V-C, obwohl im allgemeinen C in grösserer Menge als V vorhanden ist. Die verschiedenen Legierungen sind in alphabetischer Reihenfolge ihrer Typenformeln angeordnet.

Unter einer gegebenen Typenformel sind die Legierungen in absteigender Ordnung des analytisch bekannten Hauptbestandteiles in der Legierung angeordnet. Ist dieser Gehalt nicht bekannt, so sind die Legierungen in aufsteigender Ordnung des Prozentgehaltes des zweiten grössten Bestandteiles angeordnet. Unter jeder Zusammensetzung folgen die Daten ungefähr nach der Zahl der verschiedenen Behandlungen, welchen die Legierung unterworfen wurde. So erscheinen die Eigenschaften des Gusses (Zeichen = G) zuerst, dann jene des heiss bearbeiteten und zum Schluss des kalt bearbeiteten Materials. Die Eigenschaften des wärmebehandelten Materials folgen unmittelbar nach denen des Materials vor der Wärmebehandlung.

Beispiel 1: Es sollen die mechanischen Eigenschaften einer in Sandform gegossenen 10% Aluminiumbronze mit einer gleichen Legierung verglichen werden, in welcher 3% des Aluminiumgehaltes durch Fe ersetzt sind. Die Kenntnis der Eigenschaften bei hoher Temperatur ist notwendig. Die erste Legierung, wir bezeichnen sie mit "A," hat die Typenformel Cu-Al, die zweite, "B" bezeichnet, hat die Typenformel Cu-Al-Fe. Aus dem Inhaltsverzeichnis (S. 359) finden wir, dass der Abschnitt, welcher die mechanischen Eigenschaften der Al-Bronzen enthält, auf S. 572 beginnt. Hier finden wir ein Inhaltsverzeichnis für diesen Abschnitt in welchem 15 Eigenschafts-Tafeln der Type Cu-Al und 6 Eigenschafts-Tafeln für die Type Cu-Al-Fe, vorhanden sind.

Wir wollen zuerst von der Legierung "A" (in *Sandform gegossen*) die Zugfestigkeit (*UTS*) in kg/mm^2, Prozent Dehnung (*El*) und die Brinell-Härtezahl (*BHN*) berücksichtigen. Aus den Tafeln finden wir:

t, °C / Tabelle	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	500	
1	46–53		20		90–100		(13)
2	49,9		21,7				(3)
3	29,1	18,2	9,4	3,1			(2, 15)
4					76,7	<50	(12)
13	42,2		28,5		118		(26)
13	52,0		19,5		100		(7)

in cui sono contenuti, eccetto nel caso degli acciai, dove C è scritto per ultimo. (*N. B.* Un elemento ritenuto solo accidentale oppure giudicato come impurezza può in seguito trovarsi che ha un effetto importante sulle proprietà di una lega: vedi, ad es. il caso del silicio nel duralluminio.) Così Pb-Sb-Cu è la formula tipo delle leghe nelle quali la proporzione maggiore in peso è di Pb, quella intermedia è di Sb e quella minore è di Cu; mentre un acciaio al vanadio ha la formula Fe-V-C, sebbene C, in genere, è presente in proporzione maggiore di V. Le diverse leghe sono disposte in ordine alfabetico secondo le loro formule tipo.

Sotto una certa formula tipo le leghe sono disposte in ordine decrescente della proporzione del costituente principale quando questa è nota. Se questa non è nota esse sono disposte nell' ordine crescente del contenuto del secondo componente più abbondante. Sotto ogni composizione i dati sono disposti approssimativamente nell'ordine della complessità del trattamento. Così le proprietà dei getti (simbolo = G) vengono per prime, poi quelle del materiale lavorato a caldo, e infine quelle del materiale lavorato a freddo. Le proprietà del materiale trattato a caldo seguono subito dopo quelle del materiale prima del trattamento a caldo.

Esempio 1: Si desideri confrontare le proprietà meccaniche di un bronzo d'alluminio al 10% colato in sabbia, con quelle della stessa lega nella quale 3% di alluminio è stato sostituito con ferro, e precisamente si desideri conoscere le proprietà della lega a temperature elevate. La prima lega, che indicheremo con "A," ha la formula tipo Cu-Al; la seconda, che indicheremo con "B," ha la formula tipo Cu-Al-Fe. Se si consulta l'indice (p. 359) si trova che il capitolo contenente le proprietà meccaniche dei bronzi di alluminio comincia a p. 572. Qui si trova un indice in cui sono riportate 15 tabelle di proprietà per il tipo Cu-Al e 6 tabelle di proprietà per il tipo Cu-Al-Fe.

Consideriamo dapprima il carico di rottura (*UTS*) in kg/mm^2, l'allungamento per cento (*El*) e il numero di durezza Brinell (*BHN*) della lega "A" colata in sabbia (G_s). Dalle tabelle si trova:

t, °C / Tabe a	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	500	
1	46–53		20		90–100		(13)
2	49,9		21,7				(3)
3	29,1	18,2	9,4	3,1			(2, 15)
4					76,7	—50	(12)
13	42,2		28,5		118		(26)
13	52,0		19,5		100		(7)

I valori della Tabella 1 rappresentano le proprietà medie della lega "A" e si accordano bene con quelli delle altre tabelle; si eccettuano solo i valori della Tabella 3, che probabilmente si riferiscono ad un materiale gettato in condizioni non soddisfacenti, cosa questa è facilmente possibile con i bronzi d'alluminio.

Se si considera le lega "B" allo stesso modo si ha:

t, °C / Tabella	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	300	
17	52,4		38,0		80		(10)
20	(7,6% Al, 2% Fe)				125	70	(12)

Sebbene si disponga di pochi dati, la lega "B" sembra sia resistente quanto la "A" e persino più duttile della "A" a 20°C, mentre la presenza del 2% di ferro ha accresciuto la durezza a 500°C. I numeri di durezza riportati nella (12) non si accordano però con quelli di altre fonti. In base alle tabelle tuttavia la lega "B" è un po' migliore.

Dall'indice (p. 370) si può sapere se nelle tabelle sono riportate leghe commerciali della composizione di "B." I numeri indici dei the Finding Index. Turning to these numbers in the Finding Index, we find No. 45, "Alcumite:" Cu; Al, 7.5; Fe, 5.5; Ni, Mn, No. 141, "Ampco bronze:" Cu; Al, 7–11; Fe, 1–5. If the alloys thus shown in the Finding Table are commercially available at the present time, reference to the firms producing them can no doubt be obtained from the advertising pages of metallurgical magazines or otherwise. It must, however, be borne in mind that other alloys, possibly of the type desired, are manufactured in various countries, without necessarily being known by a name which could be included in the Finding Index, while there are numerous manufacturers in every country having a well-developed metallurgical industry, who will be prepared to make up alloys to any desired specification, provided that patent rights do not interfere. In some instances, it may be noted that the properties of the materials as represented by data given in the corresponding table, can only be obtained by definitely stated methods of manufacture and treatment and these are, sometimes, available only at the hands of an individual manufacturing firm. Further, where alloys having trade names are given in the list, and if no definite data for these alloys as such are included, the inference that the alloy bearing the trade name will have the same properties as the alloy of similar composition listed in the detailed table, must be regarded as subject to the limitations just indicated.

Example 2: Given a Ni-Cr steel containing 3.5% Ni, 0.8% Cr and 0.25% C, to find the heat treatment giving the optimum combinations of tensile and notched-bar impact properties. From the Table of Contents, it is found that Ni-Cr steels are treated in the section beginning on p. 483. The first numbered table of this section is a table of compositions, in which No. 262 is found to correspond to the above composition. The table of contents at the beginning of the section (p. 483) shows that mechanical properties are given in Table 7, p. 510. Turning to this table, we locate alloy No. 262 (p. 511) and find that values of properties are given for 42 different conditions of this steel. Notched-bar impact test results are given under the following designations: IS_u (Izod machine using B. E. S. A. standard specimen), IS_v (Charpy machine using 45° V notch specimen), IS_x (Guillery machine, Mesnager notch). The energy absorbed in fracture is given in each case as there is no satisfactory basis for comparison of results as between the different types of specimen. The largest Izod values of No. 262 are for treatments h, j, k, and z, being respectively 8.85, 9.15, 9.0, and 9.0. Of these, "h" gives a material somewhat stronger and considerably more ductile than do the others. Meanings of symbols and abbreviations used in describing treatments are given in the table on p. 392. Treatment "h" reads as it stands "Same, Tp 650° Q_w." The "Same" refers to the previous treatment, *i.e.*, condition before tempering, which is N 820°. The whole treatment interpreted is: Normalized at 820° (*i.e.*, cooled in still air from 820°C), then tempered at 650°C and quenched in water. The other treatments which give high impact strengths, are: "1000° Q_o Tp 670°/120 Q_w" (*i.e.*, quenched in oil from 1000°C, tempered at 670° for 120 min, and quenched in water); "1000° Q_o Tp 650°/120 C_s 650° Q_w" (*i.e.*, quenched in oil from 1000°C, tempered at 650° for 120 min, cooled slowly, retempered at 650°C and quenched in water); and "850° Q_o Tp 675°/495 Q_w" (*i.e.*, quenched in oil from 850°C, tempered at 675° for 495 min, and quenched in water). These treatments give nearly as good properties, thus showing the necessity of a final water quench from 650–675°C. Consideration of some of the other treatments shows that cooling slowly from this temperature gives decidedly inferior notched-bar impact figures while not greatly affecting the tensile values. Quenching from lower temperatures gives better tensile properties, but inferior notched-bar impact figures. Inspection of values obtained on the other machines for these treatments and for others tables excepté celles de la Table 3, qui se rapportent probablement à un matériel fondu dans les conditions non satisfactoires, une circonstance qui est très possible avec le bronze d'aluminium.

Considérant l'alliage "B" de la même manière, nous avons:

t, °C / Table	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	300	
17	52,4		38,0		80		(10)
20	(7.6% Al, 2% Fe)				125	70	(12)

Quoiqu'il y ait peu de données disponibles, l'alliage "B" paraît être aussi résistant et plus ductible que "A" à 20°C, alors que la présence de 2 % de Fe a augmenté la dureté de l'alliage à 500°C. Les chiffres de dureté de (12) cependant, ne sont pas en accord avec ceux d'autres sources. On peut déduire sur la base des tables que l'alliage "B" est sensiblement le meilleur alliage.

L'index (p. 370) montre s'il y existe un alliage commercial de la composition de "B." Les nombres index des bronzes d'aluminium sont disposés en liste dans l'une des tables des alliages types qui se trouvent à la suite de l'index de recherche. En se reportant à ces nombres dans l'index de recherche, on trouve N° 45, "Alcumite:" Cu; Al, 7,5; Fe, 5,5; Ni; Mn, et N° 141, "Ampco bronze:" Cu; Al, 7–11; Fe, 1–5. Si les alliages ainsi mentionnés dans la table de recherche sont disponibles dans le commerce actuellement, on trouvera sans doute les références des firmes qui les produisent dans les annonces des magazines métallurgiques ou autre part. Il ne faut pas oublier cependant que d'autres alliages, qui peuvent être du type désiré sont fabriqués dans des pays divers, sans être nécessairement connus par un nom qui pourrait se trouver dans l'index de recherche; il existe en effet de nombreux fabricants dans chaque pays possédant une industrie métallurgique bien développée qui peuvent fabriquer des alliages suivant les spécifications variées, à condition que les droits de patente ne s'y opposent pas. Dans certains cas, il faut remarquer que les propriétés des matières ainsi qu'elles sont représentées par les valeurs données dans les tables correspondantes, ne peuvent être obtenues que par des méthodes de fabrication et des traitements établis d'une façon définie, qui quelquefois ne sont réalisés que chez un seul fabricant. Lorsqu'il s'agit d'alliages portant des noms commerciaux mentionnés dans la liste, il n'a pas été indiqué de données définies pour ces alliages considérés comme tels, et, déduire que les alliages portant un nom commercial ont les mêmes propriétés que l'alliage de composition similaire mentionné dans la table détaillée, doit être regardé comme étant sujet aux limitations indiquées ci-dessus.

Exemple 2: Etant donné un acier au Ni-Cr contenant 3,5% Ni, 0,8% Cr et 0,25% C, trouver le traitement thermique donnant la combinaison optimum relativement aux propriétés de traction et à l'essai de choc sur éprouvette entaillée. De la table des matières, on trouve que les aciers au Ni-Cr sont traités dans la section commençant à p. 483. La première table de cette section est une table de compositions, dans laquelle le N° 262 correspond à la composition donnée ci-dessus. La table des matières au commencement de la section (p. 483) montre que les propriétés mécaniques sont données dans la Table 7, p. 510; à cette table nous trouvons l'alliage N° 262 (p. 511) et constatons que les valeurs des propriétés sont données pour 42 différentes conditions de cet acier. Les résultats concernant l'essai de choc sur éprouvette entaillée sont donnés sous les désignations suivantes: IS_u (Machine d'Izod, utilisant des éprouvettes types B. E. S. A.), IS_v (Machine de Charpy utilisant une éprouvette avec entaille 45°V), IS_x (Machine de Guillery, éprouvette avec entaille Mesnager). L'énergie absorbée dans la rupture est donnée dans chaque cas, car il n'existe pas de base convenable pour la comparaison des résultats entre les différents types d'éprouvettes. Les valeurs Izod les plus fortes concernant le N° 262 sont obtenues avec les traitements

Der Wert in der Tabelle 1 stellt die Durchschnittseigenschaften der Legierung "A" dar, und stimmt ziemlich gut mit jenen in den anderen Tabellen überein. Ausgenommen jedoch die Werte der Tabelle 3, welche wahrscheinlich für ein Material gelten, das unter nicht befriedigenden Bedingungen gegossen worden ist. Bei Aluminiumbronzen ist ein solcher Fall sehr möglich. Nehmen wir die Legierung "B," so hat man in gleicher Weise:

Tabelle \ *t*, °C	*UTS*		*El*		*BHN*		Lit.
	20	500	20	500	20	500	
17	52,4		38,0		80		(10)
20	(7.6% Al, 2% Fe)				125	70	(12)

Obgleich weniger Daten vorliegen, scheint die Legierung "B" bezüglich der Zugfestigkeit ebenso gut wie "A," bezüglich der Duktilität bei 20° besser zu sein, während die Anwesenheit von 2% Fe die Härte bei 500°C erhöht. Die Härtezahlen von (12) aber stimmen mit denen aus anderen Quellen stammenden nicht überein. Auf Grund der Tafeln ist "B" eine etwas bessere Legierung als "A."

Der Index (S. 370) zeigt an, ob irgend eine Handelslegierung von der "B" Zusammensetzung gegeben ist. Die Indexzahlen der Aluminiumbronzen sind in einer der Tafeln für Legierungstypen eingetragen, die dem Nachschlage-Index folgen. Sehen wir diese Zahlen im Nachschlage-Index nach, so finden wir No. 45, "Alcumite:" Cu; Al, 7,5; Fe, 5,5; Ni, Mn; No. 141, "Ampco bronze:" Cu; Al, 7–11; Fe, 1–5. Sind diese Legierungen gegenwärtig handelsüblich, so kann vermutlich die Erzeugerfirma in dem Inseratenteil der Fachzeitschriften und auch sonst, gefunden werden. Es muss jedoch berücksichtigt werden, dass andere Legierungen, möglicherweise gerade von der gewünschten Type, in den verschiedenen Ländern erzeugt werden können, die vielleicht keinen Namen tragen, der in dem Nachschlage-Index angegeben werden konnte. Es gibt in jedem Lande mit einer gut entwickelten Metallindustrie, eine Anzahl von Fabriken die imstande sind, soweit nicht Patentrechte vorliegen, jede Legierung von besonderer Zusammensetzung herzustellen.

Es möge noch bemerkt werden, dass in mancher Beziehung, die in den entsprechenden Tabellen angegebenen Eigenschaften nur durch bestimmte Fabrikations-Methoden und Behandlungen erreicht werden können, die zuweilen nur den einzelnen Erzeugerfirmen zur Verfügung stehen. Ferner, wo in den Tabellen Legierungen mit Handelsmarken angegeben sind und keine definitive Werte für solche in den Tafeln angeführt sind, ist eine Schlussfolgerung, wie aus dem Vorhergegangenen folgt, dass eine Legierung mit Handelsmarke dieselben Eigenschaften habe als eine ähnlich zusammengesetzte Legierung die sich in der Tabelle vorfindet, sehr einzuschränken.

Beispiel 2: Gegeben ist ein Ni-Cr-Stahl mit 3,5% Ni, 0,8% Cr, und 0,25% C. Es ist die Wärmebehandlung zu finden, die ein Optimum an Zugfestigkeit und Schlagfestigkeit an einem gekerbten Probestück gibt. Aus dem Inhaltsverzeichnis findet man, dass Ni-Cr-Stähle in dem S. 483 beginnenden Abschnitt behandelt werden. Die erste Zahlentafel dieses Abschnittes gibt die Zusammensetzungen an worunter No. 262, der angegebenen Zusammensetzung entspricht. Das Inhaltsverzeichnis zu Beginn des Abschnittes (S. 483) gibt an, dass die mechanischen Eigenschaften in der Tafel 7, S. 510, zu finden sind. Hier findet man die Legierung No. 262 (S. 511) und sieht, dass die Eigenschaften für 42 verschiedene Behandlungen für diese Stahlsorte vorliegen. Die Schlagfestigkeit (Kerbeneinschnitt) ist unter der folgenden Bezeichnung angegeben: IS_u (Izod Machine, B. E. S. A. standard Probe), IS_v (Charpy-Machine, mit 45° V-Kerbe), IS_x (Guillery Machine, Kerbenformstück nach Mesnager). *Die beim Bruch absorbierte Energie* ist in jedem Falle angegeben, da keine befriedi-

bronzi di alluminio sono elencati in una delle tabelle dei tipi di leghe che seguono l'indice. Andando a cercare questi numeri nell'indice, si trova No. 45, "Alcumite:" Cu; Al, 7,5; Fe, 5,5; Ni; Mn; e No. 141, "Ampco Bronze:" Cu; Al, 7–11; Fe, 1–5. Se le leghe così indicate si trovano in commercio, si può sapere il nome delle ditte che le producono dalla réclame delle riviste metallurgiche o in qualche altro modo. Può darsi però che nei diversi paesi vengano fabbricate altre leghe, e che esse non siano conosciute con un nome che potrebbe essere incluso nell'indice. In ogni nazione con una industria metallurgica bene sviluppata, vi è un gran numero di produttori i quali sono in grado di fabbricare leghe con qualsiasi requisito purchè non esistano diritti di brevetti. Deve ancora osservarsi che le proprietà, quali sono rappresentate dai valori contenuti nelle tabelle, in alcuni casi possono solo ottenersi con processi di fabbricazione e trattamento ben definiti, e che questi talvolta sono a conoscenza esclusiva di una singola ditta fabbricante. Inoltre, quando nell'elenco sono contenute leghe con nomi commerciali, nessun valore definito è riportato per esse, e la deduzione che la lega con quel certo nome avrà le stesse proprietà di quella di composizione simile elencata nella tabella deve considerarsi sottoposta alle limitazioni sopraindicate.

Esempio 2: Dato un acciaio al Ni-Cr contenente 3,5% Ni, 0,8% Cr e 0,25% C, trovare qual'è il trattamento termico che dà l'optimum di carico di rottura e di resilienza. Nell'indice si trova che gli acciai al Ni-Cr sono trattati nel capitolo che comincia a p. 483. La prima tabella di questo dà le composizioni, e in essa si trova che il numero 262 corrisponde alla composizione di sopra. Dall'indice all'inizio del capitolo (p. 483) si ricava che le proprietà meccaniche sono esposte nella Tabella 7 (p. 510). Consultando questa si vede che a p. 511 sono riportati valori delle proprietà per 42 condizioni differenti dell'acciaio No. 262. I risultati delle prove di resilienza sono riportati sotto le seguenti designazioni: IS_u (macchina Izod con provino B.E.S.A.), IS_v (macchina Charpy con provino munito di intaglio V a 45°), IS_x (macchina Guillery con barretta Mesnager). L'energia assorbita nella rottura è data per ogni caso, giacchè non vi son elementi sufficienti per confrontare i risultati ottenuti con i diversi tipi di prove. I più grandi valori Izod del numero 262 sono per i trattamenti h, j, k, e z, e sono rispettivamente 8,85; 9,15; 9,0 e 9,0. Fra essi, "h" dà un materiale un po' più resistente e notevolmente più duttile che gli altri. I significati dei simboli e le abbreviazioni adoperate nel descrivere i trattamenti sono indicati nella tabella a p. 392. Il trattamento "h" è indicato con "Same, Tp 650° Q_w." Il "Same" (lo stesso) si riferisce al trattamento precedente, e cioè alla condizione prima del rinvenimento, che è N 820°. L'intero trattamento perciò è normalizzato a 820° (e cioè raffreddato in aria calma a partire da 820°C), quindi rinvenuto a 650° e temprato in acqua. Gli altri trattamenti che danno resilienza elevata sono "1000° Q_o Tp 670°/120 Q_w" (e cioè temprato in olio a partire da 1000°C, rinvenuto a 670° per 120 min, e temprato in acqua; "1000° Q_o Tp 650°/120 C_s 650° Q_w" (cioè temprato in olio a partire da 1000°C, rinvenuto a 650° per 120 min, raffreddato lentamente, rinvenuto di nuovo a 650°C e temprato in acqua; e "850° Q_o Tp 675°/495 Q_w" (cioè temprato in olio a partire da 850°C, rinvenuto a 675° per 495 min, e temprato in acqua). Questi trattamenti danno tutti quasi le stesse buone proprietà e mostrano così la necessità di una tempra finale in acqua a partire da 650–675°C. Se si considerano alcuni altri trattamenti, si vede che il raffreddamento lento a partire da questa temperatura dà valori di resilienza decisamente inferiori, anche se non influenza molto i valori del carico di rottura. La tempra a partire da temperature più basse dà proprietà tensorie migliori, ma valori di resilienza più bassi. L'esame dei valori ottenuti per questi trattamenti e per altri per i quali non sono dati valori Izod, mostra che il trattamento "h" dà l'optimum dei valori desiderati.

for which no Izod values are given, show that treatment "h" gives the optimum desired values.

II. Name of Alloy Is Known, Its Composition and Properties Are Desired

Refer to the Finding Index, p. 370. The first column of this index contains the Index Numbers by which commercial alloys are identified when their properties occur in the tables. The second column contains 1510 trade names of alloys included in the following classes:

(*a*) Trade mark names of patented alloys, as "Alpax."

(*b*) Trade mark names of alloys no longer protected by patent (*cf.* Duralumin in France, where name "Aldal" is used for an alloy of approximately the same composition, the name Duralumin being protected).

(*c*) Names of inventor or manufacturer given to alloys, the names or compositions not necessarily being protected, as Babbitt metal.

(*d*) Names generally applied to certain types of alloys, as Cartridge Brass.

(*e*) Names of types of alloys including a wide range of compositions, as Chrome Nickel steel. In this case, particular alloys of this type may be found from Tables of Alloy Classes, p. 388.

(*f*) Designations of standard or tentative standard alloys, and certain government-specification alloys. These will be found under the alloy type as: Brass ingots, A. S. T. M. Spec. B30–22 or Government Bronze, Spec. G.

No distinction is made in the Finding Index among the first four classes, except that in some cases it has been necessary to identify an alloy, known usually by a number, by adding the manufacturer's name, as in the case of alloy No. 193 of the Driver Harris Co. This is listed under Ferronickel, but cross-reference is given to this and similar alloys under "Numbered Alloys." In other cases the manufacturer is not mentioned.

In class (*d*) no attempt has been made to include all alloys to which usage has given a name, as Spring Steel, Dynamo Sheets, etc., although such alloys are useful for the purpose indicated.

With regard to class (*f*) it should be mentioned that specifications may be drawn up regardless of existing patents and, of course, in ignorance of pending ones.

The names of alloys are arranged alphabetically regardless of type, excepting in the case of: (1) Alloys known by a manufacturer's number. (2) Specification alloys known by number or letter. (3) Alloys, the first part of whose name is descriptive of condition (*e.g.*, hard solder), where there are several such included in one type. Such alloys are listed under the name of the type and where commonly used, cross-references are also given under first part of name.

The third column of the Finding Index gives the compositions of the alloys. In stating the composition, the elements together with their weights % are given in descending order of amounts in the alloy. Where the % of the first, *i.e.*, largest constituent, is not given, it has not been determined by analysis. Where the amounts of the last constituents are not given, they are only incidental or impurities. Where no percentages are given, the information has not been available.

Where the composition of an alloy varies over a range of values, the limits have been stated, as Index No. 915, MS steel: Fe; Cr, 0.8–1.1; Mo, 0.3–0.4; Mn, 0.6–0.9; C, 0.4–0.6.

The fourth column of the Finding Index contains the page numbers where values of properties of the alloy may be found; the page numbers where the values of properties of a similar alloy may be found are indicated by italic type.

The electrical, magnetic and optical properties of metals and alloys will be found in a succeeding volume of I. C. T.; no page reference to such data can therefore be given in the Finding Index.

h, j, k et z, et sont respectivement 8,85, 9,15, 9,0 et 9,0. Parmi ceux-ci, "h" donne une matière un peu plus résistante et considérablement plus ductile que les autres. La signification des symboles et les abréviations utilisées pour spécifier les traitements sont données dans la table à la p. 392. Le traitement "h" représente "Same, Tp 650° Q_w," "Same" (c'est-à-dire le même) se rapporte au traitement antérieur, c'est-à-dire, à la condition avant le revenu, qui est N 820°. L'interprétation de tout le traitement est la suivante: Normalisé à 820° (c'est à dire refroidi dans l'air calme à partir de 820°C), ensuite revenu à 650° puis trempé à l'eau. Les autres traitements qui donnent une grande résistance au choc sont: "1000° Q_o Tp 670°/120 Q_w" (c'est à dire, trempé à l'huile à partir de 1000°C, revenu à 670° pendant 120 minutes, refroidi doucement, de nouveau revenu à 650°C et trempé à l'eau); et "850° Q_o Tp 675°/495 Q_w" (c'est-à-dire trempé à l'huile à partir de 850°C, revenu à 675°C pendant 495 min. et trempé à l'eau). Ces traitements donnent tous à peu près d'aussi bonnes propriétés montrant ainsi la nécessité d'une trempe à l'eau finale à partir de 650–675°C. L'examen de quelques autres traitements montre que le refroidissement lent à partir de cette température donne décidément des chiffres inférieurs à l'essai de choc sur éprouvette entaillée tout en n'affectant pas beaucoup les valeurs de traction. Une trempe à partir de températures plus basses donne des meilleures propriétés à la traction, mais des chiffres inférieurs à l'essai de choc sur éprouvette entaillée. L'examen des valeurs obtenues sur les autres machines pour ces traitements et pour d'autres pour lesquels il n'a pas été donné de valeurs Izod montre que le traitement "h" donne l'optimum désiré.

II. Le nom de l'alliage est connu; on désire connaître sa composition et ses propriétés

Consulter l'index de recherche, p. 370. La première colonne de cet index contient les nombres index au moyen desquels les alliages commerciaux sont identifiés lorsque leurs propriétés sont mentionnées dans les tables. La deuxième colonne contient 1510 noms commerciaux des alliages compris dans les classes suivantes:

(*a*) Noms commerciaux d'alliages brevetés, comme "Alpax."

(*b*) Noms commerciaux d'alliages dont le brevet est expiré; (par exemple: Duralumin en France, où le nom "Aldal" est utilisé pour un alliage ayant approximativement la même composition, le nom Duralumin étant déposé).

(*c*) Noms de l'inventeur ou du fabricant donnés aux alliages, les noms ou les compositions n'étant pas nécessairement déposés, comme métal "Babbitt."

(*d*) Noms généralement employés pour désigner certains types d'alliages, comme "Cartridge brass," laiton pour cartouches.

(*e*) Noms de types d'alliages comportant un large intervalle de composition, comme acier en chrome nickel. Dans ce cas on peut trouver des alliages particuliers de ce type dans les "Tables of Alloy Classes," p. 388.

(*f*) Désignation d'alliages standards ou alliages standards tentatifs et certains alliages suivant spécifications gouvernementales. Ceux-ci seront trouvés sous le type d'alliage comme par exemple: Brass ingots (laiton en lingots), A. S. T. M. Spec. B30–22 ou Bronze du Gouvernement, Spec. G.

Il n'a pas été fait de distinction dans l'index de recherche pour les quatre premières classes, excepté dans quelques cas où il a été nécessaire pour identifier un alliage connu ordinairement par un nombre, d'ajouter le nom du fabricant comme dans le cas de l'alliage N° 193 de la Driver Harris Co. Celui-ci est inscrit sous ferronickel, mais il y a une référence pour cet alliage et pour les alliages similaires sous "Numbered Alloys." Dans d'autres cas le fabricant n'est pas mentionné.

Dans la classe (*d*) on n'a pas cherché à inclure tous les alliages auxquels l'usage a donné un nom, tels que acier à ressorts, tôles gende Basis zum Vergleich der Ergebnisse bei verschiedenen Typen der Proben vorhanden sind. Der höchste Izod-Wert für No. 262 ergibt sich für die Behandlung h, j, k und z, und beträgt der Reihe nach 8,85, 9,15, 9,0 und 9,0. Von diesen gibt "h" ein Material höherer Zugfestigkeit und ein deutlich duktileres Material als die anderen. Erklärungen der Zeichen und die Behandlung betreffenden Abkürzungen sind in der Tabelle S. 392 angegeben. Die Behandlung "h" ist durch "Same, Tp 650° Q_w" in den Tafeln ausgedrückt. "Same" zeigt vorhergegangene Behandlung an, d. h. Zustand vor der Anlassung, welche "N 820°" ist. Die ganze Behandlung ist angezeigt: Normalisiert bei 820° (d. h. gekühlt in ruhender Luft von 820° herunter), dann bei 650°C angelassen und in Wasser abgeschreckt. Die anderen Behandlungen, welche eine sehr grosse Schlagfestigkeit geben, sind: 1000° Q_o Tp 670°/120 Q_w (d. h. bei 1000° in Öl abgeschreckt bei 670°, 120 Minuten lang angelassen und in Wasser abgeschreckt); "1000° Q_o Tp 650°/120 C_s 650° Q_w" (bei 1000° in Öl abgeschreckt, für 120 Minuten lang bei 650° angelassen, langsam gekühlt, nochmals bei 650° angelassen und in Wasser abgeschreckt); ferner "850° Q_o Tp 675°/495 Q_w" (d. h. bei 850° in Öl abgeschreckt, 495 Minuten lang bei 675° angelassen, und in Wasser abgeschreckt). Diese Behandlungen geben ungefähr gleich gute Eigenschaften und zeigen die Notwendigkeit einer am Schlusse vorgenommen Wasserabschreckung von 650–675°. Die Betrachtung einiger anderer Behandlungen zeigt, dass eine langsame Kühlung von dieser Temperatur herunter entschieden niedrigere Werte für die Schlagfestigkeit gibt, während die Zugfestigkeit und Duktilität nicht stark beeinflusst wird. Abschreckung bei tieferen Temperaturen gibt bessere Zugfestigkeit und Duktilität, aber niedrigere Werte für die Schlagfestigkeit. Eine Durchsicht der Werte die mit anderen Maschinen erhalten werden, zeigt für diese Behandlungen und andere, für welche keine Izod-Werte gegeben sind, dass die "h" Behandlung das Optimum der gewünschten Eigenschaft gibt.

II. Der Name der Legierung ist bekannt, es sind ihre Zusammensetzung und Eigenschaften zu ermitteln

Siehe im Nachschlage-Index S. 370 nach. Die erste Kolonne in diesem enthält die Index-Zahl, durch welche Handelslegierungen bezeichnet sind, wenn ihre Eigenschaften in den Tabellen vorkommen. Die zweite Kolonne enthält 1510 Handelsnamen von Legierungen die in folgende Klassen eingeteilt sind.

(*a*) Handelsmarken patentierter Legierungen, wie z. B. "Alpax."

(*b*) Handelsmarken von Legierungen, nicht mehr unter Patentschutz stehend (*vgl.* Duralumin in Frankreich, wo der Name "Aldal" für eine Legierung von ungefähr derselben Zusammensetzung benützt wird, da der Name Duralumin geschützt ist).

(*c*) Die Legierung trägt den Namen des Erfinders oder des Erzeugers. Der Name selbst braucht nicht notwendig geschützt zu sein; z. B. Babbitt-Metall.

(*d*) Namen die im allgemeinen gewissen Legierungstypen gegeben werden; z. B. "Cartridge brass," Patronen-Messing.

(*e*) Namen von Legierungen deren Zusammensetzung in weitem Ausmasse varieren kann, z. B. Chrom-Nickel Stahl. In solchem Fall, die besondere Legierung dieser Type in "Tables of Alloy Classes," S. 388 zu finden ist.

(*f*) Als Standards bestimmte Legierungen oder solche als Prüfungs-Standard geltende, ferner gewisse staatlich vorgeschriebene Legierungen. Diese werden unter folgenden Legierungstypen gefunden: Brass ingots, A. S. T. M. Spec. B30–22 Government Bronze, Spec. G.

Es ist in den ersten vier Klassen kein Unterschied im Nachschlage-Index gemacht, ausgenommen, dass es in manchen Fällen notwendig war eine, sonst nur durch eine Zahl bekannte Legierung durch Hinzufügung des Namens des Fabrikants näher zu bezeichnen, z. B. bei der Legierung No. 193 der Driver

II. Si suppone noto il nome della lega e si desidera conoscerne la composizione e le proprieta

Si consulti l'indice di ricerca a pag. 370. La prima colonna contiene i numeri indici con cui sono indicate le leghe commerciali, e la seconda 1510 nomi commerciali di leghe suddivisi nelle classi seguenti:

(*a*) Nomi commerciali di leghe brevettate, come "Alpax."

(*b*) Nomi commerciali di leghe non più protette da brevetti (ad es. in Francia si usa il nome "Aldal" per una lega che ha approssimativamente la stessa composizione del duralluminio, essendo il nome duralluminio protetto da brevetto).

(*c*) Nomi di inventori o fabbricanti dati alle leghe. I nomi o le composizioni non sempre sono protette da brevetti, come ad es. nel caso del metallo "Babbitt."

(*d*) Nomi generalmente applicati a certi tipi di leghe, come ad es. "Cartridge brass," ottone per cartucce.

(*e*) Nomi di tipi di leghe che possono avere composizioni oscillanti entro limiti larghi, come ad es. acciai al cromo-nichel. In questi casi, si possono trovare leghe particolari di detto tipo nelle "Tables of Alloy Classes," p. 388.

(*f*) Indicazioni di leghe standard, o tentativi standard, e di certe leghe con le caratteristiche richieste da amministrazioni governative. Queste si troveranno riportate sotto i tipi di leghe come: Brass ingots (lingotti di ottone), A. S. T. M. Spec. B30–22, oppure bronzo secondo le prescrizioni governative, Spec. 9.

Nessuna distinzione è fatta nell'indice tra le prime quattro classi eccetto che in alcuni casi è stato necessario aggiungere, al numero che ordinariamente contradistingue una lega, il nome del fabbricante, come nel caso della lega N° 193 della Driver Harris Co. Questa è elencata tra i ferro-nichel, ma sotto "Numbered Alloys" vi è un rapporto a questa ed a leghe simili al N°. 193. In altri caso non è fatta menzione del fabbricante.

Nella classe (*d*) non si è tentato di comprendervi tutte le leghe alle quali l'uso ha dato un nome, come acciaio per molle, lamierini per dinamo, ecc., sebbene dette leghe siano utili per gli scopi indicati.

Riguardo alla classe (*f*) deve ricordarsi che determinate caratteristiche possono ottenerdi indipendentemente dal brevetti esistenti e, naturalmente, nell'ignoranza di eventuali in corso.

I nomi delle leghe sono disposti per ordine alfabetico senza tener conto del loro tipo tranne il caso di: (1) Leghe indicate con il numero di un fabbricante. (2) Leghe speciali note con un numero o una lettera. (3) Leghe di cui la prima parte del nome ne descrive la natura (per es. "hard solder," saldatura forte) quando ve ne sono parecchie comprese in uno stesso tipo. Tali leghe sono elencate sotto il nome del tipo, e, quando esse sono comunemente adoperate, si trovano riportate indicazioni anche sotto la prima parte del nome.

La terza colonna dell'indice dà le composizioni delle leghe. Nell'indicare la composizione, gli elementi e le rispettive percentuali sono date in ordine decrescente del contenuto nella lega. Quando il percento del primo costituente, e cioè quello più abbondante, non è indicato, significa che esso non è stato determinato con l'analisi. Quando le proporzioni degli ultimi componenti non sono indicate, essi sono soltanto costituenti accidentali o impurezze. Se le percentuali non sono riportate, significa che non si è potuto avere l'informazione relativa.

Quando la composizione di una lega può assumere tutta una serie di valori, sono stati indicati i limiti entro i quali i valori possono oscillare, come per es. per Index No. 915, MS steel: Fe; Cr, 0,8–1,1; Mo, 0,3–0, 4; Mn, 0,6–0,9; C, 0,4–0,6.

Nella quarta colonna dell'indice sono indicate le pagine dove si possono trovare valori delle proprietà della lega (in caratteri romani) oppure dove si possono trovare i valori delle proprietà di una lega simile (in corsivo).

No data on resistance to corrosion are included in these tables. In the opinion of the most competent experts on the subject, it is not possible to give quantitative data for the corrosion resistance of metals and alloys. No page references can therefore be given in regard even to certain alloys which are chiefly valued on account of their resistance to corrosion. These, however, are listed in the tables of alloy types.

The sources of information for the Finding Index have been as follows: William Campbell's List of Names of Alloys, prepared for Committee B-2 of the A. S. T. M.; names and compositions given by the co-operating experts; and current metallurgical and technological literature.

III. It Is Desired to Find an Alloy Having Certain Desired Properties

For this purpose consult the Table of Properties on p. 610, directions being given there.

de dynamo, etc., quoique de tels alliages soient utiles pour le but indiqué.

En ce qui concerne la classe (*f*), il faut mentionner que des spécifications peuvent être rédigées sans tenir compte des patentes existantes et naturellement aussi dans l'ignorance des brevets demandés.

Les noms des alliages sont disposés dans l'ordre alphabétique sans tenir compte de leur type, excepté dans les cas suivants: (1) Alliages connus par un numéro de fabrique. (2) Certains alliages connus par un nombre ou une lettre. (3) Alliages dont la première partie de leurs noms est descriptive de la condition (par ex. "hard solder," soudure dure) et où il existe plusieurs variétés incluses dans un type. De tels alliages sont inscrits sous le nom du type et lorsqu'ils sont d'un usage commun, sont aussi mentionnés dans l'index par la première partie de leur nom.

La troisième colonne de l'index de recherche donne les compositions des alliages. En établissant la composition, on a inscrit les éléments avec leurs poids en % successivement dans l'ordre des proportions décroissantes dans l'alliage. Lorsque le pourcent du premier, c'est-à-dire le constituant principal, n'est pas donné, c'est qu'il n'a pas été déterminé par l'analyse. Lorsque les proportions des derniers constituants ne sont pas mentionnés, ceux-ci ne sont qu'accessoires ou bien sont des impuretés. Lorsqu'aucun pourcentage n'est donné, c'est que l'information n'a pas été disponible.

Lorsque la composition d'un alliage varie suivant un intervalle de valeurs, les limites ont été fixées: par ex. Index No. 915, MS steel: Fe; Cr, 0,8–1,1; Mo, 0,3–0,4; Mn, 0,6–0,9; C, 0,4–0,6.

La quatrième colonne de l'index de recherche contient en caractères romains les numéros des pages où l'on peut trouver les propriétés de l'alliage, ou en italique les numéros des pages, où l'on peut trouver les valeurs des propriétés d'un alliage similaire.

On trouvera les propriétés électriques, magnétiques et optiques des métaux et alliages dans un volume suivant des T. C. I.; on ne peut donc donner aucune page de référence pour de telles données dans l'index de recherche.

On ne trouvera dans ces tables aucune donnée relative à la résistance à la corrosion. D'après l'opinion des experts les plus compétents sur ce sujet, il n'est pas possible de donner des valeurs quantitatives pour la résistance à la corrosion des métaux et alliages. On ne peut donc donner aucune référence en ce qui concerne même certains alliages dont la valeur est surtout due à leur résistance à la corrosion. Ceux-ci, cependant sont mentionnés dans les tables des types d'alliages.

Les sources d'information pour l'index de recherche ont été les suivantes: List of Names of Alloys établie par William Campbell préparée pour le Comité B-2 de l'A. S. T. M.; noms et compositions données par les experts coopérants; et la littérature métallurgique et technologique courante.

III. On désire trouver un alliage ayant certaines propriétés désirées

Pour cela, consulter la Table des Propriétés à la p. 610, où les instructions sont données.

Harris Co. Sie ist unter Ferronickel mit einem entsprechenden Hinweis angeführt, der dieser und ähnlichen Legierungen unter "Numbered Alloys" beigefügt wird.

Zu (*d*). Es ist nicht die Absicht gewesen, alle solche Legierungen hier zu vereinigen denen der Gebrauch besondere Namen, wie Feder-Stahl, Dynamo-Lamellen, u. s. w., beigelegt hat, obgleich diese Legierungen für die angezeigte Verwendung nützlich sind.

Hinsichtlich (*f*) wäre zu bemerken, dass die Vorschriften ohne Rücksicht auf vorhandene und in Unkenntnis angemeldeter Patente, niedergeschrieben werden können.

Die Namen der Legierungen sind in alphabetischer Reihenfolge ohne Rücksicht auf die Type angeordnet. Ausgenommen: (1) Die Legierung hat die Nummer eines Erzeugers. (2) Besondere Legierungen die durch eine Zahl oder Buchstaben kenntlich gemacht sind. (3) Legierungen in deren Namen der erste Teil ihre Natur beschreibt (z. B. "hard solder," hart Lot). Es sind dann mehrere in einer Type vereinigt. Solche Legierungen sind unter dem Namen der Type angeführt unter welcher sie gewöhnlich gebraucht werden. Unter dem ersten Teil der Namen sind Hinweisdaten gegeben.

Die dritte Kolonne des Nachschlage-Index enthält die Zusammensetzung der Legierungen. Die Elemente, welche die Zusammensetzung ausdrücken sind zusammen mit ihrem Prozentgehalt absteigend nach diesem, angeordnet. Ist der Prozentgehalt des Hauptbestandteiles nicht angegeben, so ist er analytisch nicht bestimmt. Sind die Mengen des letzten Bestandteiles nicht angegeben, so ist dieser nur zufällig vorhanden oder nur Verunreinigung. Fehlen der Prozentzahlen bedeutet, dass keine diesbezügliche Angaben erreichbar waren.

Ändert sich die Zusammensetzung einer Legierung innerhalb einer Grenze, so werden nur die Grenzwerte angegeben, z. B. Index No. 915, MS steel: Fe; Cr, 0,8–1,1; Mo, 0,3–0,4; Mn, 0,6–0,9; C, 0,4–0,6.

Die vierte Kolonne des Nachschlage-Index enthält die Seitenzahlen, wo die Werte für die Eigenschaften gefunden werden können. Die Eigenschaften ähnlicher Legierungen sind auf den kursiv gedruckten Seitenzahlen zu finden.

Die elektrischen, magnetischen und optischen Eigenschaften der Metalle und Legierungen sind Gegenstand späterer Bände der I. C. T. Aus diesem Grunde sind keine diesbezügliche Hinweise im Nachschlage-Index angegeben.

In den Tafeln finden sich keine Angaben über Korrosion. Nach der Meinung massgebender Fachleute ist es nicht möglich quantitative Angaben über den Widerstand gegen Korrosion zu machen. Es sind daher diesbezüglich keine Angaben vorhanden, selbst in Hinblick auf gewisse Legierungen die gerade wegen ihres Widerstandes gegen Korrosion besonders geschätzt werden. Sie sind aber unter den Legierungstypen zu finden.

Für den Nachschlage-Index sind folgende Quellen massgebend gewesen: William Campbell's List of Names of Alloys, prepared for Committee B-2 of the A. S. T. M.; Namen und Zusammensetzung wie sie von den Mitarbeitern (Experten) angegeben worden sind; die vorhandene metallurgische und technologische Literatur.

III. Es ist eine Legierung mit gewünschten Eigenschaften aufzufinden

Zu diesem Zwecke benütze man die S. 610 vorhandenen Eigenschaftstafeln, wo weitere Richtlinien gegeben sind.

Le proprietà elettriche, magnetiche e ottiche dei metalli e delle leghe si troveranno in un volume successivo delle I. C. T.; non è possibile perciò fare richiami a questi valori nell'indice.

Dati sulla resistenza alla corrosione non sono inclusi nelle tabelle, giacchè, secondo i maggiori conoscitori dell'argomento, non è possibile indicare con dati quantitativi la resistenza alla corrosione. Valori numerici non sono perciò riportati neppure per certe leghe che sono sopratutto apprezzate per la loro resistenza alla corrosione. Esse tuttavia sono elencate nelle tabelle dei tipi di leghe.

Le fonti per la compilazione dell'indice sono state: William Campbell's List of Names of Alloys, preparato per il Comitato B-2 della A. S. T. M.; nomi e composizioni fornite dai collaboratori; la letteratura tecnologica e metallurgica corrente.

III. Si desideri trovare una lega che abbia certe proprietà

A questo scopo si consulti la tabella delle proprietà a p. 610 dove si troveranno indicazioni in proposito.

DEFINITIONS

1. Proportional Limit.—Stress at which the deformation ceases to be proportional to the load as determined by strainometer (extensometer for tension, compressometer for compression, and deflectometer for transverse tests, value being read from plotted results).

2. Elastic Limit.—In tensile and compressive tests: The stress at which the initial permanent elongation or shortening of the gage length occurs, as shown by an instrument of high precision (determined from set readings with extensometer or compressometer). In transverse tests: The extreme fiber stress at which the initial appreciable permanent deflection occurs as determined with deflectometer.

Tests are rarely made to determine the elastic limit, since such tests involve repeated application and release of load, and require considerable time. For practical purposes the elastic limit may be regarded as equal to the proportional limit.

3. Yield Point.—Stress at which marked increase in deformation of specimen occurs without increase in load as determined usually by drop of beam or with dividers for tensile, compressive, or transverse tests.

4. Tensile, Compressive, or Shearing Strength (Ultimate).—Maximum stress to which the test specimen is subjected by slowly increased load until rupture, divided by the original cross-sectional area of the test specimen.

5. Modulus of Rupture.—Maximum stress in the extreme fiber of a specimen tested to rupture, as computed by the empirical application of the flexural formula to stresses above the transverse proportional limit. For simple rectangular test piece with concentrated center load, it equals

$$\frac{1.5 \times \text{load} \times \text{span}}{\text{area} \times \text{depth}}$$

6. Torsional Strength (or **Modulus of Rupture in Torsion**).—Maximum stress in the extreme fiber of a specimen tested to rupture as computed by the empirical application of the torsional formula to stresses above the torsional proportional limit. For a round specimen it is

$$S = \frac{5.1 \times \text{twisting moment}}{\text{diameter}^3}$$

In ductile materials the stress at rupture may be considered uniformly distributed over the cross-sectional area and the above formula assumes the form

$$S = \frac{3.82 \times \text{twisting moment}}{\text{diameter}^3}$$

7. Elongation.—The percentage of elongation is found by dividing 100 × the increase of length after rupture by the original gage length. The percentage of elongation depends on the gage length. The elongation indicates the ductility of the material.

8. Reduction of Area.—The percentage of reduction is found as the ratio of 100 × the difference between the original and broken area of cross section to the original area. Reduction of area indicates generally the ductility of material.

9. Poisson's Ratio.—The ratio of lateral contraction per unit of diameter to longitudinal extension per unit of length of a bar under terminal tension within the elastic limit of material.

DEFINITIONS

1. Limite de proportionnalité.—C'est la tension pour laquelle la déformation cesse d'être proportionnelle à la charge, cette tension étant déterminée à l'aide d'un appareil approprié: extensomètre pour la traction, compressomètre pour la compression, et déflectomètre pour les essais de flexion, la valeur de cette tension étant déduite d'une courbe tracée par points.

2. Limite d'élasticité.—Pour les essais de traction et de compression: c'est la plus petite tension pour laquelle la déformation permanente de la longueur entre repères devient appréciable au moyen d'un instrument de haute précision (cette tension étant déterminée au moyen des lectures effectuées à l'aide de l'extensomètre ou du compressomètre). Pour les essais de flexion: c'est la plus petite tension de la fibre extrême, pour laquelle la déformation permanente devient appréciable au moyen du déflectomètre.

Comme la détermination de la limite d'élasticité implique une succession de mises en charge et de décharges de l'éprouvette, et demande un temps considérable, ces essais sont rarement effectués. Dans la pratique on peut considérer la limite d'élasticité comme étant égale à la limite de proportionnalité.

3. Limite d'étirage.—C'est la tension pour laquelle se produit une augmentation importante de la déformation de l'éprouvette sans augmentation de la charge, cette détermination étant faite ordinairement par la chute de l'aiguille ou au compas pour les essais de traction, compression et flexion. (Limite élastique apparente.)

4. Résistance à la traction, à la compression; Résistance au cisaillement.—C'est l'effort maximum auquel l'éprouvette est soumise, par l'augmentation lente et progressive de la charge, jusqu'à rupture, divisé par la section transversale initiale de l'éprouvette.

5. Module de rupture.—C'est la tension maximum de la fibre extrême d'une éprouvette essayée jusqu'à rupture, ainsi qu'elle est calculée par l'application empirique de la formule de flexion, à une tension supérieure à la limite de proportionnalité de la flexion. Pour une éprouvette simple de section rectangulaire, avec une charge concentrée au milieu de la portée, elle est égale à:

$$1{,}5 \times \text{charge} \times \text{portée}/\text{section} \times \text{hauteur de la pièce}$$

6. Résistance à la torsion (**ou module de rupture à la torsion**).—C'est la tension maximum de la fibre extrême d'une éprouvette essayée jusqu'à rupture, ainsi qu'elle est calculée par l'application empirique de la formule de torsion à une tension supérieure à la limite de proportionnalité de la torsion. Pour une éprouvette de section circulaire, elle est égale à:

$$S = 5{,}1 \times \text{moment de torsion}/\text{diamètre}^3$$

Pour les matières ductiles, la tension lors de la rupture peut être considérée comme étant répartie uniformément dans la section transversale et la formule ci-dessus prend la forme:

$$S = 3{,}82 \times \text{moment de torsion}/\text{diamètre}^3$$

7. Allongement.—Le pourcentage d'allongement est obtenu en multipliant par 100 le rapport de l'augmentation de la longueur après rupture à la longueur initiale entre repères. Le pourcentage d'allongement dépend de la longueur entre repères. L'allongement donne une mesure de la ductilité de la matière.

8. Striction.—Le pourcentage de striction est le rapport multiplié par 100 de la différence entre la section initiale et la section de rupture à la section initiale. La striction donne généralement une mesure de la ductilité de la matière.

9. Coefficient de Poisson.—C'est le rapport de la contraction transversale (par unité de diamètre) à la dilatation longitudinale

DEFINITIONEN

1. Proportionalitäts-Grenze.—Spannung, bei der die Formänderung aufhört proportional zur Belastung zu verlaufen; sie wird bestimmt durch ein Formänderungsmessinstrument (Dehnungsmesser für Zug, Zusammendrückungsmesser für Druck und Durchbiegungsmesser für Biegeversuche, der Punkt wird aus dem Diagramm ermittelt).

2. Elastizitäts-Grenze.—Bei Zug- und Druckversuchen: Diejenige Spannung bei der die erste bleibende Dehnung oder Verkürzung der Messlänge eintritt, bestimmt durch ein Messinstrument von hoher Präzision (bestimmt aus den Restablesungen am Dehnungs- oder Zusammendrückungsmesser). Bei Biegeversuchen: Die Spannung der äusseren Faser bei der die erste bemerkbar bleibende Durchbiegung eintritt, bestimmt mit dem Durchbiegungsmesser.

Versuche zur Bestimmung der Elastizitäts-Grenze werden selten ausgeführt, da solche Versuche wiederholte Belastung und Entlastung erforderlich machen und beträchtliche Zeit beanspruchen. Für praktische Zwecke kann die Elastizitäts-Grenze als gleichbedeutend mit der Proportionalitäts-Grenze angesehen werden.

3. Streck-Grenze.—Spannung, bei der ein deutliches Anwachsen der Formänderung der Probe eintritt, ohne dass die Belastung steigt, gewöhnlich bestimmt durch Absinken des Lastanzeigers oder an den Formänderungsmasstäben für Zug-, Druck- oder Biegeversuch.

4. Zug-, Druck- oder Scherfestigkeit (Höchstlast).—Grösste Spannung, der die Probe unterworfen ist, bei langsamer Steigerung der Belastung bis zum Bruch, dividiert durch den ursprünglichen Probenquerschnitt.

5. Biegespannung (oder Bruchmodul).—Grösste Spannung in der äusseren Faser einer bis zum Bruch geprüften Probe in der Annahme, dass die empirische Biegeformel für Spannungen oberhalb der Proportionalitäts-Grenze angewendet werden kann. Für Proben mit einfachem rechteckigen Querschnitt und zentrischer Belastung gilt

$$1{,}5 \times \text{Last} \times \text{Stützweite}/\text{Querschnitt} \times \text{Höhe}$$

6. Torsions-Festigkeit (oder Bruchmodul für Torsion).—Grösste Spannung in der äusseren Faser der Probe beim Bruch, unter der Annahme, dass die Torsionsformel auch für Spannungen oberhalb der Proportionalitätsgrenze gilt. Für eine zylindrische Probe ist diese Torsions-Festigkeit

$$S = 5{,}1 \times \text{Drehmoment}/\text{Durchmesser}^3$$

Bei sehr formänderungsfähigen Materialien kann diese Bruchspannung als gleichmässig über den ganzen Querschnitt verteilt angesehen werden, und die obige Formel geht über in die Formel:

$$S = 3{,}82 \times \text{Drehmoment}/\text{Durchmesser}^3$$

7. Bruchdehnung.—Die prozentuale Dehnung wird gefunden, indem man die Längenzunahme nach dem Bruch durch die ursprüngliche Messlänge dividiert und mit 100 multipliziert. Die Bruchdehnung hängt von der Messlänge ab. Die Bruchdehnung ist ein Masstab für die Formänderungsfähigkeit des Materials.

8. Querschnittsverminderung.—Die prozentuale Querschnittsverminderung wird gefunden als das Verhältnis des Unterschiedes zwischen ursprünglichem und Bruchquerschnitt zu dem ursprünglichem Querschnitt multipliziert mit 100. Die Querschnittsverminderung zeigt allgemein die Formänderungsfähigkeit des Materials an.

9. Poisson'sche Konstante.—Das Verhältnis der Querkontraktion eines Stabes bezogen auf die Einheit des Durchmessers zur Längsdehnung, bezogen auf die Einheit der Länge eines

DEFINIZIONI

1. Limite di proporzionalità.—È quel valore della forza applicata dopo il quale le deformazioni cessano di essere proporzionali alla forza stessa. Le deformazioni sono misurate da apposito apparato (estensometro per le prove di trazione, compressometro per le prove di compressione, e deflettometro o flessimetro per le prove alla flessione). I valori vengono desunti da grafici.

2. Limite elastico.—Nelle prove di trazione e compressione. È quel valore della forza al quale corrisponde l'inizio dell'allungamento o del raccorciamento permanente. La deformazione permanente è messa in evidenza da un istrumento di alta precisione, e determinata mediante una serie di letture all'estensometro o compressometro.

Nelle prove di flessione. Quel valore della forza che si ha nella fibra estrema quando si manifesta una deflessione permanente apprezzabile determinata con il flessimetro.

Le prove per determinare il limite di elasticità si eseguono raramente, perchè richiedono ripetute applicazioni ed annullamenti della forza applicata, e quindi molto tempo. Per scopi pratici, si può considerare il limite di elasticità come coincidente con il valore del limite di proporzionalità.

3. Punto di snervamento.—È quel valore della forza in corrispondenza del quale si ha un aumento marcato nella deformazione del provino senza che il carico aumenti. Esso viene determinato osservando il momento in cui l'apparato registratore della forza applicata al provino cade rapidamente, oppure a mezzo di misurazione sul provino calibrato alle prove di trazione, compressione e flessione.

4. Carico di rottura alla trazione, compressione e taglio.—È il valore massimo dello sforzo al quale il provino è soggetto alla rottura, quando lo sforzo viene accresciuto lentamente. Questo valore viene riferito all'area della sezione trasversale primitiva del provino.

5. Modulo di rottura.—Massimo sforzo che si verifica nelle fibre maggiormente sollecitate di un provino che venga provato a flessione fino a rottura. Esso è calcolato con l'applicazione empirica della formula di sollecitazione per flessione, anche quando lo sforzo supera il limite di proporzionalità per sollecitazione della flessione stessa. Per pezzi di forma rettangolare semplice con carico concentrato nel centro, è eguale a:

$$\frac{1{,}5 \times \text{carico} \times \text{distanza tra gli appoggi}}{\text{area} \times \text{spessore}}$$

6. Sforzo di torsione (oppure modulo di rottura alla torsione).—Massimo sforzo che si verifica nelle fibre più sollecitate di un provino provato fino alla rottura, calcolato applicando empiricamente (anche al di sopra del limite di proporzionalità per torsione) la formula che dà la sollecitazione per torsione. Per un provino a sezione rotonda, la formula è:

$$S = \frac{5{,}1 \times \text{momento torcente}}{\text{diametro}^3}$$

Nei materiali duttili lo sforzo di rottura può essere considerato uniformemente distribuito sull'area della sezione trasversale, e la formula (2) diventa:

$$S = \frac{3{,}82 \times \text{momento torcente}}{\text{diametro}^3}$$

7. Allungamento.—L'allungamento percentuale è calcolato dividendo l'aumento di lunghezza dopo rottura per la lunghezza originale calibrata. L'allungamento percentuale dipende dalla lunghezza calibrata, cioè dalla lunghezza alla quale è riferito l'allungamento stesso. Questo allungamento indica la duttilità dei materiali.

10. Modulus of Elasticity (*(a)* **in Tension or** *(b)* **in Compression).**—Ratio of stress within the proportional limit to the corresponding strain as determined with a precise extensometer. Accurate determinations of the modulus of elasticity are made with a gage length at least 8 in. (203.2 mm) in length.

11. Modulus of Elasticity in Shear.—Ratio of stress within the proportional limit to the corresponding angular strain (in radians). The following theoretical relation exists between the modulus of elasticity in shear and the modulus of elasticity:

$$G = \frac{E}{2(1 + \lambda)}$$

where G is the modulus of elasticity in shear, E modulus of elasticity, and λ Poisson's ratio.

It is difficult to make a direct experimental determination of G on account of the presence of other stresses. It is usually determined by the torsion of a round bar.

12. Brinell Hardness Number.—Ratio of load, on a sphere used to indent the material to be tested, to the area of the spherical indentation produced. The standard sphere used is a 10 mm diameter hardened steel ball. The loads are (*a*) 3000 kg (6615 lb.) and (*b*) 500 kg (1102 lb.), and the time of application of load is 30 sec. Values shown in the tables are based on spherical areas computed from measurements of the diameters of the spherical indentations, by the following formula:

$$H_B = \frac{P}{\pi h D} = \frac{P}{\pi D\left(\frac{D}{2} - \sqrt{\frac{D^2}{4} - \frac{d^2}{4}}\right)}$$

P being load in kg, h being depth of indentation, D being diameter of ball and d being diameter of indentation, all lengths being expressed in millimeters. Brinell hardness values have a certain relation to tensile strength, and hardness determinations may be used to determine tensile strengths approximately by employing the proper conversion factor for the material under consideration.

13. Shore Scleroscope Hardness.—Height of rebound of a diamond-pointed hammer falling on the object from a fixed, stated height through a tube under the acceleration due to its own weight. On very soft materials a "magnifier" hammer is used in place of the commonly used "universal" hammer, and values may be converted to the corresponding "universal" value by multiplying the reading by $4/7$.

14. Erichsen Value.—The test is conducted by supporting the sheet on a circular ring and deforming it at the center of the ring by a spherical-pointed tool. The depth of impression (or cup), in millimeters, required to obtain fracture is the Erichsen value.

15. Bend Test.—(*a*) Angle through which the material can be bent without fracture; or (*b*) the number of bendings around a predetermined diameter; or (*c*) a minimum diameter around which the test piece can be bent through a stated angle.

16. Impact Resistance.—(Bibliography on Impact Testing, Whittemore, *Proc. A. S. T. M.*, 1922.) Indicates the shock-resisting qualities of material. Is of particular value in ascertaining the influence of heat treatment. Impact value depends on the form of the specimen and type of apparatus, both of which must be stated.

(par unité de longueur) d'une barre soumise à une tension inférieure à la limite d'élasticité de la matière.

10. Module d'élasticité (*a*) **de traction,** (*b*) **de compression.**—C'est le rapport de la tension (celle-ci étant inférieure à la limite de proportionnalité) à la dilatation correspondante, cette détermination étant faite au moyen d'un extensomètre de précision. Les déterminations précises du module d'élasticité se font sur une longueur entre repères d'au moins 203,2 mm.

11. Module d'élasticité de glissement.—C'est le rapport de la tension (celle-ci étant inférieure à la limite de proportionnalité) au glissement correspondant (en radians). Il existe entre le module d'élasticité de glissement et le module d'élasticité la relation théorique suivante:

$$G = \frac{E}{2(1 + \lambda)}$$

ou G est le module d'élasticité de glissement, E le module d'élasticité et λ le coefficient de Poisson.

Il est difficile de faire une détermination expérimentale directe de G par le fait de la présence d'autres tensions. G est ordinairement déterminé par la torsion d'une barre de section circulaire.

12. Nombre de dureté Brinell.—C'est le rapport de la charge appliquée sur une bille qui pénètre dans la matière à essayer, à la surface de l'empreinte sphérique produite. La bille type utilisée est une sphère en acier trempé de 10 mm de diamètre. Les charges sont de (*a*) 3000 kg et (*b*) 500 kg et la durée d'application de la charge est de 30 secondes. Les valeurs données dans les tables sont basées sur les surfaces des calottes sphériques calculées d'après les diamètres mesurés des empreintes sphériques produites, par la formule suivante:

$$H_B = \frac{P}{\pi h D} = \frac{P}{\pi D\left(\frac{D}{2} - \sqrt{\frac{D^2}{4} - \frac{d^2}{4}}\right)}$$

P est la charge en kg, h la profondeur de l'empreinte, D le diamètre de la bille et d le diamètre de l'empreinte, toutes les longueurs étant exprimées en millimètres.

Il y a une certaine relation entre les nombres de dureté Brinell et la résistance de rupture, et des déterminations de dureté peuvent être employées pour déterminer approximativement la résistance de rupture en employant le facteur de conversion relatif à la matière considérée.

13. Dureté au scléroscope de Shore.—C'est la hauteur de rebondissement d'un petit marteau à pointe de diamant tombant sous l'effet de son propre poids sur l'object d'une hauteur fixe définie, en se déplaçant dans un tube. Lorsqu'il s'agit de matières très tendres, on utilise un marteau amplificateur à la place du marteau "universel" généralement employé, et les valeurs peuvent être converties en valeurs "universelles" correspondantes en multipliant la lecture par $4/7$.

14. Nombre d'Erichsen.—On effectue l'essai en supportant la tôle sur une bague circulaire et en la déformant au centre de la bague par un outil à pointe sphérique. Le nombre d'Erichsen est la profondeur de l'empreinte exprimée en millimètres, nécessaire pour produire la rupture.

15. Essai de pliage.—(*a*) C'est l'angle sous lequel la matière peut être pliée sans rupture; ou (*b*) le nombre de pliages successifs autour d'une barre de diamètre prédeterminé; ou (*c*) le diamètre minimum du cylindre autour duquel l'éprouvette peut être pliée sous un angle défini.

16. Résistance au choc.—(Bibliographie concernant l'essai de choc, Whittemore, *Proc. A. S. T. M.*, 1922.) Elle donne une mesure des qualités de résistance de la matière au choc. Elle est d'une importance particulière pour se rendre compte de l'influence d'un traitement thermique. Les valeurs obtenues aux essais de choc dépendent de la forme de l'éprouvette et du type d'appareil employé; ces deux éléments doivent être définis.

Stabes bei bestimmten Zugspannungen innerhalb der Elastizitätsgrenze des betreffenden Materials.

10. Elastizitäts-Modul (*a*) **für Zug oder** (*b*) **für Druck.**—Das Verhältnis der Spannung innerhalb der Proportionalitätsgrenze zur entsprechenden Formänderung, ermittelt durch einen präzisen Dehnungsmesser. Genaue Bestimmungen Elastizitätsmoduls werden ausgeführt mit einer Mindestmesslänge von 203,2 mm.

11. Elastizitäts-Modul bei Scherbeanspruchung.—Verhältnis der Spannung innerhalb der Proportionalitätsgrenze zu der entsprechenden Winkeländerung (in radians). Die folgende theoretische Beziehung besteht zwischen dem Elastizitätsmodul bei Scherbeanspruchung und den Elastizitätsmodul bei Zugbeanspruchung $G = E/2\ (1 + \lambda)$, worin G der Elastizitätsmodul für Scherbeanspruchung, E der Elastizitätsmodul für Zugbeanspruchung und λ die Poisson'sche Konstante ist. Es ist schwer, den Gleitmodul G direkt experimentell zu bestimmen wegen des Vorhandenseins von Nebenspannungen. Gewöhnlich wird er bestimmt durch einen Drehversuch mit einem Rundstab.

12. Brinell Härtezahl.—Das Verhältnis der Last, mit der eine Kugel in das zu prüfende Material eingedrückt wird, zur Fläche des erzeugten Kugeleindruckes. Die gebräuchliche Normalkugel ist eine gehärtete Stahlkugel von 10 mm Durchmesser. Die Kugelbelastungen sind (*a*) 3000 kg (6615 engl. Pfund) und (*b*) 500 kg (1102 engl. Pfund). Die Zeitdauer der Belastung beträgt 30 Sekunden. Die in den Tabellen angegebenen Werte für die Härtezahl werden aus Messungen der Durchmesser der erzeugten Kugeleindrücke unter Verwendung folgender Formel gewonnen:

$$H_B = \frac{P}{\pi h D} = \frac{P}{\pi D\left(\frac{D}{2} - \sqrt{\frac{D^2}{4} - \frac{d^2}{4}}\right)}$$

Darin bedeuten P die Kugelbelastung in kg, h die Eindrucktiefe in mm, D den Kugeldurchmesser in mm und d den Durchmesser des Eindrucks in mm. Die Brinell-Härtezahlen haben eine gewisse Beziehung zur Zugfestigkeit, Härtebestimmungen können deshalb angewandt werden, um angenähert die Zerreissfestigkeiten zu bestimmen, unter Anwendung eigenen Koeffizienten eines für jedes Material.

13. Shore Skleroskope-Härte.—Die Höhe des Rückpralls eines mit Diamantspitze versehenen Fallhammers, der aus einer bestimmten festgelegten Höhe durch eine Röhre unter Beschleunigung durch sein Eigengewicht auf die Probe fällt. Bei sehr weichen Materialien wird ein Spezialhammer angewandt an Stelle des gewöhnlich benutzten "Universalhammers;" die mit diesem Spezialhammer erzielten Werte können auf den Universalhammer bezogen werden durch Multiplikation der Ablesungen mit $4/7$.

14. Erichsen-Wert.—Der Versuch wird ausgeführt, indem ein Blech am Rande kreisförmig eingespannt und in der Mitte durch einen kugelförmigen Stempel eingedrückt wird. Die Tiefe des Eindrucks (oder der Beule) in mm, die erforderlich ist um Bruch hervorzurufen, ist der Erichsen-Wert.

15. Biegeprobe.—(*a*) Winkel, um den das Material gebogen werden kann ohne zu brechen; oder (*b*) die Zahl der Biegungen um einen bestimmten Durchmesser: oder (*c*) der kleinste Durchmesser, um den die Probe um einen bestimmten Winkel gebogen werden kann.

16. Schlag- oder Stossfestigkeit.—(Bibliography on Impact Testing, Whittemore, *Proc. A. S. T. M.*, 1922.) Gibt die Eigenschaften eines Materials an, Stossbeanspruchungen zu widerstehen und ist von besonderem Wert zur Feststellung des Einflusses von Wärmebehandlung. Der gefundene Schlagfestigkeitswert hängt von der Form der Probe und der Art des Apparates ab, beides muss also festgelegt werden.

17. Widerstand gegen Ermüdung.—Widerstand eines Materials gegen wiederholte, zwischen zwei bestimmten Spannungsgrenzen

8. Riduzione di area.—Percentuale di riduzione di area calcolata come rapporto della differenza tra l'area del provino prima e dopo la rottura (nel punto dove è avvenuta la rottura) e l'area originale. La riduzione di area indica generalmente la duttilità dei materiali.

9. Rapporto di Poisson.—Il rapporto della contrazione laterale per unità di diametro e l'allungamento longitudinale, riferito alla unità di allungamento di una barra sottoposta, nei suoi estremi, a sollecitazioni di tensione entro i limiti di elasticità del materiale.

10. Modulo di elasticità (*a*) **alla trazione,** (*b*) **alla compressione.**—Il rapporto del valore dello sforzo entro i limiti di proporzionalità e le corrispondenti deformazioni determinate con un estensometro molto preciso. Determinazioni accurate del modulo di elasticità sono fatte sopra una lunghezza calibrata del provino di almeno mm 203,2.

11. Modulo di elasticità al taglio.—Rapporto del valore dello sforzo entro i limiti proporzionali corrispondenti alle deformazioni angolari espresse in radianti. La relazione teorica che esiste tra il modulo di elasticità al taglio e il modulo di elasticità è:

$$G = \frac{E}{2(1 + \lambda)}$$

dove G è il modulo di elasticità al taglio, E quello di allungamento e λ il rapporto di Poisson.

È molto difficile eseguire un esperimento per misurare direttamente il valore di G, a causa della presenza di altri sforzi. Generalmente viene determinato eseguendo una prova di torsione sopra una barra rotonda.

12. Numero di durezza Brinell.—Rapporto tra il carico applicato sopra una sfera che penetra nel materiale sottoposto alla prova e l'area della impronta prodotta.

La sfera tipo è del diametro di mm 10 ed è di acciaio temprato. I carichi applicati sono: (*a*) kg 3000: (*b*) kg 500. Il tempo di applicazione del carico è di 30 secondi.

I valori riportati nelle tabelle si riferiscono alla misura dell'area fatta in base al diametro dell'impronta sferica.

$$H_B = \frac{P}{\pi h D} = \frac{P}{\pi D\left(\frac{D}{2} - \sqrt{\frac{D^2}{4} - \frac{d^2}{4}}\right)}$$

dove P è il carico in kg, h la profondità dell'impronta, D il diametro della sfera adoperata e d il diametro della impronta. La durezza Brinell ha una certa relazione col carico di trazione, e le determinazioni della durezza possono servire a determinare appunto i carichi di trazione, in via approssimativa, mediante un fattore di conversione caratteristico per il materiale in esame.

13. Durezza allo scleroscopio di Shore.—Altezza del rimbalzo di un martello munito di una punta di diamante che cade sull'oggetto da una altezza nota e determinata, percorrendo un tubo sotto l'accelerazione dovuta al proprio peso. Per materiali molto teneri si usa un martello "moltiplicatore" invece del martello comune chiamato "universale," ed i valori possono essere convertiti in corrispondenti valori del martello universale moltiplicando la lettura per $4/7$.

14. Valori di Erichsen.—La prova si fa appoggiando il foglio di lamiera contro un anello e deformandolo nel centro a mezzo di un utensile pure sferico. La profondità dell'impressione in mm, che si ha per ottenere la frattura, è il valore di Erichsen.

15. Prove di piegamento.—(*a*) Angolo di cui il materiale può essere piegato senza fratturarsi, oppure: (*b*) numero di piegature attorno ad un predeterminato diametro, oppure: (*c*) diametro minimo attorno al quale il provino può essere piegato percorrendo un determinato angolo.

16. Resistenza all'urto.—(Bibliography on Impact Testing, Whittemore, *Proc. A. S. T. M.*, 1922.) Indica la resistenza del materiale all'urto, ed ha particolare valore per accertare l'influenza dei trattamenti termici. Il valore all'urto dipende dalla forma del provino e dal tipo della macchina, ed entrambi questi elementi devono essere specificati.

17. Fatigue Resistance.—Resistance of material to a load varying continuously and cyclically between two fixed stress values.

Numerical values of Fatigue Resistance for the case of zero mean stress (Reversed Stresses) may be given as follows:

17a. Fatigue Strength.—The numerical values of upper and lower limits of stress cycle which cause failure after a definite number of repetitions.

17b. Endurance Limit.—The value of the upper (or lower) limit of stress cycle which is just insufficient to cause failure after a stated number of repetitions have been endured.

17c. True Endurance Limit.—The limiting value of the endurance limit, *i.e.*, the upper limit of a cycle of stress which can be applied an indefinitely great number of times without causing failure. The true endurance limit can never, of course, be determined experimentally. For many materials, however, it is found that if values of fatigue strength are plotted against the number of cycles N to fracture (logarithmically or semi-logarithmically) the resulting curve tends to become parallel to the N axis, affording strong evidence of the existence of a "true endurance limit."

Numerical values of fatigue resistance for cycles of stress whose mean stress is *not* zero may be given by stating the upper and lower limits of the stress cycles corresponding to 17*a* above, or by stating the value of the mean stress and the range (or semi-range) of the cycle. Consequently, corresponding to the above we shall have:

17d. Fatigue Strength Range.

17e. Endurance Range.

17f. True Endurance Range.
