18. Ductility.—The *ductility* is the elongation of the test specimen measured after rupture on a distance distributed symmetrically on both sides of the place of rupture, and should be specified in % of the original length of the distance.

19. Acetyl Value.—Defined as g KOH (56.1) to neutralize the acetic acid from 1000 g acetylated oil (**1, 2, 7**). It gives hydroxy-acids + alcohols + oxidized fatty acids + unknown acids + mono- and di-glycerides + rancidity (**7**).

20. Iodine Value.—Per cent I_2 or its equivalent of other halogen absorbed (**3, 6, 12, 13**). Heat of bromination is proportional to I-value for most non-oxidized oils and fats (**4, 8**).

21. Saponification Value.—Mg KOH for complete saponification of 1 g of the oil, fat or wax. The corresponding mean equivalent weight of the substance is the "saponification equivalent." (**5**) gives a method for cold saponification.

22. Hehner Value.—Per cent insoluble fatty acids + unsaponifiables.

23. Polenske Value.—Proportion of insoluble volatile fatty acids (in terms of cm^3 of 0.1N KOH per 5 g of fat) obtained by Polenske's method of distillation (**10**).

24. Acid Value.—Mg KOH required to neutralize the free fatty acids in 1 g of oil or fat. The free fatty acids are also often expressed as a percentage of the principal fatty acid in the fat. Except in the case of the waxes, this value is not a constant, but varies with the degree of hydrolysis of the fat.

25. Reichert-Meissl Value.—Soluble volatile fatty acids in terms of 0.1N KOH per 5 g fat, under Meissl's test conditions (**9, 11, 14**).

LITERATURE

(For a key to the periodicals see end of volume)

(5) Henriques, *92*, **8**: 721; 95. **9**: 221; 96. (6) Hübl, *112*, **253**: 281; 84. (7) Lewkowitch, *173*, **24**: 319; 99. (8) Marden, *45*, **8**: 121; 16. (9) Meissl, *112*, **233**: 229; 79.

(10) Polenske, *279*, **7**: 273; 04. (11) Reichert, *91*, **18**: 68; 79. (12) Waller, *136*, **19**: 1831; 95. (13) Wijs, *25*, **31**: 750; 98. (14) Wollner, *173*, **12**: 203; 87. *352*, **16**: 609; 87.

17. Résistance à la fatigue.—Résistance des matériaux soumis à une sollicitation variant d'une façon continue et périodique entre deux valeurs fixes.

Les valeurs numériques de la résistance à la fatigue pour le cas d'un effort moyen nul (efforts alternatifs) peuvent être données comme suit:

17a. Résistance à la fatigue.—Ce sont les valeurs numériques des limites supérieures et inférieures du cycle de tension qui produisent la rupture après un nombre défini de répétitions de l'effort.

17b. Limite d'endurance.—C'est la valeur de la limite supérieure (ou inférieure) du cycle de tension qui est juste insuffisante pour produire la rupture après un nombre défini de répétitions de l'effort.

17c. Limite d'endurance vraie.—C'est la valeur limite de la limite d'endurance, c'est-à-dire la limite supérieure d'un cycle de tension, qui peut être appliqué un nombre indéfini de fois sans produire la rupture. La limite d'endurance vraie ne peut naturellement jamais être déterminée expérimentalement.

Cependant, pour plusieurs matériaux, on a constaté que si l'on représente graphiquement les valeurs de la résistance à la fatigue en fonction du nombre de cycles N jusqu'à rupture (logarithmiquement ou semi-logarithmiquement), la courbe qui en résulte tend à devenir parallèle à l'axe des N, mettant ainsi bien en évidence l'existence d'une "limite d'endurance vraie."

Les valeurs numériques de la résistance à la fatigue pour des cycles de tension dont la valeur moyenne *n'est pas* zéro, peuvent être obtenues en fixant la limite supérieure et la limite inférieure des cycles de tension correspondant à 17*a* ci-dessus, ou en fixant la valeur de la tension moyenne et l'amplitude (ou demi amplitude) du cycle. Par conséquent, correspondant à ce que nous avons ci-dessus, nous aurons:

17d. Amplitude de la résistance à la fatigue.

17e. Amplitude d'endurance.

17f. Amplitude d'endurance vraie.

18. Ductilité.—*La ductilité* est l'allongement d'une éprouvette essayée, mesuré après rupture sur une distance répartie symétriquement de part et d'autre de la section de rupture. Elle doit être exprimée en % de la longueur initiale entre repères.

19. Indice d'acétyle.—Il est défini par le nombre de g de KOH (56,1) nécessaires pour neutraliser l'acide acétique de 1000 g d'huile acétylée (**1, 2, 7**). Il donne les hydroxyacides + alcools + les acides gras oxydés + acides inconnus + mono et diglycérides + rancidité.

20. Indice d'iode.—Pourcentage de I_2 ou son équivalent d'un autre halogène absorbé (**3, 6, 12, 13**). La chaleur de bromuration est proportionnelle á l'indice d'iode pour la plupart des huiles et graisses non oxydées (**4, 8**).

21. Indice de saponification.—Mg KOH pour la saponification complète de 1 g d'huile, graisse ou cire. Le poids équivalent moyen correspondant à la substance est "l'équivalent de saponification." (**5**) donne une méthode pour la saponification à froid.

22. Indice de Hehner.—Pourcent d'acides gras insolubles + insaponifiables.

23. Indice de Polenske.—Proportion d'acides gras volatils insolubles (exprimés en cm^3 de 0,1N KOH pour 5 g de graisse) obtenue par la méthode de distillation de Polenske (**10**).

24. Indice d'acide.—Mg KOH nécessaires pour neutraliser les acides libres contenus dans 1 g d'huile ou de graisse. On exprime aussi souvent les acides gras libres en pourcent des acides gras principaux contenus dans la graisse. Excepté dans le cas des cires, cette valeur n'est pas une constante, mais elle varie avec le degré d'hydrolyse de la graisse.

25. Indice de Reichert-Meissl.—Acides gras volatils, solubles exprimés en 0.1N KOH pour 5 g de graisse, suivant les conditions de l'essai de Meissl (**9, 11, 14**).

schwingenden Beanspruchungen. Zahlenmässige Werte für den Ermüdungswiderstand können für den Fall, dass der Spannungsmittelwert Null ist (vollkommene Umkehrung der Spannung nach Richtung und Grösse) folgendermassen ausgedrückt werden:

17a. Ermüdungsfestigkeit.—Die zahlenmässigen Werte der oberen und unteren Grenzen des Spannungswechsels, welche nach einer bestimmten Anzahl von Wiederholungen Bruch hervorrufen.

17b. Dauerbruchgrenze.—Der Wert der oberen (od. unteren) Grenze des Spannungswechsels, welcher gerade noch nicht ausreicht, um den Bruch nach einer bestimmten Zahl von der Probe erlittener Lastwechsel hervorzurufen.

17c. Wahre Dauerbruchgrenze.—Der Grenzwert der Ermüdungsgrenze, d.h., die obere Grenze eines Spannungswechsels, welcher unbegrenzt häufig—ohne Bruch zu verursachen—angewandt werden kann. Die wahre Dauerbruchgrenze kann selbstverständlich niemals experimentell bestimmt werden. Sie ist jedoch für viele Materialien festgestellt, sobald man die Werte der Ermüdungsfestigkeit in Abhängigkeit von der Zahl der Spannungswechsel N, die zum Bruch führen, logarithmisch (oder für die eine Achse logarithmisch) aufgetragen, darstellt, die sich ergebende Kurve parallel zur N-Achse zu verlaufen strebt und damit einen sicheren Anhalt für das Vorhandensein einer "wahren Dauerbruchgrenze" bietet. Zahlenmässige Werte des Widerstandes gegen Ermüdung für Lastwechselfolgen, deren Spannungsmittelwerte nicht Null sind, können wiedergegeben werden durch Angabe der oberen und unteren Grenzen des Spannungswechsels, entsprechend 17*a* oder durch Angabe des Spannungsmittelwertes und der ganzen (oder halben) Amplitude. Entsprechend obigem, kann man demnach setzen:

17d. Ermüdungsfestigkeit für bestimmte Spannungswechsel.

17e. Dauerbruchfestigkeit für bestimmte Spannungswechsel.

17f. Wahre Dauerbruchfestigkeit für bestimmte Spannungswechsel.

18. Formänderungsfähigkeit.—Die Formänderungsfähigkeit ist die Verlängerung des Probestabes, gemessen nach dem Bruch auf eine Länge, die symmetrisch zu beiden Seiten der Bruchstelle verteilt ist. Sie ist in Prozenten der ursprünglichen Messlänge anzugeben.

19. Acetyl-Zahl.—Gibt die Gramme KOH (56,1) an, die für die Neutralisation der Essigsäure in 1000 g des acetylierten Öles notwendig sind (1, 2, 7). Damit sind bestimmt: Oxysäuren + Alkohole + oxydierte Fettsäuren + unbekannte Säuren + Mono und Diglyceride + Ranzigkeit (7).

20. Jod-Zahl.—Ist durch Prozente Jod bestimmt(Äquivalent den anderen absorbierbaren Halogenen) (3, 6, 12, 13). Die Bromierungs-Wärme ist proportional der Jod-Zahl bei den meisten nicht oxydierten Fetten (4, 8).

21. Verseifungs-Zahl.—Gibt die mg KOH an die für die vollständige Verseifung von 1 g Fett, Öl, Wachs notwendig sind. Das entsprechende mittlere Äquivalent-Gewicht der Substanz ist das "Verseifungs-Äquivalent." (5) gibt eine Methode für die Verseifung in der Kälte.

22. Hehner'sche-Zahl.—Ist Prozente unlösliche Fettsäuren + Unverseifbares.

23. Polenske-Zahl.—Gibt die Anzahl cm^3 0.1N KOH an die nötig sind, um die flüchtigen unlöslichen Fettsäuren für 5 g Fett zu neutralisieren, die entsprechend der Destillationsmethode nach Polenske (10) erhalten werden.

24. Säure-Zahl.—Ist die Anzahl mg KOH die für die Neutralisation der freien Fettsäuren von 1 g Öl oder Fett notwendig sind. Die freien Fettsäuren werden öfters in Prozenten der Hauptfettsäure im Fett angegeben. Mit Ausnahme bei den Wachsarten ist diese Zahl nicht konstant und ändert sich mit dem Grade der Hydrolyse des Fettes.

25. Reichert-Meissl'sche-Zahl.—Lösliche flüchtige Fettsäuren ausgedrückt in cm^3 0.1N KOH für 5 g Fett, bestimmt nach dem Vorgange von Meissl (9, 11, 14).

17. Resistenza alla fatica.—Resistenza del materiale sottoposto a sforzi varianti in modo continuo e ciclico tra due valori fissi.

Valori numerici della resistenza alla fatica nel caso di uno sforzo medio eguale a zero (sforzi invertiti) possono essere indicati nella maniera seguente:

17a. Resistenza alla fatica.—I valori numerici dei limiti superiore ed inferiore delle sollecitazioni cicliche che producono rottura dopo un numero definito dei ripetizioni.

17b. Limite di durata.—Valore superiore (o inferiore) della massima sollecitazione ciclica insufficiente a produrre la rottura dopo essere stata applicata un determinato numero di volte.

17c. Limite vero (o pratico) di durata.—Valore limite del limite di durata, cioè valore superiore della massima sollecitazione ciclica che può essere applicata un gran numero di volte senza produrre rottura. Naturalmente, il vero limite di durata non può mai essere determinato sperimentalmente. Tuttavia, per molti materiali si è trovato che, se si riportano in un diagramma i valori della sollecitazione in funzione del numero di cicli N che producono la frattura (logaritmicamente o semilogaritmicamente) la curva risultante tende a divenire parallela all'asse N mostrando all' evidenza che esiste un "vero limite di durata."

Valori numerici di resistenza alla fatica per sollecitazioni cicliche nelle quali i valori medi delle sollecitazioni sono diversi a zero possono essere dati stabilendo i limiti superiore ed inferiore dei cicli delle sollecitazioni corrispondenti a 17*a*, oppure stabilendo il valore della sollecitazione media e l'intervallo (o semintervallo) del ciclo. Di conseguenza, d'accordo con quanto sopra si avrà:

17d. Ampiezza delle oscillazioni tra i valori delle sollecitazioni cicliche alla fatica.

17e. Ampiezza od oscillazioni di durata.

17f. Ampiezza od oscillazioni pratiche di durata.

18. Duttilità.—La duttilità è l'allungamento del provino, e viene misurata dopo la rottura sopra una lunghezza distribuita simmetricamente da entrambe le parti del punto di rottura. Essa è specificata in percento della lunghezza originale primitiva.

19. Numero di acetile.—Indica i grammi di KOH (56,1) necessari per neutralizzare l'acido acetico in 1000 g di olio acetilato (1, 2, 7). Esso è in relazione: con gli ossiacidi + gli alcooli + gli acidi grassi ossidati + acidi sconosciuti + mono e digliceridi, + la rancidità (7).

20. Numero di iodio.—Percento di I_2 (o suo equivalente di altri alogeni) fissato (3, 6, 12, 13). Il calore di bromurazione è proporzionale al numero di iodio per la maggior parte degli olii e grassi non ossidati (4, 8).

21. Numero di saponificazione.—Mg di KOH necessari per la completa saponificazione di 1 g di olio, grasso o cera. Il corrispondente peso equivalente medio della sostanza è "l'equivalente di saponificazione." (5) dà un metodo di saponificazione a freddo.

22. Numero di Hehner.—Percento di acidi grassi isolubili + sostanze insaponificabili.

23. Numero di Polenske.—Quantità di acidi grassi volatili insolubili (riferito in cm^3 di KOH 0.1N per 5 g di grasso) ottenuta col metodo di distillazione di Polenske (10).

24. Numero di acidità.—Mg di KOH richiesti per neutralizzare gli acidi grassi liberi di 1 g di olio o grasso. Gli acidi grassi liberi sono spesso riferiti come percentuale dell'acido principale contenuto nel grasso. All'infuori del caso delle cere questo numero non è una costante, ma varia col grado di idrolisi del grasso.

25. Numero di Reichert-Meissl.—Acidi grassi volatili solubili, espressi in cm^3 di KOH 0.1N per 5 g di grasso, ottenuti nelle condizioni di procedimento Meissl (9, 11, 14).

LITERATURE REFERENCES

LITERATURE REFERENCES

In all literature references cited in International Critical Tables the name of the journal or publication is indicated by means of a *Key Number* corresponding to the list given below. The numbers which follow this key number in a literature citation are, in the order named: (1) the volume, (2) the page, and (3) the last two figures of the year. Thus *64V*, **31**: 253; 22, indicates Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Series numbers are not given. Key Numbers referring to books and other non-serial publications are preceded by the letter *B*, and the volume number is given in Roman numerals. Thus, *B10*, **IV**: 191; 18 indicates Doelter, Handbuch der Mineralchemie, page 191 of Vol. 4 of the 1918 edition. The Key Number *O* is used to indicate "private communication from."

DAS LITERATURVERZEICHNIS

In allen Literaturstellen, die in I. C. T. verzeichnet sind, ist der Name der Zeitschrift oder der Publikation mit Hilfe einer *Schlüsselnummer*, entsprechend der unten folgenden Liste, angegeben. Die Zahlen, welche diesen Schlüsselnummern bei einem Literaturzitat folgen, bedeuten der Reihe nach: (1) der Band, (2) die Seite und (3), die letzten zwei Zahlen des Jahrganges. So bedeutet z. B. *64V*, **31**: 253; 22, Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, Band 31, Seite 253, 1922. Serien-Nummern werden nicht angegeben. Der Schlüsselzahl wird ein *B* vorausgesetzt, wenn sie Bücher, oder eine andre nicht periodische Veröffentlichung bezeichnet. Die Bandnummer wird durch römische Ziffern angegeben. Es bedeutet z. B. also *B10*, **IV**: 191; 18, Doelter, Handbuch der Mineralchemie, Seite 191, des 4 Bandes, der Auflage des Jahres 1918. Die Schlüsselzahl *O* wird gebraucht, um anzuzeigen, dass es eine "private Mitteilung" ist.

RÉFÉRENCES BIBLIOGRAPHIQUES

Le nom du journal ou de la publication de toutes les références bibliographiques citées dans les Tables Critiques Internationales est indiqué au moyen d'un nombre-clé correspondant à la liste donnée ci-dessous. Les nombres qui suivent ce nombre-clé dans un renvoi bibliographique indiquent dans l'ordre suivant: (1) le volume, (2) la page, et (3) les deux derniers chiffres de l'année. Ainsi *64V*, **31**: 253; 22, indique Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, vol. 31, page 253, 1922. Les numeros des séries ne sont pas donnés. Les nombres-clés se rapportant à des livres ou à des publications non périodiques sont précédés de la lettre *B* et le numéro du volume est donné en chiffres romains. Ainsi, *B10*, **IV**: 191; 18 indique Doelter, Handbuch der Mineralchemie, page 191 du volume 4 de l'édition de 1918. Le nombre-clé *O* est employé pour indiquer "communication privée de."

INDICAZIONI BIBLIOGRAFICHE

In tutte le indicazioni bibliografiche che si incontrano nelle "Tabelle Critiche Internazionali" il nome del giornale o della pubblicazione è espresso con un *numero chiave* riportato nell'elenco dato più oltre. I numeri che, nella citazione, vengono dopo il numero chiave sono disposti con l'ordine seguente: (1) il volume, (2) la pagina, e (3) le ultime due cifre del millesimo. Cosi *64V*, **31**: 253; 22, indica la Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, pagina 253, 1922. I numeri di serie non vengono dati. Quando un numero chiave è preceduto dalla lettera *B* si riferisce a libri o ad altre pubblicazioni non periodiche, e il numero del volume viene allora scritto in cifre romane. Cosi *B10*, **IV**: 191; 18 indica Doelter, Handbuch der Mineralchemie, pagina 191 del IV° volume dell'edizione 1918. Il numero chiave *O* indica "Comunicazione privata da . . . "

KEY TO THE PERIODICALS

IMPORTANT NOTICE

ANNUAL TABLES OF CONSTANTS AND NUMERICAL DATA CHEMICAL, PHYSICAL, BIOLOGICAL, AND TECHNOLOGICAL

Published by an International Committee, under the authority of the International
Research Council and the International Union of
Pure and Applied Chemistry

THE data given in International Critical Tables are based upon determinations published previous to January 1924.

In order to keep always up to date with future progress in physical measurements, the purchaser of International Critical Tables should become a regular subscriber to *International Annual Tables*, which will bring to his desk each year a volume in which he will find assembled and classified all of the data which has appeared in the world's literature, for the year covered by the volume.

Thus, *Annual Tables*, Volume VI, will contain all the data published in the literature of 1923–1924; Volume VII will contain the data published in the literature of 1925–1926; Volume VIII, the data to be found in the literature of 1927, etc. . . .

The older volumes of Annual Tables go back to 1910 and contain all of the original determinations published during that period and which served as all or part of the basis of selection of the "best" values recorded in International Critical Tables. These older volumes thus constitute a handy and accessible source of reference to the original determinations.

Through special arrangements made with the International Commission in charge of Annual Tables, all purchasers of International Critical Tables will be given special discounts on all purchases of International Annual Tables, as follows:

1. Volumes I, II, III, IV, V (data for 1910–1922), cloth, $52.50 (regular price, $71.00). This reduction will be valid only till June 30th, 1928.
2. 25% discount on Volumes VI to X inclusive, covering the period 1923–1929. This reduction will only be valid for each volume during the period known as the subscription period.
3. 25% discount on the index to Volumes I–V, which will be published in 1928.

These discounts apply only on subscriptions addressed to—*For United States and Canada*, McGraw-Hill Book Company, Inc., 370 Seventh Avenue, New York City, *For all other countries*, Dr. C. Marie, 9 rue de Bagneux, Paris VI, France.

All subscriptions should be accompanied by draft or money order payable at New York or Paris.

SPECIMEN SECTIONS

A free copy of any one of the following specimen sections may be obtained on application to Dr. C. Marie.

A: Spectroscopy. *B*: Electricity, Magnetism, Electrochemistry. *C*: Radioactivity. *D*: Crystallography, Mineralogy. *E*: Biology. *F*: Engineering, Metallurgy. *G*: Colloids.

The following identification form should be filled out and transmitted with the first subscription.

Address. . . . .

INTERNATIONAL CRITICAL TABLES

P-V-T RELATIONS FOR ONE-PHASE SYSTEMS (DENSITY, SPECIFIC GRAVITY, THERMAL EXPANSION AND COMPRESSIBILITY)

---

* *See also* Vol. I, p. 102.

† This chapter covers only data showing the variation of density or volume with temperature. For additional density data at single temperatures, *see* Vol. I, p. 98–314 and 338–347.

* *Voir aussi* Vol. I, p. 102.

† Ce chapitre ne comprend que les données indiquant la variation de la densité ou du volume avec la température. Pour d'autres données de densité à une seule température, *voir* Vol. I, p. 98–314 et 338–347.

* *Siehe auch* Bd. I, S. 102.

† Dieser Abschnitt enthält nur Angaben über die Änderung der Dichte oder des Volumens mit der Temperatur. Weitere Angaben über Dichten bei einzelnen Temperaturen, *siehe* Bd. I, S. 98–314 und 338–347.

* *Vedi anche* Vol. I, p. 102.

† Questo capitolo contiene solo notizie sulla variazione della densità e del volume in funzione della temperatura. Per ulteriori notizie sulle densità a singole temperature, *vedi* Vol. I, p. 98–314 e 338–347.

---

‡ *See also* **Vol. I**, p. 98–314 and 338–347.

‡ *Voir aussi* Vol. I, p. 98–314 et 338–347.

‡ *Siehe auch* **Bd. I**, S. 98–314 und 338–347.

‡ *Vedi anche* **Vol. I**, p. 98–314 e 338–347.

P-V-T RELATIONS IN THE GASEOUS STATE FOR SUBSTANCES WHICH ARE GASES AT 0° AND 1 ATMOSPHERE

PART II. THERMAL EXPANSION AND COMPRESSIBILITY

$\alpha_{0,t} = \dfrac{v - v_0}{t v_0}$, the coefficient of expansion at constant pressure, p_0, between 0° and t, °C

$\beta_{0,t} = \dfrac{p - p_0}{t p_0}$, the coefficient at constant volume, v_0, between 0° and t, °C

LOUIS DÉCOMBE

COMPRESSIBILITY

Low Pressures

At 16°C and between p = 76 and 152 cm Hg, $\frac{p_0 v_0}{pv} = 1 + 3 \times 10^{-6} (p - p_0)$ (13).

At 14.9°C and between $p_0 = \frac{1}{2}$ and p = 1 atm., $\frac{p_0 v_0}{pv} = 1.00015$ (15).

Between p = 1 and 1.4 m Hg and with unit of v = v at 0°C and 1 m Hg, $pv = 1.000571 - 0.000571p$, at 0°C; and $pv = 1.366966 + 0.000347p$, at 100°C (4).

Between p = 1 and 27 atm., and 4.1 and 5.2°C, $\frac{pv}{p_0 v_0} = 1 + A\left(\frac{v_0}{v} - 1\right) + B\left(\frac{v_0}{v} - 1\right)^2$, where $\log_{10}(-A) = \bar{4}.8389375$ and $\log_{10} B = \bar{6}.8476020$ (16).

VAPOR PRESSURES AND ORTHOBARIC DENSITIES ABOVE ONE ATMOSPHERE

d_l (resp. d_v) = density of saturated liquid (resp. vapor) in g per cm³; $d_m = \frac{1}{2}(d_l + d_v)$.

All values at the critical point are given in bold-face type.

The latent heat of vaporization (l) in joules per g is given by the equation:

$$l = 0.10133\left(\frac{1}{d_v} - \frac{1}{d_l}\right)T \cdot \frac{dp}{dT} = \frac{0.10133}{0.4343}\left(\frac{1}{d_v} - \frac{1}{d_l}\right)pT\,\frac{d\log_{10} p}{dT}$$

VAPOR PRESSURES OF THE ATMOSPHERIC GASES

C. A. Crommelin

I. VAPOR PRESSURES UP TO TWO ATMOSPHERES

p, in mm Hg (=1/760 A_n); t, in °C (Leiden scale, *v.* Vol. I, p. 54); the following equation applies over the range covered by the tabulated data, except as otherwise indicated:

$$\log_{10} p_{mm} = \frac{0.05223A}{T} + B + CT + DT^2 + ET^3$$

Trp. = triple point.

VAPOR PRESSURES OF THE METALS

J. JOHNSTON, F. FENWICK AND H. G. LEOPOLD

The value, for the several metals, of the coefficient A (in kilojoules) and of B (for pressures p in mm of mercury) in the equation $\log_{10} p = -52.23\ A/T + B$, together with the values (calculated from the equation) of the temperatures corresponding to the pressures 760, 1, and 0.001 mm Hg. (l) = liquid, (s) = solid.

Substance	State	Range covered by equation, °C	A (kilojoule)	B (for p in mm Hg)	°C at which p in mm Hg equals			Lit.

( ) Extrapolated beyond experimental range.

* Extrapolated below freezing point.

† These two curves are mutually inconsistent.

‡ Extrapolated above melting point.

§ These are the only two cases in which the accuracy of the present data seems to justify the use of a curved line. The equations of these curves are respectively:

$$\log_{10} p_{\mathrm{Cd}} = -111 \times 52.23/T - 1.203 \log_{10} T + 12.107$$

and

$$\log_{10} p_{\mathrm{Zn}} = -127 \times 52.23/T - 1.203 \log_{10} T + 12.184$$

‖ Slope made equal to that of iron.

VAPOR PRESSURE OF CHEMICAL COMPOUNDS IN THE CRYSTALLINE STATE

A. C. Egerton and W. Edmondson

This section covers the pressure-temperature relations for systems composed of a single crystalline phase in contact with its own vapor. In the case of substances which dissociate on vaporization the value given is the total pressure. The literature references given first are to data to which most weight has been given.

* Over the range −150 to −114°C, Karwat gives the equation:

$$\log p = -\frac{1171.62}{T} - 2.3577 \log T + 14.57497,$$

the coefficient of log T being obtained from specific heat measurements at low temperatures.

† Henglein gives the equation:

$$\log p = -\frac{2202.0}{T^{1.1602}} + 7.5030,$$

over the range of his measurements from −130 to −95°C.

‡ Henglein gives the equation:

$$\log p = -\frac{1435.9}{T^{1.0496}} + 7.5030$$

§ The results when plotted give an unusual curve.

‖ For amount of dissociation see (76).

¶ Karwat gives the equation: $\log p = -\frac{1790.00}{T} - 1.81630 \log T + 14.97593,$ the coefficient of log T being obtained from specific heat measurements at low temperatures.

** Smith and Calvert give the equation:

$$\log p = -\frac{1920.357}{T} + 9.778609 \log T - 21.21708.$$

†† Smith and Calvert give the equation:

$$\log p = -\frac{7714.591}{T} + 10.04345 \log T + 42.69560.$$

‡‡ Over the range −110 to −80°C Henning, to express his experimental results, gives the equation:

$$\log p = -\frac{1279.11}{T} + 1.75 \log T - 0.0020757T + 5.85242.$$

The simpler equation:

$$\log p = -\frac{1352.6}{T} + 9.8318$$

expresses his experimental results closely.

§§ The vapor is strongly dissociated.

THE VAPOR PRESSURES OF ICE AND WATER UP TO 100°C

E. W. WASHBURN

In the following tables, the values given are the vapor pressures for the condition that the solid or liquid phase is under its own vapor pressure. If the solid or liquid phase is in contact with the atmosphere, the corresponding vapor pressures will be somewhat higher, and can be obtained by adding to the value given in the table a small increment, Δp, computed by means of the following equations:

Dans les tables suivantes, les valeurs données sont les tensions de vapeur dans la condition de la phase solide ou liquide se trouvant sous la pression de sa propre vapeur. Si la phase liquide ou la phase solide se trouve en contact avec l'atmosphère, les tensions de vapeur correspondantes seront un peu plus élevées, et elles peuvent être obtenues en additionnant aux valeurs données dans les tables un petit accroissement, Δp, calculé au moyen des équations suivantes:

Die in den folgenden Tafeln angegebenen Werte für die Dampfdrucke gelten für den Zustand, dass die feste oder flüssige Phase unter dem eigenen Dampfdruck steht. Ist die feste oder flüssige Phase mit der Atmosphäre in Verbindung, so werden die entsprechenden Dampfdrucke etwas höher sein. Man erhält sie, wenn man zu dem in der Tafel angegebenen Wert das Inkrement Δp addiert, das sich nach den Gleichungen berechnen lässt:

Nelle tabelle seguenti le tensioni riportate sono quelle del solido o del liquido a contatto col solo vapore proprio. Quando il solido o il liquido si trovano in contatto con l'atmosfera, le tensioni di vapore corrispondenti sono un po'più alte e si possono avere aggiungendo al valore della tabella, un incremento Δp, calcolato per mezzo della seguente equazione:

For ice and for water below 0°C:

$$\frac{100\Delta p}{p} = \frac{20}{t + 273}$$

For water above 0°C:

$$100\,\frac{\Delta p}{p} = 0.0775 - 3.13 \times 10^{-4}t \text{ (valid up to } t = 40\text{°C)}$$

and

$$100\,\frac{\Delta p}{p} = 0.0652 - 8.75 \times 10^{-5}p \text{ (valid above 50°C)}$$

THE VAPOR PRESSURE OF ICE

Computed from the equation

$$\log_{10}p = \frac{-2445.5646}{T} + 8.2312\log_{10}T - 0.01677006T + 1.20514 \times 10^{-5}T^2 - 6.757169, \text{ mm Hg}$$

Based upon the measurements of Weber (2) and Scheel and Heuse (1); *see* Washburn (3).

$$T = 273.1 + t$$

VAPOR PRESSURES OF CHEMICAL COMPOUNDS IN THE LIQUID STATE FOR PRESSURES UP TO TWO ATMOSPHERES

Otto Maass

In addition to the vapor-pressure data for the compounds given, the 𝔅-Table is a complete index to the vapor-pressure data for all pure chemical compounds in the liquid state. The literature references given first are those upon which the values given are based; confirmatory references are marked *cf.*

𝔅-TABLE, STANDARD ARRANGEMENT (*v.* p. viii)

$$\log_{10} p_{\mathrm{mm}} = \frac{-0.05223\mathrm{A}}{T} + \mathrm{B}$$

The tables contain either the values of A and B in the above equation (together with the range of applicability of the equation), tabulated values of *t* and *p*, or both.

The values in the B. P. column are based on the best available direct determinations of the boiling point. These values not infrequently differ considerably from those interpolated from the vapor-pressure data, a situation which can be cleared up only by further research.

Formula	Range, °C	A, joule	B	Normal B. P., °C	Lit.

VAPOR PRESSURES OF ORGANIC LIQUIDS

H. R. Raikes and E. J. Bowen

ℭ-TABLE

The ℭ-arrangement, *v.* p. viii

$$\log_{10} p_{\mathrm{mm}} = -\frac{0.05223}{T} A + B$$

The values in the B. P. column are based upon the best available direct determinations of the boiling point. These values not infrequently differ considerably from those interpolated from the vapor-pressure data, a situation which can be cleared up only by further research.

LITERATURE REFERENCES

LITERATURE REFERENCES

In all literature references cited in International Critical Tables the name of the journal or publication is indicated by means of a *Key Number* corresponding to the list given below. The numbers which follow this key number in a literature citation are, in the order named: (1) the volume, (2) the page, and (3) the last two figures of the year. Thus *64V*, **31:** 253; 22, indicates Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Series numbers are not given. Key Numbers referring to books and other non-serial publications are preceded by the letter *B*, and the volume number is given in Roman numerals. Thus *B10*, **IV:** 191; 18, indicates Doelter, Handbuch der Mineralchemie, page 191 of Vol. 4 of the 1918 edition. The Key Number *O* is used to indicate "private communication from."

DAS LITERATURVERZEICHNIS

In allen Literaturstellen, die in I. C. T. verzeichnet sind, ist der Name der Zeitschrift oder der Publikation mit Hilfe einer *Schlüsselnummer*, entsprechend der unten folgenden Liste, angegeben. Die Zahlen, welche diesen Schlüsselnummern bei einem Literaturzitat folgen, bedeuten der Reihe nach: (1) der Band, (2) die Seite und (3), die letzten zwei Zahlen des Jahrganges. So bedeutet z. B. *64V*, **31:** 253; 22, Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, Band 31, Seite 253, 1922. Serien-Nummern werden nicht angegeben. Der Schlüsselzahl wird ein *B* vorausgesetzt, wenn sie Bücher, oder eine andre nicht periodische Veröffentlichung bezeichnet. Die Bandnummer wird durch römische Ziffern angegeben. Es bedeutet z. B. also *B10*, **IV:** 191; 18, Doelter, Handbuch der Mineralchemie, Seite 191, des 4 Bandes, der Auflage des Jahres 1918. Die Schlüsselzahl *O* wird gebraucht, um anzuzeigen, dass es eine "private Mitteilung" ist.

RÉFÉRENCES BIBLIOGRAPHIQUES

Le nom du journal ou de la publication de toutes les références bibliographiques citées dans les Tables Critiques Internationales est indiqué au moyen d'un *nombre-clé* correspondant à la liste donnée ci-dessous. Les nombres qui suivent ce nombre-clé dans un renvoi bibliographique indiquent dans l'ordre suivant: (1) le volume, (2) la page, et (3) les deux derniers chiffres de l'année. Ainsi *64V*, **31:** 253; 22, indique Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Les numéros des séries ne sont pas donnés. Les nombres-clés se rapportant à des livres ou à des publications non périodiques sont précédés de la lettre *B* et le numéro du volume est donné en chiffres romains. Ainsi *B10*, **IV:** 191; 18, indique Doelter, Handbuch der Mineralchemie, page 191 du volume 4 de l'édition de 1918. Le nombre-clé *O* est employé pour indiquer "communication privée de."

INDICAZIONI BIBLIOGRAFICHE

In tutte le indicazioni bibliografiche che si incontrano nelle "Tabelle Critiche Internazionali" il nome del giornale o della pubblicazione è espresso con un *numero chiave* riportato nell'elenco dato più oltre. I numeri che, nella citazione, vengono dopo il numero chiave sono disposti con l'ordine seguente: (1) il volume, (2) la pagina, e (3) le ultime due cifre del millesimo. Cosi *64V*, **31:** 253; 22, indica la Verslag Koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, pagina 253, 1922. I numeri di serie non vengono dati. Quando un numero chiave è preceduto dalla lettera *B* si riferisce a libri o ad altre pubblicazioni non periodiche, e il numero del volume viene allora scritto in cifre romane. Cosi *B10*, **IV:** 191; 18, indica Doelter, Handbuch der Mineralchemie, pagina 191 del IV° volume dell'edizione 1918. Il numero chiave *O* indica "Comunicazione privata da . . . "

KEY TO THE PERIODICALS

Data regarding the libraries which receive many of these periodicals may be found through the following sources:

United States and Canada: "Periodicals Abstracted by Chemical Abstracts, 1926" (Chemical Abstracts, Ohio State Univ., Columbus, Ohio); "Union List of Serials in the Libraries of the United States and Canada, 1925–1927" (H. W. Wilson & Co., New York City); "A Catalogue of Scientific Periodicals in Canadian Libraries, 1924" (McGill Univ., Montreal, Canada).

Great Britain: "A World List of Scientific Periodicals Published in the Years 1900–1921" (Oxford Univ. Press, London, 1925–).

Holland: "Chemisch Jaarboekje tevens Jaarboekje der Nederlandsche Chemische Vereeniging, Vol. 3." (Amsterdam, D. B. Centen, 1920.)

IMPORTANT NOTICE

ANNUAL TABLES OF CONSTANTS AND NUMERICAL DATA CHEMICAL, PHYSICAL, BIOLOGICAL, AND TECHNOLOGICAL

Published by an International Committee, under the authority of the International
Research Council and the International Union of
Pure and Applied Chemistry

THE data given in International Critical Tables are based upon determinations published previous to January 1924.

In order to keep always up to date with future progress in physical measurements, the purchaser of International Critical Tables should become a regular subscriber to *International Annual Tables*, which will bring to his desk each year a volume in which he will find assembled and classified all of the data which has appeared in the world's literature, for the year covered by the volume.

Thus, *Annual Tables*, Volume VI, will contain all the data published in the literature of 1923–1924; Volume VII will contain the data published in the literature of 1925–1926; Volume VIII, the data to be found in the literature of 1927, etc. . . .

The older volumes of Annual Tables go back to 1910 and contain all of the original determinations published during that period and which served as all or part of the basis of selection of the "best" values recorded in International Critical Tables. These older volumes thus constitute a handy and accessible source of reference to the original determinations.

Through special arrangements made with the International Commission in charge of Annual Tables, all purchasers of International Critical Tables will be given special discounts on all purchases of International Annual Tables, as follows:

1. Volumes I, II, III, IV, V (data for 1910–1922), cloth, $52.50 (regular price, $71.00). This reduction will be valid only till June 30th, 1928.
2. 25% discount on Volumes VI to X inclusive, covering the period 1923–1929. This reduction will only be valid for each volume during the period known as the subscription period.
3. 25% discount on the index to Volumes I–V, which will be published in 1928.

These discounts apply only on subscriptions addressed to—*For United States and Canada*, McGraw-Hill Book Company, Inc., 370 Seventh Avenue, New York City, *For all other countries*, Dr. C. Marie, 9 rue de Bagneux, Paris VI, France.

All subscriptions should be accompanied by draft or money order payable at New York or Paris.

SPECIMEN SECTIONS

A free copy of any one of the following specimen sections may be obtained on application to Dr. C. Marie.

A: Spectroscopy. *B*: Electricity, Magnetism, Electrochemistry. *C*: Radioactivity. *D*: Crystallography, Mineralogy. *E*: Biology. *F*: Engineering, Metallurgy. *G*: Colloids.

The following identification form should be filled out and transmitted with the first subscription.

TRIPLE POINTS, TRANSITION POINTS AND MELTING POINTS AT ORDINARY AND LOW PRESSURES[1]

H. W. Foote

INTRODUCTION

The following triple points are possible: (1) Crystal—liquid—vapor. (2) Crystal—crystal—vapor. (3) Crystal—crystal—liquid. (4) Crystal—crystal—crystal.

The last two types have not been found at pressures below one atmosphere. In general, the temperature at a triple point, when the pressure is less than one atmosphere, coincides within the limits of experimental error with the freezing point or the transition point. For temperature and pressure data for such triple points, the reader should therefore consult the tables of freezing points or transition temperatures (Vol. I, p. 98); and of vapor pressures (of one-component systems, Vol. III, p. 199) respectively. It has, however, been shown by Richards, Carver and Schumb (11) that the freezing point of benzene saturated with air at a pressure of one atmosphere is 0.003° lower than the temperature at the triple point (5.496° and 35.4 mm). The temperature commonly given for the corresponding triple point of water (0.0075°) is based only upon the effect of pressure in defining the freezing point of water, 0°, and takes no account of the effect of dissolved air at atmospheric pressure. If the latter effect (0.0023°) is taken into account in defining the freezing point of water, the temperature of the triple point is +0.0098°C.

ONE-COMPONENT SYSTEMS

Melting Points Known with a Probable Accuracy of ±0.05°

For the purpose of this table, the *melting point* is defined as the temperature on the I. C. T. scale (*v.* Vol. I, p. 53), at which the crystalline and liquid phases are in equilibrium with dry air at a pressure of one atmosphere. Richards, Carver and Schumb (11) have shown that dissolved air, at a pressure of one atmosphere, lowers the freezing point of benzene 0.031°, so that the freezing point is lower by this amount than would be the case if the pressure were applied by a piston or an insoluble gas. The standard temperature of the melting point of ice, as usually determined, may also be slightly uncertain depending on the extent to which the water is saturated with air. The lowering in freezing point due to the solubility of the air in this case amounts to about 0.0023°. The melting points of all compounds in the following list were taken in air, but saturation with air was demonstrated only in the case of benzene. As it has been repeatedly shown that saturation of a liquid with air takes place rather rapidly when there is thorough contact between the two, the possible error in melting point from incomplete saturation is probably not greater than the other errors of experiment.

The table gives a list of melting points which appear to be known, with reasonable certainty, within ±0.05°. The list is quite probably incomplete; but where any doubt existed as to the accuracy of a result, it has not been included. For numerous melting points which are probably nearly as good, *see* de Visser (18), Block (3), and especially Timmermans (13, 14, 15, 16).

When more than one reference is given in the table, the melting point adopted is the weighted average of the data to which reference is made. No references are given to data which were not actually used, though nearly every melting point given has been determined repeatedly with considerable accuracy. Except for water, the melting point of benzene is probably the most accurately known.

Transition Temperatures

For the purpose of these tables, the term *transition temperature* refers to the temperature at which two crystalline forms of a substance are in equilibrium at a pressure of one atmosphere. This temperature coincides, within the limits of experimental error, with the triple point, crystal—crystal—vapor, when the vapor pressure in the latter system does not differ greatly from one atmosphere. In the tables, the transition temperatures given are the weighted averages of values, references to which are given by numbers. No references are given to data which were not used in obtaining the values in the tables. Where the number of determinations is sufficient, the weighted average deviation is given under the heading "±°C." Where this is not significant, a probable accuracy or reliability has been indicated.

Transition temperatures of molecular compounds such as double salts or salts with water of crystallization have, of course, only been included when the compounds behave as one-component systems, *i.e.*, when there is no change in composition of the phases at the transition point.

ℭ-Table, the ℭ-Arrangement

Comparatively few transition temperatures of C-compounds are known, and most of them are quite inaccurate or uncertain. From the study of a large number of compounds, Schaeling (*Diss.*, Marburg, 1910) has concluded that polymorphous organic compounds are usually monotropic and that enantiotropy is rare.

For "liquid crystals," *v.* Vol. I, p. 314.

Formula	Name	$t_{Tr.}$, °C	±, °C	Lit.
CBr_4	Carbon tetrabromide	46.9	<1	(21, 66, 106, 116)
CCl_4	Carbon tetrachloride	−45	>5	(45)
C_2H_8BrN	Ethylamine hydrobromide	83	*	(80)
C_2H_8ClN	Ethylamine hydrochloride	80	*	(80)

		109	>5	(46)
C_2Cl_6	Hexachloroethane	45	<5	(21, 116, 123)
		71.3	0.4	(21, 94, 116, 123)
		125	*	(94)
$C_3H_4O_4$	Malonic acid	94	*	(136)
$C_4H_{12}ClNO_4$	Tetramethylammonium perchlorate	355	*	(127)
$C_6H_4Br_2$	*p*-Dibromobenzene	8.5	*	(6)
$C_6H_4Cl_2$	*p*-Dichlorobenzene	25	*	(134)
		29	*	(134)
$C_6H_8N_2O_3$	Aniline nitrate	98	>5	(137)
C_7H_7NO	*α*-Benzaldoxime	−28	*	(6)
C_7H_9N	*p*-Toluidine	22	*	(6)
$C_8H_9NO_2$	*α*-Anisaldoxime	20	*	(6)
$C_8H_9NO_2$	*α′*-Anisaldoxime	13	*	(6)
$C_{10}H_8O$	*α*-Naphthol	49	*	(6)
$C_{10}H_9N$	*α*-Naphthylamine	13.5	*	(6)
$C_{10}H_{13}NO$	Butyric anilide	16	>5	(5)
$C_{10}H_{15}ClO$	Camphor monochloride	74	<5	(92, 136)
$C_{10}H_{16}O$	Camphor	−32	>5	(23, 135)
$C_{10}H_{16}O$	Camphor	90	<5	(23, 135)
$C_{13}H_{10}N_4O_5$	*m*-Dinitrodiphenylcarbamide	55	*	(91)
		180	*	(91)
$C_{14}H_{10}Cl_4$	1, 1, 2, 2-Tetrachloro-1, 2-diphenylethane	100	*	(77)
$C_{14}H_{10}N_2O_2$	Phthalylphenylhydrazide	9.4	<1	(28)
$C_{14}H_{13}NO$	*o*-Hydroxy-*m*-methylbenzylideneanilide	34	>5	(59)
$C_{15}H_{12}N_2O_2$	Phthalylphenylmethylhydrazide	55.1	<1	(27)
$C_{16}H_{18}N_2O_2$	*p*-Azophenetole	95.5	<5	(17, 31)
$C_{20}H_{17}NO_3S$	*α*-Naphthylamine naphthalene-*α*-sulfonate	66	†	(131)
$C_{20}H_{17}NO_3S$	*α*-Naphthylamine naphthalene-*β*-sulfonate	54	†	(131)
$C_{27}H_{46}O$	Cholesterol	43	>5	(82)

* Existence of transition uncertain.

† This transition temperature undoubtedly exists, but it is uncertain whether the system is of 1 or 2 components.

EFFECT OF PRESSURE UPON MELTING AND TRANSITION POINTS; VOLUME CHANGE ON MELTING AND TRANSITION; DIRECTLY MEASURED COMPRESSIBILITY- AND THERMAL EXPANSION-DIFFERENCES

P. W. Bridgman

INTRODUCTION

Units.—Throughout the following tables the pressure unit is the normal atmosphere; the temperature unit, the absolute centigrade degree; and all volume changes, unless otherwise indicated, are expressed in cm³/kg.

Abbreviations and Conventions.—The liquid phase is indicated by "L," and solid phases by the Roman numerals I, II, etc. In cases where the observed melting point at one atm. is less than the I. C. T. normal M. P. (*v.* Vol. I), the I. C. T. value is inserted in brackets for comparison.

Latent Heat.—The latent heat of any phase change may be calculated from the equation:

$$l\left(\frac{\text{joule}}{\text{kg}}\right) = T\Delta V\frac{\mathrm{d}P}{\mathrm{d}T} \times 0.10133,$$

where T is the absolute centigrade temperature, P is the pressure in atm. and ΔV is the accompanying volume change in cm³/kg. This calculation will be facilitated in many cases by reference to the original papers, where tabulated values of $\mathrm{d}T/\mathrm{d}P$ are given. An approximate method for computing differences of thermal expansion and specific heat for the reacting phases may be found in (8).

EINLEITUNG

Einheiten.—Grundsätzlich ist in den folgenden Tafeln die normale Atmosphäre die Druckeinheit, als Temperatureinheit gelten absolute Centigrade, die Volumänderungen sind (wenn nichts anderes angegeben) in cm³/kg ausgedrückt.

Abkürzungen und Festlegungen.—Die flüssige Phase ist durch "L" angezeigt, die festen Phasen durch römische Zahlen (I, II, III, . . .). In den Fällen, in denen der beobachtete Schmelzpunkt bei einer Atmosphäre niedriger ist, als der Normal-Schmelzpunkt [M. P. (Bd. I)] der I. C. T., so ist dieser letzte Wert zum Vergleich in Klammer daneben gesetzt.

Latente Wärme.—Die latente Wärme jeder Phasenänderung ergiebt sich nach der Gleichung:

$$l\left(\frac{\text{joule}}{\text{kg}}\right) = T\Delta V\frac{\mathrm{d}P}{\mathrm{d}T} \times 0{,}10133,$$

T = absolute Centigrad Temperatur, P = Druck in Atmosphären, ΔV ist die dabei auftretende Volumänderung in cm³/kg.

Diese Rechnung wird in vielen Fällen durch Heranziehung der in der Literatur sich vorfindenden Werte für $\mathrm{d}T/\mathrm{d}P$ erleichtert. Eine angenäherte Methode zur Berechnung der Differenz der thermischen Ausdehnungen beziehungsweise der spezifischen Wärme der Phasenänderung ist in (8) zu finden.

INTRODUCTION

Unités.—L'unité de pression utilisée dans les tables suivantes est l'atmosphère normale; l'unité de température, le degré centigrade absolu; et tous les changements de volume sont exprimés en cm³/kg à moins d'une autre indication.

Abréviations et conventions.—La phase liquide est indiquée par "L"et les phases solides par les chiffres romains I, II, etc. Lorsque le point de fusion observé sous une atm. est inférieur au Pt. de F. normal des T. C. I. (*v.* Vol. I), la valeur des T. C. I. a été écrite entre parenthèse pour comparaison.

Chaleur latente.—La chaleur latente de chaque changement de phase peut être calculée au moyen de l'équation:

$$l\left(\frac{\text{joule}}{\text{kg}}\right) = T\Delta V\frac{\mathrm{d}P}{\mathrm{d}T} \times 0{,}10133,$$

où T est la température absolue en degrés centigrades, P est la pression en atm. et ΔV est le changement de volume produit en cm³/kg. Ce calcul sera facilité dans bien des cas si l'on se réfère aux mémoires originaux, où l'on trouvera une table donnant les valeurs de $\mathrm{d}T/\mathrm{d}P$. On trouvera à (8) une méthode approximative pour le calcul des différences dans le cas de la dilatation thermique et de la chaleur spécifique pour les phases réagissantes.

INTRODUZIONE

Unità.—Nelle tabelle seguenti viene fatto sempre uso dell'atmosfera normale come unità di pressione, e di gradi centigradi assoluti come unità di temperatura. Tutte le variazioni di volume, tranne che non sia diversamente indicato, sono indicate in cm³/kg.

Abbreviazioni e convenzioni.—La fase liquida viene indicata con "L" e le fasi solide sono indicate con numeri romani (I, II, ecc.). Nei casi in cui il punto di fusione osservato ad un atmosfera, è più basso del punto normale di fusione [normale M. P. (*v.* Vol. I)], delle I. C. T., quest'ultimo valore, è riportato tra parentesi per confronto.

Calori latenti.—I calori latenti dei cambiamenti di fase si possono calcolare dall'equazione:

$$l\left(\frac{\text{joule}}{\text{kg}}\right) = T\Delta V\frac{\mathrm{d}P}{\mathrm{d}T} \times 0{,}10133,$$

dove T è la temperatura assoluta, P la pressione in atmosfere e ΔV è la variazione di volume in cm³/kg.

Questi calcoli sono in molti casi facilitati da richiami alla letteratura originale dove si trovano tabelle per i valori $\mathrm{d}T/\mathrm{d}P$. Un metodo approssimato per calcolare le differenze nel caso della dilatazione termica e dei calori specifici delle fasi reagenti si trova riportato in (8).

ELEMENTARY SUBSTANCES (*v.* p. 11)

CHEMICAL COMPOUNDS

PART I. MELTING-POINT DATA REPRODUCIBLE BY POWER SERIES (*v. also* Part II, p. 11)

$$\text{M. P. } (^\circ\text{C}) = t_0 + \text{a} \times 10^{-4}P - \text{b} \times 10^{-8}P^2. \quad \text{Range: up to } P_{\text{max}}.$$

Example: The M. P. of formic acid at 2000 atm. is 7.8 (resp. 8.4) + (132 × 10^{-4} × 2000) − (85 × 10^{-8} × $(2000)^2$) = 30.8° (resp. 31.4)°C.

TRIPLE POINTS AND VOLUME CHANGES

P, atm.	t, °C	Direction of volume change	ΔV, cm³/kg
I–II–IV			
1770	198.6	I–II	1.97
		II–IV	1.13
		I–IV	3.10
II–III–IV			
2805	118.2	II–III	5.70
		II–IV	1.10
		III–IV	6.80

THERMAL EXPANSION DIFFERENCE

At 1 atm. I > II by 0.5 cm³/kg per °C.

At 1 atm. II > III by 0.04 cm³/kg per °C.

III probably > IV.

KNO_2 (11)

P, atm.	t, °C	ΔV, cm³/kg
5 000	− 0.3	31.0
6 000	+17.4	32.4
7 000	35.7	33.8
8 000	56.6	35.1
9 000	83.1	36.5
10 000	122.3	37.8

KNO_3 (12); *cf.* (17); *see* Fig. 8

P, atm.	t, °C	ΔV, cm³/kg
I–III

6000	136.3	26.3
7000	167.8	25.7
8000	196.3	25.3
9000	221.5	24.9

TRIPLE POINTS AND VOLUME CHANGES

P, atm.	t, °C	Direction of volume change	ΔV, cm³/kg
I–III–IV			
2835	21.3	II–III	15.6
		III–IV	28.4
		II–IV	44.0
I–II–III			
110	128.3	I–III	14.2
		II–III	8.9
		I–II	5.3

COMPRESSIBILITY DIFFERENCE

III > I, by *ca.* 0.001 cm³/kg per atm.

III > IV, by *ca.* 0.06 cm³/kg per atm.

III probably > II.

THERMAL EXPANSION

III > I, by *ca.* 0.06 cm³/kg per °C.

KCNS (11)

P, atm.	t, °C	ΔV, cm³/kg
L–I		
1	171.2* [173.2]	49.7*
1000	193.3	46.2

* Extrapolated.

P, atm.	t, °C	ΔV, cm³/kg
I–II		
1	140.0	3.06
1000	158.5	2.43
2000	174.9	1.98
3000	190.6	1.68
4000	205.7	1.49

$RbNO_3$* (12)

P, atm.	t, °C	ΔV, cm³/kg
II–III		
1	164.4	6.88
1000	174.4	6.45
2000	184.1	6.00
3000	193.5	5.57
4000	202.6	5.12
5000	211.5	4.69
6000	220.3	4.26

The difference of volume between I and II is probably very small (35).

* Material somewhat impure with acid.

$CsNO_3$ (12)

P, atm.	t, °C	ΔV, cm³/kg
1	153.7	4.05
1000	163.4	3.86
2000	172.9	3.68
3000	182.2	3.50
4000	191.3	3.32
5000	200.1	3.13
6000	208.8	2.94

At 80 atm., thermal expansion of I > II by 0.033 cm³/kg per °C. At 4850 atm., the compressibility of I > II by 0.00031 cm³/kg per atm.

ℭ-Table, the ℭ-arrangement

CBr_4 (11, 34); *see* Fig. 9

I–II

$t = 46.2 + 0.0315P$;

$\Delta V = 20.5 - 0.0026P$ cm³/kg per atm.

I–III

$t = 119.5 + (P - 2175) \times 0.1089$;

$\Delta V = 2.9$ cm³/kg per atm.

II–III

$t = 108.5 + (P - 1930) \times 0.0246$;

$\Delta V = 12.3 - 0.0013P$ cm³/kg per atm.

Triple point, I–II–III,
2110 atm., 112.6°

W. Wahl (34) has determined the melting point at atm. pressure to be 92° and finds this to be raised 1° by 15.5 atm. for a small pressure range. He also has made initial determinations of the transition I–II.

CCl_4 (7); *cf.* (2, 29); *see* Fig. 10

DIAGRAMS

The arrows denote the direction in which the volume change on transition is becoming numerically less.

α, β, C_p. The location of these symbols shows the side of the transition line corresponding to the form having the higher value of compressibility, thermal expansion, or specific heat at constant pressure.

The dotted enclosing lines delimit the region of indifference.

OSMOTIC PRESSURE

W. E. Garner

In this section are included data on osmotic pressure obtained by direct measurement. With few exceptions, only those pressures are given which are generated by solutions of pure substances when separated from the pure solvent by a semipermeable membrane. Where appreciable amounts of diffusion have occurred or the solution is not opposed by the pure solvent, this is indicated in the tables. Wherever possible the pressures are expressed in normal atmospheres and the concentrations of the solutions in gram formula weights per 1000 g of the solvent (M/1000) in terms of the table of atomic weights, Vol. I, p. 43. Where the pressures measured are small they are given in mm Hg. Values are given to the last significant figure for which *relative* accuracy can be claimed.

For the osmotic pressure of salt solutions, K and Na salts, nitrates, sulfates, salts of organic acids, alums, etc., *see* Adie (2), König and Hasenbaumer (30) and Pfeffer (43); for camphorates, naphthionates, benzenesulfonates, *o*-nitrobenzoates, silicofluorides, cobalticyanides and other salts, *see* Berkeley and Hartley (7). Adie's and Pfeffer's results are uncertain by several %; deviations between similar experiments often occur of the order of 10%. Those of Berkeley and Hartley (6, 7) show variations of 1–2%.

ADDITIONAL DATA

Aqueous Solutions of Non-colloids.—Antipyrine (42); electrolytes (25, 30); glycerol (42); mannitol (42); membranes of chemically inert substances (10); salicin (42); sucrose (3, 44, 48).

Colloidal Solutions.—Arsenious sulfide (33); gelatin (37); gums (37); hemoglobins (1, 26, 45); influence of electrolytes on osmotic pressure of colloids (32); proteins (34, 36, 47); serum proteins (46); starch (37).

---

* γ alone means that the liquid or solution was studied in the presence of its own vapor only. γ (air) means that air was present above the surface of the liquid and that, therefore, the liquid surface was in contact with air, saturated, of course, with the vapor of the liquid. γ (air or vapor) means that some measurements were made under each of the above conditions and that the values given are for either within the limits prescribed. γ (H_2), resp. (N_2), states the medium in which measurements were made, while γ (?) indicates that the medium was not stated.

EQUATIONS

Formula for capillary rise:

$$\gamma = \tfrac{1}{2}(d_l - d_g)ghr \text{ (\textit{v. further} p. 435)} \qquad (1)$$

Formula for capillary constant:

$$a^2 = \frac{\gamma}{\tfrac{1}{2}(d_l - d_g)g} \text{ (}=hr\text{ for capillary rise)} \qquad (2)$$

Formula of Eötvös:

$$\gamma_M = \gamma\left(\frac{M}{d_l}\right)^{2/3} = A_C - k_E t \text{(resp. } A_K - k_E T) \qquad (3)$$

A_C (resp. A_K) is a constant evaluated from the experimental data. For normal liquids this linear relation holds up to $t \ngtr t_c - 35°$. $A_C = k_E(t_c - 6)$ approximately, a relation which has found application as a means of computing t_c; $k_E = -\frac{d\gamma_M}{dt}$

Formula of van der Waals: $\gamma = \alpha\left(1 - \frac{T}{T_C}\right)^n$ (4)

α and n are constants evaluated from the experimental data.

Formula of Macleod: $\gamma = K(d_l - d_v)^4$, where the constant K is nearly independent of T for normal liquids.

Formula of Sugden: $P = \frac{M}{d_l - d_v}\gamma^{1/4}$

$P = 0.78V_C$ approx. for certain normal liquids.

V_C = molecular volume in cm³ at the critical temperature.

TENSILE STRENGTH AND ANGLE OF CONTACT

T. Fraser Young and William D. Harkins

TENSILE STRENGTH AND TENSILE ENERGY

The free tensile energy of a liquid is defined as equal to 2γ. It is the reversible work done on the system (increase of free energy) to rupture a bar of liquid of one cm² cross section to form two plane surfaces of 1 cm² area each. The total tensile energy (e_t) per cm² is given by the relation: $e_t = 2(\gamma + l) = 2h$, (l = latent heat, h = surface energy of unit surface).

It has not been found possible to measure the tensile strength of a liquid, since the rupture does not occur simultaneously over more than a minute area. The maximum value of the pull which has thus far been attained, is given below:

Maximum negative pressure in megabaryes (13): H_2O = 34 at 24.4°C; C_2H_5OH = 40 at 22.5°C; $(C_2H_5)_2O$ = 73 at 17.7°C.

The pull necessary to rupture a film of various liquids between two flat steel surfaces of contact, 4.5 cm² in area, has been found to be as large as 3–4 megabaryes, but this is probably much lower than that corresponding to the true tensile strength of the liquid (4).

ANGLE OF CONTACT

The angle of contact (θ) between the surface of a liquid and that of a solid is highly dependent upon the nature of the surfaces, and is in general different for contaminated surfaces from what it is for clean surfaces. In few of the experiments in which θ has been determined has cleanliness of the surface of the liquid been demonstrated, and the difficulty of cleaning the surface of a solid is so great that no experiments with what may be called pure surfaces have been carried out with solids.

By use of various optical methods it has been shown (Table 1) that θ between glass and a small number of liquids is zero provided the glass is already covered by a film of the liquid. θ may be greater than zero provided the liquid is evaporating (14), or the glass surface has become dry (15).

Table 1.—Angle of Contact (θ) between Liquid and Glass Covered with a Film of the Liquid at Room Temperature as Determined by Various Optical Methods

Liquid	θ	Lit.
Water	0	(1, 3, 14, 15)
Ethyl alcohol	0	(14)
Benzene	0	(14)
Carbon tetrachloride	0	(14)
Chloroform	0	(14)
Acetic acid	0	(3)
Aqueous solutions of various salts	0	(15)
Glycerol	0	(1)
Ethyl ether	0	(3, 14)
Turpentine	0	(1, 3)
Olive oil	0	(1)
Hydrogen peroxide	0	(12)

That θ for liquid-to-glass is zero within the limits of error of the methods employed is indicated in the case of about 100 other liquids by the data used in compiling these tables, which show that the surface tension determined by the capillary-height method on the basis of the assumption that θ is zero, is the same for each of these liquids as the value obtained by the drop-weight method by the use of the corrections of Harkins and Brown or by the bubble-pressure method by the use of the corrections of Sugden. In addition Volkmann (16) found a^2 for H_2O = constant ± 0.0002 at 20.2°C for seven different kinds of glass and Carver and Hovorka (5) found a^2 for H_2O = constant ± 0.0002 at 20° for glass, zinc, copper and silver.

Table 2.—Angle of Contact Greater than Zero

Interface	t, °C	θ, °arc	Lit.
H_2O—azobenzene	14	77°	(3)
H_2O—paraffin	14	106° 43′	(3)
Hg—glass	4.4	144.48°	(2)
	3	148.28°	
	4	147.71°	
	3	140.00°	
	9	139.41°	(2)
	16	>139°	(1)
	18	128°	(8)
H_2O—various plates coated with oleic acid			(11)
H_2O—plates coated with 65 different organic compounds			(18)

For angle of contact of a lens of H_2O on CCl_4, *v.* (6).

It should be noted that in cases where the last terms of the Laplace-Poisson equation (*v.* (2), p. 8)

$$h = a\sqrt{2}\sin\frac{\theta}{2} - \frac{a^2}{\mu} + \frac{a^2}{3r'\sin\frac{\theta}{2}}\left(1 - \cos^3\frac{\theta}{2}\right)$$

are not used, the values of θ given are often 5 or more degrees in error; $r' = r + (\sqrt{2} - 1)a$; h is approximate thickness of a drop of liquid of horizontal radius r which lies on a horizontal plane plate; μ is its radius of curvature.

METHODS OF MEASURING SURFACE TENSION

T. Fraser Young and William D. Harkins

For critical discussion of various methods, their sources of error, corrections, precautions, etc., *see* especially (3, 4, 5, 6, 14); *cf.* (7) and the references cited below.

The *Capillary-Height Method.*

$$2\pi r\gamma = V(d_1 - d_2)g/\cos\theta,$$

in which d_1 is the density of the fluid of greater density and d_2 is the density of the other fluid; V is the volume which lies inside a capillary tube of uniform bore, between the small meniscus and the level of a horizontal plane which lies in the surface of the (extremely) large meniscus.

$$V = \pi r^2 h,$$

in which h may be considered as the average vertical distance between the two surfaces. If h_0 is the vertical distance between the plane of the large meniscus and a horizontal plane tangent to the small meniscus, then for capillary tubes of very small diameter (< 1 mm for H_2O):

$$h = h_0 + \frac{r}{3} - 0.1288\frac{r^2}{h_0} + 0.1312\frac{r^3}{h_0^2} \text{ (Poisson, Rayleigh)}$$

or approximately

$$h = h_0 + \frac{a^2 r}{3a^2 + r^2} \text{ (Hagen and Desains)}$$

This expression is not equivalent to that given by Rayleigh.

For tubes of considerably larger diameter $\left(\frac{r}{a} > 4.3\right)$,

$$1.4142\frac{r}{a} - \log_e\frac{a}{h_0} = 0.6648 + 0.19785\frac{a}{r} + \frac{1}{2}\log_e\frac{r}{a} \text{ (Rayleigh)}$$

For tubes of intermediate diameters neither equation is accurate and the tables of Bashforth and Adams (1) should be used to obtain h. *See further* (2, 5, 11, 12, 15).

Drop-Weight Method.

$$\gamma = \frac{mg}{r} \times F,$$

m is the mass of a slowly formed drop which falls from a horizontal tip of circular cross-section (radius = r) and sharp edge. F is a function of V/r^3, where V is the volume of the drop, and its value may be interpolated from the following table (for theory, *v.* (9)).

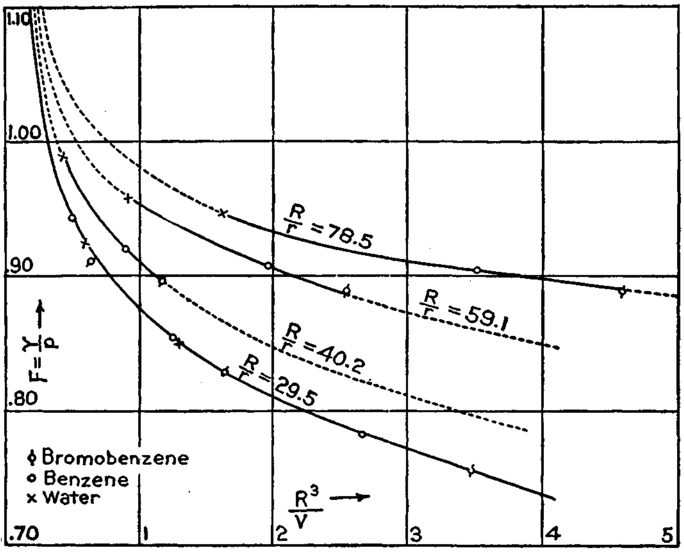

Fig. 1.

Method of Maximum Pull on a Ring.—When a circular ring of radius R (center of ring to center of wire) is pulled from the surface of a not-too-viscous liquid into the gas phase above, the surface tension is given by

$$\gamma = p \times F,$$

where p is the pull in dyne/cm and F is a function of R^3/V whose value may be interpolated from Fig. 1 for any ring of radius R constructed from a wire of radius r. V, the volume of the liquid lifted by the ring $\equiv \frac{p}{g(d_l - d_g)}$, where d_l is the density of the liquid and d_g that of the gas above it (8, 10, 13).

Other Methods.—*v.* (3, 4, 7, 14).

INTERFACIAL TENSION FOR SOLID-LIQUID AND LIQUID-LIQUID INTERFACES

T. FRASER YOUNG AND WILLIAM D. HARKINS

CONTENTS

INTERFACE, SOLID—LIQUID

Free surface energy at the interface solid—liquid

No method has as yet been discovered for the determination of the free interfacial energy between a solid and a liquid. For values calculated from the Ostwald-Freundlich equation, *v.* (5, 25). *See further* (1, 2, 7, 9, 25, 26, 34).

INTERFACE, LIQUID—LIQUID

Abbreviations; *see also* p. 433

γ_i Interfacial tension, cgs.

γ Surface tension of organic liquid, cgs.

d_p (resp. d_o and d_w) Density of pure organic liquid (resp. the organic phase, and the aqueous phase), g/cm³.

Except where otherwise noted all values recorded below were obtained by the drop-weight method.

Accuracy.—No attempt has been made to estimate accuracy except in cases where independent determinations with different samples are available. The attainable precision by the drop-weight method appears to be about 0.1 % at a water interface and 1 % at a mercury interface. Other methods have thus far yielded considerably less accurate results.

The interfacial tension at the phase boundary liquid—liquid is in general varied much more by impurities than the surface tension at the liquid—gas interface. It is not yet known how well the drop-weight method applies to the determination of γ_i at the liquid—liquid interface since the corrections were determined under the somewhat different conditions existing at the liquid—gas interface.

Benzene against aqueous soap solutions (II); sodium oleate (13); effects of oleic acid and of NaOH (22); *see further* final index under Soaps.

Effect of Hydrogen Ion Concentration on Tension at the Interface Aqueous Phase—Organic Phase

Inorganic acids and bases at concentrations up to 0.2 normal have only a very slight effect (≯ *ca.* 1%) upon the interfacial tension at the phase boundary benzene—aqueous solution, and have in general a marked effect at low concentrations only in case they react with the organic phase. Thus with esters the presence of a base in the aqueous phase accelerates the hydrolysis. For example, the interfacial tension, ethyl oleate—water, is lowered very rapidly as the concentration of strong base in the aqueous phase is increased, since the rapidity at which sodium oleate is produced at the surface increases with the concentration of the base. Since the chemical composition of the interfacial region changes in such a case with the time, no equilibrium values can be obtained, but in many cases somewhat definite values are obtained provided the liquids are left in contact only about one-half hour.

For numerical data see the literature cited below: Ethyl oleate (19); ethyl caproate (19); chloropicrin (20); diisoamylamine (19); *sec.*-octyl alcohol (19); dichloroethyl sulfide (14); benzene (13).

For aqueous solutions buffered by borate or phosphate against benzene solutions of organic acids and esters, *v.* (23).

Interfacial Tensions of Liquid Metals against Non-metallic Liquid Phases

γ_i (resp. γ_{Hg}, γ_l) = interfacial tension, resp. surface tension of Hg, resp. surface tension of the second liquid.

SURFACE-TENSION DATA FOR CERTAIN PURE LIQUIDS BETWEEN 0 AND 360°C AND FOR ALL TYPES OF SOLUTIONS AT ALL TEMPERATURES

T. FRASER YOUNG AND WILLIAM D. HARKINS*

LIQUID—GAS INTERFACE

For abbreviations and symbols, *v.* p. 433

The greater part of the surface-tension values listed in the following tables have been corrected, in so far as possible, to agree with certain "standard" values for water and for benzene (C_6H_6) as determined by the capillary-height method. As the primary standard, the value of γ for water is taken as equal to 72.75 ± 0.05 dyne/cm at 20° in the presence of air at ordinary pressure. The values used in selecting this standard are those of Richards and Coombs, 1915, corrected 1921 (64) 72.72; Harkins and Brown, 1919 (40) 72.80; Richards and Carver, 1921 (63) 72.73; and Young and Gross (for these tables) 72.80. So far as is known all of these values have been determined with about the same degree of precision, and also with the same order of accuracy with respect to known errors.

The "standard" value for benzene in air at 20° is 28.88 ± 0.03, and is based on the work of Richards and Coombs (64), Richards and Carver (63) and Harkins and Brown (40).

SURFACE TENSION OF SOLUTIONS

Abbreviations and Symbols; *v. further* p. 433

M = Moles per kg solvent.
M/l_s = Moles per liter solution.
g/l_s = grams per liter solution.
x_A = Mole fraction of A.

Contents

The values for *pure liquids* which appear in the tables of this section are not the best values but are those obtained with the liquid actually used in preparing the solutions (corrected, however, for obvious errors, such as the use of too small a tube for the larger tube in the capillary-height method). The use of these values is necessary in order to give the best values of $\Delta\gamma$ and the proper shape to the γ-composition curves.

See p. 474, 475 for effect of various inorganic gases and p. 475 for effect of organic vapors on the surface tension at the interface, liquid—gas.

Aqueous Solutions, One Solute

𝔅-Table,* Standard Arrangement (*v.* Vol. III, p. viii)

* Very dilute aqueous salt solutions have been studied by Gradenwitz (15, 22) and Kleine (22, 25). The results of these workers indicate that $d\gamma/dM$ decreases as M increases. The value of $\Delta\gamma$ found by them for relatively large values of M do not agree well with reliable modern determinations. Therefore, their results are not reproduced in these tables. Until their work is repeated the shape of the $\Delta\gamma$-M curves in dilute solutions (M < 0.2) will remain uncertain.

LITERATURE REFERENCES

LITERATURE REFERENCES

In all literature references cited in International Critical Tables the name of the journal or publication is indicated by means of a *Key Number* corresponding to the list given below. The numbers which follow this key number in a literature citation are, in the order named: (1) the volume, (2) the page, and (3) the last two figures of the year. Thus *64V*, **31**: 253; 22, indicates Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Series numbers are not given. Key Numbers referring to books and other non-serial publications are preceded by the letter *B*, and the volume number is given in Roman numerals. Thus *B10*, **IV**: 191; 18, indicates Doelter, Handbuch der Mineralchemie, page 191 of Vol. 4 of the 1918 edition. The Key Number *O* is used to indicate "private communication from."

DAS LITERATURVERZEICHNIS

In allen Literaturstellen, die in I. C. T. verzeichnet sind, ist der Name der Zeitschrift oder der Publikation mit Hilfe einer *Schlüsselnummer*, entsprechend der unten folgenden Liste, angegeben. Die Zahlen, welche diesen Schlüsselnummern bei einem Literaturzitat folgen, bedeuten der Reihe nach: (1) der Band, (2) die Seite und (3), die letzten zwei Zahlen des Jahrganges. So bedeutet z. B. *64V*, **31**: 253; 22, Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Band 31, Seite 253, 1922. Serien-Nummern werden nicht angegeben. Der Schlüsselzahl wird ein *B* vorausgesetzt, wenn sie Bücher, oder eine andre nicht periodische Veröffentlichung bezeichnet. Die Bandnummer wird durch römische Ziffern angegeben. Es bedeutet z. B. also *B10*, **IV**: 191; 18, Doelter, Handbuch der Mineralchemie, Seite 191, des 4 Bandes, der Auflage des Jahres 1918. Die Schlüsselzahl *O* wird gebraucht, um anzuzeigen, dass es eine "private Mitteilung" ist.

RÉFÉRENCES BIBLIOGRAPHIQUES

Le nom du journal ou de la publication de toutes les références bibliographiques citées dans les Tables Critiques Internationales est indiqué au moyen d'un *nombre-clé* correspondant à la liste donnée ci-dessous. Les nombres qui suivent ce nombre-clé dans un renvoi bibliographique indiquent dans l'ordre suivant: (1) le volume, (2) la page, et (3) les deux derniers chiffres de l'année. Ainsi *64V*, **31**: 253; 22, indique Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Les numéros des séries ne sont pas donnés. Les nombres-clés se rapportant à des livres ou à des publications non périodiques sont précédés de la lettre *B* et le numéro du volume est donné en chiffres romains. Ainsi *B10*, **IV**: 191; 18, indique Doelter, Handbuch der Mineralchemie, page 191 du volume 4 de l'édition de 1918. Le nombre-clé *O* est employé pour indiquer "communication privée de."

INDICAZIONI BIBLIOGRAFICHE

In tutte le indicazioni bibliografiche che si incontrano nelle "Tabelle Critiche Internazionali" il nome del giornale o della pubblicazione è espresso con un *numero chiave* riportato nell'elenco dato più oltre. I numeri che, nella citazione, vengono dopo il numero chiave sono disposti con l'ordine seguente: (1) il volume, (2) la pagina, e (3) le ultime due cifre del millesimo. Cosi *64V*, **31**: 253; 22, indica la Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, pagina 253, 1922. I numeri di serie non vengono dati. Quando un numero chiave è preceduto dalla lettera *B* si riferisce a libri o ad altre pubblicazioni non periodiche, e il numero del volume viene allora scritto in cifre romane. Cosi *B10*, **IV**: 191; 18, indica Doelter, Handbuch der Mineralchemie, pagina 191 del IV° volume dell'edizione 1918. Il numero chiave *O* indica "Comunicazione privata da . . . "

KEY TO THE PERIODICALS

Data regarding the libraries which receive many of these periodicals may be found through the following sources:

United States and Canada: "Periodicals Abstracted by Chemical Abstracts, 1926" (Chemical Abstracts, Ohio State Univ., Columbus, Ohio); "Union List of Serials in the Libraries of the United States and Canada, 1925–1927" (H. W. Wilson & Co., New York City); "A Catalogue of Scientific Periodicals in Canadian Libraries, 1924" (McGill Univ., Montreal, Canada).

Great Britain: "A World List of Scientific Periodicals Published in the Years 1900–1921" (Oxford Univ. Press, London, 1925–).

IMPORTANT NOTICE

ANNUAL TABLES OF CONSTANTS AND NUMERICAL DATA CHEMICAL, PHYSICAL, BIOLOGICAL, AND TECHNOLOGICAL

Published by an International Committee, under the authority of the International
Research Council and the International Union of
Pure and Applied Chemistry

THE data given in International Critical Tables are based upon determinations published previous to January 1924.

In order to keep always up to date with future progress in physical measurements, the purchaser of International Critical Tables should become a regular subscriber to *International Annual Tables*, which will bring to his desk each year a volume in which he will find assembled and classified all of the data which have appeared in the world's literature, for the year covered by the volume.

Thus, *Annual Tables*, Volume VI, will contain all the data published in the literature of 1923–1924; Volume VII will contain the data published in the literature of 1925–1926; Volume VIII, the data to be found in the literature of 1927, etc. . . .

The older volumes of Annual Tables go back to 1910 and contain all of the original determinations published during that period and which served as all or part of the basis of selection of the "best" values recorded in International Critical Tables. These older volumes thus constitute a handy and accessible source of reference to the original determinations.

Through special arrangements made with the International Commission in charge of Annual Tables, all purchasers of International Critical Tables will be given special discounts on all purchases of International Annual Tables, as follows:

1. 25% discount on Volumes VI to X inclusive, covering the period 1923–1929. This reduction will only be valid for each volume during the period known as the subscription period.
2. 25% discount on the index to Volumes I–V, which will be published in 1929.

These discounts apply only on subscriptions addressed to—*For United States and Canada*, McGraw-Hill Book Company, Inc., 370 Seventh Avenue, New York City, *For all other countries*, Dr. C. Marie, 9 rue de Bagneux, Paris VI, France.

All subscriptions should be accompanied by draft or money order payable at New York or Paris.

IMPORTANT NOTICE

Beginning with Volume VII all the texts and all useful explanations for the comprehension of the numerical data will be given both *in English and in French.*

SPECIMEN SECTIONS

A free copy of any one of the following specimen sections may be obtained on application to Dr. C. Marie.

A: Spectroscopy. *B*: Electricity, Magnetism, Electrochemistry. *C*: Radioactivity. *D*: Crystallography, Mineralogy. *E*: Biology. *F*: Engineering, Metallurgy. *G*: Colloids.

The following identification form should be filled out and transmitted with the first subscription.

Address. . . . .

INTERNATIONAL CRITICAL TABLES

VISCOSITY AND FLUIDITY

VISCOSITY OF GASES

L. L. Bircumshaw and Vaughan H. Stott

DEFINITIONS AND FORMULAE

For small velocities, the rate of shear in a gas is proportional to the shearing stress. The ratio of the latter to the former is known as the viscosity (η). The C. G. S. unit of viscosity is called the "poise."

In the case of most gases, the influence of temperature on the viscosity may be represented by the following formula due to Sutherland (1893):

$$\eta = \eta_o \frac{T_o + C}{T + C}\left(\frac{T}{T_o}\right)^{3/2},$$

where η and η_o are the viscosities at the absolute temperatures T and T_o, respectively, and C is "Sutherland's constant." C may readily be determined graphically from a number of observations by plotting T against $T^{3/2}/\eta$, since we have

$$T = \left[\frac{T^{3/2}}{\eta}\right]\left[\frac{\eta_o\left(1 + \frac{C}{T_o}\right)}{T_o^{1/2}}\right] - C$$

FLOW OF GAS THROUGH A CAPILLARY TUBE

For very small velocities, the following equation due to Meyer may be used:

$$F = \frac{\pi r^4}{16\eta l p}\left(1 + \frac{4\xi}{r}\right)(p_1^2 - p_2^2),$$

where F = volume of gas (measured at mean pressure p) flowing per second, p_1 = entrance pressure, p_2 = exit pressure, l, r = length and radius of the tube, respectively, and ξ, the slip coefficient, is approximately equal to the mean free path of the molecules.

Except at very small velocities, the above formula requires a considerable correction for kinetic energy. The corrected formula may be written, according to Brillouin (3)

$$p_1^2 - p_2^2 = \frac{p}{\rho}\left[\frac{16\eta l M}{\pi r^4\left(1 + \frac{4\xi}{r}\right)} + \frac{2M^2}{\pi^2 r^4}\right],$$

where M = the mass of gas transpired per second and ρ = the density of the gas at the mean pressure p.

Fisher (4) gives the following correction to the pressure at the entrance end due to the kinetic energy effect:

$$RT \log_e \frac{p_1}{p_1} = -\frac{1}{384}\left[\frac{p_1^2 - p_2^2}{\eta p_1 l}\right]^2 [r^4 + 12\xi^2 r^2 + 6\xi r^3],$$

where R = the gas constant, T = the absolute temperature, p_1 = the pressure to be used in Poiseuille's law, and p_1' = the manometer pressure measured in the vessel at the end of the tube. A similar formula with subscripts "2" gives the correction at the exit end.

Rapp (28) found that the following empirical formula gives the same results as Fisher's formula within the limits of experimental error:

$$\eta = \eta'\left[1 + \mathrm{A}\frac{r^4(p_1 - p_2)}{l}\right],$$

where η is the corrected value of η'. The constant A is negative.

FLOW OF GASES THROUGH TUBES

The flow becomes turbulent when the value of $\mathrm{K} = \rho\frac{Vd}{\eta}$ exceeds a certain value depending on the material of the tube, where ρ is the density, η the viscosity, V the velocity of the gas, and d the diameter of the tube. For practical purposes, K may be taken as >2000 for ordinary tubes.

It has been found that when due allowance is made for slip, the viscosity of a gas is independent of the pressure. The coefficient of slip between a solid and a gas depends both on the nature of the gas and on that of the solid surface [Van Dyke (39), Millikan (14) and States (35)].

In most measurements of gaseous viscosities, the value for air at a given temperature is either assumed or determined. Unless otherwise indicated, the viscosity values in the following tables have been corrected, in cases where the air value assumed or determined by the author is known, by assuming that for air η_{23} = 1822.6 × 10^{-7} (9) and that C = 120.

A-TABLE.—ELEMENTARY SUBSTANCES AND ATMOSPHERIC AIR

Gas	t, °C	η, micropoise (10^{-6} poise)	Remarks	Lit.
A	0	209.6	C = 142	(20, 21, 22)

VISCOSITY OF METALS AND ALLOYS

W. ROSENHAIN, EDITOR

Definitions and Meanings of Symbols

S_e	Tensile stress.
S_g	Shearing stress.
e	Unit elongation.
g	Shear.
E	Young's modulus of elasticity.
G	Modulus of rigidity.
ξ	"Normal" coefficient of viscosity.
η	Tangential coefficient of viscosity.
δ	Logarithmic decrement of damped vibrations.

The coefficients of elasticity and viscosity of an isotropic solid body are defined by the equations:

$$S_e = Ee + \xi\frac{de}{dt}$$

$$S_g = Gg + \eta\frac{dg}{dt}$$

The coefficient of viscosity of a liquid is defined by:

$$S_g = \eta\frac{dg}{dt}$$

The physical significance is different, however, the order of magnitude being 10^{-12} that for a solid.

The logarithmic decrement is the logarithm of the ratio of two successive maximum displacements, on the same side of the equilibrium configuration.

NOTE.—For material possessing no symmetry whatever, there are 21 elastic and 36 viscous constants, which are coefficients in the six linear equations giving the six stress components in terms of the six strain components and their time derivatives. The constants in the following tables have been computed on the assumption that the material is isotropic, though this is admittedly not the case in unannealed wires and possibly not in the other materials investigated.

In general, the coefficients of viscosity computed on this basis from the logarithmic decrement of vibrations, increase linearly with the amplitude of vibration. This may be due either to "after-effect" or to the fact that terms quadratic in the strain-velocities are necessary completely to define the stress components in terms of the strain components. For a discussion of the theory, *see* (11). The values of the coefficients for an amplitude of θ° are designated by ξ_θ and η_θ.

The values of the coefficients of viscosity of solid metals and alloys depend not only upon their chemical composition but very largely on their condition, especially their microstructure. The values given below are to be applied only to material in the same condition and only to specimens whose size is of the same order of magnitude as the specimens for which the results are given.

VISCOSITY OF SOLID METALS AND ALLOYS

* Results of (5) were each obtained from damping of vibrations *in vacuo* of a strip loaded at lower end. Results of (11) were each obtained from damping of vibrations of a strip fixed at one end and at the other attached to a heavy disk rotatable in the plane of flexure, the plane of strip when unstrained passing through axis of disk. In (11) only values of $\frac{\xi_0}{E}$ were given. Values of ξ are computed from values of E given below.

In (5) $\delta = \frac{mn^3T}{8Ml^3}\xi$, where M is mass of load and T is period (½δ is called log decrement in the original). In (11) $\delta = \frac{mn^3T}{4M'l^3}\xi$ where M' is mass of heavy disk. The results in this table are not corrected for effect of non-rigidity of support.

For methods, *v.* (16). For more recent data, *v.* (17).

† Average dimension of strips, 10 × 0.6 × 0.1 cm.

‡ Assumed E = 6 570 kg/mm².

§ Assumed E = 7 070 kg/mm².

‖ Assumed E = 10 800 kg/mm².

¶ Assumed E = 9 400 kg/mm².

** Assumed E = 20 750 kg/mm².

†† Assumed E = 9 000 kg/mm².

‡‡ Assumed E = 20 300 kg/mm².

TANGENTIAL COEFFICIENT OF VISCOSITY FOR ZERO AMPLITUDE (6)

Determined from damping of torsional vibrations of annealed wires; for effect of temperature, *v.* Figs. 1–10

VISCOSITY OF WATER, SULFURIC ACID, LIQUID CARBON DIOXIDE AND CERTAIN ORGANIC LIQUIDS*

N. Ernest Dorsey

Formulae and Units

At a pressure of 1 atm., $\eta = a/(b + t)^n$.

At a pressure of P kg/cm², $\eta_p = \eta_1[1 + k_t(P - 1) \times 10^{-4}]$.

η_1 is the value of η when P is 1 kg/cm², which may be taken as the value of η at 1 atm.

The unit of η is the poise unless otherwise stated.

Water between 0 and 100°. I. C. T. Values

The following table was prepared from a critical evaluation of all available data. It is estimated that the accuracy is of the order of 0.1% between 0 and 40° and of 0.5 to 1% at higher temperatures. Linear interpolation may be safely employed throughout the table.

Values in millipoises (**1, 12, 16, 17, 22, 24, 30, 31, 32, 38**)

362	55	+0.6	(14)
516	40	+0.4	(14)

In disagreement with the preceding data, the observations of (29, 37) indicate that at 20°C and pressures not exceeding 150 kg/cm², $k_t = -1.7$.

SULFURIC ACID

$$\eta = \frac{1}{3(1 - 0.0075t - 0.001t^2)}$$ if *t* lies between 11 and 90°C (5, 6, 7, 8, 25, 26). The observations are discordant by ±5% and more; the composition of the acid is indefinite but presumably between 98 and 100%. At 0°, η is 45% greater than that given by the formula (5); *cf.* (19); there is only one recorded observation at 0° and none between 0 and 11°.

t, °C	0	11	15	20	30	40	50	60	70	80	90
$10^3\eta$	484	321	299	267	199	145	107	80	62	49	40

LIQUID CARBON DIOXIDE

Under essentially the pressure of its saturated vapor (36)

t, °C	5	10	15	20	25	29
p, atm	40.4	45.7	51.6	58.2	65.6	73.6
$10^3\eta$	0.925	0.852	0.784	0.712	0.625	0.539

At higher pressures

20°C (23)

p, atm	59	72	83
$10^3\eta$	0.697	0.771	0.823

25.1°C (36)

p, atm	70	75	85	95	105
$10^3\eta$	0.628	0.665	0.703	0.741	0.800

30°C (23)	*p*, atm	72	73	74	76	80
	$10^3\eta$	0.458	0.478	0.495	0.529	0.565

30°C (23)	*p*, atm	82	90	96	104	110.5
	$10^3\eta$	0.592	0.643	0.693	0.733	0.770

At the critical point, $10^3\eta$ is 0.321 (23).

ORGANIC LIQUIDS

$CHCl_3$, CHLOROFORM

a = 93.3±0.5, *b* = 163, *n* = 1.865, if *t* lies between −15 and 60° (32); *cf.* (13, 21, 40)

$(C_2H_5)_2O$, ETHYL ETHER

Excepting from 0 to +30°C, only non-overlapping series of data are available for variation of η with *t*; different series do not agree satisfactorily; for each, $\eta = c(10)^{-3}/[1 + dt(10)^{-3} + et^2\,(10)^{-6}]$ with average deviation of δ. Actual uncertainty exceeds δ and, except between 0 and +30°C, may amount to several %.

Range	*c*	*d*	*e*	δ	Lit.

C_6H_6, BENZENE

$a = 14.42 \pm 0.03$, $b = 90$, $n = 1.64$; if t lies between 0 and 75°C (27, 32, 40); *cf.* (10)

t, °C	0	10	20	30	40	50	60	70
$10^3\eta$	9.00	7.57	6.47	5.61	4.92	4.36	3.893	3.502

For the liquid under the pressure of its saturated vapor the viscosity ($\eta_{p,t}$) may be calculated by means of the equation $\eta_{p,t} = \eta_{1,t}\ [1 - 0.0123(p - 1)]$, if t lies between 0 and 190°C, where $\eta_{1,t}$ is value of η at $t°$ and 1 atm. as computed by the preceding formula ($\eta_{1,t} = 14.42/(90 + t)^{1.64}$), and p is the pressure (in atm.) of the saturated vapor. Observations between 0 and 100°C lie on the average 1.3% below the computed values, from 100 to 190° observed and computed agree to within 0.1% (15, 16).

VISCOSITY OF AQUEOUS SOLUTIONS OF STRONG ELECTROLYTES

Stuart J. Bates and Warren P. Baxter

In the following tables, the concentration F, is given in formula weights per 1000 g of water, and η* is the viscosity referred to that of water at the same temperature as unity, except as otherwise noted. Temperature in °C is indicated by the subscript.

Few of the investigators have determined and applied any correction for failure of their viscometers to obey Poiseuille's law exactly. Where feasible, corrections of this nature have therefore been applied.

In general, the last figure given is to be regarded as not being in error by more than 5 units. Where it is given in smaller type, the probable error is somewhat greater, and the last figure may or may not be significant. In cases where it has been possible to estimate the probable error with considerable certainty, this is given. Thus for HCl at 25° and 1F the relative viscosity is 1.060 ± 0.003. This indicates that the probable error for all solutions up to a concentration of 1F is about 0.3%.

For some electrolytes, additional data, chiefly at higher or lower temperatures or at higher concentrations than those covered by the tables, may be found by consulting the literature.

Should it be desired to interpolate the viscosity data to other units of concentration, for example to (volume) normal, this may usually be readily done algebraically by noting that, in general, for small changes of concentration, the expression $\frac{\eta/\eta_0 - 1}{F}$ changes but slowly with the concentration.

---

* All interconversions between η and η/η_w have been based upon the values for water given on page 10.

AQUEOUS SOLUTIONS CONTAINING A SINGLE STRONG ELECTROLYTE

$Na_2O.xSiO_2$ (86)
Viscosity in centipoises at 20°C

The solutions employed in determining the data for the following table were commercial solutions of sodium silicate. The only sample completely analyzed was $Na_2O.2.06SiO_2$; for this the following analysis is given: Na_2O, 18.42%; SiO_2, 36.84%; Al_2O_3, 0.23%; Fe_2O_3, 0.16%; CaO, 0.14%; MgO, 0.05%. The compositions given in the table below refer to the percentages by weight of $Na_2O.xSiO_2$. For given values of x the original data lie on fairly smooth curves which were interpolated to round concentrations. But for a given percentage composition, particularly in the less concentrated solutions, the viscosity data considered as a function of x are quite irregular and it did not seem practicable to smooth them. This effect may be due to varying amounts of impurities in the different solutions.

3.95	121.6	103.6	50.1

There is considerable discrepancy between the values at 20° and 25°, probably due to the difference in previous history of the solutions.

KINETICS OF PHYSICAL PROCESSES

VELOCITY OF VAPORIZATION (AND GAS EVOLUTION) AND OF CONDENSATION (AND GAS ABSORPTION)

A. C. Egerton

EVAPORATION IN VACUO

GENERAL FORMULA

$m = \alpha p\,(M/2\pi RT)^{1/2}$ (28, 41); *see further* Vol. I, p. 91.

m = mass in grams vaporized per cm² per sec.

p = vapor pressure at T, °K.

M = gram-molecular weight.

R = gas constant.

$\alpha = 1 - \nu$, where ν is the fraction of molecules reflected without condensation ("accommodation coefficient").

EVAPORATION FROM HOT FILAMENTS

For more recent critical compilation, *v.* (83.5)

Substance	$\log_{10} m$ (for p in mm Hg and $\alpha = 1$)	Range, °K	Lit.
Carbon*...........	$14.19 - 47\,000/T - 1.25 \log T$	3 100–3 800	(1, 77)
Molybdenum.......	$17.11 - 38\,600/T - 1.76 \log T$	2 000–2 400	(46)
Platinum..........	$14.00 - 27\,800/T - 1.76 \log T$	1 680–2 000	(46)
Tungsten†..........	$9.42 - 45\,450/T$	2 000–3 000	(18, 19, 41, 83)
Calcium‡...........	$10.97_8 - 10\,350/T$	770–970	(59)

* *See* (1); α varies with adsorption layer.

† Zwikker gives $\log_{10} m = 11.92 - 48\,400/T - 0.368 \log_{10} T - 0.00016T$; Langmuir gives $\log_{10} m = 15.402 - 47\,440/T - 1.4 \log_{10} T$ (M. P. 3540°K); Forsythe in close agreement with Zwikker's equation; Fonda's value at 2825°K lies between those of Langmuir and of Zwikker. For small crystals m is 30 % greater than for large (18). In N_2, m is 6 % of the value *in vacuo;* 3.9 % in argon (18). Rosenhain and Ewen (63) found the following ratio of m for coarse and for fine crystals: Zn, 2.3; Ag, 1.2; Cu, 1.4.

‡ Formula deduced from vapor pressure formula given by Pilling for $\alpha = 1$; the measurements of p included allowance for value of α obtained by comparative measurements with Zn and Cd (59).

EVAPORATION THROUGH AN APERTURE

If the diameter of the aperture is $\not> 0.1$ of the mean free path, m is the same as from a free surface, $\alpha = 1$. Measurements have been made by this method for Cd, Hg, K, Na, Pb, Zn and benzophenone (13, 35, 62, 73).

EVAPORATION OF SMALL DROPS (74, 75)

Spherical drop (*see* general formula for evaporation *in vacuo*).

For a drop of mercury resting on plane, $m = -1.11 \dfrac{dr}{dt} \times \rho$, where ρ is the density of mercury and $\dfrac{dr}{dt}$ is the rate of change of radius with time.

ACCOMMODATION COEFFICIENTS

Values of α for Saturated Vapors

Substance	α	t, °C	Lit.
Hg (liquid)...........	1.00 ± 0.01	60 to −30	(37, 74, 75)
Hg (solid)............	0.85	−64	(74, 75)
Cd (solid)............	0.98 ± 0.2	(*ca.* 200)	(4, 14)
Th, Ta, W............	1.0	(*ca.* 2000)	(42)
Benzophenone.........	0.2 to 0.5		(73)

Values of α for Gases on Various Solids (36, 43, 64)

Gas	Polished Pt*		Pt black at 20°C	W at 1500°K	Glass at 0°C
	°C	α			
H_2.............	−190	0.42	0.71	0.19	0.26
	0	0.26			
CO_2............	20	0.86	0.96		
O_2.............	20	0.83	0.95		
N_2.............	20	0.87		0.60	
He.............	−100	0.49			
	+200	0.38			
A..............	30–260	0.85			
Ne.............		0.65			

* Soddy and Berry found same results for Pd as for Pt surface.

CONDENSATION IN VACUO

Observed Temperature Region for Irreversible Condensation

Substance	On glass, t, °C	Lit.	Substance	t, °C	Lit.
NH_4Cl......	< −183	(39)	Cd on paraffin.....	−70	(9)
Hg*.........	−140 to −130	(39, 81)	Cd on mica	−80	(9)
			Cd on glass........	−90	(81)
Zn*.......	−183 to −78	(39)	Vapor at 280°....	−110	(16)
Cd*.......			Vapor at 365°....	−50	(16)
Mg.......					

Observed Temperature Region for Irreversible Condensation.—(*Continued*)

Substance	On glass, *t*, °C	Lit.	Substance	On glass, *t*, °C	Lit.
Cu	350 to 575	(39)	Ag*	< 575	(39)
			I_2	−60	(39)

* *Cf.* (15, 44).

Substance (16); *cf.* (38, 44, 78)	Vapor pressure, mm Hg	*t*, °C	Latent heat of adsorption, g-cal/g
Cd on glass	0.008	−107	5200
	0.03	−86	
Cd on copper	0.008	−111	2940
	0.03	−83	
Cd on silver	0.008	−86	3540
	0.03	−66	
Hg on silver	0.0083	−120	2560
	0.033	−88	

Although vaporization occurs according to the cosine law (38, 81), and for Ag, Zn, Sb_2S_3, and S (40), condensation is directed in the case of Cd, Hg, Zn and As but not HgI_2 or S, *v.* (23, 71, 72, 75).

EVAPORATION IN STILL AIR AND OTHER GASES

THEORETICAL EQUATIONS (66)

For values of diffusion coefficients, *v.* p. 62.

From flush circular area:

$$V = 4r\Delta \log_e \frac{p - p_0}{p - p_s}$$

when p_s is small, $V = Kp_s/p$ [Dalton (11)]. V = rate of evaporation (volume per unit time), p_s = saturation pressure at surface of liquid, p_0 = pressure of vapor in gas at distance from surface, p = total gas pressure, r = radius of circular area, Δ = diffusion coefficient (50, 58, 66, 80).

From elliptical area (a and b = axes of ellipse) approximate formula:

$$V = 4\sqrt{ab}\Delta \log_e \frac{p - p_0}{p - p_s} \text{ (58, 60, 66).}$$

From circular vessels (surface distant h below rim):

$$V = 4(\sqrt{h^2 + r^2} - h)\, \Delta \log_e \frac{p - p_0}{p - p_s} \text{ (6, 47, 68, 69, 70, 80).}$$

From vertical tube (distance from upper end of tube to surface of liquid in the tube, greater than the diameter):

$$V = \frac{A\Delta}{h} \log_e \frac{p - p_0}{p - p_s}.$$

A = area of cross section of tube, h = distance from upper end to surface (48, 52, 69, 79).

From spherical drop:

$$V = 4\pi r\Delta \log_e \frac{p - p_0}{p - p_s} \text{ (65)}$$

or

$$m = 4\pi r\Delta \frac{Mp_s}{RT} \text{ (45) } \left(\text{for small values } \frac{p_s}{p}\right)$$

m = mass evaporated per unit time; M = mol. wt.; r = radius of sphere, *v.* (84, 85).

The references refer to experimental work on the subject; the formulae hold only under ideal conditions. The essential conditions are adequacy of rate of supply of heat to maintain temperature of the surface (48) and absence of disturbance of the atmosphere in the neighborhood of the evaporating liquid (50, 58).

EVAPORATION OF SMALL DROPS

I_2 in air: $dm/dt = 1.83 \times 10^{-6} r$ (r radius of drop; m = g cm^{-2} sec^{-1} (54, 84).

Hg in air: $dr/dt = 1.4 \times 10^{-10}$, cm/sec for drops 10^{-4} to 10^{-3} cm radius. [Evaporation of small drops is checked by oxidation of droplet, *v.* (51)].

H_2O: Evaporation of small drops less than 10^{-4} cm radius checked by absorption of gases other than hydrogen (24).

Change in Radius with Time

Minutes	Air	H_2, 70%; Air, 30%
5	0.89×10^{-4} cm	0.99×10^{-4} cm
20	0.86×10^{-4} cm	0.90×10^{-4} cm
45	0.86×10^{-4} cm	0.74×10^{-4} cm

PLATINUM METALS IN AIR

Loss in weight, g/cm²/sec in air at atmospheric pressure (7)

t	Pt	Pt + 1% Ir	Pt + 2.5% Ir	Pt + 8% Rh
900	0	0	0	0
1000	2.2×10^{-7}	8.3×10^{-7}	1.6×10^{-6}	1.9×10^{-7}
1200	2.2×10^{-6}	3.3×10^{-6}	7.0×10^{-6}	1.5×10^{-6}

Crookes (10) found the following percentage loss of total weight at 1300°C in air but did not mention extent of surface: 8 hr, Ru, 25%; 22 hr, Ir, 7.3%; 30 hr, Pd, 0.745%; Pt, 0.245%; Rh, 0.131%. (In case of Ru and Ir oxidation occurred. Ir *in vacuo* at 1300°C lost 0.069% in 30 hr.)

EVAPORATION IN A CURRENT OF GAS

In steady horizontal wind (velocity W):

$$V = k\sqrt{W} \text{ and } V = \alpha r^{1.5}$$

k and α, constants (circular area of radius r, areas 250 m² to 10 cm² or in gentle draughts 25 m² to 1 cm²) (33, 68). For very large areas, *see* especially (21).

Numerous meteorological formulae connect evaporation with temperature, hygrometric and wind conditions (*see* annotated bibliography (49).

General form: $dE/dt = A(p_s - p_d) + B(p_s - p_d)W$ (Dalton-Weilermann).

E, fall of level due to evaporation in time, t; p_s, saturation pressure at temperature of surface; p_d, saturation pressure at dew point; W, wind velocity; A and B, constants, *v. also* (53).

Typical formula: $E_{mm} = 0.425\ (p_s - p_d)\ (1 + 0.805W)$ (Fitz-Gerald); W measured in km/hr (up to 20 km/hr). p in mm. *See* especially (5, 17, 61, 67).

Similar formulae are used for *chemical engineering* purposes; *e.g.*, evaporation from pans in still air: $M = 0.02\ (p_s - p_d)^{1.2}$ (29).

Evaporation from pans in air current:

$$M = (0.031 + 0.0135W)(p_s - p_d)\frac{p_0}{p_1}$$

M kg m^{-2}hr^{-1}; W = air velocity m/sec from 0.5 to 4 m/sec; p_0 = 760 mm and p_1 = barometric pressure; range 20 − 70°C (28.5, 29, 31).

Notes

Rate of evaporation of water approximately proportional to vapor pressure up to (B. P. − 15°) (3).

At 50°C evaporation of water in a current of air (W = 2.5 m/sec) is 2.8 times as rapid as in still air, and for W = 5 m/sec, 3.8 times (3).

Number of gram-molecules of a liquid evaporated per unit time and unit surface is proportional to vapor pressure, *v.* (26, 30); for evaporation of toluene, nitrobenzene, *m*-xylene, and chlorobenzene in wind tunnel, *v. also* (69).

Evaporation from large areas (lakes, etc.) about two-thirds evaporation from small pans.

Evaporation of sea water approximately 5% less than fresh water.

Evaporation of ocean approximately 820 mm *per annum* (34, 82).

VAPOR PRESSURE BY STREAMING METHOD

$$\log_e \frac{p_s}{p_s - p} = \frac{\text{const.}}{\sqrt{W}}$$

where W is velocity of gas stream and p is partial pressure of vapor in gas.

Dependence of velocity of vaporization on pressure, temperature and nature of gas (27, 32). For measurements on Ag, Tl, Pb and Sn, *v.* (76).

THE VELOCITY OF DISSOLVING OF CRYSTALS IN LIQUIDS

R. G. VAN NAME

The velocity constant K has usually the value given by equation I or II. As recorded in the tables it has the dimensions [cm min^{-1}] and is independent of the unit of concentration. In cases where it has been necessary to give the constant in the author's or arbitrary units, it is designated by K_{arb}.

For the case of simple solution in a solvent (reversible)

$$K = \frac{v}{S(C_s - C)} \frac{\mathrm{d}C}{\mathrm{d}t} = \frac{v}{S(t_2 - t_1)} \ln \frac{C_s - C_1}{C_s - C_2} \qquad \text{(I)}$$

in which v = volume in cm^3, t = time in min, S = surface of contact in cm^2, C = concentration at time t, C_s = concentration at saturation, and $\ln = \log_e$.

For the case of solution by interaction with a dissolved reagent

$$K = -\frac{v}{SC} \frac{\mathrm{d}C}{\mathrm{d}t} = \frac{v}{St} \ln \frac{C_0}{C} \qquad \text{(II)}$$

in which C_0 and C are the concentrations of the reagent at time zero and time t, respectively; other symbols as in I.

Since K depends upon the intensity of the stirring and upon the form and dimensions of the apparatus, a quantitative comparison of the results of different investigators is usually impossible.

The velocities of dissolving of metals in acids are subject to various disturbing effects, such as passivity, period of induction, large influence of physical state and of traces of certain impurities, evolution of gas, etc., and are often not expressible by definite velocity constants. The results obtained are frequently too complicated and difficultly reproducible to justify their inclusion in the following tables. In the case of magnesium, however, the disturbing effects seem to be of minor importance.

La constante de vitesse K a ordinairement la valeur donnée par l'équation I ou II. Dans les tables elle a la dimension [cm min^{-1}] et elle est indépendante de l'unité de concentration. Dans les cas où il a été nécessaire de donner la constante dans les unités arbitraires de l'auteur, elle est désignée par K_{arb}.

Pour le cas d'une simple dissolution dans un solvant (reversible)

$$K = \frac{v}{S\ (C_s - C)} \frac{\mathrm{d}C}{\mathrm{d}t} = \frac{v}{S(t_2 - t_1)} \ln \frac{C_s - C_1}{C_s - C_2} \qquad \text{(I)}$$

où v = volume en cm^3, t = temps en min, S = surface de contact en cm^2, C = concentration au temps t, C_s = concentration à la saturation et $\ln = \log_e$.

Pour le cas d'une dissolution par reaction avec un réactif dissout

$$K = -\frac{v}{SC} \frac{\mathrm{d}C}{\mathrm{d}t} = \frac{v}{St} \ln \frac{C_0}{C} \qquad \text{(II)}$$

où C_0 et C sont respectivement les concentrations du réactif au temps zéro et au temps t; pour les autre symboles comme en I.

Comme K dépend de l'intensité de l'agitation et de la forme et des dimensions de l'appareil, une comparaison quantitative des résultats obtenus par différents expérimentateurs est ordinairement impossible.

Les vitesses de dissolution des métaux dans les acides sont sujets à des effets perturbateurs variés, tels que: la passivité, la période d'induction, la grande influence de l'état physique et des traces de certaines impuretés, l'évolution du gaz, etc., et de la sorte ne peuvent souvent pas être exprimées par des constantes de vitesse définies. Les résultats obtenus sont fréquemment trop compliqués et difficilement reproductibles pour justifier leur publication dans les tables suivantes. Cependant, dans le cas du magnésium, les effets parasites paraissent être d'importance moindre.

Die Geschwindigkeitskonstante K hat gewöhnlich den nach Gleichung I oder II sich ergebenden Wert und wie aus den Tabellen folgt, besitzt sie die Dimension [cm min^{-1}] und ist von der Einheit der Konzentration unabhängig. In Fällen wo es nötig war die Konstante in den vom Autor gegebenen, oder in sonst willkürlichen, Einheiten anzuführen, wird sie mit $K_{\text{arb.}}$ bezeichnet.

Für den Fall der einfachen reversiblen Lösung in einem Lösungsmittel gilt

$$K = \frac{v}{S(C_s - C)} \frac{dC}{dt} = \frac{v}{S(t_2 - t_1)} \ln \frac{C_s - C_1}{C_s - C_2} \qquad \text{(I)}$$

wo v = Volumen in cm³, t = Zeit in Minuten, S = Kontaktoberfläche in cm², C = Konzentration zur Zeit t, C_s = Sättigungskonzentration und ln = $\log_e$.

Für den Fall der Wechselwirkung mit einem gelösten Stoff, hat man

$$K = -\frac{v}{SC} \frac{dC}{dt} = \frac{v}{St} \ln \frac{C_0}{C} \qquad \text{(II)}$$

Es bedeutet, C_0 und C die Konzentration des reagierenden Bestandteiles zur Zeit Null bezw. zur Zeit t. Die anderen Zeichen sind die gleichen wie bei I.

Da K von der Rührgeschwindigkeit, der Form und der Dimension des verwendeten Apparates abhängt, ist ein quantitativer Vergleich der Ergebnisse der verschiedenen Beobachter meist nicht möglich.

Die Lösungsgeschwindigkeit der Metalle in Säuren unterliegt den verschiedenen störenden Einflüssen, wie Passivität und Induktionsdauer. Bedeutend ist der Einfluss des physikalischen Zustandes der Probe, der Spuren von Verunreinigungen, der Gasentwickelung, u.s.w. Dies alles ist nicht durch eine bestimmte Geschwindigkeitskonstante ausdrückbar. Die Ergebnisse sind häufig zu kompliziert und zu schwer reproduzierbar um in diese Tafeln aufgenommen zu werden. Beim Magnesium scheinen sich jedoch die störenden Einflüsse weniger bemerkbar zu machen.

Generalmente il valore della costante di velocità K è quello dedotto dalle equazioni I o II. Questa velocità, come è indicato nelle tabelle, ha le dimensioni di [cm min^{-1}] ed è indipendente dalla unità di concentrazione. Nei casi in cui si è dovuto dare la costante in unità arbitrarie, quelle adoperate dagli autori, essa è stata indicata con K_{arb}.

Nel caso che si tratti di semplice dissoluzione in un solvente (riversibile)

$$K = \frac{v}{S(C_s - C)} \frac{dC}{dt} = \frac{v}{S(t_2 - t_1)} \ln \frac{C_s - C_1}{C_s - C_2} \qquad \text{(I)}$$

nella quale v = volume in cm³, t = tempo in minuti, S = superficie di contatto in cm², C = concentrazione al tempo t, C_s = concentrazione al punto di saturazione e ln = $\log_e$.

Nel caso di dissoluzione con reazione con una sostanza disciolta si ha:

$$K = -\frac{v}{SC} \frac{dC}{dt} = \frac{v}{St} \ln \frac{C_0}{C} \qquad \text{(II)}$$

nella quale C_0 e C rappresentano le concentrazioni della sostanza reagente al tempo 0 ed al tempo t, mentre gli altri simboli hanno lo stesso significato che nella I.

Poichè K dipende dalla intensità della agitazione, dalla forma e dalle dimensioni dell'apparecchio, è impossibile confrontare quantitativamente i risultati dei vari sperimentatori.

Le velocità di dissoluzione dei metalli negli acidi risentono molto della azione di varie cause perturbatrici, come ad esempio: passività, periodo di induzione, stato fisico, presenza di tracce di certe impurezze, svolgimento di gas, ecc., e perciò spesso non sono esprimibili con valori ben definiti delle costanti. Spesso i risultati ottenuti sono troppo complessi e difficili a riprodursi per poter essere compresi nelle tabelle che seguono. Nel caso del magnesio tuttavia sembra che le cause perturbatrici non abbiano molta importanza.

VELOCITY CONSTANTS

1. Salts in Water

Rotary stirring, 400 r.p.m.; exposed surface horizontal, below stirrer; 25°C (30)

Salt	C_s,* g/100 g H_2O	K, cm/min
KI	146.45	0.186
KBr	67.75	0.171
KCl	36.32	0.147
NaCl	35.92	0.105
TlCl	0.385	0.204†
TlBr	0.057	0.144†
$PbCl_2$	1.08	0.060†
$PbBr_2$	0.974	0.078†
$BaCl_2.2H_2O$	36.9	0.096
K_2SO_4	12.04	0.102
$K_4Fe(CN)_6.3H_2O$	32.0	0.048‡
$FeSO_4.7H_2O$	29.7	0.048
$NiSO_4.7H_2O$	39.6	0.033
$CoSO_4.7H_2O$	37.8	0.036

$MgSO_4.7H_2O$	38.3	0.030
$CuSO_4.5H_2O$	22.29	0.039
$CdSO_4.\frac{8}{3}H_2O$	77.0	0.021
$CaSO_4.2H_2O$	0.210	0.021§

* Calculated as anhydrous salt. ‡ ∥ to cleavage surface.
† Fused salt used. § Selenite, ∥ to face (010).

2. Salts in Water

Rotary stirring, 50 r.p.m.; whole crystal exposed (12)

Salt	C_s, g/100 g soln.	$K_{\text{arb.}}$, 4.8°C	C_s, g/100 g soln.	$K_{\text{arb.}}$, 30.1°C
K_2SO_4	7.82	0.027	11.43	0.071
$NaClO_3$	45.47	0.043	51.22	0.083
$K_2Cr_2O_7$	5.52	0.026	15.17	0.069

3. Metals in Dissolved Iodine (and Bromine)

Disk of metal 40 mm diameter, 0.6 mm thick, supported vertically, whole surface exposed. Rotary stirring, 240 r.p.m.; S = 2.60 cm², but velocity per unit area not accurately calculable on account of difference in stirring on the two sides of the disk. Aqueous solution of I_2 (resp. Br_2) in KI (resp. KBr); 25 ± 0.1°C (27)*.

Metal	Salt, mole/l, I_2 in KI	$K \times S$, cm³/min	Metal	Salt, mole/l, I_2 in KI	$K \times S$, cm³/min
Hg	0.6	8.81	Zn	1.2	9.64
Cd	0.6	8.69	Hg	2.4	10.48
Zn	0.6	8.64	Cu	2.4	9.98
Hg	1.2	9.55	Ag	2.4	9.93
Cd	1.2	9.56		Br_2 in KBr	
			Hg	3.3	12.27

* These and further results in original seem to show that these five metals dissolve in I_2 + KI with the same velocity, expressed in equivalents of metal dissolving.

4. METALS IN DISSOLVED IODINE

Method as above: Disk 38.3 mm × 0.5 mm. $S = 2.36$ cm^2; velocity per unit area not accurately calculable, (*cf.* 3); 25 ± 0.1°C (26).* 0.5 mole KI and 0.02 mole H_2SO_4 per l.

Metal	Cd	Fe	Ni	Co
$K \times S$, cm^3/min	6.86	6.88	6.88	6.87

Cd in acid solutions of iodides

H_2SO_4, mole/l	0	0.02						
Iodide, mole/l	0.5				0.25			
Iodide	HI	LiI	NaI	KI	MgI_2	CaI_2	BaI_2	CdI_2
$K \times S$, cm^3/min	6.45	6.41	6.56	6.86	6.25	6.23	6.45	6.82

* The results show that K is independent of the metal but varies to a marked extent with the nature of the other cation present.

5. METALS IN AQUEOUS FERRIC SULFATE, FERRIC CHLORIDE AND CHROMIC ACID

Values of $K \times S$, cm^3/min; method and dimensions of disk as in 4 (28)

Ferric sulfate (ferric alum)* 24.6 ± 0.1°C

H_2SO_4, mole/l	0.01	0.25	1.25	5.0
Zn	4.38			
Cd	4.12	4.15	3.54	1.76
Fe	3.95	3.92	3.37	1.74
Ni	3.80	3.75	3.27	1.71
Sn		3.96		1.72
Cu		3.74	3.30	1.71
Ag		1.67	1.63	1.24

Ferric chloride, 24.6 ± 0.1°C

HCl, mole/l	0.1	0.5
Cd	4.19	4.17
Fe	4.14	4.35
Cu	3.44	4.20

Chromic acid* (added as CrO_3), 25 ± 0.1°C

H_2SO_4, mole/l	0.25	1.25	5.0
Cd	7.02	5.32	2.67
Ni	irregular		2.67
Sn			2.74
Cu	6.95	5.34	2.72
Ag	4.28		1.22

* Velocities for different metals tend to become the same with increasing H_2SO_4 concn., probably because it increases the viscosity and thus retards diffusion.

6. METALS IN AQUEOUS FERRIC SULFATE (9)

18 ± 0.1°C; no stirring; dissolving surface vertical; $S = 22.5$ cm^2

Metal	Cu	Fe	Cd	Sn
K, cm/min	0.0142	0.0138	0.0144	0.0137

The agreement between the different metals in spite of the low acidity (*see* 5) is probably due to the slowness of diffusion in the unstirred solutions.

7. COPPER IN AQUEOUS FERRIC CHLORIDE AND CUPRIC CHLORIDE

All solutions contained NH_4Cl, 3.7 to 4.7 mole/l. Variations in concentration of NH_4Cl were without effect on K when over 2.5 mole/l were present. Rotary stirring, 1500 r.p.m.; dissolving surface horizontal; $S = 34$ to 35.3 cm^2; 25°C (2).

Salt	No. of exps.	Initial concentration, mole/l	Mean, K, cm/min
$FeCl_3$ alone	3	(0.186) (0.191) (0.290)	0.205
$CuCl_2$ alone	2	(0.166) (0.195)	0.205
$FeCl_3 + CuCl_2$	4	Various	0.204
		Mean of the 9 exps.	0.2044

8. MAGNESIUM AND ZINC IN AQUEOUS ACIDS

Rotary stirring, 300 r.p.m.; value of S in doubt, but apparently 0.22 cm^2 in all experiments; 25°C. K_a = Ionization constant (22).

Solution, initial concn. in mole/l	$K \times S$, cm^3/min*	K_a
Mg		
HCl, 0.1	1.12	
HCl, 0.1 + $MgCl_2$, 0.0671	1.25	
HCl, 0.1 + $MgCl_2$, 0.1341	1.31	
HAc (Acetic acid), 0.1	0.405	
HAc, 0.1 + $Mg(Ac)_2$, 0.1	0.366	
HAc, 0.1 + $Mg(Ac)_2$, 0.2	0.326

		0.125		0.27	
		0.25		0.32	

* Cut from rolled bar. † Kahlbaum. ‡ Sheet metal, Kahlbaum. § A different sample of Mg from the above, not rolled.

10. PbS, ZnS AND RELATED MINERALS IN DILUTE SULFURIC ACID

Material, screened fragments of uniform size. No stirring. Velocities were proportional to concentration of acid between 0.0125 and 1.25% H_2SO_4. The relative values of the velocity constant tabulated below were the same at all temperatures between 0 and 50° (15, 16).

Mineral	Locality	$K_{\text{arb.}}$
Galena (PbS, about 98%)	Clausthal	1.00
Sphalerite (ZnS, about 99%)	Spain	3.2
Sphalerite (Pb, 11.4%; Fe, 3.6%)	Clausthal	6.3

10.—(*Continued*)

Mineral	Locality	$K_{arb.}$
Sphalerite (Pb, 14.9%; Fe, 3.5%; SiO_2, 11%)	Bensberg	11.1
Christophite (ferriferous ZnS; Fe, 16%; SiO_2, 19%)	Breitenbrunn	14.0

11. Mineral Carbonates in Acids

Material, except in cases of malachite and marble, large crystals. Single exposed surface vertical. Stirring by gas evolved only; 15°C (19, 20).

Mineral	Acid	$K_{arb.}$	Remarks
Iceland spar ($CaCO_3$)	HCl, HNO_3 or HI	1.00	Cleavage face. Velocity with HBr *ca.* 40% higher
Aragonite ($CaCO_3$)	HCl or HNO_3	0.48	Face (010)
Dolomite ($CaCO_3.MgCO_3$)	HCl or HNO_3	0.025	Face not specified
Witherite ($BaCO_3$)	HCl or HNO_3	1.28	Face not specified
Smithsonite ($ZnCO_3$)	HCl or HNO_3	0.087	Face not specified
Cerussite ($PbCO_3$)	HNO_3	0.76	Face (010)
Azurite [$2CuCO_3.Cu(OH)_2$]	HCl or HNO_3	0.33	Face not specified
Malachite [$CuCO_3.Cu(OH)_2$]	HCl or HNO_3	0.23	Massive
Marble ($CaCO_3$)	HCl or HNO_3	1.7	Massive

12. Copper in Aqueous Ammonia

Reaction autocatalytic, accelerated by dissolved copper. $K = \frac{v}{S(C+\alpha)}\frac{dC}{dt} = \frac{v}{S(t_2 - t_1)} \ln \frac{C_2 + \alpha}{C_1 + \alpha}$ in which C = concentration of dissolved copper. $\alpha = \frac{K_0}{K}$, $K_0 = \left(\frac{v}{S}\frac{dC}{dt}\right)_{C=0}$, the initial velocity. For a given concentration of dissolved oxygen K_0 and α are constants. K_0 is approximately proportional to the square root of the oxygen concentration; K is practically independent of it. The validity of this equation ends abruptly with the formation of an oxide coating on the metal, due to accumulation of OH^- ions produced by the reaction. This stage is deferred by a higher concentration of ammonia, and also by ammonium salts.

Mean values of K for various constant concentrations of ammonia in solutions kept saturated with air. Two copper plates 1.5 × 1.3 cm describe in liquid a circular path 2 cm in radius, 1120 r.p.m.; S = 7.6 to 8.6 cm²; 24.8°C (32).

$K_0 = 13.6 \times 10^{-4}$		$\alpha = 0.0020$
NH_3, mole/l	NH_4 salt, mole/l	K,* cm/min
1.047	0	0.640
1.921	0	0.703
3.963	0	0.653
1.047	$(NH_4)_2SO_4$, 0.01	0.710
1.088	$(NH_4)_2SO_4$, 0.05	0.680
1.080	$(NH_4)_2SO_4$, 0.1	0.671
1.080	NH_4NO_3, 0.1	0.681
1.080	NH_4Cl, 0.1	0.691
		Mean 0.679

* The results show that within these limits K is independent of the concentration of free ammonia and of ammonium salts.

13. Silver in Aqueous Potassium Cyanide

For constant concentration of dissolved oxygen $K = \frac{v}{St}\left[m(C_0 - C) + \log_{10}\frac{C_0}{C}\right]$ in which C = concn. of KCN, C_0 = initial concn., m = a constant = $0.4343 \frac{k_2}{k_1}$ (k_2 = velocity constant of the diffusion of cyanide. k_1 = velocity constant of the chemical reaction at interface). The validity of this equation is ultimately disturbed by OH^- ions produced by the reaction itself, and the sooner the smaller the value of C_0.

Mean values of K and m for various initial concentrations of KCN for solutions kept saturated with air.* Stirring like last; 600 r.p.m.; two silver plates 1.5 × 1.2 cm; S = 7.3 to 8.7 cm², 25°C (33).

C_0, mole/l	m	K, cm/min	C_0, mole/l	m	K, cm/min
0.1480	135	0.226	0.0042	140	0.231
0.0632	140	0.230	0.0022	150	0.217
0.0316	145	0.231	0.0011	150	0.209
0.0158	155	0.222		——	——
0.0079	140	0.225		Mean 144.4	0.224

* In solutions saturated with pure oxygen the velocity of dissolving, $\frac{dC_{Ag}}{dt}$, was 2.5 times larger, indicating approximate proportionality with $[O_2]^{1/2}$. K was also increased but in a somewhat smaller ratio.

14. Zinc in HCl Dissolved in Alcohols and in Acetone

A thin rod of zinc mechanically raised and lowered in liquid 72 times per minute. S = 2.78 cm²; organic solvents anhydrous, and contained initially 0.5 mole/l of HCl; presence of a small amount of H_2O in CH_3OH, C_2H_5OH and $(CH_3)_2CO$ lowered velocity; 20°C (34).

* Two other determinations at different concentrations but same temperature range gave 1.29 and 1.30, respectively.

† Practically the same value was obtained also in mechanically stirred solutions.

RELATIVE VELOCITIES FOR DIFFERENT CRYSTAL FACES

In the case of simple (reversible) solution in a solvent a difference in the observed velocities of dissolving of two faces of the same crystal may be partly or wholly due to a difference in the solubilities (C_s) of the two faces, rather than in their velocity constants K. In some cases the evidence decidedly favors this explanation, notably when the velocities for the two faces differ appreciably only when the solution is nearly saturated.

Sodium Chloride in Water and in Various Solutions

Dissolving face vertical. No stirring. 25°C (14). The table summarizes results for other faces compared with results for cube. Owing to influence of convection currents, K for cube increased linearly with $(C_s - C)$. A face other than the cube gave a different value of K and a different rate of increase if C_s for cube was used in the calculations, but complete agreement was obtained by assuming C_s for the second face to differ by the percentage amount, Δ. Differences were appreciable only in solutions very nearly saturated, and disappeared entirely if saturation was 90% or less. The author concludes that K has the same value within error of experiment for all faces of NaCl, and that Δ represents actual percentage differences in the solubility of the given face from that of the cube.

Iceland Spar in HCl

Single exposed surface vertical. Stirring by gas evolved only. 15° (21). For surfaces cut, 1, parallel to principal axis; 2, parallel to cleavage plane; and 3, perpendicular to axis.

$$V_1: V_2: V_3 = 1.00: 1.05: 1.14$$

α-Chlorodinitrobenzene in Ether (1)

Prism (110) was compared with pinacoid (001). When the same value of C_s was used in the calculations for both faces the ratio $K_{(110)} : K_{(001)}$ varied with the concentration, reaching 0.4 in nearly saturated solution but approaching unity at slightly lower concentration. The author concludes that $K_{(110)} = K_{(001)}$ and that observed differences are due entirely to the fact that prism face is less soluble than the pinacoid. 15.1° and 19.8°; mechanical stirring.

VELOCITY OF CRYSTALLIZATION

H. C. Burger

FORMATION OF CRYSTAL NUCLEI

If extraneous influences are eliminated, the number, N, of nuclei which are formed at a given temperature should be proportional to the volume of the liquid and to the time. This number is a characteristic temperature function of the liquid. Transition in the crystal state from one form to another can occur spontaneously in a similar manner.

The measurements of the number of nuclei are however not very accurate, and the values given below represent, therefore, only order of magnitude. The first temperature given is the melting point. N is given in cm^{-3} sec^{-1}.

FORMATION DES NOYAUX CRISTALLINS

Si l'on élimine les influences extérieures, le nombre, N, de noyaux qui sont formés à une température donnée doit être proportionnel au volume du liquide et au temps. Ce nombre est pour un liquide une fonction caractéristique de la température. La transition à l'état cristallin d'une forme dans une autre peut se produire spontanément d'une manière analogue.

Les mesures du nombre de noyaux ne sont cependant pas très précises et les valeurs données ci-dessous ne représentent par conséquent que l'ordre de grandeur. La première température donnée est le point de fusion. N est exprimé en cm^{-3} sec^{-1}.

BILDUNG VON KRISTALLKEIME

Wenn äussere Einflüsse eliminiert sind, sollte die Zahl, N, der bei gegebener Temperatur gebildeten Keime, dem Volum der Flüssigkeit und der Zeit proportional sein. Diese Zahl ist eine für die Flüssigkeit charakteristische Temperaturfunktion. In ähnlicher Weise können im kristallisierten Zustande spontan Übergänge von der einen Form in die andere stattfinden.

Die Messungen der Keimzahl sind aber nicht sehr genau, und die folgenden Werte geben deshalb nur die Grössenordnung an. N ist in cm^{-3} sec^{-1} gegeben.

FORMAZIONE DEI GERMI CRISTALLINI

Quando siano eliminate influenze esterne, il numero, N, di germi che si formano ad una data temperatura, deve essere proporzionale al volume di liquido ed al tempo. Questo numero è una funzione della temperatura caratteristica per il liquido. In maniera simile possono verificarsi trasformazioni (allo stato solido) di una forma cristallina nell'altra.

Le misure del numero di germi non sono però molto esatte, ed i valori seguenti danno perciò solo un'idea dell'ordine di grandezza. La prima temperatura data è il punto di fusione. N è dato in cm^{-3} sec^{-1}.

Piperine, $C_{17}H_{19}NO_3$.—N is a maximum at 40 ± 5° and equals 0.2 to 10 (45); *cf.* (54).

CRYSTAL GROWTH

The linear crystallization velocity at the crystal-liquid boundary is a function of its temperature (9, 10) which, however, is seldom measured (10, 53), the temperature of the surrounding bath only, being known. The maximum linear crystallization velocity (K. G.) of the liquid or transition velocity (U. G.) of one crystal phase to another is a characteristic property of the substance, which, however, is very sensitive to impurities, so that the values recorded below may be 5–10% in error from this cause, in cases where another precision is not indicated.

Maximum linear crystallization (K. G.) and transition (U. G.) velocities. The unit is millicentimeters (10^{-3} cm) per sec; M. P. = melting point, °C; (*s*) = stable form; (*m*) = metastable form.

ACCROISSEMENT DU CRISTAL

La vitesse de cristallisation linéaire dans la zone cristal liquide est une fonction de sa température (9, 10) qui est cependant rarement mesurée (10, 53). Dans la plupart des cas on ne connait que la température du bain environnant. La vitesse maximum de cristallisation linéaire (K. G.) du liquide, ou la vitesse de transition (U. G.) d'une phase cristalline en une autre, est une propriété caractéristique de la substance qui est cependant très sensible aux impuretés. Les valeurs données ci-dessous peuvent donc être entachées d'une erreur de 5 à 10% lorsque la limite de l'erreur n'est pas exprimée.

Vitesse maximum de cristallisation linéaire (K. G.) et vitesse de transition (U. G.). L'unité est le millicentimètre (10^{-3} cm) par sec; M. P. = point de fusion, °C; (*s*) = forme stable; (*m*) = forme metastable.

KRISTALLWACHSTUM

Die lineare Kristallisationsgeschwindigkeit an der Grenze Kristall-Flüssigkeit ist eine Funktion deren Temperatur (9, 10), welche aber selten gemessen ist (10, 53). Meistens ist nur die Temperatur des umgebenden Bades bekannt. Die maximale lineare Kristallisationsgeschwindigkeit der Flüssigkeit (K. G.) oder die Umwandlungsgeschwindigkeit (U. G.) der einen Kristallphase in die andere ist eine charakteristische Eigenschaft der Substanz, welche aber sehr empfindlich gegen Verunreinigungen ist. Deshalb können die unten angegebenen Werte mit einem Fehler von 5–10% behaftet sein, wenn keine andere Fehlergrenze genannt wird.

Maximale lineare Kristallisationsgeschwindigkeit (K. G.) und Umwandlungsgeschwindigkeit (U. G.). Die Einheit ist 10^{-3} cm pro sec; M. P. = Schmelzpunkt, °C; (*s*) = stabile Form; (*m*) = metastabile Form.

ACCRESCIMENTO DEI CRISTALLI

La velocità lineare di cristallizzazione in corrispondenza della zona di contatto cristallo-liquido è una funzione della temperatura (9, 10) alla quale essa si trova; questa temperatura però raramente è stata misurata direttamente (10, 53). Per lo più si conosce soltanto la temperatura del bagno nel quale il sistema in esame è immerso. La velocità lineare massima di cristallizzazione di un liquido (K. G.) o di trasformazione (U. G.) di una fase cristallina nell'altra è una proprietà caratteristica delle sostanze. Essa risente però molto l'influenza delle impurezze, per modo che i valori sotto riportati possono essere inesatti del 5–10%, quando non siano indicati altri limiti di errore.

Velocità lineare massima di cristallizzazione (K. G.) e velocità di trasformazione (U. G.). L'unità è 10^{-3} cm al secondo; M. P. = punto di fusione, °C; (*s*) = forma stabile, (*m*) = forma metastabile.

INTERDIFFUSION OF GASES AND VAPORS

W. P. BOYNTON AND W. H. BRATTAIN

By the coefficient of diffusion of one gas or vapor into another is meant the quantity D occurring in the equation $\frac{\delta p_1}{\delta t} = \frac{\delta}{\delta x}\left(D\frac{\delta p_1}{\delta x}\right)$; t = time, p_1 = partial pressure of the diffusing gas, and x = a length in the direction of the diffusion (14, 15, 22, 24). As D varies only slightly with p_1, a good first approximation is $\frac{\delta p_1}{\delta t} = D\frac{\delta^2 p_1}{\delta x^2}$. For a given pair of gases (A, B), the value of D for diffusion of A into B is the same as that for B into A; also $D = D_0\left(\frac{T}{T_0}\right)^m \frac{p_0}{p}$, where D_0 = the value of D at T_0 (=273°K) and p_0 (= 1 atm.), D is its value at absolute temperature T and pressure p, and m is a constant which theoretically lies between 1.5 and 2.0, and practically may be taken either as 1.75 or as 2.00, depending upon the gases (9, 10, 14, 15). For methods of measurement, *see* (13, 17, 22). A temperature gradient in a mixture of two gases produces a diffusion of the more massive molecules towards the region of lower temperature (1, 2, 3, 4, 5). For separation of gases by diffusion through porous septa, *see* (7, 20); for diffusion through metals, *see* p. 77; through glass, rubber, and other solids, *see* p. 76. For diffusion of radioactive gases, *see* Vol. I, p. 364; of ions in gases, consult the index at the end of the last volume.

𝔄-𝔅-TABLE

DIFFUSION OF GASES INTO GASES

$D = D_0\left(\frac{T}{T_0}\right)^m \frac{p_0}{p}$, m = 2.00 for all cases except those marked * for which m = 1.75

COEFFICIENTS OF DIFFUSION IN LIQUIDS

H. R. Bruins

CONTENTS

Abbreviations and Conventions

Δ.—Defined by the equation $\frac{\partial c}{\partial t} = \Delta \frac{\partial^2 c}{\partial x^2}$ where c is the concentration of the diffusing substance at the time t and x is the distance in the direction of the diffusion. The diffusion coefficient, Δ, ("*true*" diffusion coefficient), is thus a function of c. In the following tables these "*true*" diffusion coefficients are in all cases marked with an *asterisk* and they correspond to the concentration given in the c-column of the table, this concentration being also marked with an asterisk.

All unmarked values in the Δ*-column of the tables represent some kind of "mean" value of* Δ over a range of concentration: they correspond to a diffusion *from* an initial concentration, c_0, (appearing in the c-column) *into* the pure solvent (unless otherwise indicated). These "*mean*" values depend also on the method employed and in some cases on the type of apparatus used; values obtained by different methods are therefore *not comparable*.

As far as possible the experimental methods employed in determining these "*mean*" values are indicated by Roman numerals as follows:

I. Method of steady state.
II. Second method of Graham (27, 93).
III. Method of Stefan-Schuhmeister (118).
IV. First method of Graham (114, 143).
V. Indicator method (2, 127).

$c = 0^*$ indicates diffusion in very dilute solution. Δ is then practically identical with Δ_∞ (diffusion coefficient for infinite dilution). Temperature coefficient $\alpha = \frac{\Delta_{t_1} - \Delta_{t_2}}{\Delta_{t_1}(t_1 - t_2)}$, where $t_1 > t_2$.

Units

Values of Δ are in cm²/sec. Values of c are in gram-moles per liter except in the case of electrolytes where they are in g-equiv. per liter.

Accuracy

The values following the ± sign indicate (*a*) in the case of the "true" Δ, the estimated *possible* error in the *absolute* value; resp. (*b*) in the case of the "mean" Δ, the *possible* deviation from the correct value for the experimental method employed. The actual errors will *probably* not exceed these values. The reliability of the Δ values is indicated in many cases as follows:

Symbol	A	B	C	D	E	F
Error probably < ±	2%	3%	5%	7%	10%	(?)

HEAT CAPACITY

MECHANICAL EQUIVALENT OF HEAT

T. H. Laby and E. O. Hercus

Data based upon electrical measurements have been recalculated to the basis of International ohm = 1.000 52 × 10^9 cgsm, International ampere (defined by silver voltameter) = 0.999 97 × 10^{-1} cgsm, International volt (defined by ampere and ohm) = 1.000 49 × 10^8 cgsm, Weston normal cell at 20°C = 1.0188 × 10^8 cgsm. Reduction to the 20°C, or the mean, calorie is by Callendar's formula (3).

$$c = 0.98536 + \frac{0.504}{t + 20} + 0.0084\,\frac{t}{100} + 0.009\left(\frac{t}{100}\right)^2$$

c = specific heat in gram-calories, t = °C.

THE HEAT CAPACITY OF GASES AND VAPORS

A. Leduc

Contents

Conversion Factors

To convert joule g^{-1} deg^{-1} C into g-cal_{15} g^{-1} deg^{-1} C or into BTU_{60} $lb.^{-1}$ deg^{-1} F, multiply by 0.2389_5.

For conversion into other units, *v.* Vol. I, p. 24.

Abbreviations, Symbols and Units

c_p (resp. c_v) Heat capacity per gram at constant pressure (resp. at constant volume).

C_p (resp. C_v) Heat capacity per gram-mole at constant pressure (resp. at constant volume).

c_m (resp. C_m) Mean capacity.

δ $c_p - c_v$.

γ $c_p/c_v = C_p/C_v$.

Units: Throughout this section, unless otherwise indicated, the unit of heat energy is the joule, the unit of mass, the gram (or gram-mole) and the unit of temperature, the degree centigrade.

Matières

Facteurs de conversion

Pour convertir les C exprimées en joules g^{-1} deg^{-1} C en cal_{15}-g g^{-1} deg^{-1} C, ou en BTU_{60} $lb.^{-1}$ deg^{-1} F multiplier par $0{,}2389_5$.

Pour convertir en d'autres unités, *v.* Vol. I, p. 24.

Abréviations, symboles et unités

c_p (resp. c_v) Capacité calorifique par gramme sous pression constante et à volume constant respectivement.

C_p (resp. C_v) Capacité calorifique par molécule-gramme sous pression constante et à volume constant respectivement.

c_m (resp. C_m) Capacité moyenne.

δ $c_p - c_v$.

γ $c_p/c_v = C_p/C_v$.

Unités: Dans cette section, à moins d'indication contraire, l'unité d'énergie calorifique est le joule, l'unité de masse le gramme (ou la molécule-gramme), et la température est exprimée en degrés centigrades.

Inhaltsverzeichnis

Umrechnungsfaktoren

Um Joule g^{-1} $Grad^{-1}$ C in Gramm-cal_{15} g^{-1} $Grad^{-1}$ C umzurechnen multipliziere man mit $0{,}2389_5$.

Für Umrechnungen zu anderen Einheiten, *siehe* Bd. I, S. 24.

Abkürzungen, Zeichen und Einheiten

c_p (bezw. c_v) Wärmeinhalt pro Gramm bei konstantem Druck (bezw. bei konstantem Volumen).

C_p (bezw. C_v) Wärmeinhalt pro Gramm-Mol bei konstantem Druck (bezw. bei konstantem Volumen).

c_m (bezw. C_m) Mittlere Wärmeinhalt.

δ $c_p - c_v$.

γ $c_p/c_v = C_p/C_v$.

Einheiten: Wenn nichts besonderes angegeben, so ist durchgehend in diesem Abschnitt die Einheit der Wärmeenergie in Joule, die Einheit der Masse in Gramm (oder Gramm-Mol) und die Temperatureinheit in Centigraden, angegeben.

Indice

Fattori di conversione

Per convertire i joule g^{-1} $gradi^{-1}$ C in g-cal_{15} g^{-1} $gradi^{-1}$ C oppure in BTU_{60} $lb.^{-1}$ $gradi^{-1}$ F bisogna moltiplicare per $0{,}2389_5$.

Per le conversioni in altre unità, *vedi* Vol. I, p. 24.

Abbreviazioni, simboli e unità

c_p (oppure c_v) Capacità calorifica per grammi sotto pressione costante (oppure a volume costante).

C_p (oppure C_v) Capacità calorifica per grammimolecola sotto pressione costante (oppure a volume costante).

c_m (oppure C_m) Calore specifico medio.

δ $c_p - c_v$.

γ $c_p/c_v = C_p/C_v$.

Unità: In questo capitolo, a meno che non sia altrimenti indicato, l'unità di energia calorifica è il joule, l'unità di massa, il grammo (o la grammimolecola) e l'unità di temperatura, il grado centigrado.

INTRODUCTION

Each of the four quantities, c_p, c_v, δ and γ, is capable of independent experimental determination and it is sufficient to know any two in order to calculate the other two, but knowledge of a third serves as a valuable check.

The most accurate determinations of γ are based upon the measurement of the velocity of sound, V, and the relations:

$$V = \sqrt{\frac{E}{d}} = \frac{1}{d}\sqrt{-\gamma\frac{\partial p}{\partial v}} \qquad \text{(Laplace)}$$

and

$$V_{\text{obs.}} = V\left(1 - \frac{\mathrm{k}}{2r\sqrt{\pi N}}\right) \qquad \text{(Kirchhoff)}$$

where d is the density of the gas; v, the specific volume; $V_{\text{obs.}}$, the velocity as measured in a tube of radius $r \geq 2.5$ cm; N, the frequency; and k, a correction factor (= *ca.* 0.65) which depends in an unknown manner upon the properties of the gas (*e.g.*, upon the viscosity) and upon the nature of the tube.

The quantity δ is computed from the thermodynamic relation

$$\delta = T\left(\frac{\partial p}{\partial T}\right)_v\left(\frac{\partial v}{\partial T}\right)_p$$

In preparing the tables in this section the values of $\partial p/\partial T$, $\partial v/\partial T$ and $\partial p/\partial v$ required in the above equations were obtained by one (or more) of the following methods, preference being given in the order shown: (1) Accurate values based upon direct measurement; (2) values deduced from an equation of state known to correctly reproduce the observed p, v, T for the gas; (3) values deduced from a general equation of state obtained by the author. Method (3) was used in the majority of cases. For details, *v.* (29, 35).

Owing to the fact that the available data give, in many instances, opportunities for frequent cross-checks, it is not always possible to indicate, except partially, the source of all of the experimental data upon which the values given below are based. For a critique of the experimental data in this field and a discussion of the various corrections required, *v.* (35.5).

In all of the tables given below the quantity recorded is the total heat capacity, that is, it includes, for example, any "heat of dissociation" which may accompany the rise in temperature. Consequently a value given cannot be taken as the "true" specific heat of a molecular species unless it is known that a dissociation equilibrium is not involved.

VALUES OF c_p AT HIGH TEMPERATURES

Mean of (13 and 41) ±10%

t	309°	422°	523°
C_p	41.4	43.9	47.08
c_p	2.43	2.59	2.76

Nernst (41) gives $C_p = 8.62 + 0.002t + 7.2 \times 10^{-9}t^2$, g-cal$_{15}$/mole. Range 0 to 680°.

For very high temperatures Budde (3) gives the equation $C_p = 11.8 + 0.024 \times (t - 1400)$, g-cal$_{15}$/mole. This gives 11.8 at 1400° and 21.4 at 2200°.

CO, *v.* p. 86

CO_2

EFFECT OF TEMPERATURE AT p = 1 ATM. (2, 11, 15, 48)

$C_p = 6.63 + 5.54 \times 10^{-3}t - 2.47 \times 10^{-6}t^2 + 4.7 \times 10^{-10}t^3$, g-cal$_{15}$/mole (53)

t, °C	$C_p - C_v$	γ	C_p	C_m, 0–t°
0	8.600	1.310	36.33	36.33

THERMODYNAMIC QUANTITIES: VALUES OF THE HEAT CAPACITY, ENTROPY, HEAT CONTENT AND "THERMODYNAMIC POTENTIAL" FOR PURE SUBSTANCES BETWEEN 0 AND 298°K

W. H. Rodebush and Esther Rodebush

Contents

Introduction

Unless otherwise indicated, the values given in this section apply in all cases to the form which is stable under 1 atm. pressure at the temperature in question.

In all cases, the mass unit is the gram-formula-weight, the energy unit is the joule, and the temperature unit is °K. The pressure is 1 atmosphere.

In all cases, the value of each of the quantities tabulated is assumed to be 0 at 0°K.

The number of units uncertain in a given place of significant figures is indicated by the number of bars over the figure in that place, one bar indicating ± 1 to 3 units, two bars, ± >3 units.

C_p Heat capacity per gram-formula-weight.

S Entropy.
H Heat content. Computed from heats of formation in the case of compounds.

Matières

Introduction

À moins d'une autre indication, les valeurs données dans cette section se rapportent dans tous les cas à la forme qui est stable sous une pression d'une atmosphère à la température en question. Dans tous les cas, l'unité de masse est le poids moléculaire, l'unité d'énergie est le joule, et l'unité de température est le degré K. La pression est 1 atmosphère.

Dans tous les cas, la valeur concernant chaque quantité mentionnée est supposée être 0 à 0°K.

Le nombre d'unités incertaines à une place donnée des chiffres significatifs est indiqué par le nombre de barres se trouvant sur le chiffre à cette place, une barre indiquant ± 1 à 3 unités, deux barres, ± > 3 unités.

C_p Capacité calorifique par molécule gramme.

S Entropie.
H Chaleur totale. Calculée à partir des chaleurs de formation dans le cas des composés.

Inhaltsverzeichnis

Einleitung

Wenn nichts anderes angegeben, so beziehen sich die gegebenen Werte dieses Abschnittes in allen Fällen auf die bei 1 Atm. und der fraglichen Temperatur, stabile Form.

In allen Fällen ist die Mengeneinheit das Grammformelgewicht, die Einheit der Energie ist Joule und die für die Temperatur ist °K. Der Druck ist 1 Atmosphäre.

In allen Fällen wird angenommen, dass jede Grösse, welche in der Tabelle angegeben ist, bei 0°K selbst Null ist.

Die Zahl der Einheiten die an einer gegebenen Stelle einer gewerteten Zahl unsicher sind, werden durch die Anzahl von Strichen über der Zahl an dieser Stelle angezeigt. Ein Strich bedeutet ± 1 bis 3 Einheiten, zwei Striche ± mehr wie 3 Einheiten.

C_p Wärmekapazität pro Grammformelgewicht.

S Entropie.
H Wärmeinhalt. Berechnet aus der Bildungswärme im Falle einer Verbindung.

Indice

Introduzione

I valori riportati in questo capitolo si riferiscono (a meno che non sia altrimenti indicato) alla forma stabile a pressione atmosferica e alla temperatura in questione.

In tutti i casi l'unità di massa è la grammimolecola, l'unità di energia il joule e l'unità di temperatura il °K. La pressione è 1 atmosfera.

In tutti i casi il valore delle quantità riportate nella tabella è supposto essere 0 a 0°K.

Le unità di cui è incerto un determinato numero significativo, sono indicate dal numero di linee stampate sopra la cifra stessa. Una linea indica ± da 1 a 3 unità, due linee ± > 3 unità.

C_p Calore specifico per un peso in grammi corrispondente alla formula.

S Entropia.
H Capacità termica. Computata, nel caso di composti, dai calori di formazione.

LATENT HEATS OF FUSION

R. DE FORCRAND AND L. GAY

Scope of the Tables.—The data given in the following tables are based solely upon the best available direct calorimetric determinations and do not take into account the values, sometimes more reliable, which can be computed by indirect methods. For such values the reader should consult the appropriate sections of I. C. T. as indicated in the index under, "Fusion, heat of."

Calorimetric Methods. *A.*—m grams of the pure substance which has been in the crystalline state for a long period of time (hereafter referred to as the "stable" crystalline form) is taken at a temperature slightly below its fusion point t_F and is introduced into a calorimeter, the temperature of which is slightly above t_F. The final state of the substance is liquid. The total effect produced is composed of (*a*) the heat absorbed by the solid up to t_F, (*b*) the heat absorbed by the liquid between t_F and the final temperature, and (*c*) the heat of fusion. Knowing the two specific heats, the heat of fusion, L_F, at the M. P., is obtained by difference.

B.—As in Method *A*, but in the reverse order, the liquid substance slightly above its fusion point is introduced into the calorimeter, where it crystallizes. This experiment gives directly the heat of solidification, L_D, rather than the heat of fusion, L_F. The heat of solidification is sometimes less than the heat of fusion, because at the moment of solidification the substance does not always liberate its entire heat of fusion. The determination of L_F is therefore preferable.

C.—Two samples of the pure substance are employed, one in the "stable" crystalline form, the other in the form of the supercooled liquid, and both at the same temperature, which is substantially that of the calorimeter. In two separate experiments the substance is brought to the same final state which may be anything, but is the same for the two samples. The difference between the two values found gives directly the heat of fusion. In this case there is no difference between L_F and L_D if the crystalline sample employed is in the "stable" form. In most cases the final state in such an experiment is a solution in the calorimetric liquid, but obviously it might be any state. The value finally obtained by Method *C* is the heat of fusion at the temperature of the calorimeter and is identical with the heat of fusion at the melting point only in case the calorimeter is operated in the neighborhood of this temperature.

D.—The super-cooled substance is maintained in the calorimeter until temperature equilibrium is secured, and crystallization is then produced by seeding. This method gives L_D.

E.—In this method (Wigand) the "stable" crystalline substance is melted in the calorimeter by means of a measured amount of electrical energy. This method gives L_F directly, but requires a calorimetric liquid with a melting point lower than t_F.

F.—The method of thermo-analysis (W. Plato) gives reliable results in cases where L_F is known for an analogous substance having approximately the same melting point. The method is a relative one.

G.—In the method of L. Meyer, a Bunsen calorimeter is employed, the calorimetric liquid being the pure substance at its melting point. The determination consists in measuring the variation in volume, ΔV, which accompanies the fusion of 1 g of the substance. In a second experiment, a known quantity of heat Q is introduced into the calorimeter electrically and the accompanying volume change $\Delta V'$ is measured. $\Delta V'/\Delta V$ gives the mass m of the substance melted. The heat of fusion is then

$$\frac{Q}{m} = \frac{Q}{\Delta V'}\Delta V.$$

The temperature t_F being constant, a knowledge of the specific heats is unnecessary.

H.—Special methods, for which see the literature cited.

I.—Method not given by the author.

Conversion Factors.—1 Kilojoule per g = 238.9 cal$_{15}$ g^{-1} = 430.1 BTU$_{60}$ lb.$^{-1}$ = 9.869 l-atm. g^{-1} = 2.778 × 10^{-4} kw hr g^{-1}. For other factors, *v.* Vol. I, p. 24.

LATENT HEAT OF VAPORIZATION

The values recorded in this section are based upon direct calorimetric determinations. For values based upon vapor pressure data, *see* the vapor pressure sections of Vol. III, p. 201, 204, 207, 213, 215, 302, and for metals, *v.* Vol. II, p. 458; Vol. III, p. 204.

CONVERSION FACTORS

1 joule = 0.2392 g-cal$_{20}$; = 0.2389 g-cal$_{15}$; = 2.778×10^{-7} kw. hr; = 0.7376 ft. lb.; = 9.870×10^{-3} l-atm.; = 9.482×10^{-4} BTU$_{60}$.

Oxygen-Nitrogen Mixtures under One Atmosphere

The quantity recorded below is the difference in heat content between the liquid at its boiling point and a vapor of the same composition at its initial condensation temperature. Accuracy: 0.2 % absolute, 0.1 % relative (7.5).

% O_2 in liq	0	5	10	15	20	25	30

CHEMICAL COMPOUNDS

Farrington Daniels and J. Howard Mathews

l_v = latent heat of vaporization, joules per gram, at t, °C to produce saturated vapor at t°, the liquid being under its own vapor pressure during evaporation.

The values marked with an asterisk (*) were obtained by measuring the heat of condensation. All other values were obtained by measuring the input of electrical energy necessary to evaporate a given weight of liquid.

The results by condensation methods (*) are usually too low on account of premature condensation and are unreliable also, because the specific heat of the liquid is usually not accurately known. Most of the results published before 1900 may be too low by 10 joules or more.

For the substances marked with a dagger (†) the value given is taken from the detailed tables of the next section, p. 138.

Parentheses ( ) around the temperature indicate that the temperature was not recorded in the original communication and that the normal boiling point has been taken. The corresponding value of Trouton's ratio is also enclosed in parentheses.

---

l_v = chaleur latente de vaporisation, joules par g à t, °C nécessaires pour produire la vapeur saturée à $t°$, le liquide étant sous sa propre tension de vapeur pendant l'évaporation.

Les valeurs marquées d'un astérisque (*) ont été obtenues en mesurant la chaleur de condensation. Toutes les autres valeurs ont été obtenues en mesurant l'apport d'énergie électrique, nécessaire pour évaporer un poids donné de liquide.

Les résultats obtenus par les méthodes de condensation (*) sont ordinairement trop faibles par le fait d'une condensation prématurée et sont aussi moins digne de confiance par le fait que la chaleur spécifique du liquide n'est généralement pas connue d'une façon précise. La plupart des résultats publiés avant 1900 peuvent être trop faibles de 10 joules et plus.

Pour les substances marquées d'une croix (†), la valeur donnée est extraite des tables détaillées de la section suivante, p. 138.

La température marquée entre parenthèses ( ) indique que la température n'a pas été mentionnée dans le mémoire original et que le point d'ébullition normal a été choisi. La valeur correspondante du rapport de Trouton est aussi mise entre parenthèses.

---

l_v = latente Wärme der Verdampfung, in Joule pro Gramm bei t, °C für die Erzeugung von gesättigten Dampf bei $t°$. Während der Verdampfung befindet sich die Flüssigkeit unter ihrem eigenen Dampfdruck.

Die mit einem Stern (*) bezeichneten Werte sind durch Messung der Kondensations-Wärme erhalten worden. Alle anderen Werte sind durch Messung der angewandten elektrischen Energie erhalten, die notwendig ist, eine gegebene Gewichtsmenge Flüssigkeit zu verdampfen.

Die nach der Kondensationsmethode (*) erhaltenen Werte sind gewöhnlich zu niedrig, einmal wegen der vorzeitigen Kondensation, dann aber auch deshalb, weil die spezifische Wärme der Flüssigkeit gewöhnlich nicht genau bekannt ist. Viele der Werte die vor dem Jahre 1900 publiziert worden sind, dürften deshalb um etwa 10 oder mehr Joule zu niedrig sein.

Für die mit einem Schwert (†) bezeichneten Stoffe ist der angegebene Wert einer besonderen Tabelle des folgenden Abschnittes, S. 138, entnommen.

Die in Klammer ( ) gesetzten Temperaturen bedeuten, dass diese nicht in der Originalmitteilung angegeben ist und der normale Siedepunkt genommen ist. Der entsprechende Trouton'sche Quotient ist ebenfalls in Klammer gesetzt.

---

l_v = calore latente di vaporizzazione, joules per g necessari a t, °C per produrre vapore saturo a $t°$, supponendo il liquido durante l'evaporazione sotto la sua tensione di vapore.

I valori segnati con un asterisco (*) sono stati ottenuti misurando il calore di condensazione. Tutti gli altri sono stati ricavati dal consumo di energia elettrica necessaria ad evaporare un dato peso di liquido.

I risultati ottenuti con il metodo di condensazione (*) sono per lo più troppo bassi a causa di una condensazione prematura e sono incerti anche perchè il calore specifico dei liquidi in genere, non è esattamente conosciuto. La massima parte dei risultati pubblicati prima del 1900, possono essere più bassi di 10 joules o anche più.

Per le sostanze segnate con (†) il valore dato è preso dalle tabelle riportate nella sezione seguente a p. 138.

Le temperature chiuse tra parentesi ( ) significano che non trovandosi indicata la temperatura nella memoria originale si è preso il punto di ebollizione normale. Il valore corrispondente del rapporto di Trouton è anche chiuso tra parentesi.

$$\text{Trouton's ratio, } \frac{L_v}{T} = \frac{Ml_v}{273.1 + t}$$

HEATS OF ADSORPTION AND OF WETTING

H. R. Kruyt and J. G. Modderman

HEAT OF ADSORPTION

Abbreviations and Units

A Total amount of gas adsorbed per g of adsorbent, expressed in cm³ reduced to *NTP*, unless otherwise indicated.

Q Total heat evolved by the adsorption of *A*, joules.

Gases on Charcoal

CO	190	115.1	0.606
2H$_2$ + O$_2$	150	71.1	0.474
2CO + O$_2$	195	144.4	0.740

Gases on various kinds of charcoal at room temperature and from 0 to *ca.* 760 mm; A and Q vary with the nature of the charcoal but the ratio is approx. constant (5)

Gas	HCl	HBr	HI	N$_2$O
Q/A	0.429	0.692	0.984	0.332

Gases on Metals

H$_2$ on Ni catalysts at 0° (7)

A, cm^3	Q	$\Delta Q/\Delta A$
Catalyst I. Prepared by heating NiCO$_3$ at 300–320° for 120 hr and out-gassing at 300°; adsorbs 0.9 cm^3 H$_2$ per g at *NTP*		
0.0396	0.1895	4.77
0.0772	0.3086	3.18
0.114	0.4184	2.93
0.180	0.5949	2.68
0.260	0.7936	2.49
0.795	2.0296	2.34
Catalyst II. Reduced for 60 hr; contained 13.5% ThO$_2$; adsorbs 0.72 cm^3 H$_2$ per g at *NTP*		
0.0315	0.0804	2.56
0.0612	0.2325	5.11
0.0918	0.4187	6.08
0.1211	0.5832	5.57
0.2082	1.0143	4.95
0.2453	1.1646	4.01
0.332	1.3581	2.23
0.722	2.1933	2.14
CO$_2$ on Ni catalyst at 0° (7)		
Catalyst III. Reduced from the oxide for 260 hr at 300–320°; contained 4% Ce$_2$O$_3$		
0.082	0.271	3.29
0.619	1.04	1.43
0.874	1.24	0.789

H$_2$ on Ni and Cu at room temperature. The H$_2$ contained an unknown but negligible amount of N$_2$ (1)

A, cm^3	Q	P, range	$\Delta Q/\Delta A$
On Ni reduced from NiO at 300°; results are greatly affected by previous treatment of the Ni			
0.403	0.998	0–2.7	2.48
0.865	2.086	2.7–8.7	2.35
1.123	2.792	8.7–703.4	2.73
On Cu reduced from CuO by H$_2$ at 145°			
0.438	0.786	0–760	1.793

Gases on Ni at 0° and from 0 to 760 mm (6)

H$_2$

Out-gassed at t, °C	A	Q	Q/A
304	5.2	15.70	3.03
240	3.7	10.98	2.97
196	2.9	8.56	2.95
145	2.1	5.49	2.61
120	1.8	4.28	2.38
90	1.5	3.22	2.15
0	0.54	1.16	2.15

Gas	A	Q	Q/A
C$_2$H$_4$	0.88	1.04	1.18
C$_2$H$_6$	0.75	0.78	1.05

H$_2$ and O$_2$ on Pt-black at 0° and from 0 to 760 mm (12); for H$_2$ on Pt-black carefully freed from O$_2$, $A = 0.87$ cm^3 and $\Delta Q/\Delta A = 2.58$; for O$_2$ the values of Q/A vary from 6 to 18 joule/cm^3. The authors consider 6.6 as the best value.

Gases on SiO$_2$ and on Meerschaum

On meerschaum (d = 2.76) (3)

A	Q	P, range	$\Delta Q/\Delta A$
SO$_2$, 0°			
24.24	46.82	0–98.9	1.932

TABLE 8.—STARCH WITH H_2O AT 0° (HEAT OF SWELLING)

The starch has been dried for 21 days in partial vacuum above H_2SO_4, Q = 110.5 joule/g (32).

TABLE 9.—DEXTRIN WITH H_2O

Q = 67.6 joule/g (33).

TABLE 10.—HEAT OF SWELLING AND OF SOLUTION, PER G MATERIAL (36)

Material	Amount	$+H_2O$	Q
Gelatin			
t = 42.5°	1 g	5 g	+13.0
t = 42.5°	1 g + 100% H_2O	4 g	− 4.18
t = 34.3°	1 g + 200% H_2O	3 g	− 4.18
t = 25°	1 g + 300% H_2O	2 g	0
Gum arabic	1 g	5 g	+37.6
	1 g + 50% H_2O	2 g	− 2.5
Gum tragacanth	1 g	5 g	+43.1

TABLE 11.—COLLOIDS WITH H_2O (9)

Colloid	Q	Colloid	Q
$Al(OH)_3$	89.6	Silica gel	101.5
$Fe(OH)_3$	39.3	Fuller's earth	88.9
Quartz	1.88		

TABLE 12.—SILICA AND ANIMAL CHARCOAL, WITH WATER (13)

	Q
Silica (dried at 200°)	55.41
Charcoal (puriss.)	59.55

TABLE 13.—WITH H_2O (18, 19)

Coconut charcoal (out-gassed)	43.9	Bone charcoal	77.4
Coconut charcoal (containing 0.04 g H_2O)	14.6	Fuller's earth	134

TABLE 14.—WITH H_2O

Graphite preheated *in vacuo*. Q = 2.85 joule/g (27).

TABLE 15.—"BAYER" CHARCOAL AT ROOM TEMPERATURE (2)

Liquid	Q	Liquid	Q
$C_2H_5OC_2H_5$	118.4	CH_3OH	126.4
C_6H_6	123.0	C_2Cl_4	137.3
CS_2	125.6	H_2O	51.5*
C_2H_5OH	118.9		

* With 0.66 cm³ H_2O per g. Possibly incomplete wetting.

TABLE 16.—VARIOUS CHARCOALS WITH H_2O AND C_6H_6

The activity, a, is taken as proportional to the adsorptive power for H_2 (21). d is approximate.

a	d	H_2O	C_6H_6	a	d	H_2O	C_6H_6
10		20.9	25.1	75	1.87	154.8	209.0
20		41.8	54.4	90		188.3	251.1
25	1.45	50.2	71.1	98	2.00	205.1	272.0
50		104.6	138.1	100		209.0	280.4

TABLE 17.—CU WITH OILS

All samples (except kerosene) diluted 1:2 with C_6H_6; Q for C_6H_6 taken as 0 (3)

Oil	Q	Oil	Q
Castor oil	0.51	Paraffin oil	0.16
Linseed oil	0.58	Kerosene	0.24
Lubricating oil, distillate	0.60	Kerosene + 1% oleic acid	0.89
Lubricating oil, refined	0.26		

For temperature rise on wetting charcoal with oils, v. (3.5).

TABLE 18.—$PbSO_4$ WITH ITS SATURATED AQUEOUS SOLUTION

For total surface of 5840 to 32 400 cm²/g, Q = 0 (24).

Calculated values for CS_2, ether, alcohol and H_2O (3). Calculated values at 0°C for ethylene chloride, ethyl chloride, ethyl bromide, ethyl iodide, methyl acetate, ethyl acetate, benzene, toluene, xylene, cymene, bromine, mercury, acetone, carbon disulfide, carbon tetrachloride, chloroform and ether (13).

HEAT OF ELASTIC EXTENSION OF METALS

$\frac{\Delta t}{\Delta \tau} = -\frac{aT}{cd}$, where $\Delta\tau$ = tension increase and Δt the corresponding temperature increase, a = the coefficient of thermal expansion, d the density, c the specific heat per gram and T the temperature in °K; Q = heat absorbed.

$\Delta\tau$, kg/cm²	Δt, °C	Q, g-cal$_{15}$/cm³	
Steel at 23.9°C, d = 7.93 g/cm³ (4)			
1656	−0.1369	0.1279	±0.4%
3312	−0.2737	0.2556	
4968	−0.4106	0.3836	
German silver at 16.4°C, d = 8.40 g/cm³ (7)			
969	−0.1405	0.1135±3%	

TEMPERATURE CHANGE IN PLASTIC EXTENSION (6)

$100\ \Delta l/l_0$ = % elongation.

Δt_t = Temp. rise with tension maintained.

Δt_r = Temp. rise on relief of residual tension.

Δt_w = Temp. rise to be expected from work done by tension.

$\frac{\Delta t_t + \Delta t_r}{\Delta t_w}$ = R = Ratio of heat evolved to work done.

Metal	$100\ \Delta l/l_0$ max.*	Δt_t	Δt_r	R
Steel....................	13.10	9.00	0.37	0.86$_5$

HEATS OF SOLUTION OF ORGANIC SUBSTANCES

ERNEST ANDERSON

CONTENTS

Tables 1 and 2 form a complete index to the whole.*

TABLE 1.—HEATS OF SOLUTION OF ORGANIC SUBSTANCES IN WATER

Q is expressed as kilojoules evolved per mole solute, at infinite dilution. These systems are arranged according to the ℭ- arrangement (*v.* Vol. III, p. viii). Inorganic salts of organic acids will be found immediately following the acid.

Formula	Name	*t*, °C	*Q*	Lit. and table numbers
$CHCl_3$	Chloroform	16	9.2	(20)
CH_2N_2	Cyanamide		−15.1	(105)
CH_2O_2	Formic acid (solid)	7	−9.83	(10)

TABLE 2.—HEATS OF SOLUTION OF BINARY ORGANIC SYSTEMS

ℭ-Table.—ℭ-Arrangement (*v.* Vol. III, p. viii)

The B-component where italicized is the solute, and otherwise is the solvent. *Q* is expressed in kilojoules evolved per mole solute, dissolved in more than one mole solvent; at room temperature where not given.

B-Component		*Q*	Lit. and Table No.*
Formula	Name (and temp., °C)		
	CCl_4		
CS_2	Carbon bisulfide	− 1.76	(127); 3
$\mathit{CHCl_3}$	*Chloroform*		3
CH_4O	Methyl alcohol	0.67	(127)

---

* The numbers not in parentheses are numbers of other tables in this section which should be consulted for further data.

HEAT OF DILUTION

FRANK R. PRATT

INTRODUCTION

If to a solution having an initial concentration C_1 and at the temperature *t*, °C water at *t*° is added in sufficient amount to change the concentration to C_2, it is necessary to *abstract* from the system *H* joules of heat in order to keep its temperature constant, the *amount* of solution being that shown by the quantities in which C_1 is expressed. For example, in the table for KCl below; if to a solution composed of 1 gram-mole of KCl and 25 gram-moles of H_2O, C_1 ($=400$) at 18°C, 25 gram-moles of H_2O at 18°C be added, the final concentration will be C_2 ($=200$) and 794 joules of heat must be *supplied* (because of the negative sign) to the resulting mixture in order to maintain it at 18°C. It is the quantity *H* which (unless otherwise indicated) is recorded below. The values given have been interpolated from the original drawings of the graphs of Pratt, *143*, **185**: 663; 18.

TABLE

Ethyl alcohol (Squibb's), C_1 ≎ 400 = 1M C_2H_5OH and 25M H_2O

HEAT OF DILUTION OF AQUEOUS SOLUTIONS OF ETHYL AND METHYL ALCOHOLS

If m grams of water are added to M grams of solution containing N gram-molecular-weights of the alcohol per 1000 g of H_2O the heat (Q) evolved per mole of water added is given by

$$Q = \mathrm{A} - 10^{-3} \times \mathrm{B}m, \text{ g-cal}_{20}/\text{Mole}$$
$$Q = \mathrm{a} - 10^{-3} \times \mathrm{b}m, \text{ joule/Mole}$$

up to m = 800 g. All weights *in vacuo*. t = 25°C. Braham, Atmospheric Nitrogen Corporation, Syracuse, N. Y., *O*. MacInnes and Braham, *1*, **39**: 2110; 17.

HEATS OF COMBUSTION OF ORGANIC COMPOUNDS

Source of the Data

All of the values given in this section have been taken from the critical compilation by Kharasch (¹) to which the reader is referred for bibliography and critical discussion.

Units

The values recorded in the tables are expressed in 1922 International Combustion Calories[1] per gram-formula-weight (*in vacuo*) of substance in the **liquid state** (unless otherwise indicated by g = gas and s = solid) when the combustion takes place **at constant pressure** (1 atm.) and at 18 − 20°C, to form gaseous CO_2 and N_2, liquid H_2O, and such compounds of other elements present as are indicated under the individual entries.

Standard Substances for Combustion Calorimetry

Primary Standard.—The Third Conference of the International Union of Pure and Applied Chemistry (Lyons, 1922) adopted the benzoic acid standard with the following values: Q = 6 324 g-cal₁₅ (≡26 466 abs. j.) per gram in air; =6 319 g-cal₁₅ (≡26 445 abs. j.) per gram *in vacuo; cf.* (³, ⁵). These values define what may be called the "1922 International Combustion Calorie."

Proposed Secondary Standard.—Salicylic acid, Q = 5 242 g-cal₁₅ (≡22 699 abs. j.) per gram in air; =5 238 g-cal₁₅ (≡21 921 abs. j.) per gram *in vacuo* (⁴).

Other Standards.—The best values for cane sugar and naphthalene may be obtained from the following carefully determined ratios of Q per gram in air (²).

$$\frac{\text{Naphthalene}}{\text{Benzoic acid}} = 1.5201. \quad \frac{\text{Benzoic acid}}{\text{Sugar}} = 1.6028. \quad \frac{\text{Naph.}}{\text{Sugar}} = 2.4364$$

Calculation of Heat of Combustion from Structural Formula

The heat of combustion of any organic compound in the liquid state may be calculated from its structural formula with an accuracy, in most cases, of better than 1%. For most purposes for which heats of combustion are required this accuracy is sufficient. Indeed it is equal to or better than the accuracy of most of the experimental values now available. For a full description of the method of calculation and comparison between observed and calculated values, *see* (¹).

Heats of Formation

The heat of formation, H, of any compound ($C_aH_bBr_cCl_dF_eI_fN_gO_hS_i$) out of its elements in their standard states (*v.* p. 169) may be calculated from its heat of combustion, Q, as given below, by means of the equation $H = (-Q + 94.38a + 34.19b +$

---

[1] Calories instead of joules have been employed in this section in deference to the wishes of the Committee on Thermochemistry of the International Union of Pure and Applied Chemistry.

THERMAL CONDUCTIVITY: GASES AND VAPORS

T. H. Laby and E. A. Nelson

Thermal conductivity, k, is defined by the relation

$$\frac{dQ}{dt} = -k\, dx dy \frac{d\theta}{dz},$$

where dQ/dt is the time rate at which heat is conducted in the direction of the temperature gradient, $d\theta/dz$, across a parallel slab of area $dx \cdot dy$.

Theory.—*See* (**1.1, 1.2, 22.1, 22.2**).

Useful Formulae.—The relation, $k = f\eta c_v$ exists between the thermal conductivity, k, the viscosity, η, and the specific heat at constant volume, c_v, where f is "constant," *e.g.*, $k \propto \eta$ if the temperature varies. f depends on the number of atoms in the molecule: for diatomic gases f = *ca.* 1.75; for triatomic *ca.* 1.4; for monatomic 2.5, which is the theoretical value for spherically symmetrical molecules (**13**).

Accuracy of Values of k.—The experimental determination of the thermal conductivity of gases is subject to very large error. For example, the 19 determinations of k for air deviate on the average from the weighted mean (given below) by 7 per cent. The number of observers whose observations were used in deriving the weighted means which follow is equal to the number of literature citations, excluding (**8**).

Units.—In all of the tables of this section the thermal conductivity, k, is expressed in kilo-erg cm^{-2} sec^{-1} $(°C, cm^{-1})^{-1}$.

Conversion Factors.—1 [kilo-erg cm^{-2} sec^{-1} $(°C, cm^{-1})^{-1}$] = 10^{-4} [joule cm^{-2} sec^{-1} $(°C, cm^{-1})^{-1}$] = 0.239×10^{-4} [cal cm^{-2} sec^{-1} $(°C, cm^{-1})^{-1}$] = 0.192×10^{-4} [BTU $ft.^{-2}$ sec^{-1} $(°F, in.^{-1})^{-1}$]. *See further* Vol. I, p. 16.

TEMPERATURE VARIATION OF THERMAL CONDUCTIVITY OF GASES

As k is not a linear function of the temperature, whenever possible a Sutherland equation,

$$k_T = k_{273}\frac{273 + C}{T + C}\left(\frac{T}{273}\right)^{3/2}$$

has been fitted to the observations, where T is the absolute temperature, and the value of the constant C so obtained is used to compute

$$\alpha_0 = \frac{1}{k_{273}}\left(\frac{dk}{dT}\right)_{273}$$

and k_T/k_{273}. When no value of C is given, no Sutherland equation would fit the observations, and the directly observed values of k_t/k_0 or of k_t are given. In parentheses is given the temperature interval over which Sutherland's equation may be applied with accuracy. If α is required for a gas not given below, it may be calculated by using a value of C obtained from viscosity observations on that gas.

VARIATION OF CONDUCTIVITY WITH PRESSURE

According to the dynamical theory of gases, the thermal conductivity of a gas is independent of the pressure if the mean free path is small in comparison with the thickness of the conducting layer.

According to Knudsen (15), when the free path is large in comparison with the distance between two parallel plates, the quantity of heat, Q erg, passing in time t sec, from the plate at a temperature θ_1 to that at a temperature θ_2, is

$$Q = eA(\theta_1 - \theta_2)pt$$

where A cm² is the area of each plate, p dyne cm⁻² the pressure, and e, the "molecular coefficient of conductivity," is a function of θ and depends on the nature of the surfaces and on the nature of the gas. For a complete interchange of energy when the molecule hits the plates, e, (g^{-1} cm^{-1} sec) has the theoretical value,

$$e = \frac{1}{4}\sqrt{\frac{2}{273\pi\rho_0 T}}\,\frac{C_p + C_v}{C_p - C_v} = 1819\,(MT)^{-\frac{1}{2}}\,\frac{\gamma + 1}{\gamma - 1}$$

where T is the absolute temperature, ρ_0, (gram) is the mass of 1 cm³ of the gas at 273° and 1 dyne cm⁻² pressure, and C_p, C_v, its heat capacity at constant pressure and constant volume, respectively. M = molecular weight of the gas and $\gamma = C_p/C_v$. (In calculating the dimensions of e, temperature is assumed to have the dimensions of kinetic energy.) Experiment shows that the heat transferred is smaller than this theoretical value, but approaches it as a limit for rough plates, *i.e.*, for complete exchange of energy, *v.* (25).

MOLECULAR CONDUCTIVITY OF GASES

Calculated value, conduction between absolutely rough surfaces,

$$e = 1819\,\frac{1}{\sqrt{MT}} \times \frac{\gamma + 1}{\gamma - 1}.$$

At 0°C, H_2, $e = 460$ g^{-1} cm^{-1} sec (*i.e.*, unit of heat = 1 erg; O_2, $e = 117$; Cl_2, $e = 127$. If unit of heat is the calorie, e for H_2 at $0° = 10.97 \times 10^{-6}$.

Observed value, Knudsen (15). H_2 at 0°C, $e = 121$ g^{-1} cm^{-1} sec for conduction between glass and rough surface; $e = 70$ for glass and glass, surfaces being cylindrical.

Schreiner's values (25), using a fine drawn platinum wire along the axis of a glass tube: mean free path must be not less than 40 times diameter of wire for data to be valid, *cf.* (27, 28).

A		O_2		H_2*		CO		N_2

THERMAL CONDUCTIVITY OF NON-METALLIC SOLIDS

M. S. Van Dusen

For industrial materials, *see* Vol. II, p. 312, 316; single crystals, p. 230; SiO_2, p. 106. Data for other non-metallic solids, and for such of the preceding as are of special importance in the construction of scientific instruments are given in the following table. Data for crystalline materials and for compressed powders are too scanty to permit any general conclusion to be drawn; the values tabulated are subject to considerable uncertainty. For conductivity of powders under reduced gas pressure, *see* Vol. II, p. 315.

Thermal Conductivity of Non-Metallic Solids

Am. = amorphous, Art. = artificial, Crys. = crystalline, Nat. = natural; B 183 = boils at 183°C; d = density of the specimen at 20°C, not of the individual grains of a powder; D = thermal diffusivity near t_R; K_t = thermal conductivity at t,°C; M 114 = melts at 114°C; p = hydrostatic pressure; P [PP] = compressed [highly compressed] powder; t_R = room temperature. $K_t = C\{1 + \alpha t(10)^{-4}\}$ if t lies within the range indicated; unless 0°C lies within the range, C is not K_0. $K_{t,p} = K_{t,1}\{1 + bp(10)^{-6}\}$. In the portion for inorganic solids, the "remarks" in section A apply also to the corresponding entries in section B.

Unit of K_t and $C = 10^{-4}$ watt/(cm°C); of D = 1 cm² sec⁻¹; of d = 1 g cm⁻³; of p = 1 atm.; t_0, M, B and range are °C

RADIOMETRY (HEAT AND LIGHT)

RADIATION CONSTANTS

W. W. COBLENTZ

For a perfect (black-body) radiator, the total hemispherical radiation (over all wave-lengths) at the absolute temperature T is $J = \sigma T^4$; σ is known as the Stefan-Boltzmann constant of total radiation. The hemispherical radiation included in the spectral region $(\lambda - \frac{1}{2}d\lambda)$ to $(\lambda + \frac{1}{2}d\lambda)$ is $J_\lambda d\lambda = C_1\lambda^{-5}[e^{C_2/\lambda T} - 1]^{-1}d\lambda$; C_1 and C_2 are known, respectively, as the first and the second radiation constants, and J_λ as the monochromatic intensity of the hemispherical radiation. At each temperature T, there is a wave-length λ_m at which J_λ is a maximum; $w(= \lambda_m T)$ is independent of T, and is known as Wien's displacement constant; $C_2 = \alpha w$, where $\alpha = 4.9651$ is a pure numeric.

STEFAN-BOLTZMANN CONSTANT (σ) OF TOTAL RADIATION

$J = \sigma T^4$; σ_o = observed, or reported value; σ_p = probable value after correcting for reflection, etc. Unit of $\sigma = 10^{-5}$ erg cm^{-2} sec^{-1} (°K)$^{-4}$ = 6.451×10^{-12} watt in.$^{-2}$ (°K)$^{-4}$.

RADIATION FROM A PERFECT (BLACK-BODY) RADIATOR

F. E. FOWLE

The following tables, giving the hemispherical radiation (J) and the monochromatic intensity (J_λ) of the hemispherical radiation of a perfect radiator, have been computed from the values of C_1 ($=3.703 \times 10^{-5}$ erg cm^{-2} sec^{-1}), C_2($=1.433$ cm, °K), and σ($=5.709 \times 10^{-5}$ erg cm^{-2} sec^{-1} (°K)$^{-4}$) which have been accepted for the purposes of International Critical Tables. A third table indicates how the values of J_λ are affected by changes in the value of C_2.

A line over a number indicates that it is negative. Thus (Table 1) at -270°C, $J = 5.272 \times 10^{-3} = 0.005272$.

The radiator receives radiation from surrounding bodies. If its temperature is T and if it is entirely surrounded by other perfect radiators, all at temperature T', its resultant loss of energy by radiation (net hemispherical radiation) will be $J_T - J_{T'}$, per unit of area. If $T = 1273.1$°K and $T' = 273.1$°K, the net hemispherical radiation will be $(1500 - 3.2) \times 10^5 = 1497 \times 10^5$ erg cm^{-2} sec^{-1}. (*See* Table 1.) Similarly for J_λ.

TABLE 1.—TOTAL HEMISPHERICAL RADIATION (J) OF A PERFECT (BLACK-BODY) RADIATOR

$J = \sigma T^4 = A \times 10^n$. $\sigma = 5.709 \times 10^{-5}$ erg cm^{-2} sec^{-1} (°K)$^{-4}$. T = absolute temperature, °K; t = centigrade temperature. Unit of $J = 1$ erg cm^{-2} sec^{-1} $= 2.389 \times 10^{-8}$ cal$_{15}$ cm^{-2} sec^{-1} $= 6.112 \times 10^{-10}$ BTU$_{60}$ in.$^{-2}$ sec^{-1}.

TABLE 2.—MONOCHROMATIC INTENSITY (J_λ) OF HEMISPHERICAL RADIATION OF PERFECT (BLACK-BODY) RADIATOR

$J_\lambda = C_1\,\lambda^{-5}[e^{C_2/\lambda T} - 1]^{-1}$, T = absolute temperature, λ = wave-length of the radiation. Total hemispherical radiation in range λ_1 to λ_2 is $\int_{1}^{\lambda_2} J_\lambda d\lambda$. If $C_1 = 3.703 \times 10^{-5}$ erg cm² sec⁻¹, $C_2 = 1.433$ cm, °K and unit of dλ = 1 cm, then $J_\lambda = A \times 10^n$ erg cm⁻³ sec⁻¹, where A and n have the values tabulated below. 1 erg cm⁻³ sec⁻¹ = 2.389×10^{-8} cal$_{15}$ cm⁻³ sec⁻¹ = 6.118×10^{-10} BTU$_{60}$ in.⁻² sec⁻¹ × $(d\lambda)_{\text{cm}}^{-1}$, where $(d\lambda)_{\text{cm}}$ indicates that unit of dλ = 1 cm. For each T the maximum value of J_λ is printed in bold face. In column λ, unit of λ = 1μ = 10⁴Å = 10⁻⁴ cm; T = absolute temperature, °K.

TABLE 3.—EFFECT OF A CHANGE IN C_2

If dJ_λ = increase produced in J_λ by an infinitesimal increase (dC_2) in C_2, then $(dJ_\lambda)/J_\lambda = -K(dC_2)/C_2$; for the units of Table 2 and C_2 = 1.433 cm, °K, K has the appropriate value tabulated below. *Example:* If C_2 = 1.433 cm, °K, then, at 300°K and $\lambda = 2\mu$, $J_\lambda = 4900$ (Table 2) and $K = 24$ (Table 3); hence, if $C_2 = 1.434$, $(dC_2)/C_2 = 0.0007$, $(dJ_\lambda)/J_\lambda = -24(0.0007) = -0.017$, $dJ_\lambda = -(0.017)(4900) = -83$ and $J_\lambda = 4900 - 83 = 4817$. Unit of $\lambda = 1\mu = 10^4$Å $= 10^{-4}$ cm; T = absolute temperature, °K.

THERMAL RADIATION FROM MATERIALS AND SELECTED SOURCES OF RADIATION

W. W. COBLENTZ

For radiation from a "black-body," *see* p. 238.

At wave-length λ, the monochromatic intensity of the normal radiation of a body is $J_{n\lambda}$, where $J_{n\lambda}d\lambda$ = amount of radiant energy, having wave-lengths lying between $(\lambda - 0.5d\lambda)$ and $(\lambda + 0.5d\lambda)$, which the body emits in a direction perpendicular to its radiating surface per unit of time, of surface, and of solid angle; $J_n = \int_0^\infty J_{n\lambda}d\lambda$ is the normal intensity of the total radiation of the body. If the emission satisfies Lambert's law, as is the case for the substances here considered, the hemispherical intensity of the total radiation is $J = \pi J_n$ = total emission per unit of time and of area, and the monochromatic intensity of the hemispherical radiation is $J_\lambda = \pi J_{n\lambda}$. If the corresponding quantities for a perfect radiator (black-body) at the same temperature be indicated by J_b and $J_{\lambda b}$, and if $e_\lambda \equiv J_\lambda/J_{\lambda b}$ and $e_t \equiv J/J_b$, then e_λ and e_t are, respectively, the monochromatic and the total emissivity of the body. If J_c = value of the hemispherical intensity of the total radiation of a black-body at such a temperature that it has the same color as that of the body considered, $e_c \equiv J/J_c$ is the color emissivity of the body; and if $e_v \equiv \left(\int_{\lambda_1}^{\lambda_2} J_\lambda d\lambda\right) \div \left(\int_{\lambda_1}^{\lambda_2} J_{\lambda b}d\lambda\right)$, where λ_1 and λ_2 mark the limits of visible spectrum (about 0.4μ and 0.75μ), e_v is the visible emissivity. The Crova wave-length is that at which $\frac{1}{J_\lambda}\frac{dJ_\lambda}{dT} = \frac{1}{J}\frac{dJ}{dT}$. Usually the quantities directly observed are $J_{n\lambda}$ and J_n, and J_λ and J are computed from them on the assumption that Lambert's law is valid.

TABLE 1.—MONOCHROMATIC EMISSIVITY (e_λ) OF ELEMENTARY SUBSTANCES AND OXIDES: TEMPERATURE OF FUSION(1)

Assumes C_2 = 14 450 micron °C. A micropyrometer was used. s = solid, l = liquid. Unit of $e_\lambda = 0.01 = 1\%$; of $\lambda = 1\mu$ = 0.001 mm = 10000 Å.

W, t = 2000 to 3200°C, $e_\lambda = 49$, same for $\lambda = 536$ as for $\lambda = 647$; independent of t (10); others (8, 12) have found e_λ varies with t. For solid W at M. P., $\lambda = 650$, $e_\lambda = 39$ (1).

* Fused in H.

† Radiator was a Pt wire in a highly evacuated enclosure; $e_{\text{calc.}} = 0.751 \times \sqrt{T\rho} - 0.632T\rho + 0.670\,(T\rho)^{3/2} - 0.607\,(T\rho)^2$, where ρ = resistivity (ohm-cm), and T = absolute temperature (°K); $e_{\text{obs.}}$ = observed emissivity.

‡ Between 20°C and 1710°C, e^λ is independent of t.

§ Extrapolated values.

TABLE 3.—TOTAL EMISSIVITY (e_t) OF OXIDIZED METALS (15)

Surfaces were oxidized at $t \geqq 600$°C; Unit of $e_t = 0.01 = 1\%$

		1182	88.2

TABLE 5.—EFFICIENCY OF COATED SHEETS AS SUN-SHIELDS, AND RELATIVE EMISSIVITIES OF PAINTS AND COATINGS (6)

While one side (upper) of a sheet was continuously exposed normally to the sun, the radiation (r) proceeding normally from the other side (lower) was measured. If r_1 and r_2 are simultaneous values for two sheets similarly exposed, r_2/r_1 measures the relative efficiency of the second with reference to the first; if the sheets are unperforated and are good thermal conductors, r_2/r_1 is the ratio of the emissivities of the two lower surfaces. All sheets were approximately at 50°C. Unit of $r_2/r_1 = 0.01 = 1\%$.

	Sheet 1		Sheet 2		r_2/r_1

* Corrugated asbestos roofing. Temperature in shade = 29°C; temperature of sheet with asbestos on both sides = 44°C; asbestos upper, Al lower = 45°C; Al both sides = 52°C; Zn sprayed on both sides = 55°C.

† Thickness of sheet. ‡ Asphalt paint. § d., p. = dull, polished. ‖ White, vitreous enamel. ¶ Balloon fabric.

** Artificial leather: (1) Single fabric. (2) Double fabric enclosing thin layer of rubber-friction stock. (3) Similar to (2), but of double-texture fabric. All three were coated on upper side with a black, rubber composition.

†† Cotton duck; 11 H is 13.08 oz./yd.^{2}; 4 H is 24.54 oz./yd.^{2}; 12 H is 11.45 oz./yd.^{2}

‡‡ Sheet 1 is 12 H; sheet 2 is 4 H.

TABLE 6.—LOSS OF HEAT FROM VERTICAL BRICK WALL (2)

In still air at 21°C, the wall, at the surface temperature t, lost heat, from one side, at the rate E. E is the same for the natural color (red), for brick coated with Ca(OH)$_2$, and for brick coated with lampblack. Uncertainty in t is about 2%. Unit of E = 0.001 watt/cm^2 = 2.39×10^{-4} cal cm^{-2} sec^{-1} = 6.12×10^{-6} BTU in.$^{-2}$ sec^{-1}.

t	47°C	66°C	86°C	131°C	199°C	218°C
E	30.8	61.7	92.5	185	370	431

TABLE 7.—NORMAL IRRADIATION (R) BY HEFNER STANDARD LAMP AND BY SPERM CANDLE: DISTANCE = 1 METER

R = radiant power, per unit area of receiving surface, which is received by a surface which is normal to the direction of propagation of the radiation and 1 meter from the source. Unit of $R = 10^{-5}$ watt/cm^{-2} = 2.389×10^{-6} cal cm^{-2} sec^{-1} = 6.118×10^{-8} BTU in.$^{-2}$ sec^{-1}.

Source	R	Remarks	Lit.

1.2	34.3	1.2	7.0	15.0	8.4			

TABLE 9.—MONOCHROMATIC INTENSITY (J_λ) OF RADIATION FROM A CYLINDRICAL ACETYLENE FLAME (5)

The value of J_λ for a flat flame, whether viewed flatwise or edgewise, is different from that for a cylindrical flame. J'_λ is the intensity of the radiation from a black-body at 2360°K, assuming $C_2 = 14350$ micron °K. Unit of $\lambda = 10^{-3}\mu = 10^{-7}$ cm = 10 Å; of J_λ = of J'_λ = (arbitrary); of $J_\lambda/J'_\lambda = 0.01 = 1\%$.

TEMPERATURE, BRIGHTNESS AND EFFICIENCY OF SELECTED SOURCES OF LIGHT

W. E. FORSYTHE

(All data and computations not credited to another have been supplied by the Nela Research Laboratory, Cleveland, Ohio, U. S. A.)

Definitions

The *brightness temperature* of a body (*B*) for a stated wavelength (frequently, $\lambda = 0.665\mu$) is the temperature at which an ideal black-body has, at this wave-length, the same brightness as *B*.

The *color temperature* of a body (*B*) is the temperature at which an ideal black-body has the same integral (or apparent) color as *B*.

The *radiation temperature* of a body (*B*) is the temperature at which the rate of total energy radiation from an ideal black-body is equal to that from *B*.

By the *brightness* of a source is meant the brightness in the direction perpendicular to the emitting surface.

SPECTROSCOPY

SPECTROSCOPIC STANDARDS OF WAVE-LENGTH

CH. FABRY

All wave-lengths (λ) given below are expressed in international ångstroms and are the wave-lengths in dry atmospheric air at 15°C and a pressure of one normal atmosphere. Some of them differ slightly from the corresponding values internationally accepted for use as secondary or tertiary standards. These differences are made necessary by the high precision of modern measurements and the very recent elimination of irregularities produced by the pole-effect (*see* p. 432). All arc lines refer to arcs in air at atmospheric pressure (not to arcs in a vacuum); those produced by arcs which are not satisfactorily defined are marked (*).

PRIMARY STANDARD

It is internationally agreed that in dry atmospheric air at 15°C and a pressure of one normal atmosphere the red line of cadmium, produced under the conditions described by Michelson (1, 9) and specified below, has the wave-length (3)

$$\lambda_{Cd} = 6438.4696\ \text{Å} = 0.64384696\mu$$

This defines the length of the international ångstrom and of the micron (μ) as used in the measurement of wave-lengths. As so defined, $1\ \text{Å} = 10^{-10}$ m and $1\mu = 0.001$ mm within the limits of experimental error.

The primary (cadmium) standard of wave-length shall be produced by high-voltage electric current in a vacuum-tube having internal electrodes and the form described by Michelson (11). The tube shall be maintained at a temperature not higher than 320°C, and shall have a volume not less than 25 cm³. The effective value of the exciting current shall not exceed 0.05 ampere. At room temperature the tube shall be non-luminous when connected to the usual high-voltage circuit.

Table 1.—Secondary Standards (2, 4, 5, 6, 7, 8, 10)

In arriving at the values here given, the papers mentioned have been critically compared. The table is divided into 3 sections: Fe-lines, Cu-, Ni-, and Si-lines that fill gaps occurring in the Fe-spectrum, and Ne-lines. Unit of λ = 1 Int. Å = $10^{-4}\mu$ = 10^{-8} cm.

FE-LINES

As far as possible the values here tabulated refer to the Pfund arc (11) in air at atmospheric pressure. That arc satisfies the following conditions:

Anode is below and consists of a bead of iron oxide supported on a massive rod of iron or other good conductor of heat; cathode is above and consists of a rod of iron 6 or 7 mm in diameter, having close to its lower end a massive cooling cylinder of copper or brass. Current not over 5 amperes, 110 to 250 volts, arc 12 to 15 mm long; zone used is midway between the electrodes and not over 1.5 mm wide.

These values are the most accurate and are unmarked. Others, obtained with the arc between two rods of iron 6 to 7 mm in diameter, current about 6 amperes and no statement of either length of arc or of portion used, are marked (*).

Table 2.—Tertiary Standards (11)

All the following tertiary standards are Fe-lines emitted by a Pfund arc under the conditions stated in Table 1. Their wave-lengths have been determined by interpolation from those of the secondary standards, and the published values have been corrected so as to make them accord with the values adopted for the secondary standards. Unit of λ = 1 Int. Å = $10^{-4}\mu$ = 10^{-8} cm.

EMISSION SPECTRA OF ELEMENTARY SUBSTANCES

H. Kayser

In the following table are given the wave-lengths (λ) of selected lines from the spectra of air, of all known elements except Ac, Ma, Pa, Po, Re, UX_2, and certain doubtful, or unidentified elements. The number of lines given in each case is determined by the spectroscopic importance of the element and by the number of lines which its spectrum contains; the strongest and the most easily reversed lines throughout the spectrum have been given, and the distribution of the lines has been chosen so that the list will satisfy the practical requirements of such a table and will exhibit all the characteristics of the spectrum. In the spark-spectrum of air all the observed lines are given, although many of them are false, being metallic lines. For each element, are given the more important literature references from which the data were taken; for a more complete list of references, *see* Kayser, *Handbuch der Spektroscopie*, Vols. 5 to 7, or Watts, *Index of Spectra*. It is assumed that the wave-length of a line is the same in the arc as in the spark, that changes in λ arise only from pressure, magnetic and electric fields, pole-effect, and apparent shifts from unsymmetrical broadening. The data given refer to atmospheric pressure, except in those cases in which the observation must be made under reduced pressure. The precision of measurements in the infra-red is so low that the correction from the Rowland to the international scale is unimportant; in all other cases λ is expressed in international ångstroms.

The values given for λ are weighted means of the best determinations available, and consequently are to some extent arbitrary. The relative intensities of the lines depend upon so many conditions, frequently undefined or even undefinable, that an average is meaningless. But the intensity of a line is an important characteristic of it, and in very many cases the relative intensities vary from one type of spectrum—arc, spark, Geissler tube—to another much more than they vary with the conditions in any one type; for this reason a kind of average, or typical value of the relative intensity is given.

Spectra obtained by means of the arc, spark, or Geissler tube are generally mixtures of different spectra. Some of the lines belong to the neutral atom (denoted by A or AI), some to the simply ionized atom (A^+ or AII), some to the doubly ionized atom—the atom which has lost two electrons—(A^{++} or AIII), etc. It is now possible to determine in many cases the particular type of atom to which a given line belongs. In such cases, the type is indicated in the following table by placing before the wave-length the proper symbol (I, II, III . . .).

WAVE-LENGTHS (λ) OF SELECTED LINES IN EMISSION SPECTRA OF AIR AND OF ELEMENTARY SUBSTANCES

There are no data for Ac, Ma, Pa, Po, Re, and UX_2. For basis of selection of lines given, etc., *see* preceding text. Uncertainty in λ is not over 3 units in the last figure. Numbers in the columns A, S, and G indicate the relative intensities of the lines in the arc, spark and Geissler-tube spectrum, respectively; in each case 1 generally denotes the weakest and 10 the strongest line, but very weak lines may be marked 0, and very strong ones 15, 20, 25, or 30. I, II, III . . . indicate that the line is emitted by the neutral, the simply ionized, the doubly ionized . . . atom; R = easily reversed, u = unsharp, broad; U = very unsharp, very broad; r [v] = unsymmetrically broadened, the excess broadening is on the red [violet] side, *i.e.*, towards the longer [shorter] wave-lengths; the number of components of an unresolved multiple line is indicated by the letters d, tr, qr, qn, s; where **d** = 2, tr = 3, qr = 4, qn = 5, s = 6.

Unit of λ = 1 Å = 0.1 mμ = $10^{-4}\mu$ = 10^{-8} cm.

Air (**3, 74, 75, 91, 101, 102, 128, 186, 198, 199, 255, 259, 274**)

ELECTRICALLY EXPLODED WIRES

J. A. ANDERSON

A fine metallic wire a few centimeters in length, weighing 1 or 2 mg, is placed in the discharge circuit of a large condenser. During the discharge the wire is heated and vaporized so rapidly that the earlier observers of the phenomenon (2, 4) described it as an explosion. The mechanical effects of such an explosion are fully described by Singer (4) and Nipher (2). The explanation of the phenomenon recorded by Nipher is probably incorrect, since recent work has shown that the rapid evaporation of the wire is quite competent to account for all observed effects. For quite recent work, *see* (7, 8, 9, 10).

Circuit.—The constants of a circuit used by Anderson and by Smith are: Capacity (C) = 10^{-6} farad; inductance (L) = 3.35×10^{-6} henry; potential applied (V) = 2×10^4 volt; observed frequency of oscillation (N) = 87 000 cycles. If R be the total resistance of the circuit, including that of the wire, or of the vapor formed from it, the value of the current (i) at any time (t) is given by equation (1)

$$i = V\sqrt{\frac{C}{L}} \cdot e^{-\frac{Rt}{2L}} \sin 2\pi Nt \qquad (1)$$

$$= 10\ 900\, e^{-\frac{Rt}{2L}} \sin 2\pi Nt \text{ amp.}$$

The rate of development of heat energy in the wire is given by i^2r, and its maximum value is shown by the experiments to be above 10^7 watt.

Spectrum.—If the wire is in open air the spectrum consists of a moderately strong continuous background upon which is superposed a system of bright and dark lines. The latter are low and moderate temperature arc lines while the former are either spark or high temperature arc lines. If the wire is confined between two parallel planes placed 2 to 10 mm apart, few, if any, bright lines appear, the spectrum being continuous, with numerous absorption lines. All arc lines and many spark lines especially those of wavelength shorter than λ3000 are dark in the spectrum of an iron wire. The absolute brightness of the continuous spectrum is approximately equal to that of a black-body at 20 000°C.

Variation of Spectrum with Time (5).—During the first half oscillation the spectrum is continuous and without bright lines, but all arc lines and many belonging to the spark spectrum appear as absorption lines. In the succeeding half oscillation bright lines appear gradually, the enhanced lines first, followed in order by the high and medium temperature arc lines. In the later stages of the explosion, when the oscillations of the circuit are no longer discernible, even the low temperature arc lines appear bright.

Pressure.—In an open air explosion the pressure,[1] which initially is high, reaches a value of from 4 to 2 atm. at the end of the first half cycle, depending upon the size of wire employed. During the second half cycle it falls to a value not very much above that of the atmosphere. When the explosion is partially confined, the pressure falls more slowly, and is likely to be considerably above 1 atm. even during the second cycle. Hence it follows that at these high temperatures the spectrum is essentially continuous at pressures above 4 atm.; from 4 down to about 2 atm. the continuous spectrum diminishes somewhat in intensity, and below 2 atm. it weakens rapidly. Anderson (1) has shown that the vapors emitting a continuous spectrum have a high opacity, so that they appear to behave very much like a black-body.

---

[1] Computed from the measured values of mass and volume, assuming a temperature of 20 000°C.

PHOTOMETRIC STANDARDS

E. C. CRITTENDEN

The standards of candlepower on which all precise photometry is based are groups of carbon-filament electric incandescent lamps maintained in several national laboratories. These lamps are burned at temperatures below those of ordinary operation so that they change very slowly with use. Since 1909 the laboratories of France, Great Britain, and the United States of America have thus maintained a common unit of candlepower variously known as the international candle, British candle, and bougie décimale. This unit, together with the procedure for maintaining it until a reproducible primary standard shall be evolved, has been accepted by the International Commission on Illumination, which includes representatives of Belgium, Italy, Spain, and Switzerland, in addition to the three countries named above. It is also used by the national laboratories of Japan and Russia, and has been adopted by the national standards committees in Australia, Canada, Czechoslovakia, Poland, and Sweden.

The Hefner candle, the unit used in the Germanic countries, is 0.9 of the international candle, this ratio being exact within the limits of accuracy with which comparisons have been made. The legal primary standard on which this unit is based is the Hefner lamp burning amyl acetate, but the light produced by any flame depends on atmospheric conditions. The precise value of the Hefner unit actually used was determined (3) in 1895 by comparisons between the flame lamps and electric lamps, and in recent years has been maintained by the electric standards, the flame standard serving as a check which would detect significant changes in the electric reference standards. No drift of the latter amounting to as much as 1% has been found (2, 3).

Secondary standards of the more recent types of electric incandescent lamps (tungsten-filament vacuum and gas-filled lamps) have been established by different procedures in the several national laboratories, and there are differences as large as 3 or 4 % between the values assigned to them. The adjustment of these differences depends upon the acceptance of a standard method of comparing lights of different colors. Experiments and comparative measurements leading toward such an agreement are in progress.

While flame standards of candlepower are now little used, individual lamps of two types (Hefner, and Vernon-Harcourt 10-candle pentane) are tested and certified by the national laboratories. The variation of their intensity with atmospheric conditions is commonly represented by an equation of the following form:

$$I = I_0[1 + a(e_0 - e) - c(760 - b)],$$

where e is the humidity expressed in liters of water vapor per cubic meter of dry air, e_0 is a normal humidity, b is the barometric pressure in millimeters of mercury, I_0 is the intensity (candlepower) of the particular lamp under normal atmospheric conditions, and I is the intensity under the conditions represented by observed values of e and b; it is assumed that variations of room temperature have a negligible effect. The accepted values of the constants are as follows:

Lamp	e_0	a	c	Lit.
Hefner	8.8	0.0055	0.00015	(3, 6)
Pentane:				
Great Britain	8.0	0.0063	0.0008	(1, 4)
United States	8.0	0.0057	0.0006	(5, 6, 7)
Japan	8.0	0.0064		(8)

The differences in the values of a for the pentane lamp arise from the fact that this "humidity factor" includes a temperature effect and that seasonal variations of humidity have a systematic relation to temperature which is nearly the same in England and Japan, but different in America. The real humidity factor is 0.0052; this combined with a temperature term, $+0.001(15 - t)$, brings observed results in the three countries into complete accord; t = room temperature, °C. The variation with barometric pressure is not actually linear, but over the range of natural pressure changes either the British or American coefficient gives results correct within the accuracy with which the lamp will reproduce its values.

For very complete bibliography, *see* (9).

PHOTOMETRIC FILTERS

E. C. Crittenden

Introduction.—In visual photometry, filters are used (1) to equalize the intensity or the color of the two lights to be compared, (2) to test the characteristics of observers, (3) to transmit a spectral band so chosen that the ratio of its intensity to the integral light is the same for each of the lights (method of Crova). The Crova method can give correct results only when the filter is chosen in accordance with the spectral distribution of the particular sources to be compared. It is more convenient to use color equalizing filters, as they can be produced much more easily and no error is introduced by a failure in exactly equalizing the colors of the lights to be compared.

Equalizing Filters.—The color filters most commonly used are blue glasses and dyed gelatin films of a yellowish or amber tint. These are not reproducible; individual filters must be calibrated.

Continuously variable color filters using the rotatory dispersion of quartz plates between nicol prisms have been devised. The relative transmissions of these can be accurately calculated; *see* (5, 9).

Reproducible color-equalizing filters of known transmissions can be prepared from the following stock solutions. (A) Yellow solution: 100 g $Co(NH_4)_2(SO_4)_2.6H_2O$ + 0.733 g $K_2Cr_2O_7$ + 10 cm³ HNO_3 (d = 1.05 g/cm³) + H_2O to make 1 l of solution at 20°C. To dilute, use H_2O.

(B) Blue solution: 50 g $Ni(NH_4)_2(SO_4)_2.6H_2O$ + 10 g $(NH_4)_2SO_4$ + 55 cm³ NH_4OH (d = 0.90 g/cm³) + H_2O to make 1 l of solution at 20°C. To dilute, use aqueous solution of 10 g $(NH_4)_2SO_4$ per l of solution.

These solutions suitably diluted are used to equalize various color differences. The following transmission data refer to a flicker photometer using a 2° field and an effective brightness of 2.5 millilambert. Transmission measurements made with the usual Lummer-Brodhun field (about 8° by 15°) give a somewhat higher transmission for the blue, and lower for the yellow solution.

For the light from a standard 4 watt-per-candle carbon filament lamp (color temperature about 2077°K), the transmission of the diluted yellow solution is given by $\log_{10} T = -0.245C^{0.9}$, and of the blue by $\log_{10} T = -0.539C^{1.03}$, where C = concentration = number of cm³ of stock solution (A or B) per cm³ of the diluted solution, and T = relative transmission of 1 cm of solution at 20°C = τ_s/τ_w, where τ_w = transmission of a 1-cm cell having colorless glass walls and filled with clear H_2O at 20°C, and τ_s = transmission of same cell filled with the diluted solution at 20°C. Transmission = L_2/L_1 where $L_1[L_2]$ = light incident upon front [leaving rear] face of cell.

For the light from a source with a spectral distribution of light like that of a black-body at a temperature >2077°K the transmission of the yellow solution, when adjusted to give a color match with the 4 watt-per-candle carbon lamp, is given by $\log_{10} T = -0.366C^{1.05}$; *see* (1, 2, 3, 8).

Filters for Testing Observers.—For a normal or average observer using a flicker photometer under standard conditions and the light from a 4-watt-per-candle lamp, the two following aqueous solutions have equal transmissions at 20°C when contained in 1-cm cells of colorless glass. Yellow solution: 72 g $K_2Cr_2O_7$ to 1 l solution at 20°C. Blue solution: 57 g $CuSO_4.5H_2O$ to 1 l solution at 20°C; *see* (2, 4, 6, 7).

Filters for Physical Photometers.—Any receiver which responds to radiant energy in a definite and quantitative manner can be used as a photometer if covered by such a filter that the resultant spectral sensitivity curve is like that of the eye. All such known receivers which are accurately reproducible are non-selective, and for such the best filter appears to be a 1-cm thickness of the following solution, supplemented by clear H_2O sufficient to absorb practically all the infra-red (about 2 cm): 61.25 g $CuCl_2.2H_2O$ + 14.5 g $Co(NH_4)_2(SO_4)_2.6H_2O$ + 1.9 g K_2CrO_4 + H_2O to make 1 l; *see* (4, 6).

MECHANICAL EQUIVALENT OF LIGHT

HERBERT E. IVES

CONTENTS

DEFINITIONS[1] AND SYMBOLS

1. *The efficiency of a source* is the ratio of the total luminous flux to the total power consumed (A. E. S. C. 46)(E_s).

2. The *luminous efficiency of the radiation* from any source is the ratio of the luminous flux to the radiant flux from the source (A. E. S. C. 22)(E).

3. The *visibility factor for the radiation* of a particular wave-length is the ratio of the luminous flux at that wave-length to the corresponding radiant flux (A. E. S. C. 18)(V_λ). (It is the luminous efficiency of monochromatic radiation of that wave-length.)

4. The *relative luminous efficiency of a source* or a *radiation* is the ratio of its efficiency to that of monochromatic radiation of maximum efficiency (about $\lambda = 0.555\mu$)(E_{sr}, E_r).

5. The *relative visibility factor* for a particular wave-length is the ratio of the visibility factor for that wave-length to the maximum value of the visibility factor (A. E. S. C. 19)($V_{\lambda r}$). (It is the relative luminous efficiency of monochromatic radiation of that wave-length.)

6. *Mechanical equivalent of the light* of a given radiation = power radiated per unit of luminous flux emitted = reciprocal of the luminous efficiency of the radiation.

7. *Least mechanical equivalent of light* = mechanical equivalent of monochromatic radiation of greatest luminous efficiency (about $\lambda = 0.555\mu$)(m).

If L = total luminous flux, R = total radiant flux, $L = \int_0^\infty L_\lambda d\lambda = \int_0^\infty V_\lambda R_\lambda d\lambda$, $R = \int_0^\infty R_\lambda d\lambda$, $E = L/R$, $E_r = E/(E_\lambda)_{\max.} = E/(V_\lambda)_{\max.} = mE$.

The value found for L, and hence for m, depends to some extent upon the conditions of observation (intensity of illumination, size of field, type of photometer, etc.). As there is no general agreement regarding what these conditions should be, the following data have a tentative character and those obtained by different observers are not always comparable.

TABLE 1.—RELATIVE VISIBILITY FACTOR ($V_{\lambda r}$) OF MONOCHROMATIC RADIATION (7)

These values, applying to photometric fields of relatively high brightness, have been tentatively adopted by the International Commission on Illumination. They are accurately represented by the formula: $V_{\lambda r} = 0.9896(R_1e^{1-R_1})^{200} + 0.0820(R_2e^{1-R_2})^{550} + 0.0650(R_3e^{1-R_3})^{2000} + 0.0375(R_4e^{1-R_4})^{630}$, where the R's are pure numbers defined by the equations $\lambda = \frac{0.555}{R_1}\mu = \frac{0.607}{R_2}\mu = \frac{0.523}{R_3}\mu = \frac{0.467}{R_4}\mu$; λ is the wave-length of the radiation considered. Mechanical equivalent $= m/V_{\lambda r}$, m = the least mechanical equivalent of light = 0.00161 watt/lumen; luminous efficiency of the radiation $= V_{\lambda r}/m$. Unit of $\lambda = 0.001\mu$ = 10 Å; of $V_{\lambda r}$ = 1%, *see* Fig. 1; *see also* (2, 9, 11, 18, 19, 20).

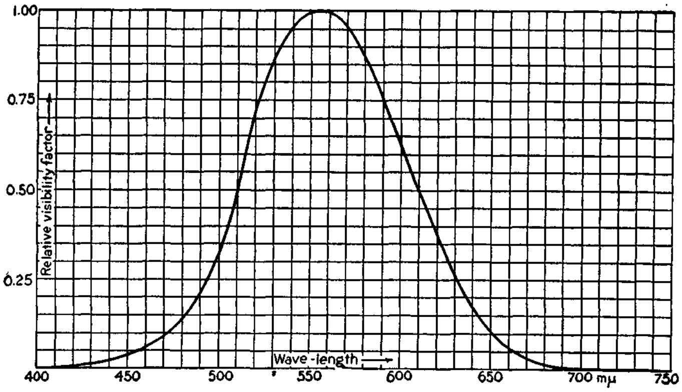

FIG. 1.—Relative visibility factor of monochromatic radiation (7.) Relative visibility factor = relative luminous efficiency. 1mμ = 10^{-7} cm = 10 Å. (*See* Table 1.)

λ	$V_{\lambda r}$	λ	$V_{\lambda r}$	λ	$V_{\lambda r}$
400	0.04	530	86.2	660	6.1

520	71.0	650	10.7		

TABLE 2.—LEAST MECHANICAL EQUIVALENT OF LIGHT

Value for green Hg-line, λ = 5461 Å, was derived from direct radiometric and photometric measurements; that for black-body (B. B.), from photometric measurements and computation of total radiation, using indicated values of σ and C_2; that for carbon lamp (C. L.), from measurement with and without a luminous efficiency screen. In column $V_{\lambda r}$ is indicated the relative visibility factor used in the reduction; $m_0[m]$ = value of the least mechanical equivalent as reported by observer (as corrected to basis of Table 1, $\sigma = 5.709 \times 10^{-12}$ watt cm^{-2} deg^{-4}, and C_2 = 14 330 micron degree). The value found for m depends to some extent upon the conditions of observation (illumination, size of field, type of photometer), and there is no general agreement regarding what these conditions should be. Unit of $\sigma = 10^{-12}$ watt cm^{-2} deg^{-4}; of C_2 = micron degree; of m_0 and m = 0.001 watt lumen^{-1}.

---

[1] The definitions, that are followed by the letters A. E. S. C. and a number, are those given by the American Engineering Standards Committee, and follow closely those adopted by the International Illumination Commission. The remaining quantities are not defined by those bodies, and it has accordingly been necessary to complete the list by definitions so worded as to be consistent with those adopted. Various authorities differ in terminology, and the definitions here given are not those elsewhere used and advocated by the writer.

TABLE 3.—LUMINOUS CHARACTERISTICS OF A BLACK-BODY

The relative luminous efficiency (E_r) of the radiation from the black-body is computed on the bases of Table 1 and the radiation constants ($\sigma = 5.709 \times 10^{-12}$ watt cm^{-2} deg^{-4}, $C_2 = 14\ 330$ micron deg) chosen for I. C. T. (*cf.* (17)). $E_r = \left(\int_0^\infty V_{\lambda r} J_\lambda d\lambda\right) \div \left(\int_0^\infty J_\lambda d\lambda\right)$; J_λ = monochromatic intensity of the radiation. B = brightness if least mechanical equivalent = 0.00161 watt lumen^{-1}; $B = b \times 10^n$; $E_r = e \times 10^{n'}$. Unit of B = 1 candle cm^{-2}.

T, °K	E_r		B*	
	e	n'	b	n
1 200	6.02	−6	1.41	−2
1 400	5.57	−5	2.42	−1

TABLE 6.—EFFICIENCIES OF COMMERCIAL ILLUMINANTS (12)

Rating = commercial rating of lamp; E_s = luminous efficiency of lamp; E_{sr} = relative luminous efficiency of lamp = mE_s, m = least mechanical equivalent of light; w.p.c. = watts per mean horizontal candlepower; cp. = candlepower; amp. = ampere; D.C. [A.C.] = direct [alternating] current; BTU = British thermal unit; h.p.[l.p.] = high [low] pressure; 60 ~ = 60 cycles per second. Unit of E_s = 1 lumen per watt consumed; of E_{sr} = 1%.

The Silver Reduction Equivalent of Photographic Developers

By silver reduction equivalent (E_{Ag}) is meant the *number of atoms of metallic silver reduced per molecule of developer oxidized.* Temperature = 20°C and Ag is added as excess AgBr except as otherwise indicated.

** cm³ of 1N NaOH.

†† Ag as ammoniacal Ag_2O.

It is clear that the so-called silver equivalent of a given developing agent varies with the other constituents of the developer, the temperature, duration of run, and the form and manner in which the silver is added. Gordon (3) found, further, that the equivalent varies markedly with the method of shaking. It is probable that none of the values represents an equilibrium system and all are therefore to be regarded as tentative. Lüppo-Cramer (24), believes all determinations on silver halides in absence of emulsifying substances to be without photographic significance.

Photographic Development Velocity Functions and Constants

The rate of development may be measured by the increase of *density*, D, at a single exposure with time of development, t, or more satisfactorily, and in closer relation to photographic theory and practice, by the increase of *gamma*, γ, (constant or development factor) with time, t.

The function for (γ, t) will be of the same form as for (D, t), provided the straight line portions of the characteristic curves (*q.v.*, p. 442) meet on the axis of exposures. If they converge to a point below the axis, as when soluble bromide is present, then if a is the depression of density at the convergence point (*cf.* (28)) the function for ($D + a$), t will be the same as for γ, t.

For some emulsions the convergence point is above the axis, in which case the function for γ, t should be compared with ($D - a$), t.

FORMS OF DEVELOPMENT VELOCITY EQUATION

	Log form	Exponential form	First derivative	Lit.
1	$Kt = \log_e \dfrac{D_\infty}{D_\infty - D}$	$D = D_\infty(1 - e^{-Kt})$	$\dfrac{dD}{dt} = K(D_\infty - D)$	(37)
2	$K(t - t_0) = \log_e \dfrac{D_\infty}{D_\infty - D}$	$D = D_\infty(1 - e^{-K(t-t_0)})$	$\dfrac{dD}{dt} = K(D_\infty - D)$	(37)
3	$K(\log_e t - \log_e t_0) = \log_e \dfrac{D_\infty}{D_\infty - D}$	$D = D_\infty(1 - e^{-K \log_e t/t_0})$	$\dfrac{dD}{dt} = \dfrac{K}{t}(D_\infty - D) = Kt^{-1}(D_\infty - D)$	(28)
4	$\log_e K + b \log_e (t - t_0) = \log_e \log_e \dfrac{D_\infty}{D_\infty - D}$	$D = D_\infty(1 - e^{-K(t-t_0)^b})$	$\dfrac{dD}{dt} = Kbt^{b-1}(D_\infty - D)$	(44)
5	$Kt = \log_e \dfrac{p\xi}{p\xi - D} - \dfrac{d}{(d + h)(D_\infty - p\xi)} \log_e \dfrac{D_\infty}{D_\infty - D}$		$\dfrac{dD}{dt} = K\dfrac{b - aD}{h(D_\infty - D) + d}(D_\infty - D)$	(33)

K = velocity constant of development. t = time of development in any unit selected. t_0 = empirical correction for the induction period in development. D_∞ = theoretical silver image density at infinite development. D = measured silver image density at time, t. a, b, d, h = empirical constants. $p\xi = D_\infty$ as used in 1–4. In 5, D_∞ represents the mass (unknown) of the latent image.

Equation 1 holds only for simple iron oxalate development, and for pyrogallol-soda (fairly). Equation 2 is of much wider application but in many cases fails in the advanced stages of alkaline development. Equation 3 has been found generally satisfactory by Nietz (28) in his extensive experimental work. Equation 4 is equally satisfactory and sometimes holds over a wider range but is more difficult of application. Equation 5 is of theoretical significance as being based upon the conception of the reversibility of the development process; it contains too many undeterminable terms to be practically useful.

DEVELOPMENT VELOCITY CONSTANTS AND RELATED DATA FOR VARIOUS DEVELOPERS ON THE SAME EMULSION (28)

Each developer contained 50 g Na_2SO_3, 50 g Na_2CO_3 and 1.19 g KBr per liter. Developing agents marked with an asterisk were of high purity, and others, excepting only edinol, duratol and eikonogen, which were the commercial product, were of better than commercial quality. D_∞, t_0, K as previously defined. γ_∞ = theoretical plate contrast reached on infinite development.

Developing agents all at 0.05 molal concn.	Constants of Eq. 3			
	D_∞	γ_∞	t_0, min	K

p-Phenylenediamine	1.7	0.58	2.10	0.34

The Temperature Coefficient of Development

Sheppard and Mees (36) found that in the case of ferrous oxalate development the temperature-development velocity relation was represented quite accurately by the integrated form of the Van't Hoff reaction isochore: $\log K = -\frac{A}{T} + C$, where K = development velocity constant, A, C = experimentally determined characteristic constants, T = absolute temperature.

The temperature coefficient for any development process for which the above relation holds is given by:

$$\alpha_{10} = \frac{K_T + 10}{K_T}$$

Ferguson (11) has proposed and successfully applied to general alkaline development the formula

$$\log b = \frac{\log M - \log m}{\Delta t}$$

in which b = temp. coeff. for 1°C. M, m = time of development giving equal factors at the higher and lower temperatures, respectively. Δt = temp. difference in °C.

TEMPERATURE COEFFICIENT OF DEVELOPMENT

Developing agent	Plate or emulsion	α_{10}	Lit.
Ferrous oxalate	"A"	1.60	(37)
Ferrous oxalate	"B"	1.90	(37)
Ferrous oxalate	"C"	1.70	(37)
Hydroxylamine	"C"	2.00	(37)
Quinol	"B"	2.20	(37)
Quinol	"C"	2.80	(37)
Quinol (tabloid)		2.25	(40)
p-Aminophenol	"C"	1.50	(37)
Metol	"C"	1.25	(37)
Pyrocatechol	"B"	2.80	(37)
Glycine (tabloid)		2.3	(40)
Metol-quinol		1.9	(40)

TEMPERATURE COEFFICIENT.—(*Continued*)

Developing agent	Plate or emulsion	α_{10}	Lit.
Rytol (tabloid)		2.2	(40)
Rodinal (*p*-aminophenol)		1.9	(40)
Pyrogallol soda, no bromide		1.5	(40)
Pyrogallol soda with bromide		1.9	(40)
Pyrogallol soda, no bromide	Wratten Panchromatic	2.0	(20)
Pyrogallol soda, no bromide	Imperial Ordinary	1.71	(12)
Pyrogallol soda, no bromide	Wratten Instantaneous	1.68	(12)
Pyrogallol soda, no bromide	Ilford Empress	1.55	(12)
Pyrogallol soda, no bromide	Imperial Special Rapid	1.76	(12)
Pyrogallol soda, no bromide	Ilford Special Rapid	1.85	(12)
Pyrogallol soda, no bromide	Wellington Rapid Special	1.99	(12)
Pyrogallol soda, no bromide	Barnet Extra Rapid	2.01	(12)
Pyrogallol soda, no bromide	Monarch	1.9	(12)
Pyrogallol soda with 0.1% bromide*	Barnet Extra Rapid	2.01	(12)
Pyrogallol soda with 0.1% bromide*	Ilford Empress	2.09	(12)

* Ferguson's results (12) for bromided pyrogallol, only two of which are quoted for illustration, gave a temp.-coeff. of approximately 2 for all the plates tested, irrespective of the unbromided values. Bromide apparently stabilizes the temp.-coeff., eliminating the emulsion effect observed by Sheppard and Mees (37). Watkins records a like conclusion (40). The temp.-coeff. of a developer is in general independent of its dilution.

Suggested Watkins' Factors (40)

Multiplication of the time of first appearance of the image by the suggested factor should give a negative of average contrast; the factor may then be adjusted to fit the peculiar requirements of the individual worker. Where the factor is evenly divisible into 60, a divisor is given: $\frac{\text{Time of appearance in seconds}}{\text{Divisor}}$ = correct development time in minutes.

Except in the case of pyrogallol and amidol the factor is independent of the developer strength. Variation in alkali does not alter the factor.

For sky, snow, and water negatives use a somewhat smaller factor, *e.g.*, ⅔ normal. For negatives devoid of high lights calculate development time on the basis of ¾ of time of appearance.

Developer	grams/fl. oz. developer		mg/ml developer		Factor (and divisor)
	Pyro	Bromide	Pyro	Bromide	
Pyrogallol with Na_2CO_3	1	0	2.16	0	18
	2	0	4.32	0	12 (div. 5)

Rodinal	40
Ortol	10 (div. 6)
Diogen	12 (div. 5)
Edinol	20 (div. 3)
2, 4-Diaminophenol (dianol)	60 (div. 1)
Quinomet	30 (div. 2)
Metol-quinol*	14

* The factors of combination developers depend upon the proportion of the two constituents, and when they contain pyrogallol, no rule can be given for finding the factor when diluted. The use of potash as an alkali instead of soda seems, with most developers, to require factors from one-quarter to one-half longer.

Reduction Potentials of Developers

The reduction potentials of developers were originally defined electrochemically (4)[1] but it has been shown that stable potentials, corresponding to equilibrium mixtures of reducer/oxidation-products, are not obtainable for alkaline organic developers (35). Relative reduction potentials were defined by Sheppard by relation to the theoretical equilibrium in development, and an empirical method of determining them worked out (34).

The relative reduction potentials π_{Br} determined by the bromide-depression method of Sheppard as applied by Nietz (28) is defined by the equation

$$\pi_{Br} = kC_0$$

where C_0 is the concentration of KBr required to produce an initial depression in the intersection point of the Hurter and Driffield curves; k is a constant as yet undetermined.

RELATIVE REDUCTION POTENTIALS OF PHOTOGRAPHIC DEVELOPERS (28)

Developer	Mole/l	π_{Br}, hydroquinol = 1.0

The Photometric Constant of the Developed Silver Image

D = density of the image, m_{Ag} = grams of silver per dm², $P = m_{Ag}/D$ = photometric constant, E = exposure in mcs. (*see* "Sensitometric constants" *below*).

DENSITY RANGE WITH FERROUS OXALATE DEVELOPMENT; *cf.* (7, 17, 37)

10^3P =	1.21	1.31	1.03	1.031	1.19*
D range	0.525–1.97	0.76–2.54	0.5–2.0	0.5–3.5	0.08–1.64
Lit.	(13)	(13)	(7)	(37)	(32)

* No specific developer mentioned. Scheffers found that quinol, pyrogallol, metol, ferrous oxalate, and glycine gave identical results in his solarization experiments. Scheffers' results indicate that the photometric constant of the developed solarized image progressively diminishes, due to smaller silver grains being formed.

EFFECT OF EXPOSURE (32)

$\log_{10} E$	D	P	$\log_{10} E$	D	P
$\bar{5}.15$	0.08	1.125	$\bar{0}.95$	1.52	1.184
$\bar{4}.55$	0.16	1.250	$\bar{0}.35$	1.64	1.195
$\bar{3}.95$	0.34	1.176	0.25	1.55	1.200
$\bar{3}.35$	0.54	1.295	0.85	1.50	1.133
$\bar{2}.75$	0.86	1.139	1.45	1.35	1.126
$\bar{2}.15$	1.01	1.248	2.05	1.23	1.089
$\bar{1}.55$	1.34	1.149	2.65	1.12	1.062

Meidinger (27), developing with metol, has found that P varies with the grain size of the emulsion, a conclusion in accord with Higson (15) and Nutting (29). Meidinger concludes that for a given density, other factors constant, P is independent of exposure and development time.

EFFECT OF GRAIN SIZE (27)

E, relative	D, range	m_{Ag}, range	Number of observations	P, average
Fast plate, large grain emulsion				
1–25 600	0.76–2.55	1.45–4.63	11	1.82
Process plate, fairly fine grain emulsion				
1–32	0.26–4.20	0.26–3.8	6	1.0
Transparency plate, very small grain emulsion				
1–512	0.05–3.05	0.04–2.95	10	0.83

The "covering power" of silver grains is proportional to the reciprocal of the photometric constant and increases with decreasing grain size. Thus Meidinger (27) found that the covering powers of a given mass of silver in the developed images of fast, process and transparency plates stood in the ratio 5: 9.1: 10.5, a conclusion in qualitative agreement with Higson and Toy (16).

Part II

Sensitometric Constants of Type Plates and Films

The definition of the sensitometric constants usually employed for expressing the characteristics of photographic materials can best be accomplished by referring to Fig. 1 which shows typical characteristic curves.

Density (D).—The blackness, or light absorbing power of a photographic deposit is expressed in terms of density defined as follows: Let F_0 = the luminous flux incident upon the deposit; F_1 = the luminous flux transmitted by the deposit; O = opacity; D = density; T = transmission.

Then

$$T = \frac{F_1}{F_0}$$

$$O = \frac{1}{T} = \frac{F_0}{F_1}$$

$$D = \log_{10} O = \log_{10} \frac{1}{T} = \log_{10} \frac{F_0}{F_1}$$

Exposure (E).—$E = It$ (expressed in meter candle seconds, mcs.); I = the illumination (in meter candles, mc.) incident on the photographic material during exposure; t = exposure time (expressed in seconds, s).

Spectral Composition of Exposing Radiation.—The values of speed given in the following table were obtained by using a light

---

[1] *Cf.* Vol. VI, section by Conant.

source approximately equivalent to noon sunlight in spectral composition. The unit of photographic intensity is defined as one visual candlepower of radiation equivalent in spectral composition to mean noon sunlight.

Gamma (γ).—γ = tangent of angle α which the straight line portion of the characteristic curve makes with the exposure axis.

Gamma Infinity (γ_∞).—γ_∞ is defined as the theoretical limiting value to which γ approaches as the development time is increased. The values of γ_∞ given in the table are computed by the formula (37).

$$\gamma_\infty = \frac{\gamma_1}{1 - e^{-Kt_1}}$$

where γ_1 is the slope of the straight portion for the development time t_1, and K is the velocity constant of development.

Velocity Constant of Development (K).—$K = \frac{1}{t}\log_e \frac{\gamma_1}{\gamma_2 - \gamma_1}$.

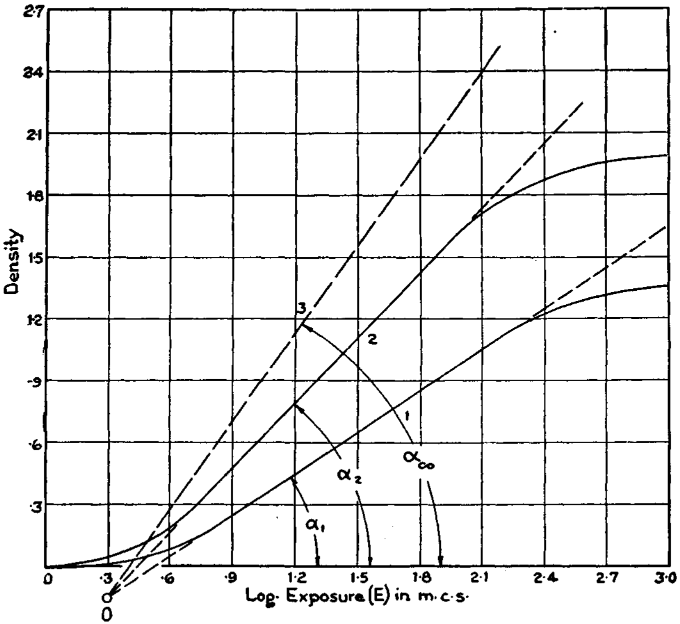

FIG. 1.

Time of Development for Gamma of Unity (t_γ = 1.0).—The rate of development for practical purposes may be indicated by the time of development required to give a gamma of unity. The values determined experimentally for the various type plates and with the developer made up according to the appended formula are given in the table of constants.

Fog (F).—Fog is defined as the density produced when the plate is developed without exposure. This value naturally depends upon the extent to which development is carried and the values given in the table are for a development time which would result in a gamma of unity.

Latitude (L).[1]—L = length of the projection (expressed in exposure units) of the straight line portion on the $\log_{10} E$ axis, assuming development to a gamma of unity.

Inertia (i).—i = the value of exposure where the straight line portion of the characteristic curve extended cuts the $\log_{10} E$ axis. The straight line portions of curves plotted for different development times in general intersect in a point 0 which may lie above, on, or below the $\log_{10}$ exposure axis. The value of i, therefore may depend upon the extent to which development is carried. The values of i given in the table were determined for a gamma of unity.

Speed (S).—$S = \frac{1}{i} \times 10$. Values in table do not include the factor of 10.

SENSITOMETRIC CONSTANTS FOR TYPE PHOTOGRAPHIC MATERIALS

Material	Fog $\gamma = 1$	K	γ_∞	t (for $\gamma = 1.00$)	L	i

FORMULA FOR LABORATORY PYROGALLOL DEVELOPER

Solution A	g	Solution B	g
Na_2SO_3	70	Na_2CO_3, anhyd	75
$NaHSO_3$	17	KBr	1
Pyrogallol	20	Water to 1 liter	
Water to 1 liter			

Temperature 20°C. For use, mix equal volumes of A and B.

Spectral Sensitivity of Photographic Materials

The spectral distribution of sensitivity for practical purposes is shown qualitatively by means of wedge spectrograms. These are made by the use of a spectrograph over the slit of which is mounted a wedge of neutral gray glass, the transmission of which decreases logarithmically from the thin to the thick end. The wedge constant was 0.75/mm. In this way the exposure incident on the photographic material for any particular wave-length decreases logarithmically in a direction parallel to the slit of the instrument. When such an exposure is developed the silver deposit on the plate outlines approximately a curve which is the resultant of the *spectral sensitivity* function of the material and the *spectral distribution of energy* in the radiation emitted by the source used for illuminating the slit of the instrument.

The source used in making the spectrograms (Figs. 2 and 3) was the acetylene flame which operates at the color temperature of 2360°K. All plates were given the same exposure. Since the same source was used in all cases, the curves as outlined by the light areas show the *relative spectral sensitivity* of the various materials. By the application of a correction based upon the spectral distribution of energy radiated by a black-body at 2360°K, an approximation to the actual spectral sensitivity of these materials may be obtained. The neutral glass wedge used over the slit of the instrument while fairly non-selective in absorption for radiation of wave-lengths longer than 450 mμ, increases in density for radiation of wave-lengths shorter than 450 mμ. The apparent falling off in sensitivity in the region of wave-lengths shorter than 450 mμ is therefore due to excessive absorption of the neutral wedge rather than to a decrease in the spectral sensitivity of the material (26, 39).

Resolving Power, Sharpness, and Astro Gamma

Resolving Power

The capacity of the photographic plate or film to render fine detail is usually referred to as its resolving power (R). Resolving power is usually determined by photographing on the material a

---

[1] Sometimes called Scale, *see* (5).

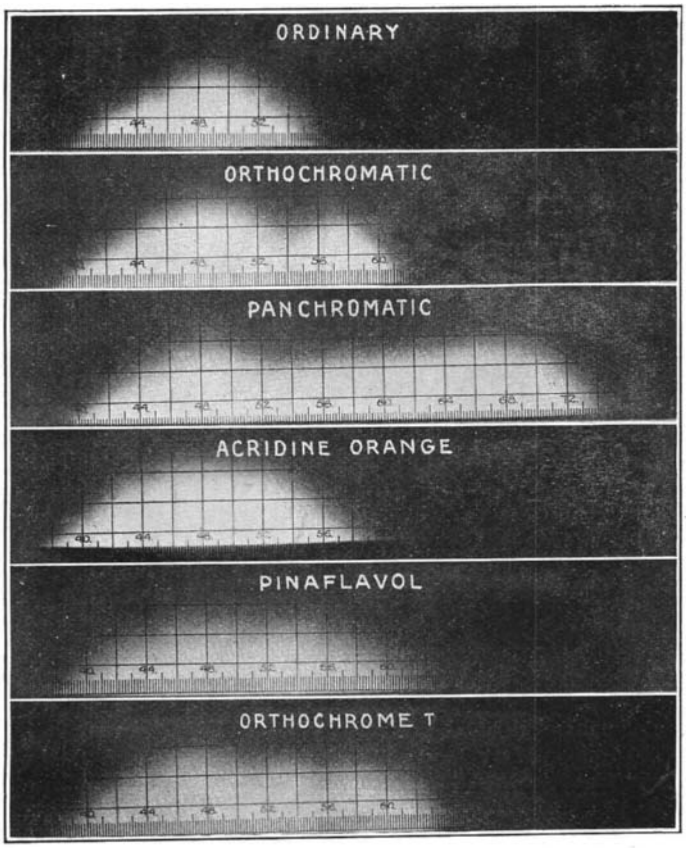

Fig. 2.

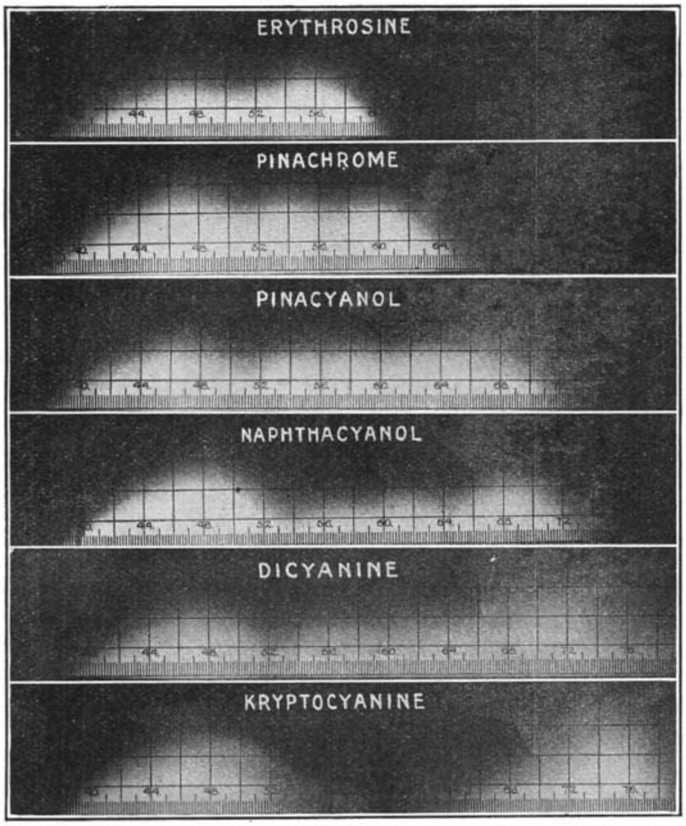

Fig. 3.

grating consisting of alternate light and dark lines, each line being of a width equivalent to the space between the consecutive lines. Resolving power is then specified by stating the number of lines per mm resolvable by the material. For detailed descriptions of methods, *v.* (25, 31).

In Table 1 are given the values of resolving power, as determined by the fan method (25), for a group of materials differing widely in sensitivity. Pyrogallol developer was used in all cases with the exception of the albumen plate, which was developed physically. The light source used in making the exposure was a gas-filled tungsten lamp operated at approximately 2800°K.

Table 1 (19)

Plate	Relative speed	Resolving power
Albumen	0.01	125
W and W Resolution	3.0	81
W and W Slow Process Pan	5.0	67
Seed Lantern (yellow label)	6.0	62
Positive Motion Picture Film	10.0	42
Seed 23	150.0	35
W and W Panchromatic	200.0	31
Seed 30	400.0	29
Seed Graflex	450.0	25

The resolving power of a photographic plate is dependent to a certain extent upon the reducing agent used in the developing solution. It is also dependent to a certain extent upon the length of time of development and upon exposure. For any given photographic material and developing solution there is a combination of development time and exposure which gives a maximum resolving power. Values of maximum resolving power, as determined by the fan method (25), for various developers are given in Table 2, the light source being a gas-filled tungsten lamp operated at 2800°K.

Table 2 (19)

Developer	Maximum resolving power	Exposure (in sec)	Development (in min)
Pyrogallol, NaOH	77.0	4	2
Glycine	69.0	3	1
Quinol	64.0	3	2
Pyrogallol, Na_2CO_3	64.0	3	2
Metol-quinol	64.0	3	2
Metol	63.0	3	2
Nepera	62.0	3	2
Pyrocatechol	62.0	8	2
Pyro-metol	62.0	8	2
Eikonogen-quinol	61.0	4	3
Ferrous oxalate	61.0	2	4
Caustic quinol	57.0	4	2
Eikonogen	57.0	4	4
Amidol	51.0	2	4
Kachin	54.0	2	5
Ortol	49.0	4	2
p-Aminophenol	49.0	8	2
Edinol	47.0	4	16

Curves showing the relation between *wave-length* and *resolving power* (fan method) for Seed 30 (S30), Seed 23 (S23), Seed Process (SP), and Wratten and Wainwright Process Panchromatic (WWPP) are shown in Fig. 4 (30, 31).

The increase in resolving power resulting from bathing the material in a solution of yellow dye prior to exposure is shown by the curves marked (YD). The ordinate values are in lines per mm (fan method) which can be resolved under the conditions specified.

Values of resolving power determined by using series of parallel lines may be more directly applicable for practical purposes especially from the standpoint of spectroscopy. In Table 4 (^{6}) are given values determined in this way for a series of typical photographic materials. The test object was illuminated by light of daylight quality. An image, at a magnification of 0.05, was projected on the surface of the photographic material by means of a highly corrected lens. The exposures were such that a development to gamma of unity in pyrogallol at 20°C gave the maximum resolving power.

Sharpness

The "sharpness" characteristic of a photographic material is defined as the differential of density (D) with respect to distance (s) in a direction perpendicular to the edge of the image; sharpness (S) = dD/ds, where s is expressed in microns (0.001 mm).

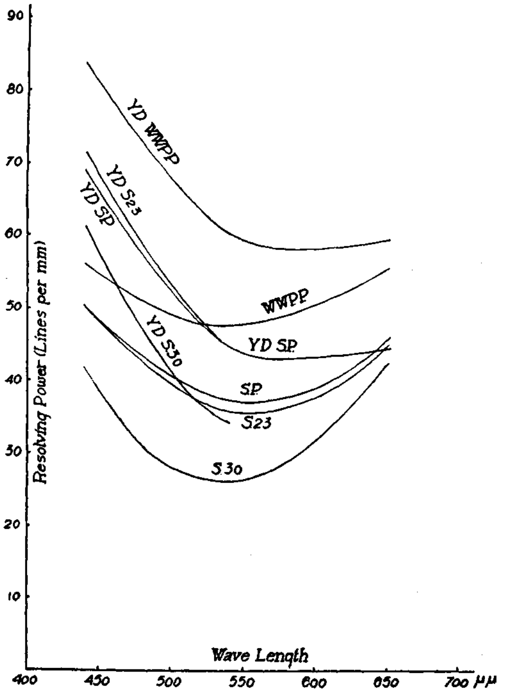

FIG. 4.

The images used for determination of sharpness are obtained by making a contact print of a very carefully prepared knife edge. The exposing radiation used in making the print is carefully collimated and incident normal to the surface of the material being examined.

The sharpness of the developed image depends upon the extent to which development is carried and this is specified by the value of gamma (γ), $\frac{\mathrm{d}D}{\mathrm{d}\log_{10}E}$.

The curves of Fig. 5 ($^{30, 31}$) show the relation between sharpness and gamma for various developers. The plate used in obtaining these values was a Seed Panchromatic and the exposing radiation was monochromatic of wave-length 440mμ.

Sharpness is independent of exposure, at least over a considerable range, as shown in Table 3. The term "light exposure" is used to designate an exposure resulting in an image density of approximately 1.0, while the term "heavy exposure" is used to designate an exposure resulting in an image density between 2.0 and 3.0. The plate used was a Seed Panchromatic developed in caustic hydroquinol.

TABLE 3.—DENSITY GRADIENTS

	λ = 420mμ			λ = 520mμ			λ = 660mμ		
Development time, min.	0.75	1.5	3.0	0.75	1.5	3.0	0.75	1.5	3.0
For light exposure....	0.107	0.136	0.143	0.051	0.059	0.069	0.053	0.070	0.082
For heavy exposure...	0.112	0.133	0.151	0.045	0.061	0.063	0.056	0.064	0.086

The relation between sharpness and wave-length of the exposing radiation is shown in Figs. 6 and 7 ($^{30, 31}$), the former applying to a panchromatic (Seed Panchromatic) and the latter to an orthochromatic (Standard Orthonon) material.

Values of sharpness for a group of typical materials are given in Table 4 (^{6}). The quality of light used in making the exposures was equivalent to average daylight. The exposure was so adjusted that development to gamma of unity in pyrogallol at 20°C gave an image density of unity. The values of sharpness express the diffuse-density gradient (dD/ds) of the straight line portion of the sharpness curve obtained by plotting diffuse-density (D) as a function of the distance (s) from the geometrical edge of the image.

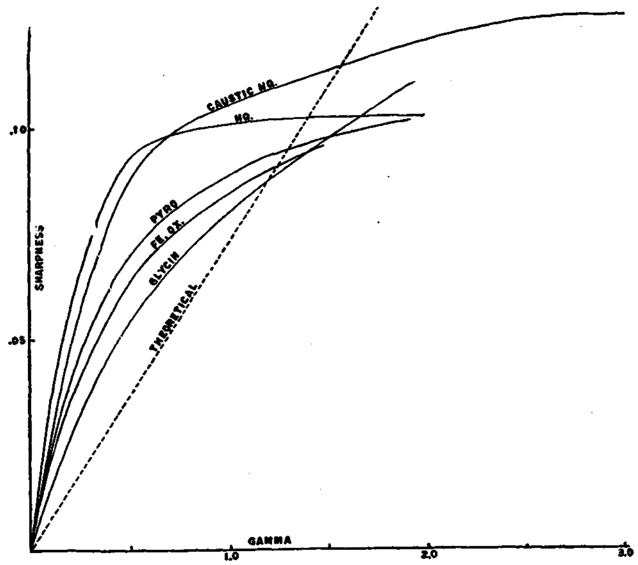

FIG. 5.

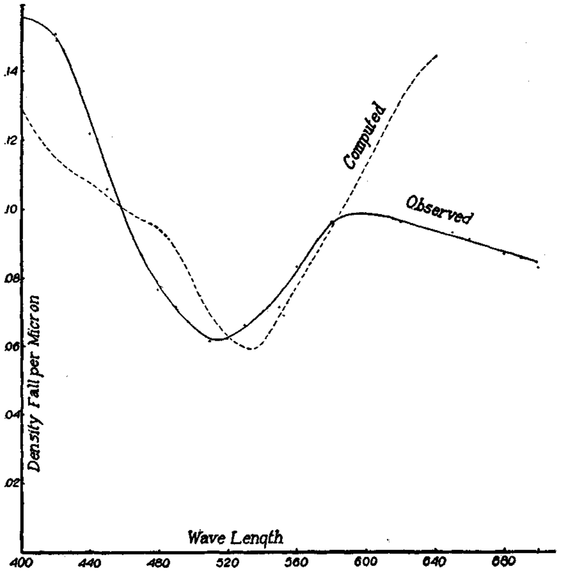

FIG. 6.

Astro Gamma

Astro gamma is defined as the coefficient (b) of $\log_{10} E$ in the Scheiner equation, which gives the relation between the diameter (D) of a stellar image and the exposure (E): $D = \mathrm{a} + \mathrm{b}\log_{10} E$.

Since exposure (E) = intensity (I) × time (t) this equation offers a means of determining the relative brightness of stars by measurement of the diameter of the stellar images obtained under known conditions of exposure and development. The ordinate values used in plotting Fig. 8 are relative and must be multiplied by 3.33 ($1/\log_{10} 2$) in order to obtain actual values of astro gamma as defined above.

In Table 4 ([6]) are given values of astro gamma for a group of typical photographic materials. These values were determined by photographing with a highly corrected lens, using a magnification of 0.05, a circular aperture having a diameter of 0.56 mm. Exposing radiation was of daylight quality and intensity was so adjusted that an exposure of 1 second was just above the threshold value. Keeping the intensity factor constant, the exposure time was increased by consecutive powers of 2 from 1 to 512 seconds. The exposed plates were developed to a gamma of unity in standard pyrogallol at 20°C.

TABLE 4

Emulsion	Resolving power	Sharpness	Astro gamma
Eastman Lantern	140	0.168	39*

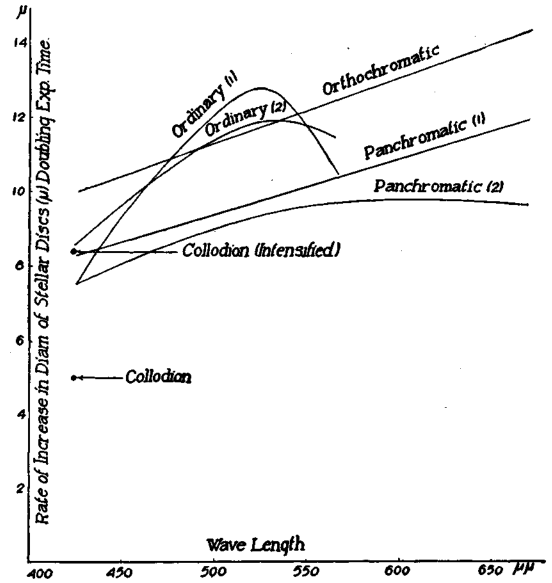

FIG. 8.

Gloss of Photographic Papers

Definition of Gloss.—With the surface illuminated by a collimated beam of light incident at 25° from the normal to the surface, B_a is the brightness of the sample as observed on the line of specular reflection (angle of observation equal to angle of incidence) and B_d is the brightness of the surface observed normally.

Specular brightness, $(B_s) = B_a - B_d$; diffuse brightness, $(B_d) = B_d$; gloss $(G) = \frac{B_s}{B_d} = \frac{B_a - B_d}{B_d} = \frac{B_a}{B_d} - 1$.

RANGE OF GLOSS VALUES

Matte	Semi-matte	Semi-gloss	Gloss
0–1	1–3	3–7	7–∞*

* Actual limit = 75.

These values apply to samples which were fixed out without exposure and hence represent the white paper without any developed silver deposit ([22]).

PROPERTIES OF SOAPS AND THEIR AQUEOUS SOLUTIONS

JAMES W. MCBAIN

A soap is here defined as a salt of any monobasic aliphatic acid containing six or more carbon atoms. The substance cetylsulfonic acid is also classed as a soap.

Un savon est défini ici comme étant un sel de tout acide aliphatique monobasique contenant six atomes de carbone ou plus. La substance acide cétylsulfonique est aussi classée comme savon.

Die Seife ist hier definiert als ein Salz irgend einer aliphatischen einbasischen Säure, welche sechs oder mehr Kohlenstoffatome enthält. Der Stoff Cetylsulfonsäure ist als eine Seife klassifiziert.

Si intende qui per sapone il sale di un acido alifatico monobasico qualunque contenente sei o più atomi di carbonio. L' acido cetilsolfonico è considerato anch' esso un sapone.

Symbols and Molecular Weights

N_w (resp. N_v) = Gram-moles per kg H_2O (resp. per l solution), % = weight per cent

PROPERTIES OF SOAPS AND THEIR AQUEOUS SOLUTIONS

JAMES W. MCBAIN

A soap is here defined as a salt of any monobasic aliphatic acid containing six or more carbon atoms. The substance cetylsulfonic acid is also classed as a soap.

Un savon est défini ici comme étant un sel de tout acide aliphatique monobasique contenant six atomes de carbone ou plus. La substance acide cétylsulfonique est aussi classée comme savon.

Die Seife ist hier definiert als ein Salz irgend einer aliphatischen einbasischen Säure, welche sechs oder mehr Kohlenstoffatome enthält. Der Stoff Cetylsulfonsäure ist als eine Seife klassifiziert.

Si intende qui per sapone il sale di un acido alifatico monobasico qualunque contenente sei o più atomi di carbonio. L' acido cetilsolfonico è considerato anch' esso un sapone.

Conversion Formulae

$$\text{Wt. \%} = \frac{\text{Mol. wt.} \times N_w}{\text{Mol. wt.} \times N_w + 1000} \times 100$$

$$N_w = \frac{\text{Wt. \%}}{\text{Mol. wt.}} \times \frac{1000}{100 - \text{Wt. \%}}$$

$$N_v = \frac{\text{Wt. \%} \times \text{density of solution} \times 10}{\text{Mol. wt.}}$$

Equilibria within Soap Solutions

The diagrams, Figs. 1–19, represent the proportions of the various constituents in equilibrium with each other in the soap solutions. They are obtained primarily from a comparison of conductivity and osmotic data but some of the results are confirmed by measurements of Na and K ion by emf, ultrafiltration, etc. In each *concentration* the sum total of *constituents containing* fatty acid radical is taken as 100% (the total height of the diagram) which is the sum of the following: Colloidal neutral undissociated soap, crystalloidal undissociated soap, fatty ion and fatty ion aggregated as ionic micelle; in addition there is free Na or K ion equal in amount to the number of equivalents of free fatty ion plus the fatty ion in ionic micelle. To read off the actual concentration of any one constituent at a given concentration the width of the field representing that constituent must be multiplied by the total concentration of the solution. The uncertainty in the position of the boundaries between fields is estimated as about 10% of the total amount of soap. For further description, *see* (89). Constituents of a soap solution containing added salt (109).

SYMBOLS

N	Neutral colloid, *e.g.*, $(KC_{18})_x$.
S	Simple soap molecules, *e.g.*, KC_{18}.
S′	Simple fatty ions, *e.g.*, C_{18}^{-}.
A	Acid soap.
M	Ionic micelle, *e.g.* $(C_{18}^{-})_n$.

Phase Equilibria

Systems soap-water and soap-water-salt

Explanatory Notes.[1]—Any soap mixed with water in various proportions and under suitable conditions, can be made to assume any one of five different forms, each of which behaves as a single phase when in equilibrium with another phase. They are: (1) Lamellar crystals of soap. (2) The crystalline curd fibers of soap curd. (3) "Neat soap"—clear, transparent, plastic anisotropic liquid. (4) "Middle soap"—anisotropic. (5) Isotropic soap solutions, which includes all the more dilute solutions.

Addition of the third component, salt, introduces no new forms but the limits of concentration for the existence of the separate phases are affected.

Figures 26, 27 and 28 illustrate the limits of existence and the compositions of the various forms of soap solution with varying temperatures in the two-component system, soap-water. Figures 29–34 are the equilibrium diagrams for systems soap-water-salt at various fixed temperatures. Compositions on these triangular diagrams are in "mole fractions" based upon a fictitious molecular weight of 1000 for H_2O and using the gram-formula-weights for the soap and the salt.

Similar phase-rule diagrams (such as Figures 35, 36 and 37) have been partially constructed for commercial soaps from the scattered fragmentary data of the early workers (4, 93, 115, 123, 124); *see also* (1), demonstrating that the phase rule is of general application to all soaps, pure and commercial, and that the same phases occur in every soap system, the limits of concentration for the existence of each phase varying with the soap.

Tables 1–4 show the relative and minimum absolute amounts of various salts required to produce phase separation at 100°, Tables 1–3 referring to formation of liquid layers and Tables 3 and 4 to beginning separation of crystalline curd fibers. These ratios are approximately independent of the nature of the soap. The effects of mixtures of electrolytes are approximately additive. A mixture of soaps behaves as expected from the constituents when forming liquid layers but not when crystallizing in either curd or fiber form. These rules applied to the tables enable approximate prediction of the behavior of any soap or soap mixture. The following are maximum concentrations of salt for the formation of the liquid-liquid system nigre-lye with soaps made from separate oils studied by Merklen (93) the numbers being accurate to 0.1 or 0.2 of the values given: Sesame oil 6.8, olive 8.1, poppy seed 6.6, poppy seed reheated 7.7, lard 6.0, lard without salt 7.2, tallow 7.0, linseed 7.5, sulfur oil 13.3, saponification olein 8.6, saponification olein with glycerol 9.1, saponification stearin 6.2, cottonseed oil 8.9, peanut oil 6.7, castor oil 25.1, castor oil and peanut oil 17.6%.

Table 1 (1, 115).—Minimum Number of Grams of Various Electrolytes in 100 Cm³ of Lye at 100° Required to Maintain Two Liquid Layers (Nigre and Lye) from Potassium and Sodium Soaps, in Dilutions between $N/8$ and $N/4$ (1).

Solubility

Any soap, pure or commercial, mixed with water or with water and an electrolyte can be made to exist as either lamellar soap crystals or curd fiber crystals; both are usually hydrated, and more than one hydrate may occur. On raising the temperature the crystals or curd dissolve to form ordinary isotropic solution, middle soap, or neat soap depending upon the concentration. The data usually refer to the form of hydrated crystals most stable under the experimental conditions.

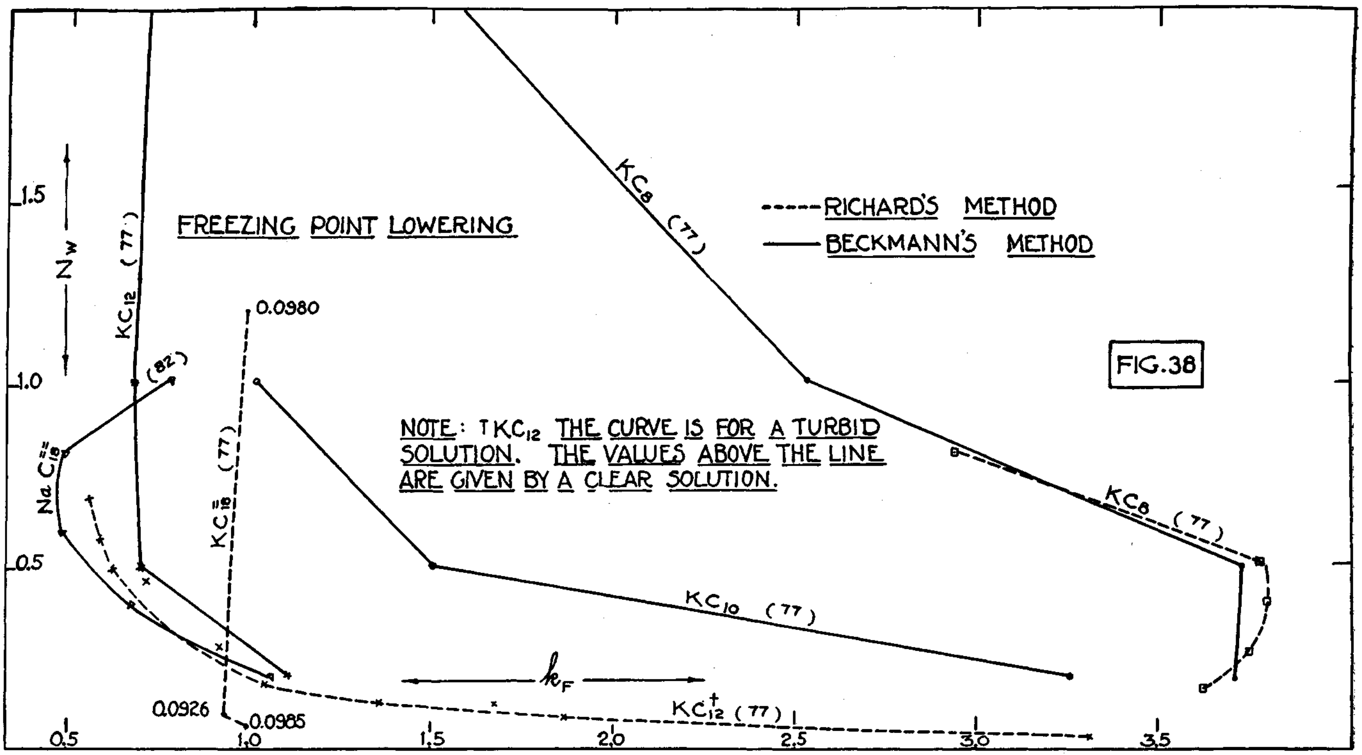
* For solutions of soap with various added constituents, *v.* (46, 77, 85, 89, 109).

Refractive Index (62)

The specific refraction, $R = (n - 1)/d$ or $R' = (n^2 - 1)/d \times (n^2 + 2)$ for soap in soap solutions at 70° is for any one soap independent of concentration (and also of solvent), the molecular refraction for the soap in solution being equal to that calculated for the pure anhydrous liquid soap. Concentrations between 2.4 and 17.8 g/100 cm³ aqueous solution.



NOTE: †KC12 THE CURVE IS FOR A TURBID SOLUTION. THE VALUES ABOVE THE LINE ARE GIVEN BY A CLEAR SOLUTION.

K and NH_4 Salts of Fatty Acids from Palm-Kernel Oil (28, 51)

Molten K and Na Soaps (9)

Mixtures: Solutions of Soaps with Additions of Salts, Acids and Bases (3, 24, 27, 28, 51, 70, 89, 109)

Gold Numbers and Detergent Action, *v.* (37, 38, 50, 57, 74, 104, 105, 106, 108, 114, 117, 119, 120, 121, 122)

Hydration

H_2O = moles H_2O per mole soap

Negative sorption from lyes which salt out curd fibers from aqueous solutions of soap, yield the following values expressed as the retention of the solvent assuming that none of the salts are sorbed. The conditions and methods of experiment are described in the reference cited. For negative sorption by NaC_{16} from salt mixtures, *v.* (81).

t, °C	Soap	Orig. N_w	Salt	N_w	H_2O	Lit.
90	NaC_{18}	0.5	NaOH	1.5	4.3	(88)

For vapor pressures during hydration and dehydration of solid NaC_{18}, *v.* (50).

Hydrolysis

The values given are % hydrolysis according to the equation:

$$\% \text{ hydrolysis} = \frac{(N_w \text{ of } OH^-) \times 100}{\text{Total } N_w \text{ of soap}}$$

1. Hydrolysis by hydrogen electrode, neglecting diffusion potential (results too high in concentrated soaps) (80).

Soap............	t, °C	$N_w = 1.0$	0.75	0.5	0.2	0.1	0.05	0.01	0.001

* Grams soap in 100 cm³ solution at room temperature.

3. Hydrolysis by indicator method. Comparison of the color given an indicator in a pure soap solution with that of standard buffer solutions. Buffers were Sörensen and Palitzsch's glycine/NaOH and borax/boric acid. Indicators were Alizarin yellow G for 0.003 to $0.0005N_w$ OH^-; phenolphthalein for 0.0008 to $0.0001N_w$ OH^-, and for extremely dilute soap, phenol red. The myristic acid used was impure. Indicator was added in amount to produce the maximum color (75).

LITERATURE REFERENCES

LITERATURE REFERENCES

In all literature references cited in International Critical Tables the name of the journal or publication is indicated by means of a *Key number* corresponding to the list given below. The numbers which follow this key number in a literature citation are, in the order named: (1) the volume, (2) the page, and (3) the last two figures of the year. Thus *64V*, **31**: 253; 22, indicates Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Series numbers are not given. Key Numbers referring to books and other non-serial publications are preceded by the letter *B*, and the volume number is given in Roman numerals. Thus *B10*, **IV**: 191; 18, indicates Doelter, Handbuch der Mineralchemie, page 191 of Vol. 4 of the 1918 edition. The Key Number *O* is used to indicate "private communication from."

DAS LITERATURVERZEICHNIS

In allen Literaturstellen, die in I. C. T. verzeichnet sind, ist der Name der Zeitschrift oder der Publikation mit Hilfe einer *Schlüsselnummer*, entsprechend der unten folgenden Liste, angegeben. Die Zahlen, welche diesen Schlüsselnummern bei einem Literaturzitat folgen, bedeuten der Reihe nach: (1) der Band, (2) die Seite und (3), die letzten zwei Zahlen des Jahrganges. So bedeutet z. B. *64V*, **31**: 253; 22, Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Band 31, Seite 253, 1922. Serien-Nummern werden nicht angegeben. Der Schlüsselzahl wird ein *B* vorausgesetzt, wenn sie Bücher, oder eine andre nicht periodische Veröffentlichung bezeichnet. Die Bandnummer wird durch römische Ziffern angegeben. Es bedeutet z. B. also *B10*, **IV**: 191; 18, Doelter, Handbuch der Mineralchemie, Seite 191, des 4 Bandes, der Auflage des Jahres 1918. Die Schlüsselzahl *O* wird gebraucht, um anzuzeigen, dass es eine "private Mitteilung" ist.

RÉFÉRENCES BIBLIOGRAPHIQUES

Le nom du journal ou de la publication de toutes les références bibliographiques citées dans les Tables Critiques Internationales est indiqué au moyen d'un *nombre-clé* correspondant à la liste donnée ci-dessous. Les nombres qui suivent ce nombre-clé dans un renvoi bibliographique indiquent dans l'ordre suivant: (1) le volume, (2) la page, et (3) les deux derniers chiffres de l'année. Ainsi *64V*, **31**: 253; 22, indique Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Les numéros des séries ne sont pas donnés. Les nombres-clés se rapportant à des livres ou à des publications non périodiques sont précédés de la lettre *B* et le numéro du volume est donné en chiffres romains. Ainsi *B10*, **IV**: 191; 18, indique Doelter, Handbuch der Mineralchemie, page 191 du volume 4 de l'édition de 1918. Le nombre-clé *O* est employé pour indiquer "communication privée de."

INDICAZIONI BIBLIOGRAFICHE

In tutte le indicazioni bibliografiche che si incontrano nelle "Tabelle Critiche Internazionali" il nome del giornale o della pubblicazione è espresso con un *numero chiave* riportato nell'elenco dato più oltre. I numeri che, nella citazione, vengono dopo il numero chiave sono disposti con l'ordine seguente: (1) il volume, (2) la pagina, e (3) le ultime due cifre del millesimo. Cosi *64V*, **31**: 253; 22, indica la Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, pagina 253, 1922. I numeri di serie non vengono dati. Quando un numero chiave è preceduto dalla lettera *B* si riferisce a libri o ad altre pubblicazioni non periodiche, e il numero del volume viene allora scritto in cifre romane. Cosi *B10*, **IV**: 191; 18, indica Doelter, Handbuch der Mineralchemie, pagina 191 del IV° volume dell'edizione 1918. Il numero chiave *O* indica "Comunicazione privata da . . . "

KEY TO THE PERIODICALS

Data regarding the libraries which receive many of these periodicals may be found through the following sources:

United States and Canada: "Periodicals Abstracted by Chemical Abstracts, 1926" (Chemical Abstracts, Ohio State Univ., Columbus, Ohio); "Union List of Serials in the Libraries of the United States and Canada, 1927" (H. W. Wilson & Co., New York City); "A Catalogue of Scientific Periodicals in Canadian Libraries, 1924" (McGill Univ., Montreal, Canada).

Great Britain: "A World List of Scientific Periodicals Published in the Years 1900–1921" (Oxford Univ. Press, London, 1925–).

Holland: "Chemisch Jaarboekje tevens Jaarboekje der Nederlandsche Chemische Vereeniging, Vol. 3." (Amsterdam, D. B. Centen, 1920).

IMPORTANT NOTICE

ANNUAL TABLES OF CONSTANTS AND NUMERICAL DATA CHEMICAL, PHYSICAL, BIOLOGICAL, AND TECHNOLOGICAL

Published by an International Committee, under the authority of the International
Research Council and the International Union of
Pure and Applied Chemistry

THE data given in International Critical Tables are based upon determinations published previous to January 1924.

In order to keep always up to date with future progress in physical measurements, the purchaser of International Critical Tables should become a regular subscriber to *International Annual Tables*, which will bring to his desk each year a volume in which he will find assembled and classified all of the data which have appeared in the world's literature, for the year covered by the volume.

Thus, *Annual Tables*, Volume VI, contains all the data published in the literature of 1923–1924; Volume VII will contain the data published in the literature of 1925–1926; Volume VIII, the data published in the literature of 1927–1928; Volume IX, the data published in 1929, etc.

Beginning with Volume VII the text will be given in both French and English.

The older volumes of Annual Tables go back to 1910. They contain all of the original determinations published during that period and which served as all or part of the basis of selection of the "best" values recorded in International Critical Tables. These older volumes thus constitute a handy and accessible source of reference to the original determinations.

Through special arrangements made with the International Commission in charge of Annual Tables, all purchasers of International Critical Tables will be given special discounts on all purchases of International Annual Tables, as follows:

1. 25% discount on Volumes VII to X inclusive, covering the period 1925–1930. This reduction will only be valid for each volume during the period known as the subscription period.
2. 25% discount on the index to Volumes I–V, which will be published in 1928.

These discounts apply only on subscriptions addressed to—*For United States and Canada*, McGraw-Hill Book Company, Inc., 370 Seventh Avenue, New York City, *For all other countries*, Dr. C. Marie, 9 rue de Bagneux, Paris VI, France.

All subscriptions should be accompanied by draft or money order payable at New York or Paris.

SPECIMEN SECTIONS

A free copy of any one of the following specimen sections may be obtained on application to Dr. C. Marie.

A: Spectroscopy. *B*: Electricity, Magnetism, Electrochemistry. *C*: Radioactivity. *D*: Crystallography, Mineralogy. *E*: Biology. *F*: Engineering, Metallurgy. *G*: Colloids.

The following identification form should be filled out and transmitted with the first subscription.

INTERNATIONAL CRITICAL TABLES

X-RAY DATA

J-PHENOMENON IN X-RAYS

C. G. Barkla

As the wave-length (λ) of the homogeneous (unifrequent) beam of X-rays incident upon a thin sheet of absorbing substance is varied, the absorption by the sheet varies discontinuously at certain values of λ. These absorption edges (or occasionally lines) are sharply defined, and correspond to the frequency required to excite the characteristic radiation (*K*, *L*, *M*, etc.) of the absorber.

When the incident beam is heterogeneous (multifrequent) and its "effective" λ is varied, similar sharp discontinuities in the absorption may occur. The "effective" λ is here defined as the λ of that unifrequent radiation for which the ionization produced in a short air-electroscope is reduced to one-half its value by such a thickness of Al as will produce the same reduction in the ionization of the incident multifrequent beam. It may be specified either in Ångstrom units, or by the "effective" mass-absorption-coefficient (μ/ρ) for the incident beam, as determined by the equation $e^{-\mu x} = 0.5$, where x is the thickness of Al required to reduce the ionization to 0.5 its value; ρ = density of Al. It must be emphasized that a discontinuity is not associated with either the minimum λ or the λ of maximum intensity of the incident beam, but with some kind of average for the whole beam—possibly analogous to temperature. Also neither the "effective" $(\mu/\rho)_{Al}$, nor "effective" λ, is an absolute constant in a given substance; it varies somewhat with other factors for the radiation, which are not yet measurable. The critical "effective" $(\mu/\rho)_{Al}$ and "effective" λ are thus approximate only. They are only tentative and cannot precisely express the complex quantity involved.

What appear to be distinct series (J_1, J_2 . . .) of discontinuities have been observed. Later work has shown that under certain conditions, intermediate discontinuities occur (4). It is *possible* that a true measure of the fundamental factor involved will show the critical values for one series to be identical in various substances.

Only tentatively then is the following table given.

J-Absorption Edges (1, 2, 3, 4)

$(\mu/\rho)_{0.5}$ = "effective" mass absorption coefficient in Al for the multifrequent radiation corresponding to the edge; λ_e = wavelength of unifrequent radiation for which mass absorption coefficient of Al = $(\mu/\rho)_{0.5}$. "Effective" coefficient is computed from thickness required to reduce ionization by 50 %. Unit of $(\mu/\rho)_{0.5}$ = 1 cm²/g; of λ = 1 Ångstrom.

Absorber	$(\mu/\rho)_{0.5}$				λ_e			
	J_1	J_2	J_3	$J_{4,5}$*	J_1	J_2	J_3	$J_{4,5}$*

POLARIZATION OF X-RAYS

C. G. Barkla

The polarization of primary X-rays was discovered by Barkla in 1904 (1, 2), and in 1906 (3) he found that certain scattered X-rays are almost completely polarized: the ionization method of intensity measurement was used. By photographic methods it has been shown that heterogeneous primary radiation from a carbon target (9), and heterogeneous scattered radiation (8) are polarized, that the homogeneous characteristic radiation after reflection in a direction at 90° to the incident radiation is fairly completely polarized (11), and that characteristic radiation excited by homogeneous radiation is unpolarized (11). In order to determine the amount of polarization, the beam is intercepted by a suitable scattering substance, and the variation in the intensity of the rays that are scattered in directions perpendicular to the incident beam is determined. With a variation of 360° in the direction of scattering, this intensity passes through 2 maxima and 2 minima; the difference in azimuth from a maximum (M) to a minimum (m) is 90°. If the incident beam is compounded of unpolarized radiation of intensity R, and of plane polarized radiation of intensity P, then $M/m = (P + 0.5R)/(0.5R)$. Hence, fraction (p) which is plane polarized is $P/(P + R) = (M - m)/(M + m)$ and the relative component variation (v) is $(M - m)/M = P/(P + 0.5R)$.

Degree of Polarization of X-Rays

$P[R]$ = intensity of plane polarized [unpolarized] constituent; $p = P/(P + R)$; $v = P/(P + 0.5R)$. $H[S]$ indicates that incident radiation is hard [soft]. Except where the contrary is indicated, the rays are heterogeneous. Unit of v and of p = 1 %.

Rays	Source	v		p		Lit.
		H	S	H	S

Primary........	Coolidge tube	16.5‡	2§	9‡	1§	(10)
Scattered‖......	Carbon	$70 + x$		$54 + y$		(3)
Scattered‖......	$\lambda = 0.25$ Å	$95 + x'$		$90 + y'$		(7)
Characteristic...		0		0		(3, 4)

* The constituents of higher frequency are the more completely polarized.

† From Ni target.

‡ $\lambda = 0.3$ Å.

§ $\lambda = 1$ Å.

‖ Data refer to rays scattered in a direction perpendicular to primary radiation. The true polarization is greater than that actually measured; correction factors x and y are necessary owing to obliquity of rays in beams of finite cross-section. Hence polarization of scattered rays in stated direction is approximately complete; *i.e.*, 100 %.

ELECTRONIC RADIATION EXCITED BY X-RAYS

Maurice de Broglie and Jean Thibaud

For unexplained symbols, *see* Vol. I, p.16

Perrin (53) and, later, Curie and Sagnac (27) observed that all kinds of matter emit electrons (28) when irradiated by X-rays. There are two distinct classes of these electrons: Those of one class have a high velocity when emitted and are often called β-rays, and those of the other have a much lower velocity and are often called δ-rays. The latter are much the more numerous (65); 85% of the electrons emitted by gold leaf irradiated by X-rays from a Coolidge tube with a tungsten target have velocities lower than that corresponding to 2 volt.

Wilson (75) and Auger (3, 4) have shown by the fog method that very often a single atom will emit a group of several electrons. In such cases, the X-ray quantum causes initially the ejection of an electron from (*e.g.*) the K-level. An L-electron replaces it and there results an emission of a $K\alpha$-ray; this detaches an electron from the L-level of the same atom. Two L-rays are thus produced and, in their turn, ionize the more exterior levels. The initial quantum releases 4 photoelectrons. Thus it may be that the energy is not emitted as electromagnetic radiation but within the atom is transformed to the electronic form.

VELOCITY OF THE EMITTED ELECTRONS

High Velocity Electrons.—Among the electrons emitted with high velocity are electrons of all velocities, within a certain range, forming a "continuous spectrum" which corresponds, at least partially, to that of the exciting X-rays. There are also groups of electrons having essentially a common velocity which varies discretely from group to group. The common velocity of each of these groups (*v.* Table 1) has been found (19, 31, 41, 58, 64) to satisfy the generalized Einstein relation (30) $\mathbf{m}_0\mathbf{c}^2\{(1-\beta^2)^{-\frac{1}{2}} - 1\} = \mathbf{h}\nu - w_0$, where $\beta \equiv v/\mathbf{c}$, v = velocity of the electron when emitted, ν = frequency of the exciting X-rays, w_0 = work done by the electron in escaping from the atom. The value of w_0 depends upon the structure of the atom and the energy-level from which the electron is ejected. Values of w_0 may be determined from ionization potentials (V_0) (*q.v.*, p. 69) by the relation $\mathbf{e}V_0 = w_0$, or from critical absorption-limits, or frequency limits of characteristic X-radiation (*v.* Emission of X-rays, p. 23), by the simple Einstein relation $w_0 = \mathbf{h}\nu_0$, where ν_0 = frequency limit. Some authors (6, 7); *cf.* (9, 12, 35, 50, 61, 71, 72) have observed in the emission from Ag and Sn a few electrons for which $w_0 = 0$. For gases, w_0 is in all cases very small, rare gases of high atomic numbers excepted.

If the X-rays are complex, there will be a group velocity corresponding to each wave-length and to each absorption-level of the atom; and superposed upon this emission will be another, arising from the fluorescent (characteristic) X-radiation emitted by the atoms which are ionized by the primary rays. On passing through a magnetic field these groups are spread out into a magnetic spectrum (19).

The Einstein relation, having been established in many cases, may be used for determining, from the observed velocity of the emitted electrons, (1) the energy corresponding to unknown levels (13, 45) and (2) the wave-length of the exciting radiation (31, 69).

Robinson (57) has discovered an interesting relation involving the electronic emission from the various subdivisions of a given level. The greatest number of electrons comes from the subdivision of smallest energy, (*e.g.*, L_{III}), provided that the critical frequency (L) of the element is not too much smaller than the frequency of the incident X-rays. But as the critical frequency is successively reduced by passage from element to element (*i.e.*, as it differs more and more from that of the X-rays), the maximum of intensity of the secondary electrons is displaced towards the subdivision of greatest energy (L_I).

From observations with gases Whiddington (71) found that when an electron has passed a distance x through matter its velocity has been reduced from v_0 to v_x, such that $v_0^4 - v_x^4 = ax$, where a is a constant characteristic of the matter. If the unit of a is 10^{40} cm³/sec⁴, the value of a for air is 2, for Al is 732, and for Au is 2540. If R = range (unit = 1 cm) in air (t = 20°C, p = 1 atm.) of electrons which have a velocity which may be annulled by a potential difference $= V$ (unit = 1 volt), then (Wilson (74, 75)) $V = 21\,000\sqrt{R}$ if $0.1 < R < 1.5$; this agrees well with Whiddington's expression.

TABLE 1.—ENERGY (E) OF ELECTRONS EMITTED BY ELEMENTARY SUBSTANCES UNDER THE ACTION OF X-RAYS

Observed energy: $E = \mathbf{e}V$; calculated energy: $\mathbf{e}V' = \mathbf{h}\nu - w_0$; Rad. = exciting radiation; Lev. = energy-level from which electron is ejected. X-rays are generated in a Coolidge tube with target of the material indicated. Estimated precision and observer: Cu target (56), 0.5%; Rh target (19), 2%; Rh target (73), 1.5%; W target (19), 2%. Unit of V and V' = 1 volt.

Low Velocity Electrons.—The velocity with which the slow electrons are emitted is independent of the nature of the radiator (63). Shearer (63) attributes these electrons to a secondary effect of the rapid electrons and Simons (65, 66) to the recoil of the atoms from which the rapid electrons are ejected; the latter notes a relation between the distribution of the velocities of these electrons (corresponding to $T = 11\,000$°K) and that of thermions in a hot body. Their origin may be associated with the diffusion of the incident X-rays, as Compton (24) has shown that the weakly bound electrons can be expelled by a quantum of radiation.

NUMBER OF ELECTRONS EMITTED

The total number (n_e) of electrons emitted per second is intimately related to the absorption of the X-rays by the substance. The law of fluorescent absorption deduced by Bragg and Peirce, $\tau A/\rho = CZ^4\lambda^3$, where τ = coefficient of fluorescent absorption (coefficient of absorption after correction for scattering), ρ = density, λ = wave-length, A = atomic weight, C = constant of proportionality, and Z = atomic number of radiator = number of electrons per atom, has also been deduced from thermodynamics and the quantum theory (20) and by means of the principle of correspondence (43). It indicates (21) that the probability of emission of an electron from an atom of atomic number Z under action of radiation of intensity (I) and frequency (ν) is proportional to $Z^4\nu^{-4}I$. Jauncey (38) has recently announced the same result in a somewhat different form. Throughout this report I is defined as proportional to the total number of ions produced, per second and per unit of solid angle, by complete absorption of the radiation in air. The experimental results are discordant, as follows:

Variation with Emitting Substance.—The value of n_c increases with Z (Laub (44)), is proportional to Z^4 (Moore (49)), is proportional to Z (Whiddington (73)). Shearer (63) states that for Al, Fe, Ni, Cu, Ag, Sn, Au, Pb and Bi, the number (N_e) of electrons excited in an atom is $N_e = K(Z - 10)$, and consequently n_e is proportional to the number of electrons contained in an atom. Actually, we observe only those which escape from the body and the law of variation of the absorption (of the electrons) with the velocity is uncertain. This may explain the discordances.

For salts and gases, n_e increases with the molecular weight; for CH_3I, it is 100 times as great as for air.

Variation with the Radiation.—For a given I, n_e decreases as penetration increases, $n_e \propto V^{-1/2}$ (Shearer (63)), where V = tube voltage. Hoepner (34) found n_e decreased more rapidly than I; Herweg and Mie (33) found $n_e \propto I$ even when I was very small. To obtain concordant results, the number of electrons belonging to each group of uniform velocity should be measured individually, and also the number composing the adjacent portion of the continuous spectrum, and these should be correlated with the distribution of I in the spectrum of the exciting radiation. This has not been done.

DIRECTION OF EMISSION

Solids.—For solids, the number of electrons emitted in the direction of propagation of the X-rays exceeds that emitted in the opposite direction (10, 18, 25, 42, 47, 54, 62, 68). This dissymmetry is independent of Z and of the physical state of the radiator (51); from his experiments with Cu, Wilson (74, 75) concludes that it arises from a curvature in the trajectories of the electrons, rather than a dissymmetry in emission.

Gases.—*Long Range Electrons.*—A polarization of the X-rays leads to a marked lateral concentration of the long range emitted electrons, in the direction of the electric vector of the X-rays (22, 74, 75). The emitted electrons are also concentrated longitudinally in a privileged direction making an acute angle with the direction of propagation of the X-rays. In air, Wilson (74, 75) found the privileged direction was 45° to the X-rays, 20% of the electrons were ejected at 90° (result of polarization) and a few had a backward component. Using polarized X-rays, Bubb (22) found ½ had a forward component, ⅙ had a backward component, and ⅓ were almost at 90°. In H, Auger (1) found privileged direction at 80° and the number of electrons with a forward component was about twice as great as that of those with a backward one. For halogens, the longitudinal dissymmetry increases in the order I, Br, Cl, F, and possibly decreases as the tube-voltage decreases (16).

Recent experiments (2, 5, 17, 22) by the fog method show that the most probable direction of ejection of a photoelectron is nearly that of the electric vector of the incident wave but there is an additional component in the direction of propagation of the wave. This component increases when either the potential difference applied to the tube or the frequency of the X-rays is increased (4). When the X-rays are polarized there is a very great preponderance in the number of photoelectrons in the plane containing the electric vector of the incident rays (22). Many attempts to account theoretically for this distribution have been made. Those of Bubb (23); *cf.* (17) and of Auger and Perrin (5) agree qualitatively with the observations, but neither completely agrees quantitatively.

The origin of the path of a swift electron is marked by a cloud of ions due to the simultaneous emission of a slow electron (1). The initial portion of the path of a swift electron is straight, but deviations of the following 3 kinds become more and more frequent as the velocity decreases: (*a*) A sudden deflection through a large angle, frequently 180°, due to the electron's passing very near an atomic nucleus. (*b*) A sudden deflection, which may attain 45°, due to a collision in such a manner with another electron that the latter is ejected, generally at 90° to the path of the primary electron, with sufficient velocity to give rise to a bifurcated or "branch track" of ions. (*c*) A progressively curved path due to an accumulation of small deflections of type (*b*) or, according to some authors, to a gyroscopic action of the electron. The end of the path is marked by a small cloud of ions. Wilson (74, 75) thinks he has shown that, when a tertiary path is grafted upon the main trajectory the two emissions, at the point where the deflection occurs, occur at appreciably different times (0.001 sec). (This conclusion is similar to Bearden's (8) that the emission of fluorescent X-rays occurs 10^{-5} sec after the arrival of the exciting radiation.) Along the entire path there are groups of one or several pairs of ions, apparently due to short and ramified paths of type (*b*).

Short Range Electrons.—Under action of X-rays of sufficiently high frequency a secondary emission of electrons of very short range ("fish-tracks" of 1 to 2 mm, "sphere-tracks" of a few tenths of a mm), which form a distinct class and do not satisfy the quantum relation, has been observed (15, 74, 75) in air, H and He. They are ejected nearly in the direction of propagation of the X-rays. At a tube voltage of 20 kv, there are no fish-tracks in air, and sphere-tracks are rare, but as the voltage increases both increase rapidly, sphere-tracks become fish-tracks and these increase in range (67), and presently short range electrons are more numerous than long range ones. The origin of these electrons is explained by the quantum theory of diffusion of radiation as developed by Compton and Debye; *see also* (24, 39).

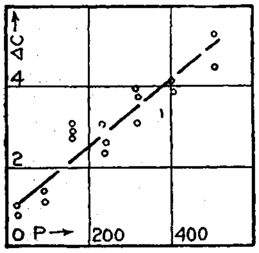

FIG. 1.

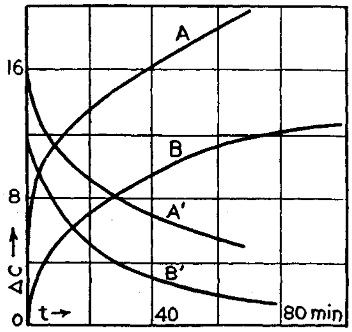

FIG. 2.

FIG. 1.—Effect of pressure (P) upon increase (ΔC) in conductance of a crystal of Se when irradiated by X-rays (48).

Unit of $\Delta C = 10^{-8}$ ohm^{-1}, of $P = 1$ g on area of 0.064 mm^2.

FIG. 2.—Progressive increase (ΔC) in conductance of a crystal of Se during irradiation by X-rays, and its recovery after cessation of irradiation (48).

Pressure = 320 g on area of 0.064 mm^2; initial conductance = 48×10^{-8} ohm^{-1}. Unit of $\Delta C = 10^{-8}$ ohm^{-1}, of time (t) = 1 minute. A = change during irradiation, A' = recovery; B and B' are similar to A and A' but apply to the crystal after it had been fatigued by exposure to γ-rays and had a conductance of 46×10^{-8} ohm^{-1}.

CONDUCTIVITY OF SOLIDS AND LIQUIDS EXPOSED TO X-RAYS

On exposure to X-rays, the conductivity of solids and liquids, especially of dielectrics, is temporarily increased (11, 14, 26, 36, 40, 70). The increases in the conduction of a crystal of Se after an exposure of 1 min to light ($\lambda = 7000$ Å), to X-rays ($\lambda = 1.5$ Å) and to γ-rays ($\lambda = 0.03$ to 0.4 Å) were 33.2, 58.5, and 108.9 ohm^{-1} per joule absorbed, respectively (48, 52). For variation with time and pressure, *see* Figs. 1 and 2. The conductivity of a plate of NaCl increases during exposure to X-rays, and gradually decreases after the X-rays are withdrawn; the exposure "activates" the plate for future action of ordinary light (59). The conductivity of S increases considerably under action of X-rays; the increase is proportional to intensity of the radiation and varies with the nature of the rays in same manner as the ionization of air; in the range of potential difference investigated (69 to 204 volt) the conduction satisfies Ohm's law; the conductivity conferred by irradiation is 3 times as great for monoclinic as for rhombohedral sulfur (32). The conductivity of crystals of calcite ($CaCO_3$), of fluorite (CaF_2), and of feldspar is increased by radiation (46), and the property of luminescence, previously reduced by heating, is restored. The apparent charges of a permanently polarized dielectric are temporarily destroyed by exposure to X-rays (29).

Under action of X-rays, insulating liquids acquire a conductivity which satisfies Ohm's law if the potential gradient does not exceed about 700 volt per cm; the value of this conductivity for a certain unstated radiation is given in Table 2. There is no appreciable dissociation of the molecules, *cf.* (37). Recently, del Regno (55) has studied the variation in the electrical resistance of a selenium cell subjected to the radiations from mesothorium, and Ross (60) has studied the increase in the conductivity of solid dielectrics (sulfur, paraffin, ebonite, amber) subjected to X-rays. For action of γ-rays, *see* (36).

TABLE 2.—CONDUCTIVITY (C) OF INSULATING LIQUIDS WHEN EXPOSED TO X-RAYS (26, 36)

Quality and intensity of X-rays are not stated, unit of $C = 10^{-4}$ ohm^{-1} cm^{-1}

Formula	Name	C
CCl_4	Carbon tetrachloride	8
CS_2	Carbon disulfide	20
C_5H_{10}	Amylene	14
C_6H_6	Benzene	4
	Liquid air	1.3
	Petroleum ether	15
	Vaseline oil	1.6

CRYSTAL GRATINGS FOR X-RAY SPECTROSCOPY

BERGEN DAVIS

The wave-length of X-rays is usually determined either by means of the ionization spectrometer or by a photographic method. With suitable crystals, the former is probably the more accurate, but it requires uniform reflecting planes sufficiently large to reflect a considerable amount of energy. The photographic method may be used with small irregular crystals and is particularly useful with powdered crystals.

Grating Constant.—The grating constant of a crystal is usually measured in terms of that of either calcite ($CaCO_3$) or rock salt (NaCl), the constant of the standard being calculated from crystal data and other physical constants. Even the best specimens of rock salt are imperfect crystals, the reflecting planes being not uniformly parallel planes throughout any considerable volume of the crystal; also the rocking curves obtained by means of the double X-ray spectrometer are wide (11.1), indicating that the crystal elements are quite imperfect. Calcite (Iceland spar) is much more nearly perfect; for it, the rocking curves are very smooth and narrow (less then $\frac{1}{60}$ of the width of the rock salt curves).

On account of the perfection of its crystal structure, it is recommended that calcite (Iceland spar) be selected as the primary standard in all measurements of the wave-lengths of X-rays; and that the value $d_{100} = (3.029 \pm 0.001) \times 10^{-8}$ cm (at 20°C) be used. This value of d_{100} for calcite is as probable as any other value yet deduced; it is equivalent (27) to $d_{100} = 2.814 \times 10^{-8}$ cm (at 20°C) for rock salt. A large number of measurements have already been made in terms of one or other of these equivalent values.

If a_0 = length of edge of unit crystal form, the observed grating space for the planes (h, k, l) of a face-centered cubic crystal, like rock salt, is $d_{hkl} = a_0/\sqrt{h^2 + k^2 + l^2}$ if h, k, and l are *all odd*, and in all other cases $d_{hkl} = 0.5a_0/\sqrt{h^2 + k^2 + l^2}$. For face-centered rhombohedral crystals $a_0\sqrt{1 + 2\cos^3\beta - 3\cos^2\beta}/\sqrt{(h^2 + k^2 + l^2)\sin^2\beta + 2(hk + hl + kl)(\cos^2\beta - \cos\beta)}$, where β = angle between edges of unit rhombohedron, replaces $a_0/\sqrt{h^2 + k^2 + l^2}$ of the preceding cubic expressions. In cubic crystals $a_0 = (nV_m)^{1/3}$, where n = number of molecules in the elementary crystal unit and $V_m(= M/\rho N_0)$ is the molecular volume, M = molecular weight, ρ = density, N_0 = Avogadro's number = number of molecules per mole. The value of n depends upon the crystal structure. For both rock salt (NaCl) and calcite ($CaCO_3$), $n = 4$. The main sources of error lie in the determination of ρ and N_0.

For calcite, $2d_{100} = [4V_m/\varphi(\beta)]^{1/3}$, where $\varphi(\beta)$ = volume of the calcite rhombohedron which has unit distance between the (100) planes $= (1 + \cos\beta)^2/(\sin\beta)(1 + 2\cos\beta) = 1.0962$, as $\beta = 101°\ 55'$. Compton (6) found $\rho = 2.7116$, corrected to 2.7102 g/cm³, at 20°C, and Compton, Beets, and Defoe (8) also found 2.7102 at 20°C. This value of ρ together with the I. C. T. values for M and N_0 (Vol. I, p. 18 and 43) lead to $d_{100} = (3.029 \pm 0.001) \times 10^{-8}$ cm at 20°C. Other values for ρ are 2.716 (9) and 2.715 (3); the average of these and the preceding two is 2.713 which gives $d_{100} = (3.028 \pm 0.002) \times 10^{-8}$ cm at 20°C.

Some of the better determinations of ρ for rock salt are 2.167 at 17°C (24, 25), 2.15 (9), 2.170 (15), 2.167 (22), 2.174 (19), 2.161 (1) and 2.1632 (13). The mean of these (2.166) gives $d_{100} = (2.814 \pm 0.002) \times 10^{-8}$ cm at 20°C. A more recent determination (14) gives $d_{100} = 2.814[1 + 0.00004(t - 18)] \times 10^{-8}$ cm at t,°C.

GRATING SPACES OF SELECTED CRYSTALS

(*c*) = measured in terms of calcite, $d_{100} = 3.029$; (*r*) = measured in terms of rock-salt, $d_{100} = 2.814$. a_0 = length of edge of the unit crystal form; d = grating space, temperature = 20°C. For other data, *see* (2, 20, 23, 26, 29, 30). Unit of a_0 and of d = 1 Å = 10^{-8} cm.

* Rhomb. = rhombohedral; Monoc. = monoclinic.

Refraction.—If the surface of the crystal is parallel to the reflecting planes in the crystal, if n is the order of the spectrum, and θ is the glancing angle of reflection corresponding to the maximum intensity of radiation of wave-length λ, then $n\lambda = 2d \sin\theta(1 - \delta \cot^2\theta)$, where $1 - \delta$ is the index of refraction of the crystal for radiation of wave-length λ. Measurements of δ for calcite (16) and for pyrites (10, 11) show (10, 11) that $\delta = \frac{\mathrm{e}^2}{2\pi\mathrm{m}} \times \left[\frac{n_1}{\nu^2 - \nu_1^2} + \frac{n_2}{\nu^2 - \nu_2^2} + \ .\ .\ .\ \right]$, where ν = frequency of incident radiation and $n_1, n_2, \ldots$ are the numbers of electrons per unit volume having the critical absorption (resonance) frequencies $\nu_1, \nu_2, \ldots$ As $\nu_1, \nu_2, \ldots$ are generally small as compared with ν, a first approximation is $\delta = \frac{\mathrm{e}^2}{2\pi\mathrm{m}}\left[\frac{n_1 + n_2 + \ .\ .\ .}{\nu^2}\right]$. For refraction of X-rays, *see* p. 49, and also (7, 12, 17, 18, 21).

TABLE 4.—REFLECTIVITY OF X-RAYS: EFFECT OF POLISH

Double spectrograph and successive reflections from two crystals. $r = 100\ I_2/I_1$, where $I_1[I_2]$ = intensity of beam incident upon [reflected by] the second crystal when so placed that the reflection is a maximum. First order reflection from planes 100 (*cf.* Fig. 3). $r_p[r_u]$ = value of r when crystals are polished [unpolished]. Unit of λ = 1 Å.

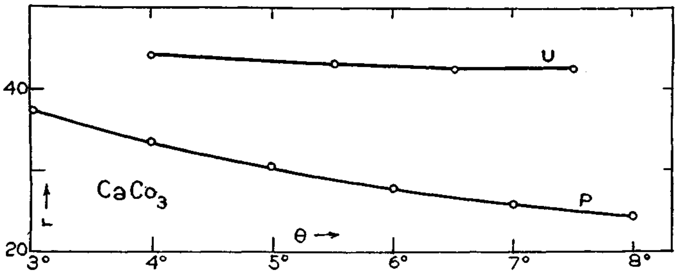

FIG. 3.—Effect of polishing: Calcite (9).
r = % reflected at glancing angle θ; P = polished; U = unpolished. λ = 0.317 to 0.842 Å, Pl = 100. (*Cf.* Table 4.)

ELECTRONICS AND GAS CONDUCTION

ELECTRIC ARCS

C. D. CHILD

CONTENTS

SYMBOLS

D	Diameter of electrodes.
E	Strength of electric field.
I	Electric current.
l	Length of arc.
R	True resistance of arc: R = limiting values of dV/dI as dI approaches zero.
T	Absolute temperature.
vp	Vapor pressure.
V	Voltage difference of electrodes.

Electrical Data.—The residual emf between cored carbon electrodes, after removal of impressed emf, is $\geqq$ 0.64 volt at 0.4 sec and 0.05 volt at 7 sec (3). Duddell defines the counter emf as $V - RI$; for carbon arcs, he finds it varies from 11.2 to 18.5 volt, depending upon the current and the nature of the electrode (5, 10). Others have defined the term in various ways; hence the recorded values vary greatly (5).

Voltage Difference: Effect of Length and Current

. $V = a + bl + cI^{-1} + dlI^{-1}$. Carbon (C) electrodes are solid unless the contrary is indicated. For metallic electrodes, I small, *see* (8). Unit of V = 1 volt, of I = 1 ampere, of l = 1 mm.

Electrodes	Gas	a	b	c	d	I	Lit.

Copper‖......		18	17.5	52.1	3.43		(28)

* D = 11 mm; l measured from tip of cathode to plane through edges of crater; for long arcs, V is less than value given by these constants (10). For flaming arcs (6) and for cored carbons (20, 21), V is less than for solid carbons; no simple equation can be given for cored carbons (32).

† l measured from tip of cathode to bottom of crater.

‡ $l \geqslant 50$ cm.

§ Cored electrodes; A. C. = alternating current arc. *See also* note.*

‖ For metal electrodes, V varies greatly (6).

Distribution of Voltage

Determined by use of exploring electrodes. For small currents between metallic electrodes, *see* (8). $V_a[V_c]$ = drop of potential at anode [cathode]; anode = electrode of higher potential. Unit of V_a, V_c = 1 volt; of E = 1 volt/cm; of I = 1 ampere.

Electrode	Gas	V_a	V_c	E	I	Lit.
C, Carbon*......	Air	33.7	8.96		10	(2)
Hg..............	Vacuum	4.08†	5.27 (27)	0.68‡	4.3	
Na-K...........	Vacuum	2.5	3.8	0.8	1.5	(23)

* Solid electrodes; l = 5 mm.

† vp = 0.45 mm Hg; value of V_a varies from 4.8 to 18, depending upon vp, I, and the shape of tube and electrodes (13); as vp and I are increased indefinitely V_a approaches 3.72 as limiting value (12, 24).

‡ vp = 2 mm Hg, T = 1000°K (2).

Mechanical Data.—Area of crater = 1.34 mm² per ampere for solid carbons (1); =(3.83 + 1.52I) mm² for positive carbon cored, negative solid, and l = 4 mm, unit of I = 1 ampere (2).

Area of cathode spot = 0.0253 mm² per ampere for Hg-arcs (14); = 0.213 mm² per ampere for C-arcs of such lengths that anode does not affect the area and for I = 1.5 to 10 ampere (14).

Consumption of electrodes (unit of l = 1 mm). Solid carbons, open arcs, D = 1 cm, anode consumption if $l \geqq 20$ mm is $(2.4 + 1.3l + 0.0044l^2)$ g per hr if I = 4 ampere, and $(1.73 + 0.086l + 0.003l^2)$ g per hr if I = 8 ampere; cathode consumption if $l \geqq 12$ mm, I = 6 ampere, is $(0.72 + 0.022l - 0.0115l^2)$ g per hr (11).

Solid carbons, enclosed arcs, D = 11 mm, I = 5 ampere, consumption of positive electrode = 1.65 mm per hr, of negative electrode = 0.319 mm per hr (21).

Flaming arc, carbon electrodes, anode D = 8 mm, cathode D = 7 mm, each electrode consumption = 30 mm per hr (26).

Magnetite arc, cathode consumption = 1.5 mm per hr (16), I = 6.6 ampere, value of D is not stated.

Temperature of the Arc.—The temperature of the cathode is usually several hundred degrees lower than that of the crater; that of the gases between the terminals is higher than that of the crater; the exact value is not known. The temperature of the crater of the carbon arc in air is between 3900 and 4000°K for graphite terminals (30); 4200°K at 1 atm., decreasing to 3940°K at 0.1 atm. for solid carbons (18, 19); 4200°K at 1 atm, increasing to 5890°K at 22 atm. for impregnated (cored) carbons (18, 19).

Photometric Data for Arcs

The luminous efficiency of the radiation (= ratio of energy of luminous radiation to that of total radiation) varies with l and I from 0.043 to 0.083 for direct current enclosed arcs between solid carbons, and from 0.115 to 0.225 for yellow flaming arcs, direct and alternating current (17).

V_t = voltage difference of lamp terminal; W = power expended in lamp; scp = mean spherical candlepower, lcp = mean lower hemispherical candle-power. Unit of I = 1 ampere; of V_t = 1 volt; of W = 1 watt; of scp, lcp = 1 candle.

THERMAL EMISSION OF ELECTRONS

SAUL DUSHMAN

The relation connecting the absolute temperature (T) and the rate of electron emission is generally expressed in terms of I, the electric current per unit area of surface, by one or other of the equations $I = A_1T^{0.5}e^{-b_1/T}$ and $I = A_2T^2e^{-b_2/T}$, which are experimentally indistinguishable within the temperature range covered in the past. In this range, $\frac{b_1 - b_2}{2.303} = \frac{3 \log_{10}(T_1/T_2)}{2(T_2^{-1} - T_1^{-1})}$ or approximately, $b_2 = b_1 - 1.5\frac{(T_1 + T_2)}{2}$, and $\log_{10}(A_1/A_2) = 1.5 \log_{10} T + (b_1 - b_2)/2.303T$ or approximately, $A_2 = 0.223A_1 \times T^{-1.5}$. In general, data obtained before 1913–1914 are quite unreliable and even data obtained more recently are, in many cases, equally unreliable either because insufficient precautions were taken to secure a good vacuum or because a very inaccurate temperature scale was used. In a few cases in which very good data are available weighted average values are given in the following tables; these, and the individual values which are especially good, are each indicated by an asterisk (*). If W is the amount of work required to remove an electron from the surface, the "work function," $\phi = W/e$, is the potential difference required to confer upon an electron an amount of energy equal to W; $\phi = k_0b/e = 8.62 \times 10^{-5}b$ volt. Unless the contrary is indicated the values of ϕ given in the following tables are derived from b_2, and will be denoted by ϕ_2. The relation between Richardson's ϕ_0 (28) and b_2 is $b_2 = 11\,600\phi_0$. Papers (12, 15, 32) should be read.

TABLE 1.—ELECTRON EMISSION AND THERMIONIC WORK FUNCTION: ELEMENTARY SUBSTANCES AND OXIDES

At temperature T, the current leaving the surface per cm² is $I_T = A_1T^{0.5}e^{-b_1/T} = A_2T^2e^{-b_2/T}$; work function is ϕ. $A_1 = a_1 \times 10^n$, $A_2 = a_2 \times 10^n$, $b_1 \doteq \beta_1 \times 10^4$, $b_2 = \beta_2 \times 10^4$, $I_T = i_T \times 10^n$. Unit of I = 1 ampere/cm² = 3×10^9 es/(sec cm²) = 0.1 em/(sec cm²) = 6.28×10^{18} electron/(sec cm²). Unit of ϕ = 1 volt = 10^8 cgsm unit of potential = 0.003335 cgse unit of potential = 1.591×10^{-12} erg per electron.

Oxides on 95% Pt + 5% Ni (3)

Electrical resistivity of core $= 2.2(10)^{-5}(1 + 0.00208t - 4.6(10)^{-7}t^2)$ ohm cm, t is centigrade temperature, °C. The coating is a mixture of the oxides of Ba and Sr plus a small admixture of Ni (and Pt) which is transferred from core to coating during preparation and activation of the filament. Thermal emissivity (ratio to black-body) $= 0.4 + 2.5(10)^{-4}T$ if $800°\text{K} < T < 1200°\text{K}$. Electron emission in zero field is given by $I_T = (10)^{-2}T^2e^{-11\ 600/T}$ ampere/cm². For anode potential = 150 volt and space-charge limited current = 0.010 ampere/cm², the average life is $1.5(10)^{-5}e^{22\ 000/T}$ hr. The following values are those most probable when anode potential = 150 volt and electric field is zero:

T	900	950	1000	1050	1100	°K
I_T	20	45	90	170	310	10^{-3} ampere/cm²
p_r¶	2.3	3.0	3.7	4.6	5.6	watt/cm²
p_e¶	0.02	0.045	0.09	0.17	0.31	watt/cm²
Life	730**	170**	55	20	7.4	10³ hr

* This value is especially good. † Monatomic layer.

‡ Emission is a function of bulb temperature; bulb at 30°C.

§ These data are not very reliable.

‖ Values on this line should not be used if $T > 1600$°K.

¶ p_r = power thermally radiated; p_e = power absorbed by electron emission.

** Computed.

TABLE 2.—ELECTRON EMISSION FROM MO, TA, TH ON W, AND W: VARIATION WITH TEMPERATURE

Electric field is assumed zero; if, at cathode, $dV/dr > 0$, a correction must be applied, *see* (31); correction must be applied for losses in the leads, *see* (41). $I = i \times 10^n$ = current per unit area $= A_2T^2e^{-b_2/T}$ ampere/cm².

		7.95	−1	6.82

* Effect for N_2 varies with anode voltage.

TABLE 4.—EMISSION OF ELECTRONS BY THORIATED W (9)

When W containing Th is heated, there is evaporation of Th from the surface and a diffusion of Th from the interior to the surface (*see* Table 5); the equilibrium condition is determined by the balancing of these two effects. If we write $\theta = (b_\theta - b_W)/(b_{Th} - b_W)$, where b_{Th} is the maximum value of b_2 for thoriated W, and b_W and b_θ are, respectively, the values of b_2 for W and for the thoriated W under study, then θ is, effectively, the fraction of the surface which is completely covered with Th. At temperatures above *ca.* 1600°K, the equilibrium value of θ is <1, and decreases as T increases (21). Kingdon (16, 23) states $b_\theta = 31\ 200\theta + 52\ 200(1 - \theta)$ and $A_2 = [7^\theta + 60^{(1-\theta)} - 1]$ ampere/(cm² deg²). $I_T = A_2T^2e^{-b_2/T}$ ampere/cm² $= i \times 10^n$; $b_2 = \beta_2 \times 10^4$.

θ	$\log_{10} A_2$	β_2	$\log_{10} I$*	i*	n
1	0.455	3.040	0.066	1.16	0
0.924	0.397	3.213	$\bar{1}.613$	4.19	−1

CONTACT POTENTIALS

SAUL DUSHMAN

If the heat absorbed when one unit of electricity passes (1) from the free surface of conductor A to the free surface of conductor B, in contact with A, is P'_{AB}; (2) across the junction from A to $B = P_{AB}$; (3) from surface of A [B] to infinity $= P_{AS}$ [P_{BS}]; then $P'_{AB} = P_{AB} - P_{BS} + P_{AS}$. Let $K_{AB} = V_A - V_B$ = contact potential of A with reference to B; V_A, V_B are the simultaneous potentials of A, B when in contact (2, 5). From thermodynamics, it follows that $\mathrm{d}K_{AB}/\mathrm{d}T = -P'_{AB}/T$; for Fe and Ni this amounts to 0.000032 volt/degree at 50°C, while the experimental value for the range 20 to 60°C is 0.0016 volt/degree (5). The discrepancy is ascribed to the formation of a thin surface layer of oxide.

The value of K_{AB} may be deduced from data pertaining to the thermo- and photo-emission of electrons. If I = current per unit area carried by the thermoelectrons, $K_{AB} = \frac{k_0T}{\mathbf{e}} \log_e \frac{I_A}{I_B}$, and if $I = AT^n e^{-\phi\mathbf{e}/k_0T}$ (*cf.* p. 53), $K_{AB} = \phi_B - \phi_A + \frac{k_0T}{\mathbf{e}} \log_e \frac{A_A}{A_B}$. If A is a universal constant (18), $K_{AB} = \phi_B - \phi_A$.

If ν_0 = threshold frequency for emission of photoelectrons, V_{rAa} = retarding voltage = potential to which A must be raised above the anode in order to prevent the emission of photoelectrons under action of radiation of frequency ν, and K_{Aa} = contact potential of A with reference to anode, then (12, 15) $(V_{rAa} + K_{Aa})\mathbf{e} = \mathbf{h}(\nu - \nu_{0A})$ and $K_{AB} = V_{rBa} - V_{rAa} + (\nu_{0B} - \nu_{0A})\mathbf{h}/\mathbf{e} = V_{rBa} - V_{rAa} + (\phi_B - \phi_A)$; this equation is confirmed by experiments (9, 15). Millikan (15) calls $(V_{rBa} - V_{rAa})$ the "spurious" and $(\nu_{0B} - \nu_{0A})\mathbf{h}/\mathbf{e}$ the "intrinsic" contact potential. For clean metals $V_{rBa} = V_{rAa}$; for others the equality may fail (15). Comparing this expression for K_{AB} with that derived from thermoelectronic data, it is obvious that $V_{rBa} - V_{rAa} = \frac{k_0T}{\mathbf{e}} \log_e \left(\frac{A_A}{B_B}\right)$, if ϕ denotes the same quantity in each case (18).

Many of the following data are not very reliable, but those obtained under similar conditions probably indicate the correct order of the conductors in a Volta series.

TABLE 1.—VALUES OF THE WORK FUNCTION (ϕ) AS DERIVED FROM THE WAVE-LENGTH LIMIT (λ_0) OF THE PHOTOELECTRIC EFFECT: ILLUSTRATIVE DATA

Values for other substances may be derived from the photoelectric data on pages 67–69.

$\phi = \frac{hc}{e\lambda_0}$; $K_{AB} = V_{rBa} - V_{rAa} + \phi_B - \phi_A = \frac{k_0T}{e}\log_e\frac{A_A}{A_B} + \phi_B - \phi_A$ where A_A and A_B have the values derived from thermal electron emission data, p. 53. For clean surfaces, $K_{AB} = \phi_B - \phi_A$. $\phi/\nu_0 = 4.117 \times 10^{-15}$ (volt sec); $\phi\lambda_0 = 12\,344$ (volt Ångstrom). Unit of $\lambda_0 = 1$ Å $= 10^{-8}$ cm $= 10^{-4}\mu$; of $\phi = 1$ volt $= 10^8$ cgsm unit $= 3.33 \times 10^{-3}$ cgse unit.

CURRENT FLOW IN VACUUM TUBES WITH HOT CATHODES

Albert W. Hull

CONTENTS

In what follows it is assumed that the emission of electrons (or ions) from the cathode (*see* p. 53) is so ample that the current through the tube is not limited by it.

Diodes.—If the carriers are emitted with velocity = 0, then in all cases $i = KGV_a^{1.5}$, where the value of KG depends only upon the construction of the tube and upon the system of units employed. K depends upon e/m and G upon certain ratios determined by the geometrical configuration of the conductors in the tube; G is dimensionless. Except in certain ideal cases, KG is treated as a single quantity and is denoted by k (*see* Table 3).

Triodes (10, 22).—If the carriers are emitted with velocity = 0, and if there is no magnetic field, $i(= i_p + i_g) = k(E_p + \mu E_g)^{1.5}$, approximately, *see* (20); k has the same value as for the corresponding diode; μ depends solely upon the geometrical configuration of the conductors in the tube (1, 4, 17, 20), but by varying the size of the grid mesh, it can be given any desired value. The mutual conductance (g_m) is a function of i_p, but for a given value of i_p, it is nearly independent of size of grid mesh. It is roughly proportional to length of cathode filament and inversely proportional to distance between grid and filament (*see* Table 4).

Tubes with Four Electrodes.—Space-charge grid tubes have the second grid next to the filament; the presence of this grid multiplies g_m by approximately 4, but the other constants remain the same as for the corresponding triode (21). Screen-grid tubes have the second grid between grid and plate. If screening is perfect, i_p is a function of E_g only, and the value of g_m is only about ¾ as great as in the corresponding triode (7, 21).

SYMBOLS

A	Area of one side of a plate electrode
c	Velocity of light *in vacuo*.
cgse	Cgs electrostatic system of units.
cgsm	Cgs electromagnetic system of units.
csva	Cm-sec-volt-ampere system of units, absolute volt and ampere.*
csVA	Cm-sec-volt-ampere system of units, international volt and ampere.*
E_p, E_g	Potential of plate, grid, above that of cathode.
e	Negative electronic charge.
e	Negative charge of the carrier of electricity (electron or ion).
G	Geometrical factor of k.
g_m	Mutual conductance of plate and grid, $g_m = -\partial i_p/\partial E_g$, E_p being constant.
H	Strength of magnetic field externally applied parallel to axis of cylindrical electrodes.
I	Current flowing through the inner cylindrical electrode parallel to its axis.
i, i_p, i_g	Current to cathode: Total, from plate, from grid; $i = i_p + i_g$.
K	Physical factor of k.
k_0	Boltzmann gas constant.
k	Space charge constant characteristic of the tube; $k = KG$.
l	Length of cylindrical electrode.
M	Molecular weight of the carrier ions.
m	Mass of the carrier of electricity (electron or ion).
$\mathbf{m}_0$	Mass of negative electron at low velocity.
r_a, r_c	Radius of anode, cathode.
r_o, r_i	Radius of outer, inner, of two coaxial cylinders, or of two concentric spheres.
R_p	Plate resistance; $R_p = 1/(\partial i_p/\partial E_p)$, E_g being constant.
T	Absolute temperature of the carriers of electricity, °K. For thermionic carriers, T = temperature of cathode (3); for electrons from low pressure arcs, T is nearly independent of current density, but depends upon the nature and pressure of the gas, and ranges from 10 000 to 50 000°K (16).
V	Excess of potential above that of cathode.
V_m	Minimum value of V in space between anode and cathode.
V_a	Potential of anode above that of cathode.
v	Velocity of carrier.
v_i	Initial velocity of carrier.
x	Distance from cathode in direction of anode.
x_m	Value of x corresponding to V_m.
x_a	Distance between anode and cathode.
α^2, β^2	Functions of r_o/r_i.
ϵ	Dielectric constant of a vacuum. In cgse system, $\epsilon = 1$; in cgsm, $\epsilon = \mathrm{c}^{-2}$; in csva, $\epsilon = (10)^9\mathrm{c}^{-2}$; in csVA, $\epsilon = 1.00052(10)^9\mathrm{c}^{-2}$.
μ	Amplification factor; $\mu = -\mathrm{d}E_p/\mathrm{d}E_g$, i_p being constant.

Table 1.—Ideal Diodes

K_e = value of K if carriers are electrons; $K = K_e\sqrt{e\mathbf{m}_0/\mathbf{e}m} = K_e\sqrt{e/(1847M\mathbf{e})}$. ‖ Plates, Coax. Cyl., Con. Sph. = parallel plates, coaxial cylinders, concentric spheres. General formulae are valid for any consistent system of units; a numerical value is valid only for the indicated system of units.

Electrodes	G	Formula, K	cgse		csVA		Lit.
			k_e	n	k_e	n	
Magnetic field = 0, $v_i = 0$; $i = KGV_a^{1.5}$; $K_e \equiv k_e \times 10^n$							
‖ Plates....	$\frac{A}{x_a^2}$	$\frac{\sqrt{2}}{9\pi}\epsilon\sqrt{\frac{e}{m}}$	3.643	+7	2.341	−6	(2, 8, 11)
Coax. cyl..	$\frac{l^*}{r_a\beta^2}$	$\frac{2\sqrt{2}}{9}\epsilon\sqrt{\frac{e}{m}}$	22.89	+7	14.71	−6	(13, 15)
Con. sph...	$\frac{1^*}{\alpha^2}$	$\frac{4\sqrt{2}}{9}\epsilon\sqrt{\frac{e}{m}}$	45.78	+7	29.42	−6	(14)
Magnetic field = 0, v_i has a Maxwellian distribution (12)							
‖ Plates....	$i = GK(V_a - V_m)^{1.5}\left(1 + C\sqrt{\frac{T}{V_a}}\right)$, where K has same value as for $v_i = 0$, $G = A/(x_a - x_m)^2$, and $C = 2.66\sqrt{\frac{k_0}{e}}$. If $e = \mathbf{e}$, then $C = 0.001426$ cgse = 0.0247 csVA.						
Magnetic field ≠ 0, $v_i = 0$							
Coax. cyl..	$i = GKV_a^{1.5}$ if $V_a > V'$; $i = 0$, if $V_a < V'$. G and K have same values as for field = 0; $V' = \frac{e}{m}\times\left[\frac{H^2r_o^2}{8} + 2I^2\left(\log_e\frac{r_o}{r_i}\right)^2\right]$. In the csVA system, $V' = 0.0221H^2r_o^2 + 0.0188I^2\left(\log_{10}\frac{r_o}{r_i}\right)^2$, if carriers are negative electrons.						

---

* In csva system, unit of mass is 10^7 g; required by relation $eV = \frac{1}{2}mv^2$. In csVA system, unit of mass is $\frac{10^7}{1.00032}$ g.

* For values of α^2 and β^2, *see* Table 2.

TABLE 2.—VALUES OF COEFFICIENTS α^2 AND β^2

For coaxial cylinders, $G = l/(r_a\beta^2)$; for concentric spheres, $G = 1/\alpha^2$ (*see* Table 1)

TABLE 3.—CHARACTERISTICS OF TYPICAL COMMERCIAL DIODES (6)

In all cases $i = kV_a^{1.5}$ (9). The tubes are so constructed that, for the size of anode used, k is as great as is now (Jan., 1927) considered practical. The values are for American tubes, but do not differ appreciably from those for similar tubes constructed elsewhere. i_f, E_f = filament current, voltage; E_m = maximum effective A.C. input voltage; i_m = maximum rectified tube current; P_n = nominal power rating; ThW, PW = thoriated tungsten, pure tungsten, filament. Unit of i_f and i_m = 1 ampere; of E_f and E_m = 1 volt; of P_n = 1 kilowatt; of k = 0.0001 ampere/volt$^{1.5}$.

Type	i_f	E_f	E_m	i_m	P_n	k

TABLE 4.—CHARACTERISTICS OF TYPICAL COMMERCIAL TRIODES

The following data for American tubes differ but little from those for corresponding tubes manufactured elsewhere. Ox, ThW; PW = oxide coated, thoriated tungsten, pure tungsten filaments; i_f = filament current, E_f filament voltage; E_p = normal plate voltage, L, D = overall length, diameter, of tube; P_a = safe continuous energy dissipation at anode; P_o = rated power output; E_g, i_p = grid voltage, plate current, for normal operation as amplifier. Unit of i_f = 1 ampere; of i_p = 0.001 ampere; of E_f, E_p, E_g = 1 volt; of L, D = 1 cm; of P_a, P_o = 1 kilowatt; of g_m = 0.001 mho = 0.001 ohm^{-1}. μ is dimensionless.

	S	*g*	16.8*	(25, 41)	16.7	Comet-tail (*g-f*)	(53)
	S	*h*	19.9*	(25, 41)	19.8	First negative (*h-f*)	(53)

Three other spectroscopic levels between *e* and *f*. From vibrational states of normal level (4), $D = 11.2$; from heat of combustion and D for O_2, $D = 10.8$; mean $D = 11.0$. From vibrational states, $D^+ = 9.8$. As $I_A (= I_M + D^+ - D) = 14.2(f) + 9.8 - 11.0 = 13.0$ is, within experimental error, $= I_A$ of O ($= 13.56$, Table 1), the dissociation of CO^+ probably gives C and O^+.

* Mean error = ±0.1.

DIELECTRIC CONSTANT AND DIELECTRIC STRENGTH

INTRODUCTION

The dielectric constant (ϵ) of a material is a measure of the ratio of the electric displacement (D) to the electric field intensity (E), $D = \epsilon E/4\pi$; for a vacuum, $\epsilon = 1$ cgse unit. The value of ϵ may be determined from the measurements (1) of electrical capacities, (2) of mechanical forces between charged conductors, or (3) of the wave lengths of electrical waves. All three methods yield the same result, except in so far as the value of ϵ varies with the frequency (ν) of E. If electrical waves experience absorption in the substance, the index of the absorption (*v.* Vol. 1, p. 34) being k', then $\epsilon = (1 - k'^2)\lambda_0^2/\lambda^2$, where $\lambda_0[\lambda]$ = wave-length, for frequency ν, in vacuum [in substance]; values of ϵ so obtained are accompanied by the corresponding values of k', if known; when k' is not given, it is believed to be too small to affect the value of ϵ within the stated limits of accuracy.

For variation of ϵ with E, *v.* p. 106; with magnetic field, *v.* p. 105; with illumination, *v.* p. 79.

The dielectric strength (S) of a material is defined as the minimum value, in the material, of the electric field intensity (E) at which a disruptive discharge occurs. In many cases it appears doubtful if S is a constant, characteristic of the material, as it frequently appears to vary with the nature of the electrodes and with the distance between them. As the determination of the actual maximum value of E occurring in the field at the instant of discharge is difficult, the value of S is frequently merely indicated by stating the kind of electrodes, the minimum distance (l) between their surfaces, and the difference in their potentials at the instant of discharge, if the difference is increasing slowly and continuously (D.C.). If the voltage is alternating (A.C.) either the effective (V_e) or the maximum (V_m) value of the alternating potential difference of the electrodes is stated. If the potential difference varies as sin ωt, $V_m = 1.414 V_e$. Electrical oscillations in the circuit may introduce serious errors and injure connected apparatus, and should be prevented from reaching the terminals by the insertion, in series with each terminal, of a non-inductive resistance of at least one ohm per volt. The effect of surrounding objects in modifying the electrical field must be considered, and very definite specifications for the construction of the gap must be followed if accurate values for the potential difference corresponding to a given spark length are desired (*cf.* p. 79, 80).

DIELECTRIC CONSTANT AND DIELECTRIC STRENGTH OF ELEMENTARY SUBSTANCES, PURE INORGANIC COMPOUNDS, AND AIR

H. L. CURTIS AND F. M. DEFANDORF

Symbols.—l = liquid, s = solid, t_R = room temperature, *v.p.* = vapor pressure of the saturated vapor at the temperature indicated. ϵ = dielectric constant, ν = frequency of field used in obtaining ϵ. Such expressions as "(80 p 160)" and "(10° t 100°)" indicate that the accompanying coefficients apply so long as p [t] lies between 80 and 160 [10° and 100°]; "25; 45" in the temperature column indicates that the same value was found at 25° as at 45°. Other symbols unexplained in Vol. I, p. 16, will be defined where used.

No data have been found for the dielectric strength of any solid or liquid included in this section.

TABLE 1.—DIELECTRIC CONSTANT (ϵ) OF PURE INORGANIC GASES

$(\epsilon_t - 1) = (\epsilon_0 - 1)[1 + \alpha t(10)^{-3} + \beta t^2(10)^{-6}]$; $\epsilon - 1 = (\mathrm{a}p + \mathrm{b}p^2)(10)^{-4} = 3\mathrm{c}d_1[1 + \mathrm{c}d_1(10)^{-6}](10)^{-6}$, where d_1 = specific gravity of the gas with reference to itself at 0°C and 1 atmosphere. $\epsilon = 1 + 0.001\Delta$; $\nu = A \times 10^n$. Unit of ϵ = 1 cgse unit; of p = 1 atmosphere; of ν = 1 cycle/sec; of t = 1°C.

TABLE 2.—DIELECTRIC CONSTANT (ϵ) OF PURE INORGANIC SOLIDS AND LIQUIDS AND ITS VARIATION WITH TEMPERATURE (t), PRESSURE (p), AND FREQUENCY (ν)

For SiO_2, *v.* p. 341; for single crystals, *v.* p. 98

From certain solids it is difficult, or even impossible, to prepare plates which are sufficiently homogeneous to be used for a direct determination of the dielectric constant (ϵ) of the material. In such case, it is customary to deduce ϵ from the effective dielectric constant (ϵ') of a dry plate formed by compressing the powdered substance, or from the effective constant (ϵ_1) of such a plate when saturated with a liquid (dielectric constant = ϵ'') which does not dissolve the powder. For such deduction, one or another of the following equations is generally used:

(1) $(\epsilon - 1)/d = (\epsilon' - 1)/d'$; (2) $(\epsilon - 1)/d(\epsilon + 2) = (\epsilon' - 1)/d' \times (\epsilon' + 2)$; (3) $(\epsilon - 1)/d(\epsilon + n) = (\epsilon' - 1)/d'(\epsilon' + n)$; (4) $(\epsilon - \epsilon'')/d = (\epsilon_1 - \epsilon'')/d'$. Here d = density of the substance, d' = density of the dry plate, and n is Wiener's number (152).

All liquids are under the pressure of saturated vapor unless contrary is indicated in first column. In column (2), l = liquid, s = solid, ls = intermediate between liquid and solid, P indicates ϵ was deduced from effective constant of a plate of compressed powder, its subscript indicates equation used.

$$\epsilon_t = \epsilon_{t_0} + \alpha(t - t_0)(10)^{-3} + \beta(t - t_0)^2(10)^{-6}; \epsilon_p = \epsilon_0(1 + \mathrm{a}p(10)^{-4} + \mathrm{b}p^2(10)^{-8}); \nu = A \times 10^n$$

Unit of ϵ = 1 cgse unit, of p = 1 atmosphere, of ν = 1 cycle/sec of t = 1°C

TABLE 3.—DIELECTRIC CONSTANT OF AIR

For gaseous air, $\epsilon = \dfrac{1 + 2c_1d_1}{1 - c_1d_1} = 1 + 3c_1d_1 + 3c_1^2d_1^2 + \ . \ . \ . = 1 + 3c_1d_1(1 + c_1d_1) + \ . \ . \ . \ ; d_1 = p/(1 + 0.003665t)$ if unit of $p = 1$ atmosphere, of $t = 1°C$. ε is independent of the frequency. If we write $c_1 = c \times 10^{-6}$, $c = 195$; tested and found

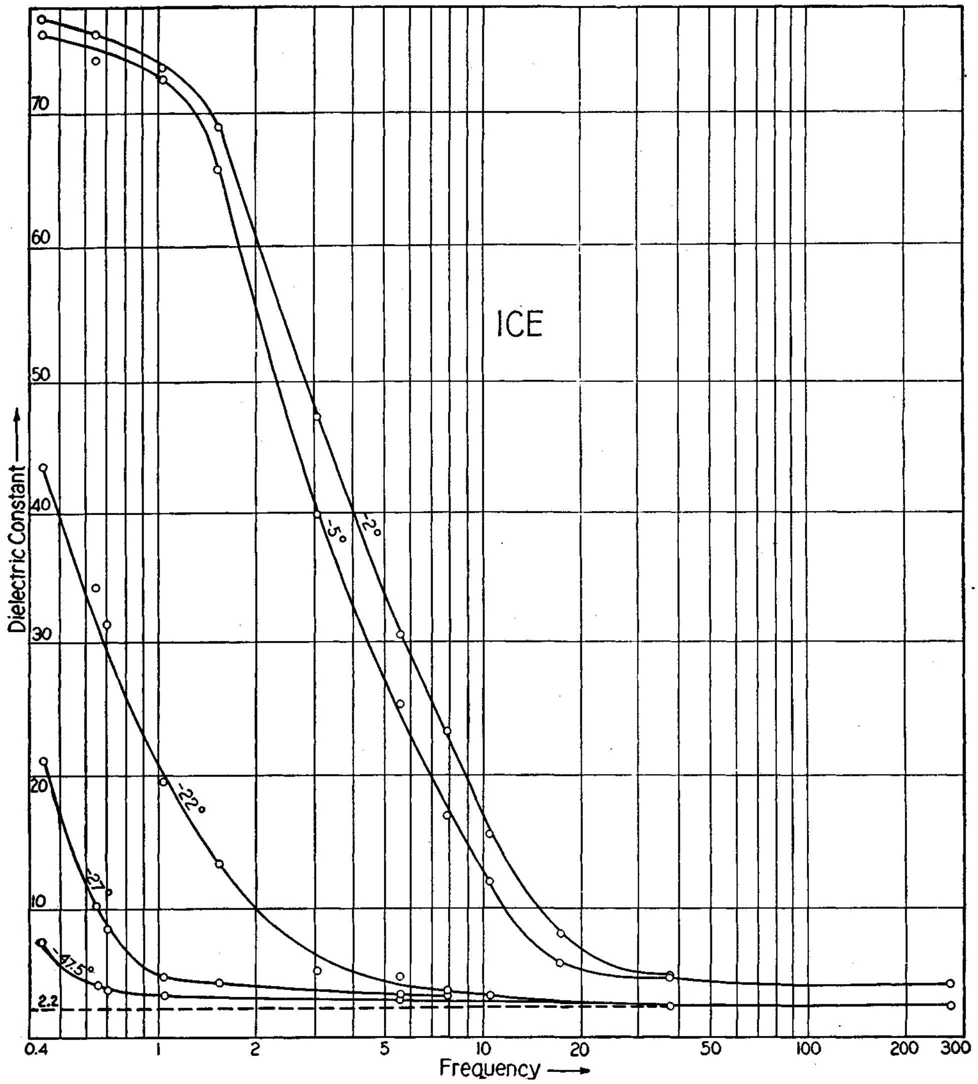

FIG. 4.—Dielectric constant (ϵ) of ice: Variation with frequency (ν) and temperature (t) (36). Unit of ν = 1 kilocycle/sec; of ϵ = 1 cgse; t = °C.

constant for (0 p 175); (0° t 70°) (9, 19, 49, 51, 75, 92, 94, 104, 126, 127, 135, 139); at very low temperatures, c is a few per cent greater than 195; at −185.5°C, $\epsilon - 1 = 0.001890/p$. ν = frequency, cycle/sec. Unit of ϵ = 1 cgse; of p = 1 atm.; of t = 1°C.

Gaseous, $p = 1$			Liquid, $p = 1$			
t	ϵ	Lit.	t	ϵ	ν	Lit.
0	1.000585		−185	1.432	(?)	(103)
−185.5	1.00189	(106)	−185	2.28	7.5×10^9	(88)

TABLE 4.—DIELECTRIC CONSTANT (ϵ) OF H_2O; STEAM, WATER, AND ICE

Unit of ϵ = 1 cgse unit, of p = 1 atmosphere, of ν = 1 cycle/sec; of t = 1°C.

Steam, $p = 1$, (140° t 150°): $\epsilon = 1.00785 - 0.00016\ (t - 140°)$ (5). If (0 p' 40) (40° t 165°), $\epsilon = 1 + [9.3 - 0.026(t - 40)]p' \times 10^{-6}$, where unit of p' = 1 mm of Hg (152).

Water, $p = 1$, (0° t 100°) (0 ν 10^8): $\epsilon = 80 - 0.4\ (t - 20°)$, (18, 23, 24, 28, 50, 65, 69, 73, 74, 86, 90, 91, 105, 107, 109, 110, 121, 122, 128, 131, 133, 150). For $\nu > 10^8$, the value of ϵ is uncertain; two observers (25, 111), using standing waves along wires, find ϵ decreases as ν increases (*see* Fig. 3); another (79), from measurements of refraction, concludes that the reverse is true.

At 16.3°C, $\nu = 6 \times 10^7$ (7 p 200), $\epsilon = 81.5 + 0.0046p$ (39).

Ice, at −5°C (10^7 ν 10^9), $\epsilon = -0.08 + 0.34 \log_{10} \nu$ (58). For variation with ν and t, *see* Fig. 4. Other determinations are tabulated below.

t	$\epsilon_{t,\nu}$	t	$\epsilon_{t,\nu}$	t	$\epsilon_{t,\nu}$
$\nu = 50$ (129)		$\nu = 120$* (27, 45)		$\nu = 320$ (28)

				−190	1.8

* Condenser charged and discharged by commutator, 120 charges per sec; *see also* Fig. 5. † From (58).

Table 5.—Effect of Illumination upon Dielectric Constant (56)

For a phosphorescent ZnS containing a trace of Cu, $\epsilon_l - \epsilon_d = B\epsilon_d(1 - e^{-aJ})$, where ϵ_l, ϵ_d = dielectric constant in the light, in the dark, and J = irradiation of the material. B and a vary with the wave-length (λ) of the light. For room temperature and $\nu = 3 \times 10^6$ cycle/sec, the following values were found. Unit of λ = 1mμ = 10 Å; of $J = 10^{-12}$ watt cm^{-2}.

λ	313	365	405	435
B	0.006	0.035	0.042	0.033
a	13.2	9.1	5.0	12.4

Table 6.—Relative Dielectric Strengths of Pure Inorganic Gases at 25°C and 1 Atmosphere (6, 13, 64, 70, 76, 85, 97, 120, 132, 147, 149)

For other pressures, *v.* (61, 62, 97, 141, 147) or use Paschen's law (*v.* Table 7). Values are not affected by the electrode material except in the case of gases of low ionization potential at low pressure, but are affected by the condition of the electrode surface (32, 154). For a mixture of two gases which do not react chemically (64, 70) $(p_1 + p_2)V = p_1V_1 + p_2V_2$ where p_1 and p_2 are the partial pressures of the two constituents of the mixture, and V_1 and V_2 are the sparking potentials for the pure constituents at 25°C and 1 atmosphere.

The presence of an ionizing radiation does not appreciably lower the electric strength of a gas, but makes the individual observations more concordant by eliminating the variable, temporary excess in voltage, which otherwise occurs (64, 89, 141, 158). For bibliography and discussion of data pertaining to the electrical breakdown of gases, *see* (120, 156).

V/V_a = potential difference at which spark passes in gas *divided by* potential difference at which spark passes in air, the temperature (25°C), pressure (= 1 atm), terminals, and gap-length being the same for each. Accuracy, *ca.* 10%.

Gas	Cl	H	N	O	SO_2	H_2S	NH_3	CO_2
V/V_a	0.85	0.65	1.15	0.85	0.30	0.90	1.00	0.95

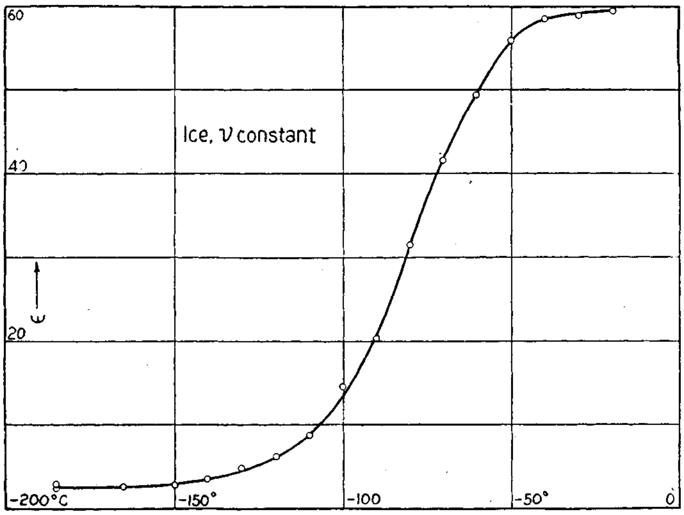

FIG. 5.—Dielectric constant (ϵ) of ice: Variation with temperature, ν is constant at 120 charges (and discharges) per second (27, 45).

Table 7.—Dielectric Strength of Air: Spherical Electrodes, 25°C and 1 Atmosphere

The tabulated data apply to gaps having the following characteristics: The electrodes are two spheres of the same diameter; variations in diameter should not exceed 0.1% and the curvature should nowhere differ from that of a true sphere by more than 1%. The spheres must be highly polished if the frequency of the emf is very high (*e.g.*, 40 000 cycle per sec); at commercial frequencies and for D.C. potential the degree of polish is much less important. Considerable deviation in successive breakdown values may occur if the sparking surfaces are not properly cleaned (154, 158). The diameter of the shanks supporting the spheres should not exceed 0.2 the diameter of the spheres, and if they pass through metal collars, the collars should be small and not closer to the gap than the length (l) of the latter. Each sphere should be at least $2l$ distant from all surrounding materials other than air.

For other temperatures and pressures, multiply the tabular values of V by the factor f (or, less accurately, by c); $c = 298p/(273 + t)A_n$, $f = \sqrt{c}(\sqrt{cr} + \delta)/\sqrt{r + \delta}$, where r = radius of the electrode, δ = 0.54 cm, p = pressure, A_n = pressure of one normal atmosphere. Paschen's law (147), V is a function of (dl), holds throughout the range within which air is essentially an ideal gas (61); *cf.* (20, 21, 35, 60, 64, 141). Values of V are independent of the humidity of the air and of the electrode material (32, 98, 99, 124, 144), d = density, D = diameter of spheres, G = one sphere grounded, connected to earth, I = both spheres insulated from earth, l = shortest distance between surfaces of spheres, u = greatest uncertainty in the data, it is probably several times greater than actual error, V_m = maximum value of A.C. voltage. Unit of D and of l = 1 cm; of V_m = 1 kilovolt = 10^{11} cgsm unit = 3.335 cgse unit.

TABLE 8.—DIELECTRIC STRENGTH OF AIR: NEEDLE ELECTRODES, 25°C AND 1 ATMOSPHERE (48, 99, 100, 101, 102, 136, 141, 157)

The tabular data apply to gaps having the following characteristics: The electrodes are new sewing needles, No. 00, supported axially at the ends of linear conductors at least $2l$ long. There must be no other material than air nearer than $2l$ to any portion of the gap. Needles must be replaced after each spark. A needle-gap is not suitable for the measurement of impulsive or high frequency voltage.

For other temperatures and pressures, multiply the tabular values of V by the factor f (or c), *v.* introduction to Table 7. Values of V vary with humidity, and for D.C. differ from V_m of A.C., h = relative humidity, u = greatest uncertainty in the data, it is probably several times greater than actual error, V_e = effective A.C. voltage. Unit of l = 1 cm; of h = 1%; of V, V_e, V_m = 1 kilovolt = 10^{11} cgsm unit = 3.335 cgse unit.

ELECTRICAL CONDUCTIVITY AND RESISTIVITY

PROPERTIES OF CARRIERS OF FREE ELECTRICITY IN GASES*

LEONARD B. LOEB

INTRODUCTION

Types of Ions.—Three types of carriers may be distinguished: Normal ions, slow ions, and free electrons.

Normal ions are the carriers generally found in dry, dust-free gases at approximately atmospheric pressure. As far as is known (**83, 97, 139**), after the first few hundredths of a second they carry a single electronic charge (4.774×10^{-10} es). Their mass is not known, but is of the same order as that of one to several molecules; their exact nature is an object of controversy (**67, 81, 82, 96, 126**) but it is certain that in *some cases* they consist of two or more molecules. Where the mobility of the completely formed positive ion is markedly less than that of the negative ion the mobility of the newly formed positive ion is abnormally great (**33, 35, 36, 37, 38, 39, 41, 79, 136, 149, 152**) and probably equals that of the negative ion (**40, 87**). In these gases the positive carrier seems to be completely formed after 0.03 second, and then its mobility no longer varies with its age. For gases in which the negative ion is the less mobile, no data exist. The mobility of both ions appears to be remarkably independent of the mass of the initially ionized molecule (**10, 38, 40, 41, 42, 49, 61, 67, 82, 100, 125, 153**). In at least one case (**40**) this can be ascribed to a transfer of the charge from an ionized molecule of higher ionizing potential to one of a lower; in other cases, such as with radioactive ions (**36, 39, 42**), this is not so. The nature of the completely formed ion does not depend upon the process by which it was formed (**38, 39, 41, 42, 49, 73**) provided this process does not directly give rise to charged particles of more than molecular mass. It does however very much depend on the electrical and chemical nature of the surrounding gases with which it has had time to come into equilibrium (**41, 81, 82, 96**). In gases with a negative mobility higher than that of the positive, the mobility of the negative ion is independent of its age; abnormalities observed at low pressures are attributed to a delay in the attachment of the electrons to neutral molecules to form negative ions (**50, 55, 56, 68, 69, 77, 97, 134, 155, 156**); in some gases, an electron must make many collisions with molecules before attaching to one to form an ion (*see* Table 12). In certain pure gases [He, A (**43**), N_2, H_2 (**68**), CO (**150**) and probably NH_3] the electron cannot attach itself to a molecule to form an ion. In such cases the negative ions are formed by the attaching of the electrons to impurities which may be present; these negative ions have mobilities which are of the same order of magnitude as those of positive ions.

Slow ions consist of pre-existing nuclei, of more than molecular mass, to which normal ions have become attached (**45, 112**). Their mobilities appear to vary somewhat with age (**8, 9, 18, 19, 20, 21, 22, 23, 45**). Two definite types (**107, 108, 112**) of such

---

* Comprende i dati anteriori al marzo 1928. Per una conoscenza completa del soggetto e per una bibliografia completa, *vedi* (**110**).

ions have been found in moist air. *Type I* is characterized by a mobility which decreases as the partial pressure of the water vapor is increased; these are not found when the partial pressure exceeds 17 mm of mercury (108). *Type II* (62, 63, 107), the so-called Langevin ion, is found at all humidities; and its mobility depends, not upon the partial pressure, but upon the relative humidity, decreasing as the latter increases (8, 9, 18, 19, 20, 21, 22, 23, 90, 98, 99, 101, 102, 103, 145). Besides the ions included in these two types, there are other carriers formed by the attachment of normal ions to solid particles of various sizes; the mobilities of these vary with the size of the particles; these will be called *heterogeneous slow ions.*

Electrons.—The velocity (v) of migration of free electrons is not proportional to the intensity of the electric field causing the migration (4, 70, 71, 112, 139, 143, 144). Under the action of an impressed electric field, the velocity of thermal agitation of the electrons exceeds (139, 143, 144) that of the surrounding gas molecules by a factor (c) depending upon both the field strength (F) and the pressure (P) of the gas. Within the limits covered by observations, the values of c and of v at a specified temperature and for a given gas are quite closely determined by the ratio F/P. *See* Table 11. (For theoretical discussions, *see* (25, 26, 51)).

Coefficient of Recombination of Ions.—Our knowledge of the coefficient of recombination of ions in gases is in a highly unsatisfactory state. Beside difficulties due to columnar ionization in the case of ionization by α-particles (131), no matter what the source of ionization, the initial density and distribution of ions are not known, and erroneous assumptions in this regard may lead to values of the coefficient (α) which are seriously in error. Thus, Rümelin (120) and Plimpton (106) have found that, during a short interval immediately following the formation of the ions, α has an apparent value that is five times the corresponding value reported below (Tables 7, 8, 9). This may be due in part to an initial recombination of free electrons with + ions (84). Values obtained by the use of α-particles have been eliminated as far as possible from Tables 7, 8, and 9, later values obtained in other ways being given. Most observers find that at low pressures and room temperatures α increases nearly proportionally to P, but at pressures greater than 1 atm. it approaches a constant value. Data for variation with temperature are discordant; those of Erikson are probably the best, and indicate that α increases with the temperature.

Mobility (k).—The mobility of an ion = velocity of migration per unit electrical field intensity. Over a wide range of densities (d), kd is a constant for a given gas. (*See* Table 4.) Value of k at 0°C and 760 mm of mercury at 0°C, is often called the mobility constant = k_0. Uncertainties in the proper interpretation of the observations and slight variations in the experimental procedure (73, 74, 128, 146), as well as traces of unsuspected active impurities present in any one of a series of gases, may introduce variations of 20 to 30% in the inferred value of k, but relative values obtained under comparable conditions (41, 81, 96, 112, 139, 147) are quite accurate except for the selective action of impurities. For methods of measurement and interpretation of observations, *see* (24, 33, 45, 46, 49, 56, 57, 60, 73, 74, 112, 118, 128, 160). For attempts at establishing theoretical relations between k and other properties of the gas, *see* (45, 61, 67, 76, 82, 94, 112).

Effective Sectional Area of Molecule.—*See* p. 117.

TABLE 1.—MOBILITY CONSTANT OF NORMAL IONS IN GASES

For mixed gases other than air, *see* Table 2

Except as another is indicated, pressure = 760 mm of Hg, temperature = 15°C. Methods: B = air-blast, C = current measurement, F = Franck's, L = Langevin's, R = Rutherford's, T = Tyndall and Grindley's; F, R, and T are alternating current methods. Range in value is indicated by {; el = negative carriers are free electrons; i = gas was slightly impure; p = gas was pure, giving free electrons even at high pressures. Mobility constant is $k_0 = kd/d_0$ where d_0 = density at 0°C and 760 mm of Hg and d = density when k was measured; excepting at the higher temperatures the values of k given below do not differ significantly from k_0. Data marked * have been reduced by dividing the observed values by 1.21 so as to bring them to the same basis as the others which were obtained by methods yielding a doubtful low value (*see* (73, 74, 128, 146)); it is believed that $k = 1.21M$ in all cases; subscripts ($_+$, $_-$) indicate the ion to which M refers. Unit of k = 1 cm sec^{-1} per volt cm^{-1} = 1 cm^2 volt^{-1} sec^{-1}.

TABLE 2.—MOBILITY (*k*) OF NORMAL IONS IN MIXED GASES

If p_a and p_b = the partial pressures of the constituents *A* and *B* of a binary mixture, $P = p_a + p_b$, $c_a = 100p_a/P$, and $c_b = 100p_b/P$, then c_a and c_b are the per cent concentrations of the two constituents. If k_a, k_b, k_{ab} are the mobilities for the pure gases and for the mixture, all reduced to 760 mm of Hg, then $k_{ab} = 100k_ak_b/(c_ak_b + c_bk_a)$ in the following cases: Both ions in $CO_2 + H_2$, and CO_2 + air (Blanc (10)), in $C_2H_2 + H_2$ (Loeb (87)), and in $O_2 + H_2$ (Mayer (96)); for + ions in $CH_3I + H_2$ (Wellisch (153)); and for − ions in $(C_2H_5)_2O + H_2$ (Loeb (81)). For both ions in NH_3 + air (Loeb (85)) and for + ions in $Cl_2 + H_2$ (Mayer (96)), $k_{ab} = k_ak_b/\sqrt{(c_ak_b^2 + c_bk_a^2)/100}$ fits the observations better. For all other mixtures yet studied, the data depart markedly from these laws if the concentration of the gas of lower mobility is small, but approximate one or other of them as this concentration is increased; *see also* (7, 61, 147). c_v = percentage of vapor. Unit of k = 1 cm²/(volt sec); of c = 1%; of P = 1 mm of Hg.

Air + vapor (*see also* Fig. Index)

Vapor	c_v	k_+	k_-	P	t, °C	Lit.
None	0	1.37	1.80	737	15	(153)

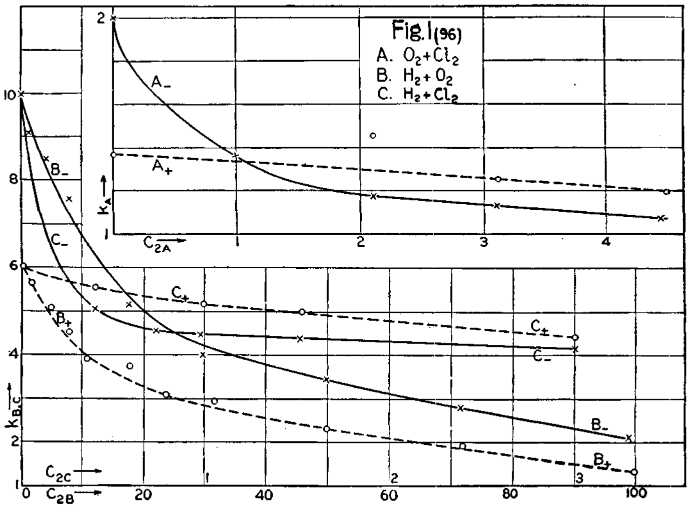
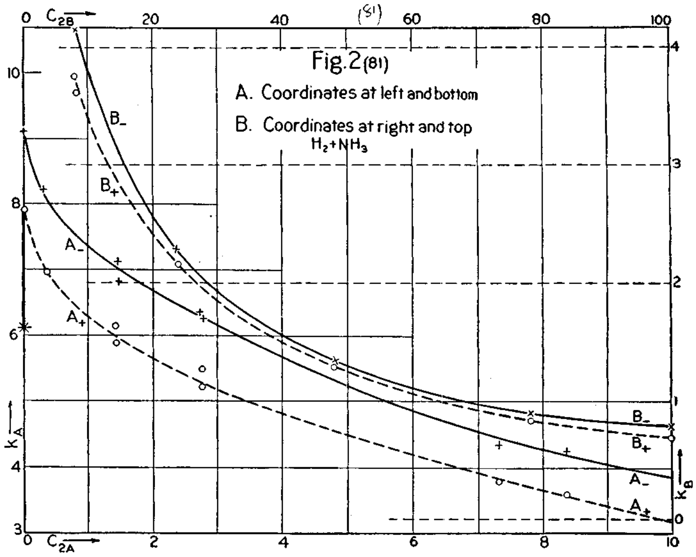
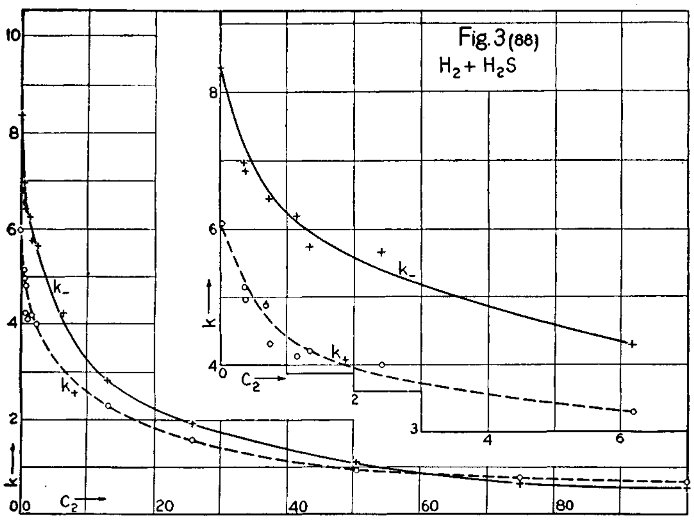
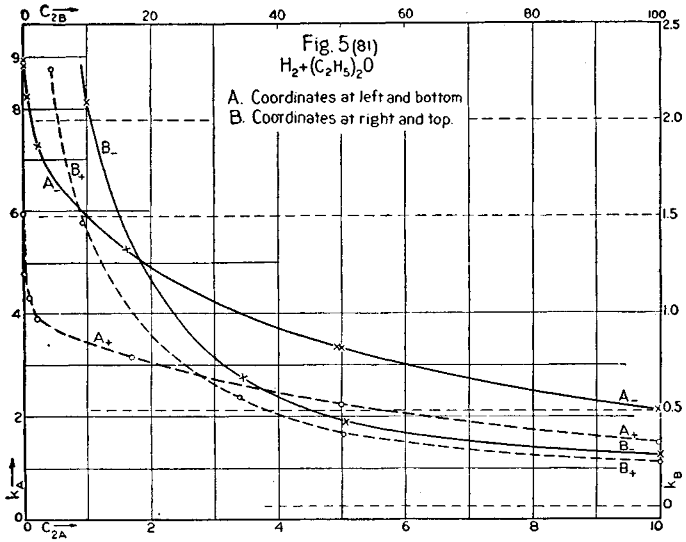


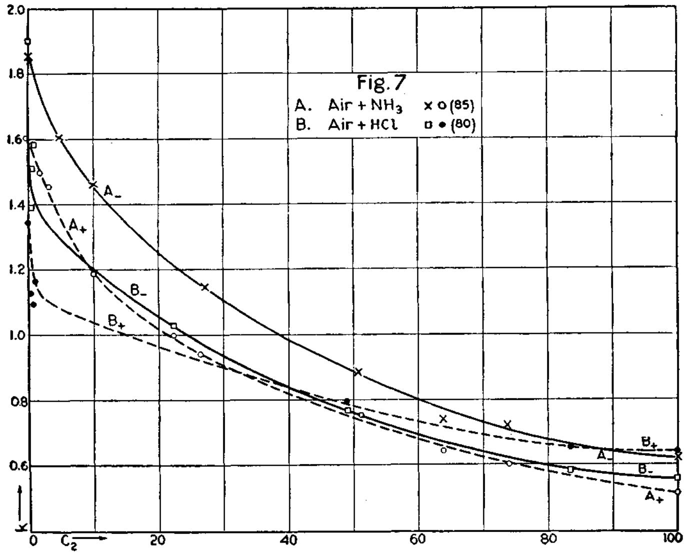


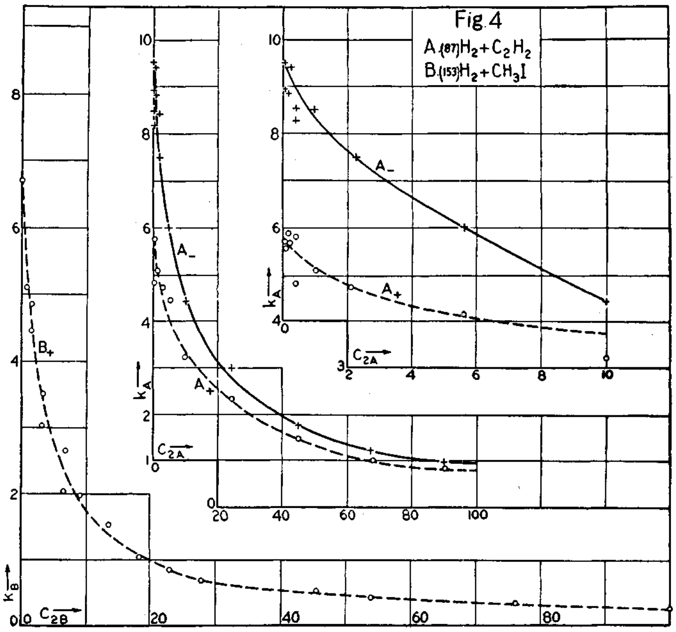
FIGS. 1 to 9.—Mobility (*k*) of normal ions in mixed gases.

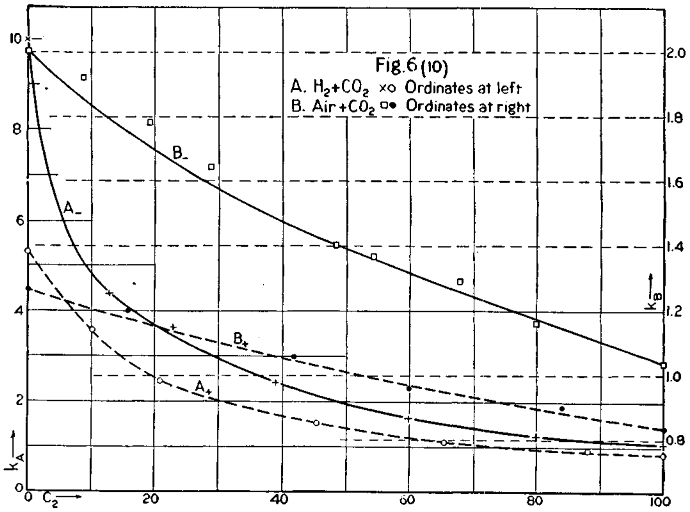
(For symbols and index, *see* Table 2.) P = 760 mm Hg, t = 15°C, C_2 = concentration of the second constituent; *e.g.* in Fig. 2, C_2 = concentration of NH_3; sign of ion is indicated by a subscript, + or −; literature reference is enclosed in ( ). Unit of C_2 = 1%; of k is nominally 1 cm²/(volt sec) but data are suitable for ratios only within the group of which they form a part.

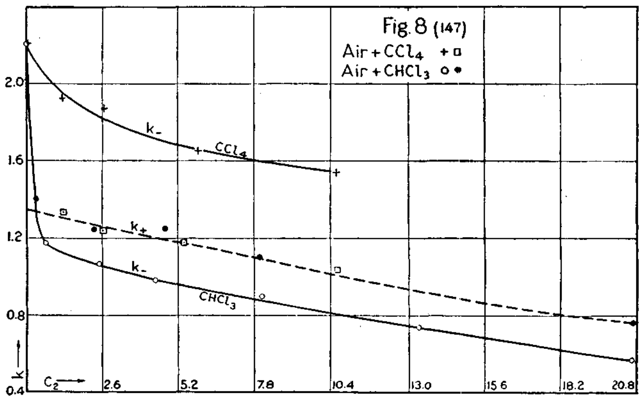






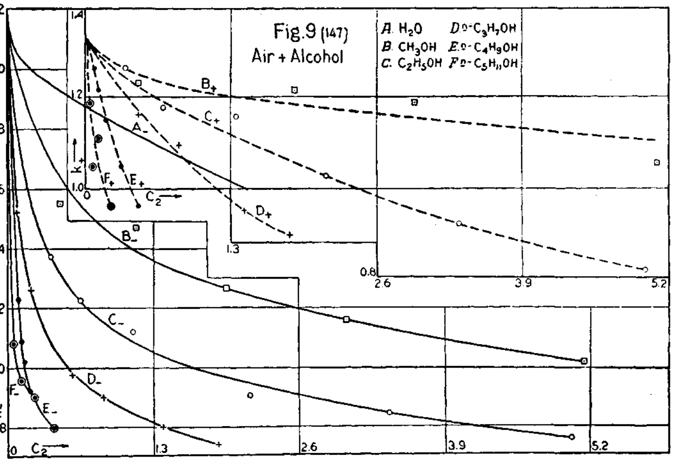






FIGS. 1 to 9.—Mobility (k) of normal ions in mixed gases.

(For symbols and index, *see* Table 2.) P = 760 mm Hg, t = 15°C, C_2 = concentration of the second constituent; *e.g.* in Fig. 2, C_2 = concentration of NH_3; sign of ion is indicated by a subscript, $_+$ or $_-$; literature reference is enclosed in ( ). Unit of C_2 = 1%; of k is nominally 1 cm²/(volt sec), but data are suitable for ratios only within the group of which they form a part.



FIGS. 1 to 9.—Mobility (k) of normal ions in mixed gases.

(For symbols and index, *see* Table 2.) P = 760 mm Hg, t = 15°C, C_2 = concentration of the second constituent; *e.g.* in Fig. 2, C_2 = concentration of NH_3; sign of ion is indicated by a subscript, $_+$ or $_-$; literature reference is enclosed in ( ). Unit of C_2 = 1 %; of k is nominally 1 cm²/(volt sec), but data are suitable for ratios only within the group of which they form a part.

TABLE 3.—MOBILITY (k) OF NORMAL IONS: VARIATION WITH PRESSURE (P)

For a given gas at a given temperature, Pk is a constant if P lies between a few mm of Hg and 75 or 100 atm. (**27, 57, 59, 92, 136, 149, 156**); at other pressures, variations are observed. At least a part of the variation at low pressures arises from the fact that an appreciable fraction of the ions present are not completely formed (**56, 97, 155, 156**) (*cf.* Table 5). Sign of ion is indicated by subscript $_+$ or $_-$. Recent results in SO_2 indicate that for saturated vapors this law may not hold (**89**). Unit of k = 1 cm²/(volt sec); of P = 1 mm of Hg or 1 atm. Temperature = 15°C.

* The density is that corresponding to 0°C and 1 atm.

† Air dried over $CaCl_2$ and liquid air; vessel unheated.

‡ Air dried over liquid air; during filling, vessel heated to 373°K = 100C°.

§ The density is that corresponding to 15°C and 1 atm.

‖ Air of highest purity in contact with Na. ¶ Dry air of less purity.

TABLE 5.—MOBILITY (k) OF NEWLY FORMED IONS

Very new + ions have the same mobility as the − ions; mobility of − ions appears to be independent of age. Values of k on any one line of the table are relatively correct, but are not in all cases comparable with those on any other line.

U_n = upper limit for the age of the new ions; L_o = lower limit for the old ions. The same age limits apply to both + ions and − ions. Pressure = 760 mm of mercury; temperature = 15°C. Unit of U and L = 1 sec; of k = 1 cm²/(volt sec).

* The > indicates that negative ion is slightly faster than initial positive ion. † Mobility of (k') measured at P = 5 to 50 mm and reduced to P = 760 mm by equation $k = k'P/760$.

TABLE 6.—DIFFUSIVITY (Δ) OF NORMAL IONS

For methods of measurements and discussion of relation of Δ and k, *see* (47, 84, 97, 133, 139)

$\frac{dN}{dt} = -\Delta\frac{dn}{dz}dxdy$; dN = resultant number of ions, of the species considered, which diffuses, in the direction of increasing z, through the area $dxdy$ in the time dt, when the gradient of the concentration (n) of these ions normal to $dxdy$ is dn/dz; n = number per unit of volume. For these data, $P\Delta$ for a given gas and a given species of ion is essentially a constant; all observations were made near room temperature. At $P = A_n$, $\theta = 0°C$, and for any given gas and species of ion $\Delta/k_0 = A_n/n_o e = 7.85 \times 10^{-5}$ erg/es; k_0 = mobility constant of the ion considered; n_o = Loschmidt's number; e = electronic charge. Sign of ion is indicated by subscript $_+$ or $_-$. Unit of $\Delta = 0.01$ cm²/sec; of P = 1 mm of Hg; of temperature (θ) = 1°C.

TABLE 9.—COEFFICIENT (α) OF RECOMBINATION OF NORMAL IONS: VARIATION WITH TEMPERATURE (*cf.* TABLE 7)

Data for variation with temperature are very discordant. For relative values for CO_2 and H_2, *see* (30). Following values are for air at constant density (α_d) and at constant pressure (α_P); the latter are relative to $\alpha = 1.7 \times (10)^{-6}$ cm³ per (ion sec) at 289°K = 16°C. Unit of α_d and $\alpha_P = 10^{-6}$ cm³ per (ion sec); temperature = T, °K.

TABLE 11.—MIGRATIONAL (v) AND THERMAL (u) VELOCITIES OF ELECTRONS IN GASES AT 15°C

If k = mobility of electrons in the gas considered, $v = kF$, where F = strength of the electric field; the velocity of agitation $u = 1.15c(10)^7$ cm/sec, where c^2 is determined from the lateral scattering of a beam of electrons in an electric field due to diffusion (*see* (139)); the mean free path (l) of the electrons is that defined (139) by $v = 0.815eFl/mu$; l_1 is the value of l when pressure (P) is 1 mm of Hg, and temperature = 15°C; in the units named below, $l_1 = 0.0797vcP/F$. For actual values of F and P, *see* original papers. Unit of F = 1 volt/cm; of P = 1 mm of Hg; of l_1 = 0.01 cm; of $v = 10^5$ cm/sec; of $k = 10^3$ cm²/(volt sec); c is dimensionless; $u = 1.15c(10)^7$ cm/sec.

TABLE 12.—NUMBER (N) OF MOLECULAR IMPACTS OF AN ELECTRON BEFORE ITS ATTACHMENT TO FORM A NORMAL NEGATIVE ION

N appears to be independent of pressure (observations from P = 20 mm to P = 760 mm), but increases with the initial velocity (v_i) of the electron (*see* end of table). Values tabulated refer to 15°C and are rather rough approximations. $N = A \times 10^n$ (**5, 72, 77, 79, 88, 148**).

TABLE 13.—CONDENSATION OF VAPORS ON IONS AND NUCLEI

The degree of supersaturation (S) of a vapor subjected to adiabatic expansion is defined as the ratio of the vapor pressure after the expansion to the pressure of the saturated vapor at the temperature of the gas after its expansion.

When water vapor is supersaturated by adiabatic expansion, four stages of condensation are recognized: Condensation occurs on dust particles and on certain products of chemical action if $S < 4$; begins to occur on $-$ ions at $S = 4$ *ca.*, on $+$ ions at $S = 6$ *ca.*, and on uncharged water nuclei at $S > 6$. The nature of the gas in which the vapor is distributed has no effect upon the value of S required to initiate a given type of condensation. $E \equiv V_2/V_1 =$ adiabatic expansion necessary to produce condensation, $V_1[V_2] =$ volume of moist gas before [after] expansion. E_0, E_-, $E_+ =$ value of E corresponding to condensation on uncharged water nuclei, on $-$ ions, on $+$ ions; S_0, S_-, and S_+ are the values of S corresponding to E_0, E_-, and E_+. When the sign of the ion is not known the value of E is placed between the columns for E_- E_+.

* For H_2O, $S_0 = 7.9$, $S_- = 4.15$ (157). † For H_2O, $S_0 = 6$ (3). ‡ For C_6H_6, ions of unknown sign, $S = 4.3$ (111).

EFFECTIVE SECTIONAL AREA OF MOLECULES* (1, 2, 11, 12, 13, 14, 15, 16, 17, 48, 54, 64, 65, 66, 93, 95, 113, 114, 115, 116, 117, 119, 121, 130, 161, 162)

When a beam of electrons passes through a gas, the number (n_x) of electrons remaining in the beam after it has gone a distance x is given by the equation, $n_x = n_o e^{-qpx}$, where p is the pressure of the gas. If the cross-sectional area of an electron is negligible as compared with that of a molecule, and if the velocities of the molecules are negligible, as compared with that of the electron, then qp will be the sum of the cross-sectional areas of all the molecules in a unit volume. By definition the mean free path of an electron, L_e is defined as $1/qp$. If the effective cross-sectional area of a molecule for an encounter with another molecule were the same as that for an encounter with an electron, then we would have $L_e = 4\sqrt{2}L$, where L is the mean free path of the molecule in the gas.† It is found that qp varies with the velocity of the electrons and that $1/qp$ or L_e is not equal to $4\sqrt{2}L$. (It should be noticed that L_e is not the same quantity as that denoted by l in Table 11.) The absorbing cross-section of all the molecules in a unit volume of gas at the temperature t and at unit pressure is q. The effective radius, r, of the absorbing cross-section of a single molecule is given by the equation $\pi r^2 = q/N_t$, where N_t is the number of molecules per unit volume at the temperature t and at unit pressure. For electrons with high velocities (β-rays), q has such a value that r is of the same order of magnitude as the radius of the nucleus, as deduced from the scattering of α-particles. In actual measurements, the beam of electrons must have a finite width, and, consequently, those electrons that have been deviated from their initial path by less than a certain amount, determined by the apparatus used, are not eliminated from the beam. This source of error makes the computed value of q too small, and causes the results of different observers to differ slightly. In most cases, the deviation of an observer's separate determinations from the mean curve representing all his values is less than 10%.

Typical data are shown in Figs. 10 to 14:

FIGS. 10 to 14.—Effective sectional areas of molecules.

(For general discussion and index, *see* p. 117.) These curves represent typical values deduced from electronic data. q = sum of the effective absorbing cross-sectional areas of all the molecules contained in a unit volume of the gas at 0°C and a pressure of 1 mm Hg; unit of $q = 1$ cm² per cm³. The velocity of the electrons is indicated by numbers equal to the square root of the voltage through which the electron has been accelerated. The equation connecting velocity (v) and volts (V), for slow electrons only, is $\frac{1}{2}\,\mathrm{m}v^2 = \mathrm{e}V$, or $v = 0.595 \times 10^8\sqrt{V}$ cm/sec, where m is the mass of an electron and e its charge.

For some gases, the corresponding sum of the cross-sectional areas involved in the molecular encounters considered in the kinetic theory of gases is indicated by a short dash at the axis of ordinates. Literature references are enclosed in ( ).

IONIZATION OF GASES

O. Stuhlman, Jr.

This section includes ionization by impact of electrons, of positively charged residues, and of α-particles, by electromagnetic radiation and by chemical action. Data for the conductivity of flames, for ionization potentials, and for photoelectric thresholds are given elsewhere; *consult* p. 156, 69 and 67, respectively.

The following symbols will be used:

c	velocity of light in vacuum.
C	Coefficient of ionization; $n = Cp/T$.
C_r	C_1/C_2 for the same ionizing radiation (corpuscular or electromagnetic) = coefficient of relative molecular ionization of gas (1) with reference to gas (2).
E_i	Energy expended in producing one pair of ions.
E_1	Kinetic energy possessed by the charged particle at the beginning of its ionizing career.
e	Electronic charge.
^-i	α/p; $^+i = \beta/p$.
^-I	$\int_0^\infty {}^-i dx$; $^+I = \int_0^\infty {}^+i dx$.
$^-Np[^+Np]$	Number of encounters of an electron [a + ion] per cm of its path; the superior $^-[^+]$ may be omitted where convenient.
n	Number of ions produced per sec in 1 cm³ of a thin layer of gas at pressure p and absolute temperature T.
p	Pressure of the gas being ionized.
p_m	Pressure at which α is a maximum for a given X.
V	Potential difference required to confer the energy E upon a charge = **e**; $\mathbf{e}V_1 = E_1$, $\mathbf{e}V_i = E_i$, etc.
v	Velocity of the ionizing particle.
X	Intensity of the applied electric field.
$\alpha[\beta]$	Number of pairs of ions produced per cm of path by each electron [each + ion].
λ	Wave-length of the exciting radiation.

If the density of the gas remains constant, α, β and the number of ions produced per sec by a given electromagnetic radiation are all independent of the temperature (10, 11, 14, 32, 33, 44); tested (10) from −180 to +1600°C. If the velocity of the particles arises solely from X, then, for a given temperature and gas, α/p and β/p depend solely upon X/p (63, 65, 66, 67, 69). If X is so great that the effects of thermal agitation may be neglected, $\alpha = N_p \mathrm{e}^{-N_pV_i/X}$ (63); hence $(\alpha_{\max.})_{p\ \mathrm{const.}} = Np$ and $(\alpha_{\max.})_{X\ \mathrm{const.}}$ occurs when $p(=p_m) = X/NV_i$ or $X/p_m = NV_i$; the value of N is determined from that of $(\alpha_{\max.})_p$.

For expressions for the total current resulting from ionization by both electrons and positive residues, *see* (3, 63); for ionization of mixed gases, *see* (3, 26); for theory, *see* Bohr (5, 6) and Fowler (19, 20).

TABLE 1.—IONIZATION OF AIR BY ELECTRONS: VARIATION WITH VELOCITY (4, 15, 16, 27, 71)

$$V_1 = 5.082 \times 10^5 \left\{ \frac{1}{\sqrt{1-(v/\mathbf{c})^2}} - 1 \right\} \text{ volt.}$$

For $V_1 < 4000$ volt, $v/\mathbf{c}$ has been computed from observed value of V_1 by means of the approximate relation $v/\mathbf{c} = 0.001983\sqrt{V_1}$, V_1 being expressed in volts; the corresponding expression for E_1 is $E_1 = 1.592 V_1 \times 10^{-12}$. Unit of α = 1 per cm; of p = 1 mm of Hg; of V_1 = 1 volt; $V_1 = A \times 10^n$.

A	n	100v/c	α/p	A	n	100v/c	α/p

TABLE 8.—IONIZATION OF AIR BY α-PARTICLES: VARIATION WITH VELOCITY

No appreciable ionization is produced by an α-particle unless $v > 0.025\mathrm{c}$ (53, 55). If, at a distance x from its source, an α-particle of range R, in the gas considered, produces βdx pairs of ions in a length of path $= dx$, then, quite roughly, $\beta = a/(R - x)^{1/3}$ and $v/\mathrm{c} = b(R - x)^{1/3}$ (22); for air, $a = 4.50 \times 10^4\ \mathrm{cm}^{-2/3}$ (23), $b = 0.0342\ \mathrm{cm}^{-1/3}$ (Vol. I, p. 362). For values of R and v_1 (initial velocity), *see* Vol. I, p. 362, 363. For α-particles from Ra-C′ in air at 12°C and 1 atm., β varies as follows (21):

x	1	2	3	4	5	6	6.5±	7± cm
$\beta/1000$	22.5	23	24	28	36	55	76	40 cm^{-1}

The total number of ions produced is $I = \int_0^R \beta dx = KR^{2/3}$, where $K = 1.50a$; for air, $K = 6.76 \times 10^4\ \mathrm{cm}^{-2/3}$ (22). Unit of $I = 1000$. Gas is air.

TABLE 11.—ATOMIC IONIZATION RELATIVE TO AIR

If C_r = coefficient of molecular ionization of the gaseous compound $F_f G_g H_h$ relative to air, and $E_r = E_i/E_{ia}$, where E_{ia} = value of E_i for air, then, in many cases, quite approximately $C_r = fc_f + gc_g + hc_h$ and $E_r = fe_f + ge_g + he_h$, where c_f, c_g, c_h and e_f, e_g, e_h are numbers characteristic of the several constituent species of atoms. The c's are called the atomic ionization relative to air. The atomic stopping power is ec.

TABLE 14.—ENERGY (E_i) EXPENDED IN IONIZING GASES

For X-rays, Kulenkampff (41) finds $E_i = (5.56 \pm 0.79) \times 10^{-11}$ erg per ion-pair and independent of wave-length (λ) if $0.56 < \lambda < 2$ Å. At shorter wave-lengths others find $E_i = ae^{-b\lambda}$; for air $a = 2.2 \times 10^{-10}$ erg per ion-pair, $b = 5.08$ Å^{-1}. In the table, E_i = observed value from which V_i is computed by relation $E_i = eV_i$. Unit of λ = 1 Å; of $E_i = 10^{-11}$ erg per ion-pair; of V_i = 1 volt.

(1) X-rays; air

λ	E_i	V_i	Lit.	λ	E_i	V_i	Lit.

Kr	3.43	21.5	Xe	3.12	19.6

TABLE 15.—IONIZATION OF GASES MIXED WITH VAPOR OF P (59)

The gas is in equilibrium with a liquid containing P. For column "*A*" the liquid is almond oil; for "*W*" it is H_2O. *See also* (28, 31, 47, 58).

Relative ionizations

Gas	A*	W*	Gas	A*	W*
Air	1.0	1.0	CO_2	59.6	28.7
H_2	48.2	15.3	N_2O		22.1
O_2	5.5	2.9			

* For air, the ionization over *W* is 2.16 times that over *A*; this ratio probably depends upon the relative amounts of P and upon its state of dispersion in the two liquids.

ELECTRICAL RESISTANCE OF ELEMENTARY SUBSTANCES AT TEMPERATURES BELOW −80°C*

H. KAMERLINGH ONNES AND W. TUYN

As it is impracticable to determine the volume resistivity at very low temperatures, merely the ratio of the resistance of a given specimen at a given temperature to the resistance of the same specimen at 0°C is given; except that in a few cases the actual resistance of the specimen at each of a series of low temperatures is given, instead of its ratio. Extremely low temperatures are occasionally expressed in terms of the pressure of saturated helium vapor at the same temperatures; this is especially convenient for those cases in which a small change in temperature is accompanied by a great change in the resistance.

If the resistances of a number of impure specimens (1, 2, . . . *n* . . .) of the same metal, all of the same dimensions at 0°C, are measured at a series of temperatures, and if the observations are plotted in rectangular coordinates (R_{nt} *vs.* t) and are connected by smooth curves, a curve for every specimen, then it is found (133) that these curves differ, roughly, solely by a displacement parallel to the axis of R, and that the purer the specimen the more nearly does its resistance approach zero as t approaches the absolute zero. The composite curve obtained by displacing these curves parallel to the axis of R until they all pass through the point $R = 0$ at the absolute zero is called the curve corresponding to a specimen of the metal of "ideal" purity and condition, and of the same dimensions at 0°C as the actual specimens. If the resistances corresponding to the points upon this "ideal" curve be denoted by R_{it} and if $p_n x_n$ is the displacement which makes the curve corresponding to specimen n coincide with the "ideal" curve, then

$$R_{x_n t} = R_{it} + p_n x_n$$

If x_n is the percentage of admixed impurity, p_n has a large value which, over a certain temperature range, is independent of t, but depends upon the nature and the amount of the impurity, and upon the state, or condition, of the specimen (133).

Expressions which are independent of the actual dimensions of the specimens may be obtained by dividing each equation by the

---

* Published in somewhat greater detail in (141).

Rosse (24) that $i_l - i_d = C\sqrt{I}$, provided I is neither very small nor extremely great; here b and C are independent of I but dependent upon λ and other physical parameters. For dependence of i_l upon duration of illumination, *see* (3, 10, 16, 29); for a more complete bibliography of the entire subject, *see* (5, 12, 23).

TYPICAL DATA FOR SELENIUM BRIDGES

Annealed Bridge of the Braun Condenser Type (16). Useful area = 151 mm²; thickness = 0.1 to 0.2 mm. Unit of $\lambda = 1 m\mu = 10^{-7}$ cm; of $I_\lambda = 10^{-8}$ watt/mm²; of $V = 1$ volt; of i_d, $i_l = 10^{-5}$ ampere.

λ	I_λ	V	i_d	$i_l - i_d$	V	i_d	$i_l - i_d$
451	2.83	5.60	15.7	1.09	11.03	34.9	2.23
529	4.07	5.60	15.6	1.76	11.02	34.7	3.56
674	3.68	5.35	14.7	4.26	10.70	33.8	9.78

Crystal Bridge (19). Useful area = 132 mm²; thickness = 0.2 to 0.3 mm; illumination by gas-filled tungsten (W) lamp, total unfiltered radiation; $I = 0.5$ phot. = 0.5 lumen/cm² = 5000 m-candle = 464 ft. candle. Unit of $V = 1$ volt; of i_d, $i_l = 1$ ampere.

V	i_d	$i_l - i_d$	V	i_d	$i_l - i_d$
2.0	1.11×10^{-4}	1.80×10^{-4}	20.0	1.43×10^{-3}	1.56×10^{-3}

Tellurium.—Some observers, neglecting effects due to the high thermoelectric power of Te with respect to other metals, have concluded that the resistivity of Te is affected by illumination. Careful investigation shows that this conclusion is incorrect (18). The absence of such an effect is in agreement with a recent interpretation of the low resistivity of Te (17).

† In the original, the compound in question is called "methylene mustard oil," and the formula "CN.CNS" is given. The boiling point (117°) indicates, however, that the liquid is probably methyl mustard oil.

$C_{14}H_8O_4$	Alizarin	233	99**	−4	(75)
$C_{14}H_{10}$	Anthracene	230	3	10	(97.2); *see* Fig. 8
$C_{14}H_{12}O_2$	Benzyl benzoate	25	< 1	9	(70, 71)

---

* Probably high.

† $\kappa = 14 \times 10^{-14}$ under the influence of radium rays; "almost a perfect insulator when shielded from the rays" (27).

‡ No noticeable change in conductivity on darkening.

§ The conductivity of the liquid decreases when enclosed by a lead mantle (111).

‖ Other temperatures also.

¶ Probably high.

** With a polarisation of 1.5 volt.

ELECTRICAL CONDUCTIVITY OF ELECTROLYTIC CONDUCTORS AT HIGH TEMPERATURES

E. B. Millard

The published values of the conductivities of compressed powders (p) are, in general, quite discordant; they are here included by literature reference only. The numerical data refer either to molten materials (l) or to solidified melts (s); in general, the latter form part of a continuous series including the former, but in some cases solid rods (r), either cast or machined from a solidified melt, were used. Some data refer to the undercooled melt; when so stated by the author, they are listed, like other molten materials, under l; in all other cases, data for temperatures below the melting point are taken as referring to a solid and are placed under (s). For compressed powders of metallic nitrides, *see* (68); for Auer mantle at 1200°C, *see* (66); for recent discussions, *see* (16, 20, 38, 60, 61, 62). Specific conductivity $= \kappa = C \times 10^n$ ohm^{-1} cm^{-1}; if $n = 0$, $\kappa = C$; t = temperature, °C; $\alpha(10)^{-3} = (R_t - R_0)/R_0t$, where R_0, R_t = resistance of same solid specimen at 0°C, at t, °C.

Im allgemeinen sind die veröffentlichten Werte über die Leitfähigkeit komprimierter Pulver (p) ganz widersprechend und werden nur durch die Literaturstellen angegeben. Die numerischen Daten beziehen sich entweder auf geschmolzenes Material (l) oder feste Schmelzen (s). Im allgemeinen sind letztere Bestandteile einer ununterbrochenen Serie die ersteren einschliessend, aber in manchen Fällen werden feste Stäbe (r) verwendet, die entweder gegossen oder aus einer festen Schmelze maschinell hergestellt wurden. Manche Daten beziehen sich auf unterkühlte Schmelzen. Ist dies vom Autor angegeben, so stehen die Daten wie auch die anderen Schmelzen unter l. In allen anderen Fällen, bei einer Temperatur unterhalb des Schmelzpunktes werden die Daten als auf den festen Zustand sich beziehend angenommen und stehen dann unter (s). Für gepresste Pulver von Metallnitriden, *siehe* (68); für Auerstrümpfe bei 1200°C, *siehe* (66); neuere Diskussionen darüber, *siehe* (16, 20, 38, 60, 61, 62). Spezifische Leitfähigkeit $= \kappa = C \times 10^n$ Ohm^{-1} cm^{-1}; wenn $n = 0$, $\kappa = C$; t = Temperatur, °C; $\alpha(10)^{-3} = (R_t - R_0)/R_0t$, wo R_0,R_t = Widerstand einiger fester Formen bei 0°C bezw. t, °C bedeutet.

En général, les valeurs publiées concernant les conductibilités des poudres comprimées (p) sont tout à fait discordantes, aussi ne sont-elles mentionnées ici que par leur références bibliographiques. Les données numériques se rapportent soit à des matières fondues (l) soit à des matières fondues solidifiées (s); en général ces dernières constituent une partie d'une série continue comprenant les premières, mais dans certains cas il a été fait usage de baguettes solides (r) préparées soit par moulage soit par usinage à partir d'une masse fondue solidifiée Certaines données se rapportent à des liquides surfondus; lorsque cet état a été établi par l'auteur, ces données sont inscrites sous l comme pour les autres matières fondues; dans tous les autres cas, les données pour des températures au dessous du point de fusion se rapportent à un solide et sont placées sous (s). Pour les poudres comprimées des nitrures métalliques, *voir* (68); pour le manchon d'Auer à 1200°C, *voir* (66); pour les discussions récentes, *voir* (16, 20, 38, 60, 61, 62). Conductibilité spécifique $= \kappa = C \times 10^n$ ohm^{-1} cm^{-1}; si $n = 0$, $\kappa = C$; t = température, °C; $\alpha(10)^{-3} = (R_t - R_0)/R_0t$, où R_0, R_t = résistance de la même éprouvette solide à 0°C, à t, °C.

In generale i valori pubblicati delle conducibilità di polveri compresse (p) sono molto discordanti; essi sono qui inclusi solamente come citazione bibliografica. I valori numerici si riferiscono sia a materiali allo stato di fusione (l) o a sostanze fuse e lasciate solidificare (s); in genere queste ultime sono parte di una serie continua che include anche le precedenti, ma in alcuni casi furono usate bacchette (r) o preparate di getto o ricavate al tornio. Alcuni valori si riferiscono a sostanze mantenute liquide allo stato di soprafusione; quando l'affermazione è fatta dall'autore i valori sono inclusi nell'elenco dei materiali allo stato di fusione (l); in tutti gli altri casi invece i valori per temperature inferiori al punto di fusione sono supposti riferentisi allo stato solido e sono collocati sotto (s). Per le polveri compresse di azoturi metallici, *vedi* (68); per le reticelle Auer a 1200°C, *vedi* (66); per discussioni recenti, *vedi* (16, 20, 38, 60, 61, 62). Conducibilità specifica $= \kappa = C \times 10^n$ ohm^{-1} cm^{-1}; se $n = 0$, $\kappa = C$; t = temperatura, °C; $\alpha(10)^{-3} = (R_t - R_0)/R_0t$, dove R_0, R_t = resistenza dello stesso campione solido a 0°C e a t, °C.

THE ELECTRICAL CONDUCTIVITY AND THE IONIZATION-PRODUCT OF H_2O

NIELS BJERRUM

ELECTRICAL CONDUCTIVITY

Ice (3)	t, °C	0	−4	−10	−19
	$10^{10}\kappa$, (mho)	280	23	11	2.6

Water.—The specific conductance of pure liquid H_2O (mho) at any temperature may be computed from the following equation using the appropriate value of p_w obtained from the tables which follow:

$$\log_{10} \kappa = [\log_{10} (\Lambda \times d) - 3 - \tfrac{1}{2}p_w],$$

where d is the density of water in g/ml and $\Lambda (= \Lambda_{H^+} + \Lambda_{OH^-})$ is the equivalent conductance for $H^+ + OH^-$, all at t, °C.

Example at 18°: $\log_{10} \kappa = \log_{10} (315.2 + 174)(0.9986) - 3 - 7.11 = 7.42$. $\kappa = 0.038 \times 10^{-6}$ mho, which may be compared with the directly measured value 0.042×10^{-6} for Kohlrausch and Heydweiller's "best" water.

IONIZATION PRODUCT

$K_w = [H^+] [OH^-]$; $[H^+]$ and $[OH^-]$ are the concentrations in moles per 1000 grams of water.

VALUES OF THE IONIZATION-EXPONENT OF WATER: $-\log_{10} K_w = p_w$*

t, °C	Calculated from the conductance of the purest water†	Calculated from the hydrolysis of salts of weak acids and weak bases: Ionization of the salt calculated from conductance		Activity-coefficient of the ions, f, calculated by means of the formula: $-\log_{10} f = 0.3.\sqrt[3]{C_i}$	
	(5, 6)	(9)	(4)	(9)	(4)
0	14.93		15.05		14.99
10	14.52	14.51		14.47	
15		14.34		14.30	
18	14.22		14.34		14.27

		(11)‡	(14)‡		
100		12.28			
156		11.57			
218			11.19		
306			11.46		

* pH in pure liquid $H_2O = \frac{1}{2}p_w - \log_{10} d$.

† The values in the table are calculated from the formula of Heydweiller (2): $-\log_{10} K_w = 6099.6/(273 + t) + 24.25 \log_{10} (273 + t) - 66.4678$.

‡ Recomputed to mole/1000 gram water.

Calculated from the potential of cells with hydrogen electrodes in acid and alkaline solutions

t, °C	Ion-concentrations calculated by means of conductance measurements				Activity-coefficients of the ions calculated on thermodynamical basis	
	(8)	(12)	(10)	(13)	(7)*	(1)†
0	14.87				14.945	14.926
18	14.15		14.13	14.14	14.239	14.222
25	13.92	13.91	13.89		13.998	13.980
30	13.76		13.72			
37			13.50		13.626	13.590
40	13.41		13.42			
50	13.06				13.273	
60	12.90					
70	12.67					
80	12.46					
90	12.37					
100					12.29	

* The potential measurements are made at 25°, and from the value of K_w at 25° the values at the other temperatures are calculated, using for the heat of neutralization $29\,210 - 53T$, which gives for K_w the following formula: $-\log_{10} K_w = 6384.7/(273.1 + t) + 26.676.\log_{10} (273.1 + t) - 73.424$

† Debye-Hückel square-root formula used as the limiting law for $C = 0$.

Best values

t, °C	p_w	t, °C	p_w
0	14.93	50	13.26
5	14.72	60	13.03
10	14.53	70	12.82

ELECTRICAL RESISTIVITY OF (1) SINGLE CRYSTALS, (2) SOLID POOR CONDUCTORS (EXCEPT SALTS), (3) MIXTURES OF RARE EARTH OXIDES AND (4) LIQUID MIXTURES SUITABLE FOR HIGH RESISTANCES

G. M. J. Mackay

Salts (excepting conduction in single crystals), pure liquids, electrolytic solutions, and industrial materials, are specifically excluded from this section of the Tables; *v.* Index at end of Vol. VII.

In view of the large effect produced by traces of impurities, by variations in absorption, polarization, surface leakage, etc., the values given should be regarded, in most cases, as mere approximations. The resistivity of specimens of minerals from different localities may differ by several hundred fold.

For high frequency alternating current resistance, *see* (16, 17); for Hall effect, *see* (24, 27); for mixtures of oxides, *see* Table 3 and (42).

Table 1.—Electrical Resistivity (ρ) of Poor Conductors: Pure Substances

$\rho = A \times 10^n$; s = solid, l = liquid; $\bar{5}$ denotes -5; if $A = 7.8$ and $n = \bar{5}$, then $\rho = 7.8 \times 10^{-5}$. (In certain cases ρ_t can be computed by means of one of the following formulae: $\rho_t = \rho_0\{1 + at(10)^{-3}\}$; $\rho_t = \rho_0\{1 + \alpha t(10)^{-3} \pm \beta t^2(10)^{-6}\} e^{-qt/TT_0}$, $T[T_0]$ = absolute temperature corresponding to $t[0°C]$, $T_0 = 273.1°K$; if $t < 0°C$ use the minus sign before the β. Values of coefficients are given after numerical data.) Unit of ρ = 1 ohm cm = 0.3937 ohm in. Centigrade temperatures, °C.

ELECTROELASTIC AND PYROELECTRIC PHENOMENA[1]

W. G. CADY

Electrostriction.—In general, when an isotropic dielectric is subjected to an electrostatic field E, its volume and form are changed. This phenomenon is known as *electrostriction*. The same kinds of effect occur in anisotropic dielectrics, but in them these effects are in many cases obscured by the far larger electrocrystallic ones described as piezoelectric (*see* p. 208). In electrostrictive effects, the tensions tending to stretch any element of the dielectric are proportional to E^2 and to $d\epsilon/dx$, where ϵ = dielectric constant and x is the amount of stretching in the direction considered. In general, $d\epsilon/dx$ depends upon the inclination of x to E; it may be either positive or negative, depending upon the nature of the dielectric (2). There are similar forces tending to move the dielectric bodily in such a way as to increase the integral value of ϵE^2, and if the dielectric is solid and if the field is produced by the charging of electrodes supported by it, then it will be subjected to the pressure arising from the mutual attraction of the electrodes. Deformations resulting from these two types of forces should not be classed as electrostrictive, although one or the other enters into many measurements of electrostriction.

Electrostrictive effects are generally derived from observations of the change in dimension of a condenser of which the dielectric is the substance to be studied (2, 14, 20, 50, 57, 63, 74, 75, 82, 96, 97, 127). If l is the dimension considered, Δl is the increase in l under action of the electric field, and if μ is the corresponding elastic modulus, then $\mu\Delta l/lE^2$ depends solely upon the configuration of the system, and upon ϵ and its variation with Δl. The changes (Δl) are very small and the sources of error are numerous; consequently the results obtained are frequently quite discordant and at times even qualitatively contradictory.

For summaries and discussions, *v.* (20, 50, 79, 81, 82); for recent developments, *v.* (2, 10, 14, 33, 34, 55, 57, 74, 75, 92.5, 123); for bibliography, *v.* (10, 100).

TABLE 1.—ELECTROSTRICTION

The following data are based upon the change in dimensions of a condenser when it is charged. This change frequently increases rapidly for several seconds; the values tabulated are presumably those approximately constant ones corresponding to an application of the field for 15 to 40 sec.

In column (2) the type of the condenser is indicated (c = cylindrical, s = spherical, p = plate) and the quantity corresponding to l in the formula below is stated; c_e = cylindrical condenser with electrodes supported by the dielectric.

Röntgen (93) found that all liquids expanded under the action of E; Quincke (81, 84) found that some contracted, the contraction for $(C_2H_5)_2O$, almond oil, and rape oil being marked.

For air and CO_2, Gans (35) found a reduction in pressure in an electric field, in rough agreement with the value predicted by theory. For other work with gases, *v.* (20, 50, 66, 82).

For other experimental work, *v.* (2, 20, 34, 35, 55, 57, 63, 66, 69, 70, 82, 96, 97, 127).

$\Delta l/lE^2 \equiv A \times 10^{-n}$. Unit of $A \times 10^{-n} = 1$ cm² cgse⁻² = $1.11_3 \times 10^{-5}$ cm² volt⁻².

(2)	p, thickness	5.4	9	(10)
(3)	p, thickness	7.6	9	(10)

* Values for (1) and (2) obtained 15 sec after application of E; at 2 or 3 sec after application of E, A is only 4. From data obtained (125, 126) with various glass tubes, electrodes not supported by the glass, Adams (2) deduces $8\pi\mu\Delta l/lE^2 = -1.35$ to -3.78; *v. also* (10, 57, 69, 70, 100).

† Flint glass. $\Delta v/vE^2$ is unchanged by a variation of E in the ratio of 1 to 5.

‡ Values 35 to 40 sec after application of E; at 5 sec after application of E, A is only 4. Temperature, 24°C. Both recorded values are for same tube.

§ Various specimens of the c_e group have been treated so as to vary μ(1.7×10^9 to 27×10^9); the products of $A \times 10^{-n}$ by the corresponding values of μ are constant (=0.18). For the c group, μ lay between 1.3×10^9 and 1.7×10^9.

‖ (1) and (2) are vulcanized "para-normal" rubber; (3) is unvulcanized pure rubber. The volume of the plate does not change when E is applied.

---

[1] This section deals with data pertaining to electrostriction, piezoelectricity and pyroelectricity. All units are of the cgse system unless the contrary is stated.

Piezoelectricity.—In general, when an anisotropic dielectric having no center of symmetry is mechanically strained, it becomes electrically polarized; the direction and magnitude of the polarization (P) depend upon the nature of the crystal, upon the nature and amount of the strain and upon the direction of the strain with reference to the axes of the crystal. Conversely, when such a dielectric is subjected to an electric field (E), not only are stresses of an electrostrictive nature set up in it, but also others which are usually much larger and which depend upon both the direction and magnitude of E. These effects are described as *piezoelectric.* The production of polarization by strain is called the *direct* effect; the other is the *converse* effect.

From experiments with calcite ($CaCO_3$), dolomite ($CaMgC_2O_6$), beryl ($Be_3Al_2Si_6O_{18}$), topaz ($Al_2F_2SiO_4$), barite ($BaSO_4$), and celestite ($SrSO_4$), Voigt (120) concludes that crystals possessing a center of symmetry may possess "central-symmetrical" piezoelectricity. Also some investigators have observed what appears to be a piezoelectric effect for certain apparently non-crystalline substances such as beeswax and resin (3, 28), sheet rubber (12, 85), ebonite, glass, hornoid, sealing wax, celluloid and paraffin (12), but it is difficult to determine how much of the observed effect is due to frictional electricity and to the presence of very small piezoelectric crystals. The observations (85) lead to a value of the order 10^{-5} for the strain-constant d for sheet rubber; this is nearly a thousand times as great as the value for most piezoelectric crystals.

If P_x, P_y, P_z are the components of the polarization (electric moment per unit of volume), E_x, E_y, E_z, the components of E; x_x, y_y, etc., the six strain components; X_x, Y_y, etc., the six stress components; then

$$P_x = e_{11}x_x + e_{12}y_y + e_{13}z_z + e_{14}y_z + e_{15}z_x + e_{16}x_y$$

$$-P_x = d_{11}X_x + d_{12}Y_y + d_{13}Z_z + d_{14}Y_z + d_{15}Z_x + d_{16}X_y$$

The expressions for the components P_y, P_z are obtained from that for P_x by changing the first digit "1" of the subscript of each e to "2," and to "3," respectively: $-P_y$, $-P_z$ are obtained from $-P_x$ by changing similarly the subscripts of each d. For the converse effect:

$$x_x = d_{11}E_x + d_{21}E_y + d_{31}E_z$$

$$-X_x = e_{11}E_x + e_{21}E_y + e_{31}E_z$$

The other five equations of each set (y_y, z_z, y_z, z_x, x_y; and Y_y, Z_z, Y_z, Z_x, X_y) are obtained in order from these by changing the second digit (1) of the subscript of each d (or e) to 2, 3, 4, 5, 6, respectively. The d's and e's are called the piezoelectric constants, the d's being the *strain constants* and the e's the *moduli:* they are mutually related by equations involving the elastic constants of the crystal (81, 82, 91, 117). Excepting triclinic asymmetric crystals, in each special case certain of these 18 parameters are necessarily zero. Those which may not be zero are indicated in Table 2.

When the polarization is parallel to the stress producing it, it is described as a longitudinal effect; it exists only when one or more of the constants with subscripts 11, 22, 33 are finite.

When the polarization is perpendicular to the direction of the strain producing it, it is described as a transverse effect; it exists whenever one or more of the constants with subscripts 12, 13, 21, 23, 31, or 32 are finite, and also for certain directions of the stress when one or more of the constants with subscripts 14, 25, 36 are finite; *v.* (15, 21, 25, 83, 117).

Owing to the smallness of the effect and to various sources of error such as twinning,[1] faulty orientation of crystal plate being studied, presence of impurities, etc., the data available are in most cases somewhat discordant. For many substances, our exact knowledge is limited to the fact that the piezoelectric constants are not all zero.

For full bibliography, including applications, *v.* (16); for recent summary of information regarding piezo- and pyroelectricity, *v.* (36); for description of piezoelectric phenomena, general theory, and bibliography, *v.* (20, 21, 24, 81, 82, 91, 117); for more recent formulation of theory, *v.* (7, 9, 11, 37, 48, 99, 110, 111, 112); for applications to high-frequency circuits, *v.* (15, 17, 27, 38, 59, 67, 78, 98); for equations giving value of P for a pressure applied in an arbitrary direction, *v.* (82, 91, 103, 117); for representation of P by means of piezoelectric surfaces, *v.* (1, 4, 51, 91, 103, 117); for effect of hydrostatic pressure, *v.* (117); *cf.* (56); for discussion of second-order effects, *v.* (82, 117, 119).

A list of crystals for which piezoelectric effects have been observed, and their constants, are given in Table 3.

Table 2.—The Piezoelectric Constants Present for Each Class of Crystals Possessing the Piezoelectric Property

Excepting the plagihedral cubic class (117), all of the 21 classes of crystals having no center of symmetry are piezoelectric.

The parameters are denoted by their subscripts in accordance with the scheme of equations. A repetition of a subscript for any crystal class indicates that for this class the corresponding parameters have the same value. In writing the equations for the five trigonal classes, a factor 2 must precede each d corresponding to parameters 16 and 26, in all other cases the equations are written as above, those parameters corresponding to blanks in the table being necessarily zero.

Hex. = hexagonal, Rho. = rhombic, Mon. = monoclinic,
P = polar

The coordinate axes are assumed to be orthogonal, to form a right-handed system, and to be directed as indicated in the footnotes.

True polar pyroelectric effects (p. 209) may be exhibited by classes 2, 4, 6, 9, 12, 14, 15, 17, 18, 19; for class 19, P_x, P_y, and P_z are all present; for 18, only P_x and P_y are present; for all the other classes, only P_z exists.

* z-axis coincides with the c-axis of 6-fold symmetry; where polar, the + direction is direction of the polarization produced by heating the crystal. The y-axis is ⊥ to a face of the first order prism.

† z-axis coincides with the c-axis of 3-fold symmetry. The y-axis and the + direction of the z-axis are as for hexagonal (*v.* *). Polarization of class 7 is not changed by hydrostatic pressure.

‡ Coordinate axes x, y, z coincide, respectively, with crystallographic axes a, b, c.

§ x-axis ‖ c-axis; z-axis ‖ b-axis; y-axis lies in obtuse angle between the a- and c-axes.

‖ Only the tetrahedral (1_a) and the tetartohedral (1_b) classes are piezoelectric.

¶ Only the asymmetric class is piezoelectric. No convention regarding directions of axes of coordinates.

---

[1] Partially twinned crystals show a reduced piezoelectric effect; complete twinning removes the piezoelectric property altogether.

Pyroelectricity.—The electrical polarization (P) of many substances is changed when the temperature of the substance is changed; this phenomenon is described as *pyroelectric.* $\delta P/\delta t$ is called the pyroelectric constant of the substance; it decreases with the temperature and perhaps vanishes at absolute zero.

Several types of pyroelectricity are distinguished. The most marked pyroelectric effects are exhibited by those crystals which have a vectorial (polar) structure defining, not merely a line, but a definite direction along that line. The type exhibited by such crystals is called the *polar* or *vectorial* type of pyroelectricity; it is the type commonly associated with the word "pyroelectric." This type can be exhibited only by crystals belonging to the classes 2, 4, 6, 9, 12, 14, 15, 17, 18, and 19 of Table 2. Another type, in which the effects are much smaller, is known as the *central* or *tensorial* type; it may be exhibited (82, 91, 116, 117, 120, 121) by changing uniformly the temperature of crystals which have a certain type of tensorial symmetry; this type of symmetry occurs in every crystal class except those of the cubic system.

As crystals which are pyroelectric are also piezoelectric, the deformations accompanying changes in temperature give rise to polarizations of piezoelectric origin. These *false* pyroelectric effects are superposed upon the *true* pyroelectric effects which result solely from changes of temperature, effects due to accompanying strain being eliminated. In general, any piezoelectric crystal, when deformed by a change in temperature, whether uniform or not, exhibits false pyroelectric effects. Those produced by non-uniform heating are the more common and are called the false pyroelectric effects of the first kind, those produced by uniform heating being called the false effects of the second kind. As the false effects are generally much greater than the true, it is difficult to determine the latter. Indeed, the true pyroelectric effect has been investigated only for tourmaline and its existence for that substance is questioned. The magnitude of the pyro effect observed depends markedly upon both the surface and the volume conductivity of the specimen (61, 94, 114, 117).

The converse, or "electro-caloric," effect (the change in temperature resulting from the application of an electric field) has been detected (58, 102, 117).

For general discussion of pyroelectricity, *v.* (20, 41, 60, 81, 82, 83, 91, 117); for its molecular theory, *v.* (6, 7, 8, 20, 82, 83, 91, 110, 112, 117); most complete quantitative data are by Ackermann (1), discussed by Boguslawski (6).

For data for specific substances, *see* Table 3.

In addition to the substances tabulated below, both pyro and piezo effects have been observed (23, 30, 82, 91, 117, 120, 121) in the following crystals possessing a center of symmetry: topaz ($Al_2F_2SiO_4$), barite ($BaSO_4$), beryl ($Be_3Al_2Si_6O_{18}$), calcite ($CaCO_3$), dolomite ($CaMgC_2O_6$) and celestite ($SrSO_4$); and by means of a high frequency method, in which the orientation of the axes of the crystal could not be determined, traces of the piezoelectric effect have been found (38) in the following crystals: proustite (Ag_3AsS_3), urea (CH_4N_2O), ammonium oxalate ($N_2H_8C_2O_4$), asparagine ($C_4H_8N_2O_3.H_2O$), ammonium acid tartrate ($NH_4HC_4H_4O_6$) pentaerythritol ($C_5H_{12}O_4$), tetraethylammonium iodide ($N(C_2H_5)_4I$), triphenylmethane ($CH(C_6H_5)_3$), potassium acid tartrate ($KHC_4H_4O_6$), magnesium sulfate ($MgSO_4.7H_2O$), ammonium acid phosphate ($NH_4H_2PO_4$), sodium tartrate ($Na_2C_4H_4O_6$), sodium sulfoantimonate ($Na_3S_4Sb.9H_2O$), nickel sulfate ($NiSO_4.6H_2O$) and zinc sulfate ($ZnSO_4.7H_2O$). For other crystals, *v.* (43, 43.5, 44, 45, 46, 49, 64, 65, 68). For piezoelectric effects with apparently non-crystalline substances, *v.* p. 208.

No observation of either kind of effect was found recorded for crystals of classes 3, 5, 8, 10, 11, 13, 14 (*v.* Table 2). Of the other classes, no direct piezo observation was found recorded for classes 2, 4, 9, 12, 15, 18, 19, but all crystals which exhibit pyro effects are also piezoelectric. Crystals of class 7 are not excited by hydrostatic pressure.

The numbers in the column "C. S." indicate the crystal class of the substance, in accordance with the numbers of Table 2. The presence of the mark " ✓ " in a column indicates that the corresponding effect has been actually observed, but the numerical value of the constant is not known with certainty; if the detected pyro effect is necessarily a "false" one, the " ✓ " is replaced by an "f;" blanks indicate that no record of observations was found. In column "C" is the symbol indicating the piezoelectric strain constant which has the value $A \times 10^{-8}$, A being the value adjacent to the symbol. For example, for tourmaline at room temperature, $d_{33} = 5.78 \times 10^{-8}$ (es/cm^2)/(dyne/cm^2). Units are cgse. Data for pyro effect refer to the total effect, the sum of the "true" and the "false."

TABLE 4.—TOURMALINE: PYRO- AND PIEZOELECTRIC CONSTANTS

The z-axis coincides with the ternary (optical) axis of the crystal, and the x-axis lies in any one of the three planes of trigonal symmetry. The positive direction of z passes through the end of the crystal which becomes charged positively when the crystal is uniformly heated. This end is called the "analogous" end of the crystal; frequently it is not possible, by mere inspection, to determine which is the analogous end (124). The opposite end is called the antilogous end. The values found for the constants vary considerably from one specimen to another; in general, those for the darker specimens are the smaller in numerical value. The permanent electrical polarization along the z-axis is about 8×10^4 cgse (87, 90, 91); hydrostatic pressure increases it about 8×10^{-8} cgse per barye (56). Whether tourmaline exhibits "true" pyroelectric effects is doubtful; Voigt (114, 117) thought the true effect amounted to 20% of the total, but Röntgen (94, 118) and Lindmann (61) decided that it is too small to measure. The values given below represent the total pyroelectric effect. Writing $\delta P/\delta t = a + 2b(t - t_0)$, where P = the polarization along the z-axis, and t and t_0 are final and initial temperatures, values of a varying, with the specimen, from 0.52 to 2.03, and of b varying from −0.000256 to +0.0117 were found (88, 91); experiments extended to t = 160°C. For pyroelectric data, *v.* (1, 81, 83, 91, 113, 117); for piezoelectric, *v.* (81, 89, 91, 114, 115, 117, 120). P = polarization, T = absolute temperature, $A_{15} \times 10^{-8} = d_{15}$, etc.; $B_{15} \times 10^4 = e_{15}$, etc. (*v.* p. 208). Unit of T = 1°K; of P, d, e = 1 cgse unit of appropriate kind.

* B. G. = blue-green, Y. G. = yellow-green, R. R. = rose-red. Data from (1).

† Data from (47).

‡ L. G. = light-green, data from (94). With darker specimens he found values only 83 % of these; discussed in (118).

§ From (86) for 5 green Brazilian specimens: $\delta P/\delta T = 1.13–0.0104(T - 291)$.

‖ Vary but little with changes in pressure and temperature; between 20°C and the temperature of liquid air (62) and for pressures up to 22 megabarye (71), the variation of d_{33} lies within the limits of experimental error. From theoretical considerations, Keys (54) concludes that, for tourmaline, the adiabatic piezoelectric constants, corresponding to suddenly applied stress, are 1.5 times as great as the usual isothermal ones. $d_{15} = A_{15} \times 10^{-8}$, etc.; $e_{15} = B_{15} \times 10^4$, etc.

TABLE 5.—QUARTZ: PYRO- AND PIEZOELECTRIC CONSTANTS

For information regarding all properties of SiO_2, *v.* (101)

The *z*-axis coincides with the crystallographic *c*-axis of 3-fold symmetry, the *y*-axis is ⊥ to a face of the hexagonal first order prism, and, in dextro crystals, the + direction of the *x*-axis is outward through one of the faces (commonly denoted by *s*) of the trigonal pyramid; in levo crystals, the direction of the *x*-axis with reference to the *s*-faces is reversed; in each case, the + direction of the *y*-axis is such as to form a right-handed system of orthogonal axes. At 573°C, ordinary SiO_2 (trigonal, trapezohedral), known as "α-quartz," becomes transformed to "β-quartz" (hexagonal, trapezohedral) and loses its pyro- and piezoelectric properties (11, 37, 77, 101). Owing to its crystal form, SiO_2 can have no "true" pyroelectric properties; $\delta P/\delta t$ is approximately proportional to the absolute temperature (73), and at room temperature is about half as great as the value for tourmaline (113). Twinning is common; dextro and levo crystals have equally strong electrical properties; hence, specimens which are completely twinned are not piezoelectric.

Quartz is not electrically excited by hydrostatic pressure. The value of d_{11} is probably unchanged by pressure parallel to *x*-axis; Nachtikal (71) found it to decrease by 0.16% per megabarye, but Röntgen and Joffé (95) found it was not changed by 0.4% by a pressure of 18 megabarye, and according to Karcher (53) it remains constant to within 0.1% for pressures ≤ 3450 megabarye.

At room temperatures d_{11} is practically independent of temperature. There is some evidence that it increases by about 20% as *t* goes from room temperature to 60°C, and then with a further increase in *t* it gradually decreases until at 573°C it vanishes (26.5, 79, 82, 86, 101). On cooling it reappears. On cooling from +17 to −193°C, d_{11} decreases by 1.2%; cooling from −193 to −253°C causes a change of less than 0.2% (73). Ze (127) reports that the piezoelectric deformation of quartz reaches a saturation value at a field intensity of about 520 cgse units. In the following, the best values are printed in bold-face. Unit of d_{11} and d_{14} = 10^{-8} cgse; of e_{11} and e_{14} = 10^4 cgse.

Piezoelectric Resonators.—From the density (2.654 g cm^{-3}) and the elastic constants (117) of quartz, the natural frequencies (ν) of compressional vibrations parallel to the edges of a quartz parallelepiped cut with its edges *a*, *b*, *c* parallel to the crystal axes *x*, *y*, *z*, are $\nu_x = 2.70 \times 10^5/a$, $\nu_y = 2.70 \times 10^5/b$, and $\nu_z = 3.08 \times 10^5/c$ cycle per sec if the lengths of the edges are *a* cm, *b* cm, and *c* cm. In each case the wave-length of the elastic wave in the crystal is twice that of the corresponding edge. Through the agency of d_{11}, the vibrations along *x* and *y* may be directly excited by a high-frequency electric field applied parallel to *x*. Also, through the same d_{11}, a transverse, or shear, mode of vibration may be excited by a high-frequency field parallel to *y*, the fundamental frequency being $\nu_{xy} = 1.79 \times 10^5/b$ cycle per sec. This vibration depends upon the rigidity of quartz for torsion about the *z*-axis. In all of these values for the frequency the effect of sectional area is ignored, but the computed frequencies agree fairly well with those observed; *v. also* (16, 26, 81, 95, 117).

TABLE 6.—ROCHELLE SALT ($KNaC_4H_4O_6.4H_2O$): PYRO- AND PIEZOELECTRIC CONSTANTS

Axes *x*, *y*, *z* coincide, respectively, with crystallographic axes *a*, *b*, *c*. Electrical properties are complicated and are greatly affected by changes in temperature and humidity, and by the past history of the specimen; great differences between individual specimens (29, 52, 72, 110, 111, 112). Valasek (110, 111, 112) thinks it has "true" pyroelectric properties although the crystal form indicates that they can not exist; his computations (110) indicate a permanent electrical polarization of the order of 50 cgse units; *v. also* (23). Rochelle salt (potassium sodium tartrate) is not electrically excited by hydrostatic pressure; its d_{14} is the largest known piezoelectric constant; *v.* especially (72). Unit of d_{14}, d_{25}, and d_{36} = 10^{-6} cgse. Note: In other tables the unit, or common factor, is 10^{-8}.

t	−70	−50	−30	−20	−10	0	10	20	30	40	°C
d_{14}	0.17	0.17	0.65	10.8	60.7	67.5	74.2	81.0	10.8	4.1	(112)

The maximum is much greater than that recorded by any other observer. Later observations (112.5) indicate that with increasing *t*, d_{14} increases rapidly from a very low value to about 23 at −20°C, increases slightly from −20 to +25°C, and then decreases rapidly. Between −60 and +30°, d_{25} and d_{36} increase linearly with *t*, their rates being, respectively, 6.8×10^{-9} and 3.1×10^{-10} cgse unit per 1°C (112.5).

Near 20°C, Pockels (80) finds d_{14} = 3.40 to 11.80; d_{25} = −1.65, and d_{36} = 0.35.

From these data and the elastic constants (66.5) it is found that $e_{14} = 56 \times 10^4$ to 194×10^4, $e_{25} = -5.33 \times 10^4$, and $e_{36} = 4.34 \times 10^4$ cgse units.

From the density (1.767 g cm^{-3}) and the elastic constants (66.5) the velocity of compressional waves in a bar of Rochelle salt cut with its length perpendicular to the x-axis and at 45° with the y and z axes is found to be 3.98 × 10^5 cm/sec. Hence, natural frequency (ν) of such vibrations in a bar a cm long is 1.99 × $10^5/a$ cycle per sec; experimental values may be expected to differ rather widely from this value (17).

TABLE 7.—PIEZOELECTRIC CONSTANTS OF TARTARIC ACID ($C_4H_6O_6$) AND OF CANE SUGAR ($C_{12}H_{22}O_{11}$)

Room temperature; precision about 3%; system = monoclinic polar. $d_{14} = A_{14} \times 10^{-8}$; etc. Unit of d = 1 cgse.

THERMOELECTRICITY

A. E. Caswell

If two metallic conductors, M and R, are connected in series so as to form a closed circuit, and if one junction is kept at the temperature, 0°C and the other at the temperature, $t (t \neq 0)$, there will be a *thermo emf* ${}_ME_R$ around the circuit. By convention, ${}_ME_R$ is regarded as positive if the current so produced flows from M to R at the junction which is at 0°C. ${}_RE_M = -{}_ME_R$; ${}_ME_R + {}_RE_S = {}_ME_S$. ${}_MQ_R \equiv \partial_ME_R/\partial t$ is called the *thermoelectric power* of M with respect to R. As a current I passes through a junction from R to M an amount of heat $({}_MP_R)I = T({}_MQ_R)I$ is absorbed per second; ${}_MP_R$ is the *Peltier coefficient* of M with respect to R, and T is the absolute temperature corresponding to t. If ${}_MQ_R$ is negative, so is ${}_MP_R$, and heat is evolved when current flows from R to M. The equations are valid for any consistent system of units; in particular, if E is expressed in volts and I in amperes, the heat is expressed in joules. If, in an unequally heated homogeneous conductor, a current, I, flows from a point where the temperature is t_2 to another where it is t_1, $t_2 > t_1$, an amount of heat $H = \int_{t_1}^{t_2} I\sigma dt$ will be absorbed per second, apart from the usual Joule heating effect. σ is the *Thomson coefficient* of the metal in question; it may be either positive or negative. Denoting by a subscript the metal to which σ refers, $\sigma_M - \sigma_R = -T\,(\partial^2{}_ME_R/\partial t^2)$.

All four quantities, ${}_ME_R$, ${}_MQ_R$, ${}_MP_R$ and σ_M are profoundly affected by anything which alters the structure of the metals to which they refer. They are greatly affected by impurities, heat treatment, drawing, rolling, pressure, tension and magnetization. Only very rarely will identical thermoelectric curves be found for two couples formed from the same pair of metals.

For a bar cut from a crystal, the value of Q will, in general, depend upon the direction which the length of the bar makes with the axis of the crystal. When Q does depend upon this direction, the bar, unless cut parallel to one of the principal thermoelectric axes, exhibits another distinct thermoelectric property, in virtue of which the longitudinal passage of an electric current through the bar is accompanied by an absorption of heat at one side of the bar and an evolution of heat at the opposite side, the two sides being kept at the same, or essentially the same, temperature. This is known as the *transverse Peltier effect.* (For a rectangular bar of Bi cut with its length at 45° to the axis of the crystal, distance between sides which became unequally heated = 1.55 mm, distance between other two sides = 2.64 mm, it was observed that $\Delta t = 0.267$°C per ampere of longitudinal current, the bar being exposed to the air and at room temperature (16).) Conversely, a difference in temperature of the two sides gives rise to a longitudinal emf.

TABLE 1.—THERMO EMF AND THERMOELECTRIC POWER OF ELEMENTARY SUBSTANCES

${}_ME_R = at + \frac{1}{2}bt^2(10)^{-2} + \frac{1}{3}ct^3(10)^{-5} + d$; one junction at 0°C.
${}_MQ_R = d({}_ME_R)/dt = a + bt(10)^{-2} + ct^2(10)^{-5}$.

${}_MP_R = T({}_MQ_R)$ = Peltier coefficient; difference in the Thomson coefficients is $(\sigma_M - \sigma_R) = Td({}_MQ_R)/dt$; T = absolute temperature corresponding to temperature t. The tabulated coefficients apply for all values of t between t_1 and t_2. For other notation, *see* introduction.

The numbers in the "Error" column indicate the possible departures (±) of observed value of E from that calculated by means of the coefficients; unit is 1%, unless another is indicated. The expression $\left.\begin{matrix}-0.38\\-0.53\end{matrix}\right\}$ indicates that the quantity varies from −0.38 to −0.53. Unit of $E = 1\mu v = 10^{-6}$ volt; t_1, t_2 = centigrade temperature, °C.

* Angle between basal cleavage plane and direction of current.

† Value of d; c = 0.

‡ d = 26 716.

§ d = −87.46.

‖ Value of d; c = 0.

¶ d = −12 400.

** d = −600.

†† Qu<$_{352}$, [An<$_{352}$] = quenched [annealed] from below 352°C; Ht>$_{353}$ = after heating above 353°C; Q_{18} = Q at 18°C.

‡‡ d = +12 420

§§ Angle between crystal axis and direction of current.

‖‖ d = 1 320.

[a] Annealed. [b] 99% pure. [c] Commercial. [d] 99.57% pure. [e] Electrolytic. [f] Filament of incandescent lamp. [g] Cold-drawn and hammered. [h] Heraeus made. [i] 99.8% Co, 0.2% Si, traces Fe. [j] Electrolytic, cold-drawn, annealed in hydrogen. [k] Pure "Swedish," hard-drawn, used for gold refining. [m] Very soft, annealed transformer Fe. [n] Deposited from nickel carbonyl. [o] 97.7% Ce, 1.2% Fe, remainder cerium oxide and cerium carbide. [p] Applies to equation for *Q* only. [q] Baker's platinum. [r] Used in cast form, solid rods soldered end to end. [s] Slight traces of carbon. [t] Traces of Fe. [u] 97.9% Tl, 1.5% Pb, traces of Cu and As. [v] Se in darkness; in light sufficient to increase its conductivity 600%, *Q* is decreased by 6%. [w] Single crystal.

TABLE 2.—THERMOELECTRIC POWER (${}_{Fe}Q_{Pt}$) OF COUPLES OF PURE IRON AND PLATINUM (22)

The pure iron contained 99.968 Fe, 0.009 C, 0.009 S, 0.001 P, 0.006 Si, 0.001 Mn and 0.006 Cu; the platinum was purest Heraeus Pt. For the Fe, the A_1 transformation point near 700°C, due to C, is absent; A_2 is at 768°C, Ar_3 and Ac_3 are at 900 and 910°C, respectively. Unit of $Q = 1\mu v/°C = 10^{-6}$ volt/°C; t = centigrade temperature, °C.

t	${}_{Fe}Q_{Pt}$	t	${}_{Fe}Q_{Pt}$	t	${}_{Fe}Q_{Pt}$
0	+19.5	775	+18.1	Temp. rising	
100	+18.1	800	+18.4	1000	+12.6
200	+15.4	880	+19.4	Temp. falling

500	+ 9.1	910	+19.4	910	+10.8
600	+10.8	920	+16.6	900	+17.5
700	+14.3	930	+11.4		

TABLE 3.—THERMOELECTRIC POWER (Q) AND THERMO EMF (E) OF ALLOYS (MAINLY BINARY ALLOYS)

For list of commercial alloys and miscellaneous mixtures, *see* end of table. $Q = a + bt(10)^{-2} + ct^2(10)^{-5}$; $E = at + \frac{1}{2}bt^2(10)^{-2} + \frac{1}{3}ct^3(10)^{-5} + d$, one junction at 0°C; E can not be obtained from Q unless the value of d is known, but d is generally zero if no transformation point occurs between 0°C and t, °C. "$t_1\ t\ t_2$" denotes that the coefficients apply if t lies between t_1 and t_2. Unit of $Q = 1\mu v/°C = 10^{-6}$ volt/°C; t = centigrade temperature, °C.

Steel; *see* **Al-Fe, Fe,** and Tables 4, 5

TABLE 4.—MEAN THERMOELECTRIC POWER (E/t) BETWEEN 0 AND t°: STEELS, t = −78.5 AND +100° (32)

For other alloys of Fe, *see* Tables 3, 5. $E = \mathrm{a}t + \frac{1}{2}\mathrm{b}t^2(10)^{-2} + \frac{1}{3}\mathrm{c}t^3(10)^{-5}$; $Q = \mathrm{a} + \mathrm{b}t(10)^{-2} + \mathrm{c}t^2(10)^{-5}$. An. = annealed; Qu. = quenched; "$t_1\ t\ t_2$" denotes that t lies between t_1 and t_2. Except where the contrary is indicated, one junction is at 0°C and the other at t, °C. Steels of low C content were annealed in magnesia; those of about 0.8% C, in turnings of pig iron. Mean error in all cases = *ca.* 30μv(= 30 microvolt). Unit of E = 1μv = 10^{-6} volt; of Q and E/t = 1μv/°C = 10^{-6} volt per 1°C; t = centigrade temperature, °C.

H6	1.58	0.09	Tr.	0.016	0.04		+ 6.73	+ 4.15	− 6.52	− 5.80		

For H1 to H5, coefficients of Q_{Cu} are: 0° t 700°, a = A, b = −0.563A, c = +0.5A, where $\mathrm{A} \equiv 18.8 - 10.5C + 4.1C^2$, carbon content = C%; $t_2\ t\ t_3$, a = −5.9 − 0.01bt_2, b = −0.38; $t_3\ t$ 1000°, a = −10.5 − 0.01bt_3, b = −2.8; t_2, t_3 = temperatures of transformations A_2, A_3 (18). For pure Fe, t_2 = 730°, t_3 = 950°; increasing C decreases both; with more than 0.4% C they coincide at *ca.* 700° (18). For piano wire, coefficients of E_{Pb} −200° t 100° are: a = +10.763, b = −1.5586, c = −18.762 (31).

* An. = annealed, time in furnace = 3 hr, time of cooling is as indicated. Qu. = quenched, specimen in furnace 11 or 12 min and for 2 min was at temperature indicated.

† For 1N and 4N groups, changes in heat treatment produce slight effect; maximum negative value of E occurs at *ca.* 25 % Ni in 1N and *ca.* 20 % Ni in 4N group.

TABLE 5.—THERMOELECTROMOTIVE FORCE (E) OF CARBON STEELS: EFFECT OF HEAT TREATMENT (23); *see also* Table 4

Specimens were quenched at 903 or 908°C, kept at 97 to 102°C for 48 hr, then heated (drawn) to temperature indicated and kept at that temperature for 1 to 2 hr, then allowed to cool slowly in furnace. Error in E not greater than 10μv. For all 8 specimens, the smallest negative value of E corresponds to drawing temperature of 696°C. Unit of E = 1μv = 10^{-6} volt; of admixture = 1%; temperature, °C.

* Error in E = ±200 microvolt. † Used Pt as reference metal, but expressed results in terms of Q_{Pb}.

TABLE 7.—EFFECT OF STRESS UPON THERMOELECTRIC PROPERTIES OF METALS

${}_sE_o$ = thermo emf around a circuit composed of two specimens of the same material, one specimen (s) is stressed, the other (o) not stressed; one junction is at 0°C and the other is at t, °C; ${}_sE_o$ is positive if the current flows from the stressed to the unstressed specimen at the junction at 0°C.

If p = hydrostatic pressure upon the stressed specimen; τ = longitudinal tension upon the stressed specimen; t = temperature (°C); f, g, h, m, n are constants depending upon the metal; then if $\tau = 0$, ${}_sE_o = \mathrm{f}pt\{1 + \mathrm{g}p(10^{-6})\}\{1 + \mathrm{h}t(10^{-3})\}$; ${}_sQ_o = \mathrm{k}p$, where $\mathrm{k} = \mathrm{f}\{1 + \mathrm{g}p(10^{-6})\}\{1 + 0.5\mathrm{h}t(10^{-3})\}$; k = f if g = 0, h = 0. If $p = 0$, ${}_sE_o = 1000\mathrm{m}\tau + \mathrm{n}\tau^2$.

The numbers in the "Error" column indicate the probable uncertainty in the value of ${}_sE_o$. Unit of $E = 1\mu\mu\mathrm{v} = 10^{-12}$ volt; of p and τ = 1 kg/cm² = 14.22 lb./in.² = 0.968 A_n; of "Error" = 10^{-6} volt; t = centigrade temperature, °C.

Mean probable error in $_sE_o$ is $\pm 2 \times 10^{-8}$ volt = 0.02μv.

TABLE 9.—EFFECT OF LONGITUDINAL MAGNETIC FIELD (H) AND OF TENSION (τ) UPON THERMOELECTRIC PROPERTIES OF METALS (12)

$_{\tau H}E_o$ = thermo emf around a circuit composed of two specimens of the same material, one specimen (τH) is subjected to tension τ and field H; for the other specimen (o), $\tau = 0$, $H = 0$; one junction is at t_1, °C and the other at t_2, °C. $_{\tau H}Q'_o = {_{\tau H}E_o}/(t_2 - t_1)$. In certain cases, $_{\tau H}Q_o = a(1 - e^{-0.001bH})$ if τ, t_1 and t_2 are kept constant. H_m is value of H at which $_{\tau H}Q_o$ is a maximum.

In general, the algebraic value of $_HQ_o$ decreases as the hardness, the intensity of magnetization, and $(t_2 - t_1)$ increase, either individually or collectively.

For the following data, t_1 = 14°C, t_2 = 100°C; probable error in $Q' = ca.\ 0.5 \times 10^{-6}$ volt/°C. Unit of Q' and a = 1mμv/°C = 10^{-9} volt/°C; of H = 1 gauss; of τ = 1 kg/cm² = 14.22 lb./in.²; of b = 1 gauss⁻¹.

Metal	H	400	450	800	∞	Maximum		a	b
	τ	$_{\tau H}Q'_o$				$_{\tau H}Q'_o$	H_m

	970	+408	+424	+480	+485			+485	−4.6

* Cast. † Rolled. ‡ Pure Fe, Q' rises rapidly to a maximum, and then decreases. If $H > 200$, $_HQ_o$ for annealed Fe is 40×10^{-9} volt/°C less than $_HQ_o$ for unannealed iron. For soft Fe, $_HQ_o > 0$; for annealed steel, $_HQ_o < 0$. § Hard steel. ‖ Annealed.

TABLE 10.—EFFECT OF MAGNETIC FIELD (H) AND TENSION (τ) UPON THERMO EMF OF BIMETALLIC CIRCUITS (75)

$\Delta E/E = ({_ME'_{Cu}} - {_ME_{Cu}})/{_ME_{Cu}}$, where $_ME'_{Cu}$ = thermo emf of the M − Cu circuit when M is subjected to H and τ, $_ME_{Cu}$ = thermo emf of the same circuit when $H = 0$, $\tau = 0$; the temperatures (t_1, t_2) of the junctions are the same for $_ME'_{Cu}$ as for $_ME_{Cu}$. Probable error in $\Delta E/E = ca.$ 2% of $\Delta E/E$. The composition of each metal M is stated in the table. H_m = value of H at which $\Delta E/E$ is a maximum. Unit of H = 1 gauss; of τ = 1 kg/cm² = 14.22 lb./in.²; of composition of M = 1 wt. %.

A. Longitudinal magnetic field; t_1 = 0°C, t_2 = 100°C

* Change due to *H*, τ being constant.

TABLE 11.—PELTIER COEFFICIENT: DIRECTLY OBSERVED

For all couples including constantan, *see* Table 12

When $_MP_R$ is positive, there is an absorption of heat as the current passes from *R* to *M*. When *M* is a binary alloy, the % by weight of the second component appears under the symbol of that component. The coefficients for other couples can be computed from data in Tables 1 to 6; the accuracy of values so computed probably exceeds that of those directly measured. Unit of $P = 1\mu v = 10^{-6}$ volt; of "Error" = 1% of *P*; *t* = centigrade temperature, °C.

* Bi ⊥, Bi ∥, Bi_{45} = current perpendicular, parallel, at 45° to axis of Bi crystal. *See also* Table 13. For *transverse* Peltier effect, *see* p. 214.

† Direction of current with reference to axis of crystal is not stated.

‡ *See* Table 12.

§ German silver, composition is not stated, it usually lies between 50Cu, 30Ni, 20Zn and 57Cu, 7Ni, 36Zn.

¶ Composition is not stated; probably 75 to 55 Cu; 18 to 32 Ni; 0 to 20 Zn.

** Compare with corresponding value for Ag-Pd, Au-Pd by same author.

TABLE 12.—PELTIER COEFFICIENT: DIRECTLY OBSERVED VARIATION WITH TEMPERATURE

Data for other couples may be derived from data in Tables 1 to 6; values so computed are probably more accurate than those directly measured. ${}_MP_R = \mathrm{u} + \mathrm{v}t + \mathrm{w}t^2$ if t lies between t_1 and t_2. Unit of $P = 1\mu\mathrm{v} = 10^{-6}$ volt; of "Error" = 1 % of P; t_1, t_2 = centigrade temperature, °C.

* Composition is not stated; probably about 60Cu, 40Ni.

TABLE 13.—PELTIER COEFFICIENT OF BISMUTH: DIRECTLY OBSERVED EFFECT OF MAGNETIC FIELD (16)

$\Delta P = P' - P$, P' = Peltier coefficient when H = 2300 gauss, P = Peltier coefficient when H = 0; the direction of the current (‖, ⊥, ∠45°) is referred to the crystallographic *c*-axis. AB denotes the plane which includes the axis and the direction of the current. Unit of $\Delta P = 1\mu\mathrm{v} = 10^{-6}$ volt.

Direction of current	⊥	‖	∠45°
Direction of H	ΔP		
⊥AB.	−565	−1393	−2560
‖ AB, ‖ axis.	−416	− 226	− 125
‖ AB, ⊥ axis.	−264	−1393	−1286
‖ AB, ‖ current.	−264	− 226	− 753
‖ AB, ⊥ current.	−416	−1393	− 991

TABLE 14.—THOMSON COEFFICIENT (σ): DIRECTLY OBSERVED

$\sigma = \alpha + \beta t(10)^{-2} + \gamma t^2(10)^{-5}$ if t lies between t_1 and t_2; when σ is positive, there is an absorption of heat as current flows from regions of higher to those of lower temperature.

For other cases, σ may be computed by means of the relation $\sigma_M - \sigma_R = -T(\partial^2{}_ME_R/\partial t^2)$, using the data in Tables 1 to 6; probably values so computed are more accurate than those directly measured. Unit of $\sigma = 1\mu\mathrm{v}/°\mathrm{C} = 10^{-6}$ volt/°C; of "Error" = 1 % of σ; t_1, t_2 = centigrade temperature, °C.

* σ varies greatly from one specimen to another. *See also* Table 1.

† C(1) = 70 % graphite; C(2) = lamp filament.

‡ Exhibits thermoelectric hysteresis, sometimes as great as 25 % of mean σ. The occurrence of signs opposite to those which would be inferred from *E* is probably due to the presence of impurities.

§ Numerical value of σ increases rapidly between 40 and 100°C.

‖ σ varies from one specimen to another; the % of Sn by weight is indicated below the Sn.

¶ The current flows perpendicular to *c*-axis of the crystal.

** Composition is not stated. Possibly: Constantan = 60Cu, 40Ni. German silver between 50Cu, 30Ni, 20Zn and 57Cu, 7Ni, 36Zn. Manganin = 84Cu, 12Mn, 4Ni. Nickelin = 75 to 55Cu, 18 to 32Ni, 0 to 20Zn. Piano wire = 98.89Fe, 0.57C, 0.09Si, 0.01S, 0.02P, 0.42Mn.

ELECTRICAL CONDUCTIVITY OF AQUEOUS SOLUTIONS

INTRODUCTION

ABBREVIATIONS, SYMBOLS AND UNITS

κ Specific conductance in ohm^{-1} cm^{-1}.

C Concentration in milliformula-weights per l of solution at the temperature t, unless otherwise indicated.

$\Lambda = 10^6\kappa/C$.

The unit of specific conductance is the reciprocal ohm and it is assumed that the standardizing solutions shown in the tables below have the specific conductances there given. To bring the older data into harmony with these values, the authors' conductance values have been increased by the appropiate amount as indicated in column 5 of Table 1.

ABRÉVIATIONS, SYMBOLES ET UNITÉS

κ Conductibilité spécifique en ohm^{-1} cm^{-1}.

C Concentration en millimolécule grammes pour l de solution à la température t, à moins d'une autre indication.

$\Lambda = 10^6\kappa/C$.

L'unité de conductibilité spécifique est l'ohm réciproque et il a été admis que les solutions étalons données dans les tables ci-dessous ont les conductibilités spécifiques mentionnées à cette place. Pour mettre en harmonie avec ces valeurs les données plus anciennes, les valeurs de conductibilité données par les auteurs ont été augmentées d'une quantité appropriée, comme cela est indiqué dans la colonne 5 de la Table 1.

ABKÜRZUNGEN, SYMBOLE UND EINHEITEN

κ Spezifische Leitfähigkeit in Ohm^{-1} cm^{-1}.

C Konzentration in Milligrammformel-Gewicht für ein l der Lösung bei der Temperatur t, wenn nichts anderes angegeben.

$\Lambda = 10^6\kappa/C$.

Die Einheit der spezifischen Leitfähigkeit ist das reziproke Ohm. Es wird angenommen, dass die Lösungen, welche zur Bestimmung der Widerstands-Kapazität den Gefässen dienten, den spezifischen Leitfähigkeit haben, welcher in den unteren Tabellen angegeben ist. Um ältere Daten mit diesen in Übereinstimmung zu bringen, werden die Leitfähigkeitswerte der Autoren um einen entsprechenden Anteil erhöht, wie es in der Kolonne 5 der Tafel 1 angegeben ist.

ABBREVIAZIONI, SIMBOLI, E UNITÀ

κ Conduttura specifica in ohm^{-1} cm^{-1}.

C Concentrazione in milliformula-grammo per l di soluzione a temperatura t, a meno che non venga altrimenti indicato.

$\Lambda = 10^6\kappa/C$.

L'unità della conducibilità specifica è il reciproco dell' ohm; si suppone inoltre che le soluzioni titolate di confronto che figurano nelle tabelle più sotto hanno la conducibilità specifica ivi indicata. Per poter mettere d'accordo con questi i valori più vecchi, i valori datdagli autori sono stati accrei sciuti nel rapporto dovuto, come è indicato nella colonna 5 della Tabella 1.

SOLUTIONS OF SALTS AND OF ALL INORGANIC STRONG ELECTROLYTES

PART I. CONDUCTIVITY OF NEUTRAL HALIDES, NITRATES AND SULFATES

EDWARD W. WASHBURN AND ALFONS KLEMENC

CONTENTS	MATIÈRES	INHALTSVERZEICHNIS	INDICE
Table 1.—Values of C up to 0.5.	Table 1.—Valeurs de C jusqu'à 0,5.	Tabelle 1.—Werte von C bis 0,5.	Tabella 1.—Valori di C fino a 0,5.
Table 2.—Values of C from 0.5 to 1000.	Table 2.—Valeurs de C de 0,5 à 1000.	Tabelle 2.—Werte von C von 0,5 bis zu 1000.	Tabella 2.—Valori di C da 0,5 a 1000.
Table 3.—Values of C above 1000.	Table 3.—Valeurs de C au dessus de 1000.	Tabelle 3.—Werte von C über 1000.	Tabella 3.—Valori di C sopra 1000.
In each table the salts are grouped according to the anion in the order F, Cl, Br, I, SO_4, NO_3 and under a given anion the cations follow the standard arrangement (*v.* Vol. III, p. viii).	Dans chaque table les sels sont groupés en accord avec l'anion dans l'ordre F, Cl, Br, I, SO_4, NO_3 et sous un anion donné, les cations suivent l'arrangement type (*v.* Vol. III, p. viii).	In jeder Tabelle sind die Salze in der Reihenfolge ihrer Anionen angeordnet; F, Cl, Br, I, SO_4, NO_3. Unter den gegebenen Anionen folgen die Kationen in der Standardanordnung (*v.* Bd. III, S. viii).	In ciascuna tabella i sali sono raggruppati secondo l'anione nell'ordine F, Cl, Br, I, SO_4, NO_3 e per un dato anione i cationi seguono l'ordinamento tipo (*v.* Vol. III, p. viii).

ELECTRICAL CONDUCTIVITY OF SATURATED SOLUTIONS OF SLIGHTLY SOLUBLE ELECTROLYTES

H. I. Schlesinger and Judith E. Wallen

Scope.—Electrolytes with solubilities less than 0.1 equivalent per liter.

Arrangement.—Table 1 gives both the conductance and the solubility computed therefrom. Table 2 gives the conductance only. In each part the arrangement is alphabetical with respect to the symbol of the cation, with organic cations at the end.

Units.—Conductivities in reciprocal ohms (*see* p. 230 for cell constant basis); solubilities in equivalents per liter.

Abbreviations and Symbols.—κ_W = specific conductance of the water used.

κ_S = specific conductance of the solution, corrected for κ_W in the case of salts, uncorrected in all other cases.

S = solubility of the electrolyte as computed from the relation $S = \frac{\kappa'_S \times 10^3}{\alpha \Lambda_0}$, in which Λ_0 is the value assumed for the equivalent conductance of the completely ionized electrolyte, α is the value assumed for the "degree of ionization" (Λ/Λ_0) of the electrolyte in the saturated solution, and κ'_S is the value of κ_S after correction (where possible and necessary) for the effects of hydrolysis. No calculation of S has been attempted in cases where the use of the above relation involves assumptions of doubtful validity. S has been calculated at round values of the temperature, only where the data justified interpolation.

Nature of Crystalline Phase.—Except as otherwise indicated, the crystalline phase was prepared by precipitation methods.

TABLE 1.—ELECTROLYTES FOR WHICH BOTH CONDUCTANCE AND SOLUBILITY ARE GIVEN

Crystalline phase	t, °C	$\kappa_W \times 10^6$	$\kappa_S \times 10^6$	Λ_0	α	$S \times 10^6$	Lit.
AgCl	1.55	0.75	0.297				(9)

TRANSFERENCE NUMBERS OF ELECTROLYTES IN AQUEOUS SOLUTION

K. G. FALK

In the following tables the values given are in all cases the transference numbers of the cation multiplied by 10^3, and except as otherwise noted are with respect to water as the reference substance. Concentrations, C, are in equivalents per liter except those marked "Wt. N" which are in equivalents per kg H_2O. For theoretical discussion of the numbers and methods of weighting results obtained by the gravimetric method, *see* Noyes and Falk, *1*, **33**: 1436; 11.

Les valeurs données dans les tables suivantes sont dans tous les cas, les nombres de transport des cations multipliés par 10^3 et, à moins d'une autre indication, se rapportent à l'eau comme substance de référence. Les concentrations, C, sont exprimées en équivalents par litre, à l'exception de celles marquées "Wt. N" qui sont exprimées en équivalents par kg H_2O. Pour la discussion théorique des nombres et des méthodes d'appréciation des résultats par la méthode gravimétrique, *voir* Noyes and Falk, *1*, **33**: 1436; 11.

In den folgenden Tabellen stellen alle angegebenen Werte die Überführungszahlen des Kations multipliziert mit 10^3 dar. Sie gelten, stets, wenn nicht etwas anderes bemerkt, in Bezug auf Wasser. Die Konzentrationen, C, sind in Äquivalenten pro Liter angegeben, mit Ausnahme der Stellen, wo die Bezeichnung "Wt. N" steht, welche Äquivalente pro kg Wasser bedeutet. Die theoretischen Besprechungen der Zahlen und der Methoden zur Abschätzung der Ergebnisse nach der gravimetrischen Methode, findet man in der Abhandlung von Noyes and Falk, *1*, **33**: 1436; 11.

I valori riportati nelle tabelle seguenti rappresentano sempre il numero di trasporto del catione moltiplicato per 10^3, e, salvo indicazioni contrarie, si riferiscono all'acqua. Le concentrazioni, C, sono in equivalenti per litro, eccettuati i casi contrassegnati con "Wt. N" nei quali le concentrazioni sono espresse in equivalenti per kg di acqua. Per la discussione teorica dei numeri e circa l'apprezzamento dei risultati ottenuti col metodo gravimetrico, *vedi* Noyes and Falk, *1*, **33**: 1436; 11.

CONTENTS

The Weston Normal Cell and the Weston Unsaturated Cell

Definitions.—The term "Weston Normal Cell" is used here to designate the cell which contains solid crystals of $CdSO_4.\frac{8}{3}H_2O$ and which is used to maintain the standard of electromotive force. The term "Weston Unsaturated Cell" is here used to designate the cell which is made up with a solution of $CdSO_4$ which is saturated at 4°C and contains no excess of solid crystals of the sulfate. This cell is more generally used in practice since it has a lower temperature coefficient than the normal cell.

THE WESTON NORMAL CELL

$HgCd_{12.5\%} \mid CdSO_4.\frac{8}{3}H_2O \text{ satd.} \mid Hg_2SO_4 \text{ paste} \mid Hg$

Emf at 20°C.—(*a*) Value in **semi-absolute volts** at 20.00°C, that is, the potential which exists between the terminals of a resistance of one *international* ohm when carrying a current of one *absolute* ampere: 1.01825; average deviation of mean = 0.00002.

This value is the arithmetical mean of the results from the following references: (**1, 23, 25, 34, 50, 57, 62**).

(*b*) Value in **international volts,** when the current through the international ohm is determined by a silver coulometer, the electrochemical equivalent of silver being taken as 1.11800 milligram per coulomb as defined by the International Congress of 1908.

Value recommended by a special technical committee to the International Committee on Electrical Units and Standards: 1.0183 international volt at 20°C (**6**).

Best average value: 1.01827_4 international volt at 20°C; average deviation of mean = 0.000003.

This average value is the weighted mean from the following references, with assigned weights equal to the square root of the number of observations, since the authors do not compute the precision measure in all cases (**19, 25, 39, 40, 59, 67**); *cf.* (**58**).

THE CHARACTERISTICS OF STANDARD CELLS AND OF PRIMARY CELLS

M. DEKAY THOMPSON

CONTENTS

The Weston Normal Cell and the Weston Unsaturated Cell

Definitions.—The term "Weston Normal Cell" is used here to designate the cell which contains solid crystals of $CdSO_4 \cdot \frac{8}{3}H_2O$ and which is used to maintain the standard of electromotive force. The term "Weston Unsaturated Cell" is here used to designate the cell which is made up with a solution of $CdSO_4$ which is saturated at 4°C and contains no excess of solid crystals of the sulfate. This cell is more generally used in practice since it has a lower temperature coefficient than the normal cell.

THE WESTON NORMAL CELL

$$HgCd_{12.5\,\%} \mid CdSO_4 \cdot \tfrac{8}{3}H_2O \text{ satd.} \mid Hg_2SO_4 \text{ paste} \mid Hg$$

Emf at 20°C.—(*a*) Value in **semi-absolute volts** at 20.00°C, that is, the potential which exists between the terminals of a resistance of one *international* ohm when carrying a current of one *absolute* ampere: 1.01825; average deviation of mean = 0.00002.

This value is the arithmetical mean of the results from the following references: (1, 23, 25, 34, 50, 57, 62).

(*b*) Value in **international volts,** when the current through the international ohm is determined by a silver coulometer, the electrochemical equivalent of silver being taken as 1.11800 milligram per coulomb as defined by the International Congress of 1908.

Value recommended by a special technical committee to the International Committee on Electrical Units and Standards: 1.0183 international volt at 20°C (6).

Best average value: 1.01827_4 international volt at 20°C; average deviation of mean = 0.000003.

This average value is the weighted mean from the following references, with assigned weights equal to the square root of the number of observations, since the authors do not compute the precision measure in all cases (19, 25, 39, 40, 59, 67); *cf.* (58).

The Temperature Coefficient.—$E_t = E_{20} - 0.0000406(t - 20) - 0.00000095(t - 20)^2 + 0.00000001(t - 20)^3$. Adopted by the International Conference on Electrical Units and Standards at London, 1908 (76).

Construction.—Normal cells are nearly always constructed in the H-form proposed by Lord Rayleigh (17, 29, 55, 75). Recently circular forms have been constructed and studied (30, 56).

Heat of the Reaction in the Weston Cell.—$\text{Cd} + \text{Hg}_2\text{SO}_4 + \frac{8/3}{m - 8/3}\,\text{CdSO}_4.m\text{H}_2\text{O} \rightleftharpoons 2\text{Hg} + \frac{m}{m - 8/3}\,\text{CdSO}_4.8/3\text{H}_2\text{O}$, where m is the number of moles of water per mole of cadmium sulfate in the saturated solution.

The heat of this reaction is 47 561 g-cal_{15} according to thermochemical measurements, and 47 437 from the electromotive force and its temperature coefficient. These values refer to 12.5% Cd in the amalgam (8, 10).

Effect of Pressure on the Emf of the Weston Cell.—*v.* (13, 15).

Influence of Ultra-violet Light on the Emf of the Weston Cell.—*v.* (52).

Effect of Size of Grain of Mercurous Sulfate.—Weston cells made with finely divided mercurous sulfate (grain size of the order of magnitude of 5μ in diameter) have an electromotive force of 40 to 100 microvolt higher than those made with coarse mercurous sulfate (grain size 30 to 360μ). Hysteresis is greatest with coarse, white mercurous sulfate and is less for acid than for neutral cells (72); *cf.* (66, 75).

The Effect of Acidity on the Weston Cell.—For the purpose of making the Weston cell stable for a long time it is sometimes made up with 0.1N sulfuric acid (65). The emf is then 1.0182_5 international volt at 20°.

When the Weston cell is made up with acid the decrease in voltage = 0.000 855 × normality of acid (42).

TEMPERATURE COEFFICIENTS OF CELLS WITH DIFFERING AMOUNTS OF ACID

$$E = E_{20} + \alpha(t - 20) + \beta(t - 20)^2 \text{ (42)}$$

Acidity	0.07_8N	0.40_2N	0.56_6N	0.75_6N
$-10^6\alpha$	42.5	43.6	43.7	45.5
$-10^6\beta$	2.3	2.5	2.6	2.7

THE CONSTANCY OF ACID CELLS (42)

Effect of Composition of the Amalgam on the Emf of Weston Normal Cells.—*v.* (12, 60, 61).

RELATION BETWEEN THE EMF AND THE CONCENTRATION OF THE AMALGAM IN THE WESTON CELL (64)

The emf = 1.01823 international volt + the correction given in the table. The corrections are expressed in hundred-thousandths of a volt.

t, °C	Percentage of cadmium in the amalgam							
	1	2	3	4	5	6	7	8

Effect of Age on the Emf of the Weston Normal Cell (63).—Average change in 10 years: −0.000063 volt.

THE WESTON UNSATURATED CELLS

The unsaturated Weston cell is made with a solution saturated at 4°C. It has an average voltage of 1.0187 international volt and a temperature coefficient of less than 0.00001 volt per °C (73). Each cell is accompanied by a certificate stating its voltage.

UNSATURATED ACID WESTON CELLS

The measurements were made against three well-aged, very constant normal cells made at the National Physical Laboratory, Teddington, England. Their values were assumed to be such that the normal cells made for this investigation would have a value of 1.018054 volt at 25°C. The saturated solutions of cadmium sulfate were made with a 0.015 molal solution of sulfuric acid. The unsaturated solutions were made by adding the number of ml of this solution shown in the table to one liter of the saturated solution.

Composition of cadmium sulfate solutions, electromotive force, and temperature coefficients (71)

Solution number	Cells	Dilute acid added, ml	$CdSO_4$, per cent	Emf at 25°C, volt	$\Delta E/\Delta T$ in mmv per deg			
					15–25°	25–35°	35–40°	40–45°

Neutral cells did not give consistent results for temperature coefficients.

Cadmium Cells with Halide Electrolytes

Cells made in H-form. Measurements refer to an unsaturated Weston cell certified by the Reichsanstalt to have 1.0190 volt at room temperature (46).

1. Cells of the type: $HgCd_{12.5\,\%}$ | CdX_2 satd. | Hg_2X_2 paste | Hg

X	Electromotive force in volt
Cl	$E_t = 0.67180 - 0.000074(t - 18) - 0.0000015(t - 18)^2$
Br	$E_t = 0.55916 - 0.000366(t - 18) - 0.0000046(t - 18)^2$
I	$E_t = 0.41470 - 0.000362(t - 18) - 0.0000003(t - 18)^2$

2. Cells of the type: $HgCd_{12.5\,\%}$ | CdX_2 soln. | Hg_2X_2 paste | Hg

The emf of these cells can be represented by the formula

$$E_{18} = a \log N + b,$$

where N is the number of moles of CdX_2 per liter and a and b are constants:

X	a	b
Cl	−0.04306	0.7017
Br	−0.03953	0.58364
I	−0.03162	0.43338
$\frac{1}{2}SO_4$	−0.02501	1.05125

The Clark Cell

$HgZn_{10\,\%}$	$ZnSO_4.XH_2O$ satd. X = 7 below 39°; = 6 above 39°	Hg_2SO_4 paste	Hg

Emf at 15°C = 1.4328 int. volt (1, 3, 24, 29, 75).

The Chicago International Electrical Congress of 1893 adopted the value 1.434 international volt as the electromotive force of the Clark Cell at 15°C.

The Temperature Coefficient of the Clark Cell.—$E_t = E_{15} - 0.00119(t - 15) - 0.000007(t - 15)^2$ (31, 32).

Heat of the Reaction in the Clark Cell.—See (9, 51).

Temperature Coefficient of the Emf

For cells containing $ZnSO_4.7H_2O$

$P_{atm.}$

1.......... $E_1 = 1.43701 - 0.0_3221t - 0.0_4188t^2$

500.......... $E_{500} = 1.44105 - 0.0_4840t - 0.0_4206t^2$

1000.......... $E_{1000} = 1.44993 - 0.0_3263t - 0.0_4178t^2$

1500.......... $E_{1500} = 1.46025 - 0.0_3528t - 0.0_4140t^2$

For cells containing $ZnSO_4.6H_2O$

1.......... $E_1 = 1.42811 - 0.0_3407t - 0.0_578t^2$

500.......... $E_{500} = 1.43277 - 0.0_3418t - 0.0_572t^2$

1000.......... $E_{1000} = 1.44475 - 0.0_3681t - 0.0_546t^2$

1500.......... $E_{1500} = 1.44331 - 0.0_3429t - 0.0_570t^2$

The Helmholtz Cell

Zn | $ZnCl_2$ soln., sp. gr. 1.391 | Hg_2Cl_2 | Hg

The reaction is: $Zn + Hg_2Cl_2 = ZnCl_2$ in soln. + 2 Hg; $E_t = 1 + 0.000094(t - 15)$ volt (7, 27, 49).

The Mercury Oxide Cell

Zn | 10% soln. of $ZnSO_4$ | HgO | Hg

The reaction is probably: $Zn + HgO = ZnO + Hg$, which may be followed by secondary reactions; $E_t = 1.390 - 0.0002(t - 12)$ (7, 22).

The Lead Chloride Cell

HgZn | $ZnCl_2$ soln., sp. gr. 1.157 | $PbCl_2$ | Pb

The reaction is: $Zn + PbCl_2 = ZnCl_2$ in solution + Pb; $E = 0.5$ volt, temperature coefficient negligible (2).

The Cu-Hg Cell

$HgCu_{1.5\text{ to }6\%}$ | $CuSO_4.5H_2O$ satd. | Hg_2SO_4 | Hg (41)

$E_t = 0.3497_9 - 0.000635(t - 20) - 0.0000024(t - 20)^2$ volt

Total energy of the reaction from emf, 103.5 kj; from thermochemical data, 103.0 kj.

The same cell containing 10 to 12% copper in the amalgam, $E_t = 0.3500 - 0.00064(t - 20) - 0.0000025(t - 20)^2$.

Total energy change of the reaction from thermochemical data, 104.0; from emf, 104.1_5 kj (47).

The Pb-Hg Cell

Cells of the type:

$HgPb_{x\%}$ | $PbSO_4$ solid | Soluble sulfate | Hg_2SO_4 solid | Hg (37)

Soluble sulfate	x, %	Observed emf, volt at 25°	Average variation of single cell, volt
$Na_2SO_4.10H_2O$*....	3.08 to 3.23	0.96466	0.00002
K_2SO_4............	3.02	1.0300 to 1.0260	0.01
$Li_2SO_4.H_2O$........	2.98	0.9615 to 0.9620	0.001
$MgSO_4.7H_2O$......	2.84	0.9600 to 0.9610	0.001
$NiSO_4.7H_2O$.......	3.50	0.96466	0.00001
$CuSO_4.5H_2O$.......	3.16	0.3489	0.0003
$CdSO_4.\frac{8}{3}H_2O$.......	3.58	0.9520 to 0.9540	0.0012
$ZnSO_4.7H_2O$.......	3.56	0.96480	0.00001
$MnSO_4.5H_2O$......	3.39	0.96478	0.00001

* For other temperatures: $E_t = E_{25} + 0.000174(t - 25) + 0.00000038(t - 25)^2$. The total energy of the reaction is calculated to be 176.5 kj from electromotive force; 175.0_5 from thermochemical data.

Low-Voltage Normal Cells (43)

Cells of the combinations (*b*) and (*c*) are most reproducible and are constant for a long period.

The LeClanché Dry Cell

Cells 2.5 × 6 in. (63 × 152 mm) are designated as No. 6. Smaller cells are designated as follows (5)

Designation*	Diameter, inches	Height, inches	Diameter, mm	Height, mm
A...............	$\frac{5}{8}$	$1\frac{7}{8}$	16	48
B...............	$\frac{3}{4}$	$2\frac{1}{8}$	19	54
C...............	$\frac{15}{16}$	$1\frac{13}{16}$	24	46
D...............	$1\frac{1}{4}$	$2\frac{1}{4}$	32	57
E...............	$1\frac{1}{4}$	$2\frac{7}{8}$	32	73
F...............	$1\frac{1}{4}$	$3\frac{7}{16}$	32	87

* Includes flat cells of equivalent capacity.

The voltage requirements are those in the following table when measured with a voltmeter of not less than 100 ohm per volt, and having not less than 50 divisions of its scale per volt.

Designation	Nominal dimensions of cell		Minimum voltage
	Diameter, mm	Height, mm	
No. 6...............			1.50
F...................	32	87	1.50
E...................	32	73	1.50
D...................	32	57	1.50
C...................	24	46	1.49
B...................	19	54	1.48
A...................	16	48	1.47

For additional data, *v.* (5).

The electromotive force of the manganese dioxide electrode of dry cells is determined by the hydrogen ion concentration, in the case of Caucasian, Brazilian, and domestic ores. For a tenfold increase in hydrogen ion concentration the electrode potential increases from 0.06 to 0.08 volt. Chemically prepared dioxide is apparently free from this concentration effect (28).

Assumed Reactions of the LeClanché Cell

Negative pole: $Zn + 2\mathbf{F} + 2Cl^- = ZnCl_2$.

Positive pole:

$$2NH_4^+ + 2MnO_2 = 2NH_3 + H_2O + Mn_2O_3 + 2\mathbf{F}$$
$$2NH_3 + ZnCl_2 = Zn(NH_3)_2Cl_2$$

Other oxides of manganese probably form.

Net reaction: $Zn + 2NH_4Cl + 2MnO_2 = Zn(NH_3)_2Cl_2 + Mn_2O_3 + H_2O$.

The reaction at the positive pole may also be considered to take place as follows (20, 36, 68):

$$MnO_2 + 2H_2O \rightleftharpoons Mn^{++++} + 4OH^-$$
$$Mn^{++++} = Mn^{++} + 2\mathbf{F}$$
$$Mn^{++} + 2OH^- = Mn(OH)_2$$

Net reaction: $MnO_2 + 2H_2O = Mn(OH)_2 + 2OH^- + 2\mathbf{F}$.

Effects of Temperature on Dry Cells (4)

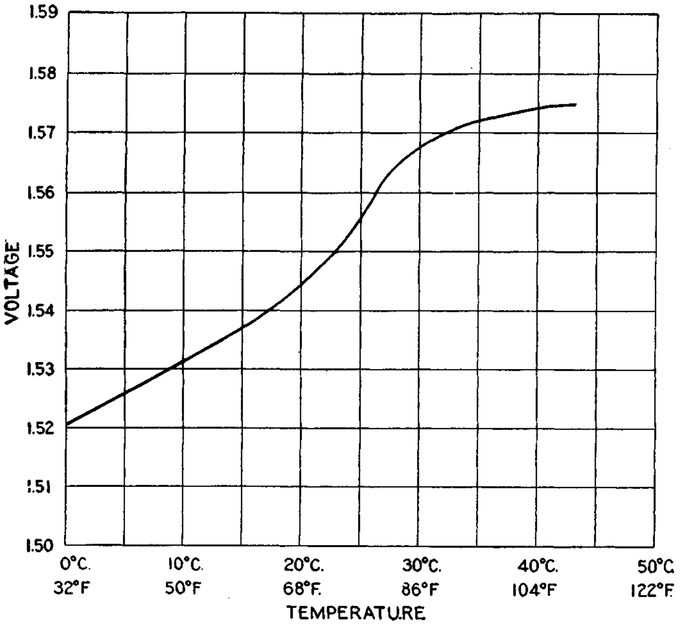

Fig. 1.—Effect of temperature on open-circuit voltage of dry cells.

Mean of measurements on 16 cells, No. 6 size, paper-lined construction, including four different brands. The cells were kept at fixed temperatures 24 hours before being measured.

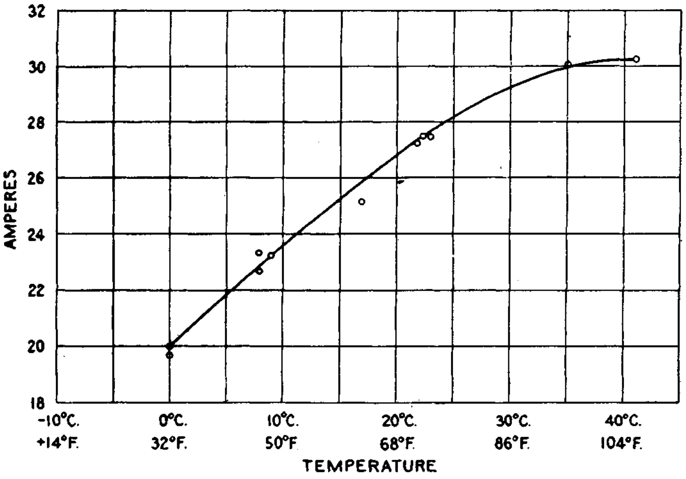

Fig. 2.—Effect of temperature on short-circuit current.

Mean values for a group of six cells maintained at each of the temperatures indicated for at least 24 hours prior to the measurements. The temperatures were taken in the following order; 22, 0, 22.5, 8, 0, 21.8, 35, 41, 8, 16.8, and 9°C.

Effect of Temperature on the Short-Circuit Current of Dry Cells Stored for 10 Weeks on Open Circuit (Pritz (53))

Temperature of storage, °C	Percentage decrease in short-circuit current at end of 10 weeks	Temperature of storage, °C	Percentage decrease in short-circuit current at end of 10 weeks
5	4.4	55	52.0
25	10.0	65	71.0
35	19.0	75	98.0
45	25.0		

Recent experiments show that the measurements of Pritz for cells stored at 25°C are approximately correct for dry cells when new, but the rate of decrease of short-circuit current becomes less as the age of the cell increases; the total decreases during a year at room temperature being about 25%.

The Féry Zinc-Carbon Cell

Similar to the LeClanché but contains no manganese dioxide. The carbon electrode is cylindrical and is made of specially prepared carbon. A horizontal plate of zinc is at the bottom of the carbon cylinder and is insulated from it. A test cell mounted in a vessel 10 cm square and 22 cm high, containing 1 liter of water + 125 g of ammonium chloride and a zinc plate weighing 160 g yielded 125 ampere hours (69).

Caustic Soda Cells

REACTIONS OF THE CAUSTIC SODA CELL (20)

Negative pole: $Zn + 2\mathbf{F} + NaOH + 2OH^- = NaHZnO_2 + H_2O$.

Positive pole: $2H^+ + 2CuO = H_2O + Cu_2O + 2\mathbf{F}$ (also: $Cu_2O + 2H^+ = H_2O + 2Cu + 2\mathbf{F}$).

Net reaction: $Zn + 2CuO + NaOH = NaHZnO_2 + Cu_2O$.

The following graphs show performance under different conditions of temperature and concentration of electrolyte (36.1).

Caustic Soda Cells.—(*Continued*)

CuO | 20 to 25% solution of NaOH covered with oil | Zn amalg.
This cell is made in capacities from 200 to 1000 ampere hours.

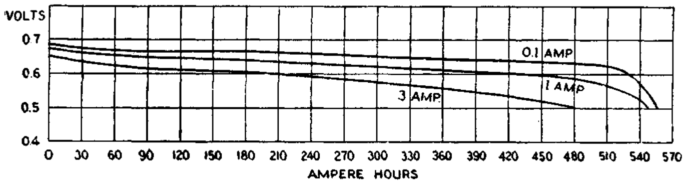

FIG. 3.—Graphs showing the voltage of a 500-ampere hour cell during discharge at 23°C. (Private Communication.)

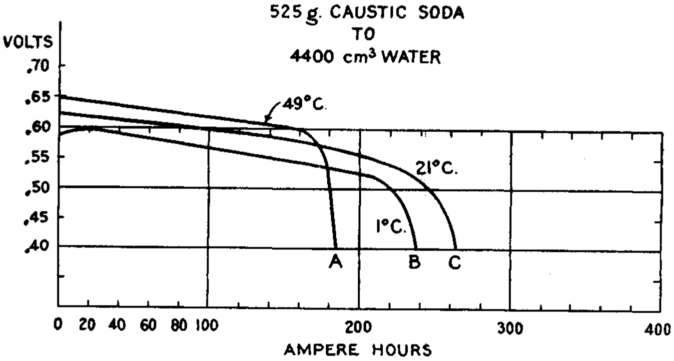

FIG. 4.—Performance of cell containing 525 g caustic soda to 4400 cm³ water. Current constant at 3 ampere.

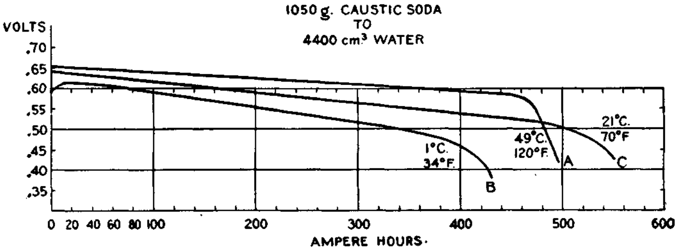

FIG. 5.—Performance of cell containing 1050 g caustic soda to 4400 cm³ water, the normal concentration. Current constant at 3 ampere.

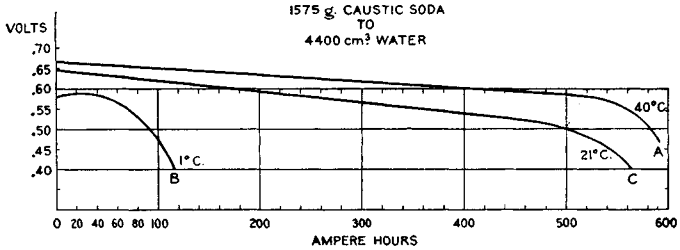

FIG. 6.—Performance of cell containing 1575 g caustic soda to 4400 cm³ water. Current constant at 3 ampere.

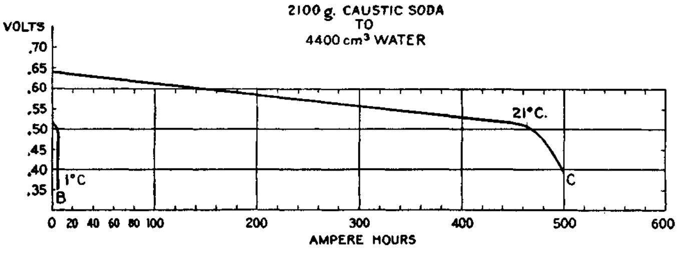

FIG. 7.—Performance of cell containing 2100 g caustic soda to 4400 cm³ water. Current constant at 3 ampere.

The Nyberg cell: Amalgamated Zn | 10% NaOH | Porous C

Voltage 1.00 to 1.18 for currents of 1 to 0.1 ampere. For a volume of 1000 cm³ and weight 1300 g the maximum capacity is 210 watt-hr (38).

The Daniell Cell

Zn | $ZnSO_4$ or H_2SO_4 soln. | $CuSO_4$ soln. | Cu

The two electrolytes are separated by a porous cup, or by difference in density in the "gravity" type of cell. *E* varies from 1.07 to 1.14 volt.

The reaction is: Zn + $CuSO_4$ in solution = $ZnSO_4$ in solution + Cu (16).

The Grove and Bunsen Cells

HgZn | 1 vol. H_2SO_4 to $12H_2O$ | Conc. HNO_3 | Pt

$E = 1.9$ to 2 volt. The two acids are separated by a porous cup.

The Bunsen cell is the Grove cell with platinum replaced by carbon.

The Poggendorff Cell

HgZn | Dil. H_2SO_4 | Conc. soln. of $Na_2Cr_2O_7$ or $K_2Cr_2O_7$ + H_2SO_4 | C

Reaction at negative pole: $3Zn + 6F + 3SO_4^{--} = 3ZnSO_4$ which is the same for all cells with zinc dipping into sulfuric acid.

At the positive pole: $Na_2Cr_2O_7 + H_2SO_4 = Na_2SO_4 + H_2O + 2CrO_3$.

$$2CrO_3 + 3H_2SO_4 + 6H^+ = 6H_2O + Cr_2(SO_4)_3 + 6F$$

Net reaction: $3Zn + 7H_2SO_4 + Na_2Cr_2O_7 = 3ZnSO_4 + Na_2SO_4 + Cr_2(SO_4)_3 + 7H_2O$.

THE POTENTIALS OF ELECTRODE CELLS

CHARLES P. SMYTH

The term "electrode cell" as employed in this section signifies a cell whose emf is determined solely or chiefly by differences in concentration or physical condition of some atomic or molecular species in the electrode. The cells are arranged in alphabetical order of the symbols of the most important chemical element of the cell. In most instances the cell is given by literature reference only and only reversible cells have been included.

ABBREVIATIONS

Ac	Acetate radical.
E_t	Emf at t, °C.
mv	Millivolts.
M	Molal.
M_x	The element M in the amount x wt. % in the electrode.
N	Normal.
satd.	Saturated.

Le terme "electrode cell" tel qu'il est employé dans cette section, signifie une cellule dont la fem est déterminée uniquement ou principalement par les différences de concentration ou de conditions physiques d'une espèce atomique ou moléculaire, dans l'électrode. Les cellules sont arrangées dans l'ordre alphabétique des symboles de l'élément chimique le plus important de la cellule. Dans la plupart des cas, la cellule n'est donnée que par une référence bibliographique et les cellules reversibles ont seules été mentionnées.

ABRÉVIATIONS

Ac	Radical acétate.
E_t	Fem à t, °C.
mv	Millivolts.
M	Molal.
M_x	L'élément M dans la proportion x % poids dans l'électrode.
N	Normal.
satd.	Saturé.

Der Ausdruck "electrode cell," wie er in diesem Abschnitt verwendet wird, bezeichnet eine Zelle deren elektromotorische Kraft ausschliesslich oder hauptsächlich durch die Differenz in den Konzentrationen oder in den physikalischen Zustand einiger atomarer oder molekularer Stoffe in der Elektrode bestimmt ist. Die Zellen sind in alphabetischer Reihenfolge der Symbole des wichtigsten Elementes der Zelle, angeordnet. In vielen Fällen ist die Zelle nur durch die Literaturstelle angegeben und es werden nur reversible in Betracht gezogen.

ABKÜRZUNGEN

Ac	Acetat-Radikal.
E_t	Elektromotorische Kraft bei t, °C.
mv	Millivolt.
M	Molar.
M_x	Das Element M ist zu x Gew. % in der Elektrode vorhanden.
N	Normal.
satd.	Gesättigt.

Il termine "electrode cell" come viene impiegato in questo capitolo significa una cella la cui fem è determinata in modo esclusivo o per la massima parte, da differenze di concentrazione o di condizione fisica di qualche specie molecolare o atomica nell'elettrodo. Le celle sono disposte in ordine alfabetico del simbolo dell'elemento più importante delle celle stesse. Nella maggior parte dei casi la cella è indicata con la citazione bibliografica, e solo le celle reversibili sono state incluse.

ABBREVIAZIONI

Ac	Radicale acetico.
E_t	Fem a t, °C.
mv	Millivolts.
M	Molale.
M_x	L'elemento M nella quantità x in peso % nell'elettrodo.
N	Normale.
satd.	Saturo.

THE EMF OF CONCENTRATION CELLS

H. S. HARNED

For the purpose of defining the scope of this section a concentration cell will be defined as one whose emf serves as a measure of the free energy change corresponding to a definite change in the activity of a molecular (or ionic) species *in the solution.*[1]

The section is divided into two parts as follows:

Part I. True concentration cells

These include all cells whose total emf is a direct measure of the free energy change. These are of two types as follows:

Type 1. Cells without transference

Example:

$$\left.\begin{matrix} H_2 \mid HCl(c_1) \mid AgCl \mid Ag \\ H_2 \mid HCl(c_2) \mid AgCl \mid Ag \end{matrix}\right\} \qquad (1)$$

or by combining

$$Ag \mid AgCl \mid HCl(c_2) \mid H_2 \mid HCl(c_1) \mid AgCl \mid Ag \qquad (2)$$

The cell reaction of cell (2) represents per faraday, the transfer of one equivalent of HCl from c_2 (activity a_2) to c_1 (activity a_1).

The equation for this cell is, $E = (RT/F) \log_e a_2/a_1$.

Type 2. Cells with transference

Example:

$$H_2 \mid HCl(c_1) \mid HCl(c_2) \mid H_2$$

The equation for this type is, $E = (nRT/F) \log_e a_1/a_2$, where n is the number of equivalents transferred from activity a_1 to a_2 per faraday.

Part II. Cells with salt bridges

Each cell listed in this group is composed of one of the standard reference electrodes joined (usually by a salt bridge) to a half cell containing the ion-species whose activity is sought. If from the total emf of such a cell, the emf of the reference electrode plus the emf's at the liquid junctions be subtracted, the result is a measure of the activity of the given ion species under the conditions which prevail in the other half of the cell.

Since the correction for liquid junction potentials is in most cases a matter of considerable uncertainty in the present state of our knowledge, these cells are listed by literature reference only.

---

[1] For cells whose emf is a function of the activity of a molecular species *in the electrode*, *v.* p. 319.

ELECTRICAL AND OPTICAL PROPERTIES OF SILICA

ROBERT B. SOSMAN

Dielectric Constant (12, 16, 27, 28.1, 38, 67, 76, 79, 81, 85)

	Most probable value	Limits between which the true value certainly lies
Quartz, axis ‖ to direction of field.	4.6	4.5 and 5.0
Quartz, axis ⊥ to direction of field.	4.5	4.2 and 4.7
Difference (‖) − (⊥)............	+0.1	+0.1 and +0.4
Vitreous silica....................	3.75	3.2 and 3.9

Electrical Resistivity

Unit, ohm-cm (1, 7, 12, 16, 22, 26, 35, 39, 67, 68, 84, 86, 90)

Reinkober (1910)	8.30		8.90		12.6	14.6		
Liebisch and Rubens							21.2	26.8

* Center of mass of two maxima, one at 8.35, and one at 8.50 (weak).

† Center of mass of two maxima, one at 8.90, and one at 9.05.

‡ Weak.

Verdet Constant

SODIUM LIGHT AT ROOM TEMPERATURE

Values of $10^3\omega$. $\omega = \alpha/lH$. α in minutes, *l* in cm, *H* in gilbert per cm.

Quartz, 17; vitreous, 15. Temperature coefficient about +0.01% per degree C (4, 45, 83).

MAGNETISM

ATOMIC AND MOLECULAR DATA IN RELATION TO THEORIES OF MAGNETISM

S. J. Barnett

A body can be magnetized either by placing it in a magnetic field or by rotating it in a neutral region (p. 347). The magnetization acquired in a magnetic field results from the superposition of two effects, either of which may practically vanish: (1) A *magnetic* effect, consisting in an alignment, more or less parallel to the applied magnetic field, of the axes of certain permanent, or approximately permanent, *magnetic elements* constituting parts of the molecules; and (2) a *diamagnetic* effect, fundamentally identical with the induction of an electric current in a conductor (88). In *diamagnetic* substances χ is negative, small, independent of H and, in many cases, independent of temperature and certain other physical conditions. *Magnetic* substances, for which χ is positive, are either *paramagnetic* or *ferromagnetic*. In *paramagnetic* substances χ is small and independent of H at ordinary temperatures and in weak fields. In *ferromagnetic* substances χ is relatively large and depends upon H, unless H is very small. When its temperature is sufficiently increased, every ferromagnetic substance becomes transformed into a paramagnetic substance. The temperature at which this change occurs is called the *temperature of transformation* or *Curie point* (Θ) for the substance. The data given in this report refer chiefly to paramagnetic and diamagnetic substances, because only a few pertinent quantitative atomic and molecular data are available for ferromagnetic substances.

SYMBOLS AND UNITS

Unless another is indicated, the basic unit in every case is the appropriate cgsm unit. Symbols which are frequently used throughout the Tables are defined in Vol. I, p. 16; those used in only a single section will be defined where used.

A	Atomic weight.
a	Constant in Langevin's equation (p. 350).
B	Number of Bohr magnetons per basal unit; $[\mu] = B[\mu]_B$.
e	Electric charge; usually, but not necessarily, it is numerically equal to the "electronic charge," $\mathbf{e}$.
H	Intensity of magnetic field.
j	Angular momentum of the body, or system, under consideration.
M	Molecular weight.
m	Mass.
$\mathbf{m}_0$	Electronic mass at low velocity.
N_0	Avogadro's number.
R	Gas constant per gram-mole.
R_0	$2\mathbf{m}_0/\mathbf{e}$.
r	Radius.
T	Absolute temperature, °K.
W	Number of Weiss magnetons per basal unit; $[\mu] = W[\mu]_W$.
Z	Atomic number.
Θ	Curie point. Temperature-constant in Weiss's relation.
$[\mu]$	Magnetic moment of the system under consideration.
$[\mu_0]$	Magnetic moment of elementary magnetic unit.
Σ	Sign of summation.
σ	Specific magnetization = magnetic moment per unit of mass.
σ_∞	Value of σ when axes of all the elementary magnetic moments are parallel.
χ	Specific susceptibility = susceptibility divided by density.

Subscripts: $_a$, $_m$ indicates the quantity is referred to the gram-atom, gram-mole. $_B$, $_W$ indicates the quantity is expressed in the Bohr magneton, the Weiss magneton, as unit moment.

Magnetons or Magnetic Elements

The term *magneton* has been applied both to the complete magnetic element within the atom or molecule, and to the ultimate magnetic units of which the element may be constituted. Of the various magnetons which have been proposed, four will be considered here; the first three are based upon theory, the fourth entirely upon experiment.

Spinning Electron (1, 32, 63, 97, 115).—The element is the rotating spherical electron. The ratio of the angular momentum (j) to the magnetic moment $[\mu]$ is $(j/[\mu])_s = m_s/e$ if the charge is distributed uniformly over the surface, and $(j/[\mu])_v = 5m_v/7e$ if the charge is distributed uniformly throughout the volume; m_s and m_v are the inertias of the electron in the two cases. If r = radius of the electron, $m_s = 2e^2/3r$. $m_v = 4e^2/5r$.

Bohr Magneton (104).—The electron is revolving in a fixed orbit; $j/[\mu_0] = 2m_0/e(\equiv R_0) = -1.13 \times 10^{-7}$ for a negative electron. On Bohr's theory, the least value of j is $\mathbf{h}/2\pi$, and the corresponding value of $[\mu_0]$ is Bohr's magneton $[\mu_0]_B = \mathbf{eh}/4\pi\mathbf{m}_0 = 9.23 \times 10^{-21}$. The Bohr gram-magneton $[\mu_g]_B$ is defined as $N_0[\mu_0]_B = 5593$ (28, 104); if there is but one such electron orbit per atom, $[\mu_g]_B = [\mu_a]_B$.

Sommerfeld Magneton (104).—On Sommerfeld's spectroscopic theory, the atomic moment of an atom is $[\mu] = gj_1[\mu_0]_B$, where g is Landé's "splitting factor," and the angular momentum of the atom is $j = j_1\mathbf{h}/2\pi$. The quantities j and g are derived from spectroscopic data, and the product gj_1 is known as the spectroscopic magneton number of the atom in the given state.

The magnetic moment of the free neutral atom of a metal may be determined directly from the effect of an intense and non-uniform magnetic field upon a high velocity stream of the vaporized metal in the atomic state (method of Gerlach and Stern) (45, 46, 47, 68, 92, 110, 137). The experimental error in the magneton number ($[\mu]/[\mu_0]_B$), so determined, ranges from 0.02 to 0.3 or 0.4.

TABLE 1.—COMPARISON OF MAGNETON NUMBERS (B) OBTAINED BY DIFFERENT METHODS (45, 46, 47, 68, 92, 110, 137)

$[\mu] = B[\mu_0]_B$; B_{GS}, B_S = value of B obtained by the Gerlach and Stern, and by the spectroscopic method, respectively

Atom....	H	Na	K	Cu	Ag	Au	Zn	Cd	Hg
B_{GS}......	1	1	1	1	1	1	0	0	0
B_S......	1	1	1	1	1	1	0	0	0

Atom..........	Tl	Sn	Pb	Sb	Bi	Te	Ni	Fe
B_{GS}..........	$\frac{1}{3}$	0	0	0	(?)	0	$\gtrless 2$	0
B_S..........	$\frac{1}{3}$	0	0	0	(?)	(?)	5	*

* Large.

Weiss Magneton (11, 50, 89, 93, 120, 126).—At very low temperatures, χ_a, for both Fe and Ni, approaches asymptotically a definite maximum as the intensity of the field is increased and the temperature is decreased. The limiting values are 1123.6×11 for Fe, and 1123.3×3 for Ni. The value 1123.5 is the magnetic moment of the gram-magneton of Weiss, $[\mu_g]_W$. At very low temperatures, the atoms of Fe and Ni contain, respectively, 11 and 3 Weiss magnetons. The moment of the elementary Weiss magneton is defined as $[\mu_0]_W = 1123.5/N_0 = 1.854 \times 10^{-21}$. Within less than the experimental error, the magnetic moments of the Weiss magnetons are ⅕ as great as those of the corresponding Bohr magnetons.

TABLE 2.—ATOMIC AND MOLECULAR MAGNETIC MOMENTS $[\mu]$ OF FERROMAGNETIC SUBSTANCES AT LOW TEMPERATURES: METHOD OF WEISS

$[\mu] = W[\mu_0]_W$

Molecular Gyromagnetic Effects

Magnetization by Rotation (Barnett) (3, 7).—In effect, each magneton is a gyrostat with a magnetic moment parallel to the axis of rotation; when a body containing magnetons is rotated, the directions of their magnetic moments tend to become parallel to the axis of rotation of the body. For a circular cylinder making n rotations per sec about its axis of figure, the resultant magnetic moment (M), so produced parallel to the axis, is $M = C\lambda n = CH$, where C is a constant, $\lambda = 2\pi j/[\mu]$, and H is the intensity of the axial magnetic field that would produce the same moment (M) without rotation; $\lambda (= H/n)$ is called the specific magnetic intensity of rotation for the substance of the rod. On the classical theory, if the magneton is an electron in a Bohr orbit, $\lambda = 2\pi j/[\mu_0] = 4\pi \mathbf{m}_0/e = 2\pi R_0 = -7.10 \times 10^{-7}$ gauss/rotation per sec. If the magneton is a spherical electron with uniform surface charge (Lorentz) spinning about a diameter, $\lambda = -3.55 \times 10^{-7}$ gauss/rotation per sec. Results of experiments are given in Table 3.

TABLE 3.—MAGNETIZATION BY ROTATION

λ = specific magnetic intensity of rotation $= 2\pi j/[\mu]$. For Bohr magneton, $j/[\mu] = R_0$; for spinning electron with surface charge, $j/[\mu] = R_0/2$. $2\pi R_0 = 4\pi \mathbf{m}_0/e = -7.10 \times 10^{-7}$ gauss/rotation per sec; unit of $\lambda(\equiv H/n) = 10^{-7}$ gauss/rotation per sec.

Material	Notes	$-\lambda$	Material	Notes	$-\lambda$
Steel	*	3.6	Heusler alloy	‡	3.62
Steel	†	3.4	Permalloy	80% Ni‡	3.78
Iron	6 rods‡	3.79	Ni-Fe	25% Ni‡	3.63

Nickel	2 rods‡	3.69	Co-Ni	54% Co‡	3.83
Cobalt	‡	3.84			

Weighted mean of observations (‡) of 1923, 3.76 ± 0.07.
Hence $j/[\mu] = (3.76/7.10)R_0 = 0.529R_0 = 1.06\mathbf{m}_0/e$.

* Observations of 1914, method of electromagnetic induction (3).
† Observations of 1915, method of 1914 (3).
‡ Observations of 1923, magnetometer method (7), error about 2%.

Rotation by Magnetization (Einstein and de Haas (40); *cf.* (9, 30, 39, 96, 105, 108, 109)).—This is the converse of the Barnett effect. A ferromagnetic rod is given an angular momentum about its axis by altering a magnetic field, parallel to the axis, impressed on the rod by means of a solenoid which may be either fixed to the earth or wound rigidly on the rod. The measurements permit the calculation of the ratio $j/[\mu]$ on the basis of the classical theory and the assumption that the momentum acquired by the rigid system which includes the rod is equal and opposite to the momentum given to the magnetons. For the results of the most reliable experiments, *see* Table 4.

TABLE 4.—ROTATION BY MAGNETIZATION

The value of $(j/[\mu])/R_0$ to be expected on the classical theory is unity for a Bohr magneton, and 0.5 for a spinning electron with surface charge.

Material	$(j/[\mu])/R_0$	Method*
Iron	0.50+	Bal (30)
	0.53	ACD (9)
	0.50+	ACN (109)
	0.52	ACN$_R$ (6)
Nickel	0.50+	Bal (30)
	0.57	ACD (9)
	0.50	ACN (109)
Cobalt	0.5	ACN (108)
Permalloy	0.52+	ACN$_R$ (6)
Magnetite	0.5	ACN (108)
Heusler alloy	0.50	ACN (109)

* Bal = ballistic; ACD = alternating current, deflection; ACN = alternating current, null; ACNR = alternating current, null, solenoid wound on rod; ACN$_R$ = both ACN and ACNR. Excepting ACNR, solenoid is fixed to earth. Data from (6) are preliminary.

Magnetism and Structure; *v. also* (108, 109)

Effect of Number of Electrons (*v. also* (19, 61, 62)).—(*a*) Pascal's Relation.—Pascal (82) found that for homologous elements in the 3 families of metalloids, $\chi_a(\equiv A\chi) = -Ce^{\alpha A}$, where C and α are experimental constants; later (85) he found the relation to apply to nearly all the other diamagnetic elements; *see* Fig. 1.

(*b*) Kossel's Relation (16, 64, 104).—For atoms and ions having 18 to 29 electrons external to the nucleus, Kossel observed that the magnetic moment depends primarily upon the number of electrons external to the nucleus; *e.g.*, A, K^+, and Ca^{++} have 18 such electrons each, and their moments are essentially identical (Fig. 2); removing 2 electrons from the neutral Ca atom ($Z = 20$) changes its moment to that of A ($Z = 18$). This illustrates Kossel's "displacement law." Meyer found the same relation for atoms and ions having 57 to 71 extranuclear electrons (Fig. 3).

Effect of Distribution of Electrons and Electron Orbits.—(*a*) Langevin's Theory.—On Langevin's (65) electron theory of magnetism, an ion, atom, or molecule with a completely symmetrical arrangement of electron orbits should be diamagnetic, as exemplified by the rare gases and Cu^+, Ag^+, Au^+; while an unsymmetrical arrangement should produce paramagnetism, as exemplified by Na, K, Ag, Cu, etc.

(*b*) Kossel's and Sidgwick's Theory.—On the theory of Kossel (64) and Sidgwick (102) the electropositive atoms of a saturated compound have lost all the electrons they will part with readily, and the electronegative atoms have taken up all they will take up, and in practically all cases the resulting orbital arrangement is symmetrical, and the compounds are diamagnetic. In a few cases, as in cupric compounds, the arrangement is not symmetrical, and the compound may be paramagnetic. Similarly, unsaturated compounds of diamagnetic elementary substances may be either diamagnetic like oxides of bivalent Pb and Sn, or paramagnetic like NO; *v. also* (10).

(*c*) Lewis's Theory.—On the magnetochemical theory of G. N. Lewis (69), those electrons in a molecule which are paired with one another produce a diamagnetic effect, while an unpaired electron gives a magnetic moment to the molecule, thus producing paramagnetism. In the case of solids and liquids the exact molecular state is in general unknown; but in the case of gases and dilute solutions it can be predicted that every substance with an odd number of electrons in the molecule will be paramagnetic, as exemplified by the following (111): The two odd molecules NO and NO_2 are paramagnetic, while the nitrogen oxides with even molecules are diamagnetic; ClO_2, which is odd, is paramagnetic even in dilute solution in CCl_4; the odd compound α-naphthyldiphenylmethyl in benzene solution is paramagnetic (the first case of paramagnetism in an organic compound); for additional data, *see* (111, 133).

(*d*) Welo and Baudisch's Theory.—On the theory of Welo and Baudisch (127, 128); *cf.* (10), the diamagnetism of certain salts of magnetic elements is due to the fact that the atoms of the magnetic element have, by sharing with, and transfer from, neighboring atoms, gained a sufficient number of electrons to attain the symmetrical electron configuration of a rare gas. Thus $K_4Fe(CN)_6$ is diamagnetic because each K atom contributes one electron to the Fe atom by transfer, and each CN group contributes one by sharing. Thus the Fe atom, originally possessing 26 non-nuclear electrons, gains 10 more, and assumes the structure of Kr with 36 electrons.

Effect of Crystal Structure.—Though numerous experiments, including the recent ones of Ingersoll and de Vinney on magnetic and non-magnetic Ni films (55); *cf.* (80), indicate clearly that ferromagnetism occurs only in crystalline masses, the type of crystal appears to have little significance (52, 129, 130). Thus α-, β- and δ-iron are all body-centered cubic, while γ-iron is face-centered cubic. At ordinary temperatures, Ni is face-centered cubic; Co

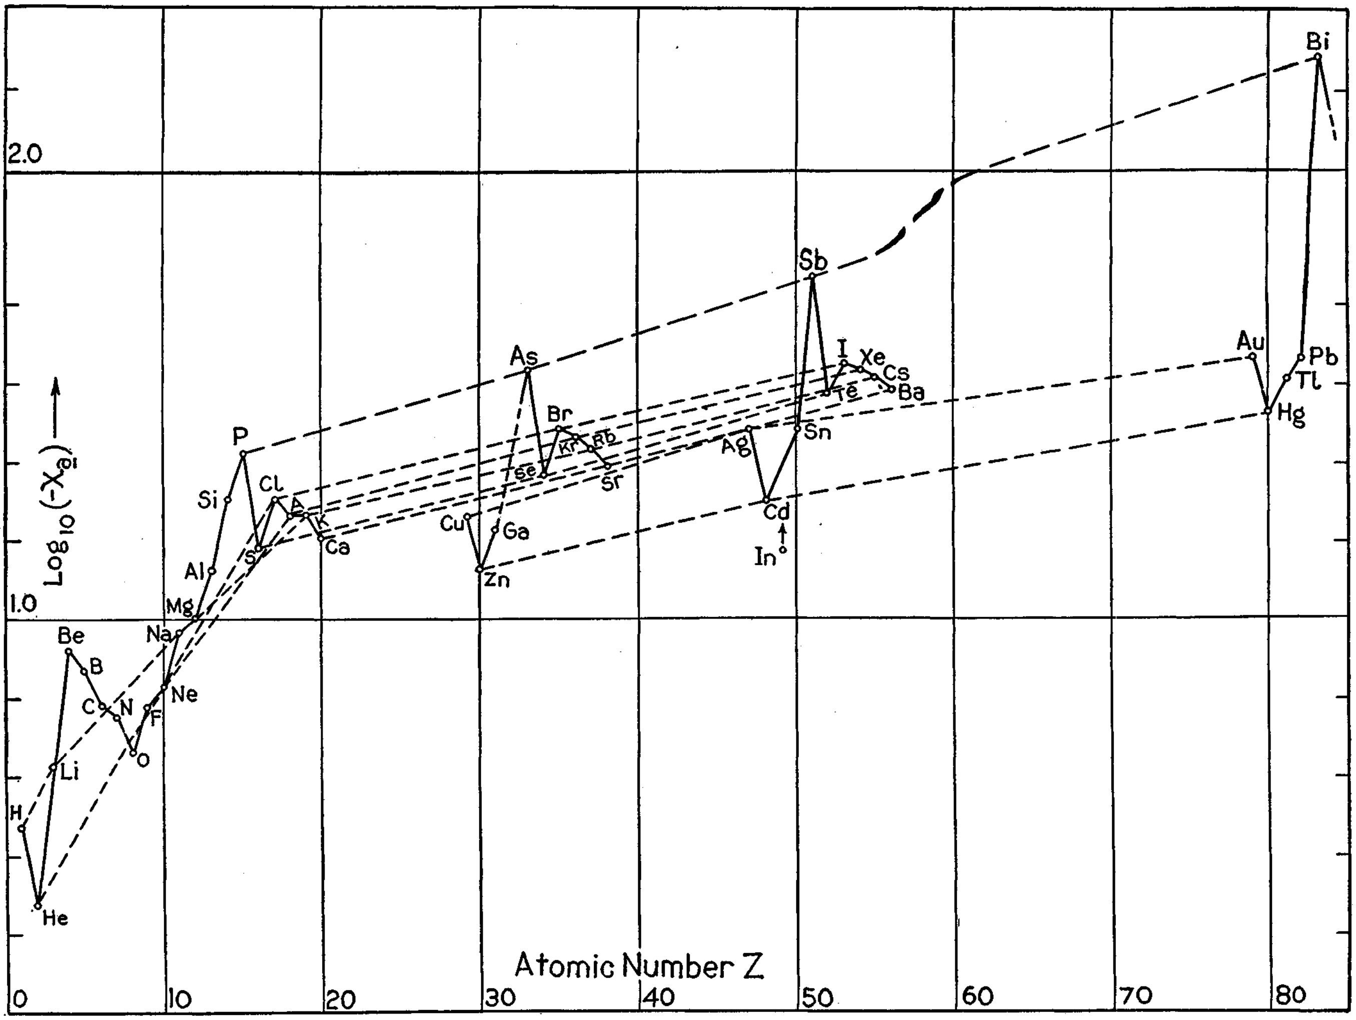

FIG. 1.—Relation between atomic susceptibility (χ_a) of diamagnetic elements and atomic number (Z) (Pascal's relation with A replaced by Z). Data for rare gases ($^{49, 134}$); *cf.* (^{10}), others from Pascal; calculations and interpolations ($^{15, 19, 32}$). Dashed (– – –) lines connect homologous elements and, for $Z > 14$, are nearly straight, as demanded by Pascal's relation (p. 347).

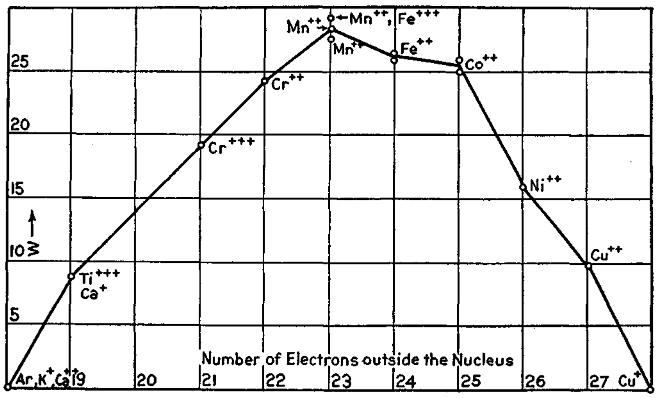

FIG. 2.

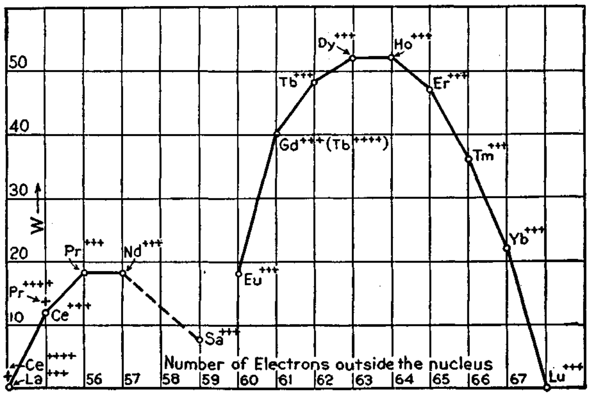

FIG. 3.

FIGS. 2, 3.—Relation between magnetic moment ($[\mu]$) of atom or ion and the number (N) of electrons external to the nucleus (Kossel's relation). $[\mu] = W[\mu_0]_W$, *i.e.*, W = number of Weiss magnetons per atom or ion. In Fig. 2, data from (^{104}); in Fig. 3, ° from (^{18}), + from (^{74}) computations assume the Langevin-Weiss theory (p. 350).

is hexagonal or face-centered cubic; pyrrhotite (Fe_7S_8), hexagonal; magnetite (Fe_3O_4), cubic; and hematite (Fe_2O_3), rhombohedric. Thermomagnetic changes in Heusler alloy are not accompanied by any change in the X-ray diffraction pattern ([139]), and the pattern of Fe-Ni alloys does not change when the composition passes through that of the extremely permeable permalloy ([2]). Paramagnetic and diamagnetic solids have a great variety of crystal forms, though in certain groups homologous elements have the same crystal structure ([10]). Magnetization may produce no change in the crystal structure ([138]); *e.g.*, Laue photographs of crystals of magnetite and of hematite are unchanged by a field of 1000 gauss ([34]), and those of Heusler alloy are unchanged by 3500 gauss ([139]), and the X-ray spectra obtained by reflection from a crystal of magnetite are not affected in any way by subjecting the crystal to a strong magnetic field ([33]); *cf.* ([138]).

Additivity Relations

Simple Additivity.—The law of additivity may be written $m\chi = \Sigma m_i\chi_i$, where m_i is the mass of a constituent i of a compound or mixture (M) of mass $m = \Sigma m_i$, and χ and χ_i are the specific susceptibilities of M and the constituent i. The summation (Σ) is extended to all constituents. For many compounds and mixtures, this law appears to be valid; for many others, the departures from it are great.

TABLE 5.—ADDITIVITY RELATION AS APPLIED TO SOLID PARAMAGNETIC HYDRATES ([43])

Some data satisfy the relation $m\chi = \Sigma m_i\chi_i$, and some do not.

χ_o = observed specific susceptibility; χ_c = specific susceptibility calculated from data in last column by subtracting the (negative) susceptibility of the H_2O lost. Error $\lesseqgtr$ 1%; unit of $\chi = 10^{-6}$ cgsm unit.

H_2O	None		$1H_2O$		nH_2O	
Salt	χ_o	χ_c	χ_o	χ_c	n	χ_o
$CuSO_4$	8.6	9.6	8.6	8.6	5	5.9
$NiSO_4$	25.5	27.8	24.1	23.8	6	15.6
$CoSO_4$	60.8	60.0	53.6	53.2	7	3.5
$Sm_2(SO_4)_3$	3.43	3.39			8	2.6
$Gd_2(SO_4)_3$	92.6	92.7			8	74.7

As applied to solutions, the law of additivity requires that the molecular susceptibility of the solute be independent of the concentration; this is known as *Wiedemann's law.* In many cases of apparent failure of Wiedemann's law, it is probable that more than one type of each of certain constituents is present and that the relative amounts of these types change with the concentration. Hydrolysis furnishes an illustration of such changes. When a salt is hydrolyzed in a solution, the value of χ for the ion, as deduced from that for the solution on the assumption that the simple additivity relation holds, commonly differs from that deduced from observations taken under other conditions. In such cases, progressive reduction of hydrolysis by addition of acid enables one to extrapolate to the condition of no hydrolysis; this extrapolated value for the ion frequently agrees with that found under other conditions of no hydrolysis ([15, 23, 41, 94]).

As applied to molecules, the additivity relation requires that the molecular susceptibility $\chi_m (\equiv M\chi)$ shall be computable from the atomic (ionic) susceptibilities of the constituent atoms (ions). Pascal so applied it, and found that consistent results could be obtained in many cases, especially of saturated organic compounds. Weiss similarly applied the relation in determining the ionic susceptibilities of metals, from the observed susceptibilities of salts and solutions; *v.* ([118]).

TABLE 6.—ATOMIC AND ATOMIC-GROUP SUSCEPTIBILITIES ([82, 83, 84])

The values given below are in general use in determining ionic susceptibilities of metals, and assume that $m\chi$ for H_2O is 13.0×10^{-6}. $m\chi$ = atomic or atomic-group susceptibility; in the former case, m = atomic weight; in the latter, m = formula weight of the group; unit of $m\chi = 10^{-6}$.

Atom	Br	C	Cl	F	H	Hg	I	K	Na	O
$-m\chi$	30.6	6.0	20.1	6.3	2.93	33.4	44.6	18.5	9.2	4.6

Atom or atom group	P	S	Se	Te	H_2O	SO_4	NO_3	NH_3	CN
$-m\chi$	26.3	15.0	23.1	37.5	13.0	33.6	14.2	14.4	10.8

Pascal's Relation ([82, 83]).—In those cases in which the application to molecules of the simple additivity relation led to inconsistent results, Pascal employed the more general equation $M\chi = \Sigma n_iA_i\chi_i + \lambda$, or its equivalent $\chi_m = \Sigma n_i\chi a_i + \lambda$, in which n_i is the number of atoms of species i and atomic weight A_i that are contained in a molecule of molecular weight M, and λ measures the deviation from the law of additivity; λ depends upon the nature of the molecule. Frequently, λ has the same value for all those organic compounds which are of similar type. Thus, if unit of χ is 10^{-7},

$$(m\chi)_{(C_6H_5Cl)} - (m\chi)_{(C_6H_5Br)} = 103$$

and

$$(m\chi)_{(CH_2ClCO_2C_2H_5)} - (m\chi)_{(CH_2BrCO_2C_2H_5)} = 107$$

while

$$(m\chi)_{Cl} - (m\chi)_{Br} = 105;$$

also

$$(m\chi)_{(C_6H_5Br)} - (m\chi)_{(C_6H_5I)} = 138$$

and

$$(m\chi)_{(CH_2BrCO_2C_2H_5)} - (m\chi)_{(CH_2ICO_2C_2H_5)} = 148$$

while

$$(m\chi)_{Br} - (m\chi)_{I} = 140;$$

the differences for the compounds are uncertain by 8 or 10 units. For values of λ, *see* Table 7.

TABLE 7.—PASCAL'S λ FOR CERTAIN BONDS IN ORGANIC COMPOUNDS

$M\chi = \Sigma n_iA_i\chi_i + \lambda$. For the saturated C_nH_{2n+2} compounds, $\lambda = 0$; unit of $\chi = 10^{-6}$ cgsm unit

Bond	λ	Bond	λ
Benzene bond	−1.5	Polyethylene bond	+10.6
Naphthalene bond	−6.1	C = O	+ 8.2
Hexamethylene bond	+3.0	C ≡ N	+ 0.8
Ethylene bond	+5.5	C ≡ N	0

TABLE 8.—EFFECTIVE ATOMIC SUSCEPTIBILITY $(\chi_a)_O$ OF O IN ORGANIC COMPOUNDS

Assumes $\lambda = 0$; unit of $(\chi_a)_O = 10^{-6}$ cgsm unit

Type of bond	$(\chi_a)_O$
Singly bound to any two atoms, —O—	−4.6
Doubly bound to a single C not carrying another O	+1.7
Doubly bound to a single C carrying a second O	−3.4

Doubly bound to any single polyvalent atom: $(a\chi_O)$ is of the same sign as for the corresponding case in which the C is the polyvalent atom.

Theories of Diamagnetism

The Weber-Langevin Theory ([65, 116]).—On this theory the magnetic moment of a diamagnetic atom in a neutral region is zero because the electron orbits are such and so arranged that the vector sum of their individual moments is zero. The orbits are assumed to be rigid, independent of T, and in general unaffected by chemical and physical changes; but *the velocities of the electrons in the orbits are changed by the application of a magnetic field.* On this last the existence of diamagnetism depends. On this theory, for an isotropic substance, or for atoms oriented at random, χ_a =

$-(e^2N_0/12\pi m_0)\Sigma n_i a_i$; a_i = area of an orbit of type i; n_i = number of such orbits per atom. Variations in χ_a may result from a *paramagnetic* relative displacement of the orbits, from distortion, due to a molecular electric or magnetic field, when a change of state occurs (69, 81, 82, 83) (Oxley (81) attributes to such fields intensities of the order of 10^7 gauss, *cf. infra*), and in the case of conductors, possibly but not certainly (67), from the presence of free electrons (99, 135).

TABLE 9.—EFFECT OF LIQUEFACTION OF DIAMAGNETIC SOLIDS: ILLUSTRATIVE (81)

If $\delta\chi/\chi$ is positive, the liquid is more diamagnetic than the solid; unit of $\delta\chi/\chi$ = 1%

Substance		$\delta\chi/\chi$	Lit.
H_2O	Water	3+	(56)
Hg	Mercury	14	(81)
C_6H_6	Benzene	0	(81)
C_6H_7N	Aniline	5	(81)
C_7H_5ClO	Benzoyl chloride	−5	(81)
C_7H_8	Toluene	5	(81)
C_8H_{10}	*o*-Xylene	5	(81)

Pauli's Theory.—On this theory (4, 86) which is applicable only to monatomic gases, diamagnetism is due to a *rotation of the complete atom* (Larmor rotation) produced by the magnetic field. For random orientation, χ_a is just twice as great as on the *Weber-Langevin* theory, *i.e.*, $\chi_a = -(e^2N_0/6\pi m_0)\Sigma n_i a_i$.

Atomic Radii

From measurements of the susceptibility of a diamagnetic substance it is possible, on the basis of either of these theories, to compute the mean of the areas of the several electronic orbits in the atom and the radius (r) of this mean area, assumed to be circular. The value obtained for r depends upon the theory applied. By the use of Bohr's theory of the atom, it is possible, in certain cases, to derive from r the radius (r_m) of the outermost orbit (19, 62). The effective atomic radius can also be obtained from viscosity and other data. For numerical values of the several r's, *see* Table 10.

TABLE 10.—ATOMIC RADII

The radii are derived as follows:

$r_w[r_p]$	From mean area of the electronic orbits as given by the Weber-Langevin [the Pauli] theory (15, 19); $r_w = r_p\sqrt{2}$.
r_m	Mean radius of outer shell of electrons, as computed by Cabrera (19) from observations of Wills and Hector (49, 134); where 2 values are given (ions of A structure) they are based on slightly different assumptions.
r_v	From measurements of viscosity; computed by Jeans (60).
r_c	From crystal data by method of Fajans and Herzfeld (42); computed by Grimm (48).
r_l	From Landé's atomic model, cubical symmetry; computed by Schwendenwein (100).
r_b	Radius of combination, Bragg (12).

Unit of $r = 1\mu\mu = 10^{-6}\mu = 10^{-10}$ cm

Theories of Paramagnetism

χ is Independent of the Temperature.—No detailed theory has been developed; *see*, however (124).

χ Varies with the Temperature.—(*a*) Langevin's Theory.—Langevin has developed a fundamental theory for gases, and on this many other theories have been based (*see infra* and p. 352). His theory leads to the relation $\sigma_a/\sigma_{a\infty}$ $(=\sigma/\sigma_\infty) = \coth a - 1/a$, where $a \equiv \sigma_{a\infty}H/RT$. If a is small, the relation becomes σ_a/H $(\equiv \chi_a) = (\sigma_{a\infty})^2/3RT = C_a/T$; or, divided by A, $\chi = C/T$, which is Curie's law (36). Curie's law is valid for O_2 both at high temperatures and (83), if density corresponds to a pressure of 100 atm. at 290°K, within the ranges 170 to 290°K and 10 to 18 kilogauss, C being $(302.8 \pm 1.5) \times 10^{-4}$; it is also valid for certain solids and solutions of salts, *see infra* and Tables 11, 12, 14.

Proceeding on quite different assumptions, Weiss has shown that in certain cases Langevin's relation may be valid for solid bodies (119), and it has been established experimentally (Onnes, Oosterhuis, Woltjer) (75, 136) for solid gadolinium sulfate, $Gd_2(SO_4)_3 \cdot 8H_2O$, over the ranges 1.3 to 300°K and 3.3 to 22 kilogauss; a was varied from a small value to 7.0; Curie's law applies if $a < 0.7$.

(*b*) Weiss's Generalization of Langevin's Theory.—Weiss and Onnes independently observed that many series of data for which Curie's law fails satisfy the more general relation $\chi(T - \Theta) = C$ (Weiss's law), and Weiss has shown that Langevin's theory leads to this expression when the orientations of the elementary moments are modified by intense molecular fields; $C_a = (\sigma_{a\infty})^2/3R$, as in Langevin's theory when a is small. The intensities of the molecular fields necessary to account for the observed values of Θ exceed 10^6 gauss if assumed to be magnetic; some of the values, as estimated by Weiss (122), are, in this unit: Fe, 6.5; Ni, 6.4; Co, 8.9; magnetite, 14.3.

If the elementary magnetic moments were each accompanied by an electric moment having the same axis, the resultant molecular electrical field would produce the same effect as the molecular magnetic field at first assumed by Weiss (121). The required elementary electric moment is $\epsilon = 1.5\sqrt{RM\Theta/\pi dN_0}$ electrostatic units, where d = density of the substance, and other symbols have same significance as elsewhere. Thus if the unit of ϵ is 10^{-18} cgse unit, the values of ϵ for Fe, Co, and Ni are, respectively, 1.09, 1.25, and 0.85, if the atom is the basal element; if the basal element for Fe is 3 atoms and for magnetite is $0.5Fe_3O_4$, the corresponding values of ϵ are 1.90 for Fe and 1.74 for Fe_3O_4. All these values are very close to those (0.34 to 1.18) obtained by Debye (37, 73) for the moments of dipoles in insulators. The value given for Ni is much the most reliable.

An explanation of the existence of Θ in mixtures of oxygen and nitrogen (*cf.* Table 14) has been given in terms of polymerization (70, 89).

For solutions, experiments of Foëx (44) and of Cabrera and Duperier (21) have shown that in general Θ is not zero; and the results of the latter indicate that Θ is independent of the concentration and of the nature of the anion.

For substances which are ferromagnetic at ordinary temperatures, Weiss's theory interprets Θ as the temperature at which the substance becomes paramagnetic (Curie point, critical temperature). For pure Fe-Ni alloys ranging from Fe_2Ni (34.4% Ni) to 100% Ni, Weiss's law is followed exactly from temperatures near the Curie point to *ca.* 1200°C, and Θ is found (91) to be a little higher than the Curie point. From many series of observations at Zürich (120), the atomic magnetic moment $[\mu]$ for pure Ni above the Curie point, calculated on the basis of the Langevin-Weiss theory, has been found to be $[\mu] = (8.02 \pm 0.02)\ [\mu_0]_w$; *cf.* p. 346.

For other ferromagnetic substances at temperatures above the Curie point, Weiss's law is not certainly followed even over moderate ranges of T.

For most paramagnetic substances, it holds over a considerable range of T, but, in general, fails at very low temperatures. This failure constitutes the *cryomagnetic anomaly* of Onnes. For ions both of the iron group and of the rare earth groups, Cabrera (20) has shown that Θ in general decreases with increase of ionic magnetic moment, the relation for ions of a given class being linear.

Table 11.—Weiss's Law as Applied to Paramagnetic Solids: Values of Θ and Ranges of Validity; Illustrative

Weiss's law, $\chi(T - \Theta) = C$, usually fails at very low temperatures. Range of T = range over which the law holds good; T' = temperature below the range; a, m, s indicate whether χ and C refer to the atomic (metal atom), molecular, or specific magnetization. Error in Θ ranges *ca.* from <1 to 2°K; unit of χ = 1 cgsm; of T, T', and Θ = 1°K.

(*c*) *Energy Quantization Theories.*—The most thoroughgoing of several investigations modifying Langevin's theory (p. 350) by introducing energy quantization, are those of Reiche (95) and Rotzahn (98). The theory so developed for gases leads to relations which frequently accord with the data for solids more satisfactorily than do those of Weiss and others, especially at very low temperatures. It accounts for the Θ in Weiss's law and permits the computation of the value of χ at 0°K, but it is consistent with only that type of cryomagnetic anomaly in which $d(\chi^{-1})/dT$ decreases with T. For the equations and their derivation, *see* (67, 69).

TABLE 16.—REICHE-ROTZAHN THEORY AS APPLIED TO PARAMAGNETIC SOLIDS: ILLUSTRATIVE

χ_0 = value of χ at 0°K; $\chi_{obs.}$, $\chi_{calc.}$ = observed (51, 76, 79), calculated from Reiche-Rotzahn theory by means of parameters derived from the observations. $\Delta = (\chi_{obs.} - \chi_{calc.})/\chi_{calc}$; Δ_m = mean value of Δ; $[\Delta]_m$ = mean of the absolute values of Δ (irrespective of sign); $[\mu]_R$ and $[\mu]_L$ = $[\mu]$ of the gram-molecule, as derived from the Reiche-Rotzahn and the Langevin theory, respectively. Range of T = range over which the theory accords with observations. $(\chi T)_l[(\chi T)_h]$ = value of χT at the lowest [highest] temperature of the range. Values of $[\mu]_R$ are from (5); unit of $\chi = 10^{-6}$; of Δ_m and $[\Delta]_m = 1\%$; of $[\mu]_R$ and $[\mu]_L = 10^{-20}$; T = absolute temperature, °K.

Solid	Range of T	$(\chi T)_l$	$(\chi T)_h$	Δ_m
$MnSO_4$	19.4–293.9	9 158	25 804	+0.50
$MnSO_4.4H_2O$	14.4–288.7	17 755	19 141	−0.47
$FeSO_4.7H_2O$	14.7–293.2	11 113	12 394	+0.17
$Fe_2(SO_4)_3$	64.0–289.8	11 334	15 446	+0.09

Solid	Range of T	$[\Delta]_m$	χ_0	$[\mu]_R$	$[\mu]_L$
$MnSO_4$	19.4–293.9	0.92	658	5.35	5.12
$MnSO_4.4H_2O$	14.4–288.7	0.88	7 294	5.45	5.13
$FeSO_4.7H_2O$	14.7–293.2	0.41	3 365	4.90	4.82
$Fe_2(SO_4)_3$	64.0–289.8	0.27	286	6.84	7.11

(*d*) *Spatial Quantization Theories* (87, 103, 104).—The Zeeman spectroscopic effects suggest a spatial quantization of the axes of the elementary magnets. Pauli (87) introduced this assumption into Langevin's theory for gases (p. 350). As modified by Sommerfeld it gives $\chi_a T(\equiv C_a) = \left\{\frac{[\mu]^2 N_0^2}{3R}\right\}\left\{\frac{j_1+1}{j_1}\right\}$, where $[\mu]$ and j_1 refer to the atom, and $[\mu] = g j_1 [\mu_0]_B$ (*see* p. 346). Hence $\sqrt{3RC_a}/N_0[\mu_0]_B (= 2.83\sqrt{C_a}) = g\sqrt{j_1(j_1+1)}$. In certain cases, g and j_1 can be determined with considerable certainty from chemical and spectroscopic data. The most conspicuous success in verifying the formula by such means has been obtained by Hund with the triply ionized rare earths, Z = 57 to Z = 71 (*see* Table 17). Similar attempts with ions of elements from Z = 18 to Z = 29 have been only partially successful, probably because at ordinary temperatures the atoms are not all in the state of excitation assumed to characterize the gas. For attempts at correlation between atomic constitution and magnetic moments, Z = 18 to 29, *see* (20, 38, 53, 66, 104). For discussion of other theories of spatial quantization, *see* (73).

Table 17.—Pauli-Sommerfeld Theory as Applied by Hund to the Rare Earths (53, 54)

This theory requires that $2.83\sqrt{C_a}$ ($\equiv 2.83\sqrt{\chi_a T}$) shall equal $g\sqrt{j_1(j_1+1)}$, where g and j_1 are numbers determined from spectroscopic and chemical data; $gj_1 = [\mu]/[\mu_0]_B \equiv B$. In the following it is supposed that the 4_{33} and lower shells are completed, and that the 5_1, 5_2, and 5_3 shells contain 2, 2, and 4 electrons, respectively. In columns (3), (4), and (5) are given the number of electrons in the shells 4_4, 4_{43}, and 4_{44}; in (6), the fundamental spectral term; in (9) $B_c \equiv W/5$ for solid salt (Table 15); in (10), $g\sqrt{j_1(j_1+1)}$, computed value of $2.83\sqrt{\chi_a T}$; in (11) and (12), values of $2.83\sqrt{\chi_a T}$ as determined by Cabrera (20) and Meyer (74). Columns (4), (5), and (9) are not given by Hund.

ATMOSPHERIC ELECTRICITY

W. F. G. SWANN

Potential Gradient.—*See* Tables 1, 2 and Figs. 1, 2, 3, 4. The values are supposed to represent the gradient as it would be if the effective surface of the earth were a true plane. The main sources of error lie in (*a*) an uncertainty of the correction for the non-planar form of the effective surface of the earth, and (*b*) errors due to leakage from the collector system (4). No precise limits of accuracy can be given without a precise study of each individual case, which is impracticable. As a result of the first (*a*) source of error, determinations on land have occasionally been unexpectedly found in error by as much as 50%. The importance of the second (*b*) source of error depends upon the speed of the collector; in a typical case in which it required one minute to obtain a reading within 1% of its final value, the error due to leakage resulting from atmospheric conductivity alone amounted to 1%.

From an analysis of the diurnal variation over the ocean, Mauchly (22) has concluded that this variation is primarily due to a 24 hour wave which progresses according to universal, rather than local, time; he finds the same 24 hour wave from land observations, but for these it is not so large a part of the entire effect.

TABLE 1.—POTENTIAL GRADIENT: LAND VALUES

For ocean values, *see* Table 2. Mean values over the interval indicated: Long. = longitude east of Greenwich, Pot. Grad. = potential gradient, potential increasing upwards. (*See also* Figs. 1 to 4.) Unit of Pot. Grad. = 1 volt/meter = $3.33_6 \times 10^{-5}$ cgse unit per cm.

TABLE 2.—POTENTIAL GRADIENT, IONIC CONTENT AND CONDUCTIVITY OF THE ATMOSPHERE, AND AIR-EARTH CURRENT DENSITY: OCEAN VALUES

For land values, *see* Table 1, potential gradient; Table 3, ionic content; Table 4, conductivity and current density. Compiled from (4, 4.1); data are averages for the region, and are based on observations distributed over one or two weeks and taken near 10 A. M. local mean time. Long. = longitude east of Greenwich; Pot. Grad. = potential gradient, potential increasing upwards; n_+ [n_-] = number of + [−] ions per cm³ of air; λ_+[λ_-] = conductivity due to + [−] ions; i = current density of positive current from air to earth, $i = (\lambda_+ + \lambda_-) \times$ potential gradient. Dates are written thus: 3:20:15 = March 20, 1915. Unit of Pot. Grad. = 1 volt/meter = $3.33_6 \times 10^{-5}$ cgse unit (per cm); of λ_+ and λ_- = 10^{-4} cgse unit; of $i = 10^{-7}$ cgse unit (per cm³).

* Deduced from observed change in potential of a conductor that is moved in the earth's field (4).

† Taken, of course, over the lesser portion of the small circle.

Ionic Content.—The numbers n_+ and n_-, of positive and of negative ions per cm³, are derived from $(n_+ + n_-)/2$ and n_+/n_- (Table 3). As the atmospheric potential gradient tends to decrease the rate at which negative ions enter the measuring instrument, the values of n_- are apt to be too low. The size of this error depends upon instrumental details and the effect of surrounding objects, and may exceed 20% (21, 23, 37, 38, 39). With the Ebert aspiration apparatus, the ions measured are mostly the so-called "small" ions, which, in laboratory experiments, have mobilities of 1.3 cm/sec per volt/cm for the +ions and 1.8

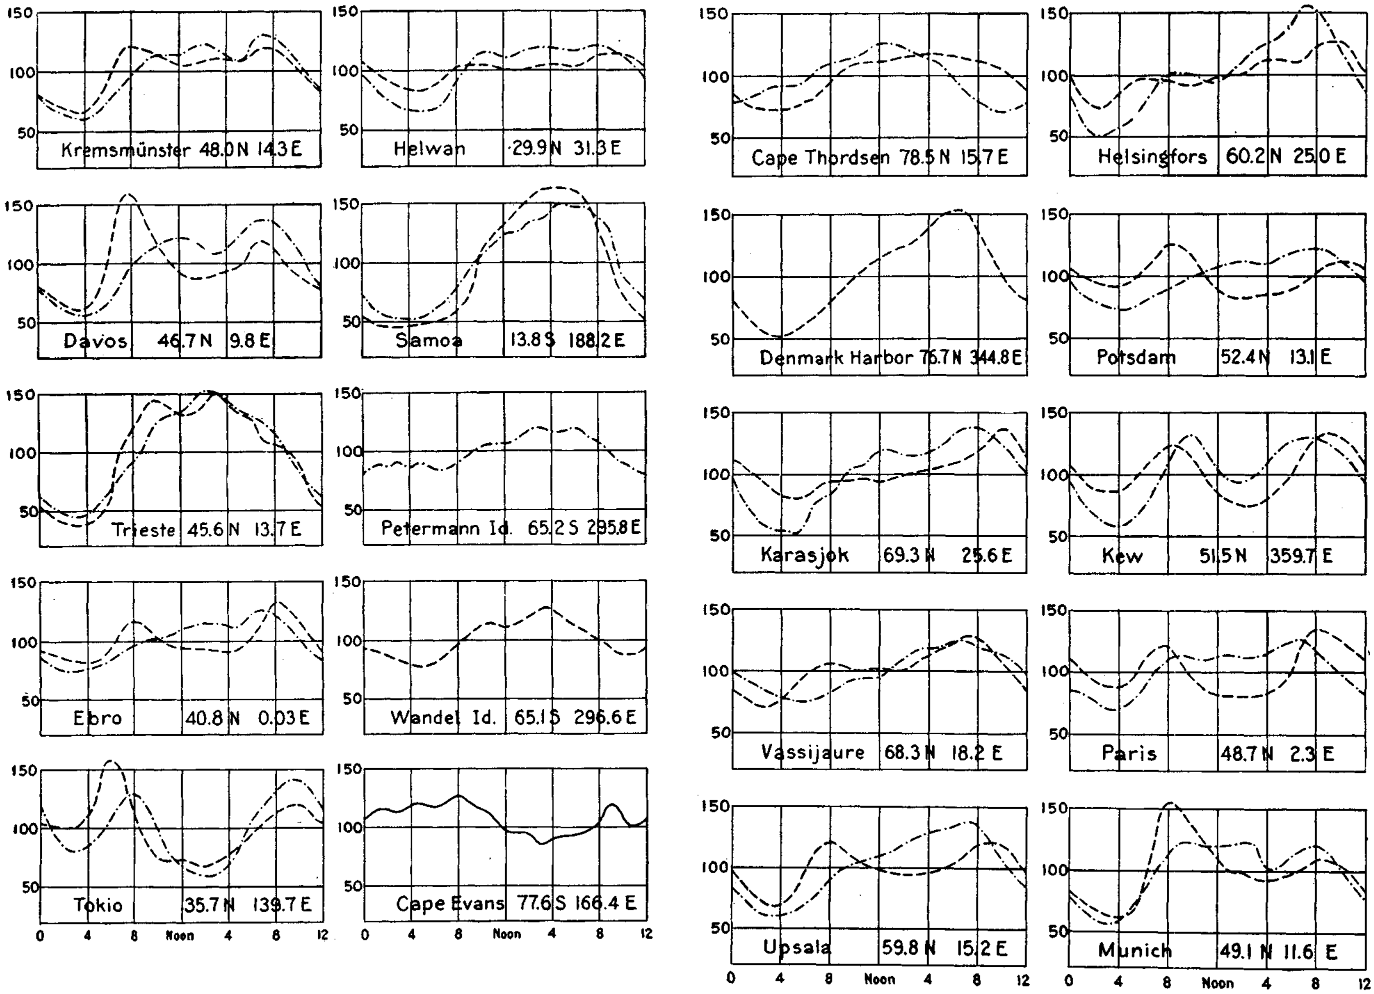

FIG. 1.—Diurnal variation of potential gradient (24).

Ordinates = percentage of the mean gradient for the season (summer, winter, or year), abscissae = local mean time. Summer – – – winter –. –, year —— .

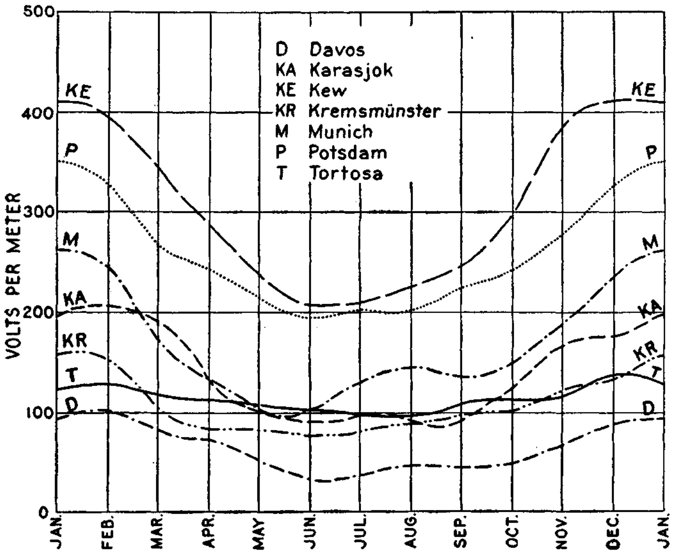

FIG. 2.—Annual variation of potential gradient: Northern hemisphere (6).

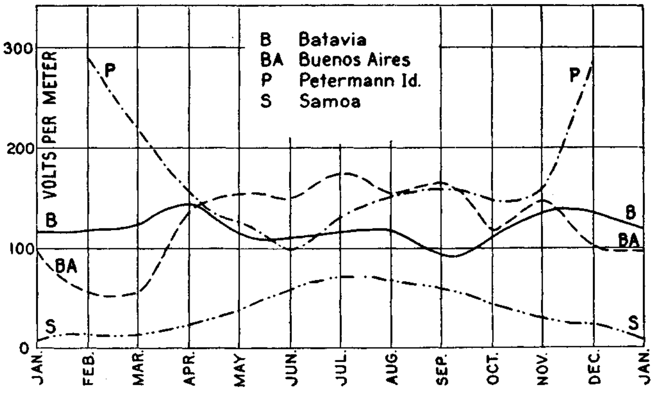

FIG. 3.—Annual variation of potential gradient: Southern hemisphere (6).

for the −ions. In addition to these, so-called "large" ions of mobility about 1/3000 cm/sec per volt/cm, and "intermediate" ions of mobility of the order 0.01 are to be found in the atmosphere. The numbers of these larger ions vary very widely. Representative ratios of large to small ions are: In Paris 50 (Langevin), in Swiss Alps and in Freiburg 2 to 3 (Gockel), in Dublin 200 (McClelland and Kennedy).

As determined on the fourth cruise of the Carnegie, the mobilities of the small ions over the Pacific and the sub-Antarctic Oceans averaged 1.3 cm/sec per volt/sec for both + and − ions. The large abnormalities in the mobilities of atmospheric "small" ions reported by some observers are probably attributable largely to experimental errors inherent in the methods used, the customary method with the Ebert apparatus leading in a large percentage of cases of observatory data to even a negative value of the mobility.

TABLE 3.—IONIC CONTENT OF ATMOSPHERE: LAND VALUES

For ocean values, *see* Table 2. These values have been reduced on the assumption that $e = 4.8 \times 10^{-10}$ es unit; most of them were obtained with Ebert's aspiration apparatus (18, 36). Values of n_+/n_- are apt to be too high, and of n_- too low. Dates are written thus: *8*: 19, 20; **05** = August 19, 20, 1905. Long. = longitude east of Greenwich. Unit of n_+ and n_- = 1 ion per cm.^{3}

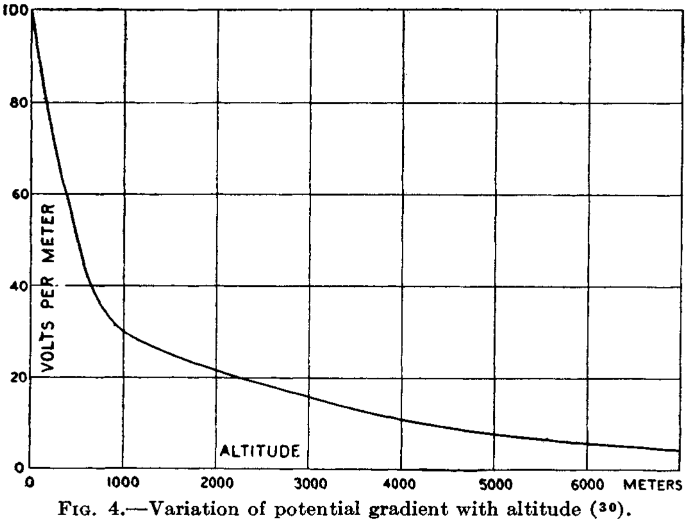

FIG. 4.—Variation of potential gradient with altitude (30).
Mean of results of various observers, each set reduced to correspond to 25 volt per meter at an altitude of 1500 meter.

Conductivity of Atmosphere.—(Tables 2 and 4.) The conductivity $(\lambda_+ + \lambda_-)$ of the atmosphere is the sum of the conductivities due to the presence of the + and of the − ions. For methods, *see* (18). Values of $(\lambda_+ + \lambda_-)$ obtained by the Gerdien apparatus are apt to be too low, owing to neglect of effect of rod supporting the central cylinder. This error may amount to 10% or 15% (35). In the ocean data recorded in Table 2, the measurements were taken in such a manner as to avoid this error. For land observations, the measured value of λ_+ is apt to be too high on account of the collection on the apparatus of radioactive material from the atmosphere. This error may amount to 5%.

Values obtained by Schering's method, which involves measurement of rate of flow of charge from a body (usually a long wire) exposed to the free air, are apt to be too low on account of effect of earth's electric field (34), unless that field near the apparatus is very small, as seems to be the case at Potsdam. When this effect is neglected the values obtained are 20% to 30% lower than those obtained with the Gerdien apparatus.

TABLE 4.—CONDUCTIVITY OF ATMOSPHERE, AND AIR-EARTH CURRENT DENSITY: LAND VALUES

For ocean values, *see* Table 2; for values at high altitude, *see* Table 5. Long. = longitude east of Greenwich; λ_+, λ_- = conductivity due to +ions, −ions; i = current density of positive current from air to earth, $i = (\lambda_+ + \lambda_-) \times$ potential gradient. Dates are written thus: *5*: **09**–*4*: **10** = May, 1909 to April, 1910; *4*: 1–17; **06** = April 1 to 17, 1906. Unit of λ_+ and $\lambda_- = 10^{-4}$ cgse unit; of $i = 10^{-7}$ cgse unit.

* By Gerdien's conductivity apparatus; values may be too low by 10 % or 15 %, *see* text.

† By C. T. R. Wilson's method. Values of $(\lambda_+ + \lambda_-) = 2\lambda_0$, λ_0 = directly observed λ; $i = 2\lambda_0 \times$ potential gradient.

‡ Vol. III, p. 123 (6); observed by Wegener.

§ By Schering's method; values may be too low, *see* text.

TABLE 5.—CONDUCTIVITY OF ATMOSPHERE AT HIGH ALTITUDES (41)

Results of 4 ascensions; in each, data are reduced to correspond with $(\lambda_+ + \lambda_-) = (1 \text{ to } 1.5) \times 10^{-4}$ cgse unit at earth's surface. Altitude = maximum altitude, tabulated values of $(\lambda_+ + \lambda_-)$ correspond to that altitude.

Ascension	1	2	3	4	Unit
$(\lambda_+ + \lambda_-)$	16.5	18.8	23.2	37.3	10^{-4} cgse
Altitude	5300	5385	8345	8865	meter

Miscellaneous Data.—The *air-earth current density* is computed from the potential gradient and the conductivity, and is usually expressed in cgs electrostatic units per cm^2 (=cgse units). *See* Tables 2 and 4.

Rate of Recombination of Atmospheric Ions.—As determined by laboratory experiments with artificial ionization, the coefficient α in $-\frac{dn\pm}{dt} = \alpha n_+ n_-$ has a value about 1.6×10^{-6} cm^3 per (ion sec) (*cf.* p. 110), but for atmospheric ions, α has, in general, been found to be of the order of (2 or 3) $\times 10^{-6}$. Recent work (25, 28) indicates that for atmospheric ions $-\frac{dn\pm}{dt} = \alpha n_+ n_- + \beta n_\pm$, where β is considerably more important than α.

Charge on Rain.—Rain may be charged either + or −. In Simla, Simpson (32) found that + precipitation occurred 2.5 times as frequently as − precipitation, and in a long series of observations the total + charge brought down was 3.2 times as great as the total − charge. The corresponding values found at Potsdam (26) by Schindelhauer (confirmed by Kähler) are 2.2 and 1.4, and at Le-Puy-en-Velay by Baldit (2) are 2.86 and 1.36, respectively. The charge on rain is generally less than 1 es unit per cm.[3]

Lightning.—Humphreys (16) estimates that the current associated with a lightning flash may, in certain cases, be of the order of 90 000 amperes. From a comprehensive series of experiments, C. T. R. Wilson (43) concludes that the average charge brought down in a lightning flash is of the order of 20 coulombs, and that the potential differences involved in the discharge are of the order of 10^9 volt.

TERRESTRIAL MAGNETISM

W. F. G. Swann

General Conclusions.—The magnetic field of the earth is roughly that of a uniformly magnetized sphere; at external points the field of such a sphere is equivalent to that due to a magnetic doublet placed at the center of the sphere. The axis of the doublet is inclined to the axis of rotation. If M is its moment, and M_p and M_e are, respectively, the axial and the equatorial components of M, then, according to an analysis by L. A. Bauer (4), $M = 8.04 (10)^{25}$, $M_p = 7.88(10)^{25}$, $M_e = 1.60(10)^{25}$ cgs magnetic unit; the axis of the doublet intercepts the northern hemisphere at latitude 78° 32′ N. and longitude 69° 08′ W.; and the average intensity of magnetization of the earth is 0.074 cgs magnetic unit.

The magnetic poles, defined as the places where the field is vertical, are not where the prolonged axis of the doublet intersects the earth's surface. From observations between 1903 and 1906, Amundsen placed the north magnetic pole at lat. 71° N, long. 96° W.; from data obtained on the "Discovery," 1902 to 1904, the probable position of the south magnetic pole is latitude 72° 50′ S., longitude 156° 20′ E.

From a harmonic analysis of the field, Gauss concluded that part of it is of external origin. Analyses by Schmidt (13) and by Bauer (4) lead these authors to conclude that a part of the field is not derivable from a potential; Bauer (4) concludes that about 3% of the field is of non-potential origin, and, of the remainder, 94% arises from internal, and 3% from external, causes. The non-potential portion would correspond, on classical electromagnetic theory, to vertical currents (*see* Table 1).

respectively. The charge on rain is generally less than 1 es unit per cm.^{3}

Lightning.—Humphreys (16) estimates that the current associated with a lightning flash may, in certain cases, be of the order of 90 000 amperes. From a comprehensive series of experiments, C. T. R. Wilson (43) concludes that the average charge brought down in a lightning flash is of the order of 20 coulombs, and that the potential differences involved in the discharge are of the order of 10^9 volt.

TERRESTRIAL MAGNETISM

W. F. G. Swann

General Conclusions.—The magnetic field of the earth is roughly that of a uniformly magnetized sphere; at external points the field of such a sphere is equivalent to that due to a magnetic doublet placed at the center of the sphere. The axis of the doublet is inclined to the axis of rotation. If M is its moment, and M_p and M_e are, respectively, the axial and the equatorial components of M, then, according to an analysis by L. A. Bauer (4), $M = 8.04 (10)^{25}$, $M_p = 7.88(10)^{25}$, $M_e = 1.60(10)^{25}$ cgs magnetic unit; the axis of the doublet intercepts the northern hemisphere at latitude 78° 32′ N. and longitude 69° 08′ W.; and the average intensity of magnetization of the earth is 0.074 cgs magnetic unit.

The magnetic poles, defined as the places where the field is vertical, are not where the prolonged axis of the doublet intersects the earth's surface. From observations between 1903 and 1906, Amundsen placed the north magnetic pole at lat. 71° N, long. 96° W.; from data obtained on the "Discovery," 1902 to 1904, the probable position of the south magnetic pole is latitude 72° 50′ S., longitude 156° 20′ E.

From a harmonic analysis of the field, Gauss concluded that part of it is of external origin. Analyses by Schmidt (13) and by Bauer (4) lead these authors to conclude that a part of the field is not derivable from a potential; Bauer (4) concludes that about 3% of the field is of non-potential origin, and, of the remainder, 94% arises from internal, and 3% from external, causes. The non-potential portion would correspond, on classical electromagnetic theory, to vertical currents (*see* Table 1).

TABLE 1.—VERTICAL CURRENT DENSITIES AS COMPUTED FROM MAGNETIC DATA

Computed by Bauer (3) from magnetic data of 1920. The average value, regardless of sign, is about 10 000 times the atmospheric-electric current density, *see* p. 442. Dyson and Furner (8) conclude that such vertical currents are not indicated with any certainty, although there is some evidence for them. A + sign indicates an upward positive current; i_N [i_S] = current density in northern [southern] hemisphere. Unit of i_N and $i_S = 10^{-3}$ ampere/km^2 = 3.0×10^{-4} cgse (per cm^2).

Lat.	i_N	i_S

TABLE 3.—MAGNETIC ELEMENTS FOR EACH 10° OF LATITUDE AND LONGITUDE

Data obtained from charts (5) compiled at Royal Observatory, Greenwich, England, 1922. A ? indicates that the curves were too widely spaced to permit satisfactory interpolation. D = declination (east or *west*); I = inclination or dip (north-seeking pole down or *up*); H = horizontal intensity; *italics* indicate that D is to the west or that I is such that north-seeking pole is up. Unit of $H = 100\gamma = 10^{-3}$ gauss $= 10^{-3}$ cgsm.

* Algebraic excess over value for 1910.

Earth Currents.—It is not practicable to do more than to indicate the order of magnitude of earth currents. At the observatory del Ebro, Tortosa, Spain, the horizontal electrical potential gradient in the earth was measured over a distance of 1.28 km in a north-south line, and over a distance of 1.40 km in a west-east line. The average of observations extending over 4 yr (1914–18) gave as the gradient along the N.-S. line 0.204 volt per km, current (+) from N. to S., and along the W.-E. line 0.114 volt per km, current (+) from W. to E.

Aurora.—Auroral activity is confined largely to two zones of the atmosphere situated at an angle of about 20° to the magnetic polar axis. The lower edge of the aurora is sharply bounded; the height of this boundary appears to vary from 70 to 300 km, with a maximum number at about 115 km.

SYMBOLS AND DEFINITIONS

d.v.	Double (or complete) vibration(s).
E	Physical intensity of a sound = power (energy per second) it transmits per a unit of area normal to direction of propagation.
N	Frequency = number of d.v. per unit of time.
P	Amount by which the r.m.s. pressure exceeds the static pressure; P_0 = threshold value of P for an average normal ear; it depends upon N; P_m = value of P required for audition in presence of a masking tone.
r.m.s.	Root-mean-square; r.m.s. pressure = square root of the time average of $(\text{pressure})^2$.
S	Sensation level.
sen	Sensation unit.
t	Time.
v.p.s.	Vibrations per second; 1 v.p.s. = 1 d.v. per sec.
φ	Phonic level.

Masking of a tone (A) by another (B) means the difficulty in distinguishing A when sounded simultaneously with B. It is expressed by the difference in phonic level between P_m and P_0, this equals $20 \log_{10} (P_m/P_0)$ sen. (*See* Figs. 2, 3, 4.)

Phonic level of P above the fixed datum corresponding to P' is $\varphi_P = 20 \log_{10} (P/P')$ sen. In this section P' is taken as 1 dyne cm^{-2}. (*Cf.* Sensation unit.)

Sensation level (S) measures the auditory intensity of sound; it is the excess of the phonic level above that of P_0. For a pure tone, $S = \varphi_P - \varphi_{P_0} = 20 \log_{10} (P/P_0)$ sen.

Sensation unit (sen) is defined as that fractional change in intensity which is just perceptible by the ear. Throughout the range of audition, it is found that if the sensation being experienced is that corresponding to $P = P_1$, then the smallest perceptible change is approximately $1/20$ of that caused by increasing P from P_1 to $10P_1$. Hence in the range P_1 to P_2 there are $20 \log_{10} (P_2/P_1)$ sen. It is convenient to regard this relation as extending indefinitely, irrespective of the range of audition, and to regard each value of P as corresponding to a phonic level of $20 \log_{10} (P/P')$ sen above some convenient fixed datum (P') which is independent of the auditor and audition. (*Cf.* (5).)

Sensitivity of the ear is inversely proportional to P_0; the unit is so chosen that the sensitivity $= 1/P_0$.

Threshold value (P_0) of P for any given auditor and tone is that least value of P, in the ear canal, which produces an audible sound of that tone.

TABLE 1.—SENSITIVITY OF THE EAR

See also Vol. I, p. 94

Absolute Sensitivity $= 1/P_0$.—*Differential sensitivity* is the reciprocal of the least perceptible fractional change ($\Delta E/E$, $\Delta N/N$) in E or N. Sensitivity in recognition of pitch may be taken as the reciprocal either of the time the tone must persist, or of the total number of d.v. that must reach the ear, in order that the tone shall be recognized.

Unit of N = 1 v.p.s.; of P_0 = 1 dyne/cm^2; of t = 1 sec; of S = 1 sen.

Limits of Audibility (6).—Lower limit varies from N = 8 to 40; upper, from N = 12 000 to 35 000.

Absolute Sensitivity = $1/P_0$.—*Differential sensitivity* is the reciprocal of the least perceptible fractional change ($\Delta E/E$, $\Delta N/N$) in E or N. Sensitivity in recognition of pitch may be taken as the reciprocal either of the time the tone must persist, or of the total number of d.v. that must reach the ear, in order that the tone shall be recognized.

Unit of N = 1 v.p.s.; of P_0 = 1 dyne/cm^2; of t = 1 sec; of S = 1 sen.

Limits of Audibility (6).—Lower limit varies from N = 8 to 40; upper, from N = 12 000 to 35 000.

Absolute sensitivity (9, 13, 20); *see also* Fig. 1.

N	64	128	256	512	1024	2048	4096
P_0	0.12	0.021	0.0039	0.0010	0.00052	0.00041	0.00042

Differential sensitivity for monaural reception of successive tones (12, 14).

$\Delta E/E$ depends upon both S and N, and is given by the empirical equation $\Delta E/E = (\Delta E/E)_\infty + \{(\Delta E/E)_t - (\Delta E/E)_\infty\} \times 10^{-rS/10}$, where $(\Delta E/E)_\infty = 126/\{80N^{0.5} + N\} + 0.000015N$, $(\Delta E/E)_t = 0.3 + 0.003N + 193/N^{0.8}$, and $r = 0.244 \times 10^6/\{358\,000N^{0.125} + N^2\} + 0.65N/\{3500 + N\}$.

$\Delta N/N$ varies with S about as $\Delta E/E$ does. For $S = 40$ sen, $\Delta N/N$ varies with N thus:

N, v.p.s.	64	128	256	512	768 to 4096
$\Delta N/N$, %	0.93	0.59	0.4	0.32	0.3

Pitch Recognition (1).—t and d.v. = least duration of the tone, and smallest number of d.v. received, consistent with recognition of the tone.

E	Weak			Medium		
N	128	384	512	256	384	512
t	0.0946	0.0627	0.0579	0.0691	0.0445	0.0427
d.v.	12.1	24.1	29.6	17.6	17.1	21.8

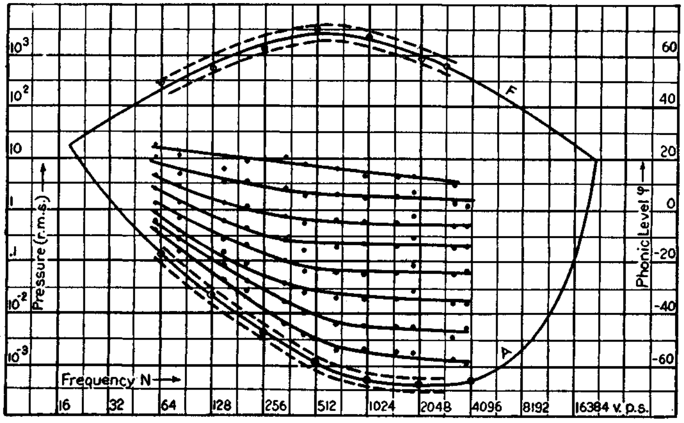

FIG. 1.—Phonic levels (φ) for equality of loudness of pure tones. Threshold values of audibility are shown by curve A (weighted mean (7, 9, 13), pitch limits range (6) from $N = 8$ to 40 and from $N = 12\,000$ to 35 000), of feeling, by curve F (18); half of observations lie between the dotted curves. Interior curves are contour lines of equal loudness, reference tone being $N = 700$ v.p.s.; each point is average of 3 observations by each of 22 observers; distance from curve A measures the sensation level. φ = phonic level, datum = 1 dyne/cm², unit = 1 sen; unit of pressure = 1 dyne/cm².

Loudness (8, 11, 16).—Until recently it was thought that the loudness of a tone is measured by its sensation level, but there is not a strict proportionality between these two quantities. Contour lines of equal loudness for pure tones show that tones below 1000 v.p.s. increase in loudness more rapidly than do tones of higher frequency. (*See* Fig. 1.)

Localization of Pure Tones (17).—If 100 v.p.s. $\lesssim N \lesssim$ 1000 v.p.s., then, approximately, $\theta = \psi/(0.8 + 0.0034N)$, if unit of N = 1 v.p.s.; θ = angle the apparent direction of the source makes with median plane of the observer; ψ = angular phase difference of the tone at the two ears. θ and ψ must be expressed in the same unit; positive direction of θ is from the front towards the ear of the leading phase.

Miscellaneous Aural Data.—Minimum audible power = $4(10)^{-}$ microwatt/cm² (9, 13, 20). Ear canal: Length = 2.1 to 2.6 cm, volume = 1 cm³, area of open end = 0.33 to 0.50 cm². Drum. Diameter = 0.85 cm vertical, 1.00 cm horizontal; area = 0.65 cm². Hammer: Length = 0.8 to 0.9 cm; weight = 23 mg. Anvil weighs 25 mg. Stirrup weighs 3 mg (10, 21). Mechanical impedance of drum (7) for N = 200 to 4000 v.p.s. = 20 to 30 dyne/(cm per sec); that is, a value of P corresponding to an r.m.s. periodic force of 20 or 30 dyne is required to impart to the drum an effective r.m.s. velocity of 1 cm/sec, the effective

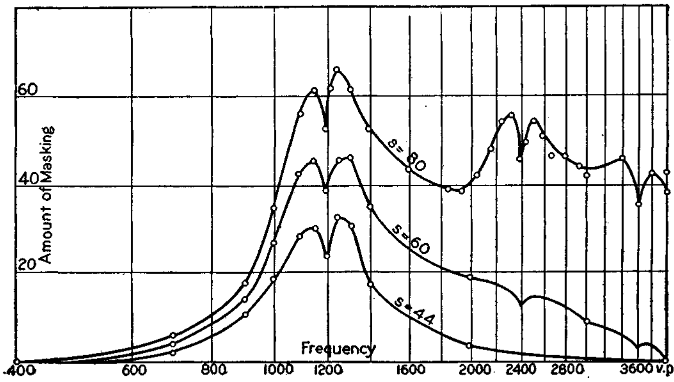

FIG. 3.—Masking of tones of various frequencies by one of N = 1200 v.p.s. and of sensation level = 44, 60 or 80 sen: Both tones sounded in same ear (19).

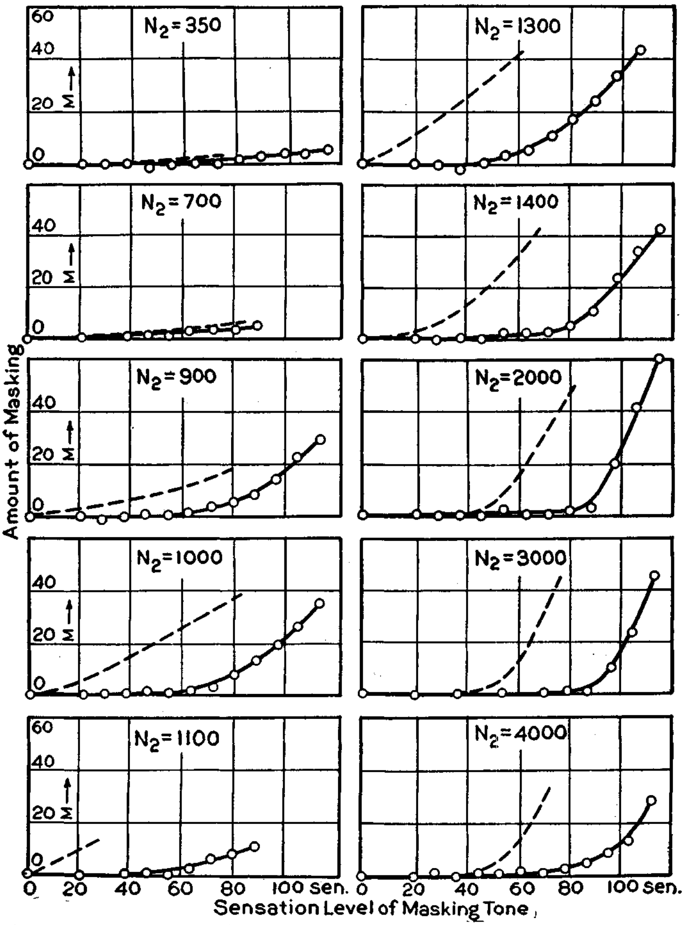

FIG. 4.—Masking of tones N_2 by tones of N = 1200 v.p.s. of various intensities: Tones sounded in opposite ears (19).

Tones introduced by telephone receivers. Dotted lines are from Fig. 2. Attenuation introduced by the skull from ear to ear is such that in monaural reception the phonic levels at the two ears differ by 40 or 50 sen. M = amount of masking. Unit of N_2 = 1 v.p.s.; of M and of sensation level = 1 sen.

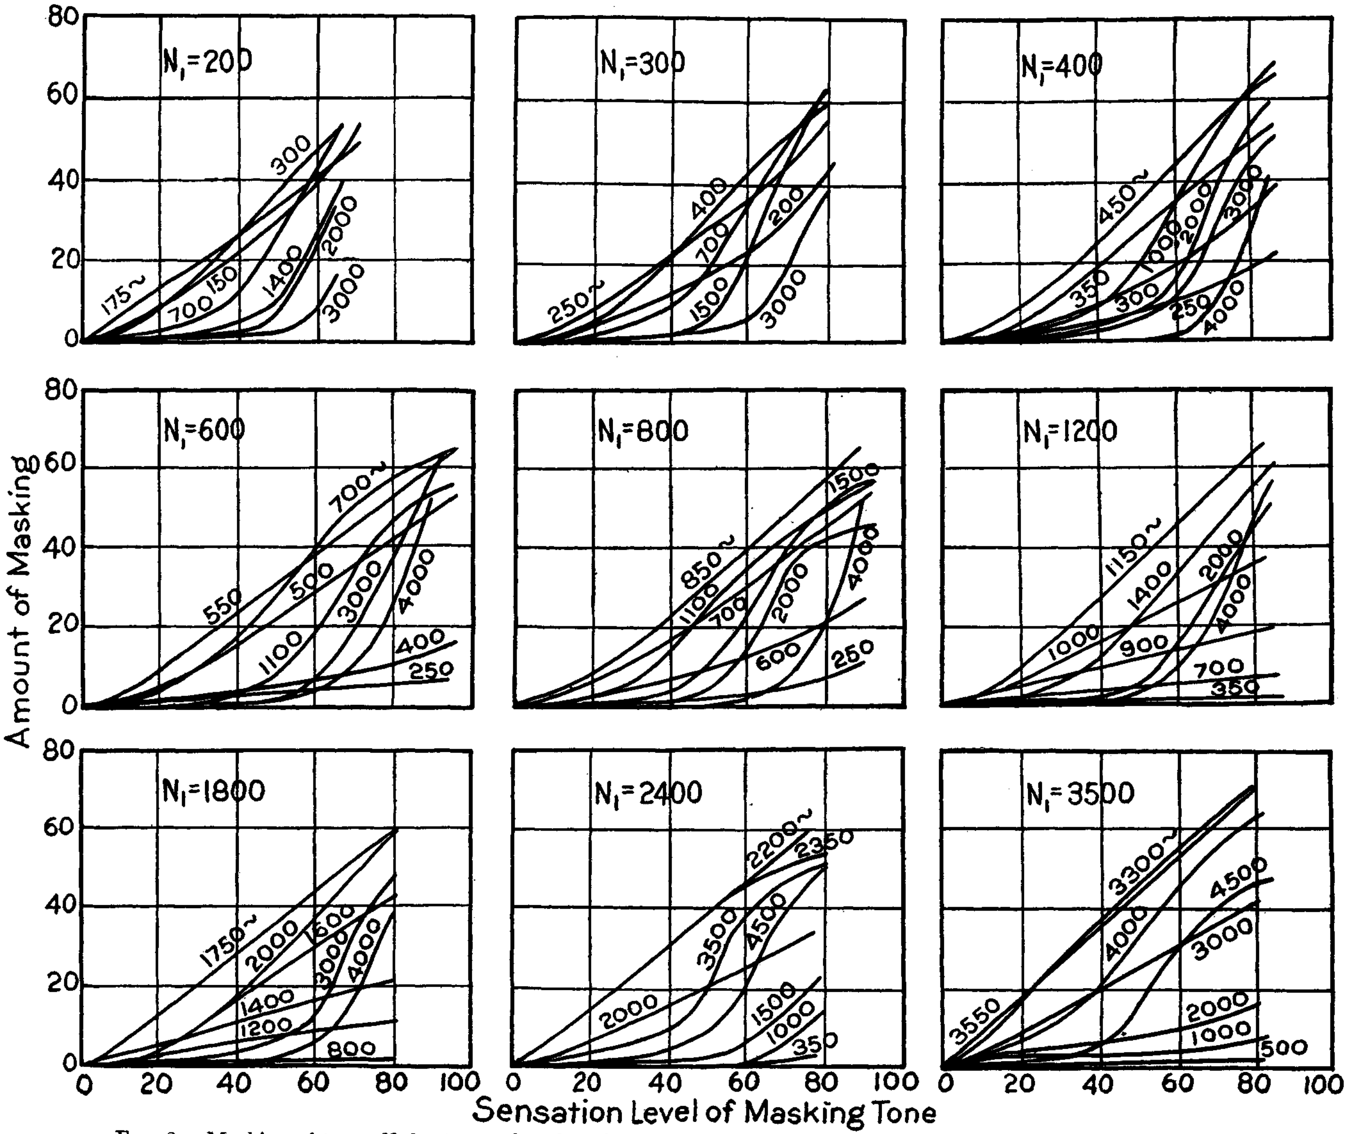

FIG. 2.—Masking of tones N_1 by tones of various frequencies and intensities: Both tones sounded in same ear (19). Frequency (N) of masking tone is marked on curve; unit of N and N_1 = 1 v.p.s.; of masking and sensation level = 1 sen.

velocity ($\bar{v}$) being defined as $\bar{v} = \frac{1}{A}\int_0^A v da$, A being the area of the drum and da being an element of area at which the velocity is v.

Recognition of English Speech (4).—In order that at least 50 % of the spoken syllables shall be recognized: (1) S must be $\gtrsim$ 25 sen if the sound is undistorted. (2) If S = 60 to 80 sen and the sound is distorted either by the removal of all frequencies above $N = N_1$, or of all below $N = N_2$, then N_1 must be >1200 v.p.s. and N_2 <1800 v.p.s. (*See* Fig. 5.)

Speech Power (7).—Mechanical speech power delivered by average speaker = 10 microwatt; if exclude silent intervals, it is 14 microwatt. Peak power frequently rises to 1000 microwatt. For unaccented vowels, average power in the particular cycle carrying the maximum energy is 35 microwatt; for accented vowels, it is 105 microwatt; instantaneous peak powers are 16 times average power (15). Telephonic speech power = electrical power output of a commercial telephone subset during a normal telephone conversation. For individual variations, *see* Fig. 6; for distribution of power among the tones, *see* Fig. 7.

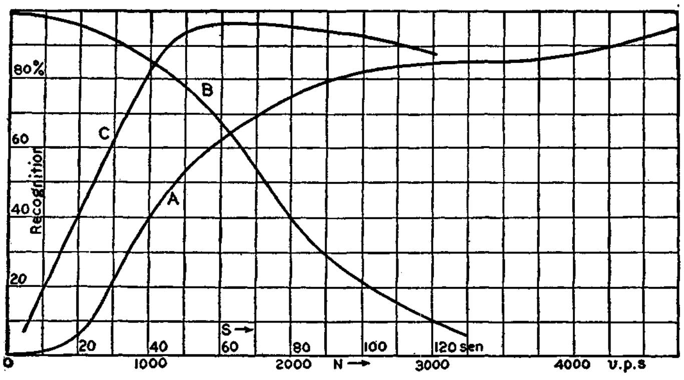

FIG. 5.—Recognition of English speech (4).
Recognition = relative number of syllables recognized. For curve A, all frequencies above N are eliminated; for B, all those below N; C shows effect of sensation level (S) upon recognition of the undistorted sounds. For A and B, S = 60 to 80 sen.

Table 2.—Relative Frequency (F) of Occurrence of Sound Elements of English Speech (3)

Sound = sound element; Key = English word containing the sound; unit of F = 1% of total

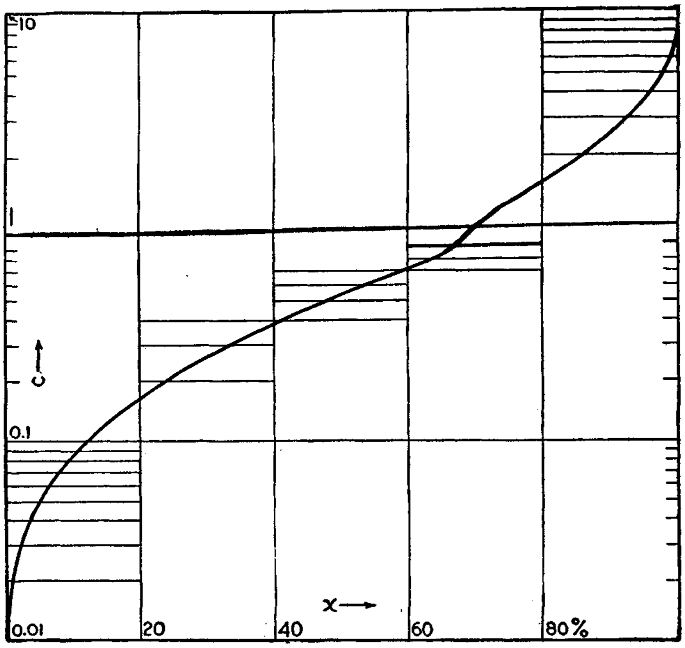

Fig. 6.—Variation in telephonic speech power of individuals (7). x = percentage of speakers having telephonic speech power $\lessgtr CA$, where A = average power of all speakers.

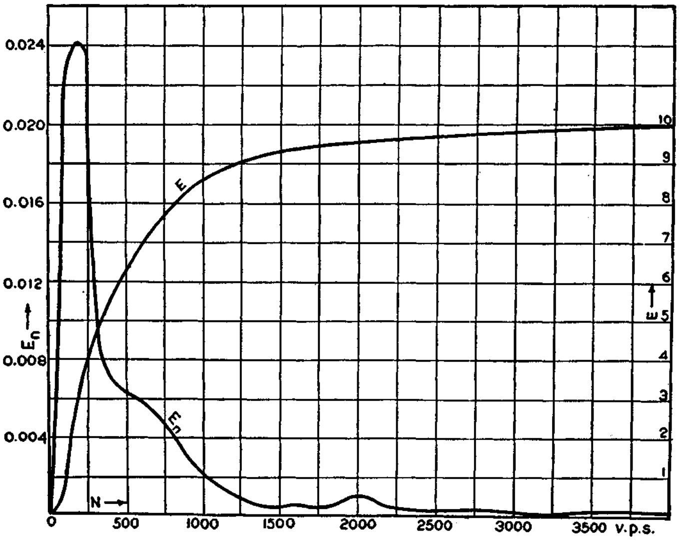

Fig. 7.—Distribution of power in average spoken English (2).

Total power carried by all the tones from $N = 0$ to $N = n'$ is $E = \int_0^{n'} E_n dn$, where $E_n dn$ = power carried by the tonal region $N = n - \frac{1}{2}dn$ to $N = n + \frac{1}{2}dn$. Unit of E_n = 1 microwatt per v.p.s.; of E = 1 microwatt; of n, n', N = 1 v.p.s.

SOUND-GENERATORS

F. R. Watson

CONTENTS

DEFINITIONS AND SYMBOLS

Amplitude.—The amplitude of the oscillation of a point is its extreme departure from that condition of rest about which the oscillations occur. If the departure (y) at the time τ satisfies the equation $y = A \sin (n\tau + \epsilon)$, A is the amplitude.

Frequency.—The frequency of an oscillation is the number of vibrations per unit of time.

Period.—The period of an oscillation is the time required for one vibration; it is the reciprocal of the frequency.

Vibration.—In each interval between successive returns of the body to exactly the same phase of its motion, it executes a single vibration. For example, from the instant a pendulum bob passes from left to right through the lowest point of its arc to the next instant in which it passes in the *same* direction (left to right) through the same point is the interval occupied by a single vibration of the pendulum.

a	Thickness in the plane of vibration.
E	Young's modulus of elasticity.
F	Tensile force.
l	Length.
N	Frequency.
N_i, N_o, N_t	Frequency for ideal case, at 0°C, at t, °C.
p	Pressure.
r, r_o	Radius, value of r at 0°C.
t	Temperature, °C.
v.p.s.	Vibrations per second.
ρ, ρ_0	Density, value of ρ at 0°C.
σ	Mass per unit of length.

Other symbols will be defined where used.

SOUND-GENERATORS

Of the sound-generators, exclusive of musical instruments, only those that are most commonly used or that appear to be useful are considered here. They may be classified as follows:

I. Strings and strips: (*A*) Transverse vibrations: (1) Plucked string. (2) Ribbon loud-speaker. (*B*) Longitudinal vibrations: (3) Stretched wires. (4) Berger's hydrophone.

II. Rods and forks: (5) Tuning fork.

III. Plates and diaphragms: (*A*) Electromagnetic drive: (6) Telephone receiver. (7) Hewlett's generator. (8) Loud-speaker. (9) Fessenden's hydrophone oscillator. (*B*) Electrostatic drive: (10) Electrostatic transmitter. (*C*) Mechanical drive. (11) Piston-phone. (*D*) Piezoelectric generator: (12) Quartz (SiO_2). (13) Rochelle salt ($KNaC_4H_4O_6.4H_2O$). (*E*) Free elastic vibrations: (14) Bell.

IV. Confined fluid: (15) Organ pipe. (16) Tonvariator. (17) Galton's pipe. (18) Singing tube. (19) Thermophone.

V. Free fluid: (20) Siren. (21) Diaphone. (22) Explosives.

Of the preceding generators, numbers 2 and 8 are especially suited for the intense emission of spoken sounds, and numbers 4, 9, 14, and 22 are suitable for the emission of sound under water.

Descriptions of other generators may be found in (**3, 4, 5, 9, 10, 18, 47, 49, 54, 59**).

1. *Plucked String* (**3, 39**).—If the string is perfectly flexible, $N_i = n/2l\,\sqrt{F/\sigma} = n/2l\,\sqrt{F(1+\alpha t)/\pi r_0^2\rho_0}$, if l, the distance between the bridges, is independent of t. Here n is the number of loops in the length l, n may have any integral value, and α is the coefficient of linear expansion of the string. Actual strings are not perfectly flexible; for them $N = N_i(1 + c)$, where c, the stiffness correction, increases as l is reduced. For a steel wire with r = 0.205 mm, F constant and such that N = 76 v.p.s. if l = 90 cm, Melde (**39**) found c varied thus:

l..............	90	45	30	22.5	18 cm
c..............	0	1.3	1.8	3.9	5.3%

2. *Ribbon Loud Speaker* (**51**).—When a variable electric current flows through a thin, corrugated, metallic ribbon mounted in a magnetic field, the ribbon vibrates, thus generating sound. For such loud speakers, an aluminum ribbon 10 cm long, 1 cm wide, 0.001 cm thick, weight = 30 mg, resistance = 0.05 ohm, is used; its maximum current, voltage, power, and amplitude are 10 ampere, 0.5 volt, 5 watt, and 0.5 cm. When fitted with a horn, the emitted speech was intelligible at a distance of 1 km (**26**).

3. *Longitudinal Vibration of a Stretched Wire* (**12**).—$N_i = 1/2l\sqrt{E/\rho}$ and is independent of F. For a steel wire of l = 676 cm and r = *ca.* 0.2 mm, N was found to be 762 v.p.s.

4. *Berger's Hydrophone* (**50**) consists of 3 steel strips, each 3.84 cm (1.5 in.) wide, 0.16 cm (1⁄16 in.) thick, and about 180 cm (6 ft.) long, attached, below the water-line, to the side of a ship, and set into longitudinal vibration by means of a friction drum driven by a 2.2 kw (3 h.p.) motor. The sound was heard under water to a distance of 6.4 km (4 miles).

5. *Tuning Forks* (**3, 40**).—$N = C\dfrac{a+\delta_a}{(l+\delta_l)^2}\sqrt{\dfrac{E}{\rho}}$, where C is a numerical constant, and δ_a, δ_l are corrections which are independent of a and l. For steel forks, $C\sqrt{E/\rho}$ = 81 800, δ_a = 0.05 cm, δ_l = 0.38 cm; l is the projection of the prong on the axis of the fork; N is independent of width perpendicular to plane of vibration. If $-26°C < t < +56°C$, $N_t = N_0/(1 + 0.000134t)$ (**11**); for higher temperatures, *see* Fig. 1. For variation of N with amplitude, *see* Fig. 2. By controlling the temperature and amplitude, and using a specially designed spark-gap, a fork of 25 v.p.s. has been vibrated several hours daily for several weeks without a change exceeding 1 in 10 000 in N (**60**). By means of a circuit containing an oscillating electron tube, forks of N = 50 to 2000 v.p.s. may be kept in vibration without the use of a mechanical contact circuit breaker (**16**).

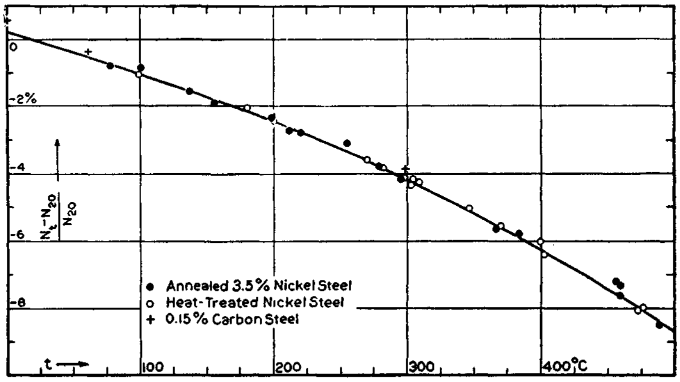

FIG. 1.—Tuning forks: Variation of frequency (N) with temperature (**31**).

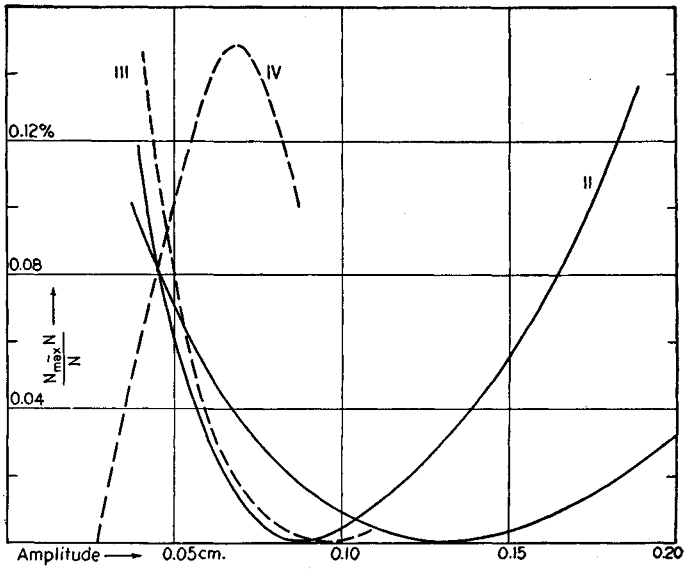

FIG. 2.—Tuning forks: Variation of frequency (N) with amplitude (**11**). The driving current was interrupted by break between spring and point. Curves I and II refer to same fork; for I the amplitude was varied by varying the current, for II it was varied by changing the positions of the pole-pieces of the magnet. Curves III and IV refer to two other forks; the contacts of fork IV were mounted quite differently from those of the others.

6. *Telephone receivers* consist of a circular metallic diaphragm, either of magnetic material or with a plate of such material attached to its center, which is clamped along its circumference and is vibrated by a varying magnetic field. For variation of the amplitude with the frequency of the field, *see* Fig. 3. The over-all efficiency (Eff.) is defined as the ratio of the acoustic energy emitted to the electric energy supplied. For a bipole, 87 ohm, Bell telephone receiver, $N = 992$ v.p.s., no cap over diaphragm, Eff. = (0.375 ± 0.025) % (33). For variation of Eff. with N *see*, Fig. 4. Minimum electrical power required to give a sound audible to a normal ear is of the order of 3.3×10^{-13} watt for a representative type of receiver (55). For acoustic characteristics, *see* (33).

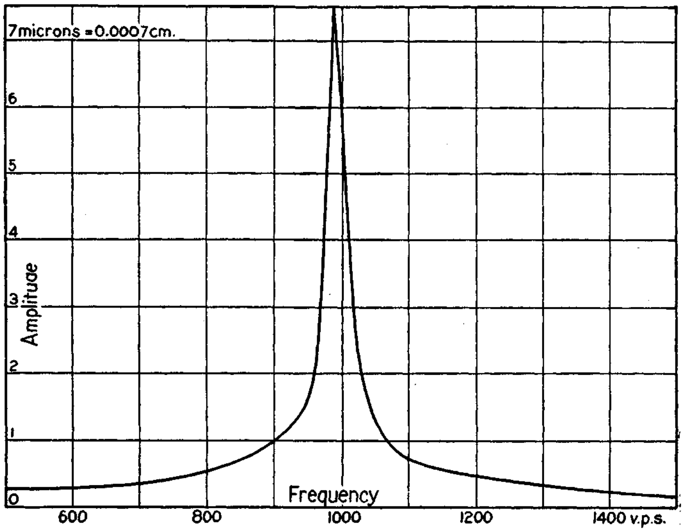

FIG. 3.—Telephone receiver: Variation of amplitude with frequency of current (30).

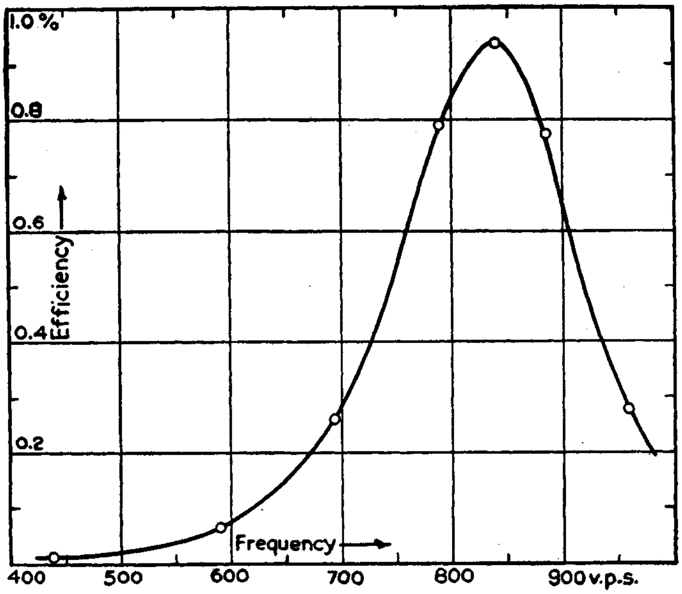

FIG. 4.—Telephone receiver: Variation of acoustic efficiency with frequency of the current (38).

Ordinates are the over-all efficiencies.

7. *Hewlett's tone generator* (27) consists of a thin, circular, metallic diaphragm clamped along its circumference, and placed between two flat circular coils, each wound in its own plane. By a suitable bridge connection, a constant direct current is passed through the coils in such a way as to produce in the diaphragm a radial magnetic field, and at the same time, an alternating current is so passed through them as to produce an axial field. As a result, the diaphragm vibrates with the period of the alternating current. If the diaphragm is nonmagnetic and the current is simply harmonic, the tone is pure. When a certain instrument was excited by a direct current of 1.5 ampere and a voice current of 0.1 ampere, the reproduced speech was comfortably audible at all points in a room 20 ft. square (28). The amplitude (A) varied thus with the frequency of the alternating current, the strength of the current remaining constant:

N........	1440	1600	2200	3700	v.p.s.
A........	4.6	4.16	4.04	1.72	$\times 10^{-5}$ cm

8. *Loud-speaker*.—For general discussion, *see* (13, 44); for "ribbon" loud-speaker, *see* 2, above. The over-all efficiency varies from 0.1 % to 1 % (13, 44). A balanced electromagnetic loud-speaker, diaphragm 7.62 cm (3 in.) in diameter, equipped with a horn, and radiating approximately 1 watt of acoustic energy, was heard loudly at a distance of 0.8 km (0.5 mile) (21). A loud-speaker equipped with a paper cone of 45°, maximum diameter = 15.25 cm (6 in.), paper 0.18 to 0.25 mm (0.007 to 0.010 in.) thick, had a general sensitivity equal to that of a good horn-type speaker, and responded to both low and high frequencies (48). Data for loud-speaker horns (19, 22).

9. *The Fessenden hydrophone oscillator* is a diaphragm operated by either an electrodynamic or electromagnetic drive. With the electrodynamic arrangement, a 5 kw. oscillator of 545 kg. wt. (1 200 lb. wt.) has a tuned diaphragm, about 60 cm (2 ft.) in diameter, clamped at the rim, and attached at the center to a light, hollow copper cylinder. This cylinder is mounted in a powerful magnetic field (about 15 000 line/cm^2) so that alternating currents about the core inside the cylinder induce in the copper alternating currents of about 10 000 ampere. The cylinder is thus pushed and pulled with magnetic forces of about 1 800 kg. wt. (4 000 lb. wt.). When suspended 366 cm. (12 ft.) below the surface of open water the sound ($N = 500$ v.p.s.) was detected under water at a distance of 57.4 km (1, 50).

10. *Electrostatic, or condenser, transmitter* (58) consists of an electric condenser composed of a thin (0.051 mm) metal diaphragm and a heavy plate separated by an air layer 0.025 mm thick. The diaphragm is under such radial tension that its natural frequency in air is 7000 v.p.s. An alternating voltage applied to the condenser causes the diaphragm to vibrate with twice the frequency of the voltage. The intensity of the emitted sound is of the same order as that from a telephone receiver. Such a transmitter may be used as a standard source of sound.

11. *Piston-phone* (56, 57).—A rotating cam imparts a simple harmonic motion to a piston which is attached to a diaphragm; $N = 10$ to 200 v.p.s.

12, 13. *Piezoelectric Generator*.—A suitably cut, thin parallelopipedon of a piezoelectric crystal (*see* p. 207) will execute dilatational-rarefactional vibrations when subjected to a transverse alternating electric field. The amplitude of the vibrations is exceedingly small unless the frequency of the field is near that of one of the natural periods of the parallelopipedon. Such plates are useful for generating waves of high pitch.

If the plate is of quartz (SiO_2) and is cut so that its broad faces are perpendicular to an electrical axis and its breadth is parallel to the optic axis, then its length (l) will be perpendicular to each of these axes, and a varying field perpendicular to its broad faces will generate vibrations in the directions of l and of e, the thickness; the natural frequencies, N_l and N_e are given by the equations $lN_l = eN_e = 275\ 000$ cm v.p.s.

Plates of rochelle salt ($KNaC_4H_4O_6.4H_2O$) may be used likewise, and in some respects are superior to those of quartz (7).

14. *Bells* rung under water may be heard under water at a distance of 3 to 5 km (2 to 3 miles) (1, 41).

15. *Organ Pipes.*—The natural pitch of an open organ pipe is $N = \frac{v}{2(l + c + c')}$, and of a closed one is $N = \frac{v}{4(l + c)}$, where c = correction for mouth-end of pipe = $2.7r$ (45), c' = correction for open end (if pipe has a flange $c' = 0.82r$ (36), if no flange $c' = 0.6r$ (45), observed value for thin brass tube of $r = 5.3$ cm is $c' = 0.576r$ (6)), v = velocity of sound in fluid filling the pipe = $\sqrt{\gamma p/\rho} = v_0\sqrt{1 + \alpha t + \beta t^2}$, γ = ratio of specific heats; for air, $v_0 = 330.6$ m/sec, $\alpha = 0.00371$, $\beta = -0.126 \times 10^{-6}$, for other fluids, *see* p. 461. The pitch of the sound actually emitted increases with the blowing pressure; for a pipe of natural pitch 255 v.p.s., the observed pitch was 255 + δ, where δ varied as follows (46):

p	1.9	2.08	2.2	2.69	3.35
δ	−0.5	+0.1	+1.5	+2.1	+4.2

p	3.88	4.72	5.74	6.92	10.7 cm H_2O
δ	+5.6	+7.1	+8.4	+9.3	+11 v.p.s.

The intensity (I) also increases with the blowing pressure (37):

p	20	24.8	30.8	35.8	39.0	cm H_2O
I	4	9	18	26	35	Arbitrary units

16. *Tonvariator* (53) is a Helmholtz resonator blown by air-blast. Its pitch can be varied continuously over about an octave; its tone is practically pure, the overtones being very high and weak (25, 47). The intensity (I) increases linearly with the blowing pressure (p cm of H_2O), at least within the range $10 < p < 39.5$, being given by $I = 0.67p - 4.7$, unit of I being arbitrary (37).

17. *Galton's pipe* gives tones varying from about 3 500 to 50 000 v.p.s., depending upon its length (l) and the width (w) of its mouth (17):

l	22.4	7.18	4.21	2.7	1.8
w	2.3	1.6	0.9	0.9	0.9
N/1000	3.48	10.0	15.0	20.0	25.0

l	1.26	0.82	0.47	0.27 mm
w	0.9	0.9	0.9	0.9 mm
N/1000	30.0	35.0	40.0	45.0 v.p.s.

18. *Singing tube* (35) consists of an outer glass (pyrex) tube closed at one end, and a shorter inner tube open at both ends and at one end sealed to the outer tube at such a place that its other end is near the closed end of the outer tube. When the relative dimensions of the tubes are suitably adjusted, a strong, pure tone is emitted when the closed end of the tube is heated. The pitch depends upon the difference in temperature of the two ends of the tube. For a certain tube the following data were obtained (34):

t_c	1	204	355	448	524	°C
t_o	−181	−88	−16	+26	+57	°C
$t_c - t_o$	182	292	371	422	+467	°C
N	213	300	378	425	450	v.p.s.

19. *Thermophone* (2, 57).—When a very thin metallic strip immersed in a fluid is heated by an alternating electric current, the periodic expansion and contraction of the adjacent film of fluid give rise to vibrations in the fluid. The intensity of the sound is low, and is indefinite unless the fluid is confined in an enclosure of which the dimensions are all small as compared with the wave-length of the vibrations. If the heating current has a pure sine-wave form, the emitted sound is a pure tone of twice the frequency of the current. (*See* Fig. 5.)

20. *Siren.*—In a "pure tone" siren, the overtones are weak (42). (*See* Fig. 6.)

21. *Diaphone* (32) is a modified siren. It consists of a cylinder fitted with a piston which is oscillated through a small amplitude by compressed air, and which intermittently interrupts an air-blast. It emits a powerful tone. It may emit 1.76 kw (2.36 h.p.) of acoustic energy with an over-all efficiency of 6 to 8% and be heard for miles.

22. *Explosives* (23, 24, 52).—The detonation of bombs containing from 225 to 900 g (0.5 to 2 lb.) of T.N.T. (2, 4, 6-trinitrotoluene, $C_7H_5N_3O_6$) has been used as an under-water source of sound. The sound from a 500 g bomb detonated at 8 to 10 m below the surface has been detected under water at distances of 15 to 18 km (52).

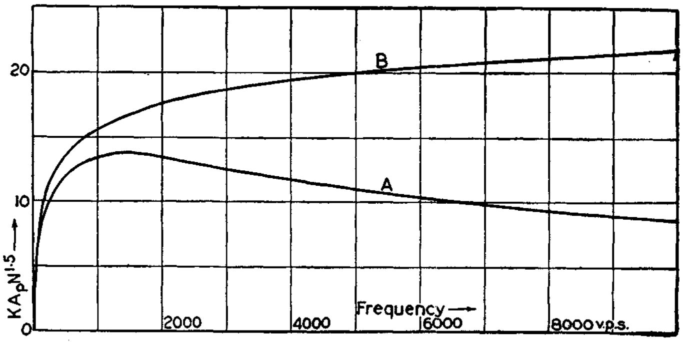

Fig. 5.—Thermophone: Relation between frequency (N) and amplitude (A_p) of oscillation of pressure (57).

In each case mean temperature of strip = 335°K, of air in enclosure = 300°K. For A, strip was a Wollaston wire 1 cm long, $2r = 0.003$ mm; volume of enclosure = 1 cm³; for B, strip was gold foil, area = 5.5 cm², thickness = 0.079μ = 0.79×10^{-5} cm; volume of enclosure = 14 cm³. K is a constant.

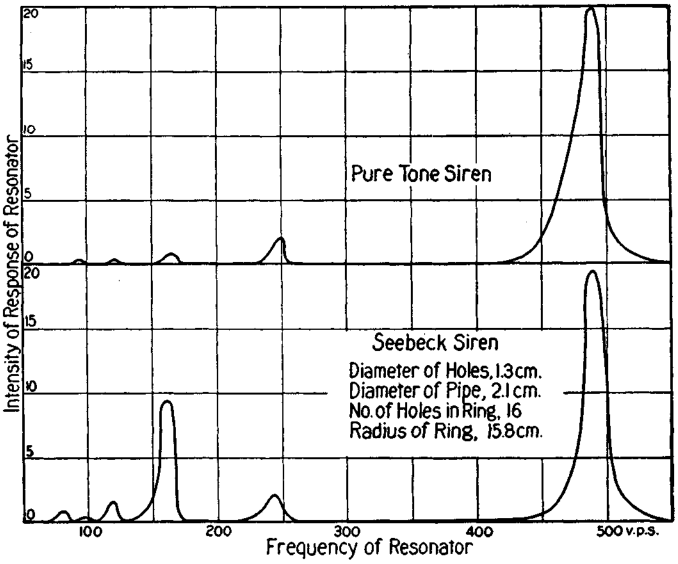

Fig. 6.—Sirens: Comparison of "Pure tone" and Seebeck sirens (42).

Notes analyzed by means of resonators. Arbitrary unit of intensity.

DEVICES FOR STABILIZING THE FREQUENCY OF OSCILLATION OF CIRCUITS CONTAINING ELECTRON TUBES

The frequency of an oscillating electron tube and circuit may be stabilized by the use of a piezoelectric resonator (*see* No. 12 above). Variations with resonator are only about 3% of those without (8).

By the use of 2 electron tubes and coupling by tuned impedances, the frequency of oscillation of the circuit may be made quite independent of changes in plate voltage and in filament current.

In one case a change of 50 % in plate voltage produced but 0.1 %, and of 43 % in filament current produced but 0.3 %, change in the frequency (20).

By the use of a tuning fork (14, 29), the frequency can be maintained constant and equal to that defined by the fork to within 1 part in 100 000. Changing tubes produced a maximum effect of 1 in 100 000; there was no change as the tubes aged and no change as the filament current was reduced, provided the current was not less than 80 % of its normal value. As the plate voltage was increased the frequency increased by 0.0002 % per volt of change.

DETECTION AND MEASUREMENT OF SOUND

E. A. ECKHARDT

This bibliography covers all devices now available for quantitative measurements. For a recent discussion of such devices, *see* (39.1). Apparatus covering the range within which the human ear is sensitive (*see* p. 450) is very elaborate and compromises are generally required to meet a given situation.

1. Interferometric measurement of amplitude of changes in density (29, 35, 39).
2. Rayleigh disc: In free air (52); in simple resonator (12, 30); in double resonator (4, 38, 41).
3. Webster's phonometer (21, 42, 43).
4. Wien's vibration manometer (47, 51).
5. Torsion balance for measuring pondermotive force (2, 31, 51), theory (31).
6. Miller's phonodeik (23).
7. Ballistic phonometer (3).
8. Acoustic valves (28).
9. Magnetophones (20, 27, 34).
10. Contact microphones (10, 27).
11. Thermo-microphones (8, 9, 15, 16, 17, 24, 25, 33, 40).
12. Condenser microphones (5, 45, 46).
13. Resonators (13, 25, 26, 32, 40).
14. Horns (7, 11, 14, 18, 26, 36, 37, 43, 44).
15. Geophones (1, 22).
16. Hydrophones (6, 19, 48, 49, 50).

TRANSMISSION, REFLECTION, REVERBERATION AND ABSORPTION OF SOUND

P. E. Sabine

SYMBOLS AND DEFINITIONS

A	Amplitude of displacement of element of the medium.
a	Absorbing power.
E	Bulk modulus, modulus of volume elasticity.
I	Intensity of the sound.
l	Length of a tube, or thickness of a septum.
N	Frequency, pitch, number of complete vibrations per unit of time.
P	Acoustic power.
R	Radius.
s	Area.
T	Duration of audible reverberation.
t	Time.
V	Volume of room or other enclosure.
v	Velocity of sound in medium considered.
v.p.s.	Vibrations per second.
α	Coefficient of absorption.
δ	Damping coefficient, coefficient of attenuation.
λ	Wave-length.
μ	Acoustic resistivity.
ρ	Density.
σ	Mass of septum per unit of area.

Absorbing Power.—As the result of the absorption of sound by a surface of area s, the intensity of the sound in an enclosure dies away exponentially after its emission ceases; $I_t = I_0e^{-\alpha svt/4V}$, where t is the time that has elapsed since I had the value I_0, the source having ceased to emit sound prior to the beginning of the interval t, and v is the velocity of sound in the medium which fills the volume V. The absorbing power of the surface is αs, and α is the coefficient of absorption. If the boundaries (walls, fittings, and occupants) consist of several types of surfaces, the total absorbing power is $a = \alpha_1s_1 + \alpha_2s_2 + \cdot\cdot\cdot$; it is of the dimensions of an area.

Acoustic power is the amount of acoustic energy that is emitted per unit of time.

Acoustic resistivity of a medium is $\mu = \sqrt{E\rho}$. It is the amount by which the r.m.s.[1] pressure in a plane wave must exceed the static pressure if the r.m.s.[1] velocity of the medium is to be unity.

Coefficient of Absorption.—*See* Absorbing power.

Coefficient of Attenuation.—As a sound travels along a tube, the intensity decreases exponentially; $I_x = I_0e^{-\delta x}$; δ is coefficient of attenuation.

Intensity (I) of a sound is used in this section to denote the amount of acoustic energy per unit volume of the medium. For a single beam of advancing sound, Iv is the acoustic energy transmitted per unit of time through a unit of area perpendicular to the direction of propagation.

Transmittivity of an interface or septum = (transmitted energy) ÷ (incident energy).

Reflectivity of a surface = (reflected energy) ÷ (incident energy).

TABLE 1.—TRANSMISSION OF SOUND THROUGH TUBES, HORNS AND WAVE-FILTERS

Amplification by horns: theoretical (1, 2, 7, 8, 14, 17, 23, 37); experimental (3, 4, 12, 14, 15, 16, 18, 20, 21, 22, 31, 38, 39).

Wave-filters are conduits with side openings and, in certain types, associated branches and air-chambers; sounds in predetermined ranges of frequencies cannot pass through them. Theory and experiments (32).

For cylindrical tubes, radii R_1 and R_2 ($R_2 = r_2R_1$), connected by a cone of length l, sound proceeding from tube 1 to tube 2,

$$\frac{A_2R_2^2}{A_1R_1^2} = \frac{1}{\left[1 + \frac{(r_2-1)^2}{r_2}\cdot\frac{(1-\cos\eta)}{\eta^2}\right]^2 + \left[\frac{(r_2-1)^2}{r_2}\cdot\frac{(\eta-\sin\eta)}{\eta^2}\right]^2},$$

where $\eta = \frac{4\pi l}{\lambda}$ (5).

For tube of constant R, $I_x = I_0e^{-\delta x}$; tabular values are δ (11). Unit of R = 1 cm = 0.394 in.; of l = 1 m = 3.28 ft.; of N = 1 v.p.s.; of $\delta = 0.01\ \text{m}^{-1} = 0.00305\ \text{ft.}^{-1}$.

$2R$	N	254	1040	2285	3280	254	1040	2285	3250

7.30	Brass	5.6	6.2	8.9	8.2	6.2	8.2	9.8	10.2
9.84	Brass		4.9	6.6	5.6	4.1	3.1	10.3	7.2

---

[1] r.m.s. = square root of the mean square.

TABLE 2.—ACOUSTIC RESISTIVITY AND TRANSMISSION OF PLANE WAVES FROM MEDIUM TO MEDIUM (5)

The external media are assumed to have a thickness that is great as compared with λ; the media are indicated by subscripts, 1, 2, 3, . . . , in the order in which they are entered by the wave, A_1, A_1r = displacement amplitude of incident, of reflected, wave in medium 1.

Two media, plane boundary, normal incidence. $A_1 - A_1r = A_2$; $(A_1 + A_1r)\mu_1 = A_2\mu_2$; $(A_1 + A_1r)/(A_1 - A_1r) = \mu_2/\mu_1$. Write m_2 for μ_2/μ_1; *i.e.*, $\mu_2 = m_2\mu_1$. Then for the interface, the transmittivity is $A_2^2\mu_2/A_1^2\mu_1 = 4m_2/(m_2+1)^2$; the reflectivity is $(m_2 - 1)^2/(m_2+1)^2$.

Three media, plane parallel boundaries, normal incidence. Let $m_2 = \mu_2/\mu_1$, $m_3 = \mu_3/\mu_2$, and l_2 and λ_2 = thickness of medium 2 and wave-length in it; then the transmittivity of the septum is

$$\frac{4m_2m_3}{(m_2m_3+1)^2}\left\{\frac{1}{1-\left[\frac{(m_2^2-1)(m_3^2-1)}{(m_2m_3+1)^2}\sin^2\frac{2\pi l_2}{\lambda_2}\right]}\right\}$$

Acoustic resistivity $(\mu) = \sqrt{E\rho}$; velocity $(v) = \sqrt{E/\rho}$. Unit of E = 1 kg wt./mm² = 1422 lb. wt./in.²; of ρ = 1 g/cm³ = 62.4 lb./ft.³; of v = 1 m/sec = 3.28 ft./sec; of $\mu = 10^4$g cm^{-2} sec^{-1} = 2.05 × 10⁴ lb. ft.$^{-2}$ sec.$^{-1}$.

Medium	E	ρ	v*	μ*
Steel	20 000	7.8	5 010	391
Cast iron	9 500	7.0	3 650	255
Brass	6 500	8.4	2 750	232
Bronze	3 200	8.8	1 890	166

Wood: Teak	1 600	0.86	4 270	37
Fir	900	0.45	4 430	20
Beech	600	0.80	2 710	22
Water	200	1.0	1 400	14
Rubber	<1	*ca.* 1	<100	<1
Air	0.014	0.0013	325	0.004

* The numbers in this column have been slightly changed in order to make them accord with the tabulated values of E and ρ.

TABLE 3.—TRANSMISSION OF SOUND THROUGH SEPTA BOUNDED BY AIR

Quilts.—Soft, flexible, porous, highly absorbent septa (25). $\text{Log}_{10}(I_1/I_3) = \beta + \gamma l_2$, where l_2 = thickness of the septum and I_3 is intensity after passage through the septum. Unit of ρ = 1 g/cm³ = 62.4 lb./ft.³; of N = 1 v.p.s.; of β = 0.01; of γ = 0.01 cm⁻¹ = 0.305 ft.⁻¹.

Material of septum	ρ	N	128		256		512		1024		2048		4096	
		Covering	β	γ	β	γ	β	γ	β	γ	β	γ	β	γ
Hair, loosely felted	0.14	None	38	5	25	8	35	10	35	15	26	17	48	17

Hair and asbestos fiber	0.55	Paper + burlap	60	36	96	34	87	63	56	100				

Wood, Glass, Steel (24).—Sound transmitted by forced vibrations of the septum: resonance may cause a large variation in transmission for a small variation in pitch. Tabulated values are averages for the 6 values of N of the preceding section. Each complete septum was 2.1 m by 0.79 m (= 6.9 ft. by 2.59 ft.); l = thickness of septum. Unit of l = 1 cm = 0.394 in.

Material	Remarks	l	I_1/I_3
Plate glass	1 pane	0.63	200
Plate glass	4 panes each, 38 by 99 cm	0.63	282
Plate glass	4 panes each, 38 by 99 cm	0.47	190
Plate glass	Small, leaded panes	0.47	302
Window glass	12 panes, each 25.4 by 48 cm	0.32	140
Steel door		0.63	1020
Wooden door	Panelled, birch veneer		74
Oak door	Solid, well seasoned	4.45	140
Oak door	Solid, damp	4.45	231

Masonry (27).—Tabulated values are averages for 20 tones covering the range N = 128 to 4096 v.p.s.; each septum was 1.88 m by 2.34 m (= 6.17 ft. by 7.68 ft.); $I_1/I_3 = K\sigma^{2.5}$, approximately, where $K = 0.0112$ m⁵kg$^{-2.5}$ = 0.590 ft.⁵ lb.$^{-2.5}$; l_t, l_p, l = thickness of tile, of plaster, of complete septum. Unit of l_t, l_p, l = 1 cm = 0.394 in.; of σ = 1 kg/m² = 0.205 lb. ft.²

Material	Remarks	l_t	l_p	l	σ	I_1/I_3	$K\sigma^{2.5}$

Plaster	Solid, metal lath		11.75	11.75	204.0	6600	6660

TABLE 4.—COEFFICIENT OF ACOUSTIC ABSORPTION BY BOUNDARIES

If I_0 is the intensity of sound in an enclosure, of volume V, at some instant after the production of the sound has ceased, the intensity at a later time is $I_t = I_0e^{-avt/4V}$, where $a = \alpha_1s_1 + \alpha_2s_2 + \cdot\cdot\cdot$; s_1 = area of the boundary for which the coefficient of absorption is α_1; α_{512} = value of α for N = 512 v.p.s.; α_{av} = average value of α for range N = 128 to 4096 v.p.s. For data for special commercial sound-absorbent materials, *see* (36).

Masonry.—l_m, l_c = thickness of material, of coating. Unit of l_m, l_c = 1 cm = 0.394 in.; of α_{512}, α_{av} = 0.01.

Finish	Material	l_m	l_c	α_{512}	α_{av}	Lit.
Unpainted	Brick	45		3.1	4.0	(26)
Painted	Brick	45		1.7	1.9	(26)
Smooth	Brick + gypsum plaster	45	1.5	1.2	1.5	(29)
Smooth	Clay tile + gypsum plaster	10		2.2	3.4	(29)
Smooth	Gypsum block + gypsum plaster	7.6		4.4	3.6	(29)
Smooth	Lime plaster, wood lath and studding			1.8	2.9	(26)
Smooth	Clay tile + gypsum plaster	10		2.0	2.8	(26)
Rough	Clay tile + gypsum plaster	10		4.9	4.4	(29)
Rough	Gypsum plaster, metal lath	6.3		4.7	3.6	(29)
Rough	Gypsum plaster, metal lath *	11.4		4.7	3.0	(29)
Rough	Lime plaster, wood lath and studding	11.4		3.4	3.0	(26)

* Wood studding.

Furnishings and Wall Coverings.—α determined by method of reverberation, unless another is indicated; "draped" = draped back one-fourth; l = thickness of covering, σ = mass of covering per unit area. 1 cm = 0.394 in.; 1 g/m² = 0.00184 lb./yd.² = 0.000205 lb./ft.²; unit of α = 0.01.

Table 5.—Absorbing Power of Objects

Absorbing power (a) of an object = αs (*cf.* Table 4). Unit of a = 0.01 m^2 = 0.108 ft.^{2}

Object	Remarks	a	Lit.
Audience	Per person	44	(26)
Chairs	Ash	1	(26)
Chairs	Wood, veneered	3	(29)
Church pews	Wood, per sitting	2	(35)
Pew cushions	Per sitting	13.5 to 19	(26)
Opera chairs	Seats upholstered	9 to 23	(35)
Opera chairs	Seats and backs upholstered	14 to 19	(29)

Table 6.—Reverberation in Rooms

Duration (T) of audible reverberation in a room of volume V and absorbing power a is $T = \frac{4V}{av} \log_e \frac{I_0}{i} = \frac{9.2V}{av} \log_{10} \frac{I_0}{i}$, where I_0 = average intensity of the sound at the instant its production ceased $= \frac{4P}{av}(1 - e^{-avt/4V})$, where t = the time the sound has been continuously produced; i = minimum audible intensity. Assume $v = 342$ m sec^{-1} (= 1122 ft. sec^{-1}) and t is so great that $I_0 = 4P/av$, and put T_0 = value of T when $I_0/i = 10^6$; T_{10} = value of T when $P/i = 10^{10}$ m^3 sec^{-1} (= 35.3×10^{10} ft.^{3} sec^{-1}). Then if units are 1 m and 1 sec, $T_0 = 0.161V/a$, $T_{10} = 0.0269 \frac{V}{a}(8.07 - \log_{10} a)$, and if units are 1 ft. and 1 sec, $T_0 = 0.049 \frac{V}{a}$, and $T_{10} = 0.0082 \frac{V}{a}(9.10 - \log_{10} a)$.

For each of the 11 rooms considered below, T is considered satisfactory for the purpose indicated. Values of T_0 and T_{10} are computed from V and the known values of α for the surfaces and furnishings, assuming $N = 512$ v.p.s. and that the audience fills the room to its capacity. Key = key number of room. Unit of V = 1 m^3 = 35.3 ft.^{3}; of T_0 and T_{10} = 1 sec.

Key	Purpose	V	Seats	T_0	T_{10}	Lit.
1	Piano	74 to 210		0.95 to 1.10	1.07 to 1.19	(26)

VELOCITY OF SOUND

ARTHUR L. FOLEY

As the determination of the velocity of sound is beset by many difficulties, the values obtained by different observers under nominally identical conditions are frequently quite different. Hence, it has seemed best to give either the individual observations, if few, or the simple average of all, if many (occasionally excluding a few that are markedly discordant); and, when data corresponding to each of a series of values of a single variable are available, to give, if possible, the coefficients of a simple empirical equation that represents the series within the estimated experimental error. Such an equation should not be used beyond the indicated limits. The averages and coefficients have been determined for these tables; the literature references indicate merely the sources of the data upon which they rest. Wherever given, the deviations from the equations refer to the deviations of the values derived by the authors, not necessarily of the individual determinations.

SYMBOLS

t Temperature, °C.

T, T_0 Absolute temperature, absolute temperature of 0°C.

V Velocity of sound in an unlimited volume of the medium, except in Table 7 where it is the observed velocity in the confined gas. Subscripts (*e.g.*, V_t) indicate the temperature, or the temperature and pressure, to which V refers.

RELATION OF VELOCITY OF SOUND TO VARIOUS FACTORS

Pitch.—For frequencies up to 800 000 per sec, the velocity in free air and in free illuminating gas has been found to be independent of the pitch (22, 58). For air and CO_2, *see* (71). When a gas is confined in a tube, the velocity is less than in the free gas, but approaches that as the frequency is increased; *see* Table 7. In liquids also, the velocity is independent of the pitch unless the viscosity is very great and the frequency is very high; in going from 43 000 to 600 000 per sec, the velocity in water decreases only 5 % (8). In glass rods, the velocity of transverse waves increases with the frequency and with the diameter; an increase from 400 m/sec to 2 400 m/sec has been observed when the frequency was increased from 285 000 to 455 000 per sec (111).

Intensity.—Even at ordinary intensities, the velocity is only approximately independent of the intensity, and at great intensities it is far from such independence, the velocity increasing with the intensity (9, 28, 32, 50, 61, 62, 72, 73, 83, 96, 97, 100, 102, 109). The effect of the motion of the medium (*q.v.*) must be considered. Velocities ranging from 331 to 1270 m/sec in air (32, 72, 100), and from 1400 to 2013 m/sec in water (96) have been observed.

Medium.—Unless the intensity is great, the velocity of sound with reference to the medium is quite approximately given by the equation $V^2 = E/d$, where E is the adiabatic volume elasticity, and d is the density of the medium. In general, both E and d vary with the temperature, pressure, and composition of the medium. For an ideal gas, $E = \gamma p$, and $V_t = V_0 T/T_0$ is independent of the pressure; γ = ratio of the specific heats. For many actual gases an equation of the form $V^2_{t,p} = V^2_{0,p}(1 + at + bt^2)$ represents the observations within their experimental error; a will usually differ from $1/T_0$. Irons (47) concludes that the best general equation is $V = a + bT^n$, where n is near 0.5 and varies with the complexity of the molecule.

Velocity of Medium.—When the medium is streaming with reference to the observer, the apparent velocity of the sound is the sum of the normal velocity and that component of the mass velocity of the medium which is in the direction of the line joining the source and the observer. The wave-front of the sound wave from a gun is a circle with a moving center (67); if the distance measured along the axis of the gun from the muzzle to the wave-front is x, then $x = V\tau + a(1 - e^{-b\tau})$, where V is the normal velocity, and τ is the time since the initiation of the wave. The apparent velocity is $dx/d\tau = V + abe^{-b\tau}$. For a 10-inch gun firing a service charge, $a = 22$ m, and $b = 27$ sec^{-1} (67); *see also* (48).

Velocity of Source.—Giving the source a velocity of 85.5 m/sec with reference to the medium and observer, relatively at rest, produces no change in the velocity of the sound (1).

Radiation.—Under the action of X-rays an increase of 5 % in the velocity in O_2 and N_2, and a greater increase in H_2 have been observed (55). The action of ultra-violet light on O_2 forms ozone and decreases the velocity. Radiation from Ra produces no change. Velocity in argon is unaffected by radiation (92). It has been suggested that the effect upon the velocity arises, in general, from a change in the ratio of the specific heats (20).

Topography.—The apparent velocity in free air is affected by the local topography and altitude (10, 59, 85).

TABLE 1.—VELOCITY OF SOUND IN FREE AIR

The following data refer to dry air. The presence of water vapor increases the velocity. If e = pressure of water vapor present in air at barometric pressure p, then

$$V_d = V_h\sqrt{1 - \frac{e}{p}\left(\frac{\gamma_w}{\gamma_a} - \frac{5}{8}\right)},$$

where V_d and V_h = velocity in dry and in humid air of the same temperature, and γ_a and γ_w = ratio of specific heats of air and of water (88). Observed values (59) of V_h at 75% of saturation and over range −14 to +27°C are significantly greater than those computed by means of this equation, the value at 21.85° being 353.0 m/sec while the values computed for 50% and 100% are only 345.5 and 346.2, V_d being taken as 344.7, which corresponds to V_0 = 331.7. Unit of V = 1 m/sec; of p = 1 atm.; temperature = t, °C.

Velocity (V_0) at 0°C, and 1 Atm.

It has been noticed (33) that, from 1738 to 1919, there seems to be a progressive decrease, totaling about 0.3%, in the recorded values of V_0, suggesting a slight change in the constitution of the atmosphere. This decrease has not been considered in taking the following averages. In the table are given (*a*) the unweighted averages of the recorded values grouped roughly according to method used; (*b*) the weighted average of all values obtained prior to 1902 (74); and (*c*) the average of the 1902 average and the best values obtained since then (33).

Method	Range	V_0	Lit.
Gun fire	330.7–332.4	331.4	(2, 3, 10, 12, 30, 34, 67, 68, 72, 90)
Pipes and tubes	330.0–331.9*	331.1	(6, 22, 23, 26, 57, 72, 80, 88, 101, 102, 105)
Other methods	331.3–332.1	331.6	(39, 40, 59, 94, 95)
Weighted mean prior to 1902		331.78	(74)
Weighted mean to 1927		331.45	(33)

* Omitting 328.6 (23).

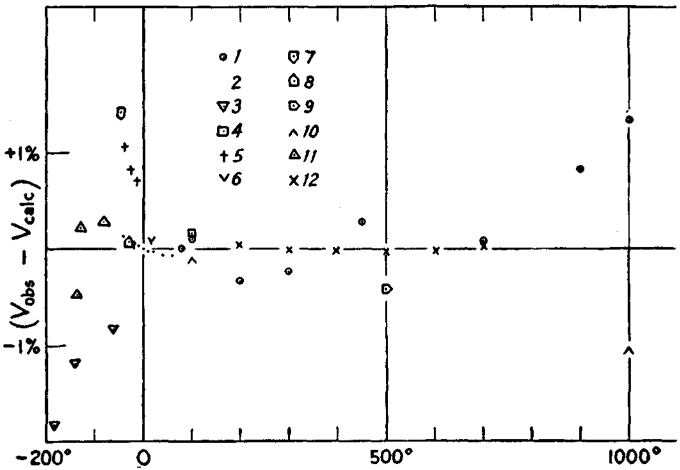

FIG. 1.—Excess of observed velocity in air above that calculated by means of the equation

$$V_t = 330.6\sqrt{1 + 0.003707t - 1.256t^2 10^{-7}}$$

1. Average of several observers.
2. Ciccone and Campanile (17).
3. Cook, and Witkowski and Cook (19, 107), values at −136° and −104°, 3.55% and 3.42% low, lie below the bottom of the figures.

12. Zoch (113).

Variation of V_t with Temperature

The recorded values between −181 and +1000° are represented by the equation $V_t = 330.6\sqrt{1 + 0.003707t - 1.256t^2 \times 10^{-7}} \times (1 + \delta)$, where δ has the values shown in Fig. 1; with two exceptions, the extreme range of δ is from −1.83% at −181° to +1.42% at −45.6°, and between 0 and 700° the range is from −0.43 to +0.29%.

Variation of V_t with Pressure (52, 107); *cf.* (53, 89)

$\Delta \equiv (V_p - V_1) \div V_1$, temperature constant. Unit of p = 1 atm.; of Δ = 0.01

TABLE 2.—VELOCITY OF SOUND IN GASES AND VAPORS: ONE TEMPERATURE

(For variation with temperature, *see* Table 3.) Temperature = t, °C; pressure = 1 atm.; Δ_a = average departure of observed velocities from the value tabulated; if no value given for Δ_a, there is but one acceptable determination. The symbols serve merely to identify the gases, and give no indication of their molecular states. Unit of V = 1 m/sec; of Δ_a = 1% of V.

TABLE 3.—VELOCITY OF SOUND IN GASES AND VAPORS: VARIATION WITH TEMPERATURE

The empirical equation $V = V'\sqrt{1 + \alpha t 10^{-3} + \beta t^2 10^{-6}}$ should not be used beyond the "range" indicated; when β is not zero, its value is given in a foot-note. Δ_a = average departure of the submitted data from the value given by the empirical formula. The pressure is not always explicitly stated by the observer; it is assumed to be 1 atm. unless another value is indicated. Unit of V' = 1 m/sec; of Δ_a = 1 % V'. Temperature = t, °C.

Symbol	Substance	V'	α	Range	Δ_a	Lit.

TABLE 5.—VELOCITY (V) OF SOUND IN NATURAL WATERS

In all oceans, the average vertical velocity for depths of 3.5 to 8.0 km is 1528 to 1529 m/sec; for lesser depths, it is less; values computed from density and adiabatic compressibility by method of Heck and Service (41) may differ by 20 m/sec from the actual value (41). Unit of V = 1 m/sec; of depth = 1 m; temperature = t, °C.

TABLE 7.—VELOCITY OF SOUNDS IN GASES CONFINED IN TUBES

The velocity of sound in a gas contained in a tube depends upon the heat conductivity of, and the velocity of sound in, the material of the tube, upon the viscosity and the heat conductivity of the gas, upon the character of the inner surface of the tube, upon the rate and the direction at which heat and vibrations are transferred between the tube and external objects, upon the pitch and intensity of the sound, and upon the thickness and diameter of the tube (27, 32, 42, 51, 69, 72, 77, 78, 81, 93). If the inner surface of the tube is smooth, and if the transfer of energy to external objects is negligible, the velocity is given by the expression $V = V_\infty(1 - K/D\sqrt{n})$, where D = diameter, n = pitch, K depends upon the properties of the tube and gas, and V_∞ = velocity in an unlimited volume of the gas. Under other conditions, this expression may be multiplied by a quantity depending upon the material and dimensions of the tube, and K may involve D and n. Some observers (77, 81) claim $V = V_\infty(1 - K/Dn^{2/3})$, another (108) concludes that the exponent of n is 0.53.

For air in iron and in porcelain (72, 93), $D \geq 4$ cm, $n = 500$, 600, and "explosion," V differs but little from its value in free air; *see also* (99). When other observations are represented by the following equations, δ has the values tabulated:

Air in glass, $D > 0.6$ cm (54, 58, 69, 81), $V = 331.0(1 - 0.501/D\sqrt{n})(1 + \delta)$.

Air in glass, $D < 0.4$ cm (78), $V = 331.0(1 - 0.441/D\sqrt{n}) \times (1 + \delta)$.

Air in brass, $D > 1$ cm (6), $V = 331.0(1 - 0.362/D\sqrt{n}) \times (1 + \delta)$.

Air in brass, $D < 0.2$ cm (78), $V = 331.0(1 - 0.834/D\sqrt{n}) \times (1 + \delta)$.

CO_2 in glass (93), $V = 260.0(1 - 0.452/D\sqrt{n})(1 + \delta)$.

H_2 in glass (93), $V = 1249.5(1 - 0.262/D\sqrt{n})(1 + \delta)$.

Unit of $\delta = 0.001$; of $D = 1$ cm; of $n = 1$ double vibration per sec.

(110) Wood and Browne, *67*, **35**: 183; 23. (111) Wood and Loomis, *3*, **4**: 417; 27. (112) Wüllner, *8*, **4**: 321; 78. (113) Zoch, *8*, **128**: 497; 66.

LITERATURE REFERENCES

LITERATURE REFERENCES

In all literature references cited in International Critical Tables the name of the journal or publication is indicated by means of a *Key number* corresponding to the list given below. The numbers which follow this key number in a literature citation are, in the order named: (1) the volume, (2) the page, and (3) the last two figures of the year. Thus *64V*, **31**: 253; 22, indicates Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Series numbers are not given. Key numbers referring to books and other non-serial publications are preceded by the letter *B*, and the volume number is given in roman numerals. Thus *B10*, **IV**: 191; 18, indicates Doelter, Handbuch der Mineralchemie, page 191 of Vol. 4 of the 1918 edition. The Key number *O* is used to indicate "private communication from."

DAS LITERATURVERZEICHNIS

In allen Literaturstellen, die in I. C. T. verzeichnet sind, ist der Name der Zeitschrift oder der Publikation mit Hilfe einer *Schlüsselnummer*, entsprechend der unten folgenden Liste, angegeben. Die Zahlen, welche diesen Schlüsselnummern bei einem Literaturzitat folgen, bedeuten der Reihe nach: (1) der Band, (2) die Seite und (3), die letzten zwei Zahlen des Jahrganges. So bedeutet z. B. *64V*, **31**: 253; 22, Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Band 31, Seite 253, 1922. Serien-Nummern werden nicht angegeben. Der Schlüsselzahl wird ein *B* vorausgesetzt, wenn sie Bücher, oder eine andre nicht periodische Veröffentlichung bezeichnet. Die Bandnummer wird durch römische Ziffern angegeben. Es bedeutet z. B. also *B10*, **IV**: 191; 18, Doelter, Handbuch der Mineralchemie, Seite 191, des 4 Bandes, der Auflage des Jahres 1918. Die Schlüsselzahl *O* wird gebraucht, um anzuzeigen, dass es eine "private Mitteilung" ist.

RÉFÉRENCES BIBLIOGRAPHIQUES

Le nom du journal ou de la publication de toutes les références bibliographiques citées dans les Tables Critiques Internationales est indiqué au moyen d'un *nombre-clé* correspondant à la liste donnée ci-dessous. Les nombres qui suivent ce nombre-clé dans un renvoi bibliographique indiquent dans l'ordre suivant: (1) le volume, (2) la page, et (3) les deux derniers chiffres de l'année. Ainsi *64V*, **31**: 253; 22, indique Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Les numéros des séries ne sont pas donnés. Les nombres-clés se rapportant à des livres ou à des publications non périodiques sont précédés de la lettre *B* et le numéro du volume est donné en chiffres romains. Ainsi, *B10*, **IV**: 191; 18, indique Doelter, Handbuch der Mineralchemie, page 191 du volume 4 de l'édition de 1918. Le nombre-clé *O* est employé pour indiquer "communication privée de."

INDICAZIONI BIBLIOGRAFICHE

In tutte le indicazioni bibliografiche che si incontrano nelle "Tabelle Critiche Internazionali" il nome del giornale o della pubblicazione è espresso con un *numero chiave* riportato nell'elenco dato più oltre. I numeri che, nella citazione, vengono dopo il numero chiave sono disposti con l'ordine seguente: (1) il volume, (2) la pagina, e (3) le ultime due cifre del millesimo. Cosi *64V*, **31**: 253; 22, indica la Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, pagina 253, 1922. I numeri di serie non vengono dati. Quando un numero chiave è preceduto dalla lettera *B* si riferisce a libri o ad altre pubblicazioni non periodiche, e il numero del volume viene allora scritto in cifre romane. Cosi *B10*, **IV**: 191; 18, indica Doelter, Handbuch der Mineralchemie, pagina 191 del IV° volume dell'edizione 1918. Il numero chiave *O* indica "Comunicazione privata da . . . "

KEY TO THE PERIODICALS

Data regarding the libraries which receive many of these periodicals may be found through the following sources:

United States and Canada: "Periodicals Abstracted by Chemical Abstracts, 1926" (Chemical Abstracts, Ohio State Univ., Columbus, Ohio); "Union List of Serials in the Libraries of the United States and Canada, 1927" (H. W. Wilson & Co., New York City); "A Catalogue of Scientific Periodicals in Canadian Libraries, 1924" (McGill Univ., Montreal, Canada).

Great Britain: "A World List of Scientific Periodicals Published in the Years 1900–1921" (Oxford Univ. Press, London, 1925–).

Holland: "Chemisch Jaarboekje tevens Jaarboekje der Nederlandsche Chemische Vereeniging, Vol. 3." (Amsterdam, D. B. Centen, 1920).

Annual Tables of Constants and Numerical Data

CHEMICAL, PHYSICAL, BIOLOGICAL AND TECHNOLOGICAL

Published under the patronage of the International Research Council and of the International Union of Pure and Applied Chemistry *by the International Committee appointed by the VIIth Congress of Applied Chemistry, London, June 2nd, 1929*

ANNUAL TABLES publishes each year a volume containing the original numerical data appearing in the world's literature for the year in question.

1. For the period 1910 to 1926 (Volumes I to VI) Annual Tables contains the original experimental values upon which the selected data of International Critical Tables are largely based.

2. Beginning with Volume VII, the volumes of Annual Tables complete the record of the most recent determinations. The text of these later volumes is given in both English and French.

3. The collected index to Volumes I to V, inclusive, has been published and facilitates the ready location, in these volumes, of the data for any given substance.

No other work in existence gives the complete record of the individual determinations of all physical constants and properties.

Special offer to subscribers to International Critical Tables

According to an agreement between the International Committee in charge of Annual Tables and the Board of Trustees of International Critical Tables, 25% discount is allowed to all subscribers of International Critical Tables on all purchases of the second series of Annual Tables.

This discount is applicable as follows:

For	*Up to*
Volume VI (1923–1924)	December 31, 1930
Volume VII (1925–1926)	December 31, 1930
Index (1st series—Volumes I to V)	December 31, 1930
Volume VIII (1927–1928)	June 30, 1931
Volume IX (1929) Volume X (1930)	Date to be determined

INTERNATIONAL CRITICAL TABLES

REFRACTIVITY

REFRACTIVITY OF ALL GASES AND VAPORS AND OF ELEMENTARY SUBSTANCES IN THE ISOTROPIC SOLID AND LIQUID STATES

J. J. Fox and F. G. H. Tate

SYMBOLS

Symbols and formulae that occur in a single table are explained there.

d Density.
F Formula-weight in accordance with the printed formula.
g As subscript, g indicates that the quantity pertains to the gas.
H As subscript, H indicates that the quantity pertains to hydrogen, H_2.
M Molecular weight.
n Index of refraction referred to a vacuum.
p Pressure.
λ Wave-length.
λ_μ Value of λ when the unit is $1\mu = 10^4$ Å; $\lambda_\mu = 10^{-4}\lambda_{\text{Å}}$.

SYMBOLE

Symbole und Formeln, die in einer einzelnen Tabelle vorkommen, sind dort erklärt.

d Dichte.
F Formelgewicht entsprechend der gedruckten Formel.
g Als untergeschriebende Index bedeutet g, dass sich die Grösse auf ein Gas bezieht.
H Als untergeschriebende Index bedeutet H, dass sich die Grösse auf Wasserstoff, H_2 bezieht.
M Molekulargewicht.
n Brechungsindex auf das Vakuum bezogen.
p Druck.
λ Wellenlänge.
λ_μ Wert von λ, wenn als Einheit $1\mu = 10^4$ Å gilt; $\lambda_\mu = 10^{-4}\lambda_{\text{Å}}$.

SYMBOLES

Les symboles et formules qui se présentent dans une seule table sont expliqués à cette place.

d Densité.
F Formule-poids en accord avec la formule imprimée.
g Comme souscrit, g indique que la quantité se rapporte à un gaz.
H Comme souscrit, H indique que la quantité se rapporte à l'hydrogène, H_2.
M Poids moléculaire.
n Indice de réfraction par rapport au vide.
p Pression.
λ Longeur d'onde.
λ_μ Valeur de λ lorsque l'unité est $1\mu = 10^4$ Å; $\lambda_\mu = 10^{-4}\lambda_{\text{Å}}$.

SIMBOLI

I simboli e le formule che si incontrano in ogni singola tabella sono ivi spiegate.

d Densità.
F Formula-peso corrispondente alla formula stampata.
g Quando viene posto sotto, g indica che la quantità si riferisce allo stato gasoso.
H Quando viene posto sotto, H indica che la quantità si riferisce all'idrogeno, H_2.
M Peso molecolare.
n Indice di rifrazione riferito al vuoto.
p Pressione.
λ Lunghezza d'onda.
λ_μ Valore di λ quando l'unità è $1\mu = 10^4$ Å; $\lambda_\mu = 10^{-4}\lambda_{\text{Å}}$.

The indices for solids and liquids are given for the actual temperatures at which they were determined; those for gases and vapors have in most cases been reduced to 0°C and 760 mm of Hg by some one of several, not always concordant, formulae. As values obtained previous to 1898 have been collected by Dufet (**23**), such values are, in general, omitted from this section if more recent data of equal or superior accuracy are available; a discussion of them will usually be found in the recent papers.

The variation of the refractivity with temperature and pressure has been given special consideration in the case of air; for other gases and vapors the available data are included with the refractivities in Table 4, if there is an indication that the ideal gas laws do not apply.

REFRACTIVITY OF AIR

Except as the contrary is stated, the following data refer to dry air containing the normal amount (0.03%) of CO_2. Doubling this amount of CO_2 will increase n by less than 1 in 10^7 (**54**).

TABLE 1.—REFRACTIVITY OF DRY AIR

For dispersion formulae, *see* Table 2; unit of λ = 1 Å; of p = 1 mm of Hg; temperature = t,°C

(*A*) Range: λ = 2218 to 8999, p = 760 mm (**54**). Observations were made at constant t, and gave directly the values of n for pressures near 760; these were reduced to p = 760 on the assumption that over this short range $(n - 1)/p$ is independent of p. For smoothed values, *see* Table 3.

Variation of Refractivity of Air with Temperature, Pressure and Humidity

Temperature.—$(n-1)_0 = (n-1)_t \cdot (1 + \alpha t)$. Meggers and Peters (54) find $\alpha = 0.00367 + \frac{0.000003}{\lambda_\mu^3}$; Koch (35) and Statescu (75) used $\alpha = 0.003670$; Pèrard (59) used $\alpha = 0.003716$; Cuthbertson (14), Howell (29), and most of the other workers have used $\alpha = 0.003663 = 1/273$. At $t = -189$ to -188°C, Ayres (3) obtained the following values, agreeing with those of Scheel (68):

λ		507	735	914 mm of Hg
5461 Å	$(n-1)10^6 =$	654.3	954.1	1189.9
5780 Å	$(n-1)10^6 =$	653.3	951.1	1186.4

Pressure.—For small ranges in p, t constant, $(n-1)/p$ may be regarded as a constant. Opinions differ regarding the effect of relatively great changes. Mathews (53) concludes that $(n-1)/p$ is constant over the range $p = 26$ to $p = 760$ mm, but many consider that Mascart's relation, $(n-1)/p = K(1 + \gamma p)$, fits the observations better; the following values have been used for γ, the unit of p being 1 mm of Hg:

λ	5 461	5 461	5 462
p	0 to 760	0 to 760	760 to 7 600
$10^8\gamma$	357 ± 39	667 ± 87	51 ± 5
Lit.	(62)	(81)	(58)

λ	4 359	4 000 to 6 500	5 000 to 86 000
p	760 to 7 600	near 760	0 to 760
$10^8\gamma$	53 ± 5	240	70
Lit.	(58)	(59)	(35)

For the range $\lambda = 4050$ to 5090 Å, $p = 30$ to 100 atm., $t = 9$ to 14°C, it has been found (70, 71, 73) that, whatever the pressure,

$$\frac{(n-1)_\lambda}{(n-1)_{5461}} = 0.98086\left\{1 + \frac{0.0056376}{\lambda_\mu^2} + \frac{54.01(10)^{-6}}{\lambda_\mu^4}\right\}$$

For variation with p at $t = -188$°C, *see* preceding text.

Humidity.—If n_d and n_m = index for dry air and for air in which the partial pressure of water vapor is m mm of Hg, then Lorenz (43) concludes that $n_d = n_m + \frac{41m(10)^{-6}}{760}$.

TABLE 2.—DISPERSION FORMULAE FOR DRY AIR

$\lambda_\mu = 10^{-4}\lambda_A$, unit of λ_A = 1 Å

For the formula $(n - 1)10^6 = \beta/(\mu - \lambda_\mu^{-2})$, Cuthbertson (14) finds $\beta = 51\,626$, $\mu = 179.17$; for the Cauchy formula $(n - 1)\,10^6 = A + B\lambda_\mu^{-2} + C\lambda_\mu^{-4}$, the following values have been found, those of (54) being the best. Temperature is t, °C; pressure = 760 mm of Hg, except as noted.

t, °C	A	B	C	$1000B/A$	$10^6C/A$	Lit.
0	287.566	1.3412	0.03777	4.6641	131.35	(54)
15	272.643	1.2288	0.03555	4.5070	130.39	(54)
30	258.972	1.2259	0.02576	4.7337	99.47	(54)
0	287.987*	1.804*	0	6.264*	0	(65)
0	288.02	1.482	0.0309	5.145	107.3	(59)
11				5.638†	54.01†	(70, 71, 73)

* Freed of CO_2.

† For pressures between 30 and 100 atm., t = 12°C, 4050 Å $< \lambda <$ 5090 Å.

TABLE 3.—CORRECTIONS FOR CONVERTING WAVE-LENGTHS AND THEIR RECIPROCALS IN AIR AT 15°C AND 760 MM OF HG TO THEIR VALUES IN A VACUUM (54)

If λ_a, λ_v = values in air and in vacuum, respectively, then $\lambda_v = \lambda_a + \delta_\lambda$ and $1/\lambda_a = 1/\lambda_v + \delta_\nu$, where δ_λ and δ_ν have the values given in the table. The values of $(n - 1)$ are those computed by means of the equation $(n - 1)10^6 = 272.643 + 1.2288\lambda_\mu^{-2} + 0.03555\lambda_\mu^{-4}$ which was derived from the observations in Table 1, section A. Unit of λ and δ_λ = 1 Å; of δ_ν = 1 cm^{-1} = 10^8 Å^{-1}.

TABLE 4.—REFRACTIVITY OF GASES AND VAPORS

For dispersion formulae, *see* Table 5

Order: Elementary substances, pure compounds, mixtures. The formula used for reducing the observations is indicated, if known, by *I*, *II*, or *III*: *I*, $r_0 = r\cdot\frac{760(1+\alpha t)}{p(1+\gamma p)}$, unless other values are given, $\gamma = 0$ and $\alpha = 1/273$; *II*, $r_0 = rd_0/d$; *III*, $r_0 = r[(F/d)_0]_{t,p} \times [(d/M)_H]_{0,760}$; $r = (n-1)10^6$. If the gas is ideal and diatomic, and if $\gamma = 0$ and $\alpha = 1/273 (= 0.003663)$, all three formulae give the same value, and $r_0 = 10^6(n-1)_{0,760}$. $K \equiv r_0/p$. Unit of λ = 1 Å; of p = 1 mm of Hg; temperature = t,°C.

* At 21°C, $\lambda = 5461$ Å, and d between $70d_0$ and $200d_0$, d_0 = density at 0°C and 760 mm, $\frac{n^2 - 1}{n^2 + 2} \cdot \frac{d_0}{d}$ (= 199.7×10^{-6}) is more nearly constant than either $(n^2 - 1)/d$ or $(n - 1)/d$ (57).

† If computed by van der Waals's equation with $a = 126\,070$, $b = 1.325$, then both $(n - 1)/d$ and $(n^2 - 1)/(n^2 + 2)d$ are constant within 2 %.

‡ $\Delta \equiv (n_{5461} - n_{5780}) \times 10^6$, where 5780 is the mean λ of the yellow lines of Hg; p is expressed in cm of Hg. At −191.6°C the coefficient of p is nearly 7 times as great at −190.6°C.

* Data given with reserve.

† Reduced to 0°C and 760 mm by using $\alpha = 0.003914$, then reduced this value to what it would be if $(n - 1)/p$ were constant and p had such a value that the number of formula-weights per unit volume was equal to the number of moles of H_2 per unit volume at 0°C and 760 mm. These would agree with the following data (47) if reduced in the same way.

* Also corrected for factor A in $[(PV)_{760} - (PV)]/(PV) = A(P - 760)$, using $A = 10.2 \times 10^{-6}$ per mm of Hg.

† Derived from same observations as preceding data.

‡ At 34°C, $\lambda = 5461$ Å, $0.10 < d < 0.74$, $\left(\frac{n^2+2}{n^2-1}\right)d = 6.581(1 + 0.0172 \times d^2)$.

§ $(n^2-1)/(n^2+2)d$ is more nearly constant than either $(n^2-1)/d$ or $(n-1)/d$; d_0 = density at 0°C and 760 mm of Hg.

Mixtures

x = vol. % of second substance (or mixture); subscripts $_{\text{mix.}}$, $_1$ and $_2$, refer to the mixture and to first and second substance, respectively. The refractivities are said to be additive if $(n-1)_{\text{mix.}} = (n-1)_1 + x\{(n-1)_2 - (n-1)_1\}$. Reduced refractivity and density of the mixture are defined as $(n-1)_r = (n-1) \times \frac{760}{p} \cdot \frac{T}{273}$ and $d_r = d \cdot \frac{760}{p} \cdot \frac{T}{273}$.

* 272°K < T < 343°K; 55 mm < p < 238 mm.

TABLE 5.—DISPERSION FORMULAE FOR GASES AND VAPORS

$\lambda_\mu = 10^{-4}\lambda_A$; unit of λ_A = 1 Å. The table is divided into 4 sections, each, except *D*, devoted to a single type of formula. In general, the data refer to 0°C and 760 mm of Hg. Certain of the parameters depend upon the formula used in reducing the observations to 0° and 760 mm; these formulae are indicated by *I*, *II*, *III* (*see* Table 4) placed at head of section or in column (2).

A. $(n-1)10^6 = A + B\lambda_\mu^{-2} + C\lambda_\mu^{-4}$ (Formula *I*)

(1)	*A*	*B*	*C*	1000*B*/*A*	$10^6C/A$	Lit.
A.......	277.826	1.558	0	5.608	0	(65)
H_2*.....	136.102	1.0246	0.009906†	7.528_2	72.78	(33)
H_2......				7.337‡	89‡	(69, 72, 74)
O_2......	269.74	0.372	0.126	1.379	467	(66)
CO_2.....				6.787§	−6.14§	(70, 71, 73)
Air......	*See* Table 2					

* Those authors who use only *A* and *B*, find values of *B* varying from 0.90 to 1.00; *see* (14).

† Author uses a fourth term, $D\lambda_\mu^{-6}$; $D = 70.51 \times 10^{-6}$, $D/A = 5.181 \times 10^{-7}$.

‡ For all pressures between 25 and 70 atmospheres, t = 20°C, 4050 Å < λ < 5090 Å.

§ For all pressures between 20 and 47 atmospheres, t = 12°C, 4050 Å < λ < 5090 Å.

B. $(n-1)10^6 = \beta'/(\mu' - \lambda_\mu^{-2}) + \beta''/(\mu'' - \lambda_\mu^{-2})$

In most cases, β'' and $\mu'' = 0$; when β'' and μ'' are not zero, their values are written below those of β' and μ', with which they are connected by {.

REFRACTIVITY OF SELECTED SOLIDS AND LIQUIDS

CHARLES CHÉNEVEAU

Scope.—The substances included in this section are those pure solids and liquids which have been studied with special care on account of their practical importance or of some unusual behavior. All are listed in Table 1.

Sujet traité.—Les substances mentionnées dans cette section, sont les solides et liquides purs qui ont été étudiés avec un soin spécial, soit à cause de leur importance pratique, soit à cause de leur façon de se comporter inaccoutumée. Elles sont toutes mentionnées dans la Table 1.

Umfang.—Die in diesem Abschnitt enthaltenen reinen festen und flüssigen Stoffe sind solche, welche zufolge ihrer praktischen Bedeutung oder ihres ungewöhnlichen Verhaltens mit besonderer Sorgfalt studiert worden sind. Alle sind in der Tafel 1 angeführt.

Sostanze incluse.—Le sostanze incluse in questo capitolo sono quei solidi e liquidi puri che sono stati studiati con cura speciale sia per la loro importanza pratica o per il loro anormale comportamento. Essi sono riuniti nella Tabella 1.

Units.—Unit of $\lambda = 1\mu = 10^4$ Å $= 10^{-4}$ cm; of $t = 1°$C; of $p = 1$ atm.; of $d = $ g/cm.^{3}

TABLE 1.—REFRACTIVITY OF PURE SOLIDS AND LIQUIDS: SELECTED SUBSTANCES

$N_D[n_D]$ = index of refraction relative to vacuum [to air at 1 atm. and same temperature as the substance] for the Fraunhofer line D ($\lambda = 0.5893\mu$); similarly for n_C, n_F, etc.; $(10)^{-4}\Delta_{C-D} = (n_C - n_D)/(\lambda_C - \lambda_D)$, etc.; $(10)^{-5}\Delta_{tD} = (n_{t''} - n_{t'})/(t'' - t')$ for $\lambda = 0.5893(D)$; Δ_λ = mean value of $dn/d\lambda$ throughout visible spectrum; $dn/dt = A_t(10)^{-6}$; $dN/dp = A_p(10)^{-6}$; C = crystal of cubic system; d = density; f = solidified from fusion; s = solid. Temperature (t) is 20°C, except as noted; $\lambda_C - \lambda_D = 0.0670\mu$, $\lambda_D - \lambda_F = 0.1032\mu$, $\lambda_F - \lambda_{G'} = 0.0520\mu$.

TABLE 5.—REFRACTIVITY OF DYES

All dyes in this table are isotropic solids which exhibit selective reflection. n is determined either by prism or by reflection, as indicated, and is with reference to air at the same (room) temperature. Designations of Fraunhofer lines are in italics; *e.g.* (*D*).

REFRACTIVITY OF BIREFRINGENT CRYSTALS

H. E. MERWIN

These tables have to do primarily with variations of refractive index with wave-length and temperature. For refractive indices at a single wave-length, for $2V$ or $2E$, for orientations, etc., *see* Vol. I, p. 166, 279, 320; and (56, 81.1, 115, 116.1, 235.1). For dispersion of birefringence, *see* (59–62); for refractivity of metallic crystals, *see* Vol. V, p. 248; for isotropic substances, *see* Vol. I, p. 165 (*cf.* p. 106), Vol. VII, p. 12, and for elementary substances, *see* Vol. VII, p. 1.

Ces tables concernent principalement les variations de l'indice de réfraction avec la longueur d'onde et avec la température. Pour les indices de réfraction concernant une seule longueur d'onde, pour $2V$ ou $2E$, pour les orientations, etc., *voir* Vol. I, p. 166, 279, 320; et (56, 81.1, 115, 116.1, 235.1). Pour la dispersion de la biréfringence, *voir* (59–62); pour le pouvoir réfractif des cristaux métalliques, *voir* Vol. V, p. 248; pour les substances isotropiques, *voir* Vol. I, p. 165 (*cf.* p. 106), Vol. VII, p. 12, et pour les éléments, *voir* Vol. VII, p. 1.

Diese Tafeln behandeln vor allem die Änderung des Brechungsindexes mit der Wellenlänge und der Temperatur. Für die Brechungsindexes einzelner Wellenlängen, für $2V$ oder $2E$, Orientierung, etc., *siehe* Bd. I, S. 166, 279, 320; ferner (56, 81.1, 115, 116.1, 235.1). Für die Dispersion der Doppelbrechung, *siehe* (59–62); für das Brechungsvermögen von Metallkristallen, *siehe* Bd. V, S. 248; für isotropischen Stoffe, *siehe* Bd. I, S. 165 (*cf.* S. 106), Bd. VII, S. 12, und für Elemente, *siehe* Bd. VII, p. 1.

Queste tabelle si riferiscono principalmente alle variazioni dell'indice di birifrangenza in funzione della lunghezza d'onda e della temperatura. Per gli indici di rifrazione ad una sola lunghezza d'onda, per $2V$ e $2E$, per le orientazioni, ecc., *vedi* Vol. I, p. 166, 279, 320; e (58, 81.1, 115, 116.1, 235.1). Per la dispersione della birifrangenza, *vedi* (59–62); per la refrattività dei cristalli metallici, *vedi* Vol. V, p. 248; per le sostanze isotropiche, *vedi* Vol. I, p. 165 (*cf.* p. 106), Vol. VII, p. 12, e per le elementi, *vedi* Vol. VII, p. 1.

LIST OF BIREFRACTING MINERALS IN TABLE 1

Those for which the dispersion of the index has been most accurately and extensively measured are indicated by a "(*d*)."

ELECTRIC AND MAGNETIC BIREFRINGENCE

H. MOUTON

Introduction.—While a non-crystalline substance is in either an electric or a magnetic field it acts optically as a uniaxial crystal with its axis parallel to the field intensity, Kerr (23), Cotton and Mouton (7, 12). Some act as positive (+) others as negative (−) crystals. Crystalline substances are excluded from this section. The molecules of "crystalline" liquids seem to be completely aligned by the applied field and the order of the resulting birefringence is 10^6 times as great as that of the liquids here considered.

General Relations.—If n = index of refraction of the substance when in zero field, n_e and n_o = indices when in a field of strength E (electric) or H (magnetic), λ = wave-length of the light *in vacuo*, l = actual length of path of the light in the substance and perpendicular to the field, δ = difference in the equivalent optical paths of the components with electric vector parallel and perpendicular, respectively, to the field, then the *coefficients of birefringence* (C_e, C_m) are defined by the equations $\delta/\lambda = (n_e - n_o)l/\lambda = C_e l E^2$ (or $= C_m l H^2$), or $(n_e - n_o) = C_e \lambda E^2$ (or $= C_m \lambda H^2$). C_e and C_m depend upon λ, the temperature (t), and the substance; for any given gas, C_e is proportional to its density (19, 27). C_e is sometimes called Kerr's constant; it should not be confused with Kerr's magneto-optic constant, Vol. VI, p. 435.

Variation with λ.—For any substance at a constant temperature, Havelock (20, 21) concludes that $n(n_e - n_o) = k(n^2 - 1)^2$, or $C_e \lambda n/(n^2 - 1)^2 = k_e$, $C_m \lambda n/(n^2 - 1)^2 = k_m$, where k, k_e, k_m are pure numbers which are independent of λ, *cf.* (30, 31, 37). For anisole (C_7H_8O), phenetole ($C_8H_{10}O$), and *m*-xylene (C_8H_{10}), k_e has been found to be independent of λ; for toluene (C_7H_8) and ethyl *n*-butyrate ($C_6H_{12}O_2$), k_e varies slightly with λ; and for ethyl ether ($C_4H_{10}O$) and acetal ($C_6H_{14}O_2$), $C_e\lambda$ varies less than this relation indicates (4). For a number of substances (37, 40), including nitrobenzene ($C_6H_5NO_2$) (8, 12), k_m has been found to be independent of λ.

Variation with *t*.—For a given λ, Langevin (25) concludes that $C_e nT/\{d(n^2 + 2)^2(\epsilon + 2)^2\} = \varphi_e$ and $C_m nT/\{d(n^2 + 2)^2\} = \varphi_m$, where d = density, ϵ = dielectric constant, and φ_e and φ_m are independent of absolute temperature (T). The constancy of φ_e has been verified for ethyl ether ($C_4H_{10}O$) and for CS_2 from −78.5°C to + 18°C (29), and for nitrobenzene ($C_6H_5NO_2$) from 6.14°C to 25°C and for 5 values of λ (38). The value of φ_m frequently varies non-linearly by several parts in 1000 per 1°C; *cf.* Table 5. In Tables 1, 2, 3, coefficients for linear interpolation over short ranges are given if available.

Time Effects.—The time required for C_e to reach its equilibrium value after the field is applied or removed is approximately proportional to C_e and is of the order of 10^{-8} sec = 0.01μ sec (1, 2, 3, 5.1, 17, 36); *see* CS_2 (Table 1), and C_7H_8 and $C_{10}H_7Br$ (Table 3). The effect of electrostriction (*see* Vol. VI, p. 207) and the heating produced by the conduction current complicate the determination of $(n_e - n)$ and $(n_o - n)$ in electric birefringence. Both effects are reduced by applying the field quickly and maintaining it for a very short time (τ); *see* following.

Ratio of Changes in Index.—Different theories of electric birefringence predict different values for $\rho \equiv (n_e - n)/(n_o - n)$. That which makes the birefringence (electric or magnetic) depend upon the orientation of the molecules makes $\rho = -2$; Voigt's theory (43) which makes it depend upon a modification of the intraatomic forces makes $\rho = +3$, and a more general form of this theory, Enderle (16), makes ρ vary with λ and approach +3 for frequencies which are small as compared with those characteristic of the electrons. Using very short times (τ) so as to minimize effects of electrostriction (Vol. VI, p. 207) and heating, Pauthenier (35) found for nitrobenzene ($C_6H_5NO_2$) and $\tau = 0.46$, 0.92, 1.6, and 2.7μ sec ($=10^{-6}$ sec), $\rho = -2.01$, −1.99, −2.03, and −2.04, respectively; the same was found for red, yellow-green and blue light; Himstedt (22) found $\rho = -1.92$; McComb (31), $\rho = -1.88$ for $0.540\mu < \lambda < 0.660\mu$. For CS_2, electrostriction compensates the change in $(n_o - n)$, making the apparent (ρ') value of ρ infinite, when $\tau = 8.1\mu$ sec. If electrostriction alone increases the index from n to $n + \delta'$, and we write $\beta \equiv \delta'(n_o - n)$, then $\rho' = (\beta + 2)/(\beta - 1)$; for CS_2, Pauthenier (35) found as follows:

τ	0.65	1.3	2.5	4.9	7	8.1	9.8
β	0	0	0.12	0.36	0.74	1	1.4

τ	20	25	30.7	41.7	49	65.6μ sec
β	2	1.47	1	1.3	1.1	1.1

Relation between Electric and Magnetic Birefringence.—The preceding temperature relations indicate that $C_e/\{C_m(\epsilon + 2)^2\} = \varphi_e/\varphi_m$ is independent of T. Cotton and Mouton (12) have proposed the simpler relation $C_e/(C_m\epsilon)$ = const., and have found it more satisfactory for nitrobenzene ($C_6H_5NO_2$); their values are as follows, a and b being arbitrary constants:

t	aC_e	bC_m	ϵ	$\frac{a}{b} \cdot \frac{C_e(10)^4}{\epsilon C_m}$	$\left(\frac{C}{C_{16^\circ}}\right)_e$	$\left(\frac{C}{C_{16^\circ}}\right)_m$
6°C	68	129	39.4	133.9	1.18	1.08
16	57.6	119.5	37.4	129.0	1.00	1.00
33	45.8	105.2	34.2	127.4	0.79_6	0.88_1
54	37.2	90.8	30.6	133.9	0.64_6	0.76_0

Units.—Unit of $\lambda = 1\mu = 10^4$ Å $= 10^{-4}$ cm.

TABLE 1.—ELECTRIC BIREFRINGENCE OF CS_2 (6, 18, 29, 30)

$n_e - n_o = C_e\lambda E^2$. $A \times 10^{-7} = C_e$ when λ is expressed in cm and E in cgs electrostatic units. Time required for A_{20} to attain equilibrium value is 0.014μ sec = 14×10^{-9} sec (17). $A_{15} = 1.025\ A_{20}$, $A_{28} = 0.966\ A_{20}$; approximately $A_t = A_{20}\ [1 - 0.005\ (t - 20)]$ if $18^\circ < t < 28^\circ$C (26, 27); for lower temperatures, *see* below. For effect of electrostriction, *see* above.

λ	A	$A\lambda$	t'	$A_{t'}/A_{18^\circ}$

TABLE 2.—MAGNETIC BIREFRINGENCE OF NITROBENZENE ($C_6H_5NO_2$) (9, 12)

$(n_e - n)/(n_o - n) = -2.00$, $k_m \equiv C_m\lambda n/(n^2 - 1)^2 = 1.11 \times 10^{-16}$ at 19 to 20°C, is independent of λ. $\varphi_m = C_m nT/\{d(n^2 + 2)^2\}$ varies non-linearly with T; $C_e/C_m\epsilon$ is nearly independent of t. $C_{m_t} = C_{m_{20}}\ [1 - \alpha(t - 20)]$; if $10^\circ\text{C} < t < 25^\circ\text{C}$, $\alpha = 1/35$; near 20°C, $\alpha = 1/44$; mean variation per 1°C between 6.4°C and 53.9°C is $1/38$ of mean value of C_m (8, 12). $n_e - n_o = C_m\lambda H^2$; $A \times 10^{-12} = C_m$, if λ is expressed in cm and H in cgsm (gauss). t = 20°C; 1μ = 10^{-4} cm.

λ	0.578	0.436	0.486	0.546	0.578	0.656
A	2.46 ±0.02*	3.62	3.10	2.66	2.46	2.14
$A\lambda$		1.580	1.509	1.450	1.422	1.405

* Basis of reference; derived from A = 2.53 ± 0.02 at 16.3°C (9).

TABLE 3.—ELECTRIC AND MAGNETIC BIREFRINGENCE OF PURE SUBSTANCES: RELATIVE VALUES

For most inorganic liquids C_e and C_m are inappreciable, but magnetic birefringence should be exhibited by those paramagnetic substances which have quite anisotropic molecules (*cf.* aqueous solution of erbium nitrate, Table 4). For organic substances containing only C, H and O, C_m is very small or zero if they are acyclic, and, so far as they have been studied, it is inappreciable if they contain a cyclic nucleus without a double bond.

In this table $\gamma_e/100 \equiv (C/C_{CS_2})_e$, where C and C_{CS_2} refer to the same temperature (20°C) and the same radiation (usually D-line, $\lambda = 0.589\mu$), and $\gamma_m/100 \equiv (C/C_{C_6H_5NO_2})_m$ where $C_6H_5NO_2$ = nitrobenzene, C and $C_{C_6H_5NO_2}$ refer to the same temperature (t_m) and to the yellow mercury line ($\lambda = 0.578\mu$). For most substances γ_e is nearly independent of λ; as a first approximation, γ_m is independent of t_m. Available data for variation of C_e and γ_e with t and λ are given in footnotes; for variation of C_m and γ_m, *see* Table 5. For $C_e(CS_2)$ and $C_m(C_6H_5NO_2)$, *see* Tables 1 and 2.

Data for γ_e are from (26) unless another source is indicated in a footnote: those for γ_m are from (9, 12). g = gas at 20°C and 1 atm., l = liquid, b. = boils at, m. = melts at.

* *See* Table 1.

† γ_e = 207 to 210

‡ From (35).

§ From (28).

‖ For $\lambda = 0.589\mu$ and 20°C, $C_e = -0.621 \times 10^{-7}$ and $\gamma_e = -19.2$ (41). $C_e\lambda$ varies with λ less rapidly than is indicated by Havelock's relation (p. 109) (4); variation with t satisfies Langevin's relation (p. 109) from −78.5° to + 18°C, giving (29):

t	18	0	−21.7	−38.9	−60.5	−78.5°C
$C_{et}/C_{e_{18}°}$	1.000	1.220	1.547	1.927	2.707	3.880

¶ Free of pyridine (C_5H_5N).

** γ_e = 184 to 191.

†† $\gamma_e/100$ = 100.7 at 21.3°, 99.5 at 22.5°, 65.7 at 49°C. Lippmann (28) gives γ_e = 11 390 at room temperature. Near 20°C, $C_{et} = C_{e_{20°}} \{1 - \frac{1}{68}(t - 20)\}$, and mean change per 1°C between 0 and 47°C is $\frac{1}{68}$ of mean value of C_e (12, 13); between 6.14 and 25°C, change of C_e with t satisfies Langevin's relation (p. 109) (38); $(n_e - n)/(n_o - n) = -2.00$ (p. 109) (22, 30, 31, 35). For C_m and its variation with λ and t, *see* Table 2.

‡‡ Undercooled.

§§ Slight departure from Havelock's relation (p. 109).

‖‖ Variation of $C_e\lambda$ with λ is less than that indicated by Havelock's relation (p. 109).

¶¶ For o-C_7H_7Cl, γ_e = 261 to 270; for p-C_7H_7Cl, γ_e = 690 to 711 (28).

*** Slight departure from Havelock's relation (p. 109). Time for C_e to reach equilibrium = 0.017μ sec = 17×10^{-9} sec (17).

††† Phenyl methyl ether = anisole; Havelock's relation for C_e is satisfied (p. 109).

‡‡‡ Havelock's relation for C_e is satisfied (p. 109).

§§§ Boils at 160 to 178°C.

‖‖‖ Time for C_e to reach equilibrium = 0.006μ sec = 6×10^{-9} sec (17). Mean decrease of C_m per 1°C increase between 11.8 and 47.9°C = $\frac{1}{308}$ of mean value of C_m (8, 9, 10, 11, 12, 13).

¶¶¶ Obtained from solution in hexane (C_6H_{14}) using $\lambda = 0.546\mu$ (Hg); value computed for camphor is independent of concentration; electric birefringence and rotary power are superposed without change in either (32).

**** Between −17 and +50.5°C, C_m varies sensibly linearly and $C_{m_t} = C_{m_{20°}}\{1 - \frac{1}{480}(t - 20)\}$ (8, 9, 10, 11, 12, 13).

†††† Mixture of saturated hydrocarbons.

TABLE 4.—ELECTRIC AND MAGNETIC BIREFRINGENCE OF SOLUTIONS AND MIXTURES

(Values of γ_e for limonene ($C_{10}H_{16}$), camphor ($C_{10}H_{16}O$), and carvenone ($C_{10}H_{16}O$) as deduced from solutions in n-hexane (C_6H_{14}) are given in Table 3.)

$\gamma_e/100 = (C/C_{CS_2})_e$, $\gamma_m/100 = (C/C_{C_6H_5NO_2})_m$; $C_6H_5NO_2$ = nitrobenzene. Generally γ can not be readily computed from the composition (Comp.) of the mixture or solution. If γ_e for one constituent of a binary mixture is very great the curve γ_e *vs.* Comp. is usually convex towards axis of Comp.; if γ_e for one is negative and not too nearly zero, the curve is concave towards this axis, and may pass through a maximum at an intermediate Comp.

TABLE 4.—(*Continued*)

Mol % = molecular per cent, Vol. % = volume % = 100 d'/d, where d' = mass of constituent in unit volume of mixture, and d = density of same constituent when pure. ⩾ = very much greater than.

THEORIES OF REACTION RATE

Reaction rate as a function of temperature and nature of the medium. Applications of statistical mechanics, theories of radiation (quantum theory) and activation theories.

GENERAL INTRODUCTION

Isothermal Monomolecular First-Order Reactions: A ⟶.

$$\frac{\mathrm{dx}}{\mathrm{d}t} = k(\mathrm{a} - \mathrm{x}) \text{ or } -\frac{\mathrm{d}C}{\mathrm{d}t} = kC \tag{I}$$

Integration gives:

$$k = \frac{1}{t}\log_e \frac{\mathrm{a}}{\mathrm{a} - \mathrm{x}} \text{ or } k = \frac{1}{t}\log_e \frac{C_0}{C} \tag{II}$$

and

$$k = \frac{1}{t_2 - t_1}\log_e \frac{\mathrm{a} - \mathrm{x}_1}{\mathrm{a} - \mathrm{x}_2} \text{ or } k = \frac{1}{t_2 - t_1}\log_e \frac{C_1}{C_2} \tag{III}$$

If $\log_{10}$ is used instead of $\log_e$, the constant will become $k' = 0.4343k$; a or C_0 = the initial concentration of the reacting substance and $(\mathrm{a} - \mathrm{x_n})$, or C_n, its concentration at a time t_n units later.

Reversible First-Order Reactions.

$$\mathrm{A} \underset{k_2}{\overset{k_1}{\rightleftarrows}} \mathrm{B}$$

$$\frac{\mathrm{dx}}{\mathrm{d}t} = k_1(\mathrm{a} - \mathrm{x}) - k_2(\mathrm{b} + \mathrm{x}) \tag{IV}$$

$$k_1 + k_2 = \frac{1}{t}\log_e \frac{\mathrm{x}_\infty}{\mathrm{x}_\infty - \mathrm{x}} \text{ or } = \frac{1}{t_2 - t_1}\log_e \frac{\mathrm{x}_\infty - \mathrm{x}_1}{\mathrm{x}_\infty - \mathrm{x}_2} \tag{V}$$

where

$$\mathrm{x}_\infty = \mathrm{x} \text{ for } t = \infty, \simeq \mathrm{x} \text{ at equilibrium,}$$

where

$$\frac{\mathrm{b} + \mathrm{x}_\infty}{\mathrm{a} - \mathrm{x}_\infty} = \frac{k_1}{k_2} = K_E, \text{ the ``equilibrium constant''} \tag{VI}$$

If π be any property of the reacting mixture such that

$$\pi = \mathrm{p}(\mathrm{a} - \mathrm{x}) + \mathrm{q}(\mathrm{b} + \mathrm{x}), \tag{VII}$$

where p and q are proportionality factors, then

$$k_1 + k_2 = \frac{1}{t}\log_e \frac{\pi_0 - \pi_\infty}{\pi - \pi_\infty} \text{ or } = \frac{1}{t_2 - t_1}\log_e \frac{\pi_1 - \pi_\infty}{\pi_2 - \pi_\infty}, \tag{VIII}$$

where the subscript identifies the time to which the π value belongs.

If A and B are optical antipodes,

$$k_1 = k_2 = k,\ k_1 + k_2 = 2k, \text{ and } K_E = 1 \tag{IX}$$

Isothermal Bimolecular Second-Order Reactions: A + B ⟶.

$$\frac{\mathrm{dx}}{\mathrm{d}t} = k(\mathrm{a} - \mathrm{x})(\mathrm{b} - \mathrm{x}) \tag{X}$$

$$k = \frac{1}{t(\mathrm{b} - \mathrm{a})}\left(\log_e \frac{\mathrm{a}}{\mathrm{a} - \mathrm{x}} - \log_e \frac{\mathrm{b}}{\mathrm{b} - \mathrm{x}}\right)$$

or

$$k = \frac{1}{(t_2 - t_1)(\mathrm{b} - \mathrm{a})}\left(\log_e \frac{\mathrm{a} - \mathrm{x}_1}{\mathrm{a} - \mathrm{x}_2} - \log_e \frac{\mathrm{b} - \mathrm{x}_1}{\mathrm{b} - \mathrm{x}_2}\right) \tag{XI}$$

or if b = a

$$k = \frac{1}{t\mathrm{a}}\frac{\mathrm{x}}{\mathrm{a} - \mathrm{x}} \text{ or } = \frac{1}{t_2 - t_1}\left(\frac{1}{\mathrm{a} - \mathrm{x}_2} - \frac{1}{\mathrm{a} - \mathrm{x}_1}\right) \tag{XII}$$

If a differs but slightly from b, a series expansion of Eq. (XI) may be used; or k may be taken as the geometrical mean of the values obtained from Eq. (XII) by putting, 1st, a = a and 2nd, a = b.

The differential equation is given in case the rate does not follow a simple law, and the integrated expression is then often omitted.

Progressive Change in k.—↓ (resp. ↑) = "the value of k is greatest at the beginning (resp. end) of the reaction."

Temperature Coefficient.—The effect of temperature will be exhibited approximately by $Q_{10} = \frac{k_{\theta+10}}{k_\theta}$ where k_θ is the value of k at $\theta°$; or more exactly by the constant A in the equation $\log_e k = \mathrm{A}/T + J$ or $\log_{10} k' = -\mathrm{A}'/T + J'$ where A' (resp. J') = $0.4343 \times \mathrm{A}$ (resp. $\times J$). E (= RA, where R is the gas constant) has been called the "internal energy" (Rice), the "critical energy" (Marcelin), the "critical energy increment" (McC. Lewis) or the "activation heat" (Arrhenius).

EXPERIMENTAL DATA

First-Order Gas Reactions

Nearly all reactions of this class take place almost entirely on the surface of the containing vessel as shown by the increase of k with increasing ratio of surface to volume; and several investigators have expressed the opinion that *true* first-order reactions do not exist (417). However, as a result of recent work, several examples are known; *cf.* $SO_2Cl_2 \longrightarrow SO_2 + Cl_2$ and $N_2O_5 \longrightarrow N_2O_4 + 1/2O_2$ below. For nearly all these first-order gas reactions k has been shown to decrease at very low pressure (254.5, 411.5); and new theories have been advanced (419.5). The important qualitative result is that the new evidence favors the collision mechanism and not the radiation theory.

Decomposition of Phosphine

$$4PH_3 \longrightarrow P_4 + 6H_2$$

Manometric method; t in seconds (309).

T, °K	845	785	719	640	583
10^6k	540	2.1	0.81	0.19	0.053

The observed values have been smoothed by graphing. The calculated values are computed from the equation:

$$\log_{10} k = \frac{-18\,963}{T} + 2 \log_{10} T + 12.130; \textit{ cf. } (160)$$

% G = % of reaction in the gas phase; 100 − % G = % on walls; t in seconds (517).

T, °K	10^3k obs.	10^3k calc.	% G	T, °K	10^3k obs.	10^3k calc.	% G
956	18.3	18.0	100	940	8.3	8.0	96

Rearrangement of Trimethylene to Propylene

$$(CH_2)_3 \longrightarrow CH_3CH{=}CH_2$$

Bodenstein and Wolgast's gas-stream method with analysis of condensate by density; t in seconds; E = 54 800 to 70 400; Q_{10} = 1.55; the reaction is influenced by the walls, whose effect can, however, be largely diminished (519).

°C	550	570	580	600	600	650
10^3k	6.87	15.2	22.2	44.7	45.7	146

Decomposition of Hydrogen Peroxide

$$H_2O_2 \longrightarrow H_2O + \tfrac{1}{2}O_2$$

Manometric method; t in minutes; k = 0.22 to 0.38 at 76.0°C; wall reaction (257).

Decomposition of Sulfuryl Chloride

$$SO_2Cl_2 \rightleftarrows SO_2 + Cl_2$$

Manometric method; t in minutes; wall reaction (257); at temperatures above 200°C in the dark, the equilibrium concentration of SO_2Cl_2 is negligibly small (514.5).

°C	$\dfrac{\log_e 2}{k}$	Q_{10}	E
211	172		
237	26.5	2.06	35 000
283	1.6	1.85	34 000

Decomposition of Sulfuryl Chloride.—(*Continued*)

Manometric method; t in minutes; at 320°C rate is uninfluenced by a 200-fold increase of the ratio of surface to volume. Concluded to be a *true* first-order reaction at and above this temperature (491.5).

T, °K	552.3	572.5	593.1	602.4
10^5k	6.09	27.1	132.1	274.2
E		46 400	51 850	55 700

Decomposition of Formic Acid

$$HCO_2H \longrightarrow H_2O + CO; \; k_{CO}$$
$$HCO_2H \longrightarrow H_2 + CO_2; \; k_{CO_2}$$

Manometric method; wall reaction dependent on nature of glass used; t in minutes; % P = % of $(CO_2 + H_2)$ formed (256); for catalysis by Al_2O_3, *v.* (16, 17).

°C	137.5	158	236	236	239	302	302	350

	calc.	2.03	0.992	0.475	0.0440

* Average using Bodenstein's calculations (51).

† Vapor saturated with solid N_2O_5; values less accurate.

Effect of NO_2 at the beginning of the reaction

According to later measurements by Daniels *et al.* (133, 134, 560), traces of NO_2 are necessary for a smooth monomolecular course of the reaction, which would thus have an autocatalytic induction period. However, White and Tolman (549.5) have found no evidence of this effect at the lowest concentration measurable, and conclude that the reaction is monomolecular in its initial stage.

Colorimetric method; t in minutes; the values of k agree with those above.

°C	20	25	35	40

Racemization

HYOSCYAMINE (HY.) $\rightleftarrows$ SCOPOLAMINE (SC.)

Polarimetric method; t in minutes; first-order reaction with reversal (194).

1 g Hy. with absolute alcohol to 15 cm³ + 1 cm³ N NaOH; $2k = 0.0148$ at 5°C.

1.048 g Hy. with absolute alcohol to 24.95 cm³ + 0.5238 g tropine; $2k = 4.97 \times 10^{-6}$ at room temperature.

4.0173 g Sc. with absolute alcohol to 70 cm³ + 8.51 cm³ absolute alcohol containing 0.004017 mole NaOH; $2k = 0.0295$ at 3°C.

15.519 g alcohol solution of Sc. (of which 1 cm³ ≈ 9.46 cm³ 0.01N H_2SO_4) + 0.3736 g tropine; $2k = 4.42 \times 10^{-6}$ at room temperature.

The reaction is useful for determining [OH^-].

POTASSIUM CHROMOOXALATE

$$K_3[Cr(C_2O_4)_3],\ l \underset{k}{\overset{k}{\rightleftarrows}} d$$

Polarimetric method; t in seconds (420); *cf.* (277, 513, 549)

In H_2O	°C	0	11	22	24	Q_{10}	E
	$2 \times 10^6 k$	149	239	542	598	1.77	9328

	60	22.22	0.000262

$$l\text{-MENTHONE} \underset{k_2}{\overset{k_1}{\rightleftarrows}} d\text{-MENTHONE};\ k = k_1 + k_2$$

According to Beckmann (33) the two menthones are not optical antipodes and hence $k_1 \neq k_2$.

Measurements in various solvents; k independent of direction. Catalyzed by alcoholates, quaternary ammonium bases, and strong acids but not proportionally to their concentration.

Slight catalysis by weak acids. Not influenced by neutral salts, by acetic esters, or by dimethylhydroresorcinols. The catalysis by alcoholates is not influenced by slowly saponifiable esters but rapidly saponifiable ones react with Na from the alcoholates and decrease the reaction velocity accordingly.

l-MENTHONE $\rightleftarrows$ d-MENTHONE.—(*Continued*)

Polarimetric method; t in minutes; catalyst, 0.02 (resp. 0.01)N alcoholate (resp. 0.01N HCl) (522, 523).

$10^3k'$	3.4	10.8	5.3	47.1

For all reactions $Q_{10} = 2.31$–3.19; A′ = 3250–4250.

For determination of the "alcoholytic constant" of the type [acetoacetic ester] [alcoholate]/[Na acetoacetic ester] = K, and for theory of the reaction, *v.* (225); *cf.* (10, 427).

Transformation of Geometric Isomers

syn-ALDOXIME $\xrightarrow{k}$ *anti*-ALDOXIME (398, 399)

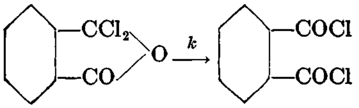
Method: change in rotation of the optically active solvent; t in minutes; θ = 20°C. 5 g oxime in 95 g solvent. Values of 1000k, (first-order):

syn-Anisaldoxime in dimethyl tartrate (3.0); in diethyl tartrate (1.8); in di-n-propyl tartrate (1.0); in dimethyl malate (5.0); in diethyl malate (6.7); in di-n-propyl malate (8.4) (398); *cf.* (399).

syn-m-Nitrobenzaldoxime in di-n-propyl tartrate (0.5) (398); *cf.* (399).

Intramolecular Transformation

PHTHALYL CHLORIDE



Reaction in liquid melt; method: initial freezing point; t in minutes; k (first-order) = 0.036 at 130°C; Q_{10} = 1.6 (90 – 170°) (130).

DIAZOAMINOBENZENE

$$C_6H_5NHN_2C_6H_5 \xrightarrow{k} C_6H_5N_2C_6H_4NH_2$$

Gas-volumetric method: t in hours; solvent, aniline; catalyzed by $C_6H_5NH_3Cl$; rate proportional to concn. of catalyst, $C_{\text{cat.}}$ (M/l); first-order k (216); *cf.* (204, 217).

°C	25			25	35	45	55	
$C_{\text{cat.}}$	0.1	0.2	0.3	0.1				
$10^3k'$	6.0	12.3	18.1	6.0	24.6	81.0	253	A′
Q_{10}					4.10	3.29	3.12	5355

TRIBROMOBENZENEDIAZONIUM CHLORIDE

$$Br_3C_6H_2N_2Cl \xrightarrow{k} ClBr_2C_6H_2N_2Br$$

Gravimetric method; t in minutes; solvent, methyl alcohol; first-order k (239); $10^3k' = 0.83$ at 0°C = 1.93 at 4°C; $Q_{10} = 8.2$. The solid salt decomposes rapidly, the aq. soln. slowly, the alcoholic soln. at measurable rate (239).

ACETOPHENOXIME

$$C_6H_5C(NOH)CH_3 \xrightarrow{k} C_6H_5NHCOCH_3$$

Beckmann rearrangement; titrimetric method; *t* in minutes; catalyst, H_2SO_4; first-order *k* (490).

% H_2SO_4		68.5	93.6	94.6	97.2	98.2
$10^3k'$	60°C		1.1	1.3	4	7
	65°C	0.6	1.9	2.1		

CINCHONINE OR CINCHONIDINE $\xrightarrow{k}$ CINCHOTOXINE

Gravimetric and polarimetric methods; *t* in hours; solvent, aqueous acids (39, 40, 41, 42, 44). Cinchonine at 99.7 ± 0.2°C; values of $1000k'$, (first-order); $C_{\text{cat.}}$ in M/l.

$C_{\text{cat.}}$ \ Cat.	$C_2H_5CO_2H$	CH_3CO_2H	HCO_2H	$(CO_2H)_2$	HCl

III	Alcohol	0.0_335	0.0_417	78	(*f*)	
III		0.0_455	0.0_52	Rm	(*f*)	

The reaction in the melt is very slow and depends on the nature of the walls, the presence of traces of impurities (*e.g.*, acids) and the previous history of the sample used. Acids are poor catalysts in H_2O and alcohol and good catalysts in non-ionizing solvents. The reaction in the gas phase is very slow even on the walls. For preparation of the pure tautomers, *v.* (370, 371).

HYDROXYTRIAZOLE ⟶ DIAZOMALONIC ESTER

$$\begin{array}{ccc} \text{Acid form} & \underset{k_2}{\overset{k_1}{\rightleftarrows}} & \text{Neutral form} \\ \text{A} & & \text{N} \end{array}$$

Method: iodine titration of the acid form; *t* in minutes; first-order *k*. Methyl 1-methyl-5-hydroxytriazole-4-carboxylate $\underset{k_2}{\overset{k_1}{\rightleftarrows}}$ Methyl methylaminodiazomalonate. Ionization constant of the acid form $= 2.8 \times 10^{-3}$.

Values for 50°C in various solvents (149)

	CH_3OH	$C_6H_5CH_2OH$	CH_3COCH_3

$CHCl_3$	61.8	172		6.5

AMMONIUM THIOCYANATE

$$NH_4CNS \underset{k_2}{\overset{k_1}{\rightleftharpoons}} CS(NH_2)_2$$

Reaction in the melt; titrimetric method; first-order k; t in minutes; at 170°C, $k_1 = 0.015$, $k_2 = 0.044$, $K_E = 1/3$ (25, 415, 528).

Decomposition Reactions

NITRAMIDE

$$H_2N_2O_2 \xrightarrow{k} H_2O + N_2O$$

For preparation of nitramide, *v.* (512). First-order k; t in minutes; solvent, water; all values at 15°C (93).

$k = k_0 + k_cC_{cat.}$, where k_0 is the constant for the uncatalyzed reaction and k_c that with a catalyst of concn. $C_{cat.}$, M/l. All substances which decrease the [H⁺] of the solution act as catalyzers. $k_0' = 366$ to 398×10^{-6}, mean = 0.0_338.

Catalysis Constants for Anions of Acids

Values of k_c for the anions of weak monobasic acids, and their relation to the ionization constants, k_D

Acid	k_c'	$100k_D$	$10^5k_c' \times k_D{}^{0.83}$
Propionate	0.65	0.00134	5.9
Acetate	0.50	0.0018	5.8
Phenylacetate	0.23	0.0053	6.5
Benzoate	0.19	0.0065	6.3
Formate	0.082	0.021	7.2
Salicylate	0.021	0.1	6.2
Dichloroacetate	0.0007	5.0	5.8
			Mean: 6.2

In the case of polybasic acids the value of k_c for each anion was found to be similarly related to the corresponding ionization constant when the latter is corrected by a "statistical" factor, n, as illustrated below. The subscripts 1 and 2 refer to the first and second ionization stages, respectively.

Catalysis Constants for Anions of Acids.—(*Continued*)

Acid	$10^3k_{D_1}$	n	k_{c_1}'	$10^5k_{c_1}'(nk_{D_1})^{0.83}$	$10^5k_{D_2}$	n	k_{c_2}'	$10^5k_{c_2}'(nk_{D_2})^{0.83}$
Succinic	0.065	$\frac{1}{2}$	0.320	6.0	0.21	2	1.8	6.2
Malic	0.40	$\frac{1}{2}$	0.0765	6.4	0.69	2	0.72	6.8
Tartaric	0.97	$\frac{1}{2}$	0.0363	6.3	3.7	2	0.165	6.2
Phthalic	1.2	$\frac{1}{2}$	0.029	6.2				
Oxalic					4.5	2	0.104	4.8
Phosphoric	8.9	$\frac{1}{3}$	0.0079	6.3	0.0049	1	86	7.2
			Mean:	6.2			Mean:	6.2

Catalysis Constant for Bases

The "acid" equilibrium constant of the base, RNH_2, is $k_B = [RNH_2][H^+]/[RNH_3^+]$

	Aniline	Quinoline	Dimethylaniline	Pyridine
10^5k_B	2.0	1.2	0.63	0.44
k_c'	0.531	1.9	2.7	4.6

For applications of the nitramide method to the determination of the ionization constants of (*a*) weak acids, (*b*) unsymmetrical dibasic acids, (*c*) H_2CO_3 (true constant), and (*d*) pseudo acids, *v.* (93).

HYDROGEN PEROXIDE

$$H_2O_2 \xrightarrow{k} H_2O + \tfrac{1}{2}O_2 \text{ (aqueous solution)}$$

Homogeneous Catalysis

Catalysis by Alkalies

First-order k; t in minutes; θ = 40°C (100)

[NaOH]	0.0004	0.0016	0.008	0.04	0.16
10^3k	0.896	1.67	3.06	4.51	7.90

Base, 0.04N	NaOH	KOH	NH_4OH	$Ba(OH)_2$
10^3k	4.51	4.68	3.98	2.26

Effect of temperature in 0.04N NaOH

10^3k	1.06	3.08	5.16	7.90	13.4	17.3	38.9	58.8
Q_{10}		2.9	2.6		2.2		2.2	1.5

Catalysis by Iodide Ion

According to Abel (3), the reactions are $H_2O_2 + I_2 \longrightarrow 2H^+ + 2I^- + O_2$ [for kinetics, *v.* (5)] and $H_2O_2 + 2H^+ + 2I^- \longrightarrow 2H_2O + I_2$. For t in minutes; first-order $k_{cat.} = k[I^-]$. At 25°C, k = 1.33 (84, 534); *cf.* (89); = 1.4 (3); = 1.38 (241).

Neutral salts alone have slight influence. In the presence of iodide their pronounced catalytic effects increase in the order K⁺, Na⁺, Li⁺ (241, 537, 538, 540).

In cases where the H_2O activity is constant, this catalysis by a neutral chloride is related to the Cl⁻-activity, a, by the simple rule, $k_{cat.}/a$ = constant, for the same salt concentration (240).

Catalysis by $K_2Cr_2O_7$

$$-\frac{d[H_2O_2]}{dt} = k[K_2Cr_2O_7][H_2O_2]$$

t in minutes; θ = 25°C; k = 20.9 to 34.5 in the interval $[K_2Cr_2O_7]$ = 0.009 to 0.0_43 (494); *cf.* (421, 495).

Heterogeneous Catalysis

By Colloidal Platinum

First-order k; t in minutes; θ = 25°C; Pt, 1 to 31 500 (76, 79), effect of age of Pt soln.

Pt-soln., days old	0	1	5
k'	0.023	0.025	0.022
k' (with Na_2HPO_4, 1 to 2000)	0.015	0.016	0.012

Effect of concentration of Pt soln.; $k = \text{constant} \times [\text{Pt}]^n$ where n is a constant dependent upon the nature of the Pt preparation.

1.13×10^6 [Pt]		32	24	16	12	6	4	3
n = 1.58	$10^3k'$(obs.)	115	72	40	24	8.4	4.6	2.7
	$10^3k'$(calc.)	115	74	39	24	8.2	4.3	2.7

Effect of Poisons

The catalytic action of colloidal Pt is diminished by various "poisons" most of which are likewise physiological poisons. With certain of these poisons the catalyst, toward the end of the reaction, partially "recovers" from the effects. This is illustrated by the following table for HCN on [Pt] = 1.03×10^{-5}.

10^6[HCN]	0	0.05	0.1	0.2	0.5	1	2
$10^2k'$, (begin)	4.1	1.6	1.3	0.75	0.33	0.20	0.15
$10^2k'$ (end)	4.1	2.4	1.5	0.86	0.36	0.29	0.35

List of "Poisons" (* = Partial Recovery)

Powerful "poisons:" HCN*, ICN, I_2, $HgCl_2$, H_2S, $Na_2S_2O_3$, CO*, P, PH_3, AsH_3, $Hg(CN)_2$, CS_2.

Moderate "poisons:" aniline, hydroxylamine,* Br_2, HCl, oxalic acid, amyl nitrite, As_2O_3, Na_2SO_3,* NH_4Cl.

Weak "poisons:" H_3PO_3, $NaNO_3$, HNO_2, pyrogallol, nitrobenzene, HF, NH_4F.

Inactive substances: dilute $KClO_3$, ethyl and amyl alcohols, ether, glycerol, turpentine, chloroform.

Positive catalysts, ("tonics"): formic acid, hydrazine, dilute HNO_3.

By Colloidal Palladium

First-order k; t in minutes; $\theta = 25°C$ (75)

[Pd]	[NaOH]	k	[Pd]	[NaOH]	k
0	1:33 000	0	1:13 200*	1:6 000	0.0073
1:100 000	1:33 000	0.003	1: 6 600	1:3 000	0.0045

Temp. interval, °C	25–35	35–45	45–55
Q_{10}	1.28	1.28	1.28

By Mercury

For pulsating catalysis on Hg surface, *v.* (19, 68)

The thinnest Hg layer on gold which exhibits catalytic action is *ca.* 3×10^{-8} cm thick (85).

Dianthracene ⟶ Anthracene

$$C_{28}H_{20} \xrightarrow{k} 2C_{14}H_{10}$$

Gravimetric method; first-order k; t in minutes (349)

Solvent	°C	10^4k	Q_{10}
Phenetole	170	39.0	
	167	28.6	2.8
	160	13.9	2.8
Anisole	154	6.7	

The reaction is complete in the dark.

Na Isonitrosoacetophenone $\xrightarrow{k}$ Na Benzoate + HCN

$$C_6H_5COCH{:}NONa \xrightarrow{k} C_6H_5COONa + HCN$$

Colorimetric method; first-order k; t in minutes (489)

In H_2O	°C	35.6	60.1	69.0	70.0	Q_{10}
	$10^3k'$	0.62	2.3	4.5	4.8	3.5

Effect of solvent at 60.1°C

Aqueous	$10^3k'$	Solvent	$10^3k'$
0.1*N* NaOH	1.4	50% C_2H_5OH	1.3
N NaOH	1.5	97% C_2H_5OH	1.0
N NaCl	1.5	97% CH_3OH	1.8
10*N* NaOH	2.2	100% CH_3OH	1.7

Hydrazobenzene ⟶ Aniline + Azobenzene

$$2C_6H_5NHNHC_6H_5 \xrightarrow{k} 2C_6H_5NH_2 + C_6H_5N{:}NC_6H_5$$

Titrimetric method; first-order k; t in minutes (499)

In C_2H_5OH dried with Na, $k = 0.00156$ at 140.3°C. Authors conclude that free radicals are formed as intermediate step.

Xanthogenic Acid

$$CS(SH)(OC_2H_5) \longrightarrow CS_2 + C_2H_5OH$$

Autocatalyzed by the alcohol. $\frac{dx}{dt} = (k + k_0x)(a - x)$. At the beginning of the reaction and in media where the reaction is rapid k_0x is negligible in comparison with k and the reaction is of first order.

Titrimetric method; t in minutes (233)

Solvent	k', 0°C	k', 25°C	A′
CS_2		0.0_5132	
Ligroin	0.0_6190	0.0_5198	2500

Acetoacetic Acid $\longrightarrow$ Acetone + CO_2

$CH_3COCH_2CO_2H \longrightarrow CH_3COCH_3 + CO_2$; solvent, H_2O

Both the undissociated acid (HA) and its anion (A^-) undergo the reaction:

$$\frac{d[CO_2]}{dt} = k_1[HA] + k_2[A^-]$$

Let k_D = the ionization constant and α the degree of ionization of the aceto-acid, then

$$\frac{dx}{dt} = k_1[(1 - \alpha) + k_2\alpha](a - x)$$

$$\frac{dx}{dt} = [k_1[H^+] + k_2k_D]\frac{(a - x)}{[H^+] + k_D}$$

k_1 is measured in strongly acid and k_2 in strongly alkaline solution. k_1 and k_2 together with a velocity measurement in an acetic acid-acetate solution give k_D. t in minutes (551); *cf.* (343). For preparation of the aceto-acid, *v.* (344).

°C	10^3k_1	10^3k_2	10^3k_D	Q_{10}
25	0.99	0.02	0.316	3.53(k_1)
37	4.5	0.08	0.24	3.16(k_2)

Catalysis by Aniline

This reaction is of interest because, as in the case of many biochemical reactions, there is a maximum catalytic effect at a given $[H^+]$. For details, *v.* (552).

Trichloroacetic Acid $\longrightarrow$ Chloroform + CO_2

$$CCl_3CO_2H \xrightarrow{k} CHCl_3 + CO_2$$

First-order k; t in minutes; solvent, aniline (207). 10^3k = 0.040 at 25°C; = 0.80 at 45°C; Q_{10} = 4.47. Addition of picric acid does not influence the velocity.

Aminobenzoic Acid $\longrightarrow$ Aniline + CO_2

$$C_6H_4(NH_2)CO_2H \xrightarrow{k} C_6H_5NH_2 + CO_2$$

Titrimetric method; first-order k; t in hours; solvent, H_2O; Temp. = B. P. of the solution (351)

Solution	10^3k
2 g Anthranilic acid in 150 cm³ H_2O...............	27
3 g Anthranilic acid in 200 cm³ H_2O...............	30
2 g *p*-Aminobenzoic acid* in 200 cm³ H_2O...........	15

* *m*-Aminobenzoic acid does not react.

d-Camphorcarboxylic acid $\longrightarrow$ Camphor + CO_2

First-order k; t in minutes (30, 69); reaction in aqueous solution; no catalytic effect by H^+ or OH^-

°C	78	88	98	Q_{10}
10^3k for the undissociated acid	0.214	0.669	2.12	3.14
10^3k for the anion of the acid			0.063	

In C_6H_6, A = 14 040	°C	68	78	88	98
	10^3k	0.305	0.958	2.91	8.48
	Q_{10}		3.14	3.04	2.91

At 98°C	In	$C_6H_5NH_2$	C_2H_5OH	C_6H_6
	10^3k	32.50	10.40	8.48

At 98°C	In	$C_6H_5OC_2H_5$	$(C_2H_5)_2O$	H_2O
	10^3k	7.36	3.02	2.12

In alcohol, esterification takes place also with a first-order $k = 0.0102$. Bases act as catalyzers; optically inactive bases act the same on the d- and the l-acids, but active bases act more powerfully on the d-acid (73, 75).

°C	Solvent	10^3k	
		d-	l-
80	Aniline	6.76	6.63
80	Acetophenone	1.14	1.15
90		3.57	3.55
70	Nitrobenzene	0.333	
70	Nicotine	4.88	4.34
70	20 cm³ Nitrobenzene + 1.02 cm³ Nicotine	3.02	2.79
70	10 cm³ Acetophenone + 1.00 cm³ Nicotine	2.77	2.33
75	10 cm³ Acetophenone + 1.65 g Quinidine	6.46	4.42

The dl-acid is made optically active by catalysis with an optically active base. The optical activity attains a maximum at the time,

$$t = \frac{1}{k_l + k_d} \log_e \frac{k_l}{k_d},$$

where k_l (resp. k_d), are the constants of the two isomers. For asymmetric synthesis, v. (74).

The catalytic action of bases in general can be interpreted in terms of two velocity constants, one for the free acid and one for its salt. For details, v. (77, 285).

Bromocamphorcarboxylic acid $\longrightarrow$ Bromocamphor + CO_2

First-order k; t in minutes (128, 128.5)

d- or l- acid in Acetophenone	°C	60	70	80
	10^3k	2.16	5.03	12.1
	Q_{10}		2.37	2.40

In ethyl benzoate as solvent the acid is polymerized (2x), and the decomposition is a second-order reaction. It is catalyzed by bases. Quinine catalyzes the l-acid; quinidine, the d-acid, more rapidly.

Dissociation of Carboxylic Acids with the Production of CO or HCO_2H

OXALIC ACID $\longrightarrow$ $CO + CO_2 + H_2O$

$$(CO_2H)_2 \longrightarrow CO + CO_2 + H_2O$$

First-order k; t in minutes; solvent, H_2SO_4 + various % H_2O. Even at 0°C the reaction is too rapid to be measured in H_2SO_4 containing 1% SO_3 (78, 338).

%H_2O	0.60	0.70	0.80	1.00	1.20	1.50	2.00	3.00

40	25	8.44		0.512	40	25	8.68	
25	25	8.90		0.738	25	25	8.95	

Measurements by Schierz; same units (434)

%H_2SO_4	98.9	97.6	94.5	91.8	89.2	85.0
$10^3k'$, 25°C	320.0	106.0	31.5	10.5	2.38	0.751
$10^3k'$, 15°C		32.6	9.9	3.29		
E		18 520	19 670	19 720		

In acetic anhydride as solvent the mixed anhydride CH_3CO_2OCH is formed. For details of the reaction with various catalyzers, v. (535). For application of this reaction to the determination of acetic acid in acetic anhydride, v. (434).

CHLORAL HYDRATE

$$CCl_3CH(OH)_2 + NaOH \longrightarrow CHCl_3 + HCO_2Na + H_2O$$

The equilibrium:

$$CCl_3CH(OH)_2 + OH^- \rightleftharpoons CCl_3CH(OH)O^- + H_2O \qquad (I)$$

is rapidly established in alkaline solution and is followed by the slower reaction:

$$CCl_3CH(OH)O^- \xrightarrow{k} CCl_3H + HCOO^- \qquad (II)$$

At low temperatures in strongly alkaline solutions the equilibrium (I) is displaced to the right and the net reaction is (II) with first-order k.

Titrimetric method; first-order k; t in minutes; reaction mixture: 1 liter, composed of a moles chloral hydrate and b equivalents of base, the titer being T, hence

$$k' = \frac{1}{t} \log_{10} \frac{b - T_\infty}{T - T_\infty} \cdot [OH^-] = b - a$$

Measurements at 0°C, with KOH and with a = 0.01 (164)

b	b − a	k'	$k'/(b - a)$
0.012	0.002	0.0062	3.10
0.014	0.004	0.0134	3.35
0.016	0.006	0.0204	3.40

For the first solution ($k' = 0.0062$) we have therefore

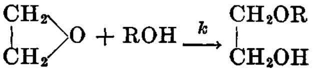
$$\frac{d[HCOO^-]}{dt} = 7.1[OH^-][CCl_3CH(OH)O^-] \text{ at } 0°C$$

Neutral salts catalyze the reaction as in the case of sugar inversion by acids.

With increasing temperature ($Q_{10} = 5$), hydrolysis of the chloral salt increases and the constant k' exhibits a progressive decrease; *cf*. (57, 412, 548).

Addition Reactions

ADDITION OF PHENOLS TO OLEFIN OXIDES IN 98% ALCOHOL



$$\begin{matrix} CH_2 \\ | \\ CH_2 \end{matrix}\!\!>O + ROH \xrightarrow{k} \begin{matrix} CH_2OR \\ | \\ CH_2OH \end{matrix}$$

With pure phenol the reaction proceeds slowly, catalyzed by the phenolate (59, 60):

$$\begin{array}{ll} (CH_2)_2O + RO^- \longrightarrow CH_2(OR)CH_2O^- & \text{(measurable)} \\ CH_2(OR)CH_2O^- + ROH \longrightarrow & \\ \quad CH_2(OR)CH_2(OH) + RO^- & \text{(rapid)} \\ \hline (CH_2)_2O + ROH \longrightarrow CH_2(OR)CH_2(OH) & \text{(net reaction)} \end{array}$$

At *constant* concentration of phenol, k for olefin oxides is of first-order. Gravimetric method; t in hours; [ROH] = 1; [RONa] = 0.05; θ = 70.4°C (59, 60). (I) k' for ethylene oxide = $0.4343k$; (II) k' for propylene oxide = $0.4343k$.

Average values in the benzene solution: $k_1 = 4 \times 10^{-3}$; $k_2 = 13.3 \times 10^{-3}$; $K = 0.3$.

POLYMERIZATION OF CYANAMIDE TO DICYANDIAMIDE BY AQUEOUS ALKALIES

$$2CNNH_2 \xrightarrow{k} (CNNH_2)_2$$

The velocity in 0.125N NaOH is a maximum (223, 224) which accords with the relation:

$$\frac{d[(CNNH_2)_2]}{dt} = k[CNNH^-][CNNH_2]$$

ADDITION OF BROMINE TO DOUBLE BONDS

$$CHCl{:}CHCl + Br_2 \xrightarrow{k} CHClBrCHClBr$$

First-order k if the concn. of olefin as solvent is constant; t in hours; θ = 25°C (249); *cf.* (31, 248).

Olefin	Formula	$k' = 0.4343k$
cis-Dichloroethylene	CHCl: CHCl	0.024
trans-Dichloroethylene	CHCl: CHCl	0.012
Tetrachloroethylene	$CCl_2{:}CCl_2$	0.077

ADDITION OF OLEFINS TO ORGANIC ACIDS TO FORM ESTERS

Acetic acid scarcely reacts with amylene. The equilibrium is toward the side of the dissociation product. In general, ester formation is more nearly complete the stronger the acid.

$$CH(CH_3){:}\,C(CH_3)_2 + CHCl_2CO_2H \rightleftharpoons CHCl_2CO_2C(CH_2CH_3)(CH_3)_2$$

$$CH(CH_3){:}\,C(CH_3)_2 + CCl_3CO_2H \rightleftharpoons CCl_3CO_2C(CH_2CH_3)(CH_3)_2$$

Reaction with Excess of Amylene

The reaction is of the third-order with respect to the acid and runs to completion at low temperatures:

$$\frac{1}{V}\frac{dx}{dt} = k\left(\frac{1 - x}{V}\right)^3$$

$$k' = \frac{1}{t - t_0}\left(\frac{1}{(1 - x)^2} - \frac{1}{(1 - x_0)^2}\right) = \frac{\text{constant}}{V^2}$$

Trichloroacetic Acid (382)

Titrimetric method; V = dilution per mole; t in minutes

Mole		V in cm³	°C	k'	$10^4k'V^2$
Acid	Amylene				
1	6.8	915	28.7	0.037	3.10
1	15.75	1986	28.7	0.0079	3.12
1	4.124	595.6	31.2	0.127	4.50
1	7.663	1018	31.2	0.041	4.25

$Q_{10} = 3.93$

The acid which combines acts therefore simultaneously as a catalyst according to its second power.

Equilibrium Reaction

$$\underset{(a - x)}{\text{Amylene}} + \underset{(b - x)}{\text{Acid}} \underset{k_1}{\overset{k}{\rightleftharpoons}} \underset{x}{\text{Amyl Ester}}$$

Both reactions are catalyzed by the acid according to the second power, hence

$$\frac{1}{V}\frac{dx}{dt} = \frac{k}{V^4}(a - x)(b - x)^3 - \frac{k'}{V^3}[x(b - x)^2]$$

Integration for b = 1 gives approximately

$$C = \frac{k(1 - \xi_1)^2\xi_2^2}{V^3(\xi_1 + \xi_2)} = \frac{1}{t}\left[\log_e \frac{\xi_1(1 - x)}{\xi_1 - x} - (1 - \xi_1)\left(1 + \frac{1 - \xi_1}{\xi_1 + \xi_2}\right)\left(\frac{1}{1 - x} - 1\right)\right]$$

where

$$\xi_1 = x \text{ for } t = \infty$$

$$\xi_2 = \frac{a}{\xi_1} \text{ for } t \text{ in minutes.}$$

Dichloroacetic Acid and Amylene at 100°C (382)

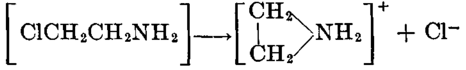
For the velocity of formation of $(C_2H_5)_3SI$, *v.* (106).

Coordination Reactions

By this is understood reactions of the type:

$$[Co(NH_3)_5Cl]^{++} + H_2O \longrightarrow [Co(NH_3)_5(H_2O)]^{+++} + Cl^-$$

and the analogous reaction of alkyl halogen amines in forming heterocyclic compounds:



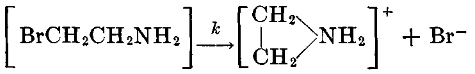
$$\left[ClCH_2CH_2NH_2\right] \longrightarrow \left[\begin{matrix}CH_2\\ |\\ CH_2\end{matrix}\!\!>NH_2\right]^+ + Cl^-$$

ALKYL HALOGEN AMINES (188, 189, 190, 192)

In alkaline media the first-order reaction runs to completion with the formation of a heterocyclic compound; in acid media the reverse reaction runs to completion; in neutral media the reaction reaches a measurable equilibrium but is accompanied by a side reaction.

Method: volumetric and coagulation of As_2S_3 sol; k, first-order; t in minutes.

Conversion of β-Bromoethylamine into Ethyleneimine in aqueous alkaline solution:

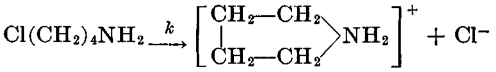


$$\left[BrCH_2CH_2NH_2\right] \xrightarrow{k} \left[\begin{matrix}CH_2\\ |\\ CH_2\end{matrix}\!\!>NH_2\right]^+ + Br^-$$

°C	0	16.65	25
10^2k	0.068	0.89	2.9

$$\log_e k = -\frac{12579}{T} + 38.770$$

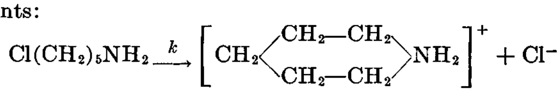
Conversion of δ-Chlorobutylamine into Pyrrolidine in aqueous alkaline solution:



$$Cl(CH_2)_4NH_2 \xrightarrow{k} \left[\begin{matrix}CH_2{-}CH_2\\ |\qquad\\ CH_2{-}CH_2\end{matrix}\!\!>NH_2\right]^+ + Cl^-$$

°C	0	25	Q_{10}
k	0.021	0.45	3.6

Conversion of ε-Chloroamylamine into Piperidine in various solvents:



$$Cl(CH_2)_5NH_2 \xrightarrow{k} \left[CH_2\!\!<\begin{matrix}CH_2{-}CH_2\\ CH_2{-}CH_2\end{matrix}\!\!>NH_2\right]^+ + Cl^-$$

The solvents immiscible with water were saturated with H_2O.

Solvent	10^2k, °C

Coordination Reactions in Stages

The complete conversion of green dichlorotetraaquochromic chloride $[CrCl_2(H_2O)_4]Cl$ into blue hexaaquochromic chloride $[Cr(H_2O)_6]Cl_3$ takes place in dilute aqueous solution:

$$[CrCl_2(H_2O)_4]^+ \xrightarrow{k_1} [CrCl(H_2O)_5]^{++} \xrightarrow{k_2} [Cr(H_2O)_6]^{+++}$$

k_1 and k_2 are first-order constants.

Conductivity method; t in minutes; $\theta = 0°C$ (46, 328). s = Concn. of HCl added, M/l. a = Initial concn. of green dichlorochloride, M/l; k_1 refers to the beginning ($t = 0$) and k_2 to the end of the reaction.

Neutral salts have no significant influence. The influence of temperature is great. For k_1, $Q_{10} = 4.80$ between 1 and 25°, = 3.80 between 20 and 25°; for k_2, $Q_{10} = 4.00$ between 20 and 25° (46).

At 25°C, k_1 and k_2 are expressed by the equations:

$$k_1 = 0.00272 + \frac{0.0000162}{[H^+]} \quad (46)$$

$$k_1 = 0.00265 + \frac{0.0000142}{[H^+]} \quad (328)$$

$$k_2 = \frac{3.1 \times 10^{-6}}{[H^+]} + \frac{5 \times 10^{-10}}{[H^+]^2} \quad (46)$$

k_1 and k_2 are aggregates of the velocity of conversion of the separate forms in which the reacting salts may appear. The hydrolytic forms act more rapidly than the ions. The first-order constants of the following forms have the values indicated (46):

$$[CrCl_2(H_2O)_4]^+ = 0.00272$$
$$[CrCl_2(H_2O)_3(OH)] = 4.26$$
$$[CrCl(H_2O)_4(OH)]^+ = 0.36$$

According to Lamb and Fonda (328) the hydrolysis constants are:

$$[CrCl_2(H_2O)_3(OH)][H^+] = 2.05 \times 10^{-6}[CrCl_2(H_2O)_4]^+$$
$$[Cr(H_2O)_5(OH)]^{++}[H^+] = 1.6 \times 10^{-4}[Cr(H_2O)_6]^{+++}$$

The large temperature coefficients of k_1 and k_2 are caused by the great increase of hydrolysis with increasing temperature. The reaction: green chromic salt ⟶ blue chromic salt is an example of the negative catalysis of hydrogen ion. For other work on negative catalysis, *see* (45, 514, 563).

Rearrangement of Dyestuffs and Indicators

Carbinol Form ⇄ Quinoid Form

Colorimetric method; t in minutes; aqueous solution with 7% alcohol; first-order $k' = 0.0434\ k$ (43); *cf.* (15, 38, 197, 236, 237, 374, 433).

THE ABSORPTION SPECTRA OF DYES

WALTER C. HOLMES

ARRANGEMENT, SYMBOLS, UNITS AND CONVENTIONS

The following tables are designed to supplement the tables of spectroscopic data on technical synthetic dyes supplied by Formánek and Grandmougin in their "Untersuchung und Nachweis organischer Farbstoffe auf spektroskopischem Wege" and the review of the spectroscopy of natural coloring matters found in Kayser's "Handbuch der Spektroskopie."

The primary aim has been that of affording a ready means of ascertaining what data are available for any given coloring matter. With this end in view the selection of dyes has been made as comprehensive and the literature references as complete as possible. There have also been recorded numerous data on the spectral location of the maxima of absorption bands, under various conditions, in the ultra-violet, visible and infra-red, which will usually prove adequate to those interested in the identification of dyes or in the correlation of color and constitution. If a more complete qualitative or quantitative definition of the absorption is desired it may, in numerous instances, be obtained readily by consulting the references recorded.

Synthetic dyes have been arranged by classes in twelve tables and listed in the order of their constitutional formulae. Natural coloring matters have been listed in alphabetical sequence in Table 13. The dye formulae are followed by the scientific names of the coloring matters, supplemented, in some instances, by names of more common usage and by C. I. (Colour Index of the Society of Dyers and Colourists) numbers.

All absorption maxima in the ultra-violet and visible spectrum are recorded in terms of wave length in millimicrons. Italicized values refer to the principal bands and bracketed values to relatively insignificant bands. (The common bracketing of several values signifies multiple maxima in a single band.) The absorption data are followed by reference numbers to the source from which they were taken, together with further reference numbers to other literature on the dye in question which may prove of further interest. References followed by (q) contain data on the more definitely quantitative aspect of the absorption.

In instances in which various data of independent origin have been available the recorded values are those which have appeared the more reliable to the writer. The question of the dependence which may be placed upon the greater portion of the material presented is left to the discrimination of the reader. Since data

Les tables suivantes ont pour objet de compléter les tables des données spectroscopiques concernant les colorants synthétiques techniques présentées par Formánek et Grandmougin dans leur ouvrage "Untersuchung und Nachweis organischer Farbstoffe auf spektroskopischem Wege" et la revue de la spectroscopie des matières colorantes naturelles, qui se trouve dans l'ouvrage de Kayser "Handbuch der Spektroskopie."

L'objectif principal a été celui de procurer un moyen rapide de s'assurer quelles données sont disponibles pour une matière colorante donnée. À cette fin la sélection des colorants a été faite aussi étendue et les références bibliographiques aussi complètes que possible. Il a aussi été mentionné un très grand nombre de données sur la position spectrale des maxima des bandes d'absorption, pour des conditions variées, dans l'ultra-violet, le visible et l'infra-rouge, qui se révèleront ordinairement suffisantes pour ceux qui s'occupent de l'identification des colorants ou de la corrélation entre la couleur et la constitution. Si une définition qualitative ou quantitative plus complète de l'absorption est désirée, celle-ci pourra être obtenue promptement dans bien des cas en consultant les références mentionnées.

Les colorants synthétiques ont été arrangés par classes en douze tables et sont inscrits en listes suivant l'ordre de leurs formules de constitution. Les matières colorantes naturelles ont été disposées dans l'ordre alphabétique dans la Table 13.

Les formules des colorants sont suivies des noms scientifiques des matières colorantes, complétés dans certains cas par les noms d'un usage plus courant, et les nombres C. I. (Colour Index of the Society of Dyers and Colourists). Tous les maxima d'absorption dans les spectres ultra-violet et visible sont exprimés en millimicrons. Les valeurs en italique concernent les bandes principales, et les valeurs entre crochets ont rapport à des bandes relativement insignifiantes. (Plusieurs valeurs comprises entre deux crochets signifient des maxima multiples dans une seule bande.) Les données d'absorption sont suivies de nombres de référence indiquant la source dont elles proviennent; d'autres nombres de référence mentionnés à la suite se rapportent à d'autres sources bibliographiques relatives aux colorants en question qui peuvent présenter par surcroit un certain intérêt. Les références suivies de (q) signifient la disponibilité de données au point de vue plus défini de l'aspect quantitatif de l'absorption.

available for a given dye are meager and difficult to locate, in general, and since any information may be of service, it has not been considered advisable to exclude any material of definite character.

Die folgenden Tafeln bilden eine Ergänzung (1) zu den Tafeln spektroskopischer Werte technischer synthetischer Farbstoffe, die von Formánek und Grandmougin in ihrem Werke "Untersuchung und Nachweis organischer Farbstoffe auf spektroskopischem Wege" beigegeben sind. Sie ergänzen (2) die Zusammenstellung über die Spektroskopie natürlicher Farbstoffe, die Kayser in seinem "Handbuch der Spektroskopie" gegeben hat.

Das Hauptziel war, ein bequemes Mittel für die Feststellung zu schaffen, welche Werte für einen bestimmten färbenden Stoff zu Gebote stehen. Unter diesem Gesichtspunkte geschah die Auswahle der Farbstoffe so umfassend wie möglich und der Nachweis der Literatur möglichst vollständig. Dort wurden zahlreiche Angaben über die spektrale Lage der Maxima von Absorptionsbanden zusammengetragen und zwar für verschiedene Bedingungen: im sichtbaren, Ultraviolett und Infrarot. In der Regel werden sie sich als ausreichend erweisen für diejenigen Forscher, denen an der Identifizierung von Farbstoffen oder an der Beziehung von Farbe und Konstitution gelegen ist. Braucht man eine vollständigere qualitative oder quantitative Definition der Absorption, so ist sie in zahlreichen Fällen bequem zu erhalten, wenn man die gesammelten Literaturangaben einsieht.

Synthetische Farbstoffe sind nach Klassen in zwölf Tafeln angeordnet und in der Reihenfolge ihrer Konstitutionsformeln aufgeführt. Natürliche Farbstoffe sind in alphabetischer Folge in Tafel 13 gesammelt.

Den Formeln der Farbstoffe folgen die wissenschaftlichen Namen der färbenden Stoffe. Zur Ergänzung dienen in einigen Fällen mehr allgemein gebräuchliche Bezeichnungen und die C. I. Nummern (des "Colour Index of the Society of Dyers and Colourists"). Alle Absorptions-Maxima im Ultraviolett und in sichtbaren Spektren sind in Millimikron angegeben. Kursiv (in Schrägschrift) gesetzte Werte beziehen sich auf die Hauptbanden, eingeklammerte Werte beziehen sich auf verhältnismässig unbedeutende Banden. (Das Zusammenklammern verschiedener Werte bedeutet mehrere Maxima in einer einzelnen Bande.) Auf die Absorptionswerte folgen die Nummern-Angaben anderer Literaturstellen für die in Rede stehenden Farbstoffe, die von weiterem Interesse sein können. Angaben, die mit einem (q) versehen sind, kennzeichnen die Brauchbarkeit von Werten für die mehr quantitative Betrachtung der Absorption.

In Fällen, in denen verschiedene Werte aus von einander unabhängigen Quellen zur Verfügung standen, hat der Herausgeber die ihm zuverlässiger erscheinenden Werte aufgenommen. Die Frage der Verlässlichkeit, die für einen grossen Teil des Stoffes gestellt werden kann, ist der Entscheidung des Lesers überlassen. Im allgemeinen sind die für einen bestimmten Farbstoff verfügbaren Werte so dürftig und auch so schwierig festzustellen—während auch der geringste Nachweis schon von Nutzen sein kann—dass es nicht ratsam erschien, irgendwelche Unterlagen bestimmten Charakters fortzulassen.

Dans le cas où des données diverses d'origines différentes ont été disponibles, les valeurs mentionnées sont celles qui ont paru les plus dignes de confiance au rédacteur. La question de la confiance, qui peut être placée dans la plus grande portion de la matière présentée, est laissée à la discrimination du lecteur. Comme les données disponibles pour un colorant donné sont en général peu abondantes et difficiles à trouver et comme chaque information peut être utile, il a été considéré comme judicieux de n'exclure aucune matière présentant un caractère défini.

Le seguenti tabelle sono compilate come complemento delle tabelle di dati spettroscopici sulle sostanze coloranti sintetiche di uso industriale dati da Formánek e Grandmougin nella loro "Untersuchung und Nachweis organischer Farbstoffe auf spektroskopischem Wege" e sulle sostanze coloranti naturali contenute nel "Handbuch der Spektroskopie" di Kayser.

Il principale nostro scopo è stato quello di fornire un modo rapido per stabilire quali sono i dati dei quali si dispone per qualsiasi sostanza colorante. Tenendo presente questo fine si è tenuto conto del maggior numero possibile di sostanze coloranti, e si è riportato nel modo più completo la bibliografia. Abbiamo pure riportato un considerevole numero di dati sopra la posizione dei massimi nelle bande di assorbimento in diverse condizioni, nell'ultra-violetto, nel visibile e nell'infra-rosso, i quali dati potranno bastare per chi si interessa della identificazione dei coloranti o dei rapporti tra colore e costituzione. Se si vuole un quadro più completo, dal punto di vista qualitativo o quantitativo, dell'assorbimento, lo si può ottenere subito in molti casi consultando le citazioni riportate.

I coloranti sintetici sono stati disposti per classi in dodici tavole e ordinati in base alle loro formule di costituzione. Le sostanze coloranti naturali sono state messe in ordine alfabetico nella Tavola 13.

Le formule dei coloranti sono seguite dai nomi scientifici della sostanza colorante completati in alcuni casi con i nomi di uso più comune e con i numeri del C. I. (Colour Index of the Society of Dyers and Colourists). Tutti i massimi di assorbimento nell'ultravioletto e nello spettro visibile sono riportati in millimicron. I valori in italici si riferiscono alle principali bande e i valori fra parentesi alle bande relativamente insignificanti. (Le parentesi comuni che racchiudono vari valori significano massimi multipli in una stessa banda.) I dati degli assorbimenti sono seguiti da numeri che si riferiscono alla memoria dalle quali sono stati presi insieme con altri numeri di riferimento ad altra letteratura sul colorante in questione, che può essere di ulteriore interesse. Quando una citazione è seguita da (q) significa che si hanno a disposizione dati quantitativi sull'assorbimento.

Nei casi nei quali si sono potuti avere dati di origine indipendente, i valori riportati sono quelli che sono sembrati i più attendibili al compilatore. La questione della fiducia che si può avere nella maggior parte dei dati riprodotti è lasciata al criterio del lettore. Siccome i valori ottenibili per un dato colorante sono in genere rari e difficili a rintracciare e siccome qualsiasi informazione può essere utile, non abbiamo creduto opportuno di escludere nessun dato di carattere definito.

$C_{12}H_8ClN_3O_3$.—*p*-Nitrobenzeneazo-*m*-chlorophenol: alkali salt, 556 in Me_2CO; 501 in EtOH; 470 in H_2O (643).

$C_{12}H_8N_4O_4$.—*p*-Dinitroazobenzene: 494 in H_2O (463).

$C_{12}H_9BrN_2O$.—Benzeneazo-*o*-bromophenol: 436, 390 in alk. H_2O (468).

p-Bromobenzeneazophenol: 445, 395 in alk. H_2O (468); *cf.* (595).

$C_{12}H_9ClN_2O$.—Chlorobenzeneazophenol: data on *o*-, *m*- and *p*-isomers (596).

$C_{12}H_9ClN_4$.—Azobenzenediazonium chloride: 340 in EtOH (260).

$C_{12}H_9IN_2$.—*p*-Iodoazobenzene: 340 in EtOH (476, *294* with HCl) (260).

$C_{12}H_9N_3O_3$.—*o*-Nitrobenzeneazophenol: 362, 235 in EtOH; *437*, 240 in alk. H_2O (62); 356 in EtOH (465 with NaOEt) (31); 487, 440 in alk. H_2O (468); *cf.* (596q, 622).

m-Nitrobenzeneazophenol: 350 in EtOH (459 with NaOEt) (31); *358*, 245 in EtOH; *436*, 262 in alk. H_2O (62); 480 in alk. H_2O (471); *cf.* (596q, 622).

p-Nitrobenzeneazophenol; *380*, 257 in EtOH; *478*, 273, (237) in alk. H_2O (62); alkali salt, 556 in Me_2CO; 505 in EtOH; 475 in H_2O (643); *cf.* (31, 468, 501, 521, 595, 596q, 624).

$C_{12}H_9N_3O_4$.—*o*-Nitrobenzeneazoresorcinol: abs. in visible and ultra-violet in neutral and alk. solns. (622).

m-Nitrobenzeneazoresorcinol; abs. in visible and ultra-violet in neutral and alk. solns. (624).

p-Nitrobenzeneazocatechol: abs. in visible and ultra-violet for neutral and alk. solns. (622).

p-Nitrobenzeneazoresorcinol: alkali salt, 605 in Me_2CO; 570 in EtOH; 550 in H_2O (643); *cf.* (501, 624).

p-Nitrobenzeneazohydroquinol: abs. in visible and ultra-violet for neutral and alk. solns. (622).

$C_{12}H_9N_3O_5$.—*p*-Nitrobenzeneazopyrogallol: alkali salt, 528 in Me_2CO (643); *cf.* (623).

p-Nitrobenzeneazophloroglucinol: abs. in visible and ultra-violet for neutral and alk. solns. (623).

$C_{12}H_9N_3O_6S$.—*p*-Nitrobenzeneazosulfocarbolate: alkali salt, 575 in Me_2CO; 514 in EtOH (643); data given in (501) are incorrect.

$C_{12}H_{10}N_2$.—Azobenzene: 463, 312 in H_2O (suspension) (471); 444, (345), *317* in EtOH; *417*, 280 in concd. HCl (59); 440 in H_2SO_4; 589 in fuming acid (diacid salt) (310). In EtOH, 455, 313 (84); (third band at 229) (393). Similar abs. in $CHCl_3$ (210) and in vapor form (532); *cf.* (26, 29, 111, 185q, 201q, 214, 220q, 231q, 385, 413, 516, 534q, 618).

$C_{12}H_{10}N_2O$.—Azoxybenzene: 323 in EtOH and in vapor form (532). Metallic salts (225); *cf.* (533).

o-Hydroxyazobenzene: 441, 390 in alk. H_2O; 480 in acid H_2O (468).

m-Hydroxyazobenzene: 415, 380 in alk. H_2O (468).

p-Hydroxyazobenzene (benzeneazophenol): 340, 315 in H_2O; 433, 395 with alkali; 490, 463 with acid (468); *429*, 268 in alk. H_2O (62); 331 in HCl (618); 465, 248 in H_2SO_4 (210); 360 in EtOH (*456*, 320 with NaOEt); 348 in Et_2O (211); (470), *355*, 235 in EtOH (62). Abs. in 30 organic solvents (12q). Abs. of various derivs. (185q, 220q); *cf.* (26, 111, 225, 469, 471, 475, 544, 595, 596q, 613q, 624).

$C_{12}H_{10}N_2O_2$.—2, 2′-Dihydroxyazobenzene: 490 in alk. H_2O (471).

2, 4-Dihydroxyazobenzene (benzeneazoresorcinol): 483 in alk. H_2O (471); *488*, 450 in H_2SO_4 (196); 408 in EtOH (352); *cf.* (624).

3, 3′-Dihydroxyazobenzene: 500, 475 in alk. H_2O (471).

3, 4-Dihydroxyazobenzene (benzeneazocatechol): 480, 430 in alk. H_2O (468); *cf.* (622).

2, 5-Dihydroxyazobenzene (benzeneazoquinol): abs. of neutral and alk. solns. in visible and ultra-violet (622).

2, 4′-Dihydroxyazobenzene: 490 in alk. H_2O (471).

3, 4′-Dihydroxyazobenzene: 480 in alk. H_2O (471).

4, 4′-Dihydroxyazobenzene: 473 in alk. H_2O, 360 in EtOH (463 with NaOEt) (619).

$C_{12}H_{10}N_2O_3$.—2, 3, 4-Trihydroxyazobenzene: abs. in visible and ultra-violet in neutral and alk. solns. (623).

2, 4, 2′-Trihydroxyazobenzene: 540, 492 in alk. H_2O (471).

2, 4, 4′-Trihydroxyazobenzene: 528, 490 in alk. H_2O (471).

2, 4, 5-Trihydroxyazobenzene: 505, 440, 345 in alk. H_2O (471).

2, 4, 6-Trihydroxyazobenzene: 460, 410 in alk. H_2O (471); *490*, 405 in H_2SO_4 (196); *cf.* (623).

3, 4, 4′-Trihydroxyazobenzene: 470, 535 in H_2O with Na_2CO_3; 470, 440 with $NaHCO_3$ (471).

3, 4, 5-Trihydroxyazobenzene: 515, 495, 420 in alk. H_2O (471).

$C_{12}H_{10}N_2O_3S$.—Azobenzene-*p*-sulfonic acid: 432 in H_2O over pH range 1–12 (613q).

$C_{12}H_{10}N_2O_4$.—2, 2′, 4, 4′-Tetrahydroxyazobenzene: 575, 540, 462 in H_2O with $NaHCO_3$ (471).

2, 4, 3′, 4′-Tetrahydroxyazobenzene: 585 in alk. H_2O (471).

3, 3′, 4, 4′-Tetrahydroxyazobenzene: 680 in alk. H_2O (471).

$C_{12}H_{10}N_2O_4S$.—*m*-Sulfobenzeneazophenol: 460, 410 in alk. H_2O (471).

p-Sulfobenzeneazophenol: 440, 400 in alk. H_2O (471); *cf.* (595, 613).

Benzeneazosulfocarbolate: 455 in alk. H_2O (468).

$C_{12}H_{10}N_2O_5S$.—*p*-Sulfobenzeneazocatechol: 520 with NaOH; 485 with Na_2CO_3 (471).

p-Sulfobenzeneazoresorcinol (C. I. 148): Na salt, 430 in H_2O (271); *cf.* (231q, 420q, 525q).

$C_{12}H_{10}N_2O_6S$.—*p*-Sulfobenzeneazophloroglucinol: 490 in H_2SO_4 (196).

$C_{12}H_{10}N_4O_2$.—3′-Nitro-4-aminoazobenzene: 518, 490 in acid H_2O (471).

$C_{12}H_{11}N_3$.—*m*-Aminoazobenzene: 430 in H_2O (pH 1) (613); (495 in acid H_2O (471)).

p-Aminoazobenzene: 490 in acid H_2O (pH 1) (613); 420 in H_2SO_4 (diacid salt); 556 in fuming acid (triacid salt); *395*, 250 in EtOH (300 with HCl) (310). Abs. of vapor (532); *cf.* (26, 260, 385, 463, 468, 469, 619).

Diazoaminobenzene: 361, 235 in EtOH; abs. of vapor (532).

$C_{12}H_{11}N_3O$.—Aminoazoxybenzene: 527 in acid H_2O (468).

3-Hydroxy-4′-aminoazobenzene: 490, 470 in acid H_2O; 485, 430 in alk. H_2O (471).

p-Aminobenzeneazophenol: 385 in EtOH; *546*, 354 in dil. HCl; 467 in conc. HCl (diacid salt) (261).

$C_{12}H_{11}N_3O_2$.—2-Amino-3′, 4-dihydroxyazobenzene: 478 in alk. H_2O; 490, 460 in acid H_2O (471).

5-Amino-2, 4′-dihydroxyazobenzene: 460 in alk. soln. (473).

$C_{12}H_{11}N_3O_3S$.—4-Sulfo-4′-aminoazobenzene (Aniline Orange): 485 in acid H_2O (pH 1) (613q); 448, (280) in dil. NaOH; 496 in dil. HCl (216).

$C_{12}H_{12}N_2$.—Hydrazobenzene: 290, *245* in EtOH (413); 310 in $CHCl_3$ (534).

$C_{12}H_{12}N_4$.—*p*-Diaminoazobenzene: 499 in acid H_2O (463); 603 in very dil. HOAc (monacid salt); 497, 310 in EtOH + 3% HCl (diacid salt); 410 in H_2SO_4 (triacid salt) (261).

Benzeneazo-*m*-phenylenediamine (hydrochloride, C. I. 20): Infra-red abs. (296). Acid salts (497); *cf.* (231q).

$C_{13}H_9N_3O_4$.—*p*-Nitrobenzeneazosalicylaldehyde: alkali salt, 564 in Me_2CO; 500 in EtOH; 478 in H_2O (643).

p-Nitrobenzeneazo-*p*-hydroxybenzaldehyde: alkali salt, 547 in Me_2CO; 494 in EtOH; 470 in H_2O (643).

$C_{13}H_9N_3O_5$.—*p*-Nitrobenzeneazosalicylic acid (C. I. 40): 609 in alk. Me_2CO; 555 in alk. EtOH; 514 in alk. H_2O (643); *cf.* (501, 525q, 595).

p-Nitrobenzeneazo-*m*-hydroxybenzoic acid: alkali salt, 583 in Me_2CO; 508 in EtOH; 474 in H_2O (643).

p-Nitrobenzeneazo-*p*-hydroxybenzoic acid: alkali salt, 566 in Me_2CO; 505 in EtOH; 475 in H_2O (643).

$C_{13}H_{10}ClN_3O_2$.—*p*-Nitrobenzeneazo-2-chloro-5-hydroxytoluene: alkali salt, 580 in Me_2CO; 524 in EtOH; 505 in H_2O (643).

$C_{13}H_{10}N_2O$.—Benzoylazobenzene: 294 in EtOH (?) (434).

$C_{13}H_{10}N_2O_3$.—4-Hydroxy-2-carboxyazobenzene: 445, 395 in alk. H_2O (471).

4-Hydroxy-2′-carboxyazobenzene: 435, 385 in alk. H_2O (471).

$C_{13}H_{10}N_2O_3$.—4-Hydroxy-3-carboxyazobenzene: 452, 402 in alk. H_2O (471).

4-Hydroxy-3′-carboxyazobenzene: 438, 388 in alk. H_2O (471).

4-Hydroxy-4′-carboxyazobenzene: 452, 402 in alk. H_2O (471).

$C_{13}H_{10}N_2O_4$.—2, 4′-Dihydroxy-5-carboxyazobenzene: 475 in alk. soln. (473).

$C_{13}H_{10}N_4O_4$.—*p*-Nitrobenzeneazosalicylamide: alkali salt, 525 in Me_2CO; 480 in EtOH (643).

$C_{13}H_{11}N_3O_3$.—*o*-Nitrobenzeneazo-*o*-cresol: *380*, 238 in EtOH; *457*, 273 in alk. H_2O (62).

o-Nitrobenzeneazo-*m*-cresol: *375*, 240 in EtOH; *445*, 278 in alk. H_2O (62).

o-Nitrobenzeneazo-*p*-cresol: abs. in visible and ultra-violet in neutral and alk. solns. (621).

m-Nitrobenzeneazo-*m*-cresol: *375*, 257 in EtOH; *436*, 273 in alk. H_2O (62).

m-Nitrobenzeneazo-*o*-cresol: *370*, 255 in EtOH; *465*, 276 in alk. H_2O (62).

m-Nitrobenzeneazo-*p*-cresol: abs. in visible and ultra-violet in neutral and alk. solns. (621).

p-Nitrobenzeneazo-*o*-cresol: *391*, 273 in EtOH; *493*, 287 in alk. H_2O (62); alkali salt, 590 in Me_2CO; 530 in EtOH; 490 in H_2O (643); *cf.* (621).

p-Nitrobenzeneazo-*m*-cresol: *398*, 266 in EtOH; *486*, 286 in alk. H_2O (62); 585 in alk. Me_2CO; 520 in alk. EtOH (643); *cf.* (501, 621).

p-Nitrobenzeneazo-*p*-cresol: alkali salt, 590 in Me_2CO: 542 in EtOH; 499 in H_2O (643); *cf.* (94, 501).

$C_{13}H_{11}N_3O_4$.—*p*-Nitrobenzeneazoguaiacol: alkali salt, 600 in Me_2CO; 540 in EtOH; 510 in H_2O (643); *cf.* (501, 622).

p-Nitrobenzeneazosaligenin: alkali salt, 565 in Me_2CO; 509 in EtOH; 483 in H_2O (643); *cf.* (501).

p-Nitrobenzeneazoorcinol: 539 in alk. Me_2CO (643).

p-Nitrobenzeneazoresorcinol methyl ether; alkali salt, 574 in Me_2CO; 520 in EtOH; 493 in H_2O (643).

p-Nitrobenzeneazohydroquinol methyl ether: abs. in visible and ultra-violet in neutral and alk. solns. (622).

$C_{13}H_{11}N_3O_7S$.—*p*-Nitrobenzeneazothiocol: alkali salt, 555 in Me_2CO; 536 in EtOH; 510 in H_2O (643); *cf.* (501).

$C_{13}H_{12}N_2O$.—Benzeneazo-*o*-cresol: (470), *358*, 238 in EtOH; *450*, 273 in alk. H_2O (62); *cf.* (621).

Benzeneazo-*m*-cresol: 352 in EtOH (431 with NaOEt); 481, 328 in HCl (618); (450), *358*, 238 in EtOH; *412*, 270 in alk. H_2O (62); *cf.* (621).

Benzeneazo-*p*-cresol: 316 in EtOH (488, 330 with NaOEt); 492, 406 in HCl (618); *cf.* (624).

Tolueneazophenol: abs. of isomers in visible and ultra-violet in neutral and alk. solns. (621).; abs. of derivs. (220q).

$C_{13}H_{12}N_2O_2$.—Benzeneazoguaiacol: 460 in alk. H_2O (468).

o-Tolueneazoresorcinol: 435 in EtOH (352); *cf.* (621).

m-Tolueneazoresorcinol: abs. in visible and ultra-violet in neutral and alk. solns. (621).

p-Tolueneazoresorcinol: 427 in EtOH (352); *cf.* (621).

p-Methoxybenzeneazophenol: 360 in EtOH (619).

p-Azoxyanisole: 355 in EtOH (533).

$C_{13}H_{12}N_2O_4S$.—*p*-Sulfobenzeneazo-*o*-cresol: 463 in alk. H_2O (468).

p-Sulfobenzeneazo-*m*-cresol: 475 in alk. H_2O (468).

$C_{13}H_{12}N_2S$.—Benzeneazothioanisole: 365 in EtOH (160).

$C_{13}H_{12}N_4O_3$.—*p*-Nitrobenzeneazo-*o*-methylaminophenol: alkali salt, 635 in Me_2CO; 573 in EtOH; 550 in H_2O (643).

$C_{13}H_{13}N_3$.—Benzeneazo-*o*-toluidine: *505*, 308 in 2*N* HCl; 392 in EtOH (216).

$C_{13}H_{13}N_3O_3S$.—*p*-Sulfobenzeneazo-*o*-toluidine (*o*-Toluidine Orange): 491 in dil. HCl (613q); 414, (280) in dil. NaOH; 488, (319) in dil. HCl (216).

m-Sulfobenzeneazo-*m*-toluidine (*m*-Toluidine Orange): 483 in dil. acid (613q); 414, (280) in dil. NaOH; 501, (320) in dil. HCl (216).

4-Sulfo-4′-methylaminoazobenzene (Monomethyl Orange): 500 in acid soln. (pH 1); 454 in alk. soln. (pH 12) (613q); 453, (280) in dil. NaOH; 506 in dil. HCl (216).

$C_{13}H_{11}N_3O_5$.—*p*-Nitrobenzeneazovanillin: alkali salt, 572 in Me_2CO; 525 in EtOH; 509 in H_2O (643).

$C_{14}H_{11}N_3O_4$.—*p*-Nitrobenzeneazohomosalicylaldehyde: alkali salt, 595 in Me_2CO; 546 in EtOH; 525 in H_2O (643).

$C_{14}H_{11}N_3O_5$.—*p*-Nitrobenzeneazomethylsalicylate: alkali salt, 530 in Me_2CO; 485 in EtOH; 467 in H_2O (643).

p-Nitrobenzeneazo-*o*-cresotic acid: alkali salt, 535 in Me_2CO; 530 in EtOH; 512 in H_2O (643).

$C_{14}H_{11}N_3O_5$.—*p*-Nitrobenzeneazo-*m*-cresotic acid: alkali salt, 544 in Me_2CO; 525 in EtOH; 508 in H_2O (643).

p-Nitrobenzeneazo-*p*-cresotic acid: alkali salt, 579 in Me_2CO; 535 in EtOH; 515 in H_2O (643).

$C_{14}H_{12}N_2O_2$.—*p*-Acetylbenzeneazophenol: 370 in EtOH; 476 in NaOH soln. (258).

$C_{14}H_{13}N_3O$.—*p*-Acetylaminoazobenzene: 345 in EtOH (619); *cf.* (385).

$C_{14}H_{13}N_3O_2$.—*m*-Acetylamino-*o*-hydroxyazobenzene (385).

$C_{14}H_{13}N_3O_4$.—*p*-Nitrobenzeneazocreosol: alkali salt, 602 in Me_2CO; 545 in EtOH; 512 in H_2O (643).

$C_{14}H_{14}N_2O$.—Benzeneazophenetole: 340 in EtOH; *474*, 331 in HCl (618).

o-Tolueneazocresol: abs. of cresol isomers in visible and ultraviolet in neutral and alk. solns. (620).

m-Tolueneazocresol: abs. of cresol isomers in visible and ultraviolet in neutral and alk. solns. (620).

p-Tolueneazocresol: abs. of cresol isomers in visible and ultraviolet in neutral and alk. solns. (620). *p*-Cresol isomer: 327 in EtOH (481, 334 with NaOEt); *505*, 427 in HCl (618).

$C_{14}H_{14}N_2O_2$.—*o*, *o*′-Azoanisole: 490 in HOAc-HCl soln. (54q).

p, *p*′-Azoanisole: 500 in HOAc-HCl soln. (54q).

p-Ethoxybenzeneazophenol: 447, 390 in alk. H_2O (468).

$C_{14}H_{14}N_2O_4S$.—2, 6-Dimethyl-4-hydroxy-4′-sulfoazobenzene: influence of pH (613q).

$C_{14}H_{14}N_2S_2$.—*o*, *o*′-Azophenylmethylsulfide: 620 in HOAc-HCl soln. (54q).

p, *p*′-Azophenylmethylsulfide: 577 in HOAc-HCl soln. (54q).

$C_{14}H_{14}N_3O_3$.—*p*-Nitrobenzeneazo-2-hydroxy-1, 3-dimethylbenzene: alkali salt, 610 in Me_2CO; 558 in EtOH; 517 in H_2O (643).

p-Nitrobenzeneazo-2-hydroxy-1, 4-dimethylbenzene: alkali salt, 599 in Me_2CO; 544 in EtOH; 510 in H_2O (643).

p-Nitrobenzeneazo-4-hydroxy-1, 2-dimethylbenzene: alkali salt, 600 in Me_2CO; 540 in EtOH; 510 in H_2O (643).

p-Nitrobenzeneazo-4-hydroxy-1, 3-dimethylbenzene: alkali salt, 605 in Me_2CO; 553 in EtOH; 513 in H_2O (643).

$C_{14}H_{14}N_4O_2$.—*m*-Nitrobenzeneazodimethylaniline: 467 in EtOH (31).

p-Nitrobenzeneazodimethylaniline: 483, 277 in EtOH (31).

$C_{14}H_{14}N_4O_3$.—*p*-Nitrobenzeneazo-*m*-dimethylaminophenol: alkali salt, 596 in Me_2CO; 564 in EtOH; 530 in H_2O (643).

$C_{14}H_{15}N_3$.—*p*-Dimethylaminoazobenzene (C. I. 19): 508 in acid soln. (pH 1); 450 in alk. soln. (pH 13) (613q); 545, 507 in 3% HCl; 420 in H_2SO_4 (diacid salt); 607 in fuming acid (triacid salt); 410 in EtOH; 550, 511, 300 in EtOH + 3% HCl (310); 405, 375 in H_2O; 490, 460 with alkali; 543, 508 with acid (469); *cf.* (26, 111, 210, 214, 218, 423q, 468, 475, 619).

$C_{14}H_{15}N_3O$.—*p*-Dimethylaminobenzeneazophenol: 413 in EtOH; *550*, 341 in dil. HCl; *477*, 314 in HCl (diacid salt) (261).

p-Dimethylaminoazoxybenzene: 545 in acid H_2O (471).

2-Dimethylamino-4-hydroxyazobenzene: 486, 463 in alk. H_2O (471).

4-Dimethylamino-2-hydroxyazobenzene: 492, 463 in alk. H_2O; 503, 473 in acid H_2O (471).

$C_{14}H_{15}N_3O_3S$.—*p*-Sulfobenzeneazodimethylaniline (Na salt, C. I. 142, Methyl Orange): 506 in acid soln. (pH 1), 472 in alk. soln. (pH 13) (613q); 442 in EtOH; *481*, 281 in H_2O; *465*, 280 in *N* NaOH; 508, (333), 283 in dil. HCl (469); *cf.* (208, 231, 269, 473, 525, 583q, 612, 647).

m-Sulfobenzeneazodimethylaniline: 535, 490 in acid H_2O (471).

o-Sulfobenzeneazodimethylaniline: 510 in acid soln. (pH 1); 435 in alk. soln. (pH 13); 516 in 6*N* HCl (613q).

p-Sulfobenzeneazoethylaniline: 498 in acid soln. (pH 1); 442 in alk. soln. (pH 12) (613q); 493 in dil. HCl; 453, (280) in dil. NaOH (216).

2, 5-Dimethyl-4-amino-4′-sulfoazobenzene: 490 in acid H_2O (613q).

3, 5-Dimethyl-4-amino-4′-sulfoazobenzene: 500 in acid H_2O (613q).

$C_{14}H_{16}N_2O_2$.—Benzeneazodimethyldihydroresorcinol: 394, 246 in EtOH (472, *349*, 283 with NaOEt) (380).

$C_{14}H_{16}N_4$.—Anilineazodimethylaniline: *513*, 306, 256 in EtOH with 0.1*N* HCl (214); *cf.* (473).

$C_{15}H_{10}N_2O_3$.—Benzeneazocarbonylcoumaranone: *417*, 250 in EtOH (*368*, 286 with NaOEt) (abs. of acetyl deriv. also described) (434).

$C_{15}H_{11}N_3O$.—Quinolineazophenol: 380 in EtOH (159).

5-Benzeneazo-8-hydroxyquinoline: 376 in EtOH; 518, 256 in HCl (159).

$C_{15}H_{12}N_4O$.—5-*p*-Aminobenzeneazo-8-hydroxyquinoline: 412 in EtOH (159).

$C_{15}H_{13}N_3O_5$.—*p*-Nitrobenzeneazoethylsalicylate: alkali salt, 531 in Me_2CO; 490 in EtOH; 465 in H_2O (643).

$C_{15}H_{15}N_3O_2$.—2-Carboxy-4-dimethylaminoazobenzene: 549, 503 (471).

3-Carboxy-4-dimethylaminoazobenzene: 531, 497 (471).

2′-Carboxy-4-dimethylaminoazobenzene (Methyl Red, C. I. 211): 517 in pH 1 soln.; 530 in pH 4.5 soln.; 447 in pH 13 soln. (613q); 530 in alk. soln. (58q) (double band, 548, 514 (469)); *cf.* (433, 471, 612q).

3′-Carboxy-4-dimethylaminoazobenzene: 538, 503 (471).

4′-Carboxy-4-dimethylaminoazobenzene: 512 in acid soln. (pH 1); 463 in alk. soln. (pH 13) (613q); 539, 495 (471).

$C_{15}H_{16}N_2O$.—Benzeneazo-*m*-cresetole: 348 in EtOH (*479*, 331 with NaOEt) (618).

Benzeneazo-*p*-cresetole: 313 in EtOH; 500, 410 in HCl (618).

$C_{15}H_{17}N_3$.—Benzeneazodimethyl-*o*-toluidine: 347 in EtOH; 493, 250 in 2*N* HCl (216).

$C_{15}H_{17}N_3O$.—2-Methoxy-4-dimethylaminoazobenzene: 575, 532 in acid H_2O (471).

4′-Methoxy-4-dimethylaminoazobenzene: 412 in EtOH; *510*, 351 in dil. HCl; *473*, 323 in HCl (diacid salt) (261); 549, 350, 200 in 0.1*N* HCl (214).

$C_{15}H_{17}N_3O_3S$.—*p*-Sulfobenzeneazodimethyl-*o*-toluidine: 374 in EtOH; 447, *311* in HCl (216).

$C_{15}H_{17}N_3O_4S$.—*m*-Methoxymethyl orange: 510, 480 (473).

$C_{15}H_{18}N_2O_2$.—Benzeneazodimethyldihydroresorcinol methyl ether: *379*, 244 in EtOH (380).

$C_{15}H_{18}ClN_3$.—Azobenzenetrimethylammonium chloride: 448, *312* (216).

$C_{15}H_{18}IN_3$.—Azobenzenetrimethylammonium iodide: 437, *314* in EtOH; 498, (314) in EtOH + 1% HCl; 428 in H_2SO_4; (500), 435 in HCl (26); *cf.* (210, 260).

$C_{16}H_{10}BrN_3O_3$.—4′-Nitrobenzeneazo-2-bromo-1-naphthol: 608 in alk. EtOH (473).

$C_{16}H_{11}BrN_2O$.—*p*-Bromobenzeneazo-*α*-naphthol: 470 in EtOH; K salt, 476 in EtOH (595).

$C_{16}H_{11}N_3O_3$.—*o*-Nitrobenzeneazo-*α*-naphthol: 476 in EtOH (540 with NaOEt) (31).

m-Nitrobenzeneazo-*β*-naphthol (*m*-Nitroaniline Orange, C. I. 38): 557.6, 524.1 in H_2SO_4 (190).

p-Nitrobenzeneazo-*α*-naphthol: alkali salt, 630 in Me_2CO; 590 in EtOH; 568 in H_2O (643); (602), 576, (552) in H_2O; (623), 598, (572) in EtOH (468); *cf.* (501).

p-Nitrobenzeneazo-*β*-naphthol (*p*-Nitroaniline Red, C. I. 44): 578.3, 541.3 in H_2SO_4 (352); alkali salt, 587 in Me_2CO; 555 in EtOH (643); *cf.* (501).

$C_{16}H_{12}N_2O$.—Benzeneazo-*α*-naphthol: 496 in alk. H_2O, (468); 469, 405 in EtOH (29); 490, 406, 275 in EtOH (352); 585 in H_2SO_4 (196); *cf.* (595).

$C_{16}H_{12}N_2O$.—Benzeneazo-β-naphthol (Sudan I, C. I. 24): 514, 311 in EtOH; 311 in H_2SO_4 (352); *563*, 517 in H_2SO_4 (196); *cf.* (423q, 619).

$C_{16}H_{12}N_2O_2$.—Benzeneazo-1, 5-dihydroxynaphthalene: 540 in alk. EtOH (174).

Benzeneazo-2, 7-dihydroxynaphthalene: *545*, 498 in H_2SO_4 (196).

p-Hydroxybenzeneazo-α-naphthol: 490 in alk. EtOH (174).

p-Hydroxybenzeneazo-β-naphthol: 610, *490* in alk. EtOH (174).

$C_{16}H_{12}N_2O_3$.—*p*-Hydroxybenzeneazo-1, 3-dihydroxynaphthalene: 490 in alk. EtOH (174).

p-Hydroxybenzeneazo-1, 5-dihydroxynaphthalene: 550 in alk. EtOH (174).

p-Tolueneazocarbonylcoumaranone: 431, 253 in EtOH (369, 288 with NaOEt) (434).

$C_{16}H_{12}N_2O_4S$.—Benzeneazo-α-naphthol-2-sulfonic acid: Na salt, (424q).

Benzeneazo-α-naphthol-4-sulfonic acid: *547*, 500 in H_2SO_4 (196).

Benzeneazo-β-naphthol-5-sulfonic acid: 525, 493 in H_2SO_4 (196).

Benzeneazo-β-naphthol-6-sulfonic acid: 526.5, *495* in H_2SO_4 (196); Na salt, *493*, 315 in H_2O (352).

Benzeneazo-β-naphthol-7-sulfonic acid: 534 in H_2SO_4 (196).

Benzeneazo-β-naphthol-8-sulfonic acid: 522, *495* in H_2SO_4 (196).

p-Sulfobenzeneazo-α-naphthol (Orange I, C. I. 150): *476*, 267, 232 in H_2O (179q); *cf.* (231q, 420q, 422q, 468, 519q, 595).

p-Sulfobenzeneazo-β-naphthol (Orange II, C. I. 151): 490 in H_2O (271); *cf.* (231q).

$C_{16}H_{12}N_2O_5S$.—*m*-Sulfo-*o*-hydroxybenzeneazo-β-naphthol (Na salt, C. I. 169), Pontachrome Violet S. W.: 548 in H_2O (concd.), 515 (dil.) (269).

$C_{16}H_{12}N_2O_7S_2$.—Benzeneazo-α-naphthol-4, 8-disulfonic acid: *557*, 500 in H_2SO_4 (196).

Benzeneazo-β-naphthol-3, 6-disulfonic acid (Na salt, Orange R, C. I. 28): 528, 496 in H_2SO_4 (196); *500*, 321 in H_2O (352); *cf.* (231q).

Benzeneazo-β-naphthol-6, 8-disulfonic acid (Na salt, Orange G, C. I. 27): 503, 487 in H_2SO_4 (196); *491*, 320 in H_2O (352); *cf.* (162, 271).

p-Sulfobenzeneazo-α-naphthol-2-sulfonic acid: Na salt (424q).

$C_{16}H_{12}N_2O_8S_2$.—Benzeneazo-1, 8-dihydroxynaphthalene-3, 6-disulfonic acid (Na salt, C. I. 29, Chromotrop 2R): 510 in H_2O (271).

$C_{16}H_{12}N_2O_8S_2$.—*p*-Hydroxybenzeneazo-α-naphthol-3, 6-disulfonic acid: 560, 494 (473).

$C_{16}H_{12}N_2O_9S_2$.—1-Hydroxy-3, 6-sulfonaphthaleneazoresorcinol: 491 in alk. soln.; 545, 491 in acid soln. (473).

$C_{16}H_{12}N_4O_2$.—2-(4′-Nitrobenzeneazomethylene)-1, 2-dihydroquinoline: 545 in EtOH; 527 in H_2SO_4; hydrochloride, 460 in EtOH; data given for isomeric phenylhydrazone (341).

$C_{16}H_{12}N_4O_9S_2$.—2-*p*-Nitrobenzeneazo-1-amino-8-naphthol-3, 6-disulfonic acid: 522 in 1% HCl; 556 in 1% NaOH; 584 in 10% NaOH; 535 in H_2O (60q).

$C_{16}H_{13}N_3$.—Benzeneazo-α-naphthylamine: 293 in H_2SO_4 (352).

Benzeneazo-β-naphthylamine (Oil Yellow A. B., C. I. 22): 585 in H_2SO_4 (196); 453, *322* in H_2SO_4; 474, 306 in EtOH (352); *cf.* (423q).

$C_{16}H_{13}N_3O$.—*p*-Hydroxybenzeneazo-β-naphthylamine: 565 in alk. EtOH (174).

$C_{16}H_{13}N_3O_3S$.—Benzeneazo-β-naphthylamine-5-sulfonic acid: 543, 498 in H_2SO_4 (196).

Benzeneazo-β-naphthylamine-6-sulfonic acid: *545*, 495 in H_2SO_4 (196).

Benzeneazo-β-naphthylamine-7-sulfonic acid: 545, 495 in H_2SO_4 (196).

$C_{16}H_{13}N_3O_4S$.—*o*-Aminosulfobenzeneazo-β-naphthol: 567.5, 537 (123).

m-Aminosulfobenzeneazo-β-naphthol: 556.3, 526 (123).

p-Aminosulfobenzeneazo-β-naphthol: 563, 533.3 (123).

$C_{16}H_{13}N_3O_6S$.—1-Amino-4-sulfo-2-naphtholazoresorcinol: 640, 590.5, 550 in alk. soln.; 583.5, 543, 513.5 in acid soln. (123).

1-Amino-6-sulfo-2-naphtholazoresorcinol: 560, 510, 472 in H_2O; 625, 582, 540 with NH_4OH (123).

1-Amino-7-sulfo-2-naphtholazoresorcinol: 566, 520, 481 in H_2O; 633, 588, 546 with NH_4OH (123).

1-Amino-8-sulfo-2-naphtholazoresorcinol: 547, 514 in H_2O; 610. 568, 530 with NH_4OH (123).

2-Amino-3-sulfo-1-naphtholazoresorcinol: 560, 483 in H_2O; 630. 541.5, 502.5 with NH_4OH (123).

2-Amino-4-sulfo-1-naphtholazoresorcinol: 561, 518, 478 in H_2O; 528 with NH_4OH (123).

2-Amino-5-sulfo-1-naphtholazoresorcinol: 574, 529, 476 in H_2O; 586, 541 with NH_4OH (123).

$C_{16}H_{13}N_3O_6S_2$.—Benzeneazo-β-naphthylamine-3, 6-disulfonic acid: 539, 495 in H_2SO_4 (196).

$C_{16}H_{13}N_3O_7S$.—2-Amino-4-sulfo-1, 8-dihydroxynaphthaleneazoresorcinol: 518 in alk. soln. (123).

$C_{16}H_{13}N_3O_7S_2$.—Benzeneazo-1, 8-aminonaphthol-3, 6-disulfonic acid: 541 in NaOH; 529, 494 in HCl; 545, 502 in HOAc (473); 495 in 10% NaOH; 530 in H_2O (60).

2, 4-Disulfo-1-aminobenzeneazo-β-naphthol: 507.5, *483* in H_2O; *560*, 528.5 in H_2SO_4; 505, *479.5* in EtOH (123).

2, 5-Disulfo-1-aminobenzeneazo-β-naphthol: 509.5, *478* in H_2O; *562*, 538 in H_2SO_4; 502, 479.5 in EtOH (123).

$C_{16}H_{13}N_3O_9S_2$.—1-Amino-3, 6-disulfo-2-naphtholazoresorcinol: 566.5, 526, 486.5 in H_2O; 635, 586.5, 550 with NH_4OH (123).

1-Amino-6, 8-disulfo-2-naphtholazoresorcinol: 543, 508.2 in H_2O; 611.5, 536, 497 with NH_4OH (123).

2-Amino-3, 6-disulfo-1-naphtholazoresorcinol: 569, 537.5, 502 in H_2O; 635, 582.5 with NH_4OH (123).

2-Amino-3, 8-disulfo-1-naphtholazoresorcinol: 564, 480.5 in H_2O; 637.5, 588 with NH_4OH (123).

2-Amino-4, 8-disulfo-1-naphtholazoresorcinol: 560, 523, 483 in H_2O; 629, 560 with NH_4OH (123).

$C_{16}H_{13}N_3O_{10}S_2$.—2-Amino-3, 6-disulfo-1, 8-dihydroxynaphthaleneazoresorcinol: 564.5, 537 in alk. soln.; 591.5, 549.5 in acid soln. (123).

$C_{16}H_{13}N_3O_{12}S_3$.—1-Amino-3, 6, 8-trisulfo-2-naphtholazoresorcinol: 555, 521 in H_2O; 626.5, 578, 541.5 with NH_4OH (123).

$C_{16}H_{15}BrN_2O$.—*p*-Bromobenzene-1-azo-1′, 2′, 3′, 4′-tetrahydro-4-naphthol: K salt, 476 in EtOH (595).

$C_{16}H_{15}N_3O_3$.—*p*-Nitrobenzene-1-azo-1′, 2′, 3′, 4′-tetrahydro-4-naphthol: K salt, 581 in EtOH (595).

$C_{16}H_{15}N_3O_4$.—*p*-Nitrobenzeneazoeugenol: alkali salt, 610 in Me_2CO; 556 in EtOH; 535 in H_2O (643); *cf.* (501).

$C_{16}H_{16}N_2O$.—Benzeneazotetrahydro-α-naphthol: 470, 430 in alk. H_2O; 471 in EtOH (595).

$C_{16}H_{17}N_3O_3$.—*p*-Nitrobenzeneazocarvacrol: alkali salt, 606 in Me_2CO; 545 in EtOH; 511 in H_2O (643); *cf.* (501).

p-Nitrobenzeneazothymol: alkali salt, 610 in Me_2CO; 559 in EtOH; 515 in H_2O (643); *cf.* (501).

$C_{16}H_{18}ClN_3O_3S$.—2-Chloro-4-diethylamino-4′-sulfoazobenzene: 510 in acid soln. (pH 1); 470 in alk. soln. (pH 12) (613q).

$C_{16}H_{18}N_2O$.—Benzeneazothymol: 455, 410 in alk. H_2O (468).

p-Tolueneazo-*p*-cresetole: 325 in EtOH; *495*, 420 in HCl (618).

$C_{16}H_{18}N_2O_2$.—Azophenetole: 384 in EtOH (431 with NaOEt) (619).

$C_{16}H_{18}N_2O_3$.—*p*-Azoxyphenetole: 360 in EtOH(533).

$C_{16}H_{18}N_2O_5S$.—*o*-Methyl-*m*-isopropyl-*p*-sulfobenzeneazoresorcinol: Na salt, 440 in H_2O (271).

$C_{16}H_{18}N_4O$.—4-Acetylamino-4′-dimethylaminoazobenzene: 540 (473).

$C_{16}H_{19}N_3O$.—4-Ethoxy-4′-dimethylaminoazobenzene: 548 (473).

$C_{16}H_{19}N_3O_3S$.—4-Diethylamino-4′-sulfoazobenzene (Ethyl Orange): 510 in acid soln. (pH 1); 470 in alk. soln. (pH 13) (613q).

$C_{16}H_{19}N_3O_5S$.—2, 2′-Dimethoxy methyl orange: 537, 495 (473).

$C_{16}H_{20}N_4$.—Tetramethyl-*p*-diaminoazobenzene: 450 in EtOH; 692, (514), 450 in dil. HOAc; 530, 497 in 3% HCl (diacid salt); (498), 410 in H_2SO_4 (triacid salt) (310); *cf.* (475).

$C_{17}H_{11}N_3O_5$.—*p*-Nitrobenzeneazo-*n*-butylsalicylate: alkali salt, 556 in Me_2CO; 496 in EtOH; 480 in H_2O (643).

p-Nitro-*α*-naphthaleneazosalicylic acid: K salt, 541 in EtOH (595).

$C_{17}H_{12}N_2O_6S$.—*o*-Carboxybenzeneazo-*α*-naphthol-2-sulfonic acid: Na salt (424q).

$C_{17}H_{13}N_3O_3$.—*o*-Nitro-*p*-tolueneazo-*β*-naphthol (Toluidine Red, C. I. 69): 569.4, 533.2 in H_2SO_4 (190); 561 in gelatin (114).

$C_{17}H_{14}N_2O$.—*o*-Tolueneazo-*α*-naphthol: *406*, 275 in EtOH (352).

o-Tolueneazo-*β*-naphthol: *515*, 313 in EtOH; 313 in H_2SO_4 (352).

p-Tolueneazo-*α*-naphthol: 402 in EtOH; 300 in H_2SO_4 (352).

p-Tolueneazo-*β*-naphthol: *495*, 312 in EtOH (352).

$C_{17}H_{14}N_2O_4S$.—*o*-Tolueneazo-*β*-naphthol-6-sulfonic acid: Na salt, *496*, 316 in H_2O; 311 in H_2SO_4 (352).

p-Tolueneazo-*β*-naphthol-6-sulfonic acid: Na salt, *498*, 316 in H_2O (352).

o-Tolueneazo-*α*-naphthol-2-sulfonic acid: Na salt (424q).

p-Tolueneazo-*α*-naphthol-2-sulfonic acid: Na salt (424q).

$C_{17}H_{14}N_2O_5S$.—2-Anisoleazo-*α*-naphthol-6-sulfonic acid (Na salt, Anisole Red): 522 in gelatin (114).

$C_{17}H_{14}N_2O_7S_2$.—*o*-Tolueneazo-*β*-naphthol-3, 6-disulfonic acid: Na salt, *503*, 323 in H_2O (352).

o-Tolueneazo-*β*-naphthol-6, 8-disulfonic acid: Na salt, *491*, 324 in H_2O; 320 in H_2SO_4 (352).

p-Tolueneazo-*β*-naphthol-3, 6-disulfonic acid: Na salt, *500*, 322 in H_2O (352).

p-Tolueneazo-*β*-naphthol-6, 8-disulfonic acid: Na salt, *497*, 323 in H_2O (352).

$C_{17}H_{14}N_4O_2$.—1-Methyl-2-(4′-nitrobenzeneazomethylene)-1, 2-dihydroquinoline: hydrochloride, 527 in H_2SO_4 (343).

$C_{17}H_{15}N_3$.—*o*-Tolueneazo-*α*-naphthylamine: 298 in H_2SO_4 (352).

o-Tolueneazo-*β*-naphthylamine (Oil Yellow OB, C. I. 61): 474, 306 in EtOH; 455, 323 in H_2SO_4 (352); *cf.* (220q).

p-Tolueneazo-*β*-naphthylamine: 473, 305 in EtOH; 323 in H_2SO_4 (352).

$C_{17}H_{16}N_4O_2$.—2-(4′-Nitrobenzeneazomethylene)-3, 3-dimethylindoline: hydrochloride, 469 in HOAc (347).

$C_{17}H_{17}N_3$.—2-(Benzeneazomethylene)-3, 3-dimethylindoline: hydrochloride, 465; base, 435 (347).

$C_{17}H_{19}N_3O_2$.—2-Carboxy-4′-diethylaminoazobenzene: 512 in pH 1 soln.; 522 in pH 4 soln.; 499 in pH 12 soln. (613q).

4-Dimethylamino-4′-ethylcarboxyazobenzene: *444*, 275 in EtOH (214).

$C_{18}H_{12}N_4O$.—Quinolineazo-8-hydroxyquinoline: 403 in EtOH (159).

$C_{18}H_{14}N_2O$.—Diphenylazophenol: 451 in alk. H_2O (468).

$C_{18}H_{14}N_2O_2$.—*p*-Hydroxydiphenylazophenol; monobasic salt, 492 ($NaHCO_3$); dibasic salt, 470 (NaOH) (463).

Benzeneazo-*α*-naphthyl acetate: 376 in EtOH (619).

Benzeneazo-*β*-naphthyl acetate: 472, 282 in EtOH (619).

p-Acetylbenzeneazo-*α*-naphthol: 467, 315 in EtOH; 526, 300 in NaOH (258).

p-Acetylbenzeneazo-*β*-naphthol: 476, 318 in EtOH; 513, 286 in NaOH (258).

$C_{18}H_{14}N_2O_6S$.—*o*-Methylcarboxybenzeneazo-*α*-naphthol-2-sulfonic acid: Na salt (424q).

$C_{18}H_{15}N_3O_3S$.—4-Phenylamino-4′-sulfoazobenzene (Na salt, C. I. 143): 527 in pH 1 soln.; 456 in pH 12 soln. (613q).

$C_{18}H_{15}N_3O_8S_2$.—Benzeneazo-8-acetylamino-1-naphthol-3, 6-disulfonic acid (Na salt, C. I. 31): Kiton Red G (22).

$C_{18}H_{16}N_2O$.—Benzeneazo-*α*-naphthol ethyl ether: 400 in EtOH (619).

$C_{18}H_{17}N_3$.—Benzeneazodimethyl-*α*-naphthylamine: 570, 525 in acid H_2O (471).

$C_{18}H_{17}N_3O_3S$.—4-Sulfonaphthaleneazodimethylaniline: (473).

$C_{18}H_{18}N_4O_3$.—2-(4′-Nitro-2′-methoxybenzeneazomethylene)-3, 3-dimethylindoline: hydrochloride, 484 in HOAc (347).

$C_{19}H_{14}N_2O_2$.—*p*-Benzoylbenzeneazophenol: 481, 333 in EtOH (?) (471); 370 in EtOH; 476 in NaOH (258).

$C_{19}H_{14}N_4O_2$.—*p*-Nitrobenzylideneaminoazobenzene: 383 in EtOH (521).

$C_{19}H_{15}N_3$.—Benzylidineaminoazobenzene: 383 in EtOH (521).

$C_{19}H_{15}N_3O$.—*p*-Hydroxybenzylidineaminoazobenzene: 375 in EtOH (521).

$C_{19}H_{17}N_3O_3S$.—*p*-Sulfobenzeneazobenzylaminobenzene: 448, (280) in dil. NaOH; 496 in dil. HCl (216); 560 in pH 1 soln. (613q).

$C_{19}H_{18}N_2O_7S_2$.—Pseudocumeneazo-*β*-naphthol-3, 6-disulfonic acid (Na salt, C. I. 80): *504*, 330 in H_2O (179q); *cf.* (422q).

$C_{19}H_{19}N_3O$.—2-(4′-Acetylbenzeneazomethylene)-3, 3-dimethylindoline: hydrobromide, 456 in EtOH (347).

$C_{19}H_{19}N_3O_4S$.—*p*-Sulfo-*o*-methoxybenzeneazodimethyl-*α*-napthylamine: 580, 525, 500 in acid H_2O (595).

$C_{19}H_{20}N_4O_2$.—2-(4′-Nitrobenzeneazomethylene)-3, 3-diethylindoline: hydrochloride, 472 in HOAc (347).

$C_{20}H_{13}BrN_2O$.—*p*-Bromobenzene-1-azo-4-anthrol: 503 in EtOH; K salt, 588 in EtOH (595).

$C_{20}H_{13}N_3O_3$.—*p*-Nitrobenzeneazoanthrol: 460 in EtOH (595).

p-Nitrobenzene-1-azo-4-anthrol: 482 in EtOH; K salt, 650 in EtOH (595).

3′-Nitro-4-hydroxyazonaphthalene: 557 in H_2O (471).

$C_{20}H_{14}N_2O$.—Benzeneazoanthrol: 466 in EtOH; K salt, 580 in EtOH (595).

Benzene-1-azo-4-anthrol: 499 in EtOH; K salt, 549 in EtOH (595).

α-Naphthaleneazo-*β*-naphthol (Autol Red RL, C. I. 82): 628, 585.8 in H_2SO_4 (190).

β-Naphthaleneazo-*β*-naphthol: 483 in EtOH (85).

β, *β*′-Azoxynaphthalene: 337, 282, 266 in EtOH (?) [550 after exposure to light] (85).

$C_{20}H_{14}N_2O_4S$.—*p*-Sulfobenzene-1-azo-4-anthrol: 503 in EtOH; K salt, 571 in EtOH (595).

α-Naphthaleneazo-*α*-naphthol-2-sulfonic acid: Na salt (424q).

β-Naphthaleneazo-*α*-naphthol-2-sulfonic acid: Na salt (424q).

4-Sulfo-*α*-naphthaleneazo-*α*-naphthol (Na salt, C. I. 175): (231).

4-Sulfo-*α*-naphthaleneazo-*β*-naphthol (Na salt, Fast Red A.S., C. I. 176): 500 in H_2O (concd.); 505 (dil.) (269); *cf.* (231, 390, 391, 516).

$C_{20}H_{14}N_2O_7S_2$.—*α*-Naphthaleneazo-*β*-naphthol-3, 6-disulfonic acid (Na salt, Bordeaux B, C. I. 88): 510 in H_2O (concd.); 515 (dil.) (269); *cf.* (421q, 516q, 588).

α-Naphthaleneazo-*β*-naphthol-6, 8-disulfonic acid (Na salt, Crystal Scarlet, C. I. 89); *508*, 329.5 in H_2O (391q); *cf.* (388q, 518q).

4-Sulfo-*α*-naphthaleneazo-*α*-naphthol-2-sulfonic acid: Na salt (424q).

4-Sulfo-*α*-naphthaleneazo-*α*-naphthol-4-sulfonic acid (Na salt, C. I. 179): "Azorubin," infra-red abs. (511); Pontacyl Ruby G, 505 in H_2O (concd.); 512 (dil.) (269); Chromotrope FB, 555.9, *519.5* in dil. HOAc; 569.5 in H_2SO_4; Chrome Lake, *620.7*, 575.7, 537.5 in 90% HOAc + HCl; *614.7*, 568.2, 530.3 in H_2SO_4 (190).

$C_{20}H_{14}N_2O_8S_2$.—α-Naphthaleneazo-1, 8-dihydroxynaphthalene-3, 6-disulfonic acid (Na salt, C. I. 90): 533 in 0.1*N* HCl; 519 in 0.1*N* NaOH; 535 in H_2O (pH 6.75) (11q).

$C_{20}H_{14}N_2O_{10}S_3$.—α-Naphthaleneazo-α-naphthol-3, 6, 8-trisulfonic acid: Na salt, 534 in 0.1*N* HCl; 514 in 0.1*N* NaOH; 535 in pH 6.75 soln. (11q).

4-Sulfo-α-naphthaleneazo-β-naphthol-3, 6-disulfonic acid (Na salt, Amaranth, C. I. 184): *522*, 331 in H_2O (179q); *cf.* (422q).

4-Sulfo-α-naphthaleneazo-β-naphthol-6, 8-disulfonic acid (Na salt, C. I. 185): Cochineal Red A, *515*, 500 on wool (522).

$C_{20}H_{15}N_3$.—α-naphthaleneazo-α-naphthylamine: (231q).

β-Naphthaleneazo-β-naphthylamine: (231q).

$C_{20}H_{15}N_3O_4S$.—4-Sulfo-1-naphthylamineazo-β-naphthol: Na salt, 500 in H_2O; 629, 587.5 in H_2SO_4 (123).

5-Sulfo-1-naphthylamineazo-β-naphthol: Na salt, 499 in H_2O; 608.5, 568 in H_2SO_4 (123).

6-Sulfo-1-naphthylamineazo-β-naphthol: Na salt, 499 in H_2O; 607.5, 568.5 in H_2SO_4 (123).

7-Sulfo-1-naphthylamineazo-β-naphthol: Na salt, 500 in H_2O; 572 in H_2SO_4 (123).

1-Sulfo-2-naphthylamineazo-β-naphthol; Na salt, 505.5 in H_2O; 589.5, 552.5 in H_2SO_4 (123).

5-Sulfo-2-naphthylamineazo-β-naphthol: Na salt, 492.5 in H_2O; 576, 541.5 in H_2SO_4 (123).

6-Sulfo-2-naphthylamineazo-β-naphthol: Na salt, 494 in H_2O; 579.5, 543.5 in H_2SO_4 (123).

7-Sulfo-2-naphthylamineazo-β-naphthol: Na salt, 493 in H_2O; 580, 543 in H_2SO_4 (123).

8-Sulfo-2-naphthylamineazo-β-naphthol: Na salt, 494.5 in H_2O; 581, 544.5 in H_2SO_4 (123).

$C_{20}H_{15}N_3O_7S_2$.—α-Naphthaleneazo-8-amino-α-naphthol-3, 6 disulfonic acid: Na salt, 544 in 0.1*N* HCl; 545 in 0.1*N* NaOH; 548 in pH 6.75 soln. (11).

3, 6-Disulfo-1-naphthylamineazo-β-naphthol: Na salt, 498.5 in H_2O; 604.5, 568 in H_2SO_4 (123).

4, 8-Disulfo-1-naphthylamineazo-β-naphthol: Na salt, 491 in H_2O; 540 in H_2SO_4 (123).

3, 6-Disulfo-2-naphthylamineazo-β-naphthol: Na salt, 493.5 in H_2O (123).

4, 7-Disulfo-2-naphthylamineazo-β-naphthol: Na salt, 495.5 in H_2O; 582, 542.5 in H_2SO_4 (123).

4, 8-Disulfo-2-naphthylamineazo-β-naphthol: Na salt, 492 in H_2O; 581.5, 544.5 in H_2SO_4 (123).

5, 7-Disulfo-2-naphthylamineazo-β-naphthol: Na salt, 490.5 in H_2O; 580, 543 in H_2SO_4 (123).

6, 8-Disulfo-2-naphthylamineazo-β-naphthol: Na salt, 494.5 in H_2O; 583.5, 546 in H_2SO_4 (123).

$C_{20}H_{15}N_3O_{10}S_3$.—5-Sulfo-1-naphthylamineazo-β-naphthol-3, 6-disulfonic acid: Na salt, 594.5, 555 in H_2SO_4 (123).

6-Sulfo-1-naphthylamineazo-β-naphthol-3, 6-disulfonic acid: Na salt, 572, 537.5 in H_2SO_4 (123).

$C_{20}H_{15}N_3O_{13}S_4$.—3, 6-Disulfo-2-naphthylamineazo-β-naphthol-3, 6-disulfonic acid: Na salt, 495 in H_2O; 583, 547 in H_2SO_4 (123).

$C_{20}H_{16}N_2O_2$.—*p*-Benzoylbenzeneazo-*p*-cresol: 327 in EtOH; 513, 341 in NaOH (258); *cf.* (618).

$C_{20}H_{16}N_4O_5S$.—4-Sulfo-1, 5-diamino-2-naphtholazo-α-naphthol: Na salt, 521.5 in alk. soln.; 518 in acid soln. (123).

$C_{20}H_{16}N_4O_{11}S_3$.—3-Sulfo-2, 5-diamino-1-naphtholazo-β-naphthol-3, 6-disulfonic acid: Na salt, 496.5 in H_2SO_4 (123).

$C_{20}H_{17}N_3O$.—*p*-Methoxybenzylideneaminoazobenzene: 327 in EtOH; 513, 341 in NaOH (521).

$C_{20}H_{18}N_4O_9S_2$.—*p*-Acetylaminobenzeneazo-8-acetylamino-α-naphthol-3, 6-disulfonic acid (Na salt, C. I. 57): Pontacyl Carmine 6B, 514 in H_2O (concd.); 525 (dil.) (269).

$C_{20}H_{20}N_2O$.—*p*-Cymeneazo-β-naphthol: 532 in H_2SO_4 (677).

$C_{20}H_{20}N_2O_3S$.—*p*-Cymeneazo-α-naphthalene-4-sulfonic acid: Na salt, 460 in H_2O (677).

$C_{20}H_{20}N_2O_4S$.—*o*-Methyl-*m*-isopropyl-*p*-sulfobenzeneazo-β-naphthol: Na salt, 495 in H_2O (271).

$C_{20}H_{20}N_2O_7S_2$.—*o*-Methyl-*m*-isopropylbenzeneazo-β-naphthol-6, 8-disulfonic acid: Na salt, 492 in H_2O (271).

$C_{20}H_{20}N_2O_8S_2$.—*o*-Methyl-*m*-isopropylbenzeneazo-1, 8-dihydroxynaphthalene-3, 6-disulfonic acid: Na salt, 520 in H_2O (271).

$C_{20}H_{20}N_2O_{10}S_3$.—*o*-Methyl-*m*-isopropyl-*p*-sulfobenzeneazo-β-naphthol-3, 6-disulfonic acid: Na salt, 498 in H_2O (677). (The 6, 8-disulfo isomer in H_2O, 485 (677).)

$C_{20}H_{20}N_2O_{11}S_3$.—*o*-Methyl-*m*-isopropyl-*p*-sulfobenzeneazo-1, 8-dihydroxynaphthalene-3, 6-disulfonic acid: Na salt, 525 in H_2O (271).

$C_{20}H_{21}N_3$.—*p*-Cymeneazo-β-naphthylamine: 570 in H_2SO_4 (677).

$C_{20}H_{26}N_2$.—Azocymene: 465 in H_2SO_4 (677).

$C_{21}H_{13}N_3O_5$.—*p*-Nitronaphthalene-1-azo-4-naphthol-3-carboxylic acid: 470 in EtOH; K salt, 606 in EtOH (595).

$C_{22}H_{17}N_3O_3S$.—4-Diphenylazo-α-naphthylamine-4-sulfonic acid: 575 in dil. HCl (468).

$C_{22}H_{18}N_4O_5S$.—8-Sulfo-4-amino-1-phenylnaphthylamineazoresorcinol: 561.5 with excess H_2SO_4 (123).

$C_{22}H_{19}N_3O_7S_2$.—3, 6-Disulfo-8-hydroxy-α-naphthaleneazoethyl-α-naphthylamine (Na salt, C. I. 307): Pontacyl Sulfon Violet R, 530 in H_2O (concd.); 550 (dil.) (269).

$C_{22}H_{20}N_2O_2$.—*p*-Benzoylbenzeneazo-*p*-cresetole: 326 in EtOH (618).

$C_{23}H_{16}N_2O_2$.—*p*-Benzoylbenzeneazo-α-naphthol: 461, 330 in EtOH; 535, 300 in NaOH (258).

p-Benzoylbenzeneazo-β-naphthol: 486, 320 in EtOH; 513, 283 in NaOH (258).

$C_{23}H_{16}N_4O_4$.—*p*-Nitrobenzeneazo-β-hydroxynaphthoic acid anilide (Fast Red GG): 570 in H_2SO_4 (677).

$C_{23}H_{22}N_4O_3$.—Phenyl-(*p*-dimethylaminobenzeneazobenzoylamino)-acetic acid: *461*, 375 (306), 274 in EtOH (abs. of *d*, *l*, and *dl* forms identical) (64q).

$C_{24}H_{16}ClN_3O_7S_3$.—Benzenylaminothiocresolazo-8-chloro-α-naphthol-3, 6-disulfonic acid (Na salt, C. I. 128): Diamine Rose BD on cotton and silk (627).

$C_{25}H_{19}N_3O_4$.—β-Naphthol deriv. of diazotized phenyl- (*p*-aminobenzoylamino)- acetic acid: *486*, (381), 314, (271) in H_2O; 516, *443* with excess alkali; 553, *522* with excess acid (abs. of *d*, *l* and *dl* forms identical) (63q).

$C_{26}H_{17}N_3O_6$.—*p*-Nitrobenzeneazophenolphthalein: alkali salt, 568 in Me_2CO; 508 in EtOH; 495 in H_2O (643); *cf.* (501).

$C_{26}H_{21}N_5O_8S_2$.—3-Sulfo-2, 5-diamino-α-naphtholazophenyl-β-naphthylamine-5-hydroxy-7-sulfonic acid: 493.8 in dil. H_2SO_4 (123).

$C_{27}H_{20}N_4O_9S_2$.—8-Benzoylamino-2-amino-3, 5-disulfo-α-naphtholazo-β-naphthol: 525, 493 in H_2SO_4 (123).

Aminobenzoyl-H-acid-azo-β-naphthol: 608, 578 in H_2SO_4 (123).

Azo dyes derived from substituted pyrroles: (33, 378, 399, 408, 409).

p-Nitrobenzeneazocephaeline: 610 in alk. Me_2CO; 550 in alk. EtOH; 525 in alk. H_2O (502).

p-Nitrobenzeneazoemetamine: 627.5 in alk. Me_2CO; 590 in alk. EtOH; 570 in alk. H_2O (502).

Table 2.—Polyazo Dyes

$C_{18}H_{13}N_5O_3$.—*p*-Nitrobenzeneazobenzeneazophenol: 395 in EtOH; Na salt, 546 in EtOH (521).

$C_{18}H_{14}N_4O$.—Benzeneazobenzeneazophenol: 435 (111); 497 in alk. H_2O (463).

$C_{18}H_{14}N_4O_2$.—Phenolazobenzeneazophenol: disodium salt, 515 in H_2O (463).

$C_{18}H_{18}N_8$.—Benzene-*m*-disazo-*bis*-*m*-phenylenediamine (hydrochloride, Bismarck Brown Y, C. I. 331): infra-red abs. (296); 460 on cotton (627); *cf.* (231).

$C_{20}H_{19}N_5$.—Benzeneazobenzeneazodimethylaniline: 509 (111).

$C_{22}H_{15}N_7O_{11}S_2$.—2-*p*-Nitrobenzeneazo-1-amino-8-naphthol-3, 6-disulfo-7-azo-*p*-nitrobenzene: Na salt, 612 in H_2O (609).

$C_{22}H_{16}N_4O$.—Benzeneazobenzeneazo-*α*-naphthol: *655*, 625 in H_2SO_4 (196).

Benzeneazobenzeneazo-*β*-naphthol (Sudan III, C. I. 248): *640.9*, 589.8 in H_2SO_4 (190); *cf.* (196).

$C_{22}H_{16}N_4O_3S$.—*p*-Sulfobenzeneazobenzeneazo-*α*-naphthalene: Na salt, 507 in H_2O; 516 in 0.02*N* HCl; 663 in H_2SO_4 (436).

$C_{22}H_{16}N_4O_4S$.—Benzeneazobenzeneazo-*α*-naphthol-4-sulfonic acid (Na salt, C. I. 249): *627*, 575 in H_2SO_4 (196).

Benzeneazobenzeneazo-*β*-naphthol-6-sulfonic acid: *610*, 580 in H_2SO_4 (196).

Benzeneazobenzeneazo-*β*-naphthol-8-sulfonic acid: 598, 572 in H_2SO_4 (196).

$C_{22}H_{16}N_4O_6S_2$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-*α*-naphthalene: Na salt, 524 in H_2O; 542 in alk. H_2O; 519 in 0.02*N* HCl; 643 in H_2SO_4 (436).

p-Sulfobenzeneazobenzeneazo-*α*-naphthalene-7-sulfonic acid: Na salt, 532 in H_2O (520 with alkali); 496 in 0.02*N* HCl; 657 in H_2SO_4 (436).

$C_{22}H_{16}N_4O_7S_2$.—Benzeneazobenzeneazo-*α*-naphthol-4, 8-disulfonic acid (Na salt, C. I. 251): *630*, 575 in H_2SO_4 (196).

Benzeneazobenzeneazo-*β*-naphthol-3, 6-disulfonic acid (Na salt, C. I. 253): *616*, 573 in H_2SO_4 (196).

Benzeneazobenzeneazo-*β*-naphthol-6, 8-disulfonic acid (Na salt, C. I. 252): *592*, 550 in H_2SO_4 (196). Brilliant Croceine M, 545 on silk (627).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-*β*-naphthol (Na salt, Biebrich Scarlet, C. I. 280): (231).

$C_{22}H_{16}N_4O_9S_3$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-*α*-naphthalene-7-sulfonic acid: Na salt, 539 in H_2O; 530 in 0.02*N* HCl; 638 in H_2SO_4 (436).

$C_{22}H_{16}N_4O_{10}S_3$.—Benzeneazobenzeneazo-*α*-naphthol-3, 6, 8-trisulfonic acid: *620*, 573 in H_2SO_4 (196).

Benzeneazobenzeneazo-*β*-naphthol-3, 6, 8-trisulfonic acid: 600, 555 in H_2SO_4 (196).

p-Sulfobenzeneazobenzeneazo-*α*-naphthol-4, 8-disulfonic acid: 642 in H_2SO_4 (196).

p-Sulfobenzeneazobenzeneazo-*β*-naphthol-3, 6-disulfonic acid: *607*, 575 in H_2SO_4 (196).

p-Sulfobenzeneazobenzeneazo-*β*-naphthol-6, 8-disulfonic acid: 587 in H_2SO_4 (196).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-*α*-naphthol-4-sulfonic acid: *688*, 596 in H_2SO_4 (196).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-*β*-naphthol-8-sulfonic acid: 620 in H_2SO_4 (196).

$C_{22}H_{16}N_4O_{13}S_4$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-*α*-naphthol-4, 8-disulfonic acid: *631*, 584 in H_2SO_4 (196).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-*β*-naphthol-3, 6-disulfonic acid: *630*, 575 in H_2SO_4 (196).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-*β*-naphthol-6, 8-disulfonic acid: 589 in H_2SO_4 (196).

$C_{22}H_{16}N_4O_{16}S_5$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-*α*-naphthol-3, 6, 8-trisulfonic acid: *629*, 582 in H_2SO_4 (196).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-*β*-naphthol-3, 6, 8-trisulfonic acid: *607*, 580 in H_2SO_4 (196).

$C_{22}H_{16}N_6O_9S_2$.—*p*-Nitrobenzeneazo-3, 6-disulfo-8-amino-*α*-naphtholazobenzene (Na salt, C. I. 246): Agalma Black 10B, 620 in H_2O (129); *cf.* (609); 600 in H_2O (concd.); 620 (dil.) (269).

$C_{22}H_{24}N_6$.—4, 4′-Benzenedisazodimethylaniline: (570), 544, 510 (473).

$C_{24}H_{18}N_4O_2$.—Diphenyldisazo-*bis*-phenol: monosodium salt, 496 ($NaHCO_3$); disodium salt, 370 (NaOH) (463).

5, 5′-*Bis*-benzeneazo-2, 2′-diphenol: 344 in EtOH (?) (544).

$C_{24}H_{18}N_4O_8S_2$.—Diphenyldisazo-*bis*-*p*-sulfophenol: 475 in alk. H_2O (468).

$C_{24}H_{18}N_6O$.—Benzeneazobenzeneazobenzeneazophenol: 436 (111).

$C_{24}H_{20}N_4O$.—*o*-Tolueneazo-*o*-tolueneazo-*β*-naphthol (Sudan IV, C. I. 258): *657.4*, 605.5 in H_2SO_4 (190); *cf.* (516).

$C_{24}H_{20}N_4O_4S$.—*o*-Tolueneazo-*o*-tolueneazo-*α*-naphthol-4-sulfonic acid: 629, 589 in H_2SO_4 (196).

o-Tolueneazo-*o*-tolueneazo-*β*-naphthol-6-sulfonic acid: *630*, 589 in H_2SO_4 (196).

$C_{32}H_{22}N_4O_2$.—Diphenyldisazo-*bis*-*β*-naphthol (C. I. 381): 640.6, 595.1 in H_2SO_4 (190).

$C_{32}H_{22}N_4O_8S_2$.—Diphenyldisazo-*bis*-*α*-naphthol-2-sulfonic acid: Na salt (424q).

$C_{32}H_{22}N_4O_{11}S_3$.—Diphenyldisazo-8-sulfo-*β*-naphthol-*α*-naphthol-4, 8-disulfonic acid (Na salt, C. I. 386): metallic salts in H_2O; Al, 542, Ba, 540, Cu, 515 (677).

$C_{32}H_{23}N_5O_7S_2$.—Diphenyldisazo-8-sulfo-*β*-naphthol-*α*-naphthylamine-4-sulfonic acid (Na salt, C. I. 376): Congo Rubine (498).

Diphenyldisazo-4-sulfo-*α*-naphthylamine-*α*-naphthol-4-sulfonic acid (Na salt, C. I. 375): (269). Metallic salts in H_2O; Na, 520, Al, 518, Cu, 495 (677).

$C_{32}H_{23}N_7O_{10}S_3$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-*α*-naphthaleneazo-6-amino-*α*-naphthol-3-sulfonic acid: Na salt, 576 in H_2O (572 with alkali, 578 with acid) (436).

$C_{32}H_{23}N_7O_{13}S_4$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-7-sulfo-*α*-naphthaleneazo-6-amino-*α*-naphthol-3-sulfonic acid: Na salt, 555 in H_2O (551 with alkali, 566 with acid) (436).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-7-sulfo-*α*-naphthaleneazo-6-amino-*α*-naphthol-4-sulfonic acid: Na salt, 581 in H_2O (569 with alkali, 580 with acid) (436).

$C_{32}H_{24}N_6O_6S_2$.—Diphenyldisazo-*bis*-*α*-naphthylamine-4-sulfonic acid (Na salt, Congo Red, C. I. 370): 497, 319 in alk. EtOH; 577, (320) in dil. H_2SO_4 (215); *cf.* (468, 525); 500 on cotton (627); influence of concn. (269); quant. data (162q).

$C_{32}H_{24}N_6O_7S_2$.—Diphenyldisazo-4-sulfo-*α*-naphthylamine-7-amino-*α*-naphthol-3-sulfonic acid (Na salt): Pontamine Bordeaux B, metallic salts in H_2O; Na, 510, Ba, 505, Cr, 480, Al, 480 (677).

$C_{32}H_{24}N_6O_8S_2$.—Diphenyldisazo-*bis*-7-amino-*α*-naphthol-3-sulfonic acid (Na salt, C. I. 394): Pontamine Violet N, 520 in H_2O (concd.); 525 (dil.) (269); 545 in EtOH (266); Ba salt, 510 in H_2O (677). Erie Violet 3R identical with above when heated. When dissolved in cold—640, 585 in H_2O (545 in EtOH) (269); *cf.*(266); Ba salt, 635, 590 in H_2O (677).

$C_{32}H_{24}N_6O_{14}S_4$.—Diphenyldisazo-*bis*-8-amino-*α*-naphthol-3, 6-disulfonic acid (Na salt, C. I. 406): Pontamine Blue BBF, metallic salts in H_2O; Na, Ba, 580, Cu, 590, Al, 570, Cr, 595 (677).

$C_{32}H_{27}N_5O_9S_2$.—4-Sulfo-2-methylbenzeneazo-*p*-methylanisoleazo-6-benzoylamino-*α*-naphthol-3-sulfonic acid: Na salt, 641, (598), 530 in H_2O; 638, 522 in 0.02*N* HCl; (630), 542 in 0.02*N* NaOH; 571, 542 in 85% EtOH (436).

$\mathbf{C_{32}H_{27}N_{9}}$.—Benzeneazobenzeneazobenzeneazobenzeneazodimethylaniline: 514 (111).

$\mathbf{C_{33}H_{25}N_{5}O_{6}S_{2}}$.—*m*-Sulfobenzeneazo-$\alpha$-naphthaleneazo-*p*-tolyl-α-naphthylamine-8-sulfonic acid (Na salt, C. I. 289): influence of neutral salts (635, 636); influence of concn. (269).

$\mathbf{C_{33}H_{26}N_{8}O_{15}S_{4}}$.—3, 3′-Disulfodiphenylurea-4, 4′-disazo-*bis*-7-amino-α-naphthol-3-sulfonic acid (Na salt, C. I. 353): soln. and dyeing (22); influence of concn. (269).

$\mathbf{C_{34}H_{24}N_{8}O_{10}S_{2}}$.—Phenolazodiphenylazo-8-amino-3, 6-disulfo-α-naphtholazo-*p*-nitrobenzene (Na salt, C. I. 593): Pontamine Green X (269).

$\mathbf{C_{34}H_{26}N_{4}O_{2}}$.—Ditolyldisazo-*bis*-$\beta$-naphthol: 654.2, 606.1 in H_2SO_4 (190).

$\mathbf{C_{34}H_{26}N_{4}O_{4}}$.—Dimethoxydiphenyldisazo-*bis*-β-naphthol (C. I. 499): 663.2, 614.2 in H_2SO_4 (190).

$\mathbf{C_{34}H_{26}N_{4}O_{10}S_{2}}$.—Dimethoxydiphenyldisazo-*bis*-α-naphthol-4-sulfonic acid (Na salt, C. I. 502): Pontamine Blue AX, metallic salts in H_2O; Na, 552, Cr, 550, Ba, 540, Al, Cu, 520 (677).

$\mathbf{C_{34}H_{27}N_{5}O_{8}S_{2}}$.—7-Sulfo-$\alpha$-naphthaleneazo-*p*-methylanisoleazo-6-phenylamino-α-naphthol-3-sulfonic acid: Na salt, 560 in H_2O; 569 in 0.02*N* HCl; 550 in 0.02*N* NaOH (436).

$\mathbf{C_{34}H_{27}N_{5}O_{11}S_{3}}$.—3, 6-Disulfo-$\alpha$-naphthaleneazo-*p*-methylanisoleazo-6-phenylamino-α-naphthol-3-sulfonic acid: Na salt, (608), 556 in H_2O; 554 in 0.02*N* HCl; 553 in 0.02*N* NaOH (436).

3, 6-Disulfo-β-naphthaleneazo-*p*-methylanisoleazo-6-phenylamino-α-naphthol-3-sulfonic acid: Na salt, 555 in H_2O; 555 in 0.02*N* HCl; 558 in 0.02*N* NaOH; 582, 555 in 85% EtOH (436).

3, 6-Disulfo-8-amino-α-naphtholazoditolylazo-α-naphthol-4-sulfonic acid (Na salt, C. I. 472): Niagara Blue BR, 568 in H_2O at 23°; 567 at 49°; 565 at 76° (677).

$\mathbf{C_{34}H_{27}N_{5}O_{12}S_{3}}$.—3, 7-Disulfo-$\beta$-naphtholazoethoxybenzidineazo-7-amino-α-naphthol-3-sulfonic acid (Na salt, C. I. 492): 580 in H_2O (dissolved cold); 575 (dissolved hot); 565 in EtOH (266); *cf.* (269).

$\mathbf{C_{34}H_{27}N_{5}O_{14}S_{4}}$.—3, 6, 8-Trisulfo-$\beta$-naphthaleneazo-*p*-methylanisoleazo-6-phenylamino-α-naphthol-3-sulfonic acid: Na salt, 562 in H_2O; 561 in 0.02*N* HCl; 560 in 0.02*N* NaOH; 580, 556 in 85% EtOH (436).

$\mathbf{C_{34}H_{28}N_{6}O_{6}S_{2}}$.—Ditolyldisazo-*bis*-$\alpha$-naphthylamine-4-sulfonic acid (Na salt, C. I. 448): Erie Red 4B, 490 in H_2O (concd.); 498 (dil.); 505 in EtOH (269). Purpurine 4B (DuP.), 490 in H_2O (concd.), 496 (dil.), 510 in EtOH (677). Benzopurpurine 4B (By), on cotton, 505 (627). Diamine Red 4B, 512.5 on cotton (627).

Ditolyldisazo-*bis*-α-naphthylamine-5-sulfonic acid (Na salt, C. I. 449). Metallic salts of Benzopurpurine 6B in H_2O: Na, Cu, Al, 500; Cr, 505 (677).

$\mathbf{C_{34}H_{28}N_{6}O_{9}S_{2}}$.—Ethoxydiphenyldisazo-*bis*-7-amino-α-naphthol-3-sulfonic acid (Na salt, C. I. 493): Diamine Black BO, dissolved with heat, 600 in H_2O (concd.); 580 (dil.); dissolved cold, 580 in H_2O (concd.); 570 (dil.); 570 in EtOH (266); *cf.* (269).

$\mathbf{C_{34}H_{28}N_{6}O_{9}S_{3}}$.—Ditolyldisazo-3, 6-disulfo-β-naphthylamine-β-naphthylamine-6-sulfonic acid (Na salt, Vital Red, C. I. 456): 500 in H_2O (269).

$\mathbf{C_{34}H_{28}N_{6}O_{14}S_{4}}$.—Ditolyldisazo-*bis*-8-amino-α-naphthol-3, 6-disulfonic acid (Na salt, Trypan Blue, C. I. 477): 585 in H_2O (485q); *cf.* (473).

$\mathbf{C_{34}H_{28}N_{6}O_{16}S_{4}}$.—Dimethoxydiphenyldisazo-*bis*-8-amino-α-naphthol-3, 6-disulfonic acid (Na salt, C. I. 520): Pontamine Sky Blue 5BX, 595 in H_2O (concd.), 603 (dil.) (269). Metallic salts in H_2O: Na, 603, Al, 605, Cr, 610, Ba, 610, Cu, 580 (677).

Dimethoxydiphenyldisazo-*bis*-8-amino-α-naphthol-5, 7-disulfonic acid (Na salt, C. I. 518): Pontamine Sky Blue 6BX, lakes with Methylene Blue (265). Metallic salts in H_2O; Na, 620, Cu, 620, 670, Cr, 590, Ba, 618 (677).

$\mathbf{C_{35}H_{27}N_{5}O_{12}S_{3}}$.—3, 6-Disulfo-$\beta$-naphthaleneazo-*p*-methylanisoleazo-6-benzoylamino-α-naphthol-3-sulfonic acid: Na salt (601), 535 in H_2O; 516 in 0.02*N* HCl; 543 in 0.02*N* NaOH: 560 in 85% EtOH (436).

$\mathbf{C_{35}H_{27}N_{5}O_{15}S_{4}}$.—3, 6, 8-Trisulfo-$\beta$-naphthaleneazo-*p*-methylanisoleazo-6-benzoylamino-α-naphthol-3-sulfonic acid: Na salt, (596), 540 in H_2O; 535 in 0.02*N* HCl; 543 in 0.02*N* NaOH; 576, 538 in 85% EtOH (436).

$\mathbf{C_{38}H_{27}N_{7}O_{10}S_{3}}$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-α-naphthaleneazo-6-phenylamino-α-naphthol-3-sulfonic acid: Na salt, 593 in H_2O (580 with alkali, 621 with acid) (436).

$\mathbf{C_{38}H_{27}N_{7}O_{13}S_{4}}$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-7-sulfo-α-naphthaleneazo-6-phenylamino-α-naphthol-3-sulfonic acid: Na salt, 575 in H_2O (556 with alkali, 578 with acid) (436).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-7-sulfo-α-naphthaleneazo-6-phenylamino-α-naphthol-4-sulfonic acid: Na salt, 601 in H_2O (580 with alkali, 608 with acid) (436).

$\mathbf{C_{39}H_{29}N_{7}O_{10}S_{3}}$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-α-naphthaleneazo-6-*p*-tolylamino-α-naphthol-3-sulfonic acid: Na salt, 595 in H_2O (587 with alkali, 620 with acid) (436).

$\mathbf{C_{39}H_{29}N_{7}O_{13}S_{4}}$.—*p*-Sulfobenzeneazo-*o*-sulfobenzeneazo-7-sulfo-α-naphthaleneazo-6-*p*-tolylamino-α-naphthol-3-sulfonic acid: Na salt, 578 in H_2O (560 with alkali, 579 with acid) (436).

p-Sulfobenzeneazo-*o*-sulfobenzeneazo-7-sulfo-α-naphthaleneazo-6-*p*-tolylamino-α-naphthol-4-sulfonic acid: Na salt, 603 in H_2O; (576 with alkali, 604 with acid) (436).

$\mathbf{C_{46}H_{34}N_{10}O_{13}S_{3}}$.—4-Sulfo-$\alpha$-naphthaleneazo-3, 6-disulfo-α-naphthol-7-azo-*m*-toluylenediamineazodiphenylazosalicylic acid (Na salt, C. I. 561): Trisulfon Brown B (22).

Diazine Black D. R. Concd. (probably identical with Zambesi Black II): 560 in H_2O (concd.); 565 (dil.); 585 in EtOH (266, 269).

Diazo Dark Blue 3B: 560 in H_2O (concd.), 570 (dil.), 590 in EtOH (266, 269).

Pontachrome Yellow 3R: on wool (10).

Pontamine Copper Blue RRX (probably N. W. acid→benzidine →2-amino-8-naphthol-5-sulfonic acid): 545 in H_2O (concd.); 555 (dil.) (269). Metallic salts in H_2O: Na, 555, Ba, 550, Al, 510, Cu, 530 (677).

TABLE 3.—TRIPHENYLMETHANE DERIVATIVES

$\mathbf{C_{19}H_{10}Br_{4}O_{2}}$.—*m*-Tetrabromobenzaurin (subst. in phenol residues): 583 in alk. H_2O (461).

$\mathbf{C_{19}H_{13}BrO_{2}}$.—*o*-Bromobenzaurin (subst. in benzene residue): 568 in alk. H_2O (461).

m-Bromobenzaurin (subst. in benzene residue): 565 in alk. H_2O (461).

p-Bromobenzaurin (subst. in benzene residue): 539 in alk. H_2O (461).

$\mathbf{C_{19}H_{13}BrN_{2}O_{4}}$.—*p*-Bromo-*p*-dinitrotriphenylmethane: 274 in EtOH; Na salt, 513 in EtOH and C_6H_6 (221).

$\mathbf{C_{19}H_{13}N_{3}O_{6}}$.—*p*-Trinitrotriphenylmethane: Na salt, 549 in EtOH (221).

$\mathbf{C_{19}H_{14}O}$.—Fuchsone: *381*, 262, 250 in EtOH; *462*, 402, (289), *248* in concd. H_2SO_4; 472, 381, 283, 278, 270 in EtOH + HCl; 286, *250*, in EtOH + KOH (491q); 379, (262) in $CHCl_3$ (219); (471 with excess $SnCl_4$ (438)); *cf.* (213, 218, 438, 442, 454, 470).

$\mathbf{C_{19}H_{14}O_{2}}$.—Benzaurin: *435*, 343, (284), 275 in EtOH; *504*, 402, (284, 276, 266) in EtOH + HCl; *473*, 410, (292, 285?), 256 in concd. H_2SO_4; 567, 379, 296, *250* in EtOH + KOH; 345, 296, 247 in 33% KOH (489q); *cf.* (155, 438, 442, 454, 461, 463, 491q).

$\mathbf{C_{19}H_{14}O_{3}}$.—Aurin: *463*, (385, 297, 276), 265 in EtOH; *476*, (428, 333, 298, 289), *260* in concd. H_2SO_4; *482*, (338, 309), 272, 266 in EtOH + HCl; *536*, (500), 283 in EtOH + KOH; (364), 298, *248* in concd. aq. KOH (491q); *cf.* (57, 155, 174, 196, 231, 454, 461, 525).

VISCOSITY OF PURE LIQUIDS

F. Giordani

Units.—All values of the viscosity, η, are expressed in poises. The values tabulated are those of 100η which are equivalent to values of η expressed in centipoises.	*Unités.*—Toutes les valeurs de la viscosité, η, sont exprimées en poises. Les valeurs mentionnées dans les tables sont celles de 100η qui sont équivalentes aux valeurs de η exprimées en centipoises.	*Einheiten.*—Alle Werte der Viskosität, η, sind in C. G. S.-Einheiten ausgedrückt. Die in Zahlentafeln stehen Werte gelten für 100η und entsprechen den Werten von η, die in Hundert-C. G. S.-Einheiten gegeben sind.	*Unità.*—Tutti i valori della viscosità, η, sono espressi in poise. I valori nelle tabelle sono quelli di 100η che sono equivalenti al valore di η espresso in centipoise.

INFLUENCE OF PRESSURE ON VISCOSITY (14.7)

η = viscosity of liquid under tabulated pressure and temperature.

$\eta_{30°}$ = viscosity of liquid at 30° and atmospheric pressure; poises.

P = pressure in kg/cm².

The reference value of $\eta_{30°}$ is indicated under the name of compound.

Values of $\log_{10} \frac{\eta}{\eta_{30°}}$

CCl_4, Carbon tetrachloride
$\eta_{30°}$ = 0.00845

FREE ENERGY OF CHEMICAL SUBSTANCES, ACTIVITY COEFFICIENTS, PARTIAL MOLAL QUANTITIES, AND RELATED CONSTANTS[1]

MERLE RANDALL, SPECIAL EDITOR

Including

EQUILIBRIA BETWEEN TWO SOLID PHASES AND A GAS PHASE (DECOMPOSITION PRESSURES OF HYDRATES, AMMONIATES, ETC.)

FRITZ EPHRAIM[2]

and

SOLUBILITY OF SLIGHTLY SOLUBLE SALTS IN AQUEOUS SALT SOLUTIONS

MERLE RANDALL AND WILLIAM V. VIETTI[3]

SCOPE OF THE SECTION

This section includes all chemical equilibria except those which have been treated in previous sections. The section also includes miscellaneous thermodynamic data, such as partial molal quantities, activity coefficients, heat capacities of substances, etc., when these are combined with other data.

The tables are not as complete as could be desired. An attempt has been made to include as many types of systems as possible, and more space has been given to those systems which have not been widely discussed in the literature than to the more common systems. Omission of a table or mention by reference only in no way reflects upon the quality or importance of the data.

OBJET TRAITÉ DANS LA SECTION

Cette section comprend tous les équilibres chimiques, à l'exception de ceux dont il a déjà été traité dans des sections précédentes. La section renferme aussi des données thermodynamiques diverses, telles que des quantités moléculaires partielles, coefficients d'activité, capacités calorifiques des substances, etc., lorsque celles-ci sont combinées à d'autres données.

Les tables ne sont pas aussi complètes qu'on puisse le désirer. On s'est efforcé d'y mentionner un nombre aussi grand que possible de types de systèmes, et il a été réservé plus d'espace aux systèmes qui n'ont pas été largement discutés dans la littérature qu'aux systèmes plus communs. L'omission d'une table ou sa mention par une référence seulement ne se rapporte en aucune manière à la qualité ou à l'importance de la donnée.

---

[1] *See also* Entropy, etc., Vol. V, p. 84.

[2] Editorial Note.—The data on this topic, compiled by Professor Ephraim, have been combined with the other data of this section according to the Standard Arrangement. They are identified by the symbol (E). Translation from the German and conversion into the units °K and atm. were effected by Gerald F. Breckenridge under the direction of the Special Editor.

[3] The senior author is alone responsible for the data on the complex ammines and for references subsequent to the year 1925. For this section, *see* p. 313.

FREE ENERGY OF CHEMICAL SUBSTANCES, ACTIVITY COEFFICIENTS, PARTIAL MOLAL QUANTITIES, AND RELATED CONSTANTS[1]

MERLE RANDALL, SPECIAL EDITOR

Including

EQUILIBRIA BETWEEN TWO SOLID PHASES AND A GAS PHASE (DECOMPOSITION PRESSURES OF HYDRATES, AMMONIATES, ETC.)

FRITZ EPHRAIM[2]

and

SOLUBILITY OF SLIGHTLY SOLUBLE SALTS IN AQUEOUS SALT SOLUTIONS

MERLE RANDALL AND WILLIAM V. VIETTI[3]

SCOPE OF THE SECTION

This section includes all chemical equilibria except those which have been treated in previous sections. The section also includes miscellaneous thermodynamic data, such as partial molal quantities, activity coefficients, heat capacities of substances, etc., when these are combined with other data.

The tables are not as complete as could be desired. An attempt has been made to include as many types of systems as possible, and more space has been given to those systems which have not been widely discussed in the literature than to the more common systems. Omission of a table or mention by reference only in no way reflects upon the quality or importance of the data.

OBJET TRAITÉ DANS LA SECTION

Cette section comprend tous les équilibres chimiques, à l'exception de ceux dont il a déjà été traité dans des sections précédentes. La section renferme aussi des données thermodynamiques diverses, telles que des quantités moléculaires partielles, coefficients d'activité, capacités calorifiques des substances, etc., lorsque celles-ci sont combinées à d'autres données.

Les tables ne sont pas aussi complètes qu'on puisse le désirer. On s'est efforcé d'y mentionner un nombre aussi grand que possible de types de systèmes, et il a été réservé plus d'espace aux systèmes qui n'ont pas été largement discutés dans la littérature qu'aux systèmes plus communs. L'omission d'une table ou sa mention par une référence seulement ne se rapporte en aucune manière à la qualité ou à l'importance de la donnée.

---

[1] *See also* Entropy, etc., Vol. V, p. 84.

[2] Editorial Note.—The data on this topic, compiled by Professor Ephraim, have been combined with the other data of this section according to the Standard Arrangement. They are identified by the symbol (E). Translation from the German and conversion into the units °K and atm. were effected by Gerald F. Breckenridge under the direction of the Special Editor.

[3] The senior author is alone responsible for the data on the complex ammines and for references subsequent to the year 1925. For this section, *see* p. 313.

ARRANGEMENT

1. The systems or reactions are listed in the standard arrangement (*see* Vol. III, p. viii) in accordance with that substance in the reaction which has the highest key-formula. Thus, for example, in the reaction

$$Pb(s) + PbO_2(s) + 2H_2SO_4(aq) = 2PbSO_4(s) + 2H_2O(l)$$

the key-formulae are:

Pb, 23; PbO_2, 23—12; H_2SO_4, 8—22—14; $PbSO_4$, 23—8—14; H_2O, 22—1.

The highest key-formula is that for $PbSO_4$, 23—8—14 and this reaction will therefore be found listed under $PbSO_4$ and can be found by turning the pages until 23 appears as the first member of the key-numbers which appear at the top of each right-hand page. After locating the proper section in this way, the desired system or reaction can then be located by inspection.

2. Where choice of condition or state is involved for a given substance the order is gas (g); liquid (l); solid (s); in aqueous solution (aq); in non-aqueous solution, standard arrangement by solvents.

3. *Important Exceptions.*—Solid hydrates, ammines, etc., containing water, ammonia, etc., "of crystallization" are listed under the parent material. Water, ammonia, etc., of crystallization should, therefore, be neglected in writing key-formulae. (These exceptions do not, however, apply to complex ions, complex cobaltammines, etc.) Solubility data are in all cases listed under the solute.

SYMBOLS AND ABBREVIATIONS

In general the notation of Lewis and Randall (885) is used.

a	Activity.
c	Concentration (moles per liter).
$c_\pm$	Geometrical mean of concentration of ions.
f	Fugacity.
het.	Two-phase system richest in solute.
ln	Logarithm to the base *e*.
log	Logarithm to the base 10.
m	Molality (moles per 1000 g H_2O, *in vacuo*).
$m_\pm$ $m^0_\pm$	*v.* p. 227.
n	Number of moles.
p	Vapor pressure (in atmospheres).
p.f.	Proportionality factor (*see* activity coefficients).
s	Solubility (moles per 1000 g H_2O, *in vacuo*).
s_c	Solubility (moles per liter).
t	Temperature, °C.
x	Mole fraction.
C_p	Molal heat capacity at constant pressure.
C_v	Molal heat capacity at constant volume.
E	Internal energy.
E	Electromotive force.
E^-	One gram atom of negative electricity.
F	Free energy.
H	Heat content.
I	Integration constant.
K	Equilibrium constant (activities) *v.* p. 227.
K'	Special equilibrium function.
K_c	Equilibrium function in terms of concentration.
K_m	Equilibrium function in terms of molalities.
K_p	Equilibrium function in terms of partial pressures.
$\bar{L}$	Relative partial molal heat content.
M	Molal.
P	Total pressure or vapor pressure, in atmospheres.
R	Gas constant.
S	Entropy.
T	Absolute temperature.
V	Volume.
w	Molal mass.

ARRANGEMENT

1. Les systèmes ou les réactions sont disposés en liste suivant l'arrangement type (*voir* Vol. III, p. viii) en accord avec la substance de la réaction qui possède la formule-clé la plus élevée. Ainsi, par exemple, dans la réaction

$$Pb(s) + PbO_2(s) + 2H_2SO_4(aq) = 2PbSO_4(s) + 2H_2O(l)$$

les formules-clés sont

Pb, 23; PbO_2, 23—12; H_2SO_4, 8—22—14; $PbSO_4$, 23—8—14; H_2O, 22—1.

La formule-clé la plus élevée est celle de $PbSO_4$, 23—8—14 et par conséquent on trouvera la réaction mentionnée ci-dessus sous $PbSO_4$; on tournera donc les pages jusqu'à ce qu'on atteigne 23, premier membre des nombres-clés inscrits au haut de chacune des pages se trouvant à main droite. Ayant trouvé de cette façon la section convenable, on y recherchera alors, le système de réaction désiré.

2. Lorsque le choix de la condition ou de l'état est impliqué pour une substance donnée, l'ordre est gaz (g); liquide (l); solide (s); en solution aqueuse (aq); en solution non-aqueuse, arrangement type par dissolvants.

3. *Exceptions Importantes.*—Les hydrates solides, les ammines, etc., contenant de l'eau, de l'ammoniaque, etc., "de cristallisation" sont inscrits en liste sous la matière principale. L'eau, l'ammoniaque, etc., de cristallisation doivent donc être négligés lorsqu'on écrit la formule-clé. (Ces exceptions cependant ne s'appliquent pas aux ions complexes, cobaltammines complexes, etc.) Les données de solubilité sont dans tous les cas inscrits sous le corps dissous.

SYMBOLES ET ABRÉVIATIONS

C'est en général la notation de Lewis et Randall (885) quies utilisée.

a	Activité.
c	Concentration (mol gr. par litre).
$c_\pm$	Moyenne géométrique de la concentration des ions.
f	Fugacité.
het.	Système à deux phases le plus riche en corps dissous.
ln	Logarithme de base *e*.
log	Logarithme de base 10.
m	"Molalité" (mol gr. par 1000 g H_2O, dans le vide).
$m_\pm$ $m^0_\pm$	*v.* p. 227.
n	Nombre de molécules grammes.
p	Pression de vapeur (en atmosphères).
p.f.	Facteur de proportionalité (*voir* coefficients d'activité).
s	Solubilité (molécules gr. par 1000 g H_2O, dans le vide).
s_c	Solubilité (molécules gr. par litre).
t	Température, °C.
x	Fraction moléculaire gramme.
C_p	Capacité calorifique moléculaire à pression constante.
C_v	Capacité calorifique moléculaire à volume constant.
E	Énergie interne.
E	Force électromotrice.
E^-	Un atome gramme d'électricité négative.
F	Énergie libre.
H	Contenu de chaleur.
I	Constante d'intégration.
K	Constante d'équilibre (activités), *v.* p. 227.
K'	Fonction d'équilibre spéciale.
K_c	Fonction d'équilibre en termes de concentration.
K_m	Fonction d'équilibre en termes de molalité.
K_p	Fonction d'équilibre en termes de pressions partielles.
$\bar{L}$	Contenu de chaleur relatif partiel moléculaire.
M	Moléculaire gramme.
P	Pression totale ou pression de vapeur, en atmosphères.
R	Constante des gaz.

γ	Activity coefficient.
μ	Ionic strength.
μ_c	Ionic strength (for concentrations).
ν	Number of ions formed by dissociation of one molecule.
Δ	Increment.

Small cap roman: molal quantities, thus H.

Small cap roman with bar: Partial molal quantity, thus H.

Subscript $_1$ (resp. $_2$) identifies solvent (resp. solute).

UNITS AND VALUES OF CONSTANTS USED*

1 cal.	4.182 joules.
T	$t + 273.1$.
R	82.07 cm^3-atm. per deg. K.
R	1.9885 cal. per deg. K.
V	(for 1 mole of a perfect gas) 22 412 cm^3 at 1 atm. and 273.1°K.
F	96 494 coulombs per equiv.
F	23 074 cal. per volt equiv.

All pressures are expressed in atmospheres, all temperatures in degrees absolute, all electromotive forces in volts and all energy quantities in calories (*v. supra*) unless otherwise expressly stated. When making further transformations of the data, it is important to use only the constants and data of this section.

FREE ENERGY DATA

In general, the accuracy of the free energy equations may be judged by the constancy of the quantity I where this has been tabulated. The lack of a definite trend with a variation in temperature indicates that the choice of the particular form of substances taking part in the reaction and the values of the ΔH and ΔC_p are probably substantially correct. The individual variations indicate the degree of precision of the experimental measurements. Since many of the derived values involve addition and subtraction of other equations, it is not possible, at this time, to give the probable error, and the number of significant figures given should not be interpreted as an indication of the accuracy. Where "revised" values are indicated, it is usually necessary to use the unrevised (^{885}) values, when these are to be combined with other equations in this section.

The free energies are given in the form

$$\Delta F^0 = \Delta H_0^0 - \Delta\Gamma_0^0 T \ln T - \tfrac{1}{2}\Delta\Gamma' T^2 - \tfrac{1}{6}\Delta\Gamma'' T^3 - \cdots + IT \quad (1)$$

where $\Delta\Gamma$, $\Delta\Gamma'$ and $\Delta\Gamma''$, etc., are the coefficients in the algebraic expression for the increase in heat capacity of the reaction.

We thus have

$$\Delta H^0 = \Delta H_0^0 + \Delta\Gamma^0 T + \tfrac{1}{2}\Delta\Gamma' T^2 + \tfrac{1}{3}\Delta\Gamma'' T^3 \quad (2)$$

$$\Delta \mathrm{S}^0 = \Delta\Gamma_0^0(1 + \ln T) + \Delta\Gamma' T + \tfrac{1}{2}\Delta\Gamma'' T^2 + \cdots - I \quad (3)$$

The superscript ^{0} on the quantities ΔF, ΔH, ΔS indicates that the quantity is that for a stated or implied reaction in which all chemical substances involved are assumed to be at unit activity, at a fugacity of 1 atm. (or, when specifically so stated, at a pressure of 1 atm.), or hypothetical unit concentration. Where the reaction is not explicitly stated it is assumed to be the reaction of formation of a stated substance out of its elements in their standard states. The standard state of an element is that state to which the value $\Delta F^0 = 0$ is assigned in the tables, the pressure being always one atm. unless otherwise specifically stated. When no standard state is thus indicated in the tables, the "ordinary" solid form of the element is assumed.

In writing the equilibrium constant, K, the activities of the substances appearing on the right of the reaction as written always appear in the numerator. For gases the units are always atmospheres, and for solutes the units are always mole fractions, or moles per 1000 g of water. For the constant K so defined, $\Delta F^0 = -RT \ln K$.

S	Entropie.
T	Température absolue.
V	Volume.
w	Masse molale.
γ	Coefficient d'activité.
μ	Force ionique.
μ_c	Force ionique (pour concentrations).
ν	Nombre d'ions formées par dissociation d'un molécule.
Δ	Incrément.

Petite majuscule romaine: Quantités moléculaires, ainsi H.

Petite majuscule romaine avec barre: Quantité moléculaire partielle, ainsi $\bar{\text{H}}$.

L'indice $_1$ (resp. $_2$) identifie le solvant (resp. le corps dissous).

UNITÉS ET VALEURS DES CONSTANTES UTILISÉES*

1 cal.	4,182 joules.
T	$t + 273{,}1$.
R	82,07 cm^3-atm. par deg. K.
R	1,9885 cal. par deg. K.
V	(pour une molécule gramme d'un gaz parfait) 22 412 cm^3 à 1 atm. et à 273, 1°K.
F	96 494 coulombs par equiv.
F	23 074 cal. par volt equiv.

Toutes les pressions sont exprimées en atmosphères, toutes les températures en degrés absolus, toutes les forces électromotrices en voltes et toutes les quantités d'énergie en calories (*v.* ci-dessus), à moins d'une autre indication. Lorsqu'on veut effectuer des transformations ultérieures des données, il est important de n'utiliser que les constantes et les données de cette section.

DONNÉES RELATIVES À L'ÉNERGIE LIBRE

En général, on peut juger de la précision des équations relatives à l'énergie libre par la constance de la quantité I en consultant la table où celle-ci est mentionnée. Le manque d'une tendance définie avec la variation de la température indique que le choix de la forme particulière des substances prenant part à la réaction et des valeurs de ΔH et ΔC_p est probablement réellement exact. Les variations individuelles indiquent le degré de précision des mesures expérimentales. Comme plusieurs des valeurs dérivées comportent l'addition et la soustraction d'autres équations, il n'est pas possible, pour le moment, de donner l'erreur probable et le nombre de chiffres significatifs donnés ne doit pas être interprété comme une indication de la précision. Lorsque des valeurs "revised" sont indiquées, il est ordinairement nécessaire d'utiliser les valeurs non revisées (^{885}), lorsque celles-ci doivent être combinées avec d'autres équations de la section.

Les énergies libres sont données sous la forme

$$\Delta F^0 = \Delta H_0^0 - \Delta\Gamma_0^0 T \ln T - \tfrac{1}{2}\Delta\Gamma' T^2 - \tfrac{1}{6}\Delta\Gamma'' T^3 - \cdots + IT \quad (1)$$

où $\Delta\Gamma$, $\Delta\Gamma'$ et $\Delta\Gamma''$, etc., sont les coefficients dans l'expression algébrique de l'augmentation de la capacité calorifique de la réaction.

On a ainsi

$$\Delta H^0 = \Delta H_0^0 + \Delta\Gamma^0 T + \tfrac{1}{2}\Delta\Gamma' T^2 + \tfrac{1}{3}\Delta\Gamma'' T^3 \quad (2)$$

$$\Delta S^0 = \Delta\Gamma_0^0(1 + \ln T) + \Delta\Gamma' T + \tfrac{1}{2}\Delta\Gamma'' T^2 + \cdots - I \quad (3)$$

L'exposant ^{0} sur les quantités ΔF, ΔH, ΔS, indique que la quantité est celle se rapportant à une reaction établie ou implicite, dans laquelle toutes les substances chimiques engagées sont supposées être à l'activité unité, à une fugacité d'une atmosphère, (ou, lorsque cela est établi spécifiquement ainsi, à une pression d'une atm.), ou à une concentration unité hypothétique. Lorsque la réaction n'est pas établie explicitement, il s'agit d'une réaction de formation d'une substance donnée à partir de ses éléments dans leur état type. L'état type d'un élément est l'état pour lequel la

---

*Note that these *are not* the accepted I. C. T. values (*see* Vol. I, p. 17). The data of the present section form a consistent whole but cannot be readily combined with other data in I. C. T.

*À noter que celles-ci *ne sont pas* les valeurs I. C. T. acceptées (*voir* Vol. I, p. 17). Les données de la présente section constituent un tout consistant, mais elles ne peuvent être directement combinées avec les autres données dans les I. C. T.

In some cases we use equilibrium functions (K_m) in which the molality of the substances or ions is used instead of the activity, and others (K_c) in which the concentrations (moles per liter) of the substances in solution are used instead of the activities. In still others we have used special functions (K'_m or K'_c) in which activities are used for all the substances except the ions present. The concentration of a gas is never used in these expressions. *See* Lewis and Randall (**885**), Randall and Vietti (**1192**), Randall (**1170.5**).

ACTIVITY COEFFICIENTS

In the case of all reactions involving only ions on the right-hand side of the equation, and a few others, the various equilibria are transformed in such a way that ($\log \gamma$ + a constant) and $\mu^{1/2}$ are given in the tables. By a simple graph of these quantities interpolations and comparisons may be made, and by superimposition of the curves so obtained upon the corresponding curves for suitable reference salts made upon the same scale, the extrapolation to unit activity coefficient can be easily made, and when these extrapolated numbers become available the activity coefficient of the particular pair of ions may be found by subtraction of log *p.f.* (given in a few cases) from the value of ($\log \gamma$ + a constant). The activity coefficient for concentration, the ionic strength for concentration, etc., are defined in the sense used by Randall and Vietti (**1192**), namely, the product of the-activity-coefficient-for-concentration by the concentration gives the activity (defined with reference to molalities).

$$\log \gamma + \text{const.} = \log \gamma - E^0/(0.00019844\nu T/N) = -E/(0.00019844\nu T/N) + \log (1/m_\pm) \quad (4)$$

where E^0 and E are the standard and measured electromotive forces, N the number of equivalents, and $m_\pm$ the mean molality of the ions studied in the cell.* Or

$$\log \gamma + \text{const.} = (1/\nu) \log p + \log (1/m_\pm) \quad (5)$$

where p is the vapor pressure of the solute. Or

$$\log \gamma + \text{const.} = (1/\nu) \log x_2 + \log (1/m_\pm)$$

where x_2 is the mole fraction of the solute in a second immiscible solvent. Or

$$\log \gamma + \text{const.} = \log (1/m_\pm)$$

where $m_\pm$ is the mean molality of the ions in equilibrium with the pure solid (solubility). Or

$$\log \gamma + \text{const.} = (1/\nu) \log (1/K'_m),$$

where K'_m is an equilibrium function in which activities are substituted for all substances taking part in the reaction (usually undissociable substances or gases) except the pair of ions considered. (*See* $CaCO_3$ (calcite) + H_2CO_3(aq) = Ca^{++} + $2HCO_3^-$, p. 296.)

INHALT DIESER ABTEILUNG

Zu dieser Abteilung gehören alle Gleichgewichte bis auf solche welche in den vorhergehenden behandelt worden sind. Die Abteilung enthält auch verschiedene thermodynamische Daten wie partielle molare Grössen, Aktivitätskoeffizienten, Molwärmen der Substanzen, usw., wenn dieselben mit anderen Daten verbunden sind.

Die Tabellen sind nicht so vollständig wie man sich wünschen könnte. Es wurde versucht, möglichst verschiedenartige Systeme zu behandeln; jenen Systemen, welche in der Literatur nicht so ausführlich diskutiert worden sind, ist mehr Raum gewidmet als den gewöhnlicheren. Das Weglassen einer Tabelle, oder die blosse Zitierung einer Arbeit ist nie als eine Unterschätzung der Qualität oder Wichtigkeit der Daten zu betrachten.

ANORDNUNG

1. Die Systeme und Reaktionen sind nach der Standardanordnung (*siehe* Bd. III, S. viii) geordnet, dem Reaktionsteilnehmer mit der höchsten Schlüsselformel entsprechend. So sind zum

valeur $\Delta F^0 = 0$ est assignée dans les tables, la pression étant toujours une atm. à moins d'une autre indication. Lorsque aucun état type n'est indiqué ainsi dans les tables, il s'agit de la forme "ordinaire" solide de l'élément.

En écrivant la constante d'équilibre, K, les activités des substances se trouvant au deuxième membre de la réaction sont écrites au numérateur comme d'habitude. Pour les gaz, les unités sont toujours atmosphères, et pour les corps dissous, les unités sont toujours fractions moléculaires grammes, ou molécules grammes pour 1000 g d'eau. Pour la constante K, ainsi définie, $\Delta F^0 = -RT \ln K$.

Dans quelques cas on s'est servi des fonctions d'équilibre (K_m), dans lesquelles la molalité des substances ou des ions est utilisée à la place de l'activité, et d'autres fonctions (K_c) dans lesquelles les concentrations (mol gr. par litre) des substances en solutions sont utilisées à la place des activités. Dans d'autres cas encore, il a été employé des fonctions spéciales (K'_m ou K'_c) dans lesquelles les activités ont été utilisées pour toutes les substances à l'exception des ions présents. La concentration d'un gaz n'est jamais utilisée dans ces expressions. *Voir* Lewis et Randall (**885**), Randall et Vietti (**1192**), Randall (**1170.5**).

COEFFICIENTS D'ACTIVITÉ

Dans le cas de toutes les réactions ne comportant que des ions au deuxième membre de l'équation, et dans quelques autres cas, les divers équilibres sont transformés de telle façon que ($\log \gamma$ + une constante) et $\mu^{1/2}$ soient donnés dans les tables. Au moyen d'un simple graphique de ces quantités, on peut faire des interpolations et des comparaisons et par superposition des courbes ainsi obtenues avec les courbes correspondantes de sels de référence convenables, dessinées à la même échelle, on peut effectuer facilement l'extrapolation pour le coefficient unité d'activité; lorsque ces nombres extrapolés sont disponibles, on trouvera le coefficient d'activité de la paire particulière d'ions en soustrayant log *p.f.* (donné dans quelques cas) de la valeur de ($\log \gamma$ + une constante). Le coefficient d'activité pour la concentration, la force ionique pour la concentration, etc., sont définis suivant le sens utilisé par Randall et Vietti (**1192**), c'est-à-dire, le produit du coefficient d'activité pour la concentration, par la concentration donne l'activité (définie avec référence aux molalité).

$$\log \gamma + \text{constante} = \log \gamma - E^0/0{,}00019844\nu T/N) = -E/(0{,}00019844\nu T/N) - \log (1/m_\pm) \quad (4)$$

où E^0 et E sont respectivement les forces électromotrices types et mesurées, N le nombre des équivalents et $m_\pm$ la molalité moyenne des ions étudiés dans la pile.* Ou

$$\log \gamma + \text{constante} = (1/\nu) \log p + \log (1/m_\pm) \quad (5)$$

où p est la pression de vapeur du corps dissous. Ou

$$\log \gamma + \text{constante} = (1/\nu) \log x_2 + \log (1/m_\pm)$$

où x_2 est la fraction moléculaire du corps dissous dans un deuxième dissolvant non miscible. Ou

$$\log \gamma + \text{constante} = \log (1/m_\pm)$$

où $m_\pm$ est la molalité moyenne des ions en équilibre avec le solide pur (solubilité). Ou

$$\log \gamma + \text{constante} = (1/\nu) \log (1/K'_m)$$

où K'_m est une fonction d'équilibre dans laquelle les activités sont substituées à toutes les substances prenant part à la réaction (ordinairement des substances non dissociables ou des gaz), à l'exception de la paire d'ions considérés. (*Voir* $CaCO_3$ (calcite) + H_2CO_3(aq) = Ca^{++} + $2HCO_3^-$, p. 296.)

ARGOMENTI COMPRESI IN QUESTO CAPITOLO

Questo capitolo comprende tutti gli equilibri chimici, eccettuati quelli dei quali si è parlato in capitoli precedenti. Vi sono pure contenuti dati termodinamici diversi, come quantità molari parziali, coefficienti di attività, capacità termiche, ecc.

---

* In general $\Delta F = -NEF$.

* En général $\Delta F = -NEF$.

Beispiel in der Reaktion

$$Pb(s) + PbO_2(s) + 2H_2SO_4(aq) = 2PbSO_4(s) + 2H_2O(l)$$

die folgenden als Schlüsselformeln zu nehmen:

Pb, 23; PbO_2, 23−12; H_2SO_4, 8−22−14; $PbSO_4$, 23−8−14; H_2O, 22−1.

Die höchste Schlüsselformel ist jene für $PbSO_4$, 23−8−14, und diese Reaktion wird deswegen unter $PbSO_4$ angegeben; man kann sie auffinden, indem man die Blätter des Bandes umschlägt, bis 23 als das erste Glied der Schlüsselnummern, die am oberen Ende jeder rechten Seite sind, erscheint. Nachdem die richtige Abteilung so gefunden worden ist, kann man das erwünschte System oder die erwünschte Reaktion nach Besichtigung festsetzen.

2. Wo es sich um eine Zustandswahl für die gegebene Substanz handelt, ist die Ordnung wie folgt: Gas (g); Flüssigkeit (l); fester Körper (s); in wässriger Lösung (aq); in nicht-wässriger Lösung, Standardanordnung nach Lösungsmitteln.

3. *Wichtige Ausnahmen.*—Feste Hydrate, Ammine, usw., Krystallwasser oder Krystall-Ammoniak enthaltend, stehen unter dem lösungsmittel-freien Salz verzeichnet. Krystall-Wasser, -Ammoniak, usw., sind deswegen im Schreiben der Schlüsselformeln fortzulassen. (Diese Ausnahmen sind aber für Komplexionen, Komplexkobaltammine, usw., nicht gültig.) Löslichkeitsdaten sind immer unter der Schlüsselformel des gelösten Stoffes zu finden.

ZEICHEN UND ABKÜRZUNGEN

Im allgemeinen werden die Formelzeichen von Lewis und Randall (885) gebraucht. (*Siehe* auch die deutsche Übersetzung von Redlich.)

a	Aktivität.
c	Konzentration (Mol pro Liter).
$c_\pm$	Geometrisches Mittel der Ionenkonzentrationen.
f	Flüchtigkeit. (Fugazität).
het.	Zwei-Phasen System am reichsten an gelöstem Stoff.
ln	Natürlicher Logarithmus.
log	Dekadischer Logarithmus.
m	Molarer Gehalt (Mol pro 1000 g H_2O *in vacuo*, Molarität).
$m_\pm$ $m^0_\pm$	*Siehe* S. 230.
n	Molzahl.
p	Dampfdruck (in Atmosphären).
$p.f.$	Proportionalitätsfaktor (*siehe* Aktivitätskoeffizienten).
s	Löslichkeit (Mol pro 1000 g H_2O *in vacuo*).
s_c	Löslichkeit (Mol pro Liter).
t	Temperatur, Grad Celsius.
x	Molenbruch.
C_p	Molwärme bei konstantem Druck.
C_v	Molwärme bei konstantem Volumen.
E	Innere Energie.
E	Elektromotorische Kraft.
E^-	Ein Gramm-Atom Äquivalent negativer Elektrizität.
F	Freie Energie.
H	Wärmeinhalt.
I	Integrationskonstante.
K	Gleichgewichtskonstante (Aktivitäten) *siehe* S. 230.
K'	Spezielle Gleichgewichtsfunktion.
K_c	Gleichgewichtsfunktion in Konzentrationen ausgedrückt.
K_m	Gleichgewichtsfunktion in Molaritäten ausgedrückt.
K_p	Gleichgewichtsfunktion in Partieldrücken ausgedrückt.
L	Relativer partieller molare Wärmeinhalt.
M	Molar.
P	Gesamtdruck oder Dampfdruck in Atmosphären.
R	Gaskonstante.
S	Entropie.
T	Absolute Temperatur.
V	Volumen.
w	Molare Masse (Molekulargewicht).

Le tabelle però non sono così complete come si potrebbe desiderare. Si è cercato di includervi il maggior numero possibile di tipi di sistemi, e sono stati trattati con maggiore estensione i sistemi non ampiamente discussi nella letteratura, anzichè quelli più comuni. Il fatto che qualche tabella sia stata omessa o che dei dati siani stati semplicemente citati non indica nulla rispetto alla qualità e alla importanza di essi.

DISPOSIZIONE

1. I sistemi e le reazioni sono elencate con l'ordinamento standard (*vedi* Vol. III, p. viii) seguendo l'ordine delle sostanze che hanno la formula-chiave più alta. Così, per esempio, nella reazione

$$Pb(s) + PbO_2(s) + 2H_2SO_4(aq) = 2PbSO_4(s) + 2H_2O(l)$$

le formule-chiavi sono:

Pb, 23; PbO_2, 23—12; H_2SO_4, 8—22—14; $PbSO_4$, 23—8—14; H_2O, 22—1.

La formula-chiave più alta è quella del $PbSO_4$, 23—8—14 e quindi questa reazione si troverà elencata sotto $PbSO_4$ e si troverà dove il 23 apparirà come il primo membro dei numeri-chiave che stannò in cima ad ogni pagina di destra. Stabilita a questo modo la sezione si può trovare il sistema di reazione per ispezione.

2. Quando una data sostanza è considerata in diversi stati, allora l'ordine è il seguente: gas (g); liquido(l); solido(s) in soluzione acquosa (aq); in soluzione non acquosa l'ordine è quello standard dei solventi.

3. *Eccezioni Importanti.*—Gli idrati solidi, le ammine, ecc., che contengono acqua, ammoniaca, ecc. "di cristallizzazione" sono elencati sotto la sostanza originaria. L'acqua, l'ammoniaca, ecc., di cristallizzazione dovrà essere tralasciata nello scrivere la formula-chiave. (Queste eccezioni non si riferiscono tuttavia agli ioni complessi, alle cobaltammine complesse, ecc.) I dati di solubilità sono in ogni caso elencati sotto i soluti.

ABBREVIAZIONI E SIMBOLI

In genere viene impiegata l'annotazione di Lewis e Randall (885).

a	Attività.
c	Concentrazioni (moli per litro).
$c_\pm$	Media geometrica della concentrazione degli ioni.
f	Fugacità.
het.	Sistema di due fasi più ricco in soluto.
ln	Logaritmo a base *e*.
log	Logaritmo a base 10.
m	Molarità (moli per 1000 g di H_2O, nel vuoto).
$m_\pm$ $m^0_\pm$	*v.* p. 230.
n	Numero di moli.
p	Tensione di vapore (in atmosfere).
$p.f.$	Fattore di proporzionalità (*vedi* coefficienti di attività).
s	Solubilità (moli per 1000 g H_2O, nel vuoto).
s_c	Solubilità (moli per litro).
t	Temperatura, °C.
x	Frazione di mole.
C_p	Capacità termica molare a pressione costante.
C_v	Capacità termica molare a volume costante.
E	Energia interna.
E	Forza elettromotrice.
E^-	Un grammo atomo di elettricità negativa.
F	Energia libera.
H	Contenuto termico.
I	Costante d'integrazione.
K	Costante di equilibrio (attività) *v.* p. 230.
K'	Funzione speciale di equilibrio.
K_c	Funzione d'equilibrio espressa in concentrazioni.

γ	Aktivitätskoeffizient.
μ	Ionenstärke.
μ_c	Ionenstärke (für Konzentrationen).
ν	Anzahl Ionen, die bei Dissoziation einer Molekül gebildet werden.
Δ	Zuwachs.

Kleingedruckte lateinische Grossbuchstaben, z. B. H, bedeuten molare Grössen.

Kleingedruckte lateinische Grossbuchstaben überstrichen, z. B. $\overline{\text{H}}$, bedeuten partielle molare Grössen.

Index $_1$ (bezw. $_2$) entspricht dem Lösungsmittel (bezw. gelöstem Stoff).

EINHEITEN UND WERTE DER GEBRAUCHTEN KONSTANTEN*

1 cal.	4,182 Joule.
T	$t + 273{,}1$.
R	82,07 cm^3-Atm. pro Grad K.
R	1,9885 Kal. pro Grad K.
V	(für einem Mol eines idealen Gases) 22 412 cm^3 bei 1 Atm. und 273,1°K.
F	96 494 Coulomb pro Äquiv.
F	23 074 Kal. pro Volt Äquiv.

Alle Drucke sind in Atmosphären, alle Temperaturen in Grad absolut, alle elektromotorischen Kräfte in Volt, und alle Energiegrössen in Kalorien (*siehe* weiter oben) ausgedrückt, wenn nicht ausdrücklich anders angegeben ist. Bei weiterer rechnerischer Verwendung dieser Daten ist es wichtig nur die Konstanten und Daten dieser Abteilung zu gebrauchen.

DATEN DER FREIEN ENERGIE

Im allgemeinen kann man die Genauigkeit der Gleichungen für die freie Energie nach der Konstanz der Grösse I beurteilen, wenn letztere tabellarisiert ist. Das Ausbleiben einer bestimmten Richtung der Konstante bei einer Temperaturänderung zeigt, dass die Wahl dieser besonderen Formen der Reaktionsteilnehmer, sowohl wie die Werte von ΔH und ΔC_p wahrscheinlich richtig ist. Die einzelnen Abweichungen zeigen den Präzisionsgrad der experimentellen Messungen. Da viele der abgeleiteten Werte durch Addition und Subtraktion anderer Gleichungen erhalten worden sind, ist es zu dieser Zeit nicht möglich, die Grösse des wahrscheinlichsten Fehlers anzugeben; die Zahl der angegebenen Ziffern soll deswegen nicht als Mass der Genauigkeit genommen werden. Wo "revised" Werte angegeben sind, ist es gewöhnlich nötig dass man die nicht revidierten (^{885}) Werte gebraucht, wenn man solche Daten mit anderen der Abteilung kombinieren will.

Die freien Energien sind in folgender Form gegeben

$$\Delta F^0 = \Delta H_0^0 - \Delta\Gamma_0^0 T \ln T - \tfrac{1}{2}\Delta\Gamma' T^2 - \tfrac{1}{6}\Delta\Gamma'' T^3 - \ . \ . \ . + IT \quad (1)$$

wo $\Delta\Gamma$, $\Delta\Gamma'$, $\Delta\Gamma''$, usw., die Koeffizienten in dem algebräischen Ausdruck für die Zunahme des Wärmeinhalts während der Reaktion sind.

So haben wir

$$\Delta H^0 = \Delta H_0^0 + \Delta\Gamma^0 T + \tfrac{1}{2}\Delta\Gamma' T^2 + \tfrac{1}{3}\Delta\Gamma'' T^3 \quad (2)$$

$$\Delta S^0 = \Delta\Gamma_0^0(1 + \ln T) + \Delta\Gamma' T + \tfrac{1}{2}\Delta\Gamma'' T^2 + \ . \ . \ . - I \quad (3)$$

Der Index ^{0} an den Grössen ΔF, ΔH, ΔS bedeutet dass die Grösse zu einer angegebenen oder angedeutenden Reaktion gehört, in welcher alle teilnehmenden chemischen Substanzen bei Aktivität Eins, bei einer Flüchtigkeit von 1 Atm. (oder, wenn es besonders angegeben ist, bei einem Druck von 1 Atm.), oder bei

---

*Es ist zu beachten das diese Werte nicht diejenigen sind welche sonst in den I. C. T. (*siehe* Bd. I, S. 17) angenommen wurden. Die Daten dieser Abteilung bilden unter sich ein einheitliches System, aber können nicht leicht mit anderen Daten in den I. C. T. kombiniert werden.

K_m	Funzione d'equilibrio espressa in molarità.
K_p	Funzione d'equilibrio in termini delle pressioni parziali.
$\overline{\text{L}}$	Contenuto termico molare relativo parziale.
M	Molare.
P	Pressione totale o tensione di vapore in atmosfere.
R	Costante dei gas.
S	Entropia.
T	Temperatura assoluta.
V	Volume.
w	Massa molale.
γ	Coefficiente di attività.
μ	Forza ionica.
μ_c	Forza ionica per le concentrazioni.
ν	Numero degli ioni formatisi per la dissociazione d'una molecula.
Δ	Incremento.

Let. cap. rom. piccola. Quantità molari, per esempio H.

Let. cap. rom. pic. sbarrata. Quantità molari parziali, per esempio $\overline{\text{H}}$.

L'indicazione sottoscritta $_1$ (risp. $_2$) si riferisce al solvente (risp. soluto).

UNITÀ E VALORI DELLE COSTANTI IMPIEGATE*

1 cal.	4,182 joules.
T	$t + 273{,}1$.
R	82,07 cm^3-atm. per grado K.
R	1,9885 cal. per grado K.
V	(per una mole di gas perfetto) 22 412 cm^3 a 1 atm. e 273,1°K.
F	96 494 coulombs per equiv.
F	23 074 cal. per volt equiv.

Tutte le pressioni sono espresse in atmosfere, tutte le temperature in gradi assoluti, tutte le forze elettromotrici in volte e tutte le quantità di energia in calorie (*v.* sopra) a meno che non venga espressamente altrimenti indicato. Nel fare ulteriori trasformazioni dei dati è importante che vengano usati solo le costanti e i dati di questo capitolo.

DATI SULL'ENERGIA LIBERA

In genere, l'accuratezza delle equazioni dell'energia libera può essere giudicata dalla costanza di I, dove questo è riportato. Quando il valore di I non mostra tendenza a variare con la temperatura deve ritenersi che la scelta delle forme particolari delle sostanze prendenti parte alla reazione, e i valori di ΔH e ΔC_p sono da ritenersi con probabilità sostanzialmente corretti. Le singole variazioni indicano il grado di accuratezza delle misure sperimentali. Siccome molti dei valori dedotti implicano la addizione e la sottrazione di altre equazioni, non è possibile, oggi, indicare l'errore probabile; non bisogna prendere quindi come indice di accuratezza il numero delle cifre riportate. Dove sono riportati valori "revised" bisognerà usare i valori non corretti (^{885}) quando dovranno essere combinati con altre equazioni di questo capitolo.

Le energie libere sono date nella forma

$$\Delta F^0 = \Delta H_0^0 - \Delta\Gamma_0^0 T \ln T - \tfrac{1}{2}\Delta\Gamma' T^2 - \tfrac{1}{6}\Delta\Gamma'' T^3 - \cdot \cdot \cdot + IT \quad (1)$$

dove $\Delta\Gamma$, $\Delta\Gamma'$ e $\Delta\Gamma''$, ecc., sono i coefficienti dell'incremento della capacità termica della reazione nell'espressione algebrica.

Così si ha:

$$\Delta H^0 = \Delta H_0^0 + \Delta\Gamma^0 T + \tfrac{1}{2}\Delta\Gamma' T^2 + \tfrac{1}{3}\Delta\Gamma'' T^3 \quad (2)$$

$$\Delta S^0 = \Delta\Gamma_0^0(1 + \ln T) + \Delta\Gamma' T + \tfrac{1}{2}\Delta\Gamma'' T^2 + \cdot \cdot \cdot - I \quad (3)$$

---

* Nota bene che questo *non sono* i valori accettati dalle I. C. T. (*vedi* Vol. I, p. 17). I dati di questa sezione formano un tutto unico, ma non possono essere combinati senz'altro con gli altri dati delle I. C. T.

einer hypothetischen Konzentration Eins angenommen sind. Ist die Reaktion nicht ausdrücklich angegeben, so wird angenommen, dass es sich um jene Reaktion handelt, in welcher eine gegebene Substanz aus ihren Elementen in dessen Normalzuständen gebildet wird. Der Normalzustand ist jener, welchem in den Tabellen der Wert $\Delta F^0 = 0$ zugeteilt ist, wobei der Druck immer 1 Atm. sein soll, falls kein anderer Wert dafür besonders angegeben wird. Im Fall, dass kein Normalzustand in den Tabellen derart angegeben ist, nimmt man den "gewöhnlichen" festen Zustand des Elementes an.

Die Gleichgewichtskonstante, K, ist immer so definiert, dass die Aktivitäten der Substanzen, welche rechts in der geschriebenen Reaktionsgleichung erscheinen, im Zähler stehen, Für Gase sind die Einheiten immer Atmosphäre, und für gelöste Stoffe immer Molenbrüche, oder Mol pro 1000 g Wasser. Für die Konstante K auf diese Weise definiert, ist $\Delta F^0 = -RT \ln K$.

In einigen Fällen gebrauchen wir Gleichgewichtsfunktionen (K_m), in welchen, anstatt Aktivitäten, die Molarität der Substanzen oder Ionen gebraucht wird, und anderere (K_c) in welchen die Aktivitäten durch Konzentrationen (Mol pro Liter) ersetzt sind. In noch anderen Fällen haben wir Spezialfunktionen (K'_m oder K'_c) gebraucht, in welchen für alle Substanzen, ausser den Ionen, Aktivitäten benutzt worden sind. Die Konzentration eines Gases kommt in solchen Ausdrücken nie vor. *Siehe* Lewis und Randall (885), Randall und Vietti (1192), und Randall (1170.5).

AKTIVITÄTSKOEFFIZIENTEN

Im Falle aller Reaktionen, welche auf der rechten Seite nur Ionen enthalten, und etlicher anderer, sind die verschiedenen Gleichgewichte so umgeformt, dass (log γ + Konstante) und $\mu^{1/2}$ in den Tabellen angegeben sind. Durch einfache graphische Auftragung dieser Grössen, kann man Interpolieren und Vergleiche ausführen; durch Auflegen der so erhaltenen Kurven auf entsprechende Kurven in demselben Massstabe für passende Bezugssalze kann man leicht zum Aktivitätskoeffizienten Eins extrapolieren. Wenn diese extrapolierten Grössen vorhanden sind, kann der Aktivitätskoeffizient für das betreffende Ionenpaar durch Subtraktion von log *p.f.* (in einigen Fällen angegeben) von dem Wert der Grösse (log γ + Konstante) erhalten werden. Der Aktivitätskoeffizient für Konzentration, die Ionenstärke für Konzentration, usw., sind in dem Sinne Randall und Viettis (1192) definiert, nämlich so, dass die Aktivität (in Bezug auf Molaritäten definiert) gleich ist dem Produkt von dem besagten Konzentrationsaktivitätskoeffizient und der Konzentration.

$$\log \gamma + \text{Konstante} = \log \gamma - E^0/(0{,}00019844\nu\ T/N) = E/(0{,}00019844\nu\ T/N) + \log(1/m_\pm) \quad (4)$$

wo E^0 die normalen und E die gemessenen elektromotorischen Kräfte, N die Nummer der Äquivalenten, und $m_\pm$ die mittlere Molarität der Ionen in der Kette bedeutet*. Oder

$$\log \gamma + \text{Konstante} = (1/\nu) \log p + \log(1/m_\pm) \quad (5)$$

wo p der Dampfdruck des gelösten Stoffes ist. Oder

$$\log \gamma + \text{Konstante} = (1/\nu) \log x_2 + \log(1/m_\pm)$$

wo x_2 den Molenbruch gelösten Stoffes in einem zweiten unvermischbaren Lösungsmittel bedeutet. Oder

$$\log \gamma + \text{Konstante} = \log(1/m_\pm)$$

wo $m_\pm$ die mittlere Molarität der Ionen in Gleichgewicht mit dem reinen festen Stoffe (Löslichkeit) ist. Oder

$$\log \gamma + \text{Konstante} = (1/\nu) \log(1/K'_m)$$

wo K'_m eine Gleichgewichtsfunktion ist, in welcher für alle Reaktionsteilnehmer (am gewöhnlichsten undissozierbare Stoffe oder Gase) bis auf das betrachtete Ionenpaar, Aktivitäten eingesetzt worden sind. (*Siehe* $CaCO_3$(Calcite) + H_2CO_3 (aq) = Ca^{++} + $2HCO_3^-$, S. 296.)

---

* In allgemeinen $\Delta F = NEF$.

Il contrassegno ^{0} sulle quantità ΔF, ΔH, ΔS, indica che esse si riferiscono ad una reazione in cui tutte le sostanze che vi partecipano vengono considerate a una attività unitaria, a una fugacità di 1 atm. (oppure, quando sia specificamente indicato, alla pressione di 1 atmosfera) o a una concentrazione unitaria ipotetica. Quando la reazione non è esplicitamente indicata, si suppone sia quella di formazione di una data sostanza dagli elementi, nei loro stati standard. Lo stato standard di un elemento è quello per il quale nelle tabelle viene dato il valore $\Delta F^0 = 0$, la pressione essendo sempre di 1 atm. salvo che non venga altrimenti indicato. Quando nelle tabelle non è indicato nessuno stato standard, si tratta della forma solida "ordinaria" dell'elemento.

Nello scrivere la costante di equilibrio, K, le attività delle sostanze del membro di destra della reazione, come essa viene comunemente scritta, appaiono sempre al numeratore. Per i gas le unità sono sempre atmosfere, e per i soluti frazioni di moli o moli per 1000 g di acqua. Per la costante K così definita, $\Delta F^0 = -RT \ln K$.

In alcuni casi è fatto uso di funzioni di equilibrio (K_m) nelle quali invece dell'attività si impiega la molarità delle sostanze o dei ioni, in altri casi (K_c) nelle quali le concentrazioni (moli per litro) delle sostanze in soluzioni sono impiegate invece dell'attività. In altri casi sono state impiegate speciali funzioni (K'_m, o K'_c) nelle quali le attività sono usate per tutte le sostanze tranne che per gli ioni presenti. La concentrazione di un gas non viene mai impiegata in queste espressioni. *Vedi* Lewis e Randall (885), Randall e Vietti (1192), Randall (1170.5).

COEFFICIENTI DI ATTIVITÀ

Nel caso delle reazioni che implicano solo gli ioni del membro di destra dell'equazione, e in pochi altri casi, i vari equilibri vengono trasformati in modo che nelle tabelle sono riportati (log γ + una costante) e $\mu^{1/2}$. Con un semplice grafico, si potranno fare interpolazioni e confronti. Sovrapponendo le curve così ottenute ad altre corrispondenti (di sali di riferimento opportunamente scelti, e disegnate sulla stessa scala) si può facilmente fare l'estrapolazione rispetto al coefficiente di attività unitaria. Quando si abbiano questi valori estrapolati si può trovare il coefficiente di attività di questa particolare coppia di ioni sottraendo log *p.f.* (dato in pochi casi) dal valore di (log γ + una costante). Il coefficiente di attività per concentrazione, la forza ionica per concentrazione, ecc., sono definite nel senso in cui sono state impiegate da Randall e Vietti (1192), cioè il prodotto del coefficiente d'attività per concentrazione moltiplicato per la concentrazione dà l'attività (definita riferendosi alle molarità).

$$\log \gamma + \text{const.} = \log \gamma - E^0/(0{,}00019844\nu T/N) = -E/(0{,}00019844\nu\ T/N) + \log(1/m_\pm) \quad (4)$$

dove E^0 e E sono le forze elettromotrici standard e misurate, N il numero degli equivalenti e $m_\pm$ la molarità media degli ioni studiati nella cella.* Oppure

$$\log \gamma + \text{const.} = (1/\nu) \log p + \log(1/m_\pm) \quad (5)$$

dove p è la tensione di vapore del soluto. Oppure

$$\log \gamma + \text{const.} = (1/\nu) \log x_2 + \log(1/m_\pm)$$

dove x_2 è la frazione molare del soluto in un secondo solvente immiscibile. Oppure

$$\log \gamma + \text{const.} = \log(1/m_\pm)$$

dove $m_\pm$ è la molarità media degli ioni in equilibrio con li solido puro (solubilità). Oppure

$$\log \gamma + \text{const.} = (1/\nu) \log(1/K'_m),$$

dove K'_m è una funzione d'equilibrio nella quale si sono sostituite le attività per tutte le sostanze che prendono parte alla reazione (generalmente sostanze indissociabili o gas) eccettuata la coppia di ioni presa in considerazione. (*Vedi* $CaCO_3$ (calcite) + H_2CO_3 (aq) = Ca^{++} + $2HCO_3^-$, p. 296.)

---

* In generale $\Delta F = NEF$.

LITERATURE; *v.* p. 347

SOLUBILITY OF SLIGHTLY SOLUBLE SALTS IN AQUEOUS SOLUTIONS OF ELECTROLYTES

MERLE RANDALL AND WILLIAM V. VIETTI

The Standard arrangement (Vol. III, p. viii) is used throughout this section. Under each A-component, printed in large type, are listed the B-components in the standard order. The A-component is the slightly soluble salt; the B-component is a solute in the aqueous solution.

L'arrangement type (Vol. III, p. viii) est utilisé dans toute cette section. Sous chaque constituant A, imprimé en grands caractères, se trouvent les constituants B disposés en liste suivant l'ordre type. Le constituant A est le sel peu soluble; le constituant B est un corps dissous dans la solution aqueuse.

In diesem Abschnitt ist die Standardanordnung (Bd. III, S. viii) durchweg verwendet. Unter jeder A-Komponente, die in grossen Buchstaben gedruckt ist, folgen die B-Komponenten in Standardanordnung. Die A-Komponente ist der wenig lösliche Salz; die B-Komponente ist ein Körper in der wässrige Lösung.

In tutto questo capitolo si fa uso dell'ordinamento standard (Vol. III, p. viii). Sotto ogni componente A stampato in lettere grosse, sono elencati i componenti B con l'ordinamento standard. Il componente A è il sale poco solubile; il componente B è un soluto nella soluzione acquosa.

SYMBOLS AND ABBREVIATIONS

c_B Concentration of B-component in moles/liter.

$c_\pm$ Geometric mean of concentration of ions.

SYMBOLES ET ABRÉVIATIONS

c_B Concentration du constituant B en mol. gr./litre.

$c_\pm$ Moyenne géométrique de la concentration des ions.

SYMBOLE UND ABKÜRZUNGEN

c_B Konzentration der B-Komponente in Mol/Liter.

$c_\pm$ Geometrisches Mittel der Ionenkonzentrationen.

ABBREVIAZIONI E SIMBOLI

c_B Concentrazione del componente B in moli/litro.

$c_\pm$ Media geometrica della concentrazione degli ioni.

M	Molal.
m_B	Moles of B-component/1000 g H_2O *in vacuo.*
$m_\pm$ $m^\circ_\pm$	*See* p. 227.
N	Normal
s_A	Solubility of A-component in moles/liter.
S_A	Solubility of A-component in moles/1000 g H_2O *in vacuo.*
γ	Activity coefficient (*see* p. 227).
μ	Ionic strength.
μ_c	Ionic strength (for concentrations).
	For other abbreviations, *see* p. 225.

M	Moléculaire.
m_B	Mol. gr. du constituant B/1000 g H_2O dans le vide.
$m_\pm$ $m^\circ_\pm$	*Voir* p. 227.
N	Normal.
s_A	Solubilité du constituant A en mol. gr./litre.
S_A	Solubilité du constituant A en mol. gr./1000 g H_2O dans le vide.
γ	Coefficient d'activité (*voir* p. 227).
μ	Force ionique.
μ_c	Force ionique (pour concentrations).
	Pour d'autres abréviations, *voir* p. 225.

M	Molar.
m_B	Gramm Mol der B-Komponente/1000 g H_2O *in vacuo.*
$m_\pm$ $m^\circ_\pm$	*Siehe* S. 230.
N	Normal.
s_A	Löslichkeit der A-Komponente in Gramm Mol/Liter.
S_A	Löslichkeit der A-Komponente in Gramm Mol/1000 g H_2O *in vacuo.*
γ	Aktivitätskoeffiziente (*siehe* S. 230).
μ	Ionenstärke.
μ_c	Ionenstärke (für Konzentrationen).
	Für andere Abkürzungen, *siehe* S. 228.

M	Molare.
m_B	Moli del componente B/1000 g di H_2O nel vuoto.
$m_\pm$ $m^\circ_\pm$	*Vedi* p. 230.
N	Normale.
s_A	Solubilità del componente A in moli/litro.
S_A	Solubilità del componente A in moli/1000 g di H_2O nel vuoto.
γ	Coefficiente di attività (*vedi* p. 230).
μ	Forza ionica.
μ_c	Forza ionica (per concentrazioni).
	Per altre abbreviazioni, *vedi* p. 228.

OPTICAL ROTATORY POWER OF SOLID CRYSTALS

W. T. ASTBURY

Optically active crystals exist in two enantiomorphous forms having equal and opposite rotatory powers for light of a given wave-length. No isotropic substances (cubic crystals) exhibit optical rotation when in solution, but some do when in crystal form. Rotatory power = θ/l where θ is the angle through which the plane of polarization is rotated while plane polarized light is passing a distance l through the crystal in the direction of an optic axis. In some cases the variation of θ/l with the wave-length (λ) can be represented by an empirical Drude equation $\theta/l = k/(\lambda^2 - \lambda_0^2)$. Temperature is stated whenever it is given in the published paper, in other cases it is presumably room temperature. $t[T]$ = centigrade (°C) [absolute (°K)] temperature. Iso = isotropic (cubic crystal), Uni = uniaxial, Bi = biaxial, *d*- [*l*-] = dextro- [levo-] rotatory. "*d*-solutions → *l*-crystals" means that levorotatory crystals form from a solution which is dextrorotatory. Yes [No] means that solutions of the substance are [are not] active. A = accuracy; example: For HIO_3, $\lambda = 0.436$, $\theta/l = (74.5 \pm 0.7)$ degrees per mm.

𝔅-TABLE, STANDARD ARRANGEMENT

Unit of θ/l and of A = 1° per mm; of $\lambda = 1\mu = 10^4$ Å $= 10^{-4}$ cm

HIO_3 Iodic acid (12), Bi, No, dimorphous, both forms are orthorhombic bisphenoidal; prism angle of specimen = 86°23′

OPTICAL ROTATORY POWER OF LIQUIDS AND SOLUTIONS[1]

THOMAS MARTIN LOWRY

ARRANGEMENT

Arrangement is by classes defined as follows:

Carbon Compounds*

I. None of the asymmetric carbon atoms forms part of a ring.

II. At least one asymmetric carbon atom forms part of a ring.

III. The compound contains no asymmetric carbon atom or contains at least one asymmetric or dissymmetric atom other than carbon.

IV. Substances of unknown, doubtful or complex structure.

Classes I to IV are subdivided according to the number and nature of the asymmetric atoms as follows:

A_n The molecule contains *n* asymmetric atoms which are attached each to only one other carbon atom.

B_n The molecule contains *n* asymmetric atoms which are attached each to two other carbon atoms.

C_n The molecule contains *n* asymmetric atoms which are attached each to three other carbon atoms.

D_n The molecule contains *n* asymmetric atoms which are attached each to four other carbon atoms.

For substances which fall within two or more of the above subdivisions the higher (in the order D, C, B, A) division receives preference in deciding the arrangement. Within a subdivision the arrangement is in accordance with the value of *n* in the order 1, 2, 3, etc.

SYMBOLS AND ABBREVIATIONS

t	Temperature in degrees centigrade (°C).
λ	Wave length of light expressed in Ångstrom units, *i.e.*, in tenths of a millimicron ($\frac{1}{10}\mu\mu$) unless otherwise indicated.
D	A wave length of 5893 Å.
α_λ^t	Observed rotation at the given values for t.
$[\alpha]_\lambda^t$	Specific rotation at the given values for t.
$[M]_\lambda^t$	Molecular rotation at the given values for $t (= M \times [\alpha]_\lambda^t/100)$.
C	Concentration in grams per 100 cm³ of solution.
%	Concentration in grams per 100 grams of solution (= Wt. %). (Values in italics.)
d	d_4^t = density at the given value for t referred to water at 4°C, unless otherwise indicated.
2% NaOH (etc.)	2% of solution of NaOH in water.
2% NaOH MeOH	2% of solution of NaOH in methyl alcohol.
M	Moles.
N NaOH	Normal aqueous solution of NaOH (= 1 equivalent/liter).

ARRANGEMENT

Arrangement par classes, définies comme suit:

Composés du carbone

I. Aucun des atomes de carbone asymétriques ne fait partie d'une chaine cyclique.

II. Un atome de carbone asymétrique au moins fait partie d'une chaine cyclique.

III. Le composé ne contient aucun atome de carbone ou contient au moins un atome asymétrique ou dyssymétrique autre que carbone.

IV. Substances de structure inconnue, douteuse ou complexe.

Les classes I–IV sont subdivisées comme suit, en accord avec le nombre et la nature des atomes asymétriques:

A_n La molécule contient *n* atomes asymétriques, chacun de ceux-ci étant seulement relié à un autre atome de carbone.

B_n La molécule contient *n* atomes asymétriques, chacun de ceux-ci étant relié à deux autres atomes de carbone.

C_n La molécule contient *n* atomes asymétriques, chacun de ceux-ci étant relié à trois autres atomes de carbone.

D_n La molécule contient *n* atomes asymétriques, chacun de ceux-ci étant relié à quatre autres atomes de carbone.

Lorsqu'une substance est comprise dans deux ou plusieurs subdivisions ci-dessus, on donnera la préférence à la division supérieure (dans l'ordre D, C, B, A) pour décider de l'arrangement. Dans une subdivision, l'arrangement est réalisé en accord avec les valeurs de *n*, dans l'ordre 1, 2, 3, etc.

SYMBOLES ET ABRÉVIATIONS

t	Température en degrés centigrades (°C).
λ	Longueur d'onde de la lumière exprimée en unités Ångstrom, *i.e.*, en dixièmes de millimicron ($\frac{1}{10}\mu\mu$) à moins d'une autre indication.
D	Une longueur d'onde de 5893 Å.
α_λ^t	Rotation observée pour les valeurs données de t.
$[\alpha]_\lambda^t$	Rotation spécifique pour les valeurs données de t.
$[M]_\lambda^t$	Rotation moléculaire pour les valeurs données de $t (= M \times [\alpha]_\lambda^t/100)$.
C	Concentration en grammes pour 100 cm³ de solution.
%	Concentration en grammes pour 100 grammes de solution (= Pds. %). (Valeurs en italique.)
d	d_4^t = densité pour la valeur donnée de t par rapport à l'eau à 4°C, à moins d'une autre indication.
2% NaOH (etc.)	Solution de NaOH dans l'eau, à 2%.
2% NaOH MeOH	Solution à 2% de NaOH dans l'alcool méthylique.
M	Molécule-gramme ou mole.
N NaOH	Solution aqueuse normale de NaOH (= 1 équivalent/litre).

Symbols for Solvents

A ≡ The acid radical under which it is used.
Ac ≡ (CH_3CO) Acetyl.
Bu ≡ (C_3H_7) Butyl.
En ≡ ($C_2H_8N_2$) α, β-Ethylenediamine.
Et ≡ (C_2H_5) Ethyl.
Me ≡ (CH_3) Methyl.
Ph ≡ (C_6H_5) Phenyl.
Pn ≡ ($C_3H_{10}N_2$) α, β-Propylenediamine.
Py ≡ (C_5H_5N) Pyridine.
Tr ≡ ($C_3H_{10}N_2$) α, γ-Diaminopropane.

---

[1] This section includes data and bibliography to January 1, 1924.

* Sugars and their derivatives (*see also* Vol. II, p. 334, 353) are classed as open chain compounds. In general, derivatives are listed under the parent compound, even when they contain additional asymmetric atoms.

ANORDNUNG

Die Anordnung erfolgt nach Klassen, die folgendermassen bestimmt sind:

Kohlenstoffverbindungen

I. Keines der asymmetrische Kohlenstoffatome bildet einen Teil eines Ringes.

II. Wenigstens ein asymmetrisches Kohlenstoffatom bildet einen Teil eines Ringes.

III. Die Verbindung enthält kein asymmetrisches Kohlenstoffatom oder enthält wenigstens ein asymmetrisches oder dissymmetrisches Atom von anderer Natur als Kohlenstoff.

IV. Stoffe unbekannter, zweifelhaftiger oder komplexer Struktur.

Die Klassen I–IV werden weiter geteilt nach der Zahl und Natur der asymmetrischen Atome wie folgt:

A_n Das Molekül enthält *n* asymmetrische Atome, von denen jedes an nur ein anderes Kohlenstoffatom gebunden ist.
B_n Das Molekül enthält *n* asymmetrische Atome, von denen jedes an zwei andere Kohlenstoffatome gebunden ist.
C_n Das Molekül enthält *n* asymmetrische Atome, von denen jedes an drei andere Kohlenstoffatome gebunden ist.
D_n Das Molekül enthält *n* asymmetrische Atome, von denen jedes an vier andere Kohlenstoffatome gebunden ist.

Für Stoffe die in zwei oder mehr der obigen Unterabteilungen fallen, erhält die höhere Abteilung (in der Reihenfolge D, C, B, A) bei der Entscheidung der Anordnung den Vorzug. Innerhalb einer Unterabteilung erfolgt die Anordnung entsprechend dem Werte von *n* in der Reihenfolge 1, 2, 3, usw.

ZEICHEN UND ABKÜRZUNGEN

t	Temperatur in Celsiusgraden (°C).
λ	Lichtwellenlänge ausgedrückt in Ångstrom Einheiten, d.h., in Zehnteln eines Millimikrons ($^1\!/_{10}\mu\mu$), wenn nicht anders angegeben.
D	Wellenlänge 5893 Å.
α_λ^t	Beobachtete Drehung bei den gegebenen Werten für *t*.
$[\alpha]_\lambda^t$	Spezifische Drehung bei den gegebenen Werten für *t*.
$[M]_\lambda^t$	Molekulare Drehung bei den gegebenen Werten für *t*($= M \times [\alpha]_\lambda^t/100$).
C	Konzentration in Gramm pro 100 cm^3 Lösung.
%	Konzentration in Gramm pro 100 Gramm Lösung (= Gew. %). (Werte in Kursivschrift.)
d	d_4^t = Dichte bei dem gegebenen Wert für *t* (bezogen auf Wasser bei 4°C, wenn nicht anders angegeben).
2% NaOH (usw.)	2%-ige Lösung von NaOH in Wasser.
2% NaOH MeOH	2%-ige Lösung von NaOH in Methylalkohol.
M	Mole
N NaOH	Normale wässerige Lösung von NaOH (= 1 Äquivalent/Liter).

DISPOSIZIONE

La disposizione è fatta secondo classi definite come segue:

Composti del carbonio

I. Nessuno degli atomi di carbonio asimmetrici fa parte di un anello.

II. Almeno un atomo di carbonio asimmetrico fa parte di un anello.

III. Il composto contiene nessuno atomo asimmetrico di carbonio o contiene almeno un atomo asimmetrico o dissimmetrico diverso dal carbonio.

IV. Sostanze di struttura sconosciuta, incerta o complessa.

Le classi I–IV sono suddivise secondo il numero e la natura degli atomi asimmetrici nella maniera seguente:

A_n La molecola contiene *n* atomi asimmetrici i quali sono attaccati ciascuno a un altro atomo di carbonio soltanto.
B_n La molecola contiene *n* atomi asimmetrici i quali sono attaccati ciascuno a due altri atomi di carbonio.
C_n La molecola contiene *n* atomi asimmetrici i quali sono attaccati ciascuno a tre altri atomi di carbonio.
D_n La molecola contiene *n* atomi asimmetrici che sono attaccati ciascuno a quattro atomi di carbonio.

Per le sostanze che rientrano in due o più delle suddivisioni indicate, la divisione più alta (nell'ordine D, C, B, A) ha la preferenza nel decidere la disposizione. Entro ciascuna suddivisione la disposizione è d'accordo con il valore di *n* nell'ordine 1, 2, 3, ecc.

SIMBOLI ED ABBREVIAZIONI

t	Temperatura in gradi centigradi (°C).
λ	Lunghezza d'onda della luce espressa in unità Ångstrom, *i.e.*, in decimi di millimicron ($^1\!/_{10}\mu\mu$) tranne che non sia altrimenti indicato.
D	Una lunghezza d'onda di 5893 Å.
α_λ^t	Rotazione osservata ai valori di *t* indicati.
$[\alpha]_\lambda^t$	Rotazione specifica ai valori di *t* indicati.
$[M]_\lambda^t$	Rotazione molecolare ai valori dati per *t* ($= M \times [\alpha]_\lambda^t/100$).
C	Concentrazione in grammi per 100 cm^3 di soluzione.
%	Concentrazione in grammi per 100 grammi di soluzione (= % in peso). (Valori scritti in caratteri italici.)
d	d_4^t = densità al valore di *t* indicato, riferita all'acqua a 4°C salvo che non sia indicato altrimenti.
2% NaOH (ecc.)	2% di soluzione di NaOH in acqua.
2% NaOH MeOH	2% di soluzione di NaOH in alcool metilico.
M	Moli.
N NaOH	Soluzione acquosa normale di NaOH (=1 equivalente/litro).

CONTENTS

Class I. Organic Substances, the Asymmetric Carbon Atoms of Which Do Not Form Part of a Ring

---

* For further data on these compounds at various temperatures, with other wave lengths, and in various solvents, *see* the forthcoming article by Professor Lowry, Miscellaneous Publications, Bureau of Standards, No. 118, 1931.

CONTENTS.—(*Continued*)

Simple dicarboxylic acids.

Monohydroxydicarboxylic acids.

Monoaminomonocarboxylic acids.

Monoaminodicarboxylic acids.

IB$_2$. *The molecule contains two asymmetric carbon atoms which are attached each to two other carbon atoms.*

Alcohols and amines.

Carboxylic acids.

Dihydroxydicarboxylic acids.

Carbohydrates and related compounds.

Sugars containing 5 carbon atoms.

Pentahydric and hexahydric alcohols.

Sugars containing 6 carbon atoms.

Nitrogen derivatives of glucose.

Sugar acids containing 6 carbon atoms.

Sugars, etc., containing 7 carbon atoms.

Sugars, etc., containing 12 carbon atoms.

IC$_1$. *The molecule contains one asymmetric atom attached to three other carbon atoms.*

Alcohols and their derivatives.

Acids and derivatives.

INTRODUCTION

Pure compounds are not used to any great extent in civil applications of explosives. Ordinary commercial blasting and propulsive explosives have usually an empirical composition, with fairly wide tolerances for the proportions of the several ingredients, and very often one or more of these constituents is a substance of indefinite chemical composition. Furthermore the treatment during the process of manufacture, for example the fineness of the ingredients used, the time of mixing, and the physical condition of the product, have considerable influence on the properties of the finished explosive.

Data are tabulated relating to the principal explosive properties of the chief pure explosive substances, but for compounded explosives only typical or limiting compositions and properties are given.

TYPES OF TESTS

The principal tests used for explosives are described briefly below:

1. Calorimetric tests to determine the *heat of explosion* and the *volume and composition of the explosion gases*. For descriptions of the method of carrying out the experiments, *see* Vol. II, p. 440–444 of (25) and (39, 40).

The explosion temperature has not been determined directly, but can in principle be calculated from the pressure developed when the substance is exploded in a closed vessel. Various types of apparatus for determining the maximum pressures developed, or for recording variations in pressure, are described in (25). Explosion temperatures may also be calculated from the heat of explosion if the nature, amounts and specific heats of the explosion products are known.

2. *Trauzl Lead-block Test.*—This test is used for blasting explosives[1] as a ready means of estimating the relative powers of explosives of the same class fired under slight confinement. At the Berlin meeting (1903) of the International Congress of Applied Chemistry, standard conditions for carrying out this test were prescribed (2). Kast (19) gives a table of corrections for temperature.

3. The *fall-hammer test* is used to measure approximately the sensitiveness to shock of an explosive. The classification of explosives for transport on the German railways is based, in part, on the results of this test. The method of carrying it out is described in (14, 15), and by Marshall (25), Vol. II, p. 423.

4. The *deflagration test* for the determination of the explosion temperature serves to measure the sensitiveness of the explosive to active decomposition by the action of heat.

5. A large number of so-called "stability tests" have been developed in order to obtain some idea of the chemical stability of explosives during storage. Among these may be mentioned the *Abel*, *Bergmann-Junk*, *Will* and *Sy* tests.

6. The *bulk density* of an explosive is an important factor in its behavior and this property can be varied within fairly wide limits by modifications in the method of manufacture.

7. The *detonation velocity* of an explosive is one of the most important factors in its brisance, and, therefore, in its practical applications. The methods used for measuring it are described in the textbooks; *see*, for example (25) Vol. II, p. 476. A discussion by Kast of the sources of error when the Siemens spark chronograph is used is largely applicable to any chronographic method (17).

The value found depends on the diameter of the train of explosive used (up to a certain limiting value, varying with the nature of the explosive); on the degree of confinement to which it is subjected; and on the method of initiation.

The detonation velocity increases in general with the density. In the case of certain explosives this increase continues up to a certain critical density, after which it falls rapidly. In the case of some of the less porous nitro bodies it has not yet been proved that the detonation value does decrease in this way after a certain limit, although there are indications that this is probably so.

Nitroglycerin gelatinous explosives have two distinct detonation velocities. That which is attained depends on various factors, but especially on the nature of the initiation and on the degree of confinement.

The following tests are of special importance in connection with coal mine explosives:

8. *Tests in an experimental gallery* to determine the maximum charge which can be fired without igniting an air-gas mixture containing specified proportions of an inflammable gas or coal dust or both. Natural firedamp, artificially prepared methane and illuminating gas have been used as the inflammable gas. A brief historical sketch of the various gallery tests is given in (13). A table appended to that pamphlet gives data regarding the principal testing galleries. On the basis of these tests limiting charges of explosive are fixed for use in mines.

9. *Ballistic pendulum tests* are used in Great Britain and the United States to furnish a comparative estimate of the strength of the explosive, the results being published as a guide to the purchaser in the selection of an explosive suitable for his requirements.

In the United States the detonation velocity of permissible coal mine explosives is also published, but this is not done for the British "permitted" explosives.

10. For propulsive explosives, tests are carried out in appropriate weapons to measure the *pressure developed in the barrel of the gun*, usually by means of crusher gages, and to determine the *velocity of the projectile*, and, for shotgun cartridges, the *shot "pattern."*

Velocities are measured over a certain distance from the muzzle of the gun by the use of a suitable target in conjunction with a chronograph. The result may be given as the average velocity over this distance or as the "remaining velocity" at half the distance, or a calculated value of the "muzzle velocity" may be reported. V_x is used to denote the remaining velocity at x meters (or other unit) found by means of a target placed at $2x$ meters from the gun.

---

[1] In the U. S. A. the ballistic mortar test described under 9, below, is largely used by manufacturers of explosives.

11. For initiating explosives, in addition to the heat of explosion, the explosion point and the result of the fall-hammer test, there may also be given the result of a test similar to the Trauzl lead-block test but using a smaller lead block; of the "*lead plate*" *test* (which, however, does not furnish definite numerical results); of tests on the *limiting charge* required to initiate the detonation of a definite quantity of some explosive (usually a nitro body); of the *Esop* and *Wöhler tests* in which an explosive is phlegmatized in some manner until it is just no longer "initiated" by the initiator under test; or of the "*sand*" *test* developed by the U. S. A. Bureau of Mines, in which a detonating charge is exploded in the center of graded sand, and the degree of pulverization of the sand produced by the explosion is measured.

SIMPLE EXPLOSIVES (PURE SUBSTANCES)

Heat of Explosion

Explosion in calorimetric bomb. The heat of explosion may also be calculated from thermochemical data (*q.v.*, Vol. V, p. 162, 169), the results agreeing well with the experimental. Alternative methods of decomposition may be possible and the heat of explosion may thus vary, for example, with the loading density or the nature of the initiation.

COMPOUNDED EXPLOSIVES

Blasting Explosives

The following classification of blasting explosives will be found useful, though the classes are by no means mutually exclusive. *A.* Non-detonating explosives. *B.* Detonating or high explosives.

A. Non-detonating explosives.

Black powder is the principal type of this class. The German "Sprengsalpeter" is similar to black powder, with sodium nitrate in place of potassium nitrate.

B. Detonating or high explosives.

I. Nitroglycerin explosives.
  (*a*) Gelatinous explosives.
  (*b*) Dynamites.
    (1) With inactive additions.
    (2) With active additions.
II. Ammonium nitrate explosives containing as sensitizer:
  (*a*) Nitroglycerin.
  (*b*) Aromatic nitro body.
  (*c*) Non-explosive substance.
III. Perchlorate explosives.
IV. Chlorate explosives.

Nitroglycerin explosives are liable to freeze and their use in the frozen condition gives rise to danger. This danger may be removed by partially or wholly replacing the nitroglycerin by nitrated chlorohydrin, ethyleneglycol dinitrate, dinitroglycerin, nitrated polyglycerin or aromatic nitro compounds such as nitrobenzene, thus forming low freezing (L. F.) explosives.

Some dynamites have a certain proportion of nitrocotton incorporated with the nitroglycerin to diminish the risk of exudation of the nitroglycerin during transport or storage. These may be called semi-gelatins. They resemble the dynamites rather than the gelatins in properties.

A special class of blasting explosives is constituted by those officially authorized for use in coal mines, which are often referred to as "safety explosives." They are known as "permitted explosives" in Great Britain, "permissible explosives" in the United States, "Wettersprengstoffe" in Germany, "Explosifs S. G. P., in Belgium, and "explosifs de sûreté" in France. They usually contain alkaline salts, or sometimes hydrated salts, to reduce the temperature of detonation, and the length and duration of flame.

COMPOSITIONS OF VARIOUS TYPICAL COMPOUNDED EXPLOSIVES
Blasting Explosives (*See* p. 495 for properties)

Key number	Explosive
1	**Black Powder:** KNO_3, 62–75.7%; S, 10–19.4%; charcoal, 12–5%. The properties can be modified to a considerable extent by varying the nature of the charcoal used, the time of mixing and the size of grain of the product.
2	**Bobbinite:** KNO_3, 65.31%; S, 2.63%; charcoal, 19.52%; paraffin, 3.35%; starch, 8.73%; H_2O, 0.46%.
3	**Blasting Gelatin:*** Nitroglycerin, 90–95%; nitrocotton, 5–10%.
4	**Nobel Gelatinous Explosives:*** Nitroglycerin, 25–85%; nitrocotton, 0.5–7%; liquid nitro body, 0.4–9%; woodmeal, 0.9–10%; K or Na nitrate, 6–45%; chalk, 0–0.3%.
5	**U. S. A. Gelatin Dynamites:*** L. F. Nitroglycerin, 20–80%; nitrocotton, 0.3–4.5%; combustible substances, 6–16%; $NaNO_3$, 1.5–6.2%; $CaCO_3$, 1%.
6	**French "Gommes":*** Nitroglycerin, 49–86%; nitrocotton, 2–6%; woodmeal, 0.25–10%; KNO_3, 4–36%.
7	**Kieselguhr Dynamite:†** Nitroglycerin, 72–75%; kieselguhr, 25–28%.
8	**Nobel Glasgow Dynamites (Semigelatinous):** Nitroglycerin, 24.4–57%; nitrocotton, 0.6–3.0%; $NaNO_3$, 21–55.75%; woodmeal, 16.5–19.25%.
9	**U. S. A. Straight Dynamites:** L. F. Nitroglycerin, 15–75%; $NaNO_3$, 5–66%; combustible substances, 5–20%; $CaCO_3$ or $MgCO_3$, 1%.
10	**Pittsburgh Standard 40% Straight Dynamite:** Nitroglycerin, 40%; $NaNO_3$, 44%; wood pulp, 15%; $CaCO_3$, 1%.
11	**Carbonites:** Nitroglycerin, 17–30%; $NaNO_3$, 24–30%; combustible (usually flour), 37–44%. Antacids are sometimes added, and the explosive may be made of the low freezing type by the use of tetranitrodiglycerin.
12	**Carbonite Type of Explosive Tested by U. S. A. Bureau of Mines (Explosive D):** Nitroglycerin, 24.92%; KNO_3, 25.37%; $Ba(NO_3)_2$, 4.42%; woodmeal, 34.60%; starch, 6.64%; H_2O, 4.05%.
13	**U. S. A. Ammonia Dynamites:** NH_4NO_3, 7–50%; $NaNO_3$, 14–60%; nitroglycerin, 12–25%; combustible substances, 8–20%; $CaCO_3$ or ZnO, 1%.
14A	**Grisoudynamite Couche:** NH_4NO_3, 87.5% (or 82.5% + KNO_3, 5%); nitroglycerin, 12%; nitrocotton, 0.5%.
14B	**Grisoudynamite Roche:** NH_4NO_3, 70% (or 65% + KNO_3, 5%); nitroglycerin, 29%; nitrocotton, 1%.
15	**Donarit:** NH_4NO_3, 80%; nitroglycerin (gelatinized or not), 4%; TNT, 12%; rye flour, 4%.
16A	**Grisounaphthalite Couche:** NH_4NO_3, 95% (or 90% + KNO_3, 5%); trinitronaphthalene, 5%.
16B	**Grisounaphthalite Roche:** NH_4NO_3, 91.5% (or 86.5% + KNO_3, 5%); dinitronaphthalene, 12%.
17	**Withnell Type of Explosive Tested by U. S. A. Bureau of Mines (Explosive J):** NH_4NO_3, 90.5%; TNT, 4.82%; flour, 4.23%; H_2O, 0.45%.
18	**Yonckites (Belgium):** NH_4ClO_4, 6–25%; NH_4NO_3, 17.5–65%; $NaNO_3$, 27–30%; $Ba(NO_3)_2$, 6–10%; TNT, 10–22.5% or TNN, 3.75%.
19	**Sabulex:** NH_4NO_3, 59–56%; $KClO_4$, 8–10%; TNT, 9–7%; NH_4Cl, 26–24%.
20	**Perchloratites (Germany):** The perchloratites authorized for use in Prussia include explosives with contents of $KClO_4$ ranging from 30–75%.
21	**Cheddites:** $KClO_3$, 70–90%; aromatic nitro compounds, 0–20%; paraffin, 0–14%.
22	**Cheddite Type Explosive Tested by U. S. A. Bureau of Mines (Explosive E)·** $KClO_3$, 75.36%; MNN, 1.3%; DNT, 17.85%; castor oil, 5.32%; H_2O, 0.17%.
23	**Silesia Type Explosive Tested by U. S. A. Bureau of Mines (Explosive F):** $KClO_3$, 75.27%; nitrated resin, 24.63%; H_2O, 0.10%.
24	**Chloratites (Germany):** The chloratites authorized for use in Prussia include explosives with contents of $KClO_3$ or $NaClO_3$ ranging from 70–91%, along with aromatic nitro derivatives and combustible substances.

* Camphor, soda or chalk have also been added in small proportions, and sometimes a little nitro body.

† Sometimes soda, talc or heavy spar is added in small proportions.

Explosives For Use in Fiery Coal Mines

POWER

The power of British "permitted explosives" is measured by means of a ballistic pendulum test. A stemmed charge is fired electrically from a gun into a ballistic pendulum and the deflection is compared with that given by 4 oz. of 60% gelignite under the same conditions. The standard charge gives a swing of 3.27 in., and the actual deflections are reduced to correspond to this value.

The values will be found in the "*Explosives in Coal Mines Orders.*"

The standard used in the United States is 40% straight dynamite. The unit deflective charge is that which gives the same deflection as 227 g (½ lb.) of the standard dynamite.

In Belgium a modified form of the Trauzl lead-block test is used for comparing the powers of S. G. P. explosives. The weight of explosive equivalent to 100 g of dynamite No. 1 is given. The values are published in the *Annales des Mines de Belgique.*

CHARGE LIMIT

For British "permitted" explosives the charge limits have in the past varied from 8 oz., to 40 oz., but are now fixed at the uniform figure of 28 oz. Results are published in the *Explosives in Coal Mines Orders.*

A general limit of 1½ lbs. is fixed for the maximum permissible charge of the U. S. A. "permissible explosives," and no explosive is placed on the list unless this maximum charge satisfies the gallery test.

Properties of Various Typical Compounded Explosives
Blasting explosives (*See* p. 494 for compositions)

Key number	Explosive	Heat of explosion, g-cal per g	Trauzl lead-block test, expansion in cm³	Fall-hammer test, weight of hammer 2 kg; fall, cm	Detonation velocity, meters per second	Loading density, g/cm³	Propagation of detonation by influence, cm	Diameter of cartridge, mm

22	Cheddite type (explosive E)*	1065.1	212	23	2771	1.28	7.6	32
23	Silesia type (explosive F)*	865.5	201	3	2722	1.04		

* Tested by U. S. A. Bureau of Mines.

The charge limits for Belgian S. G. P. explosives vary from 400 g to 900 g. The values are published in the *Annales des Mines de Belgique*.

The charge limits fixed in the Prussian official regulations for the use of "Wettersprengstoffe" are 700 or 800 g, separate limits being fixed for fiery and non-fiery mines. In the great majority of cases the limit is 800 g in each case. *See* "Das Sprengstoffwesen im preussischen Bergbau."

DETONATION VELOCITY

The detonation velocities of U. S. A. permissible explosives vary from 1792 meters per second for Red H.C. L.F. to 4651 for Gelobel.

Values are not published by the authorities in Great Britain The detonation velocities of the permitted explosives made by Nobel Industries Limited range from 1900 to 5000 meters per second.

Propulsive Explosives

Propulsive explosives may be arranged under the following classes:

1. Black powder type.
2. Nitrocellulose powders.
   (*a*) Without additions.
   (*b*) With additions.

3. Nitroglycerin powders containing both nitrocellulose and nitroglycerin.

(*a*) Without other additions.

(*b*) With other additions.

Examples are given showing the composition and properties of various compounded explosives.

Black Powder, *see* Blasting Explosives.

Amide Powder (Chilworth Special Powder): NH_4NO_3, 35.38%; KNO_3, 40–46%; charcoal, 14–22%.

Ammonpulver: NH_4NO_3, 80–90%; charcoal, 10–20%.

Nitrocellulose Powders

American Pyrocollodion Powders: nitrocellulose 99.4% (mixture of di- and trinitrocellulose, average nitrogen content 12.60%), diphenylamine. Together with residual solvent and water 0.6%.

French B Powder: CP_2, 20–25% to 50–55% according to the liveliness of the powder, along with CP_1. The solvent used is ether-alcohol. Amyl alcohol or diphenylamine may be used as stabilizer. These are indicated by AM or D after the name. CP_1 is a nitrocotton with nitrogen content of about 13%. About 10% (<15%) is soluble in ether-alcohol. It gives off 205–214 cm^3 of N_2O_4/g in nitrometer test. CP_2 is a nitrocotton with nitrogen content of about 12%, almost completely soluble in ether-alcohol (>96%) and giving off 190–198 cm^3 of N_2O_4 per g in nitrometer.

Walsrode Shotgun Powder: Nitrocellulose, 97%; chalk, 2%; ether, 1%.

Nitrocellulose Powders with Additions

Amberite:* Nitrocellulose (insoluble, 18.6%, soluble, 46%); mineral nitrates, 2.8%; vaseline, 6%; H_2O, 1.4%.

Clermonite: Nitrocellulose with mineral nitrates.

E. C. Powder: Contains from 14% of mineral nitrates and vaseline, camphor, resin and woodmeal or some of them in addition to nitrocellulose.

Empire Powder: Contains mineral nitrates, 9%, and vaseline in addition to nitrocellulose.

Hasloch Jagdpulver: Contains $Ba(NO_3)_2$, 17%, and vaseline in addition to nitrocellulose.

J. Powder (French): Contains $(NH_4)_2Cr_2O_7$, 14%, and $K_2Cr_2O_7$, 3%, in addition to nitrocellulose.

T. Powder (French): Contains 2% KNO_3 in addition to nitrocellulose, CP_1 gelatinized with acetone.

S. Powder:† CP_1, 37%; CP_2, 28%; $Ba(NO_3)_2$, 29%; KNO_3, 6%.

Rottweil Smokeless Powder (Shotgun): Insoluble nitrocellulose, 72.3%; soluble nitrocellulose, 24.5%; camphor and diphenylamine, 1%; H_2O, 1.5%; metallic nitrates, 0.7%.

Rottweil Smokeless Powder (Rifle): Insoluble nitrocellulose, 72.8%; soluble nitrocellulose, 25.0%; camphor and diphenylamine, 1%; H_2O, 1.2%.

Nitroglycerin Powders

Ballistite:‡ Guncotton, 50%; nitroglycerin, 49%; diphenylamine, 1%.

Ballistite, Norwegian: Guncotton, 50%; nitroglycerin, 40%; nitronaphthalene, 5%; diamyl phthalate, 5%.

Sporting Ballistite: Nitrocellulose, 60.5%; nitroglycerin, 39.5%.

Cordite Mk. I: Guncotton, 37%; nitroglycerin, 58%; mineral jelly, 5%; H_2O, 0.5%.

Cordite M. D.: Guncotton, 65%; nitroglycerin, 30%; mineral jelly, 5%; H_2O, 0.5%.

Cordite R. D. B.: Nitrocotton (N = 12.2%), 52%; nitroglycerin, 42%; mineral jelly, 6%.

Nitroglycerine Powders with Additions

Köln-Rottweil TNT powder: Nitrocellulose, 61%; nitroglycerin, 20%; TNT, 15%; DNT, 3.5%; centralite, 0.5%.

Allestite: Nitrocellulose, 60%; nitroglycerin, 25%; DNT, 15%.

Austrian Flake Powder No. 1: Nitrocellulose, 36%; nitroglycerin, 36%; $Ba(NO_3)_2$, 18%; charcoal, 10%.

Austrian Flake Powder No. 2 (Graphited): Nitrocellulose, 40%; nitroglycerin, 40%; $Ba(NO_3)_2$, 20%.

Wetteren Smokeless Powder:* Nitrocellulose, insoluble, 16%, soluble, 46.2%; nitroglycerin, 27.3%; charcoal, 9%; H_2O, 1.5%.

In the application of propulsive explosives the nature of the weapon, the velocity of the projectile, and the maximum permissible pressure in the barrel are usually fixed, and the powder is modified in composition or physical properties to give the ballistics demanded.

The following table from an article by MacNab and Leighton ([24]) gives the heat of explosion and the volume and composition of the explosion gases for a number of sporting powders.

Properties of Some Sporting Powders ([24])

Powder	Heat of explosion, g-cal/g	Permanent gases per g, cm^3	Water vapor per g, cm^3	Total volume of gas at 0°C and 760 mm, cm^3 per g	Composition of permanent gases, %				
					CO_2	CO	CH_4	H	N
Imperial Schultze.	742	763	152	915	8.9	52.7	1.0	27.0	10.4
Amberite.........	745	635	156	791	12.0	50.0	0.4	25.5	12.1

Standard Ballistics for Shotgun Powders

A. TYPICAL AMERICAN STANDARD PROOF

Lead crushers are used, the Eley 1913 tables being employed to calculate the pressures from the remaining length.

The following are the average ballistics aimed at for various typical powders. They refer to matured powder containing $1\frac{1}{8}$% moisture.

Charges	Velocity over 40 yards = V_{20} yd. or $V_{18.3}$ M	Pressure at 1 in. (2.54 cm) from base
Smokeless Shotgun		
3 drams powder = about 5.30 g. $1\frac{1}{8}$ oz. = 31.89 g shot. $2\frac{5}{8}$ in. flat base case.	875 ft./sec = 307.38 m/sec	3.5 ton/in.^{2} = 551.2 kg/cm^2
$3\frac{1}{2}$ drams powder = about 6.20 g. $1\frac{1}{4}$ oz. = 35.44 g shot. $2\frac{3}{4}$ in. flat base case.	925 ft./sec = 282 m/sec	$4\frac{3}{4}$ ton/in.^{2} = 748 kg/cm^2
E. C. and Schultze Powders		
3 dram charge = 5.30 g. $1\frac{1}{8}$ oz. = 31.89 g shot. $2\frac{5}{8}$ in. flat base cases.	870 ft./sec = 265.2 m/sec	
$3\frac{1}{2}$ drams charge = 6.20 g. $1\frac{1}{4}$ oz. = 35.44 g shot. $2\frac{3}{4}$ in. flat base cases.	890 ft./sec = 271.3 m/sec	4.1–4.5 ton/in.^{2} = 645.7–718.7 kg/cm^2

---

* Fibrous 42 % grain bulk.

† Partially gelatinized with ether-alcohol

‡ Gelatinized with acetone.

* Gelatinized with rifle powders.

TYPICAL BRITISH STANDARD PROOF

Lead crushers are used, the Eley 1918 Tables being employed to calculate the pressures from the remaining length. Pressure: 2½–3 ton/in.^{2} = 393.7 – 472.5 kg/cm.^{2} Velocity over 20 yards = V_{10} yd. or $V_{9.15}$ m = 320–335 m/sec.

Charges Which Give Standard Ballistics

Powder	Caliber	Length of cartridge case		Powder charge, wt.		Shot charge, wt.	
		in.	mm	grains	g	ounces	g
Smokeless Diamond E. C. Empire in flat base cases, 3 drams = 33 grains	12	$2\frac{3}{4}$	70	36	2.33	$1\frac{1}{4}$	35.44
	12	$2\frac{1}{2}$	65	33	2.14	$1\frac{1}{16}$	30.12
	16	$2\frac{3}{4}$	70	31	2.01	1	28.35
	16	$2\frac{1}{2}$	65	28	1.81	$\frac{7}{8}$	24.81
Schultze Amberite in flat base cases, 3 drams = 42 grains	12	$2\frac{3}{4}$	70	46	2.98	$1\frac{1}{4}$	35.44
	12	$2\frac{1}{2}$	65	42	2.72	$1\frac{1}{16}$	30.12
	16	$2\frac{3}{4}$	70	40	2.59	$1\frac{1}{16}$	30.12
	16	$2\frac{1}{2}$	65	36	2.53	$\frac{7}{8}$	24.81
Ballistite condensed powder in cone base cases	12	$2\frac{3}{4}$	70	28	1.81	$1\frac{1}{4}$	35.44
	12	$2\frac{1}{2}$	65	25	1.62	$1\frac{1}{16}$	30.12
	16	$2\frac{3}{4}$	70	23	1.49	1	28.35
	16	$2\frac{1}{2}$	65	21	1.36	$\frac{7}{8}$	24.81
				drams			
Black powder in flat base cases, 3 drams = 84 grains	12	$2\frac{3}{4}$	70	$3\frac{1}{4}$	5.75	$1\frac{1}{4}$	35.44
	12	$2\frac{1}{2}$	65	3	5.30	$1\frac{1}{8}$	31.89
	16	$2\frac{3}{4}$	70	3	5.30	1	28.35
	16	$2\frac{1}{2}$	65	$2\frac{3}{4}$	4.87	$\frac{7}{8}$	24.81

The bulk density of the 33 grain powders is 375–385 g per liter.
The bulk density of the 42 grain powders is 475–485 g per liter.
The bulk density of Sporting Ballistite is 700–710 g per liter.

RIFLE POWDERS

For rifle powders there are no fixed standard ballistics such as have been established for shotgun powders. As an example some data are given for the 7 mm Mauser rifle.

7 mm Mauser Rifle

Powder	Powder charge, grains	Weight of bullet, grains	Muzzle velocity, ft./sec	Pressure
American Military Rifle powder (*a*)...	48	139	2900	Best burning pressure, 3515–3967 kg/cm^2
(*b*)..........	42.5	139	2750	2109–3151 kg/cm^2
	44.0	139	2900	
(*c*)..........	36.9	175	2300	2320–2671 kg/cm^2
	40	175	2400	
	44	139	2786	
	45.5	139	2950	
(*d*)..........	5.0	84	950	703–1055 kg/cm^2
	8.0	120	1150	
British Rifle Neonite..........	38	173	2300	Pressure aimed at: 17.5 ton/in.^{2}
	43	140	2800	19.5 ton/in.^{2}

ORDNANCE POWDER

Here also, as in the case of rifle powders, the ballistic values required are fixed in advance, and the powder is modified in composition, in size and shape of grain, or by coating to modify its rate of burning. Examples are given of ballistics for the 7.5 cm field gun.

7.5 cm Field Gun

Gun	Powder charge, kg	Weight of projectile, kg	Muzzle velocity, m/sec	Range, km
U. S. A., 75 mm (Model 1923)....		6.8	665	13.5
Switzerland........		6.35	250–485	8.6
France............		7.25 (shrapnel)	550	11
		7.98 (H. E. shell)		
Japan (Model 05)..	0.631	6.8 (shrapnel)	510	5.8
	0.631	6.4 (H. E. shell)		8.35

LITERATURE REFERENCES

LITERATURE REFERENCES

In all literature references cited in International Critical Tables the name of the journal or publication is indicated by means of a *Key number* corresponding to the list given below. The numbers which follow this key number in a literature citation are, in the order named: (1) the volume, (2) the page, and (3) the last two figures of the year. Thus 64*V*, **31**: 253; 22, indicates Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Series numbers are not given. Key numbers referring to books and other non-serial publications are preceded by the letter *B*, and the volume number is given in roman numerals. Thus *B10*, **IV**: 191; 18, indicates Doelter, Handbuch der Mineralchemie, page 191 of Vol. 4 of the 1918 edition. The key number *O* is used to indicate "private communication from."

RÉFÉRENCES BIBLIOGRAPHIQUES

Le nom du journal ou de la publication de toutes les références bibliographiques citées dans les Tables Critiques Internationales est indiqué au moyen d'un *nombre-clé* correspondant à la liste donnée ci-dessous. Les nombres qui suivent ce nombre-clé dans un renvoi bibliographique indiquent dans l'ordre suivant: (1) le volume, (2) la page, et (3) les deux derniers chiffres de l'année. Ainsi *64V*, **31**: 253; 22, indique Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, page 253, 1922. Les numéros des séries ne sont pas donnés. Les nombres-clés se rapportant à des livres ou à des publications non périodiques sont précédés de la lettre *B* et le numéro du volume est donné en chiffres romains. Ainsi *B10*, **IV**: 191; 18, indique Doelter, Handbuch der Mineralchemie, page 191 du volume 4 de l'édition de 1918. Le nombre-clé *O* est employé pour indiquer "communication privée de."

DAS LITERATURVERZEICHNIS

In allen Literaturstellen, die in I. C. T. verzeichnet sind, ist der Name der Zeitschrift oder der Publikation mit Hilfe einer *Schlüsselnummer*, entsprechend der unten folgenden Liste, angegeben. Die Zahlen, welche diesen Schlüsselnummern bei einem Literaturzitat folgen, bedeuten der Reihe nach: (1) der Band, (2) die Seite, und (3) die letzten zwei Zahlen des Jahrganges. So bedeutet z. B. *64V*, **31**: 253; 22, Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Band 31, Seite 253, 1922. Serien-Nummern werden nicht angegeben. Der Schlüsselzahl wird ein *B* vorausgesetzt, wenn sie Bücher, oder eine andre nicht periodische Veröffentlichung bezeichnet. Die Bandnummer wird durch römische Ziffern angegeben. Es bedeutet z. B. also *B10*, **IV**: 191; 18, Doelter, Handbuch der Mineralchemie, Seite 191, des 4 Bandes, der Auflage des Jahres 1918. Die Schlüsselzahl *O* wird gebraucht, um anzuzeigen, dass es eine "private Mitteilung" ist.

INDICAZIONI BIBLIOGRAFICHE

In tutte le indicazioni bibliografiche che si incontrano nelle "Tabelle Critiche Internazionali" il nome del giornale o della pubblicazione è espresso con un *numero chiave* riportato nell'elenco dato più oltre. I numeri che, nella citazione, vengono dopo il numero chiave sono disposti con l'ordine seguente: (1) il volume, (2) la pagina, e (3) le ultime due cifre del millesimo. Così *64V*, **31**: 253; 22, indica la Verslag koninklijke Akademie van Wetenschappen te Amsterdam, Vol. 31, pagina 253, 1922. I numeri di serie non vengono dati. Quando un numero chiave è preceduto dalla lettera *B* si riferisce a libri o ad altre pubblicazioni non periodiche, e il numero del volume viene allora scritto in cifre romane. Così *B10*, **IV**: 191; 18, indica Doelter, Handbuch der Mineralchemie, pagina 191 del IV° volume dell'edizione 1918. Il numero chiave *O* indica "Comunicazione privata da . . ."

KEY TO THE PERIODICALS

IMPORTANT NOTICE

ANNUAL TABLES OF CONSTANTS AND NUMERICAL DATA CHEMICAL, PHYSICAL, BIOLOGICAL, AND TECHNOLOGICAL

Published by an International Committee, under the authority of the International
Research Council and the International Union of
Pure and Applied Chemistry

THE data given in International Critical Tables are based upon determinations published previous to January 1924.

In order to keep always up to date with future progress in physical measurements, the purchaser of International Critical Tables should become a regular subscriber to *International Annual Tables*, which will bring to his desk each year a volume in which he will find assembled and classified all of the data which have appeared in the world's literature, for the year covered by the volume.

Thus, *Annual Tables*, Volume VI, contains all the data published in the literature of 1923–1924; Volume VII will contain the data published in the literature of 1925–1926; Volume VIII, the data published in the literature of 1927–1928; Volume IX, the data published in 1929, etc.

Beginning with Volume VII the text will be given in both French and English.

The older volumes of Annual Tables go back to 1910. They contain all of the original determinations published during that period and which served as all or part of the basis of selection of the "best" values recorded in International Critical Tables. These older volumes thus constitute a handy and accessible source of reference to the original determinations.

Through special arrangements made with the International Commission in charge of Annual Tables, all purchasers of International Critical Tables will be given special discounts on all purchases of International Annual Tables, as follows:

1. 25% discount on Volumes VII to X inclusive, covering the period 1925–1930. This reduction will only be valid for each volume during the period known as the subscription period.
2. 25% discount on the index to Volumes I–V, which will be published in 1928.

These discounts apply only on subscriptions addressed to—*For United States and Canada*, McGraw-Hill Book Company, Inc., 370 Seventh Avenue, New York City, *For all other countries*, Dr. C. Marie, 9 rue de Bagneux, Paris VI, France.

All subscriptions should be accompanied by draft or money order payable at New York or Paris.

SPECIMEN SECTIONS

A free copy of any one of the following specimen sections may be obtained on application to Dr. C. Marie.

A: Spectroscopy. *B*: Electricity, Magnetism, Electrochemistry. *C*: Radioactivity. *D*: Crystallography, Mineralogy. *E*: Biology. *F*: Engineering, Metallurgy. *G*: Colloids.

The following identification form should be filled out and transmitted with the first subscription.
