

Introducing *The Companion to Language Assessment*

Almost all of us in the world have experienced an assessment or a test of our language ability at one time or another. It surely would have started in an elementary/primary school classroom where a teacher asked us to say the letters of the Roman alphabet, or read a paragraph or recite a poem in English, or learn the written script in Arabic, or write a description or a story in Korean, or converse in Hindi. In high school, the teacher might have asked us to perfect the kanji or Chinese characters, or the fall-rise tone in Cantonese or Swahili, or delve into a Shakespeare or Miller play, or a Tagore or Gibran poem, or watch a Fellini or Renoir film, and speak eloquently and write elegantly on the finer points of such masterpieces.

A history teacher might have asked us to write a report on the horrors of wars or a science teacher to report on recycling waste or a debate teacher to consider the pros and cons of the death penalty. Beyond school and into college and university, there were probably more such activities and related assessments. If we started working as a nurse, we would have had to read doctors' prescriptions to help patients with medications, or as a repair technician, to read a manual to repair a TV, or as a train driver, to understand the schedule for the morning, or as a tour guide, to speak about exhibits in museums, or as an air traffic controller, to communicate with pilots. If we were considering immigration or citizenship, we might have been asked to demonstrate our language ability of the new country or to take part in social integration programs. In all these activities and assessments, from elementary school to the workplace to a new country, language is the central component in our ability to succeed, whether it is by using our first/native or home language or a second or third language. And, in all these contexts, a teacher, a supervisor, an examiner (or a standardized examination) would have assessed our performance and graded us in order to select us into a program, promote us to the next level of study, certify us as competent, offer us a job, qualify us for a pay raise, or permit us to immigrate or gain citizenship.

Broadly speaking, this is the wide arena where language assessments are used: from a village or town elementary school to the urban professional workplace, from the local district to the international arena, from a public college or university

to a multinational corporation, and from first language ability to bilingual and multilingual abilities. This is certainly a vast arena of operation. Therefore, in order to carry this out successfully, an increasingly complex training program, along with sophisticated assessment development and research expertise, is required. Various types and levels of expertise are needed for different personnel: school and college teachers, teacher trainers, principals; the small assessment agency staff, the large corporate professional researchers; and assessment policy officials in business, military, and government.

The Companion to Language Assessment, the first multivolume collection of 140 chapters on language assessment, has been developed to address all these issues. It is comprehensive in terms of topics and themes, theories and practice, technical and research expertise, and international in coverage in terms of authors, assessments, and languages. It is a four-volume set of state-of-the-art chapters with forward-looking perspectives useful for readers of every persuasion and training.

The *Companion* also celebrates the history and success of the field by bringing together authors from 45 countries from various professions: school teachers, college and university professors, assessment administrators, assessment researchers, and policy makers.

Celebrating History

If we were to outline the history of language assessment, depending on how wide we draw this circle, we could include the Chinese imperial civil service examinations as the earliest recorded public assessments. These assessments had language elements such as poetry writing, calligraphy, and knowledge of classic Chinese texts. Many scholars believe that the examinations were established in AD 605 during the Sui Dynasty, expanded during the Song Dynasty, and finally discontinued in 1905 before the fall of the Qing Dynasty. The almost 1,300 years of examinations, despite some interruptions, is the longest use of an examination system, which lasted until a little more than 100 years ago.

On the European side, scholars have documented that a Jesuit missionary, Matteo Ricci, brought back ideas of the Chinese examinations in the late 16th century. France soon started using examinations in Catholic schools but it was under Napoleon, in 1808, that the Baccalauréat was introduced. The examination has many subject areas, such as French, philosophy, and science. It is still in use and is employed to admit students into college as well as qualify them for certain government positions. This examination was started just a little more than 200 years ago.

In the USA and the UK, the year 1913 was important. In the USA, it marked the formation of the first committee appointed by the Association of Modern Language Teachers of the Middle States of Maryland for the assessment of French, German, and Spanish. In the UK, the Certificate of Proficiency in English, the first examination in English as a foreign language, was established by the University of Cambridge Local Examinations Syndicate (now Cambridge Assessment, an umbrella organization that includes Cambridge English for Speakers of Other Languages, the developer of the CPE and other academic examinations). A quick

review of the components of the 1913 examination shows they are not very dissimilar to the ones used today. These components included translation from English into French or German, translation from French or German into English, questions on English grammar, English essay writing, English literature, English phonetics, dictation and reading aloud, and conversation. This examination was started over 100 years ago.

More recently, in 1961, three important events took place in the USA. First, a conference sponsored by the Center for Applied Linguistics in Washington, DC, and other relevant organizations adopted a plan to assess the English ability of foreign students entering US colleges and universities. This later became known as the Test of English as a Foreign Language (TOEFL, now known as the Internet-based TOEFL or iBT). Second, Robert Lado's *Language Testing: The Construction and Use of Foreign Language Tests*, the first full-length textbook on language assessment, was published by Longman. As the title indicates, it was primarily focused on the development and construction of tests. Finally, John Carroll's significant paper titled "Fundamental Considerations in Testing for English Language Proficiency of Foreign Students" was published. He promoted the idea of integrative testing (of skills and components) with focus on what has come to be known as communicative ability. Many scholars, therefore, consider 1961 as the start of the modern era of language assessment. This occurred a little more than 50 years ago!

Davies (see Chapter 1, Fifty Years of Language Assessment) takes 1961 as the starting point of his survey of the last 50 years of language assessment and brings us up to 2012.

Celebrating Success

Another reason to celebrate language assessment is the success the field has had in the last 50 years, especially the enormous popularity of many standardized assessments. Three international English language tests for college entrance dominate the college/university entrance market. The Internet-based TOEFL (iBT), developed and administered by the Educational Testing Service, Princeton, has had the largest success with a sustained test-taker base over the last 50 years. The iBT assesses the readiness of test takers in English to take college and university courses (in English-medium institutions) in the USA and Canada. The International English Language Testing System (IELTS), administered by the University of Cambridge, the British Council, and the International Development Program, Australia, is a relative newcomer but has gained a large test-taker base in the last 20 years. The Pearson Test of English (PTE) is the newest entrant into this arena and is poised to gain substantial market share in the next decade. The University of Cambridge also administers several important assessments such as the First Certificate in English, the Certificate of Proficiency in English, and the Certificate of Advanced English, and many assessments for young learners, legal and business professionals, and teachers of English. These large nonprofit, university, or private organizations employ many dozens of staff to cover all the development, operational, and research needs and have worldwide affiliations to market and administer their assessments.

Several regional standardized language assessments have also been successful. For example, members of the Association of Language Testers of Europe have developed 33 language assessments from Basque to Welsh. A few examples are the Test d'évaluation de français, the Test Deutsch als Fremdsprache, and the Certificati di Italiano generale/commercial. Similar assessments have been developed in Asia. The most well-known are the College English Test and the National Matriculation English Test in China, the General English Proficiency Test in Taiwan, and the Step Eiken in Japan. As these assessments are developed and administered by organizations that are smaller, they vary in their capacity to conduct research and to be innovative.

Language assessments are also entering the workplace arena. Assessments for aviation professionals (air traffic controllers, pilots), health professionals (doctors, nurses, and pharmacists), business professionals, court translators and interpreters, language teachers and teaching assistants, and tour guides and domestic helpers have been developed in many parts of the world. In addition, language assessments are now being used for immigration, citizenship, and asylum.

While these standardized assessments mentioned above always capture the limelight, the unrecognized school and college teacher is in the midst of classroom assessments on a daily basis all over the world. Their assessments often mimic those of the standardized assessments but their practices generally suffer from lack of exposure to good language assessment practice. It is this group of assessors who need attention in terms of assessment literacy so that they can better help their students.

The Volumes

The *Companion's* 140 chapters are presented in four volumes that focus on different language assessment matters. The first three volumes deal with theories, interests, and expertise, and the last volume offers a wide view of assessment practices from around the world. Here is a brief summary of the chapters in each volume.

Volume 1, titled "Abilities, Contexts, and Learners," presents chapters on **assessing abilities** (aptitude, listening, literacy, responses to literature, grammar, pragmatics, pronunciation, speaking, vocabulary, reading, writing, integrated skills, language and content, translation, language varieties) in different **contexts** (international assessments, school exit and college admissions examinations, government and military, courts, immigration, citizenship, and asylum), and for diverse language **learners** (young and adult learners, teachers and teaching assistants, workplace professionals in aviation and health care, and learners with communication disorders).

Volume 2, titled "Approaches and Development," offers chapters on **approaches** to assessment (large-scale, norm-referenced and criterion-referenced, and task-based and computer-assisted), assessment and **learning** (performance assessment, monitoring progress and achievement, portfolio assessment, dynamic assessment, diagnostic feedback, self-, and peer assessment, assessment literacy), assessment **development** (defining constructs, writing specifications and items, item banking, developing source material, writing scoring criteria and score

reports, response formats, field testing, test-wiseness, using standards and statistics, standard setting, planning administration, and detecting cheating), and **technology** (media, corpora, eye-tracking technology, acoustic analysis, and automated scoring).

Volume 3, titled "Evaluation, Methodology, and Interdisciplinary Themes," includes chapters on issues related to **evaluation** (designing evaluations, fairness and justice, accommodations, and consequences), **quantitative analysis** (classical test theory, reliability, dependability, generalizability theory, factor analysis and structural equation modeling, questionnaire development and analysis, item response theory, differential item functioning, and Rasch analysis), **qualitative and mixed method analysis** (content analysis, introspective methods, raters and ratings, spoken and written discourse, mixed methods research, research reports), and **interdisciplinary** themes (philosophy, language acquisition, bilingualism, classroom-based assessment issues, program evaluation, forensic sciences, and law and ethics). The volume concludes with a chapter on ongoing challenges.

Volume 4, titled "Assessment Around the World," first describes assessment practices in **English language assessment** (as a lingua franca, and in Australia and New Zealand, Canada and the USA, Mexico and Central America, the Middle East and North Africa, South, East, and Southeast Asia, South America, and Europe). The rest of the volume addresses **language assessment practices in languages other than English in Africa** (Swahili and Shona and Ndebele), **North and South America** (American Sign Language, Hawaiian, North American indigenous languages, and Spanish), in the **Middle East and South Asia** (Arabic, Farsi, Hebrew, Hindi, Malayalam, Nepali, Sinhala, Tamil, and Telugu), **Southeast and East Asia** (Bahasa Melayu and Indonesia, Cantonese, Japanese, Korean, Mandarin Chinese, Taiwanese indigenous languages, and Thai), **Australia and New Zealand** (Australian and New Zealand indigenous languages and Māori indigenous languages), and **Europe** (Armenian, Finnish, French, German, Greek, Italian, Norwegian, Polish, Portuguese, Russian, Spanish, and Welsh).

These 140 chapters are all accessible to interested readers with some background in assessment and education. A few technical chapters may need more background as they deal with psychometric matters related to development and research. On the other hand, a few chapters bring outside knowledge and relate it to language assessment in an interdisciplinary fashion. All chapters have cross-references to other chapters and references.

For those who have imagined that language assessment is a "one-note samba," I hope reading the *Companion* will reveal the rich variety and diversity of theories, interests, expertise, and themes, and a 360-degree view of practices from around the world. Language assessment, like language learning, is one of the activities that all children and adults alike engage in, from birth to death, by using language, and in making and negotiating meaning.

Introduction to Volume I

This volume starts off with a chapter which surveys the last 50 years of language assessment. This chapter provides the necessary historical and contextual background of the field. The volume is focused on abilities, contexts, and learners—all key components of language assessment. Chapters on assessment of language abilities are presented first. These abilities include aptitude, listening, literacy, literature, grammar, pragmatics, pronunciation, speaking, vocabulary, reading, writing, integrated skills, language and content, translation, and language varieties. Chapters on contexts where language assessments are popular are presented next. These contexts include school exit examinations, college and university admission examinations, workplace assessments in the military, government, courts, and the newest areas of immigration, citizenship, and asylum. Chapters on specific learners in these contexts conclude the volume. These learners include young and adult language learners, language teachers and teaching assistants, and professionals in aviation and health.

Fifty Years of Language Assessment

Alan Davies

University of Edinburgh, Scotland

It is difficult to write on language testing “without being aware of a debt to Robert Lado.” (Heaton, 1988, p. 2)

Introduction

I take as the starting point for this chapter the publication in 1961 of Robert Lado's *Language Testing*. The activity of language testing has, of course, a much longer history but the institutional and professional activity that is practiced today by researchers, academics, and commercial enterprises began to emerge in the early 1960s, in part encouraged by Lado's single-authored volume.

Lado was clear about the purpose of language testing: it was to test control of the problems of learning a new language. The problems, for him, were structural ones: “they can be predicted as described in most cases by a systematic linguistic comparison of the two language structures” (Lado, 1961, p. 24), that is the native language (or L1) and the foreign language (or L2). This was a seriously structural view, one common among linguistics and applied linguistics scholars in the 1960s. That view, from the vantage point of 2012, seems narrow and restrictive, representative of the modernist emphasis on the one grand narrative, in this case structuralism, eventually put into question by the critique of postmodernism and its short-lived dalliance with communication.

But there was more to Lado than mindless structuralism:

Lado has two defences, the first that language must be tested in the way in which it is taught; and in the early 1960s teaching orthodoxy was in favour of language components. His second defence is that he tests lots of other things as well as minimal language contrasts. Hence his chapters on “Testing the integrated skills” (auditory

comprehension, reading comprehension, speaking, writing, translation, overall control, cross-cultural understanding, and the higher values). If analytical testing consists solely of language contrasts in isolation both from language and from context, a set of language contrasts all at the same level being summed in order to construct a homogeneous test, then there is more to Lado than analytical tests, since his culture, literature, comprehension tasks, while themselves offering points of contrasts on critical points of difficulty, all subsume within themselves control over a whole range of forms which are, in miniature, integrative. (Davies, 1978/1982, pp. 132–3)

Over the period 1978–2001, the journal *Language Teaching* (formerly *Language Teaching and Linguistics: Abstracts*) published three surveys of language testing:

- Davies, A. (1982). “Language Testing Parts 1 and 2.” In V. Kinsella (Ed.), *Cambridge Surveys 1* (pp. 127–59). Cambridge, England: Cambridge University Press. (Originally published in *Language Teaching and Linguistics: Abstracts*, 1978).
- Skehan, P. (1988). “State of the Art Article: Language Testing Part 1.” *Language Teaching*, 211–21; (1989a). “State of the Art Article: Language Testing Part 2.” *Language Teaching*, 1–13.
- Alderson, J. C., and Banerjee, J. (2001). “State of the Art Review: Language Testing and Assessment Part 1.” *Language Teaching*, 34, 213–36; (2002). “State of the Art Review: Language Testing and Assessment Part 2.” *Language Teaching*, 35, 79–113.

1960–78

The first of these surveys covered the period from about 1960 to the late 1970s; the second took the analysis on for a decade and the third for yet a further decade, bringing the surveying up to the early 2000s. Taken together, these three surveys cover most of the period between Lado’s *Language Testing* and the early 2010s. I therefore begin this account by considering the issues the three surveys focused on. I then consider developments in language testing over the period 2002–12, the decade following the Alderson and Banerjee survey. Finally, I offer a brief critical overview of the last 50 years.

Central to Davies (1978/1982) is the progression during the period under survey from structural to integrative communication tests. The proposal by Spolsky (1977) for the development of language testing in the 20th century is offered as an explanation for this move, as is the revision of Valette (1967) to Valette (1977). Spolsky identified “three stages for the development of language testing in this century: the pre-scientific, the psychometric-structuralist and the psycholinguistic-sociolinguistic” (Davies, 1978/1982, p. 130). What Lado did was to develop the psychometric-structuralist approach; over the following 20 years this turned into the psycholinguistic-sociolinguistic approach.

In 1977, Rebecca Valette published a revised edition of her book *Modern Language Testing: A Handbook* (1967). She explains:

When *Modern Language Testing* appeared ten years ago, its aim was to introduce teachers to a diversity of testing techniques based on the teaching and testing theories of the mid 1960s. This revised and expanded edition [the 1977 edition] represents a natural extension of that basic objective . . . several changes characterize the new edition . . . it reflects contemporary concerns in measurement and evaluation . . . [it] reflects contemporary changes in teaching aims. The growing interest in language as a means of interpersonal communication has led to the development of a variety of tests of communicative competence. Chapters 5 through 8 of Part 2 all end with sections devoted to the evaluation of listening, speaking, reading and writing as communication skills. Chapter 9 describes a broad range of techniques for measuring students' progress in the area of culture. The testing of literature is the topic of a new Chapter 10. Finally, Chapters 11 and 12 touch lightly on new developments in testing and the role of evaluation in bilingual programs. (Valette, 1977, preface, pp. 28–9)

Spolsky's analysis and Valette's practice are symptomatic of the development in language testing between 1960 and the 1980s. Davies was not persuaded that this showed a paradigm shift; instead, he preferred to explain the change as a continuum between the structural and the communicative, the analytical and the integrative, pointing out that the demands of reliability necessarily rein in the more creative possibilities of the communicative and insist on scorable test items often of the discrete point variety.

It is probable . . . that no test can be analytical or integrative alone, that on the one hand all language bits can be (and may need to be) contextualized; and on the other, that all language texts and discourse can be comprehended more effectively by a parts analysis. The two poles of analysis and integration are similar to . . . the concepts of reliability and validity. . . . Test reliability is increased by adding to the stock of discrete items in a test; the smaller the bits and the more of them there are, the higher the potential reliability. Validity, however, is increased by making the test truer to life, in this case more like language in use. (Davies, 1978/1982, p. 131)

Davies reckoned that language testing and applied linguistics were somewhat at odds with one another, no doubt because many language testers come from backgrounds other than applied linguistics. In the 1970s, the sociolinguistic view of language as purposeful and always context related drew language testers more and more toward integrative tests. John Oller's concept of the grammar of expectancy and his research on cloze and dictation (1979) were influential, as was the rhetoric of Keith Morrow (1977, 1979) and Brendan Carroll (1978) on context-based and specific purpose tests. This development was more gradual than a conceptual shift would have brought about:

The typical extension of structuralist language frameworks (eg Lado 1961) could accommodate the testing of the communicative skills through, for example, context. Naturalism is a vulgar error; all education needs some measure of idealization and the search for authenticity in language testing is chimerical. (Davies, 1978/82, pp. 151–2)

By the end of the 1970s, language testing had been recognized as an academic field of research. Teaching and training courses in language testing were

established, and an international newsletter (the precursor of *Language Testing*) was in regular production. Davies offered: "Language testing has come of age and is now regarded as providing a methodology that is of value throughout applied linguistics" (1978/1982, p. 152).

Even so, "no theory of language testing had emerged and the history from 1980 onwards continues that search: the greater acceptance of construct validity may have been a sign of what was to follow" (Davies, 1978/1982, p. 153). Davies concluded his survey with a warning:

It would . . . be unsatisfactory if the effect of the greater prominence now given to language testing research were to divorce research from development, to separate language testing research from the necessary and continuing development of language tests. That rift has emerged in Interlanguage Studies [now Second Language Acquisition Research], with the result that Interlanguage research seems to have less and less to do with language teaching. (Davies, 1978/1982, p. 153)

1978–89

Ten years after Davies's survey, Peter Skehan published his follow-up review in two parts (Skehan, 1988, 1989a). He reported, somewhat optimistically, that "Many of the issues identified by Davies have been superseded, implying that ten years on, we do not have to be preoccupied with exactly the same problems" (Skehan, 1988, p. 211). In a discussion of work on the structure of language proficiency, Skehan considers research on the proposition that a single factor, or an internalized expectancy grammar, underlies language proficiency, usually referred to as the unitary competence hypothesis (UCH). Once John Oller had conceded that his findings in support of the UCH had been "an artifact of the variant of the factor analytic technique that he used" (Skehan, 1988, p. 212), the extreme form of the UCH was no longer tenable. The J. B. Carroll data reanalysis (1993) suggests that language proficiency consists of a general factor plus specific factors concerned with oral/aural skills, literacy skills and then more specific aspects still of test material (Skehan, 1988, p. 213). While work related to Bachman and Palmer on the multitrait-multimethod (MTMM) suggested that language proficiency consisted of both competence and performance, the most influential argument at this time was the Canale and Swain framework (1980), "since it has widened the scope of language testing to bring it much more in line with other areas of applied linguistics" (Skehan, 1988, p. 213).

Skehan reiterates his view that considerable progress had taken place in the 1980s. That progress was, he admits, largely speculative, offering proposals for constructing models of communicative competence, the Bachman (1982) and the Canale and Swain (1980) models in particular. "But," he continues, "even though the models represent considerable progress, they have not been adequately validated as yet and a large programme of research is required" (Skehan, 1988, p. 215).

The two tangible improvements he points to were:

1. "the dismissal of the UCH construct which Skehan attributes to advances in research design" and

2. “greater sophistication of analytic techniques”—he points to the MTMM approach and to the use of confirmatory (as opposed to explanatory) factor analysis.

From the vantage point of 2012, a simpler conclusion can be drawn: what really moved the debate forward was, indeed, more speculative than empirical. The progress to which Skehan refers both in research design and in analytic techniques was primarily down to the recognition that the UCH was untenable on logical grounds, that it depended on a faulty understanding of factor analysis.

In terms of development in types of test, Skehan highlights communicative language testing and English for specific purposes. For him, the problem with communicative language testing was that the models (for example Canale and Swain’s) were competence based. The trick was to link it to performance. Skehan mentions the advocacy of Morrow (1977, 1979) but accepts that the required performance constraints, such as the need for purposive communication, are difficult to achieve. As for performance tests themselves, Skehan notes that: “We can consider performance tests to be a special case of direct tests” (Skehan, 1988, p. 216). The examples he gives of performance tests are those of the Foreign Service Institute and the American Council for the Teaching of Foreign Languages, the Inter-Agency Roundtable Oral Interview, the Australian Second Language Proficiency Ratings (Ingram & Wylie, 1982), and the Royal Society of Arts Communicative Use of English Test. Interesting and innovative as these tests were, they faced severe practical problems as well as a failure of generalizability.

Skehan discusses the main developments in English for specific purposes (ESP) testing, the ELTS test (Davies, 2008), the AEB TEEP test (Weir, 1983), and the Ontario Test of ESL (Wesche, 1987). Apart from the practical problems of administering such tests, it did appear that, for example, when the ELTS test was compared with the earlier English Proficiency Test Battery (Davies, 1964), a non-ESP test, “the two tests are measuring fairly similar abilities” (Skehan, 1988, p. 218). That being so, Skehan was led to conclude that ESP testing “seemed to be encountering difficulty when performance on higher-order skills is probed in any depth” (Skehan, 1988, p. 219). It does seem questionable, he admits, “whether it is worth the effort to produce such test types and whether, except for the issue of washback, a measure of a more generalised competence would do just as well” (Skehan, 1988, p. 219).

When he considered development in achievement testing (as opposed to proficiency testing), Skehan was dismayed that there had been such little progress: “The most interesting developments and actual progress in achievement testing have been teacher-led” (Skehan, 1988, p. 220). He refers to the Graded Objectives Movement in foreign language teaching (Clark & Hamilton, 1984), foreshadowing, perhaps, the later and hugely influential Common European Framework of Reference for Languages (CEFR, 2001). For Skehan, the significance of such schemes was the link between language testing and applied linguistics, which could give testing the positive image it lacked, demonstrating “that tests would not always be done to people but with them” (Skehan, 1988, p. 221).

Skehan discusses what he refers to as influences on test performance: the study of contaminating influences on test scores (Skehan, 1989a, p. 1). He refers to three of these:

1. Language-based problems, notably the fact of variation within languages (Tarone, 1988). The general problem of context-embeddedness of languages, which means that every performance is unique. Overcoming variability requires, he admits, an appeal to additional, not strictly testing, criteria.
2. Learner-based problems: studies of age, gender, intelligence, attitude: these had produced very unclear findings.
3. Method factors: the influences of the specific test format on the candidate. Different methods seemed to be measuring somewhat different things (Bachman & Palmer, 1982), for example “the multiple-choice format was easier than the open-ended format, while gap-filling was the easiest format of all” (Skehan, 1989a, p. 3).

A particularly significant development in the field during the 1980s was in statistical techniques, notably the application of item response theory (IRT) to challenge (Woods & Baker, 1985) classical item analysis. For Skehan, IRT concerned reliability assessment. He refers also to advances in how test validity was established, quoting convergent-discriminant approaches (Campbell & Fiske, 1959) exploited by Bachman and Palmer’s MTMM research (Bachman & Palmer, 1981) and confirmatory factor analysis:

The potential of the technique is clear since it will enable testers to move from a research-then-theory perspective to a more theory-then-research orientation in which hypotheses are tested out, rather than data being simply assembled and trawling operations carried out. (Skehan, 1989a, p. 5)

Again, looking back at such optimism in 2012, one can be skeptical that we have reached a theory-then-research state. So much for confirmatory factor analysis! As for the undoubted development in statistical and analytical techniques, there is the tail wagging the dog doubt: are the statistics the servant or the master? Or, as Lord Beaverbrook asked, “Who is in charge of the clattering train?”

Skehan gives considerable space to a discussion of criterion-referenced measures (CRM). He distinguishes four senses of CRM:

not norm referenced,
having an external standard,
a cut-off score,
a scale of behavior.

The cut-off approach appears to have engendered most research (Hudson & Lynch, 1984; Hughes, 1986). Skehan notes two main advantages of the criterion-referenced approach: washback and the necessary use of domain specifications. But Skehan is not overly optimistic about the use of criterion-referenced testing (CRT), largely because of its lack of attainability. Perhaps the link between CRT and norm referencing was always closer than Skehan admitted (Davies, 1978/1982).

One of the major developments in the 1980s was the level of activity of testing boards and agencies such as the RSA and its Communicative Use of English Language (test), the Cambridge examinations, the Educational Testing Service and its

Test of English for International Communication and Test of English as a Foreign Language (Stansfield, 1986), the Test of English for Educational Purposes and the British Council's English Language Testing Service test (Criper & Davies, 1987), and, in the Netherlands, CITO and their foreign language tests. Skehan notes the very useful publication of the reviews of English language proficiency tests (Alderson, Krahnke, & Stansfield, 1987), which, for perhaps the first time, made available the thinking and explaining of boards and agencies.

In his conclusion, Skehan notes the increase in books on language testing, both introductory and advanced, as well as the launch of the specialist international journal *Language Testing*. Looking forward, Skehan forecasts more research on the recent proficiency models, re-examination of the problem of coherence of a communication problem, and a closer link between applied linguistics and language testing.

Above all, writes Skehan, what is desirable is

testing related to developmental stages in language learning, allowing in turn a more useful relationship between achievement and proficiency testing: testers will have to address the issue of development, of proficiency and acquisition. There is clear scope here for bridge-building with SLA theories and findings. (Skehan, 1989a, p. 9)

Since Skehan's survey, his hope for an alignment between language testing and applied linguistics has met with some success: not so the closer link he wanted between language testing and second language acquisition research (SLAR). Both disciplines are interested in the knowledge of the (native) speaker but their assumptions are very different, as are their purposes. Sharing a common origin does not guarantee a shared target.

1989–2002

The third in this sequence of surveys (Alderson & Banerjee, 2001, 2002) was published in two parts in 2001 and 2002. Between the second and third survey the amount of research and other language-testing activity had increased so much that the Alderson and Banerjee survey was twice the length of the Skehan one. Alderson and Banerjee recognized the task before them with some trepidation:

The field has become so large and so active that it is virtually impossible to do justice to it, even in a multi State-of-the-Art review like this, and it is changing so rapidly that any prediction of trends is likely to be outdated before it is printed. (Alderson & Banerjee, 2001, p. 215)

This section reports here on the major issues addressed by Alderson and Banerjee: washback, ethics, politics, computer-related matters, validation research.

By washback, Alderson and Banerjee mean "the impact that tests have on teaching and learning. Such impact is usually seen as negative . . . however . . . a good test should or could have positive washback" (Alderson & Banerjee, 2001, p. 214).

Wall (2000) provides a useful overview and argues that test washback needs to be seen in the context of the materials and practices it is based on. Others have argued for broadening washback to cover impact, while Messick (1989) even more broadly discusses the consequences of test score interpretations, sometimes referred to as consequential validity. Such arguments fueled a concern for an ethics of language testing which prompted the International Language Testing Association (ILTA) to develop both a code of ethics (ILTA, 2000) and a code of practice, known as "Guidelines for Practice" (ILTA, 2007). The publication of these codes was, Davies (1997) suggested, clear evidence that language testing had matured into a profession in which codes are aspirations rather than laws to be obeyed.

The ILTA code of ethics was established in 2000. Alderson and Banerjee quote from the code:

[It] is a set of principles which draws upon moral philosophy and strives to guide good professional conduct . . . All professional codes should inform professional conscience and judgement . . . Language testers are independent moral agents, and they are morally entitled to refuse to participate in procedures which would violate personal moral belief. Language testers accepting employment positions where they foresee they may be called on to be involved in situations at variance with their beliefs have a responsibility to acquaint their employer or prospective employer with this fact. Employers and colleagues have a responsibility to ensure that such language testers are not discriminated against in their workplace. (ILTA, 2000, quoted in Alderson & Banerjee, 2001, p. 217)

They comment:

These are indeed fine words and the moral tone and intent of this Code is clear: testers should follow ethical practices and have a moral responsibility to do so. Whether this Code of Ethics will be acceptable in the diverse environments in which language testers work around the world remains to be seen. Some might even see this as the imposition of Western cultural or even political values. (Alderson & Banerjee, 2001, p. 217)

Some might indeed! However, the authors of the code of ethics (one of whom was the present writer) were conscious of the need to avoid local bias and Western hegemonic influence. The code's appeal internationally may be judged by the absence of objections from the non-Western world since its publication. True enough, there was a growing concern among language testers for accountability, concerning their activities, influenced by a coming together of professionalism and a concern for ethics. It was this concern which Shohamy (1997) presented as showing the need for a critical language testing.

Discussion of ethics inevitably prompted an interest in the relation between testing and standards and between testing and politics, a link examined more closely below. Alderson and Banerjee's survey made few predictions: one, which turned out to be accurate, concerned the Common European Framework of Reference (North, 1995): "It is now clear that the Common European Framework will become increasingly influential because of the growing need for international recognition of certificates in Europe, in order to guarantee educational and

employment mobility” (Alderson & Banerjee, 2001, p. 219). They also comment that the Common European Framework underlay the European Language Portfolio, as well as new diagnostic tests such as DIALANG (Alderson, 2005). They could have said that the CEFR would turn out to be influential not just in Europe but worldwide. Such a juggernaut-like acceptance is not without its critics (Fulcher, 2004, and see comments *passim* on the LTest eList).

Alderson and Banerjee briefly survey work on language for specific purposes (LSP) and, following Skehan, conclude on a somewhat skeptical note:

Perhaps the real challenge to the field is in identifying when it is absolutely necessary to know how well someone can communicate in a specific context or if the information being sought is equally obtainable through a general purpose language test. The answer to this challenge might not be as easily reached as is sometimes presumed. (Alderson & Banerjee, 2001, p. 224)

Their survey notes a considerable growth in the use of computer-based testing. They refer to the development of a computer-delivered version of the Test of English as a Foreign Language which later became the computer-delivered TOEFL iBT, computer-adaptive rating for tests such as the Graduate Management Admission Test, PhonePass (www.ordinate.org), a telephone delivery test procedure that led to a computer system, and DIALANG, a suite of computer-based diagnostic tests available in 14 European languages.

Testing young learners had increased but, the survey concludes, had left doubts: first, that the increase had led to a growth in formal assessment, precisely the form of testing that advocates of testing for young children have never favored (Rea-Dickins & Gardner, 2000). Second, the expansion had led “to increased specification of the language targets young learners might plausibly be expected to reach and indicates the spread of centrally specified curriculum goals” (Alderson & Banerjee, 2001, p. 231).

During the 1990s and into the following decade, the issue of validity dominated the language-testing literature. Messick (1989) argued that validity is a unified concept, that validity is not a characteristic of a test but is derived from the inferences made from test scores. In other words, it makes no sense to speak of the validity of a test since validity depends on the outcome of each test event. Although this view has been influential, it has also been challenged (Fulcher & Davidson, 2007; Davies, 2012a) on the grounds that test selection must in part take account of validity estimates earlier accrued. Even more contentiously, Messick maintained that validity should also include test outcomes or test consequences but, as Alderson and Banerjee point out, “it is far from clear whether this is a legitimate area of concern or a political posture” (Alderson & Banerjee, 2002, p. 79).

The attention at the time given to questions of validity meant that language testers were compelled to move beyond psychometric issues and pay attention to language concerns. Alderson and Banerjee consider that this meant a closer relationship between language testing and applied linguistics. Lyle Bachman (1990) supported this relationship in his interactional model, building on the earlier work of Hymes (1972) and Canale and Swain (1980). This apparent move toward applied linguistics was not sufficient for every researcher;

McNamara, for example, maintained that the Bachman model ignored the social dimension of language proficiency, an omission McNamara attempted somewhat later to rectify in his coauthored volume with Carston Roever (McNamara & Roever, 2006).

The bulk of Part 2 of the Alderson and Banerjee survey is devoted to summarizing the volumes in the *Cambridge Language Assessment Series* (edited by Alderson and Bachman since 2000), each volume dealing with a different aspect of the current state of the art: reading, listening, vocabulary, speaking, writing, grammar, and language for specific purposes. Cambridge University Press also publishes the *Studies in Language Testing* series (edited by Milanovic and Weir since 1995) in partnership with Cambridge ESOL. This series is mainly concerned with publishing research related to Cambridge ESOL examinations.

Alderson and Banerjee end Part 2 of their survey (Alderson & Banerjee, 2002) by reflecting on a number of issues which, they say, “are currently preoccupying the field” (Alderson & Banerjee, 2002, p. 98). They discuss authenticity, how to design language tests, the reliability–validity distinction, and the validation of language tests. They reserve judgment on the authenticity issue, noting that the little evidence available does not support the need for authenticity in language tests. Central to work on the design of language tests, they claim, is understanding the nature of the task we present to test takers. This, they say, is “the most important challenge for language testers for the next few years” (Alderson & Banerjee, 2002, p. 101).

As for reliability and validity, Alderson and Banerjee follow Messick optimistically: “We need not agonise . . . over whether what we call reliability is actually validity. What matters is how we identify variability in test scores” (Alderson & Banerjee, 2002, p. 102). This harks back to Swain (1993), which at the time seemed heretical.

We return, write Alderson and Banerjee, to where Part 2 of the survey began, to validity and validation (Alderson & Banerjee, 2002, p. 102). They admit this remains a contested issue. Much recent work on validity has adopted the validity argument approach following Messick (1989) and Mislevy. This approach involves two steps: the specification of the proposed interpretations and uses of the test scores and the evaluation of the plausibility of these interpretations and uses (see the recent discussion in Kane, 2012). At the end of their review, Alderson and Banerjee agree that old concerns continue (Alderson & Banerjee, 2002, p. 105), not a view that Skehan took, as my earlier discussion indicated. However, while Skehan was mildly optimistic, Barnwell (1996), on the other hand, in his history of language testing in the USA, was dismayed that language testers keep coming back to the same old issues, most of which, he wrongly claimed, had been solved long ago:

Insights into the constructs we measure as language testers have certainly been enhanced by a greater understanding of the nature of language . . . but dilemmas faced by any attempt to measure language proficiency remain. To use Davies’s classic phrase, testing is about **operationalising uncertainty** (Davies 1988) . . . The challenge for the next decade will be to enhance our understanding of these issues. (Alderson & Banerjee, 2002, p. 105)

The 2002–12 Decade

This section refers briefly to developments in language testing over the period following the Alderson and Banerjee survey, the decade 2002–12. The following section then offers a critical overview of the whole period from 1960 to 2012. Given the wide coverage of this chapter, there are no cross-references.

Along with a continuing research interest in vocabulary, in LSP—for example aviation English—and in web-based and computer-delivered tests, what emerges over the next period is a growing interest in national tests (e.g., the College English Test in China, Asian tests more widely, Dutch tests, and test translation such as that in PISA). The long-felt need for a comprehensive account of the statistics used for language assessment is now fully met by Bachman (2004). Research articles in the last 10 years or so have indicated emerging interest in social and political issues, for instance Shohamy (2001) and McNamara and Roever (2006). Researchers have shown growing interest in the role of language tests in immigrant and citizenship issues (Kunnan, 2012). Technical developments get a look-in (Alderson, 2005; Sawaki, 2012). Validity and now its doppelgänger, ethics, continue to take pride of place in research: a concern for validity means professionalism, means taking account of language in use in diurnal settings, and means a concern for fairness which questions the use of tests in areas of potential discrimination such as immigration and citizenship (Shohamy & McNamara, 2009). The concern for test development, for the suitable architecture of a test, moves into a concern for test use: validity takes central place, dislodging reliability, and the earlier questions for testers—“how?” and “what?”—become “why?” and “should we?” Of course, reliability is not forgotten and, while test use matters, it is accepted that it is intended and not unintended test use that contributes to test validation, which, it is to be hoped, is what Messick really meant (Fulcher & Davidson, 2007; Davies, 2012b).

Much recent work on validity has adopted the validity argument approach, following Messick, Mislevy, and Kane. This approach involves two steps: the specification of the proposed interpretations and use of the test scores and the evaluation of the plausibility of those interpretations and uses. The test developer’s decision in interpretation is central to the validity argument. This interpretative argument ranges from scoring to a theory-defined construct to evaluation and concludes with a decision (Kane, 2012).

Language aptitude testing has been little researched since the 1960s. The Modern Language Aptitude Test (Carroll & Sapon, 1959) in the 1950s remains the model for all such research. Perhaps because of that test’s robustness, few scholars have pursued research, with the exception of Pimsleur (1966) and Skehan (1989b), that is until recently when Charles Stansfield launched a major language aptitude project under the aegis of his Second Language Testing Institute (Stansfield, 1989; Reed & Stansfield, 2004).

Oral assessment has always been problematic. Some years ago, the communicative search for authenticity in language teaching led to the use of pair and group work in oral language assessment. This form of oral assessment has attracted a good deal of research in recent years. It seems that it may resolve some of the

weaknesses in the usual oral interview. Of course, there are still problems, such as that of assigning individual scores, but results suggest that paired/group oral assessment offers advantages which individual interviews do not (Taylor & Wigglesworth, 2009).

The increasing attention given to World Englishes, the varieties of English around the world (Singapore English, Indian English, Nigerian English, and so on, and in Europe the so-called English as a lingua franca), has raised the question of the appropriate model in each case that English tests should use. What evidence there is suggests that, in formal assessment and education, Standard English is the model that local stakeholders invariably choose.

Overview

Three concerns have dominated language testing since the 1960s. They are:

1. How to test?
2. What to test?
3. Who are the testers?

These concerns are present throughout the period (and, indeed, could be said to be the enduring business of language testing), although the third—the “who?”—comes into prominence only after developments of the “how?” and the “what?”

How to Test?

Much of the discussion and much of the practice has been on refining reliability and on improving methods of analysis (for example, IRT, structural equation modeling). While such refining never ends, it seems evident that the profession is now confident of its ability to write test items, including in the difficult areas of the productive skills, and to analyze the results whether the items are quantitative or qualitative. The process of writing items and analyzing results causes imaginative views of test delivery to be tempered by a realistic view of practice. In addition to creative innovation with test items such as interactive dialogue in speaking tests, cloze in reading tests, and dictation in listening tests, computing developments have allowed TOEFL to become web based and the new Pearson Academic Test of English to be delivered entirely by computer. This can be a problem for poorer countries where there are few computers. The decision by Cambridge ESOL to offer both computer and written versions of IELTS acknowledges this disparity.

What to Test?

The argument about the nature of language, the unforgiving dispute between nominalism and realism, underlies the question of what to test. Robert Lado, properly praised at the start of this chapter for his pioneering structuralist work, represents a realist approach (as, indeed, does Noam Chomsky), while

the communicative response to structuralism in the 1970s and 1980s belongs to nominalism. Realism says that language is a set of ideas such as grammar, phonology, and so on, constructed in the minds of linguists, since native speakers do not operate top-down from a grammatical or phonological construct in order to construct sentences. The nominalist approach says that, whether our perceptions are correct or not, we deal with real things in the world: there is language in use.

After the communicative revolution had, quite quickly, run its course, the profession settled down to a compromise position (Bachman, 2005), which is where we are today. Indeed, the strong focus on what to test has given way to a serious concern for the profession's own professionalism.

Who Are the Testers? A Profession

Many developments over the later part of this half-century indicate that the practice of language testing has become professionalized. These indications include the two international journals: the journal *Language Testing* is now nearly 30 years old; it was joined in 2004 by *Language Assessment Quarterly*. Attempts to distinguish the two journals on the grounds of special interests have so far not been wholly successful. There are several dedicated Web pages (for example www.iltaonline.com), a number of textbooks and dictionaries (for example Davies et al., 1999), and international and national language-testing associations, among them the International Language Testing Association, the Association of Language Testers of Europe, the European Association for Language Testing and Assessment, the Japan Language Testing Association, three regional associations in the USA—the Midwest Association of Language Testers, the East Coast Organization of Language Testers, and the Southern California Association for Language Assessment Research—the newly formed Canadian Association, and the Australian–New Zealand Association. Codes of ethics and codes of practice have been published, and the profession has available training programs and research degrees in language testing and regular national and international conferences, notably the annual Language Testing Research Colloquium. In addition, testing organizations (for example Cambridge ESOL, ETS, Pearson Language Testing) have reviewed their delivery systems and established research arms to support the profession.

Such are the outward indicators of professionalism. But the inward, perhaps the more important, are also evident. These are all concerns for the profession's accountability, that its practice is transparent and fair to all stakeholders. Hence the major concerns with washback, with ethics, and with validity. Washback requires that the profession recognize that its language-testing products have an effect on the world, an effect which it is the profession's responsibility to make beneficial as much as possible. Alas! This admirable aim is not easy to achieve but it remains a potent ambition. Ethics goes further than washback, taking into account not just what effect a test has but whether it is morally right to develop/use a particular test. The profession has been much exercised about this concern ever since Western governments imposed language tests for immigrants, refugees, and new citizens.

Being ethical (or, perhaps more appropriately, claiming to be ethical) is the stance that marks out a profession, hence the various codes of ethics and of practice which declare, in the sense of an oath, that those involved promise to uphold the virtues of the profession.

Validity, including accountability, may be seen as an overarching construct, a promise to perform justly, as well as to include in tests only what should be there, and a concern for the effects on stakeholders plus a commitment to ensuring that the consequences of a test are those that were intended.

That is one view of validity, the Messick–Kane–Chapelle view. A simpler definition can also be proposed, one that does not aim at an umbrella-like validity which acts as a judgment on all aspects of a test. The simpler view is that washback and ethics (and accountability) are distinct: each has its proper role. Validity, for instance, asks the questions: Does the test embody in its items the original intention and do the scores it achieves provide an appropriate outcome?

Conclusion

Has there been progress in language testing since the 1960s, given that the same issues appear again and again, issues that remain, it appears, unresolved? This chapter argues that yes, there has been progress. Of course, issues such as validity and the structural–communicative debate remain. And so they should, since they are fundamental to the theory and practice of language testing. But the professionalizing of the activity with all that entails, the serious concern for ethics, the development of a research culture—these are real signs of progress, of a profession that is comfortable in its practice and alert to its shortcomings.

Assessing Aptitude

Catherine J. Doughty

University of Maryland Center for Advanced Study of Language, USA

Purpose of Language Aptitude Assessment

The purpose of language aptitude assessment is to measure potential for success in learning a second language (L2). Often, language aptitude is assessed in adolescents and adults, after the close of the critical period.¹ Since adult second language learning is notoriously difficult and by no means guaranteed to succeed, an important aim of language aptitude assessment is to capture the range of individual differences in post-critical period language-learning potential. All other factors such as motivation and opportunity being equal, after age of initial L2 exposure, language aptitude, arguably, is the next most important predictor of adult language-learning outcomes.

Language aptitude assessment is often a key component in decisions that lead to substantial investments of time, effort, and money. Most language aptitude tests are used to identify people who can learn a second language fastest under the same classroom conditions. The most widely used of these tests—for example, the Modern Language Aptitude Test (MLAT; Carroll & Sapon, 1959) and the Defense Language Aptitude Battery (DLAB; Peterson & Al-Haik, 1976; Lett et al., 2004)—were originally designed to predict initial rate of learning in intensive courses that last 6–18 months and yield basic proficiency in the second language, although the MLAT has sometimes been used in much less intensive settings, such as university language courses. Given globalization in the past decades, basic proficiency is no longer adequate for government and international business endeavors. Thus, more recently, researchers have turned their attention to assessing language aptitude for the purpose of predicting the ultimate level of L2 attainment, for instance the proficiency needed for professional or distinguished professional language use (see Interagency Language Roundtable, ILR, *n.d.*, for descriptors), levels of expertise that take many years to acquire. In the High-Level

Language Aptitude Battery (Hi-LAB; Doughty, Campbell, Bunting, Bowles, & Haarmann, 2007; Doughty et al., 2010), language aptitude is conceptualized as a ceiling on second language learning.

Uses for Language Aptitude Assessment

Selection

Since language aptitude assessment captures individual differences in potential for language-learning success—whether the focus is on rate or ultimate attainment—the information can be used to select from among a pool of candidates those who are most likely to do well in a particular language course or over their career of language learning. Sometimes language aptitude assessment is one in a series of hurdles used to select personnel for further training. An example is the aforementioned DLAB, which is administered in order to select for matriculation into the Defense Language Institute Foreign Language Center (DLIFLC). Persons who wish to enlist initially take the Armed Services Vocational Aptitude Battery (ASVAB), a multiple aptitude test that determines whether they meet enlistment qualifications and for which military occupations they might be best suited. Subsequently, each service uses one or another composite of ASVAB test sections to select among qualified recruits those who will take the DLAB in order to assess their potential for success at DLIFLC (Schmitz, Stoloff, Wolfanger, & Sayala, 2009). Research has shown that a subset of ASVAB test sections alone predict success at DLIFLC, but that surmounting both hurdles, ASVAB and DLAB, predicts success at DLIFLC incrementally better (Silva & White, 1993; Bunting et al., 2011).

Diagnosis

Aptitude assessments typically employ tests with sections derived from one or more separate language aptitude constructs, as discussed further below. Provided that data are available from each section, this information indicates potential strengths and weaknesses for each individual, and, taken together, represents the individual's language aptitude profile. For example, an aptitude profile can provide information on the ability to handle a new sound system or to induce the grammar or acquire the vocabulary in different learning modes (i.e., implicitly or explicitly). Such diagnostic information can be used too for the purposes of placement, tracking, and counseling, and tailored instruction. A further use of diagnostic information is to identify a language-learning disability, which could lead to a waiver of a foreign language requirement in cases where individuals could be expected to struggle excessively or to fail (Ganschow, Sparks, Javorsky, Pohlman, & Bishop-Marbury, 1991; Sparks & Ganschow, 1991).

Placement

Once language aptitude scores or profiles are obtained, the information can be used to place students in language courses. For example, students with high aptitude scores can be grouped into accelerated classes, enabling those students

expected to learn faster to excel. In addition to grouping, aptitude tests can inform placement into languages on the bases of anticipated difficulty of learning, defined on the basis of degree of distance of the L2 from the first language (L1), or by the observed number of weeks needed to reach basic proficiency. For example, the DLIFLC uses cut scores on the DLAB to place students into four categories of language in courses that last between 26 weeks (Romance languages) and 64 weeks (Arabic, Chinese, Japanese, Korean, and Pashto).

Counseling

Whereas language aptitude scores can be used to select only those individuals most likely to succeed in language learning, such information can also be used to diagnose potential difficulty in language learning, for instance, where selection has not been possible, or where the individual is otherwise qualified for a job, and is required to learn a foreign language to the best of his or her ability. In these circumstances, aptitude information is used as the basis for counseling language learners to help them cope with difficulty. An example is the use of the Modern Language Aptitude Test (MLAT) at the Foreign Service Institute, which is the language school of the US State Department (Ehrman, 2004). Because the MLAT provides subsection scores, diagnostic information is available, and counseling is possible. Aptitude tests that provide only one composite score are less useful in this regard.

Tailoring Language Instruction

In addition to counseling learners to enable them to make the most of their language-learning opportunities, aptitude test information can potentially be used by teachers and materials developers to tailor instruction to match students' aptitude profiles. The purpose of tailoring instruction in this way is to take advantage of findings on individual differences in cognitive aptitude in order to optimize training and learning outcomes for learners with differing abilities. While individualizing instruction is not a new idea, the use of language aptitude tests as the scientific basis to more accurately inform such tailoring is attracting current research interest (Tare et al., 2011). Aptitude-by-treatment interaction research, by intentionally matching or not matching measured aptitudes with instructional treatment variables, investigates whether the students who are matched outperform the students who are mismatched or not matched.

Predicting Performance Outside the Classroom

As Ehrman (2004) pointed out, aptitude tests are not typically used to predict performance beyond classroom instruction, for example in autonomous maintenance, at the workplace, or during immersion experiences, such as studying or living abroad. In fact, the most widely used aptitude tests, the MLAT and the DLAB, were expressly designed to predict performance in academic classrooms. Nevertheless, prediction of success outside the classroom on the basis of aptitude deserves investigation, focusing on constructs that could be expected to underpin less structured or naturalistic learning. For example, in an investigation of at-home

versus study-abroad speaking gains by L2 Spanish learners, O'Brien, Segalowitz, Freed, and Collentine (2007) found that, while study-abroad students made greater oral proficiency gains than at-home students, after controlling for the learning context, aptitude, as measured by phonological short-term memory, accounted for differences in oral proficiency gains. Moreover, an interaction effect, this time naturalistic, was found for two of the oral proficiency measures, that is, aptitude explained a significant amount of variance in fluency gains for study-abroad students, but not for at-home students.

Aptitude Testing Formats

Traditional aptitude tests like MLAT and DLAB are group or individually administered in multiple choice format, delivered in booklets or, more recently, on computers. As such, they are relatively indirect tests of language aptitude. These aptitude tests are timed in the sense that each section has a time limit or that test takers follow the pace of recorded instructions. Most are not speeded, but some tests have sections that contain more items than can be completed during the allotted time, thus allowing the most capable learners to show their full potential, since there is no ceiling effect.

As Carroll (1990) noted, traditional aptitude tests are limited by the multiple choice testing format and by constraints of administration time. A recent advance in aptitude testing has been the development of more direct tests of potential for language learning. For example, the Cognitive Ability for Novelty in Acquisition of Language (Foreign) Test (CANAL-FT; Sternberg, Grigorenko, Ferrari, & Clinkenbeard, 1999; Grigorenko, Sternberg, & Ehrman, 2000) is a dynamic test, during which language learning takes place and is measured. In the new computer-delivered Hi-LAB (Doughty et al., 2007), test takers perform tasks that engage the cognitive abilities comprising the constructs. For example, in a Hi-LAB test, a test of attention allocation, test takers are asked to switch between identifying numbers as high or low or odd or even, and in another Hi-LAB test, one of memory updating, they are asked to retrieve only relevant items from short-term memory. Many of these more direct tests also measure cognitive processing speed, which is captured precisely by recording response times in milliseconds. The computer delivery of direct cognitive tests has posed a challenge in terms of ensuring the reliability of the tests, since cognitive measures are often designed to be administered one on one. The solution has been to take great care in designing instruction screens and to include practice for every test section (Doughty et al., 2007, 2010). An advantage of computer delivery of direct cognitive aptitude tests, like tests of other kinds of aptitude, is that they cannot be prepared for in advance, and test exposure is much less of a concern than with multiple choice tests.

Threats to Validity of Language Aptitude Tests

Since language aptitude indicates potential for—rather than already demonstrated—successful language learning, assessments can be administered prior to the start of L2 learning. Depending on one's view of whether the experience of language

learning alters language aptitude (as yet untested), assessments also can be conducted even after L2 learning has begun. However, there are a number of potential threats to validity in aptitude assessment that must be avoided. A key requirement is that knowledge of language, either L1 or L2, should not impact the results. For this reason, language aptitude test items should be in the native language or be language-independent, such as with the iconic representations in test items used in LLAMA Language Aptitude Tests (Meara, 2005). Also, test instructions must be entirely comprehensible to test takers (preferably in their native language). For computer-delivered tests, separate screens should present the goal of the test section, the expected responses, the timing conditions, etc., and practice items should be provided. Other threats to validity, particularly in direct cognitive tests of aptitude, are distraction and fatigue. Guidelines for preparing for and taking the test, plus frequent breaks, can mitigate these threats. Such mitigation has been shown to increase the reliability of direct tests of cognitive aptitude (Doughty et al., 2007; Mislevy et al., 2010). Finally, technical knowledge of grammar, which is often characteristic of advanced language learners who have spent years in traditional classrooms, can lead to rapid performance and good results on aptitude tests; however, in this case the tests are not engaging the aptitude, but rather are measuring acquired metalinguistic knowledge.

Traditional Language Aptitude Constructs

Modern Language Aptitude Test, Pimsleur Language Aptitude Battery, and Defense Language Aptitude Battery

There is a long history in the USA of assessing language aptitude (Carroll, 1981), each new effort catalyzed by wartime requirements for Americans to learn foreign languages, and each influenced by substantial changes in the language pedagogy of the time. From 1920 to 1945, the prevailing approach to language teaching was grammar-translation. Aptitude for language learning under those conditions was tested by “posing linguistic puzzles in an artificial language that could be solved analytically” and depended on “knowledge of grammatical terminology and recognition of morphological processes” (Carroll, 1962, p. 92). During World War II, the emphasis switched to listening and reading comprehension, and language courses were full-time and intensive (e.g., the “Army Method”). Since it was not possible to reduce the time allotted to learn a language (8–12 months at that time), the US Army funded research on language aptitude in order to enable selection of personnel who could learn languages the fastest under intensive learning conditions. The Psi-lambda (for “psycholinguistic”) aptitude test was developed by John Carroll and Stanley Sapon between 1953 and 1958 for use in selecting students for the then Army Language School (now DLIFLC). The commercial version of this test (MLAT) was developed and validated in a range of settings by the Psychological Testing Corporation, and has since been used to assess language aptitude in learners of all ages and in a variety of learning conditions (Stansfield & Reed, 2004).

Around the same time, the Pimsleur Language Aptitude Battery (PLAB; Pimsleur, 1966) was designed specifically for high school language learners by Paul Pimsleur (between 1958 and 1966). And, the Defense Language Aptitude

Table 2.1 Categorization of DLAB/MLAT/PLAB parts with respect to Carroll's four aptitude abilities (adapted from Kelly, Stansfield, Reinhart, & Doughty, 2008)

	<i>DLAB</i>	<i>MLAT</i>	<i>PLAB</i>
Phonetic coding ability	Part 2, Recognition of stress patterns Part 3, Foreign language grammar	Part 2, Phonetic script Part 3, Spelling clues	Part 5, Sound discrimination Part 6, Sound-symbol association
Grammatical sensitivity	Part 3, Foreign language grammar Part 4, Foreign language concept formation	Part 4, Words in sentences	Part 4, Language analysis
Rote learning ability	Part 3, Foreign language grammar	Part 1, Number learning Part 5, Paired associates	Part 4, Language analysis
Inductive language learning ability	Part 4, Foreign language concept formation	Part 1, Number learning	Part 4, Language analysis

Battery (DLAB) was later developed for use by the military in the early 1970s with the aim of incrementally improving the selection of recruits who would be trained as language personnel. The impetus for this test development was an increased emphasis on communicative language teaching at DLIFLC. The DLAB has been validated (Petersen & Al-Haik, 1976) and has been in continual use for selection to DLIFLC, but is not available to the public.

The MLAT, the PLAB, and the DLAB have four constructs in common, as shown in Table 2.1 (Kelly, Stansfield, Reinhart, & Doughty 2008²). Phonetic coding, the ability to relate phonological sounds to visual symbols with speed and accuracy, is a prerequisite for literacy in both L1 and L2. The PLAB, for example, measures this ability with a nonword recognition task during which test takers hear recordings of phonotactically possible (in English), but lexically meaningless nonwords, and must choose the written answer whose spelling corresponds to the auditory stimulus, from among distracter nonwords involving the same letters in scrambled orders (Pimsleur, Reed, & Stansfield, 2004).

Grammatical sensitivity is understood as the ability to recognize the grammatical role a word or constituent plays in a sentence (Carroll, 1962). For instance, the MLAT measures grammatical sensitivity in the section called “words in sentences,” where an underlined word or phrase in one sentence must be matched to the analogous part of another sentence. (The underlined parts of “The fish swallowed the hook,” and “The man mailed the letter,” are grammatically analogous, though they have little in common semantically, because both are the objects of their respective verbs; Carroll, 1981). The comparable component of the PLAB, the language analysis subtest, provides test takers with a sample of linguistic data, including glosses, in a foreign language, which they must use to translate a novel sentence into the target language (Pimsleur et al., 2004).

The MLAT includes a measure of rote memory—the conscious process of storing information in long-term memory, often by repetition—that has no exact DLAB

or PLAB analogue. The memorization of new vocabulary is generally recognized as an integral part of language learning (Nation, 1990), and the MLAT tests this construct with the “paired associates” subtest, wherein test takers are given non-words along with their English translations, which they must memorize and then recall during the test. Although not tested directly, rote memorization of vocabulary is also helpful in the foreign language grammar subtest of DLAB and in the language analysis subtest of PLAB.

In the DLAB concept formation subtest, inductive reasoning is employed to match artificial language captions to pictures. At the top of the page, there is a set of four pictures with captions. Learners are given three additional pictures and four new captions and must choose the correct caption for each of the three pictures by generalizing from the information at the top of the page. Similarly, neither the PLAB language analysis subtest nor the MLAT words in sentences subtest require any metalinguistic vocabulary; that is, there is no need to be able to verbalize that “the hook” is a direct object in order to note that it plays the same role in its sentence as “the letter” plays in the other in the example above. Conscious metalinguistic awareness is distinct from grammatical sensitivity in that the latter is understood to be a stable trait, whereas the former is thought to be the result of experience and training, and, therefore, subject to change (Carroll, 1990). As noted above, a very experienced language learner may alter the nature of an aptitude test by rapidly utilizing metalinguistic knowledge rather than drawing upon inherent grammatical sensitivity or by inductively reasoning as intended by the tests.

There are some constructs contained in one or two, but not all three of these aptitude tests. Because it is a measure of learned knowledge, vocabulary is neither static nor easy to conceptualize as a trait. Nevertheless, L1 vocabulary is included in both the PLAB and the MLAT, as proxy for verbal ability (Carroll, 1962; Pimsleur et al., 2004). English vocabulary is directly assessed in the PLAB with a “choose the right synonym” task, whereas the MLAT incorporates vocabulary as a necessary subcomponent of “spelling clues,” a speeded task in which test takers must choose the nearest synonym to a “disguised” (i.e., phonetically spelled) target word.

In addition to the constructs it shares with the MLAT, the PLAB includes a measure of auditory ability. The sound discrimination task requires test takers to distinguish sound contrasts, to which their native language does not require them to be sensitive. PLAB tests the ability to distinguish between pitch, orality, and nasality in aurally presented words in an unfamiliar language. Test takers are taught three words which differ from one another in terms of these features. They then listen to sentences in the unfamiliar language and must indicate which of the three words appears in each sentence.

Innovations in Language Aptitude Constructs

LLAMA

According to the manual, LLAMA is “a set of exploratory tests designed to assess aptitude for learning foreign languages. The tests are loosely based on pioneering work by John Carroll (e.g., Carroll & Sapon, 1959) but over the years . . . the design

of the tests has significantly diverged from the originals on which they were based" (Meara, 2005, p. 2). Most notably, in order to adapt LLAMA for speakers of L1s other than English, and to circumvent familiarity with stimuli, sections of the test were recast using icons. In one section, where language stimuli are required, the stimuli are based on a little known dialect of a language from north-west British Columbia.

According to Meara (2005), three sections of LLAMA have been most successful in predicting language outcomes (LLAMA B, D, and E). Like MLAT Part 5, LLAMA B measures the ability to learn relatively large amounts of vocabulary in a relatively short time. The words to be learned are real words taken from a Central American language arbitrarily assigned to images. The task is to learn the names of as many objects as possible in the time available without taking notes.

The aptitude construct in LLAMA D is not based on any MLAT construct. LLAMA D tests the ability to recognize previously spoken words. According to Meara (2005, p. 8), "if you can recognise repeated patterns, then you are more likely to be able to recognise words when you hear them for a second time. This helps you to acquire vocabulary. It also helps you to recognise the small variations in endings that many languages use to signal grammatical features." LLAMA D presents stimuli, which are machine-generated phonetic realizations of words in a dialect of an isolated language spoken in northern Canada. The task is to listen carefully to a list of the words and then to hear them again, this time in a longer list that also contains new words. For each word in the longer list, test takers indicate whether they have heard the word before.

Like MLAT Part 2, LLAMA E is a sound-symbol correspondence task. A set of recorded syllables is presented, along with a transliteration of these syllables in an unfamiliar alphabet. The task is to work out the relationship (within two minutes) between the sounds and the writing system by pressing buttons that play a short sound file. The text on each button represents how that particular sound is written in the language. Note taking is allowed.

Hi-LAB

As noted earlier, a major change in the 21st century has been the realization that advanced rather than basic language proficiency is the minimum necessary for most government and professional work. Earlier aptitude validity studies involved predicting outcomes in language courses with goals of ILR Level 2 (basic). Thus, an important question is whether existing aptitude tests, which were designed to predict rapid rate of learning to levels of basic proficiency, can predict ultimate attainment of ILR Level 3 (professional) or ILR Level 4 (distinguished professional) proficiency. FSI data show that the MLAT total score predicts Level 3 attainment (Ehrman, 1998), but there is not yet solid evidence for prediction at Level 4 (Ehrman & Lord, 2003). As yet, there are no studies of the usefulness of PLAB or DLAB to predict very high level ultimate attainment in a foreign language.

To address the need for an aptitude battery geared to professional levels, Doughty et al. (2007) developed the Hi-LAB specifically to "predict the ultimate success of adult language learners in reaching high levels of language ability,

where advanced levels are considered to be ratings on the Inter-agency Language Roundtable scale of ILR 3+ and above" (Mislevy et al., 2008, p. 4). High level language aptitude, operationalized in cognitive and perceptual constructs, is conceptualized as a measurable ceiling on language learning ability, holding equal all other factors such as motivation, other individual differences, and opportunities for instruction or immersion. The development of Hi-LAB drew upon recent research in second language acquisition (SLA) and cognitive psychology to include constructs theorized to underlie foreign language learning at advanced levels. For example, from the perspective of SLA research, ultimate attainment involves learning complex linguistic systems, including elements that are not particularly salient in the input. "SLA is largely driven by what learners pay attention to and notice in target language input and what they understand the significance of noticed input to be" (Schmidt, 2001, pp. 3–4: see also Schmidt, 1990, 1995). From the perspective of psychology, the memory constructs in traditional aptitude tests are out of date. Empirical studies have specifically linked working memory to foreign language learning, suggesting that greater memory resources and attentional control predict both a faster rate of learning and a higher attained level of proficiency (Miyake & Friedman, 1998). Hi-LAB was the first foreign language aptitude battery to incorporate these advances in the understanding of the human memory system, as called for by Carroll (1990).

Hi-LAB measures an individual's cognitive and perceptual aptitude. Table 2.2 lists and briefly defines the Hi-LAB constructs. (For a complete discussion see the Hi-LAB assessment use argument in Mislevy et al., 2008.) Memory is measured both as rote memory and working memory (WM), a complex system that subsumes short-term memory (STM) and executive control constructs. Hi-LAB taps verbal-acoustic STM, also called phonological STM, which aids in the rehearsal or maintenance of unfamiliar words, such as vocabulary in a foreign language. In Hi-LAB's STM test, test takers view phonotactically plausible, one-syllable non-words, presented serially on a computer screen and are required to indicate in a subsequent longer list whether or not they have seen each one. The central executive system, also called executive control, is another component of WM probed by Hi-LAB. Three distinguishable subconstructs—updating, inhibition, and task switching—were all included in the Hi-LAB design. Updating refers to the process of refreshing the contents of working memory with new, more relevant information (Morris & Jones, 1990). An individual's ability to update information in WM, which includes monitoring and coding information for relevance while new information is incoming, is crucial in the context of high level language learning (Doughty et al., 2007). The running memory span task measures updating in Hi-LAB (Bunting, Cowan, & Saults, 2006). In this task, learners hear pseudo-randomly ordered strings of letters and must try to recall the last six letters in the string, in the same order presented, beginning with the sixth to last and ending with the last letter. In contrast to updating, inhibition is the ability to ignore a dominant or automatic response when necessary. Recent developments in studies of bilingual processing have implicated inhibition as a key cognitive mechanism supporting bilingual language use (Abutaleb, 2008; Kroll, Bobb, Misra, & Guo, 2008). A classic inhibition task is the Stroop task (1935), which measures the ability to inhibit the automatic response to read a word when the task objective

Table 2.2 Hi-LAB constructs (adapted from Doughty et al., 2010, p. 12)

Constructs		Brief definitions and components
Memory		The capacity to process and store input with active trade-offs among these components:
<i>Working memory</i>	◆ Short-term memory capacity	The small amount of information that can be kept in an accessible state in order to be used in ongoing mental tasks: <i>verbal-acoustic STM; verbal-semantic STM</i>
	◆ Executive control	A set of processes that, collectively, regulate and direct attention and control voluntary processing: <i>updating, inhibition, and task-switching</i>
<i>Long-term memory</i>	◆ Rote memory	Explicit, intentional <i>long-term storage</i> that results from rehearsal
Acuity	◆ Perceptual acuity	An above-average capacity to hear or see cues in the auditory or visual input: <i>auditory perceptual acuity; visual perceptual acuity</i>
Speed	◆ Processing speed	The speed of response to stimuli: <i>processing speed; decision speed</i>
Primability	◆ Priming	The extent to which prior experience of stimuli in the input facilitates subsequent processing: <i>semantic priming, repetition priming</i>
Induction		The process of reasoning from the specific to the general, i.e., noticing similarities among several instances and drawing a generalization based on these similarities:
	◆ Implicit induction	Acquiring the patterns in input without awareness of them
	◆ Explicit induction	Acquiring the patterns in input with awareness of the patterns in examples
Pragmatic sensitivity	◆ In research and development	The ability to hypothesize connections between context and use: registering and tracking salient context cues; detecting miscommunication
Fluency	◆ In research and development	The automaticity of planning and articulating speech

is to name the color of the font (e.g., the word “red” printed in blue ink). Finally, task switching, the ability to shift between multiple tasks, operations, or mental sets (Monsell, 2003), is hypothesized to reflect an aspect of cognitive control that is critical for efficient bilingual lexical selection and for advanced language tasks such as translation, code switching, or switching registers (Hernandez, Martinez, & Kohnert, 2000; Segalowitz & Frenkiel-Fishman, 2005; Abutalebi et al., 2008). In Hi-LAB, test takers see numbers superimposed on a background box and make one of two judgments about each number, depending on the color of the box, to classify the target number as odd or even, less than five or greater than five. The last memory construct, rote memory, is the conscious process of storing

information in long-term memory, often by repetition. The Hi-LAB rote memory task requires remembering associations between a familiar lexical item in English and a novel lexical item, mirroring an aspect of lexical acquisition in language-learning domains. This task is similar to the paired associates task in the MLAT, but one word of each pair is an English noun, and the other a nonword, which learners are told is a word in “a foreign language.” Test takers choose the correct foreign word from a set of five options when prompted with the corresponding English word.

Hi-LAB also probes perceptual acuity, the ability to detect and encode important cues. Auditory perceptual acuity is the capacity to attend to and discriminate among speech cues. Discrimination tasks in Hi-LAB test the ability to resist the normal tendency to assimilate new language sounds into existing L1 categories (Kuhl, Williams, Lacerda, Stevens, & Lindblom, 1992) by measuring the ability to hear contrasts between stimuli which are normally in the range for just one English phoneme. A category assignment task tests the ability to learn new phonemic boundaries. To succeed, test takers not only have to tune in to differences in phonological information that are unimportant in English but also must use that information to form new categorical boundaries. The test measures accuracy and improvement in categorization over the course of the test.

Cognitive processing speed is derived from tasks in Hi-LAB that direct test takers to respond as quickly as possible. For example, in the serial reaction time test, processing speed is computed as the mean response time in the first random block of items. Hi-LAB measures another construct, primability, or the susceptibility to previously encountered input, in a synonym task. After seeing a list of words that belong to two categories, test takers see the category names, and they have to indicate which of the two categories contained more exemplars in the just-heard list. The words in each category, including the words that are used as the names of the categories, are synonyms or near synonyms. Test takers also perform comparisons in which they are asked if two new words (that are primed by the lists) have similar meanings. Finally, induction tasks in Hi-LAB present test takers with patterned stimuli and ask them to respond by shadowing the pattern or detecting the pattern: The serial response time task test measures a person’s ability to implicitly learn patterns, while the explicit induction task in Hi-LAB directs them to try to see the patterns.

Uniqueness of Language Aptitude

An often quoted general definition of language aptitude is “how well, relative to other individuals, an individual can learn a foreign language in a given amount of time and under given conditions” (attributed to John Carroll). While it is generally agreed that language aptitude comprises a set of constructs that are predictive of language-learning success, there are two issues that spark discussion: Is language aptitude separable from general intelligence? And, are motivation and personality facets components of language aptitude or separate predictors of language-learning success in their own right? (Gardner & Lambert, 1965).

Aptitude and Intelligence

At the completion of his extensive research program, Carroll (1962, p. 89) came to two conclusions on the basis of factor analyses of measures of intelligence, language aptitude, and motivation: (1)

that facility in learning to speak and understand a foreign language is a fairly specialized talent (or group of talents), relatively independent of those traits ordinarily included under "intelligence"; and (2) that a relatively small fraction of the general population seems to have enough of this talent to be worth subjecting to the rigorous, intensive, expensive training programs in foreign languages operated by military and governmental organizations.

It is important to note that Carroll was discussing the role of aptitude in language learning under intensive conditions, and he emphasized that this was the impetus for focusing on selectivity. His belief was that anyone could learn a foreign language to a certain degree under more favorable conditions.

In her study of naturalistic SLA, discussed further below, Granena (2012) hypothesized that general intelligence is more relevant for explicit than for implicit language learning, since intelligence is closely related to analytical ability (DeKeyser 2003). General intelligence measures are weighted in favor of explicit processes (Woltz, 2003), but have low correlations with implicit processing measures such as priming (Woltz, 1999). Granena expected that, in ultimate L2 attainment, relationships between explicit aptitude and general intelligence to learning outcomes would pattern in the same way and would be different from effects of implicit aptitude on outcomes. She based this prediction on studies of artificial grammar learning, in which fluid intelligence correlates with learning when test takers are instructed to look for patterns in the training materials, but not under more incidental learning conditions. Granena's hypothesis was supported by the findings summarized in Table 2.3 which show that high intelligence late L2 learners outperformed their low intelligence counterparts on two measures of controlled L2 use (a metalinguistic test and an untimed grammaticality judgment test), but not on any other L2 outcome measures. Moreover, there were no effects of intelligence for any other group (early child starters and native speaker controls) on any ultimate L2 attainment measures.

Aptitude and Other Predictors of Language Outcomes

As noted earlier, DLIFLC relies on a multiple hurdles approach to select for matriculation into language training, comprising the ASVAB, which is g-loaded, and DLAB, which is particular to language aptitude. In 2003, DLIFLC hosted a specialized conference with invited experts from the fields of SLA, language testing and industrial psychology, to consider whether selection could be improved (Kenyon & McGregor, 2003). The recommendation made by one of the experts, Robert Sternberg, was that perhaps the only way to improve prediction of language-learning success at DLIFLC would be by adding other tests of augmented cognitive abilities, motivation, and personality (Sternberg, 2004).

Table 2.3 Predicted relationships between aptitudes, general intelligence, and ultimate L2 attainment (from Granena, 2012, p. 225)

	<i>Automatic L2 use</i>			<i>Controlled L2 use</i>		
	<i>Early age of onset</i>	<i>Late age of onset</i>	<i>Control</i>	<i>Early age of onset</i>	<i>Late age of onset</i>	<i>Control</i>
General intelligence	No ✓	No ✓	No ✓	No ✓	Yes ✓	No ✓
Explicit learning aptitude	No ✗	No ✓	No ✓	No ✗	Yes ✓	No ✓
Implicit learning aptitude	Yes ✓	Yes ✓	No ✓	Yes ✓	No ✓	No ✓

Note. A check mark (✓) stands for confirmed (or partially confirmed) and a cross mark (✗) stands for refuted.

As a result, a comprehensive study of the incremental predictive validities of ASVAB, DLAB, new cognitive measures, and personality and motivation measures was undertaken (Bunting et al., 2011). Personality measures were limited to fairly stable measures of personality characteristics, including ambiguity tolerance, need for cognitive closure, self-monitoring, along with some measures developed by the Drasgow Consulting Group for use in military assessment settings (Tailored Adaptive Personality Assessment System, TAPAS; Drasgow, Stark, & Chernyshenko, 2009). Motivation tests measured goals and aspects of a student's academic performance, including learning and coping strategies, thought to be relevant to the DLIFLC intensive learning context. Results of regression analyses of existing DLAB and ASVAB sections, biographical variables, cognitive measures (similar to those in Hi-LAB), and personality and motivation measures indicated that a model of DLAB 2 containing predictors from both existing tests (ASVAB and DLAB) plus some of the new measures showed substantial improvement over the predictive power of the current scaled DLAB score (and over the existing multiple hurdles of ASVAB plus DLAB). The recommendations for DLAB 2 test development include grammatical sensitivity (using measures from the original DLAB), g-loaded measures from ASVAB (verbal and mathematical), working memory and executive control, explicit induction, indicators of previous language-learning experience, and 11 facets of personality and motivation (order, sociability, persistence, learning orientation, adjustment, optimism, tolerance, physical conditioning, academic achievement, academic efficacy, and intellectual efficacy).

Carroll himself directly addressed the question of the relative contributions of motivation, quality of instruction, time, intelligence, and aptitude in two settings, a week-long trial intensive course and an actual 8–12 month intensive course. His conclusion based on these findings was that, when motivation is low or quality of instruction is poor, aptitude will not be engaged, and general intelligence may be more important with respect to getting a good grade (Carroll, 1962). Thus, it is when language courses are excellent and intensive, and the students are motivated, that aptitude emerges as a good predictor of success.

Criteria for Success in Language Learning

A great weakness in language aptitude testing is the lack of sophistication of language-learning outcome measures. Typical criterion measures are course

grades, semester grades, and global proficiency tests, such as the Defense Language Proficiency Test (DLPT). These measures are not granular enough to capture the influence of just the language aptitude per se. For example, Table 2.3 shows findings from a study of differential effects of two types of aptitude (implicit and explicit) on two types of ultimate attainment measures, automatic versus controlled L2 use (Granena, 2012, discussed in the next section.) Much more language assessment research on the specific relationship of aptitudes and language outcomes is needed. In the meantime, studies of SLA that include an aptitude variable typically employ language outcome measures granular enough to capture the language learning under investigation.

Aptitude in SLA Research

Aptitude and Age

Several SLA studies have investigated language aptitude in interaction with age of onset (i.e., the age of first exposure to a second language, AO) to examine whether aptitude can mitigate critical period effects and whether different kinds of language aptitude are engaged during early (child) versus late (adult) SLA. DeKeyser (2000) examined the interaction between aptitude and L2 proficiency in Hungarian immigrants to the USA, and showed that, of the only 6 of 42 adult arrivals who achieved near-native English proficiency, only one did not also have high aptitude but did demonstrate high analytic skills. Furthermore, there was a significant correlation between aptitude and language outcomes (grammaticality judgment tests) for the adult arrivals, but not for the child arrivals, such that all the child learners achieved native or near-native L2 proficiency, regardless of their aptitude level, whereas only adult learners with high aptitude did so. Abrahamsson and Hyltenstam (2008) further tested DeKeyser's (2000) hypothesis that aptitude predicts L2 proficiency for late learners in a study of L1 Spanish L2 Swedish speakers who were judged to be native speakers of Swedish on a screening test (two groups: AO = 3–6 and AO ≥ 16). However, Abrahamsson and Hyltenstam also proposed that careful scrutiny of early learners' L2 ability would reveal an effect for aptitude for child starters. As expected, the late learner group of near-native speakers had a higher mean aptitude score (Swansea Language Aptitude Test³) than the early learner group, and no late learners had low aptitude, implying that, "in order to pass for a native speaker in everyday language use, a high degree of aptitude is required for the adult learner but not for the child learner" (p. 498). In addition, the early learner group also showed an effect of language aptitude, with a significant correlation between aptitude scores and grammaticality judgment scores.

Following DeKeyser's (2000) claim that relationships between individual differences in language aptitude and eventual learning outcomes potentially constitute evidence for differences in underlying language-learning processes, Granena (2012) probed the effects of different types of cognitive language aptitude on ultimate level of L2 attainment by early (AO = 3–6) and late (AO ≥ 16) L1 Chinese learners of L2 Spanish. In this investigation of whether individual differences in explicit and implicit language aptitudes predict ultimate attainment in early (child starters) and late (adult starters) L2 learning, Granena expected child starters to have used the same (implicit only) language-learning mechanisms as native

speakers, but to show greater inter-individual variability on ultimate attainment measures. On the other hand, she expected that adult starters would differ from native speakers both in terms of learning mechanisms (employing both explicit and implicit) and ultimate attainment (i.e., incomplete). These differences would be revealed in a set of L2 attainment measures comprising a continuum from automatic to controlled use of L2 knowledge. On these tasks, administered when all learners in the study were adults with advanced levels of proficiency, child starters were expected to employ the same type of (implicitly learned) knowledge regardless of type of language proficiency task (both automatic and controlled). Adult learners were expected to be able to draw upon both implicitly and explicitly learned language, and those with a higher aptitude for explicit language learning were predicted to do better on controlled tasks as a result of their greater analytical, metalinguistic abilities. Like Abrahamsson and Hyltenstam (2008), Granena also anticipated that aptitude effects would obtain for both child starters and adult starters, in contrast with native speakers, who would have learned their first language independently of aptitude differences. Finally, since she had shown earlier that L2 learners may have high ability in one aptitude component, but low ability in another (Granena, 2012; Granena & Long, in press), she expected differential effects for implicit and explicit aptitudes.

Since they all allow time to think and engage in problem solving to work out relationships, LLAMA (Meara, 2005) aptitude subtests B (vocabulary learning), E (sound–symbol correspondence), and F (grammatical inferencing) served as measures of explicit cognitive processes that are relevant for explicit language learning. LLAMA D (phonetic memory), with no study phase and no time to rehearse during recognition of phonological sequences, and a probabilistic serial reaction time (SRT) task (implicit pattern learning) were the measures of implicit cognitive processes thought to underpin implicit language learning. Indeed, results of a principal components analysis showed that LLAMA B, E, and F loaded on one factor, and LLAMA D and the SRT task loaded on a separate factor.

As shown in Table 2.3, with respect to effects of aptitude on L2 learning outcomes overall, results of MANCOVA analyses indicated no significant relationships between native speakers' language attainment and cognitive aptitudes on any of the attainment measures, confirming that aptitude was unrelated to first language outcomes. Second, there were no significant interactions between early and late learner groups and covariates in any of the analyses, revealing effects of aptitude on L2 language attainment for both child starters and adults. More specifically, Granena found that both child starters and adult starters (but not native speakers) with high aptitude for explicit learning outperformed counterparts with low aptitude for explicit learning on the three language tasks at the explicit end of the continuum (a metalinguistic knowledge test, and untimed visual and untimed auditory grammaticality judgment tests, GJTs). In addition, both child starter and adult starter L2 learners (but not native speakers) with high aptitude for implicit learning showed greater grammatical sensitivity than counterparts with low aptitude for implicit learning on the word monitoring task, which is at the most implicit end of the continuum, but only on the word monitoring score for sensitivity toward agreement violations, suggesting that the effect of aptitude is selective. Interestingly, only within the child starter group were there significant effects of aptitude for explicit learning as a covariate on two measures originally

hypothesized to require automatic use of L2 knowledge (the timed auditory and visual GJTs), perhaps due to the fact that GJTs of any kind focus attention on language correctness. On the basis of all these findings taken together, Granena concluded that aptitude for explicit learning is related to ultimate attainment by early and late learners when the L2 outcome measure is untimed and focuses on language forms and language correctness, aptitude for implicit learning is related to ultimate attainment by early and late learners when the L2 outcome measure focuses on meaning, and aptitude for implicit learning did moderate L2 attainment for the adult learners on the word monitoring task (agreement structures), suggesting that adults do not exclusively learn their L2 explicitly.

Finally, work by DeKeyser, Alfi-Shabtay, and Ravid (2010) suggests that aptitude may be particularly important during certain periods in the lifespan. DeKeyser et al. measured the effect of aptitude on the acquisition of L2 morpho-syntactic structures (via a grammaticality judgment test) for three different age-of-acquisition groups (AO <18; AO = 18–40; AO >40). In addition to finding evidence for a critical period effect, in which a decline in ability to acquire an L2 occurred during adolescence with no further decline throughout adulthood, ultimate attainment was predicted by aptitude only for the learners in the middle group (18–40), and not for the young learners (<18) or for the older learners (>40).

Aptitude-by-Treatment Interaction

SLA researchers have examined individual differences in learners' cognitive aptitudes and how those differences interact with instructional methods, using aptitude-by-treatment interaction (ATI) research designs (Tare et al., 2011; Doughty, in press). Two recent studies illustrate the potential of the ATI paradigm for language instruction. In a study involving working memory (the executive control subcomponent, including attentional ability), Brooks, Kempe, and Sionov (2006) examined the interaction of test takers' aptitude for attention allocation and the size of the training vocabulary they were given during their learning of Russian noun gender. The cognitive tests included Cattell's Culture-Fair Nonverbal Intelligence Test, which has been shown to be a good measure of executive functioning as well as language-learning aptitude (Duncan, Emslie, Williams, Johnson, & Freer, 1996; Grigorenko et al., 2000). Their measures also included nonword retention to test phonological memory and reading span to test verbal working memory. The training variable was the amount of "type variation" of the nouns in the input that students heard when learning the correct gender declensions, during six separate training sessions. Type variation is the number of different words that were presented in the training input. All test takers heard the same number of examples, but were pseudo-randomly assigned to 3 conditions where they heard 24 different words once each, heard 12 different words repeated twice, or heard 6 different words repeated 4 times. The research question was the extent to which individual differences in the cognitive assessments could explain how learners are able to make use of the type variation in the learning materials when learning Russian inflectional morphology, as measured by their production of accurately inflected new nouns in the testing session. The greater type variation condition did not lead to more learning across all learners; only the test takers above the

median executive functioning score could effectively utilize the extra vocabulary types to learn the grammar rules. This significant aptitude-by-treatment interaction suggests that greater executive functioning, specifically attention allocation, allowed participants to take advantage of greater variation in the learning materials when learning Russian morphology.

In another study matching aptitude to learning condition, Perrachione, Lee, Ha, and Wong (2011) investigated the interaction between individual differences in learners' perceptual ability (measured by a pitch contour perception test) and training of non-native phonological contrasts in learning lexical tones. Generally as with the case of Russian morphology, in learning to comprehend spoken language, a high variability training environment is considered superior to a low variability training environment, since learners are exposed to more varied exemplars of the feature that they are learning, which should support generalization to new examples. However, lack of consistency or predictability in phonetic features across input trials also increases processing costs. To investigate the effectiveness of the variability in training conditions based on perceptual aptitude, half each of all low and high aptitude learners were assigned to low variability (one speaker only) and high variability (four speakers) conditions, in which participants listened to pseudowords, minimally distinguishable by pitch contrast, each associated with a common object (e.g., bus, table) during the training.

Results showed that, during training, all participants initially learned significantly faster in the low variability condition and that the high aptitude group learned significantly faster than the low aptitude group, regardless of training condition. For learning achievement (matching spoken pseudowords to the correct object), results revealed that, once again, the high aptitude learners outperformed the low aptitude learners in both training conditions. However, this time a significant interaction between aptitude group and training condition obtained, such that the high aptitude group demonstrated significantly greater learning in the high variability condition than in the low variability condition, whereas the low aptitude group demonstrated the reverse. That is, the high aptitude learners benefited from the high variability training, and the low aptitude learners were impaired by it. A somewhat puzzling finding is that both high and low aptitude learners in the high variability group, despite the latter group's achievement score impairment, were then better able to generalize to novel speakers than high and low aptitude learners in the low variability group. Overall, Perrachione et al. concluded that, while the high variability training resulted in better generalization ability for all learners, the high aptitude learners benefited even more from high than low variability training, though not without cost revealed in their initial slower learning rate, and the low aptitude learners not only benefited more from the low variability training, but were acutely impaired by the high variability training in terms of achievement outcomes.

Remaining Issues

There are at least two language aptitude assessment issues that have not been adequately addressed by research: Does language-learning experience influence

language aptitude?; Can language aptitude be trained? While the first question remains to be investigated, there are some initial findings suggesting that at least one component of cognitive aptitude, working memory, can be trained (Bunting et al., 2010). Novick, Hussey, Teubner-Rhodes, Harbison, and Bunting (2013) have demonstrated that, in comparison to no-contact controls, training on a working memory task leads to improved performance on that same task during training and generalizes to other working memory tasks (near transfer) as well as to sentence processing tasks involving ambiguity resolution, such as in garden path sentences (far transfer).⁴ Work at the University of Maryland Center for Advanced Study of Language is underway to determine whether improvements in working memory training translate into accelerated gains in foreign language learning. More questions have arisen as well. For example, is there a ceiling within individuals such that, while everyone improves with training, those individuals with inborn high working memory will always be better than those with lower working memory before the training? Or, can working memory training level the playing field, so to speak, at least with regard to aspects of language learning that are promoted by working memory functions? Preliminary findings from studies of working memory training comparing groups of balanced bilinguals (who tend to have higher working memory than monolinguals; Bialystok, Craik, & Ryan, 2006; Emmorey, Luk, Pyers, & Bialystok, 2008) with advanced learners suggest that “the rich get richer” (Novick, personal communication).

Notes

- 1 The overall critical period for language learning (birth to about age 15) entails a set of sensitive periods: first year of life for phonology, age 6 for some morphosyntax, and age 15 for other aspects of language. After age 15, a language learner is considered to be a psycholinguistic adult. Post-critical period language learners are distinguishable from native speakers, although some may closely approach native ability (see Granena & Long, in press).
- 2 The purpose of this work was to develop Pre-DLAB, a short version of DLAB, which has been shown to predict full DLAB scores with about 78% accuracy.
- 3 The Swansea Language Aptitude Test has been revised and is now called LLAMA.
- 4 In garden path sentences, the initial parsing has to be revised when new information is encountered. For example, in “*The government plans to raise taxes were defeated,*” the primary meaning is not that the government plans to raise taxes, but rather that those plans were defeated.

Assessing Listening

Elvis Wagner

Temple University, USA

Introduction

The ability to listen is recognized as an integral component of communicative language ability, as well as language learning. Children learn their first language almost exclusively through listening and responding to spoken input. It is estimated that 50% or more of a person's time in communicative situations is spent listening. Similarly, second language (L2) researchers (e.g., Rost, 2011) have stressed the importance of listening in language acquisition because so much of the input needed for language acquisition is provided orally. Nevertheless, assessing a person's L2 listening ability presents unique challenges to teachers and test developers, and perhaps because of these challenges, the assessment of listening has historically been somewhat neglected and even overlooked in the language assessment literature. This chapter will provide a brief overview of L2 listening assessment, and the necessity of assessing this component of communicative language ability. The chapter will also present some of the unique challenges that the assessment of listening ability presents for test developers, and will provide theoretical justification for how to address these particular challenges.

It is now widely accepted that individual language learners have varying levels of ability in the different language skills, and that a divisible model of language ability with a general factor plus distinct traits is the most plausible (Bachman & Palmer, 1983). As a result, it is recognized by language assessment researchers that listening ability, being a distinct trait, should be assessed. Nevertheless, because of the unique and challenging aspects of assessing listening ability, test developers might be tempted to avoid including a listening section. After all, many of the components of listening are similar to the other modalities, especially reading. However, there are also many characteristics that are unique to listening. Listening ability is obviously a subset of general language ability, and any assessment of

listening ability will also be an assessment of general language ability (Rost, 2011). The reverse is not necessarily true, however, in that an assessment of general language ability might not assess listening ability specifically. Buck (2001) argued that because the testing of listening is technically more complicated than testing the other language modalities (i.e., it requires audio or video equipment to create the texts, and then to play these texts for test takers), it might not actually be worth the trouble unless the test developer were “particularly interested in the knowledge, skills and abilities that are unique to listening” (p. 32). Similarly, Rost (2002) argued that if the goal is to test listening ability, it is necessary to focus on those characteristics that are unique to listening. Doing so can make test developers “*more comfortable with the ‘construct validity’ of the listening test*” (p. 171) than if they are not included.

Each skill or modality presents challenges for test developers, but assessing a person’s listening ability presents unique challenges. Perhaps the most obvious difficulty is that listening (like reading), is an internal process. While speaking and writing involve some sort of output that can be observed and measured, listening goes on inside a person’s head. Thus, a test developer must create some sort of task that the listener must respond to in some way, and based on this response output, the test developer is able to make inferences about the individual’s listening ability. In addition, reading and listening assessments require selecting or creating the written or spoken input to present to test takers. For reading tests, it is relatively simple to present the written input to test takers, either on paper (for a paper and pencil test) or on a computer monitor (for a computer-based test). But the presentation of spoken texts to listening test takers proves more problematic. How should the spoken texts be presented to the listeners? Should the text be spoken by a test interlocutor, or should it be recorded and played using technology? How long should the text be? How fast should the texts be spoken? What sort of language characteristics should the spoken texts include? One way to address these sorts of questions is to utilize Bachman and Palmer’s (1996) framework of task characteristics when selecting, creating, and developing spoken texts for listening assessment, and this notion of the “characteristics of the input” will be investigated in more depth below.

Identifying the Target Language Use Domain and Construct Validity

For this section, two separate yet complementary notions fundamental to language assessment will be reviewed and applied to the assessment of listening. The first notion is that of defining the target language use (TLU) domain, as described by Bachman and Palmer (1996). The second is the two major threats to construct validity, as described by Messick (1989, 1996).

In order to determine appropriate texts and response formats for a particular listening assessment, it is vital that the test developer identify the purpose and the situational context for the assessment (Buck, 2001). In other words, how is the construct of listening ability defined, and what aspects of listening ability should be tested? It is very rare for the goal to be to assess an individual’s overall

listening proficiency. Instead, the test developer usually has some sort of listening context in which the test takers' ability is to be assessed. Bachman and Palmer (1996) define TLU domain as the "situation or context in which the test taker will be using the language outside of the test itself" (p. 18). In other words, what type of listening ability should be assessed? For example, if the goal of the test is to assess a learner's ability to comprehend an academic lecture (an academic TLU domain), then it is necessary to identify the distinguishing characteristics of academic lecture texts and include those characteristics in the assessment task. The test developer needs to first identify those distinguishing language characteristics of the TLU domain, and then make the test task characteristics similar to and representative of the TLU domain. The characteristics of the listening test tasks are always going to affect test scores to some extent, and thus it is necessary to control them as much as possible so that the tests will be appropriate for their intended use. Bachman and Palmer (1996) created a framework of language task characteristics that allows test developers to understand how the test task characteristics can be varied to tailor tests for different purposes. Their framework of task characteristics has five sections: characteristics of the setting, characteristics of the test rubrics, characteristics of the input, characteristics of the expected response, and relationship between input and response (pp. 49–50).

Utilizing this framework should serve to minimize threats to construct validity. For listening assessment, particularly relevant are the third and fourth components of the framework (characteristics of the input, and characteristics of the expected response). To relate it back to the academic lecture example, the first step would be to identify the characteristics of academic lecture spoken texts. For "characteristics of the input," things to consider would be the "format" of the input, including its channel (an academic lecture obviously involves oral input, but also includes visual input because the listeners can see the speaker, her gestures and body language, as well as things like PowerPoint slides and other types of visuals), the length of the lecture, and the speech rate of academic lecturers. Important too are characteristics of the language of input, including the way academic lectures are typically organized textually, their grammar and vocabulary, and their pragmatic and topical characteristics. The test developer also needs to consider how the listening test taker is expected to respond to the input. Again, using an academic lecture TLU domain, what is the listener in an academic lecture expected to do with the input? How is she expected to respond to the input? For an academic lecture, the listener might be expected to remember the information so that she can create some sort of future response, which might include answering questions for a future test (and these test questions might include selected response, limited production, or extended production items, or all of these). The listener might be expected to discuss the information with classmates, and write a paper in which she can demonstrate that she has understood the information presented in the lecture.

Identifying the distinguishing language characteristics of the TLU domain, and then making the test task characteristics similar to and representative of this domain, should serve to minimize threats to the construct validity of the test, and should allow the test developer to make more valid inferences about the test takers' listening ability beyond the testing context. L2 listening tests that have

tasks that are not representative of the TLU domain present threats to construct validity in two ways: Unrepresentative tasks introduce sources of invalidity, and also lead to construct under-representation (Messick, 1989, 1996). An example of an unrepresentative listening task would be the use of a speaking text that involves two friends discussing their vacations in a listening test meant to assess academic lecture listening ability. Because this speaking text is not representative of the textual characteristics of academic lectures, using such a text would introduce sources of invalidity (construct-irrelevant variance). The test might provide information about a listener's ability to understand conversational language, but not the TLU domain of interest (i.e., academic lectures). Similarly, a speaking text that includes characteristics of the TLU domain, but is not an adequate representation of that domain, would represent a threat to construct validity. For example, using an oral text taken from a real academic lecture for a listening test but having that text be only 30 seconds long might be a source of construct under-representation. A 30-second academic lecture is very different from a 30-minute one. Longer texts require the speaker to utilize textual organizational characteristics (such as discourse markers and other cohesive devices) that would not be appropriate or necessary for a 30-second utterance. Thus, test developers have not only to be cognizant of the importance of using speaking texts that are similar to those of the TLU domain; they must also make sure that the characteristics are representative of the characteristics of the TLU domain.

With criterion-referenced listening testing, the criteria to be assessed will dictate the characteristics of the test task. For a classroom teacher, the assessment context is necessarily closely aligned with the curricular goals of the class, and not all listening test tasks must necessarily be listening comprehension tasks. For example, for some learners, the learning goals might include promoting learners' ability to discriminate different sounds in the target language, or the ability to segment incoming speech into words. If the curricular goals and the teaching focus on this type of decoding (Field, 2008), then the test tasks should as well. There are, of course, many times when it might not be advisable to use texts spoken at a normal speaking rate, or that contain the characteristics of unplanned spoken discourse.

Current Research and Challenges for L2 Listening Assessment

Current research in L2 listening suggests a number of issues that are particularly relevant for L2 listening assessment pertaining to specific language characteristics of possible TLU domains, and will be discussed here.

Assessing a Learner's Ability to Listen Using Integrated Test Tasks

Traditionally, language assessment has often involved separating the different skills in order to assess them. There are many justifications for doing this. First, there is often a diagnostic component to assessment, where the test developers want to examine what specific aspects of language a person might be weaker in

than in other areas, and use this information for placement purposes, and to design and personalize instruction according to that test taker's needs. Another reason for separating the skills in language assessment involves validity and reliability issues. For example, an integrated skills assessment task might include reading a written text, and then writing some sort of response to that text. The writing sample that is produced by the test takers is then scored. The difficulty for test developers here, however, is how to interpret the score from this writing sample. If a test taker performs poorly in the writing sample, is it because she has weaker writing skills? Or perhaps it is because she has weaker reading skills, and was not able to understand the text she was required to read. The test taker's inability to respond appropriately in writing to the prompt might not have been because she lacked the writing ability to do so, but because her weaker reading ability made it impossible for her to demonstrate her writing ability.

This phenomenon presents difficulties for language test developers. For example, in most real-life listening domains, listeners must listen to and process oral information, and then immediately do something with that information. The obvious example would be a communicative situation where a person is using language to interact with another person. Here the person is both listener and speaker. The person must listen to the oral text provided by the speaker, and simultaneously formulate an appropriate response, and then speak that response at the correct time. This is cognitively demanding of many language learners, which is exactly the point. Working memory capacity has emerged as an area of intense research in L2 learning, the theory being that individuals with more working memory capacity are better able to learn and use an L2 (Juffs & Harrington, 2011; Mackey, Adams, Stafford, & Winke, 2010) because of the intense cognitive processing demands found in communicative language contexts. Again, test developers need to identify and incorporate the characteristics of the TLU domain into the test tasks, and thus creating integrated test tasks that mimic the intensive cognitive processing demands of real-life communicative language situations should result in more valid inferences about a test taker's interactional communicative ability outside of the testing situation.

Being able to interact in a conversation is obviously a language use domain of interest for language learners and language teachers. Yet it is a very difficult domain to assess, due mainly to reliability issues. For a classroom assessment, where reliability concerns are of less importance, it is certainly feasible to create an interactive speaking/listening test task that can assess this ability. But for a larger-scale exam, in which reliability is of great importance, this type of task is problematic. Standardized tests, by definition, involve the same testing conditions for every test taker. The same (or equivalent) prompts are given to all test takers, who are all exposed to the same or equivalent input. With an interactive task, involving two or more speakers, standardization is not possible, presenting real reliability challenges for test developers. This is an example where the tension between validity and reliability is apparent. In an attempt to maximize the validity of the inferences made from the results of the test, a test developer might identify some of the distinguishing characteristics of a conversational domain, and then include some of these in the assessment task. In the process, however, reliability might suffer.

Some standardized tests of English proficiency provide examples of how different components of a conversational TLU domain can be assessed. The Test of English as a Foreign Language Internet-based test (TOEFL iBT) seems to focus more on the reliability of the scoring of the speaking and listening components of the test, and less on including many of the characteristics of interactive conversational language use in the assessment. While some of the listening and speaking tasks are integrated, in that the listener must first listen to a spoken text, and then speak a response based on the oral input, there is no interlocutor for the test taker to interact with. The test taker listens to a recorded response from a computer, then has time to formulate a response, and then speaks that response into a microphone, where it is later scored by trained raters. For the International English Language Testing System (IELTS), there is a human interlocutor that administers the speaking task, and the interlocutor asks (prescribed) questions that the test taker must respond to. Here there are more of the characteristics of interactive conversational language, but still the domain coverage is fairly narrow, in that the interlocutor seeks to provide standardized input to the test taker, rather than an authentic conversation in which the language is unscripted. For the Cambridge English: Advanced test, the speaking section is also face to face, with two test takers and two assessors. The test takers converse with each other in completing a collaborative task. Then they speak with the interlocutor about the task they have just completed.

Integrating speaking and listening tasks in order to maximize coverage of an interactive conversational language use domain remains challenging in assessment, but it is a necessary and advisable goal. Douglas (1997) argues that “because listening and speaking are theoretically and practically very difficult to separate” (p. 25), the two skills should be integrated in assessment. Similarly, other skills can also be integrated with listening tasks in assessments. For example, many tests (e.g., TOEFL iBT, with an academic listening TLU domain) involve tasks that require the test taker to listen to a spoken text, and then incorporate this information into some sort of written response.

Including Linguistic Features Characteristic of Unplanned Spoken Discourse in the Spoken Texts Used in L2 Listening Assessment

Again returning to the need to identify and incorporate the characteristics of the TLU domain into the test tasks, an important consideration for test developers is the linguistic characteristics of unplanned spoken discourse. Written texts and spoken texts are often very different because of features found in unplanned spoken discourse. These can include things like hesitations, filled and unfilled pauses, false starts, and the phonological characteristics of connected speech (i.e., assimilation, vowel reduction, epenthesis, linking, elision) (Celce-Murcia, Brinton, & Goodwin, 1994). In addition, spoken language can be seen as having a different set of rules than written language. Spoken language often has run-on sentences, grammatical “mistakes,” shorter idea units, and ellipsis. Spoken language usually involves shared knowledge between two speakers, and is often deictic in nature (the here and now, when a speaker says “I” or “that” or “now,” or points to an

object) (Brown, 1995). Finally, because of the nature of most speaking events (with obvious exceptions), planning what is going to be said is usually done in real time. This results in texts that are less logically and systematically organized. Most spoken texts are “first draft,” unedited, and messy, as compared to written texts, in which the writer can plan, organize, and revise.

These linguistic characteristics of unplanned spoken discourse often present difficulties for L2 listeners. Many or even most L2 listeners are often not even aware of the differences between written and spoken texts. Tannen (1982) described how spoken texts can be arranged on a continuum of orality; that is, some texts will be more oral than others. It is necessary for test developers to identify the TLU domain and the characteristics of spoken texts in that domain. Texts that are written, rehearsed, and then read aloud will be at one end of the continuum (literate), while extemporaneous conversations will be at the other end (oral). According to the theory that individual differences in working memory capacity influence learner performance, the processing of unplanned speech might require more of a listener’s cognitive resources than speech that is planned and rehearsed. Because more attentional resources have to be devoted to segmenting and decoding the oral input, the listeners have fewer resources to devote to other parts of the comprehension process. The difficulty L2 listeners face in comprehending unplanned spoken texts is probably exacerbated in part by the nature of the spoken input that many language learners (especially foreign language learners) receive. Audiotexts that are created for language textbooks and classrooms usually involve a scripted text that is written and revised, and then read aloud, often by professional actors trained to speak clearly and comprehensibly. Some TLU domains might involve spoken texts at the literate end of the spoken text continuum (e.g., the ability to listen to television or radio), but it seems more likely that the TLU domains most teachers and test developers would be interested in would include spoken texts at the “oral” end of the continuum. To not include these types of spoken texts in tests of L2 listening ability would be an example of construct under-representation (Messick, 1989, 1996).

The most obvious way to include these natural characteristics of unplanned spoken discourse is to use authentic spoken texts, in which speakers are recorded in a real-life communicative language situation, rather than to use scripted and polished written texts that are read aloud. However, in reality, it is difficult to use unscripted texts. As assessment researchers have described (e.g., Buck, 2001; Carr, 2011), it is often difficult to create comprehension questions using authentic, unplanned spoken texts. Usually test developers will create a text to be used in a listening test, and simultaneously write comprehension items based on the text. Doing so is efficient, in that the test developer can make sure that there is enough testable information in a text of a given duration. Authentic texts usually do not have the same amount of testable information in the same length of time. For high stakes exams, created by high profile companies or organizations, there is also the issue of “face validity,” in that spoken texts with pauses, false starts, grammar mistakes, and “poor pronunciation” might appear unprofessional. A review of the spoken texts used in the listening section of some of the high stakes English proficiency tests (i.e., the IELTS, TOEFL, and Pearson Test of English [PTE]) suggests

that virtually all of the texts are indeed scripted, written, and read aloud, and tend to fall at the “literate” end of the orality continuum. For classroom tests, the goal is to assess what is taught in the curriculum. If the curriculum includes communicative language ability, and being able to listen to and comprehend spontaneous spoken discourse, then it is essential that the assessment includes those linguistic phenomena found in spoken discourse.

Types and Varieties of the Spoken Language to Use as Input

Another consideration for test developers includes the types and varieties of spoken texts to include. Spoken language tends to have much more variety than written language, and phenomena like dialects, accents and regional variations, and colloquial language and slang are much more likely to be found in spoken than in written texts. The dilemma for test developers is whether and how this variation should be integrated into listening tests. For classroom tests tied to a specific curriculum, this issue is less problematic, because the curriculum and goals of the class dictate the criteria to be assessed. If the goal of the class is to teach listeners to be able to comprehend the standard variety of a language, then the standard variety should be used in the listening assessment. But for other assessments in which the construct definition is less easily defined, this issue of language variety can be problematic. For example, the TOEFL iBT purports to assess a test taker’s ability to use North American academic English in a higher education context. Thus, North American accented English is used in the listening test task. However, very few, if any, of the listening texts use speakers that are non-native speakers of English, even though a substantial proportion of higher education instructors in North America are non-native speakers of English, and thus this variety of English is part of the TLU domain. The IELTS (Academic) also purports to assess a test taker’s ability to use academic English in a higher education context, but it is used by institutions of higher learning in North America, Britain, Australia, and other areas. Because of this, the IELTS uses speakers with American, Canadian, British, Australian, and New Zealand accented English. Similarly, the Cambridge English for speakers of other languages (ESOL) exams use regional varieties of British English in their spoken texts. Finally, another point to consider is that in many language use contexts, the variety of English that listeners might usually encounter is that in which none of the speakers are native speakers of the language, and English is being used as a lingua franca.

While this issue of the particular variety of a language to use in a listening test has begun to receive research attention (e.g., Taylor, 2008), many of the major proficiency tests in English have been reluctant to use texts with speakers that have regional or non-native accents, or who speak nonstandard varieties of English. This might be due to resistance to the use of nonstandard varieties of English by the test stakeholders, including the test developers, test users, and the test takers themselves. Again, the TLU domain should dictate the language variety and dialect that should be used as the input for listening tests, yet social and political considerations often override these dictates, which can be a threat to the validity of the test results.

Using the Visual Channel to Include the Nonverbal Components of Spoken Texts

Traditionally, tests of L2 listening ability have focused on the oral information in a spoken text (Wagner, 2010), and have neglected to include the visual, nonverbal components of spoken language. Numerous L2 acquisition researchers have described how the visual components of a spoken text can assist listeners in comprehending that text, including the physical appearance of the speaker, the physical background setting, gestures, body language, lip movements, facial expressions, and many others (e.g., Baltova, 1994; Gruba, 1997; Wagner, 2008, 2010). L2 listening teachers have incorporated audiovisual texts into their classrooms in the last few decades, and with the proliferation of technology in everyday life, it seems likely that the use of audiovisual input for L2 learners will only continue to expand.

For a few limited domains such as listening to the radio, or participating in a telephone conversation, the listener is not able to see the speaker, and thus it would be inappropriate to include the visual channel in assessing a listener's ability in these particular domains, because doing so would serve to introduce construct-irrelevant variance into the measurement. However, for the vast majority of TLU domains, the listener is able to see the speaker, and is able to utilize the information provided by the physical setting and the speaker's appearance, gestures, and body language. Again, the listening test developer must incorporate the characteristics of the TLU domain into the test tasks, and if the TLU domain includes these nonverbal components, then the test task should as well. A number of researchers (Sueyoshi & Hardison, 2005; Ockey, 2007; Wagner, 2008; Cross, 2011) have found that L2 listeners vary in their ability to interpret and utilize the nonverbal information provided by the speaker. Because this varying ability can be seen as part of the construct, to not include the visual channel in L2 listening tests is an example of construct under-representation (Wagner, 2008). However, large testing organizations have resisted using the visual channel in delivering input to L2 listening test takers. Currently, the PTE and IELTS exams have listening sections that use audio-only input. The TOEFL uses audiovisual input, but the visual input is limited to a series of still pictures and graphics, rather than video. Although the theoretical justification for the use of both the oral and visual channels for the input for listening tests is strong, practical constraints have often overridden these theoretical arguments.

Item Types and Response Formats

The previous discussion has focused on the type of input that the test takers listen to during listening tests. Listening, like reading, presents challenges to test developers because it is an internal process, and since they cannot see inside the brain of the test takers, the test developer is forced to make inferences about test takers' ability based on their response to the input. This section will focus on the types of response formats that can be used with L2 listening tests, and will explore related issues including how many times to present the oral text, providing some sort of context for test takers before the listening text is played, and the issue of question preview.

Unfortunately, looking to the TLU domain for the most appropriate type of item response format to use in a test of listening is less clear cut than it is for the type of input to provide. For a writing and speaking test, the output of the test takers can be modeled on the type of output learners are expected to produce in that TLU domain. Even with reading, the TLU domain provides more clues to the most appropriate type of item response format to utilize. Readers (especially in academic settings) are usually expected to read a text and respond to it in some way, perhaps in writing, or perhaps by answering a series of questions about the text that they have read. In an academic listening domain, the learner is usually expected to listen to a text (e.g., a lecture). However, the way the listener is expected to respond to the input is less clear. The inherent artificiality of a testing situation becomes apparent in choosing or creating a response format for a listening test, so the test developer has to try to make the best informed and most theoretically plausible decisions possible.

Perhaps the most common response format in listening tests is a set of usually discrete-point comprehension questions. The listener must read (or listen to) the question, and then choose the most appropriate answer or answers (selected response such as a multiple choice item), or write (or speak) the answer (constructed response). Because these types of items are relatively easy to create, and can be reliably scored, they are commonly used in listening tests, and some examples from these are provided below.

Types of selected response items that are sometimes used in listening tests include filling out a timetable, itinerary, calendar, or chart based on the spoken input. An example from the TOEFL iBT is provided in Figure 3.1.

TOEFL Listening

Re-tell lecture

TIP STRIP

Scan the picture quickly to prepare for the lecture. As you listen, try to get an overall feeling for the meaning and the speaker's attitude.

Take notes but don't try to write every word you hear. Only write key words, e.g. *purpose of museums – relevant in info age? should be educ. – think about visitors, engage – social change, relevant.*

Think about how you will organize what you will say to be ready when the microphone opens.

In the test, there are 3–4 tasks. For each task, you see an image on the screen. Listen to the lecture and then speak into the microphone. The wording in the instructions below is the same as you will see in the actual test. See page 20 for help.

40 sec. You will hear a lecture. After listening to the lecture, in 10 seconds, please speak into the microphone and retell what you have just heard from the lecture in your own words. You will have 40 seconds to give your response.

Figure 3.2 Oral summary task example. Re-tell lecture Test 2, p. 67. Jakeman, Chandler and da Silva. Pearson Test of English Academic Practice Tests Plus. ISBN 9781447934950 © Pearson Education Limited 2013

This type of response format presupposes that the learner is proficient enough to be able to read the items and prompts. With lower ability test takers, some listening tests require the test taker to respond orally, or with some sort of non-verbal physical response to the input. Alternatively, test takers might have to repeat a phrase or sentence that they have heard, or to summarize an oral text, as shown in the example from the PTE in Figure 3.2.

The oral summary response is an example of more integrative test tasks. Others include things like dictation, or listening cloze tasks, as shown in Figure 3.3, also from the PTE.

While the desire to move beyond discrete-point testing in listening is understandable, the more integrative tasks shown here are also problematic in their own ways. Dictation as a listening test task can be criticized because the word-for-word listening it requires is not representative of the type of listening that most L2 listeners do. How to score dictations also presents reliability concerns. Listening cloze tests necessarily involve a written text, and these types of tasks can be seen as more of a reading assessment than a test of listening ability, and again, it is difficult to associate this type of task with a TLU domain of interest.

How the Listening Texts and Test Questions Should Be Presented to Test Takers

One of the unique challenges in assessing L2 listening ability is due to the ephemeral nature of spoken texts. With written input, test takers can repeatedly refer back to the input as needed (within the time constraints of the test). The nature of spoken texts, however, makes this less possible, and thus test developers need to make difficult decisions regarding the number of times the text should be

TIP STRIP

- 1 Quickly read the text before the recording begins and decide what it is about. Use important nouns, such as *languages, school curriculum, business* and *CVs* to help you do this.
- 2 Note down the missing words as you hear them on the Erasable Noteboard Booklet provides. Write down every missing word you think you hear. When the recording is over, use your notes to help you decide on the correct spelling.

Fill in the blanks

In the test, there are 2–3 tasks. For each task, there is a text with several gaps. You type the correct answer for each gap into the box in the text. The wording in the instructions below is the same as you will see in the actual test. See page 49 for help

You will hear a recording. Type the missing words in each blank.

1 ▶ 29

Learning a language in the classroom is never easy and, quite¹ , it's not the way that most people would choose to learn if they had other² . Having said that, there are plenty of reasons for keeping languages on the school curriculum. For one thing, a fair number of students go on to take jobs in business and commerce that require a³ knowledge of a second language. When you talk to young⁴ in top companies, it seems that they had a career plan from the start; they were motivated to find additional things to put on their CVs – and of course language is one of those added, but⁵ extras.

TEST
I

Figure 3.3 Listening cloze task example. Listening Test 1, p. 50. Jakeman, Chandler and da Silva. Pearson Test of English Academic Practice Tests Plus. ISBN 9781447934950 © Pearson Education Limited 2013

played for test takers, and how to present the test questions (written versus orally, or both; before, during, or after the spoken text).

To some extent, the difficulty in deciding the most appropriate (according to the TLU domain) testing procedures comes down to the artificial nature of testing listening ability. In virtually all real-world listening situations, the listener has some sort of idea about what an imminent speech event will be about. Knowledge of the situation, the physical context of the setting, the appearance of the speaker, the co-text, and real-world knowledge all provide useful information to the listener, and help her anticipate aspects of what the speaker will say, thus allowing her to activate the relevant schemata and facilitate the comprehension of the spoken text. However, many listening tasks (both teaching and testing) are very different, in that the listener often has absolutely no idea about what an upcoming spoken text will be about. The tester (or teacher) pushes the play button, and the listeners hear a text that could be on virtually any subject. The listener is then forced to do intensive and cognitively demanding bottom-up processing, listening for each individual word, in the attempt to discern what the topic of the text is. Once the listener is able to do this, she can then simultaneously perform bottom-up and top-down (interactive) processing, similar to most real-world listening situations.

This manner of presenting a listening text to the test takers, without providing any background context to the text, presents threats to validity, in that this is usually not representative of the TLU domain of interest. A simple thing testers can do to make the test task demands more authentic is to provide some sort of introduction or summary of the listening text before it is played for the test takers. That is, by introducing and providing information about what the upcoming text will be about, the test developer can better mimic real-world listening situations, and thus better assess the desired TLU domain.

Regarding the number of times that a text should be played, a superficial analysis of the TLU domain would suggest that in most instances, listeners do not get repeated chances to listen to spoken input, and thus playing the text once would usually be the most appropriate. However, it could also be argued that in many dialogic communication settings, listeners often have the ability to ask the speaker to repeat herself. In most listening test settings, it seems that the text is usually played once, sometimes twice, and very rarely three times. Not surprisingly, research (Sakai, 2009) has shown that the more times a text is played, the higher the test takers' score.

A related issue is when, and in what manner, to present the test questions to the test takers. Buck (1991) argued that allowing the test takers to preview the test questions before the text is played provides the listeners with contextual information that allows them to know what to listen for, and will serve as positive motivation. Some studies have found that question preview led to increased test scores, while others have found no effect on performance. Similarly, Yanagawa and Green (2008) have investigated how full multiple choice question preview, preview of the multiple choice answer options only, and preview of the multiple choice stems only affected test performance, and found that the answer-only preview condition scored significantly lower than the other two conditions.

As can be seen, the research on these different issues is ambiguous and certainly incomplete, and illustrates the difficulties developers of listening assessment face. While there is no single right answer to these issues, one thing that testers can do is to try to make the test tasks as authentic as possible by making the characteristics of the test task as similar as possible to the language tasks in the TLU domain.

Test Consequences and Washback

Washback in language testing is an important (yet often overlooked) consideration for test developers. Tests obviously have many important functions, and are a necessary part of any educational system. But large-scale, high stakes language tests can have a profound impact on course curricula, national curricula, and even whole societies. It is thus important to consider test washback in relation to some of the issues unique to the testing of listening as described above. It seems obvious that teachers and testers should be interested in L2 learners developing the ability to listen to and comprehend authentic spoken discourse, which usually includes things like connected speech, reduction, phonological modifications, vernacular language, language variation, and nonverbal communication. The need to assess a learner's ability to speak and understand conversational language in an interactive, speaking and listening, communicative language use setting would also seem to be obvious. Yet most large-scale, high stakes tests of listening focus on a very narrow aspect of the construct, using spoken texts that include almost none of these natural characteristics, but instead are planned, prepared, practiced, polished, and then read aloud and artificially enunciated. These texts are usually recorded, then played back using the audio channel only, with listening and speaking ability being assessed separately, rather than integratively. This can have

a direct (and negative) impact on how listening is taught to language learners. If the goal of the learners is to pass the test, then it is understandable that they might not be interested in learning how to listen to and comprehend authentic spoken discourse. It is also understandable that teachers and curriculum designers might decide against focusing instruction on these aspects of listening. Similarly, if the high stakes tests that drive curriculum design do not include the nonverbal components of spoken language in the listening process, then the curriculum (often driven by those high stakes tests) will not include them either. In addition, it is important that high stakes tests include the varieties of language that learners would encounter in the TLU domain, rather than just the standard variety of the language. "Consequential validity" involves the idea that a validity of a test should be gauged at least in part on the extent to which it has a positive influence on teaching (Messick, 1989). Thus, creating L2 listening tests that include these components of unplanned spoken discourse could have a positive impact on how L2 listening is taught.

Future Directions and Conclusion

There has been a decided movement in assessment in recent years toward more integrated tasks. For L2 listening testing, this is evidenced by tasks in which the listening text is presented, and then test takers have to respond by speaking or even writing about the text. In addition, there has been a strong movement toward the use of group oral testing, in which two, three, or even four test takers are tested simultaneously, and the test takers have to interact appropriately, listening to the discourse from one participant, and responding orally. This type of testing is necessary, in that it seeks to truly assess test takers' interactive speaking and listening ability. However, it also presents a number of reliability and validity concerns, and while it has been the subject of a large amount of more recent research (e.g., Galaczi, 2008), most of this seems to have been focused on the speaking component, and less on the listening. One of the obvious concerns is how the test taker's listening ability is assessed in group oral testing, since the rater can only guess as to how well the participant comprehended the spoken input based on her spoken response. While this seems a fruitful direction for assessment, much more research is needed on this type of test task.

Another obvious future direction of testing listening includes the increased use of technology to allow test developers to address at least some of the threats to the construct validity of current testing formats, by allowing testers to more fully include important components of the TLU domain in tests. Increased use of computers to deliver the input to test takers would allow for the inclusion of the visual channel, thus reducing the amount of construct under-representation found in many tests of listening. Similarly, innovations in assessing interactive speaking and listening ability seem possible, going beyond the current two-turn design found in many tests, where the first turn is a delivered spoken text (usually only in oral form) and the second turn requires the test taker to respond in some way. Rather, a more innovative design might involve multiple turns, allowing for a more authentic assessment of interactive speaking and listening ability. Another

area in which technology has made great progress is in the analysis of large corpora, especially spoken corpora. Using the results of these analyses, future test developers could create texts for listening assessments that include the characteristics of unplanned spoken discourse, thus resulting in the assessment of a much broader construct of L2 listening ability than is usual currently. Even for the assessment of low ability listeners, in which it might not be appropriate to use texts spoken at a normal rate of speech, technology can be used to slow down the speech rate electronically, or by inserting pauses at the appropriate speech boundaries.

Technology in itself, however, is certainly no panacea. Lynch (2009) questions how useful technology is for teaching and testing L2 listening ability, and the increased use of technology also presents issues that need to be much more thoroughly researched. Vanderplank (2010) argues that various facets of the use of technology related to L2 listening are only beginning to be researched. While there has been some research into how the use of the visual channel affects test-taker performance, and how test takers interact with a video listening test (e.g., Ockey, 2007; Wagner, 2008, 2010), much more research is needed on how the use of different types of technology affects L2 listening test-taker performance.

Assessing Literacy

Sara Cushing Weigle

Georgia State University, USA

Introduction

In the 21st century, few would argue against the proposition that literacy is important for success on both an individual and a societal level. At first glance this seems like an obvious statement that requires no explanation; however, a closer look at the issue raises a number of questions. What exactly is literacy? Most people would say “the ability to read and write.” But this statement leads to another question: What is it that people are able to read and write? Or, to be more precise, the question that needs to be answered in order to define literacy for the purpose of assessment might be: Who is reading and writing what kinds of materials or texts, in which languages, for what purpose, and how effectively?

A preschool child learning to recognize and name letters is learning literacy skills; so is a middle school student studying the formation of Chinese characters, or a graduate student learning how to write research reports, or a nurse learning how to read and write notes on patient charts. It is clear from these examples that there are different types of literacy, and that what counts as literacy in any given setting differs depending on variables related to the question formulated above. To begin, the “who” in this question may be divided into several categories. Among children, there are monolingual ones, acquiring their first language and adding literacy skills to their developing oral language; linguistic minority children, acquiring the majority language in school and trying to catch up with their native language peers; and linguistic majority children in schools, learning a foreign language for enrichment. Among adults, there are those who did not acquire literacy skills in school because of interrupted education, learning disabilities, or other factors; those who learn a second language for enrichment or work needs; and those who need specialized reading and writing skills for their work.

All of these different populations have different literacy needs, and literacy must be defined differently in each case.

Turning to the next element of the question, we can now consider the “what” of literacy. If literacy is considered to be primarily reading and writing, the “what” concerns the thing to be read or written—is it a medical form to be filled out, a novel, a set of instructions, a poem? Knowing how to read or write any or all of these requires a set of skills: linguistic skills such as vocabulary and grammar, other cognitive skills such as the ability to follow someone’s line of reasoning or come up with a cogent argument, and social-cultural skills such as knowledge about norms of politeness and formality in writing. The next consideration is the language of literacy, particularly in multilingual settings. The notion of a “continuum of biliteracy” (Hornberger, 1989, 2003) provides a framework for much recent discussion in this area. One can be more or less literate in several different languages: many people are quite literate in their first language but only have speaking knowledge of a second; conversely, many people speak one language at home and are schooled in a second language, so they may have more developed literacy skills in their second language than in their first. Finally, it must be recognized that people read and write for a purpose: reading a novel for enjoyment is quite different from reading a recipe; by the same token, sending a text message is a very different writing task from writing a letter to the editor.

All of this discussion assumes that reading and writing are the central components of literacy; however, some definitions of literacy go beyond this simple definition, to consider other factors such as medium (paper and pencil, computer), and even beyond words, to the messages inherent in symbols and visual images. For example, there are numerous books and articles on topics such as media literacy, digital literacy, health literacy, and even assessment literacy.

From this brief introduction it is clear that the construct of literacy is complex and multidimensional, and thus difficult to define, let alone assess, simply. Furthermore, scholars approach the study of literacy from multiple perspectives and through multiple lenses, which complicates the search for a unified definition of this phenomenon. Perhaps the one idea that scholars do agree on is that literacy cannot be defined in the same way for all situations; in fact many scholars prefer the term “literacies,” to emphasize the fact that literacy is not a single phenomenon but is dependent upon situational variables. Much current scholarship invokes the concept of multiliteracies (New London Group, 1996), which involves consideration of both the multiplicity of linguistic and cultural variations faced by students in a globalized world and the variety of new text types they encounter beyond the printed word. Because of this multiplicity of definitions and perspectives, I will not attempt to cover all facets of literacy in this chapter. Fuller discussions of literacy can be found in handbooks such as Olson and Torrance (2009) and Christenbury, Bomer, and Smagorinsky (2009). Rather I start by reviewing purposes for assessing literacy in different populations. Next I review older and more current conceptions of literacy, discuss literacy for school-aged populations and adults, and present challenges and future opportunities in literacy assessment.

A useful starting point for any discussion of assessment is to review the purposes for assessing a given ability or set of abilities. Literacy, in one form or another, is

assessed for different purposes for different populations. On an individual level, literacy is assessed to measure achievement, diagnose problems, or provide an overall evaluation of readiness for school or work. Somewhat more on a macro-level, literacy (defined broadly as reading and writing) can be assessed to evaluate the success of a particular program, such as a school, a school system, or a particular intervention or teaching innovation. Finally, on a national level, literacy is assessed as an indicator of progress and development. As clarified later in this chapter, there is an inverse relationship between the scope of the assessment in terms of population and the depth to which skills can be measured; when the focus is on teaching individuals, a more fine-grained, in-depth assessment is more feasible and useful than when the focus is on setting national policy, for example.

Shifting Views of Literacy

The expectations for literacy in society and in the workplace are much higher than they were a century ago. Jobs that require little or no literacy are much rarer than they were even 25 years ago; most jobs require at least a high school education or the equivalent (Elish-Piper, 2007). With the expansion of literacy as a necessary life skill, the definition of literacy has expanded as well.

The term “literacy” has a long history of meaning changes; for a historical overview see Triebel (2005). Before the late 19th century “literate” meant “familiar with literature” or well-educated (UNESCO, 2006). Only in the past century has literacy been conceptualized as a more fundamental, quantifiable ability—specifically, the ability to read and write. In this sense literacy has often been conceptualized as a binary distinction: either one can read and write, or one cannot. Indeed, literacy rates in the world have traditionally been measured through self-reported answers to some form of the question: “Do you know how to read and write?” (Ahmed, 2011).

The United Nations Educational, Scientific and Cultural Organization’s (UNESCO’s) 2006 report on literacy summarizes four ways in which this phenomenon has been conceptualized in the research literature. The first is literacy as an autonomous set of skills, particularly reading and writing, and the cognitive sub-skills that underlie them, such as phonetics, word recognition, and vocabulary. This is the definition that most people have in mind when they think of literacy. This skills approach has been broadened to include a variety of other skills and competencies such as “media literacy” and “health literacy.” The assumption behind this conceptualization is that literacy is something that resides in the individual: that is, a trait like personality or intelligence, which can be measured. The second approach to the definition of literacy expands the simple concept of a set of skills possessed by an individual to include the notion of applied skills, or how people use literacy skills for real-world purposes. In the 1970s the concern for “functional literacy” emphasized the role of literacy in socioeconomic development: increasing functional literacy among the general population in a country would have economic and social benefits, and thus countries began pursuing policies designed to expand literacy rates in their populations. Originally underlying the notion of functional literacy were certain assumptions about literacy that

have since been largely discarded: in particular, the idea that literacy consists of a universal set of skills that are culturally neutral and can be taught essentially in the same way to everyone. This idea was rejected when ethnographic studies revealed differences in the literacy practices engaged in by different social groups and cultures. Third, literacy can be seen as “an active and broad-based learning process,” (UNESCO, 2006, p. 151) rather than as the product of educational interventions. The notion of “critical literacy,” associated most strongly with the work of Brazilian educator Paulo Freire, involves “reading” (i.e., interpreting, reflecting on, interrogating, theorizing, investigating, exploring, probing, and questioning) and “writing” (i.e., acting on, and dialogically transforming) the social world. Finally, the fourth way of looking at literacy involves looking at the nature of the texts that literate individuals produce and use. This approach “locates literacy within wider communicative and socio-political practices that construct, legitimate and reproduce existing power structures” (UNESCO, 2006). International literacy policy is influenced by these four approaches, although, as Ahmed (2011) notes, the assessment of literacy is primarily accomplished through the first two approaches (literacy as a set of skills and the application of those skills to particular contexts).

Current Views or Conceptualization

Most current scholars subscribe to a multidimensional view of literacy, which includes the ability not merely to decode print but also to use and create materials for a variety of personal goals. UNESCO defines literacy as follows:

Literacy is the ability to identify, understand, interpret, create, communicate, and compute using printed and written materials associated with varying contexts. Literacy involves a continuum of learning in enabling individuals to achieve their goals, develop their knowledge and potential, and participate fully in their community and wider society. (UNESCO 2005, cited in Ahmed, 2011)

More recently, Schleicher (2008, p. 630) defines literacy as “the interest, attitude and ability of individuals to appropriately use socio-cultural tools, including digital technology and communication tools, to access, manage, integrate and evaluate information, construct new knowledge, and communicate with others.”

These definitions contain several important concepts that are worth expanding upon. First, literacy involves engaging with and creating handwritten or printed materials, or both; it includes both reading and writing (and simple arithmetic; but we will leave this alone for the time being). Second, it is not binary; that is to say, it is not something that one either has or does not have. Rather literacy is a continuum, and it is context-dependent, so that one may be considered very literate in one context but less so in another. An obvious example is the case of multiple languages: an individual may be highly literate in his or her mother tongue but not at all literate in a second language. Another example is the area of health literacy: even though the reported literacy rate in the US is 99% (CIA, 2011), fully one third of Americans are estimated to be unable to read simple instructions

regarding health materials (Kutner, Greenberg, Jin, & Paulsen, 2006). Finally, these definitions acknowledge that literacy is a tool for personal development and for participation in society. Clearly, then, literacy is a complex phenomenon, which goes well beyond simple reading and writing.

The implication of these definitions for literacy assessment is that, like any construct, literacy must be defined for the particular context in which it is to be assessed. For example, assessing literacy among refugee populations in New York City is very different from assessing English literacy in a middle school classroom in Seoul.

Unfortunately, for the purposes of assessment, literacy frequently ends up with a narrow rather than a broad definition. As Ahmed (2011, p. 183) states:

A broad vision of literacy comprises a range of skills, competencies, and awareness about self and the world that enables individuals and communities to exercise choices regarding the fulfilment of their human potential. A narrow view, on the other hand, confines literacy to acquiring the skills to decode written symbols as a means of communication.

Current Scholarship

Scholarship on literacy assessment can be roughly divided into two categories: assessments of individuals for the purposes of diagnosis and intervention; and assessment of populations for policy reasons. Research can also be thought of in terms of ways to assess literacy (how to define and assess literacy), results of literacy assessments (what do existing assessments tell us about literacy in specific populations?) and implications of these results, principally in terms of instruction and policy. In this section of the chapter I discuss both methods for assessments and the uses to which such assessments are put.

At the individual level we can talk about specific methods for assessing reading and writing individually or in combination, for different populations (e.g., children, adults, first or second language learners), and across different technological media (print, digital).

Assessing Literacy in Children

In early childhood literacy is not measured so much as predicted through measurement of skills such as phonemic awareness, letter knowledge, oral skills, and awareness of print (Byrnes, 2001, cited in Thurman & McGrath, 2008). Roskos (2004) argues that early literacy assessment is critical because the preschool years set the stage for further linguistic and cognitive development. However, assessing literacy as distinct from other developing skills remains challenging, as literacy concepts are intertwined with other developing systems—such as physical, emotional, and cognitive ones. Emerging preliteracy skills are also unstable, and thus challenging to assess in traditional ways. For these reasons it is important to test literacy and preliteracy skills in very young children (i.e., preschoolers) through multiple measures, at different times, and through play activities (Roskos, 2004; Thurman & McGrath, 2008).

For school-aged children, an important component of literacy assessment is the identification and remediation of reading problems. There is a great deal of literature on the development of literacy skills for both first and second language speakers; see, for example, August and Shanahan (2006); Olson and Torrance (2009); Christenbury et al. (2009). Some research has found that phonological processing difficulties contribute to lack of reading skills. Oral language is also a factor, and it needs to be particularly attended to when assessing second language learners. Manis and Lindsey (2011) suggest that English language learners suspected of having reading disabilities or delays should be screened for reading problems by using parallel measures of phonological decoding and oral language comprehension both in their first and in their second languages. They argue that reading disabilities are frequently missed among L2 speakers, as teachers assume that the issue is primarily language proficiency. Starting from the early grades, it is important to measure literacy skills in addition to oral language skills, preferably in both L1 and L2.

Typical school-based assessments of literacy are conducted for four main purposes: screening, to identify at-risk children who may need additional support for literacy skills; diagnosis, to obtain in-depth information about children's strengths and weaknesses in literacy; progress monitoring, usually through short curriculum-based measurements (CBMs); and outcomes assessment (Teale, 2008). Tests used for outcomes assessment are typically standardized tests, such as the Iowa Tests of Basic Skills (Riverside Publishing, 2010). The Iowa Test of Reading Comprehension, for example, tests reading skills from kindergarten through grade 8. Depending on the level of the test, the items range from simple word identification from picture cues through factual and inferential questions on a variety of reading passages.

In the US, reading tests are typically multiple choice ones; while this method of testing is efficient and generally reliable, several scholars have noted objections to multiple choice testing and advocate other ways of measuring reading comprehension (e.g., Rupp, Ferne, & Choi, 2006; Grabe, 2009). Further information about reading assessment can be found elsewhere in this volume.

Similarly, writing is typically assessed either directly, through prompt-based or source-based writing (depending on the setting), or in some cases indirectly, through multiple choice tests of grammar and usage, though most scholars in writing teaching and assessment argue that such measures lack authenticity and validity. The chapter on writing assessment in this volume discusses these issues at length.

An important international survey of student literacy is the Programme for International Student Assessment (PISA), conducted by the Organization for Economic Cooperation and Development (OECD). PISA assesses reading, math, and science among 15-year-olds in 65 countries. An executive summary of the most recent results is found in OECD (2010), which contains average results for each country as well as useful information for policy makers about the factors that are related to higher scores; see also Kirsch et al. (2002) for results from PISA 2000. The reading literacy construct for PISA includes accessing and retrieving information, interpreting texts, and reflecting upon and evaluating texts—both continuous texts such as essays or newspaper articles and non-continuous texts such as charts and graphs (OECD, 2009).

To summarize, literacy assessment in children is primarily a school-based endeavor. Two subpopulations for whom literacy assessment is particularly a concern are learners with reading disabilities and second language learners. For both populations, testing components of reading and writing ability such as word recognition, sentence comprehension, and oral language ability may provide useful diagnostic information, which can be helpful in designing effective interventions. Internationally, comparisons among countries in large-scale literacy assessment can yield information that may help policy makers and curriculum developers improve outcomes.

Assessing Literacy in Adults

In contrast to assessing literacy in childhood, assessing literacy in adulthood is a somewhat more complicated matter, as adults are much more diverse in terms of their backgrounds and of their literacy needs and problems. The reasons for assessing literacy among adults are also more diverse, ranging from instructional needs to national policy setting. For the purposes of this chapter literacy assessments are divided into three types. First I discuss literacy assessments at a very basic level, to determine levels of functional literacy; that is, what most people think of as literacy assessment. An important subcategory with functional literacy is health literacy. Since functional literacy is assessed both at the individual level and at the societal level, both types of assessment are discussed here. Then I discuss more specialized areas within literacy assessment: academic literacy for the purpose of higher education; and literacy assessment as it relates to technology—that is, media/information literacy.

Assessing Functional Literacy Given the increased need for literacy skills in the workplace, developing accurate assessments of functional literacy skills is a critical need. As Reder and Bynner (2009) note, low literacy skills are not only problematic for individual adults in their daily lives, but pose serious societal problems. For example, individuals with low literacy skills tend to have low levels of civic participation, poorer health, and lower rates of employment.

Assessing low level literacy among adults for diagnosis and instructional purposes has frequently proven problematic, however, in part because of limited resources to support assessment and education at the adult level. One solution that has sometimes been used is to rely on tests that were designed for assessing children's literacy (Greenberg, Pae, Morris, Calhoun, & Nanda, 2009). However, as Greenberg et al. (2009) point out, assessments that are normed on young children may not be appropriate for adults. For example, tests that provide scores in terms of concepts such as reading grade equivalency (RGE) are usually based on developmental stages and materials more appropriate for children. As an illustration of what can happen when inappropriate materials are used, Greenberg and colleagues found that a significant subgroup of their adult participants had difficulties with the (supposedly) easiest stories in a graded assessment and, if standard procedures had been followed, would have failed the entire assessment. However, they were allowed to proceed and found the next stories manageable, performing much better on the higher level stories than on the lower level ones.

FROM	John Lang
TO	Susan Meyer
SUBJECT	Raises

Susan,

Dave and two other employees talked to me today about the possibility of getting a raise. What do you think about this? I'll call you this afternoon. Thanks.

-
3. Who will John call ?
- A. Dave
 - B. the employees
 - C. Mr. Lang
 - D. Susan Meyer

Although Greenberg and colleagues are not able to explain this discrepancy, they speculate that some adults may have found the easier stories less interesting and relevant to their lives and may not have attended to them carefully. This is an example of why it is important to use assessments that are normed on an appropriate population.

However, standardized literacy assessments at the adult level are few and far between. One example of an assessment that was designed for adults is the Comprehensive Adult Student Assessment Systems (CASAS) suite of tests. CASAS tests are used frequently in adult programs, because they are easy to administer and score. An example of a CASAS item is shown in Figure 4.1. However, these tests are not without their own difficulties. In particular, multiple choice tests such as CASAS tests require a level of literacy that not all students possess. As Warriner (2008) shows, the use of such tests for exit or promotion can actually lead to teachers and students focusing on passing the test rather than spending class time improving the skills that are critical for gaining entry into the workforce. CASAS tests have also been criticized for a lack of authenticity (Gorman & Ernst, 2004); furthermore, a review of CASAS tests (Weigle, Kahn, Butler, & Sato, 1994) revealed that even the most advanced reading items appeared to test the ability to scan a text for a specific piece of information rather than the ability to interpret a text; thus the CASAS literacy construct appears to be somewhat narrow.

Perhaps the most appropriate way to assess the most basic literacy skill is through a one-on-one interview with a trained examiner rather than using paper and pencil (or, these days, computer-based) tests. Although this may seem counterintuitive, the skills that are required in order to take a test (particularly a standardized multiple choice test) are actually relatively advanced literacy skills and are inappropriate for very low literacy examinees, particularly those who are unfamiliar with US testing conventions such as filling in bubbles or choosing among alternatives (Warriner, 2008).

The BEST literacy skills test (Center for Applied Linguistics [CAL], 2008) is an example of a test used for assessing low level English language skills, including literacy, for placement into adult English as a second language (ESL) programs in the USA. The BEST literacy assessment consists of both reading and writing tasks. Reading tasks contain items such as food and clothing labels, newspaper wanted ads, and short announcements. Writing tasks include writing a check, addressing an envelope, filling out a form, and writing a short note (CAL, 2008). The BEST test is one of very few commercial tests designed for non-native speakers of English.

One framework for assessing functional literacy is proposed by White (2011), who posits texts, task, and respondents as the three central aspects of literacy that need to be examined. Specifically, White poses three questions for researchers to investigate:

- What features of texts make them easy or difficult to use?
- What cognitive and linguistic demands do literacy tasks entail?
- What literacy skills do individuals need to meet these task demands? (p. 9)

Furthermore, White proposes that literacy scales¹ be developed to capture individual abilities in the following skill areas:

- Basic reading skills: the ability to decode unfamiliar words and recognize familiar words with fluency.
- Language comprehension skills: the ability to use knowledge of language (i.e., vocabulary, syntax, semantics, discourse) to understand texts.
- Text search skills: the ability to search texts efficiently by using knowledge about text features such as structural elements, typographical/orthographic devices, and identifying key search terms.
- Inferential skills: the ability to draw appropriate text-based inferences using prior knowledge, language knowledge, and logical reasoning.
- Application skills: the ability to use new information from searches, inferences, or computations to accomplish goals such as making predictions or explaining causal relationships. (p. 9)

Literacy Assessment for Policy Purposes The second major use of literacy assessments is to describe the literacy of populations for the purposes of setting policy. As noted previously, in many countries literacy rates rely on self-reported data. However, over the past two decades more emphasis has been placed on defining literacy more broadly and on designing assessments to measure this broader definition.

Figure 4.2 Sample NAAL item. © National Center for Education Statistics, US Department of Education

In the USA an influential large-scale assessment, the National Assessment of Adult Literacy (NAAL), was conducted in 1992, and again in 2003 (Baer, Kutner, & Sabatini, 2009). The NAAL consists of an interview in which trained examiners present items one at a time to examinees and record their scores (correct/incorrect/no response) on a computer score sheet. An example of a NAAL question is found in Figure 4.2.

The NAAL measures three types of literacy among US adults aged 16 and over; the types are defined as follows:

- Prose literacy. The knowledge and skills needed to perform prose tasks (i.e., to search, comprehend, and use continuous texts). Examples include editorials, news stories, brochures, and instructional materials.
- Document literacy. The knowledge and skills needed to perform document tasks (i.e., to search, comprehend, and use non-continuous texts in various formats). Examples include job applications, payroll forms, transportation schedules, maps, tables, and drug or food labels.
- Quantitative literacy. The knowledge and skills required to perform quantitative tasks (i.e., to identify and perform computations, either alone or sequentially, using numbers embedded in printed materials). Examples include balancing a checkbook, figuring out a tip, completing an order form, or determining the amount.

The results of the NAAL suggest that actual functional literacy rates are far below the published 99% literacy rate. For example, 14 percent of the adult population in the US tested below the basic level, which suggests that approximately 30 million adults can only perform the most simple and concrete literacy tasks. An additional 29% scored at the basic level, indicating that they can perform simple, everyday literacy activities such as using a television guide or comparing the ticket

prices for two events. These figures were similar to the literacy rates from the previous administration of NAAL in 1992, with some minor differences.

On an international level, functional literacy is frequently defined in similar terms. Ahmed (2011) reports on international efforts to promote literacy through UNESCO; these include a major effort supported by the UNESCO Institute for Statistics (UIS), the Literacy Assessment and Monitoring Project (LAMP). LAMP's goal is to generate information on prose and document literacy, numeracy skills, and the reading components (e.g., letter and number recognition, vocabulary, sentence processing) that explain performance in these domains that can be compared cross-nationally. Like the NAAL, LAMP assesses reading only, not writing. LAMP was developed in collaboration with experts in the US and Canada and with national teams from El Salvador, Kenya, Mongolia, Morocco, Niger, and the Palestinian Autonomous Regions, and it defines five levels of literacy. While LAMP is claimed to be a credible and reliable way to collect literacy information that can be compared internationally, Ahmed notes that the complexities of test development and administration, the need for supervision and technical support from UIS, and the expense have discouraged some countries from adopting LAMP's approach in its totality. Instead, countries such as Kenya and Bangladesh have adopted some of the methodologies promoted by UIS to develop their own assessments, which may lack the methodological and statistical rigor of LAMP but are superior to the self-report methods more common in the past.

Ahmed notes that these tests have estimated literacy rates to be much lower than the officially published rates. For example, in Bangladesh the official literacy rate in 2002 was 63%, but tests of a representative sample of the population found that 41% had basic literacy skills and only 21% had a level of literacy that was "sustainable and self-sufficient" (p. 190); that is, a level that allowed people to use literacy in their daily life without assistance. Ahmed estimates that, "when reasonable measurement method and criteria are applied" (p. 192)—that is, if literacy rates were measured through assessments that go beyond simple yes/no self-report data but actually measure the kinds of literacy activities that are critical to success in the 21st century—world illiteracy rates would be upward of one and a half billion people.

OECD has established a strategy for assessing adult competencies: the OECD Programme for the International Assessment of Adult Competencies (PIAAC; Schleicher, 2008). The definition of literacy used by this project goes beyond traditional notions of literacy, to include knowledge and skills needed to function in a technological world. The PIAAC assesses literacy through the following instruments. First, a locator test is administered to establish whether participants have the minimum skills to participate in a reading test and their familiarity with information and communication technology (ICT). Those who do not meet the minimum requirements for the reading test are given a low level test of the basic components of literacy (word recognition, etc.). Those who can read but are not technologically literate are given an extended paper and pencil literacy test, while those who can both read and use technology are given a computer-adaptive test of literacy skills, including ICT literacy. The goal of PIAAC is to inform policies relevant to several themes around literacy, including the relationship between literacy and socioeconomic risk, designing educational systems for adult

learners, improving school to work transitions, and lifelong learning for an aging population.

Literacy Assessment for Specific Purposes As noted above, literacy is defined in different ways for different purposes. In this section I discuss three types of literacy that have become particularly important in recent decades: health literacy, information/media literacy, and academic literacy. The first of these—health literacy—is an essential component of basic functional literacy. Information/media literacy and academic literacy are of concern primarily in educational settings, though information literacy is also a workplace concern.

Health literacy is defined by the US Centers for Disease Control (CDC) as “the capacity to obtain, process, and understand basic health information and services to make appropriate health decisions” (Centers for Disease Control, 2011). Health literacy is a critical area of inquiry because research suggests that the majority of adults have difficulty using available health information (Kutner et al., 2006), a situation leading to more chronic diseases, lack of compliance with medical instructions, and increased visits to emergency rooms (Rudd, Anderson, Oppenheimer, & Nath, 2007, cited in CDC, 2011). Current conceptions of health literacy include oral literacy (that is, the ability to seek and understand information to make informed health decisions) as well as print/document literacy and numeracy. Much of the research around health literacy has to do with whether interventions have positive health outcomes; however, accurate measures of health literacy are not readily available. Tests of functional literacy such as the CASAS exams and the NAAL include several health-related questions; analyses of NAAL health literacy questions estimate that over one third of Americans lack sufficient health literacy to navigate the health-care system (Kutner et al., 2006).

Information literacy—sometimes called digital literacy, media literacy, or technological literacy—is more difficult to define and assess, in part because there is a proliferation of terms that cover a range of skills, from the ability to use a mouse and/or a keyboard to the ability to design a Web page or critically evaluate the reliability of information from an Internet source. The construct of “computer familiarity” (Kirsch, Jamieson, Taylor, & Eignor, 1998) can be thought of as a combination of access to computers, attitudes toward computers, experience with computers, and familiarity with related technology. Of more concern for the purposes of this chapter is the assessment of the critical reading and writing skills that are needed to understand, interpret, use, and disseminate information using rapidly changing technological tools.

UNESCO (2006, p. 150) defines information literacy as “the development of a complex set of critical skills that allow people to express, explore, question, communicate and understand the flow of ideas among individuals and groups in quickly changing technological environments.” The PIACC project includes the construct of Information & Communication Technology (ICT) and focuses on “the cognitive processes underlying literacy, such as dealing with dynamic and interactive problems as well as non-linear information structures, rather than on aspects of the use of specific information technologies” (Schleicher, 2008, p. 632). Both of these definitions respond to the need to address information technology primarily in the workplace.

Turning to academic information literacy concerns, Chase and Laufenberg (2011) point out that educators disagree as to whether it is the tools—the technology—or the use that is made of such tools that defines digital literacy. They provide examples rather than a definition, for example: “the students deal with multiple, authentic texts, navigating them by using numerous tools and code switching to understand the writing of multiple authors on a single subject” (p. 536). Authenticity (reading and writing for an authentic audience and purpose), multiple modalities (speaking, reading, writing, listening), and writing for a wider audience than the teacher seem to be the hallmarks of digital literacy.

Burniske (2008) defines media literacy as “the ability to read and understand a communications medium by looking through the processes it enables, interpreting its signs and symbols, while also looking at the medium’s effect on an author, audience, and message” (p. 11). Burniske argues that media literacy involves looking at the three points of the rhetorical triangle: ethos (credibility of the author), pathos (emotional appeal to the audience) and logos (logic of the argument) to see whether a weak message is disguised by ethos and pathos. For example, advertisements using celebrity endorsements rely on ethos to persuade the public to buy a product. Burniske provides teaching suggestions for improving media literacy; perhaps some of these suggestions could be adapted for use as assessment tasks. For instance, one suggested task is the analysis of an advertisement; this could easily be used as a summative assessment task designed to determine the degree to which students can identify the rhetorical strategies used to sell products.

Academic literacy refers generally to the literacy practices of academic settings: that is, the inter-related reading and writing skills needed for success in school (e.g., Geisler, 1994; Spack, 1997). From an assessment perspective, discussions of academic literacy center on the notion that reading and writing are interdependent and can more usefully be assessed in combination rather than as discrete skills. It is this sense of academic literacy I discuss here. In many large-scale tests for admission and placement decisions in higher education, reading and writing are integrated. For example, the University of California requires incoming first year students to demonstrate writing ability by reading a prose passage of 700–1,000 words and by writing an essay in response to the passage (University of California, *n.d.*). The TOEFL iBT (Test of English as a Foreign Language, Internet-based test) now uses both an independent and an integrated writing topic; the integrated topic requires examinees to read a short passage, listen to a lecture, and write an essay synthesizing information from both input texts (Educational Testing Service, 2012). Such tasks are more closely linked to academic tasks than to independent writing tasks, as most academic writing is based on source texts. Reviews of research on integrated reading/writing tasks, particularly for second language learners, can be found in Weigle (2004), Plakans (2009, 2010), and Gebril (2010).

Challenges

Challenges in literacy assessment are many. In schools, where literacy is a key outcome of education, literacy assessment rightfully has a central place. Some critics, however, maintain that the current focus on assessment and standards has

led to a narrowing of the curriculum, to the detriment of broader learning, which cannot be quantified (e.g., Hillock, 2002; Teale, 2008). Other challenges include the impact of technology on literacy. As a result of the explosion of information available electronically, the ability to evaluate sources and read critically is increasingly important. However, some recent research suggests that access to computers in schools and at home may have a beneficial effect on test scores for students from high socioeconomic backgrounds but a negative effect for students from lower socioeconomic status (SES) backgrounds (Warschauer & Matuchniak, 2010).

What to do about low levels of literacy in certain segments of the population is a nagging issue that is not likely to go away soon. Research on literacy has demonstrated convincingly that the amount of linguistic input received by very young children can have long-term impacts on language acquisition and literacy (see, e.g., Huttenlocher, Vasilyeva, Cymerman, & Levine, 2002; Hoff, 2006). Questions still remain about whether deficits from an impoverished background can be made up by schools. In the case of second language learners the issues are even more complicated, as literacy development in a second language is influenced by a variety of linguistic, sociocultural, psychological, and educational factors (Helman, 2009).

One of the dangers of the use of standardized tests in literacy assessment is that such tests tend to determine what is taught and learned, which may not be what students actually need (see Hillocks, 2002 for a full-length critique of standardized tests in school). As Warriner (2008, p. 320) states:

When students are learning how to decode the meaning of words and questions on multiple-choice tests, how to choose correctly from among the available options, and how to fill in the circles on the answer key, they are not engaged in meaningful reading and writing experiences, authentic face-to-face communication, or general problem-solving activities that would help them achieve some of their most important goals (e.g., finding a job; negotiating with a landlord; communicating with a child's teacher, etc.).

Warriner makes the point that, when adult ESL courses rely on standardized tests for monitoring progress and for demonstrating success to authorities who provide funding, the choice of assessment can have serious consequences for students. This is especially the case as adult classes tend to be limited in time and resources. Policies of large classes, open enrolment, and the need to prepare students for a test that will determine their eligibility for benefits such as job placement assistance reduce the amount of time that can be spent in class dealing with other urgent language needs of students. Literacy as defined by these tests does not in fact equate to job success, as Warriner notes that some students have found jobs on their own before passing the test, while others who work hard to pass the tests, have difficulties finding jobs. It is not always possible to convert the social currency gained by the test into a real-world success—that is, a job.

For second language learners, it is important to know about literacy levels in the first language in order to make sound instructional decisions. Literacy skills in a second language can be achieved much faster for someone who is already literate in their first language; furthermore, literacy supports oral language

acquisition (Strucker, 2007). People come to a second language without literacy in the first for several reasons: their first language does not have a writing system, or their education was interrupted or nonexistent, or they have learning disabilities of one form or another. Teaching literacy skills to such people requires special training and skills.

Future Directions

Given the increasing importance of literacy in the global environment and the rapid expansion of technology, there are several ways in which we can anticipate progress in assessing literacy. One important direction is the further specification of the subskills that underlie literacy. Many large-scale literacy assessments such as the NAAL only report overall literacy levels, without providing information that could be useful in diagnosing and remediating specific problems. As White (2011) suggests, assessment tasks can be fine-tuned with specific linguistic and cognitive characteristics so that skills-based reporting is possible. Such reporting could, for example, specify the estimated percentage of a population that has fundamental language comprehension skills but minimal text search or inferential/application skills.

Similarly, large-scale functional literacy assessments typically measure reading only, and not writing. Given the importance of writing in education and in the workplace, and the possibility of automated scoring of writing (see Shermis & Burstein, 2003, and Dikli, 2006, for overviews), it is likely that assessing functional writing on a large scale may soon be feasible. One working definition of functional writing is the following:

Functional writing ability is the ensemble of skills and knowledge needed for full participation in written communication in work, home, and community settings. Functional writing ability enables the creation of handwritten or digital texts ranging from single words to coherent discourse blocks, each of which is appropriate in form and content to a given purpose, audience, and context. (McCloskey, Weigle, & Yancey, 2008)

This definition could be useful in designing tasks for the assessment of functional writing ability in the future.

In terms of specific areas of literacy assessment, it is probable that information/media literacy will play an ever increasing role, and rapidly changing technology will require a continuing expansion of the definition of literacy. Because of the vast proliferation of available information, critical thinking skills will be more important than ever, and literacy assessments need to include such skills. At the same time, it must always be recognized that too much emphasis on assessment may detract from learning.

Furthermore, the limitations of literacy assessment must also be acknowledged. As Bartlett (2008) found in an ethnographic study of literacy courses in Brazil, students enrolled in the course were successful in finding jobs not because of their new literacy skills per se, but because of the social networks that being in an

educational setting afforded, and because they were perceived as more educated. It may well be that the social capital acquired through the perception of literacy is as relevant to job success as actual literacy skills themselves.

While scholars and literacy experts agree on the notion of literacy as a continuum of skills that are different in different contexts, this view has not made its way into policies on an international level. The complexities of assessing literacy and the pressures to “claim certain literacy rates for the benefits of the international league table” (Ahmed, 2011, p. 293) may be a disincentive for countries to define and assess literacy in a broad way. Ahmed contends that this may only be possible with sustained support from UNESCO and other international organizations.

In conclusion, it is clear that literacy is a complex and multidimensional set of skills that must be defined for specific contexts. Assessing literacy is thus a complex challenge, but one that must be faced by teachers, schools, organizations, and nations in order for them to be able to meet the personal and societal needs for educated, literate populations.

Assessing Responses to Literature

Richard Beach

University of Minnesota, USA

Introduction

This chapter examines issues of assessment related to students' ability to employ literary responses to different literary genres—poetry, novels, drama, short stories, or literary essays. In contrast to assessment of reading comprehension, assessments of literary responses focus on students' "aesthetic responses" related to their experiential transaction with a literary text as opposed to their "efferent responses" related to their reading for information (Rosenblatt, 1995).

This chapter reviews research related to two different uses of assessment of students' literary responses: summative assessment *of* learning literary responses versus formative assessment *for* fostering learning of literary responses (Black, Harrison, Lee, Marshall, & Wiliam, 2003).

Previous Views of Assessment of Literary Responses

A key consideration in any assessment is whether that assessment provides a valid and reliable measure of a certain phenomenon, in this case, the processes of literary response. One aspect of validity is whether an assessment is consistent with the kinds of instruction or ways of learning valued in a certain historical or cultural context. How students are taught literature will influence what they learn and how that learning is assessed. The rise of formalist/New Criticism approaches to learning literature popular from the 1930s to the 1960s emphasized the importance of close readings of figurative language or narrative structures (Beach, Appleman, Hynds, & Wilhelm, 2011). Students' own unique, subjective, individual responses were considered less relevant than their ability to explicate

meanings using close-reading methods. A valid assessment of students' responses within this approach was therefore determined according to students' ability to employ methods of close reading, for example, their ability to analyze how uses of figurative language in a poem conveyed thematic meanings.

Current Views of Summative Assessment of Learning Literary Responses

In reaction to the formalist/New Criticism approaches to teaching literature, reader response theorists of the 1960s and 1970s posited that the meaning of a text is not simply "in" the text as extracted through close readings, but that the meaning of a text was also constituted by an aesthetic, lived-through transaction with a text related to how the literary features and quality of a text shape that transaction (Rosenblatt, 1995). Then, during the 1970s and 1980s, given an increased interest in cognitive-processing models of reading, the focus shifted to defining and assessing the specific response processes involved in reading texts, for example, how readers apply prior knowledge of schema or cognitive structures of narrative to interpret stories. This focus on literary response processes, coupled with the equivalent focus on the composing processes in writing instruction during the 1970s and 1980s, led to the development of more open-ended summative assessment tasks as opposed to assessments based on multiple choice item options.

More recently, the adoption of sociocultural learning theories has led to increased attention in literature instruction on creating engaging classroom social contexts for fostering oral or written development of responses through small and large group discussions and drama activities to help students to collaboratively construct text meaning (Galda & Beach, 2001; Applebee, Langer, Nystrand, & Gamoran, 2003). This emphasis on collaborative construction of text meaning resulted in an increased use of formative assessment tasks related to fostering students' use of oral and written response, particularly through sharing responses in face-to-face or online discussions that built on differences in students' social and cultural perspectives (Lee, 2007; Bowers-Campbell, 2011; Macken-Horarik & Morgan, 2011).

Issues of Validity and Reliability in Summative Assessment of Literary Responses

Any summative assessment of students' literary responses seeks to employ tasks that provide a valid and reliable measure of students' ability to produce open-ended literary responses. These assessments therefore need to go beyond the use of multiple choice reading comprehension tests which assume that there is a definitive "correct" answer, an assumption inconsistent with reader response theories (Rosenblatt, 1995; Galda & Beach, 2001).

The use of these standardized reading assessments as mandated by the No Child Left Behind law has assumed that these tests provide incentives for

improving reading instruction (Hout & Elliott, 2011). If the results of reading tests are not positive, then teachers and their schools would be more motivated to improve their reading instruction. However, a research review by the National Research Council found that standardized testing provides few incentives for improving reading instruction, and, in some cases, has negative incentives in terms of lowering graduation rates (Hout & Elliott, 2011).

Use of these mandated, high stakes assessments also narrows literature instruction to reading-comprehension test preparation. A survey of 182 preservice and 254 practicing English teachers in the UK found that the adoption of the “Framework for English” curriculum framework and accompanying standardized assessments limited their literature instruction to addressing more narrow objectives associated with preparing students for multiple choice assessments (Goodwyn, 2010). The teachers reported that the assessments fostered an instructional focus on “analytic” and “formal” responses rather than on “personal” or “creative” responses consistent with a reader response approach. Another study of classroom instruction of a required novel across different 10th grade English classes in a Chicago high school documented the influence of testing on their instruction (Anagnostopoulos, 2003). In discussions of the novel, interpretation was limited to students having to accept the teacher’s or author’s perspectives as interpretations more likely to be consistent with reading test item answers.

Open-Ended Standardized Assessment of Literary Responses

In contrast to the use of these standardized reading comprehension tests, summative assessment of literary responses involves open-ended tasks designed to determine students’ ability to:

- describe their transactional engagement with a literary text;
- recount or retell narrative events by elaborating on the details of these events;
- interpret the consistent uses of figurative language, rhyme, and rhythm to convey meanings;
- explain characters’ actions/dialogue in terms of traits, knowledge, beliefs, plans, and goals;
- infer or adopt speakers’ or characters’ perspectives to define those speakers’ or characters’ beliefs, attitudes, and stances;
- infer social and cultural conventions and norms constituting the world of a literary text;
- interpret thematic and symbolic meanings of texts;
- apply background cultural experiences and knowledge to interpret thematic and symbolic meanings of texts;
- judge the aesthetic quality of texts in terms of their inventiveness or originality of language use;
- infer connections between texts based on similarity in genre features, themes, ideology, or literary period;
- analyze the characters’ and authors’ cultural and ideological perspectives.

Any valid measure of students' ability to employ these response processes needs to employ open-ended oral and written responses that require students to formulate their own interpretations.

At the same time, employing open-ended responses poses the challenge of achieving high inter-rater reliability between judges analyzing literary responses. However, with appropriate training and clarification of criteria, high inter-rater reliability can be achieved (Burgin & Hughes, 2009). An analysis of judges' scoring of readers' writing samples found relatively high reliability, suggesting that open-ended items could be used in lieu of standardized multiple choice tests for the purpose of summative assessment (Burgin & Hughes, 2009).

National Assessment of Educational Progress (NAEP) Achievement Tests

Another challenge in designing authentic or ecologically valid summative assessments of students' literary responses has to do with the degree to which these assessments are consistent with the kinds of literature learning occurring within specific classroom or school contexts, as well as what teachers value in terms of their own approaches to teaching literature.

One significant standardized assessment of students' literary responses is the NAEP reading assessment that has been administered since 1974 every two years at grades 4, 8, and 12 (National Center for Education Statistics, 2011). The NAEP reading assessment attempts to employ assessment items consistent with the kinds of literature instruction tasks found in schools. And, in contrast to many reading assessments, the NAEP reading assessment has a relatively high number of open-ended items requiring students to write their responses to a literary text. (An alternative international assessment, the Program for International Student Assessment or PISA, has fewer items focused on literary responses than does the NAEP reading assessment.)

The NAEP reading framework aligns specific assessment questions to "cognitive targets," defined as mental processes or kinds of thinking: locating or recalling information; integrating and interpreting what students have read, for example, explaining character motivation; and critiquing or evaluating what they have read. For example, for the 2011 NAEP assessment at the 4th grade level, for a measure of locating or recalling information, students were asked to read a story excerpt and respond to the following prompt: "At the beginning of the story, when some of the boys point and laugh at Daisy, she thinks, 'We'll see about that.' What does this tell you about Daisy?" (National Center for Education Statistics, 2011, p. 28). An "acceptable" response, provided by 63% of 4th graders nationwide, involved identifying the character traits, while an "unacceptable" response involved identifying story information that was not a character trait or other irrelevant story details. Another open-ended item stated: "In the story, Daisy's father describes her as 'tough.' What are two other ways to describe Daisy's character? Support your answer with information from the story." "Extensive" responses, as formulated by 12% of students nationwide, provided two character traits, with supporting information. "Essential" responses, as formulated by 22% of students, provided one character trait with supporting information. "Partial" responses consisted of only "a text-based generalization about Daisy's character

but did not support it with information from the story,” while “Unsatisfactory” responses consisted of “incorrect information or irrelevant details” (p. 30).

This analysis of the level of students’ performance provides useful information related to the need for certain kinds of instruction. Based on 4th graders’ overall performance across all items on the 2011 NAEP, which did not change significantly between 2009 and 2011 (National Center for Education Statistics, 2011), 67% of 4th graders were categorized as at or above the “Basic” category, meaning that they “should be able to make simple inferences about characters, events, plot, and setting. They should be able to identify a problem in a story and relevant information that supports an interpretation of a text” (National Center for Education Statistics, 2011, p. 22). A total of 34% were categorized as in the “Proficient” category, meaning that they should be able to “identify implicit main ideas and recognize relevant information that supports them . . . judge elements of authors’ craft and provide some support for their judgment [and] analyze character roles, actions, feelings, and motives” (p. 23). And, 8% of 4th graders were categorized as in the “Advanced” category, meaning that they should be able to

use story events to support an opinion about story type to identify the theme in stories and poems and make complex inferences about characters’ traits, feelings, motivations, and actions. They should be able to recognize characters’ perspectives and evaluate character motivation. Students should be able to interpret characteristics of poems and evaluate aspects of text organization. (p. 23)

These results indicate that only one third of 4th graders were able to engage in analysis of characters’ actions or interpret thematic meanings, results that have implications for the need for an increased focus on fostering literary analysis and interpretation at the elementary school level that go beyond basic reading comprehension inferences.

The NAEP reading assessment also provides educators and the public with some understanding of changes in students’ reading ability over time, particularly in terms of disparities in learning related to differences in race and class. For example, despite an increased focus since 2002 on reading instruction given No Child Left Behind mandated reading tests, the NAEP reading scores have been relatively flat since 1992 (National Center for Education Statistics, 2011). This lack of change in test scores raises questions about the degree to which these reading tests have succeeded in improving reading since 2002 (Hout & Elliott, 2011).

Limitations of Open-Ended Writing Assessment Items

At the same time, the use of open-ended writing assessment items raises validity and reliability issues associated with the influence of students’ language proficiency on their performance. On the 2011 NAEP reading tests, nationwide, 4th grade Hispanic students’ scores were 24 points lower than those of White students, and the scores of 8th grade Hispanic students were 21 points lower than those of White students—differences that were statistically significant (National Center for Education Statistics, 2011). This gap between English language learner (ELL) and non-ELL students raises questions about the influence of English language proficiency on the students’ performance. ELL students’ ability to employ

certain literary response processes or strategies do not readily transfer from L1 to L2 reading in that students need more than simply L2 linguistic ability to interpret L2 literary texts (Bernhardt, 2005).

The language of assessment tasks employed in standardized reading assessments itself can also challenge ELL students. A word frequency analysis of language employed in state assessments indicated a high percentage of words that would be unknown to ELL students (Menken, 2010).

Even if ELL students grasp the meaning of the task prompt, they have difficulty expressing their interpretations in writing as a function of their language proficiency. Analysis of New York City 9th and 10th grade ELL students' reflections on their performance on a standardized assessment writing task indicated that 85% noted challenges related to translating to achieve the conventions of formal written English, as well as generating ideas (48%) and considering audience needs (26%) (Llosa, Beck, & Zhao, 2011). Having to focus primarily on translating and encoding their thoughts in a different language for a decontextualized audience in a testing context poses difficulty when faced with a time limit to simultaneously plan, organize, translate, monitor, and revise a text to generate coherent written responses (Bernhardt, 2005; Llosa et al., 2011; Urlaub, 2011).

Another limitation of the use of open-ended writing items is the conflation of reading versus writing ability (Bernhardt, 2005; Llosa et al., 2011; Marshall, 2011). Students' low writing ability may adversely influence any valid measure of their reading ability. While they may experience relatively sophisticated interpretations when responding to a text, they may lack the writing skills needed to adequately express their responses in writing, particularly if they are constrained by a limited time to write (Marshall, 2011).

Another limitation in the use of open-ended writing tasks involves the use of a single writing sample to make valid generalizations about a student's ability in responding to literature. Students' performance across different writing tasks varies according to their engagement or interest in the literary text, their prior knowledge of the content of a particular text, or their ability to adopt the text genre (expository, argumentative, narrative, descriptive) employed with an assessment task (Anagnostopoulos, 2003; Burgin & Hughes, 2009; Graham, Hebert, & Harris, 2011). A review of research on the validity and reliability of the use of a single writing sample indicated that, in six studies, there were statistically significant differences in writing quality on different expository, argumentative, narrative, and descriptive tasks (Graham et al., 2011). And, in five studies, there were low correlations for performance on different genre tasks, suggesting that using just one sample does not provide a valid and reliable measure of students' writing ability, and suggesting the need for use of multiple writing tasks (Graham et al., 2011).

Alternative Forms of Summative Assessment of Literary Responses

These limitations suggest the need to employ alternative forms of summative assessment of literary responses to achieve high levels of validity and reliability. There is a need to employ writing tasks and prompts that are designed to support

students who have difficulty transferring their reading responses into a written interpretation (Bernhardt, 2005; Llosa et al., 2011; Marshall, 2011). This includes providing students with an extended period of time to initially generate informal notes based on their responses, as well as scaffolding prompts to assist them in organizing those notes into a draft, and then allowing them time to revise and edit their draft. Students also benefit from having specific criteria as to how their writing will be assessed, criteria that should support their generation of notes, organization of their draft, and revising and editing that draft.

There is also a need for assessments to be consistent with the highly contextualized, open-ended response activities employed in classrooms versus the more limited writing tasks employed in standardized assessments. This tension was evident in analyses of the use of test items related to writing about Shakespeare plays employed in the Standard Assessment Tasks (SATs) that were used in Britain up to 2008 (Marshall, 2011). In their classrooms, students participated in open-ended tasks, studying Shakespeare through drama activities or responding to film adaptations. Students were highly engaged in these drama and film production activities because they had a sense of producing interpretations for specific audiences in creative ways. In contrast, in the SATs, students were limited to narrowly defined, decontextualized tasks in which they had no sense of any actual audience for their responses. Further, to prepare students for the SATs, teachers resorted to highly focused questions typically found in the assessments, a focus that undermined students' potential engagement in the plays (Marshall, 2011).

In critiquing the effects of these standardized assessments on literature instruction, Harrison (2004) argues for an alternative, "evidence-based," "responsive assessment" model that involves uses of portfolios for collecting evidence that is consistent with teachers' instructional practices and that provides teachers with useful information about students' literary responses. One advantage of portfolios is that they contain multiple examples of students' work over time rather than being limited to one single piece of writing. Students also select certain illustrative samples of their writing and reflect on the strengths and weaknesses of these writing samples. Comparing initial with later writing samples in a portfolio provides evidence of changes in students' work over time.

One primary objection to the use of portfolios for assessment purposes is the lack of reliability in judges' inter-rated agreement in scoring writing samples. Contrary to the critique of the difficulty achieving high reliability in scoring assessments, Harrison (2004) cites the example of a portfolio-based assessment of British 16-year-old students' work in English language and literature collected over a two-year period that was regarded as reliable and valid by universities, parents, and employers.

One major future development in the use of standardized assessment of literary responses involves the development of new multistate assessments for use in 2014 associated with the reading and math Common Core State Standards adopted by 44 US states in 2010 (National Governors' Association Center for Best Practices, Council of Chief State School Officers, 2010). These new multistate assessments are being developed by two consortia, the Smarter Balanced Assessment Consortium (SBAC, <http://k12.wa.us/smarter/default.aspx>), which includes 30 states,

and the Partnership for the Assessment of Readiness for College and Careers (PARCC, www.achieve.org/PARCC), which includes 25 states.

Given a major focus on responding to literature in the Common Core reading standards, the development of these assessments will have a major influence on the instructional practices in literature associated with the adoption of these standards. The open-ended literary interpretation items in these assessments will employ computer-based scoring, which represents a positive development in terms of a focus on open-ended responses, but also raises questions about the validity and reliability of computer scoring of students' writing.

Current Views on Formative Assessment of Oral Literary Responses

In contrast to summative assessment, formative assessment is used to provide students with ongoing feedback to enhance their learning in employing literary response processes (Black et al., 2003). Teachers draw on a range of different methods and tools for providing formative assessment to individual students, including individual conferences, written comments on students' writing, audio files shared online with students, and checklist feedback based on rubrics.

In providing formative assessment of students' oral responses in discussions, teachers provide students with feedback about their:

- amount of participation in a discussion,
- use of written responses about a text to contribute to a discussion,
- use of different response processes (see above list of response processes),
- ability to collaboratively build on and extend peers' responses,
- formulation of their own questions to ask peers,
- reflection on the direction and quality of a discussion (Beach et al., 2011).

Assessing these oral responses presupposes that students have ample opportunity to express and develop their responses. However, in many literature discussions, students are often limited to simply answering teacher questions. One study of hundreds of classrooms nationwide found that, out of every 60 minutes of discussion, only 1.7 minutes were devoted to "open discussion" in which students expressed their own responses (Applebee et al., 2003). Only 19% of teacher questions were open, authentic questions, and, only 31% of the questions asked students to elaborate on their responses. When students are only providing short, unelaborated answers to these questions, they are then assessed primarily in terms of whether they are providing the "correct" answer, as opposed to the degree to which they have employed different response processes, built on and extended peers' responses, or formulated their own questions (Applebee et al., 2003).

Assessing students' oral literary responses therefore requires that teachers employ open-ended discussion questions or activities that foster students' extensive expression of responses so that teachers have enough data to make valid and reliable assessments of individual students' oral responses. Increases in teacher uses of open-ended discussion questions over time resulted in increases not only

in students' elaboration of their *oral* responses, but also in students' level of abstraction and elaboration in their *written* literary responses (Applebee et al., 2003).

Teachers can also enhance the quality of students' discussion contributions by encouraging students to apply their cultural background experience to interpreting texts, leading to assessment of their ability to transfer that background experience to their interpretations, an important response process (Galda & Beach, 2001). For example, students in an urban Chicago school with largely African American students drew on their use of African American Vernacular English (AAVE), figurative/exaggerated language, word play, signifying, repetition, and aphorisms to interpret symbolic language use in Shakespeare's plays (Lee, 2007). Assessment of their ability to transfer their prior cultural knowledge served to validate the importance of their own AAVE language use to interpret figurative/symbolic language in literature (Lee, 2007).

The criteria for assessing students' contributions can also include their ability to collaboratively build on previous students' contributions. To assess high school students' discussion contributions, a checklist was developed based on the criteria related to a student's ability to: make insightful comments that significantly contributed to interpreting a text; refer to specifics from the text and compare and contrast that text to related texts, personal experiences, and social and cultural issues; explain ideas clearly and connect those ideas to others being discussed; clarify a specific point being discussed or elaborate on specific examples from the text; and adopt tentative stances that serve to invite peers to contribute (Beach, Eddleston, & Philippot, 2004, p. 135). For example, when students frame their initial responses as tentative hunches, implying that they are seeking further confirmation and testing out their hunches, peers are more likely to extend and elaborate on their responses than when students adopt a definitive stance about their interpretations (Beach et al., 2004). Providing students with ongoing feedback using this checklist served to enhance the quality of their contributions over time, particularly in terms of collaboratively sharing and building on each other's responses (Beach et al., 2004).

At the same time, while these criteria were appropriate for a particular high school class of relatively advanced students, the use of such criteria needs to be modified according to variation in classroom contexts and students' ability and developmental levels, as younger students with less knowledge of literary conventions will have more difficulty inferring thematic or symbolic meanings than older students (Rezaei & Lovorn, 2010). Consideration of these developmental differences has led to the elaboration of what are defined as "learning progressions" in the Common Core State Standards or trajectories of growth based on assumptions about prototypical grade level differences in students' reading ability and knowledge of literary conventions, reflected, for example, in the Literacy Learning Progressions (LLP) developed in New Zealand (www.literacyprogressions.tki.org.nz).

Assessing Online Oral or Written Discussion Responses

In addition to assessing students' face-to-face discussion responses, teachers also assess students' sharing of responses in online oral or written discussions (Love,

2006; Ruzich & Canan, 2010; Bowers-Campbell, 2011). One advantage of online discussions is that students who are intimidated by sharing thoughts in face-to-face discussions are often more comfortable sharing their thoughts in online discussions (Myers & Eberfors, 2010).

Online discussions also allow for crosscultural exchanges between students from different countries sharing their responses in ways that reflect cultural differences. Teachers then assess students in terms of their ability to adopt certain beliefs or values related to cultural differences. For example, in an online asynchronous crosscultural exchange between college students in the USA and Sweden responding to a short story about a friendship between an American girl and a Swedish immigrant girl, students' responses were assessed in terms of the degree to which they referred to cultural beliefs and values shaping their interpretations, based on the following categories (Myers & Eberfors, 2010, p. 157):

1. asserting an interpretation (or confirming another's interpretation) about the events, actions, identities, or practices in the story;
2. comparing how people in one's own culture might act in a similar way;
3. exploring possible beliefs and values that might contextualize cultural identities or actions, diversify the meaning of the identities or actions, or explain why or how cultural practices exist;
4. seeking comparative information about cultural practices or beliefs and possible explanations for identities and actions from other cultures; and
5. posing self-reflective questions or problems about one's cultural practices, how practices shape beliefs and values, and how identities and actions might be transformed.

Teachers can also use discussion transcripts to provide feedback to students, and students can also use a transcript for self-assessment. In one study (Ruzich & Canan, 2010), teachers assessed students' online interactions about two novels in terms of the quality of their questions, their reactions, the length of discussion, and the quality of interpretations, and gave feedback that enhanced the quality of the students' discussions. Another study of online literature circles employed the criteria of promoting group membership related to fostering group harmony and the degree to which students negotiated text meaning in the discussion (Bowers-Campbell, 2011).

Teachers can also use transcripts to assess students' adoption of critical stances in responding to texts. An analysis of Australian secondary students' online responses examined students' adoption of three different types of stances: affective/subjective, ethical/moral, and critical analysis of literary and linguistic structures related to the text's social purpose (Love, 2006). Analysis of discussions over a seven-week period indicated that over time, while students were more likely to adopt affective and ethical rather than critical stances, the degree to which they adopted critical stances increased through exposure to their peers' adoption of critical stances in the online discussions.

However, there are multiple challenges to assessing online discussions. One challenge in assessing students' contributions is the large amount of data to

review, the difficulty identifying specific individual students' contributions, and the lack of valid and reliable rubrics for assessing online interactions (Ruzich & Canan, 2010).

Current Views on Formative Assessment for Written Literary Responses

Teachers also employ formative assessment in responding to students' written literary responses. One limitation of teacher feedback to students' writing is that, in responding to students' draft writing, teachers often focus prematurely on correcting errors associated with the editing phase of composing, as opposed to responding to the formulation of ideas in a draft (Ferris, Brown, Liu, & Stine, 2011). As with oral literary responses, teachers can provide descriptive feedback at the drafting phase through individual conferences, written comments, or audio recordings to foster students' self-assessing and revision of drafts (Beach & Friedrich, 2006; Ferris et al., 2011).

The success of providing this descriptive, reader-based feedback depends on students' ability to self-assess by identifying their use of certain literary response processes, suggesting the value of instruction in reflecting on the use of these response processes (Olson, Land, Anselmi, & AuBuchon, 2010; Lewis & Ferretti, 2011). An analysis of 55 secondary teachers' instruction in helping their ELL students identify their uses of literary response processes found that the students had significantly higher essay-writing quality, higher statewide writing assessment scores, and higher scores in English placement exams at a local community college than students not receiving this instruction (Olson et al., 2010). In another study, to assist high school students in self-assessment, students were provided with a mnemonic ("THE READER") indicating the need for a thesis (THE), reasons supporting their thesis (REA), use of details (D) as illustrations of those reasons, explanations (E) of how quotes and references are related to their reasons or thesis, and a summary review (R) of their main points in a conclusion (Lewis & Ferretti, 2011). Use of this self-assessment mnemonic resulted in higher quality argumentative essays that included more textual evidence to support their literary interpretations.

One alternative to teacher feedback is to train students to provide peer feedback; without extensive training, students' peer feedback is often not productive (Beach & Friedrich, 2006). Teachers in a British school trained their year 10 students to engage in peer feedback in writing about *Romeo and Juliet* (Marshall, 2011). Students wrote their comments in the margins of their peers' drafts, comments such as "good thoughts and opinions from Romeo on the situation" and "Too brief 'Mercutio wants to fight' . . . 'then they were fighting.' You need more info and emotions in between what causes them to fight do they threaten each other first" (Marshall, 2011, p. 66). Analysis of the students' revisions indicated that this peer feedback led to substantive revisions. The effectiveness of the students' peer feedback was attributed to the teachers' instruction in and modeling of their own use of descriptive, dialogic feedback that was then emulated by the students in their peer feedback.

Metalinguistic Awareness of Literary Language Use

Fostering students' ability to self-assess includes helping them acquire a metalinguistic awareness of their own uses of language as well as of the use of literary language in texts. The fact that students can adopt a metalinguistic stance about their own literary responses enhances their need to revise or elaborate on their responses. A study comparing Dutch 10th grade students identified as good versus weak readers found that good readers were better able to metacognitively reflect on their uses of different response processes leading them to elaborate on their responses to a greater degree than less able readers (Janssen, Braaksma, & Rijlaarsdam, 2006).

Instruction in metalinguistic awareness includes identifying how language use or adoption of multiple voices in literary texts and in their own responses reflects certain beliefs or ideological stances. A group of 17–18-year-old students in Queensland, Australia, were taught to analyze authors', characters', critics', and their own use of intertextual references to or double-voicing of other authors', characters', or their peers' prior claims or language use (Macken-Horarik & Morgan, 2011). For example, in the student's response "Why does my interpretive community value something of a type it rejects? It had motifs and narrative structure used in all Austen novels, and was therefore considered 'unoriginal'" (p. 147), students learned how the use of "unoriginal" deliberately placed in quotes represents an intertextual reference to a critic's use of that word. Interpreting this use of intertextual references and double-voicing of others' language use led students to infer how authors', characters', critics', or their own language use was constituted by certain beliefs and ideological stances. Analysis of changes in students' written responses noted that the students moved from initially adopting individually centered voices to adopting alternative, multiple voices that included more intertextual references or double-voicing of prior language use. Making these intertextual references led students to critique the beliefs or ideological stances represented in authors', characters', or their own beliefs or ideological stances.

Metalinguistic awareness can also be enhanced by having students compose their own literary texts. By composing their own literary texts, students are reflecting on how their use of language functions to construct characters, settings, or story events. One study of students in a college German literature class found that their rewriting of German short stories helped students become more aware of the formal literary conventions operating in the German stories (Urlaub, 2011). By assuming the role of a character in the story who wrote a letter to another character in the same story or a fictional diary entry, students engaged with reflecting on the ways in which the use of the German language served to construct certain social and cultural perspectives, requiring a metalinguistic ability to employ L2 language for literary purposes.

Employing Rubrics for Formative and Summative Assessment of Written Literary Responses

There are a number of different types of rubrics for use in assessing students' written literary responses, for both formative and summative purposes, including

holistic and analytic rubrics. Holistic rubrics involve an overall rating of students' written literary response. In one study, students' written essays were assessed based on the students' level of abstraction (0 = generalization without any development, 1 = record, 2 = report, 3 = generalized narrative/descriptive information, 4 = low level analysis, 5 = analysis) and the level of elaboration (1 = unsatisfactory, 2 = minimal, 3 = adequate, 4 = elaborated) (Applebee et al., 2003).

In other cases, analytic rubrics involve specific criteria based on different levels of a certain type of literary response, for example, different levels of literary interpretation as evident in the use of Hillocks's (1980) "Hierarchy of Skills in the Comprehension of Literature" scale:

Level 1: Comprehend basic stated information that is prominent or repeated in the text.

Level 2: Understand key details important to the plot but less prominent in the text.

Level 3: Understand basic stated relationships between bits of information in the text.

Level 4: Understand simple implied relationships in the text.

Level 5: Understand complex implied relationships in the text.

Level 6: Understand the author's generalization.

Level 7: Understand the structural generalization. (p. 55)

This scale moves from literal level (levels 1–3) to inferential level (levels 4–7) interpretation. The higher, inferential levels require that students go beyond literal inferences to interpret relationships between characters' actions, beliefs, and goals, as well as story events, to then make generalizations about the author's theme and how the overall story line structure conveys that theme. However, one limitation of this scale is that it does not consider interpretations associated with a reader's subjective experience with a text or application of related texts or experiences (Rosenblatt, 1995; Galda & Beach, 2001).

This scale also does not consider how the quality of students' writing about literary texts can vary according to their knowledge of literary genre conventions constituting understanding of poetry, stories, novels, drama, and nonfiction essays (Marshall, 2011). Students may have less difficulty comprehending stories or novels because they draw on their knowledge of everyday narrative anecdotes to interpret story development (Lee, 2007). Students may have more difficulty interpreting poetry given their lack of knowledge about the uses of figurative language, although these differences will vary based on individual texts (Lee, 2007).

There is considerable debate about the validity and reliability of use of these scoring rubrics in classrooms and summative assessment (Rezaei & Lovorn, 2010). On the one hand, they can provide students and teachers with specific criteria based on a continuum of successful versus less successful writing. They work particularly well when teachers provide instruction and practice scoring of sample writing, as well as when students are involved in generating criteria themselves and then practice applying those rubrics to sample writing (Rezaei & Lovorn, 2010).

On the other hand, they can have low reliability related to alternative interpretations of concepts such as “effective organization,” “insightful interpretation,” and “elaboration of ideas” (Rezaei & Lovorn, 2010). The previously cited review of research on writing assessment (Graham et al., 2011) examined the issue of judges’ scoring reliability, finding that, in nine studies using holistic ratings, the scores were reliable (70% or better agreement) for 78% of the nine studies, and, for 12 studies using analytic scales, only 50% were reliable. While this research focused on standardized writing assessment using judges with some training, the same issues can apply to the validity and reliability of teachers’ use of rubrics.

Summary

This review suggests that effective summative assessment of literary responses involves the use of:

- open-ended writing tasks as employed in the NAEP reading assessments in lieu of multiple choice items so that students can formulate their responses; at the same time, use of open-ended tasks needs to take into account the influence of differences in language proficiency, requiring development of prompts and tasks designed to accommodate for variations in language proficiency;
- alternative forms of assessment including use of portfolios for students to collect examples of their written responses and to then reflect on changes in their responses over time.

This review also suggests that effective formative assessment of oral literary responses involves the use of:

- effective facilitation of discussions so that students have opportunities to express their oral responses and teachers can assess those responses;
- criteria or rubrics for students’ self-assessing their oral responses to clarify expectations for how to effectively contribute to discussions, particularly in terms of their ability to collaboratively build on each other’s responses in a discussion;
- online discussions that provide recordings or transcripts of discussion for use in assessing students’ contributions.

Finally, this review suggests that effective formative assessment of written literary responses involves the use of:

- engaging, open-ended writing assignments with clearly specified criteria for defining effective interpretations;
- descriptive feedback to foster student self-assessing and revision of their writing through individual conferences, written comments, or audio recordings, as well training peers to provide feedback;
- metalinguistic awareness of uses of language in a text or in students’ own writing.

Assessing Grammar

James E. Purpura

Teachers College, Columbia University, USA

Introduction

Although it is generally accepted that much of second language acquisition (SLA) happens incidentally while learners are focused on meaningful input and engaged in interaction, the explicit teaching of a second or foreign language (L2) and the assessment of a learner's development of grammatical ability have always been of critical concern for L2 educators. This interest in grammar is bolstered by findings in SLA, showing that while all instruction does not impact learning positively, learners receiving explicit, form-based instruction are more likely to optimize natural learning processes, develop grammatical ability at more accelerated rates, and achieve higher levels of L2 proficiency (Ellis, 2008) than learners not receiving form-focused instruction. This is especially so if L2 input is rich, abundant, and meaningful; grammar explanations and corrective feedback summon awareness of patterns previously undetected; and instruction is sequenced to promote processing and skill acquisition.

L2 testers have also acknowledged the importance of grammar in assessing communicative language ability (Purpura, 2004). Interest in grammar assessment stems from the fundamental role that it plays in predicting the ability to communicate precisely and effectively in the L2, and from the potential it has for providing learners and teachers with information, at various grain sizes, on the grammar needed to improve. Several researchers (e.g., Hulstijn, Schoonen, de Jong, Steinel, & Florijn, 2012) are also interested in grammar assessment for the potential it offers in helping to characterize L2 knowledge in different contexts, or at diverse proficiency levels, as referenced by some external standard, framework, or proficiency scale. Finally, interest in grammar assessment has increased considerably as a result of the potential role that grammatical

features play in developing speech and writing recognition and processing technologies on the one hand, and automated scoring and feedback systems of L2 assessments on the other (Xi, 2010).

The current chapter examines how grammatical assessment has been conceptualized, implemented, and researched over the years. It also discusses challenges and future directions of grammar assessment.

Previous Conceptualizations of Language Knowledge and Research: Focusing on Grammar

While grammar as a construct has been conceptualized in many different ways with reference to one or more linguistic frameworks (e.g., structural linguistics), L2 educators have generally defined “grammar” as a set of structural rules, patterns, norms, or conventions that govern the construction of well-formed and meaningful utterances with respect to specific language use contexts. And most L2 educators would agree that the ability to generate well-formed and meaningful utterances in context-rich or impoverished situations (e.g., a traditional discrete-point grammar test) depends on a range of linguistic resources involving phonology, morphology, syntax, semantics, discourse, and pragmatics.

Drawing on eclectic but principled descriptions of grammar for educational purposes, several L2 testers have proposed conceptualizations of L2 proficiency in which grammatical knowledge has played a consistently prominent role. The resulting conceptualizations of grammatical knowledge have then been used as a basis for constructing grammar assessments. In other words, they have been used to describe how grammatical knowledge might be represented in a learner’s head, described at different proficiency levels, defined with respect to some given assessment purpose, and importantly, conceptualized within a comprehensive framework of L2 proficiency. I will discuss how grammatical knowledge has been defined theoretically in three such conceptualizations before describing four approaches to grammar assessment.

Lado’s Conceptualization of Language Knowledge

In an insightful attempt at describing L2 communication, Lado (1961) proposed a model of L2 proficiency in which language is characterized in terms of two individuals who use linguistic *forms* in some variational distribution to create word and sentence *meanings*. These basic elements are then used as resources for communicating cultural and individual meanings. The form–meaning elements for Lado involve phonology, structures, and the lexicon. Cultural meanings refer to concepts or notions associated with a specific culture (e.g., “American breakfast”) or speech community (e.g., “business meeting” at a conference). And individual meanings are viewed as outside the culture, referring to the personal associations individuals make with words and concepts (e.g., personal associations with “Christmas”). Lado’s depiction of language, culture, and the individual is presented in Figure 6.1.

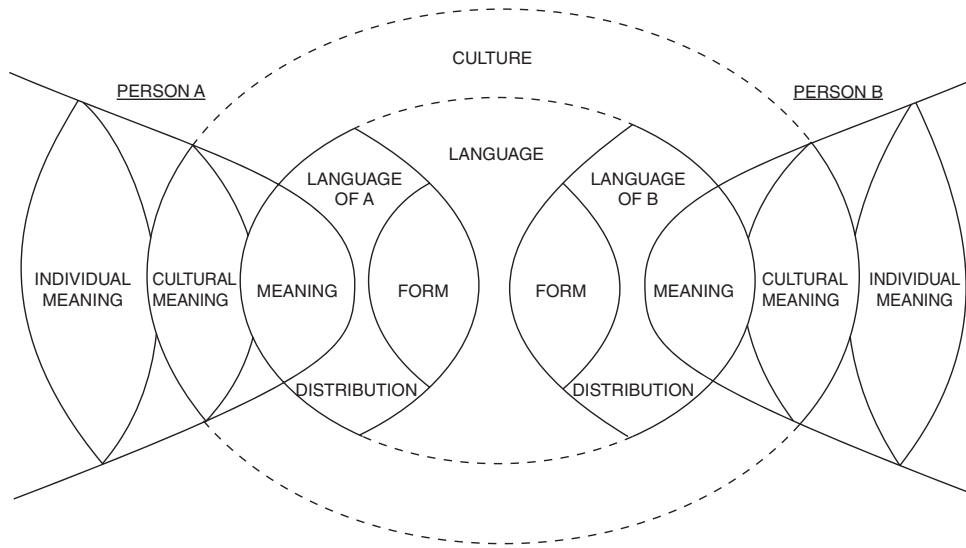

Figure 6.1 Lado's conceptualization of language knowledge: Language, culture, and the individual (Lado, 1961, p. 6). © Longman. Reprinted with permission

Lado's view of L2 proficiency was operationalized in terms of a skills-and-elements approach to assessment. This approach viewed L2 knowledge in terms of the language elements (i.e., knowledge of phonology, structures, lexis), measured in the context of the language skills (i.e., reading, writing, speaking, listening). The individual elements were taken to be the principal building blocks of L2 proficiency—the assumption being that L2 proficiency was achieved by internalizing simple, discrete components of the L2 before acquiring more complex units, the accumulation of which constituted “proficiency.” This view led to a discrete-point approach to assessment, where discrete linguistic elements (e.g., 20 multiple choice [MC] grammar items) are presented to learners and scored dichotomously for accuracy (e.g., 1 for a right answer, 0 for a wrong one). The scores from the correct responses are then aggregated to produce an overall proficiency estimate.

Probably the best example of a test grounded in Lado's skills-and-elements conceptualization of L2 proficiency is the Comprehensive English Language Test (CELT) (Harris & Palmer, 1986). The grammar subtest assessed five structures: (1) choice of verb forms and modals; (2) form and choice of nouns, pronouns, adjectives, and adverbs; (3) word order; (4) choice of prepositions; and (5) formation of tag questions and elliptical responses. The subtest consisted of 75 discrete-point, MC items with four response options.

The listening section was also organized around different grammatical structures, but assessment focused on the meaning of those structures. For example, the first task aimed to measure the ability to understand *wh*- and *yes/no* questions. The second focused on the comprehension of conditionals, comparisons, and time and number expressions. And the third task targeted the comprehension of lexical

items in two-turn conversations by asking examinees to respond to detail questions (e.g., “on what day”). In sum, the CELT was designed to measure language elements in reading and listening tasks.

Lado’s (1961) theoretical conceptualization of proficiency was truly visionary. However, the operationalization of proficiency as knowledge related to discrete structural and lexical items presents a highly restricted view of the construct. Most L2 educators would now want to assess how grammatical forms are associated with a range of semantic meanings, not just lexical meanings, and they would want to target the ability to understand and use pragmatic meanings, where context is a critical resource for meanings specific to a situation. Nonetheless, Lado’s approach to grammar assessment remains highly useful for measuring isolated forms, when this is the assessment goal.

In terms of determining what grammatical content to put on grammar tests, Lado (1961) argued that contrastive analysis and transfer from the first language (L1) to the L2 should play a major role in item selection. He maintained that when structures in the L1 and L2 have the same form, meaning, and usage distribution (e.g., the present perfect in French and Italian), learning is assumed to be easier. However, when these features differ across the L1 and L2, the structures are assumed to be more difficult to learn. In sum, Lado believed that L2 assessment should be rooted in SLA theory.

Bachman and Palmer’s (1996) Conceptualization of Language Knowledge

Another insightful and well-known conceptualization of L2 proficiency in which grammatical knowledge plays a prominent role was proposed by Bachman and Palmer (1996). They described language use in terms of an interaction between the individual characteristics of the language user on the one hand and the context of language use on the other. The characteristics of the user are further defined as the interaction among an individual’s language ability (i.e., language knowledge and strategic competence), topical knowledge (e.g., information on how to book a flight online), and affective schemata (e.g., motivation). Language knowledge is defined in terms of organizational knowledge (involving grammatical and textual knowledge) and pragmatic knowledge (comprising functional and sociolinguistic knowledge). In this framework, grammatical knowledge refers to how individual utterances or sentences are organized with respect to knowledge of phonology or graphology, vocabulary, and syntax. Textual knowledge relates to how utterances or sentences are organized to form texts, and involves knowledge of cohesion and rhetorical or conversational organization. Finally, grammatical and textual knowledge are seen as resources for being able to communicate the goals of a language user in a given L2 use setting. Bachman and Palmer’s conceptualization of language knowledge is presented in Figure 6.2.

Bachman and Palmer’s model of language knowledge has been used as a heuristic for guiding test development in numerous L2 tests throughout the world, including the Test of English as a Foreign Language (TOEFL) and the Cambridge exams.

Current Conceptualizations of Language Knowledge

A more recent depiction of L2 proficiency was proposed by Purpura (2004). His conceptualization of L2 proficiency was inspired by L2 assessment theory, SLA research, and years of experience in L2 teaching and testing. From the L2 assessment perspective, Purpura's conceptualization of L2 proficiency was inspired by the theoretical models of proficiency proposed by Lado (1961), Canale and Swain (1980), Bachman and Palmer (1996), and many others, described in the previous sections. These models helped identify the components of L2 proficiency. Purpura's model was also influenced by Larsen-Freeman's (1991) and Rea-Dickins's (1991) conceptualizations of L2 proficiency as form, meaning, and use in the context of teaching and testing communicative grammar.

From the SLA perspective, L2 proficiency in Purpura's view acknowledges the research on the connections between grammatical forms and their associated semantic meanings (e.g., VanPatten, Williams, Rott, & Overstreet, 2004). Rather than questioning the nature of these two dimensions, SLA research is more concerned with the behavioral and cognitive processes that allow form–meaning mappings to occur and be maintained. Findings from this research have generally shown that low proficiency learners tend to learn simple forms or parts of forms based on the need to communicate lexical meanings (e.g., *going to* vs. *will* to express future time), thereby making learners less likely to process how more complex forms (e.g., *going to*) might encode morphosyntactic meanings such as modality or aspect. Advanced learners, on the other hand, seem more capable of using the linguistic and situational context to connect how forms encode semantic or pragmatic meanings (Bardovi-Harlig, 2000). In sum, as Larsen-Freeman (1991) always reminds us, learners vary on which dimension of grammatical knowledge is acquired on the acquisitional pathway—a finding which, I believe, has serious implications for L2 assessment, and for grammar assessment in particular.

Finally, and just as important, Purpura's conceptualization of L2 proficiency was strongly influenced by years of observing the kinds of linguistic challenges (in terms of forms, meanings, and uses) that learners exhibit in classrooms when attempting to learn an L2 (Purpura & Pinkley, 1991) and on language assessments

when attempting to respond to language tasks—especially as this regards the provision of feedback for formative purposes.

Purpura's Conceptualization of Language Knowledge

Purpura (2004, 2012) describes language knowledge as the interaction between *grammatical knowledge* and *pragmatic knowledge*. Grammatical knowledge is further defined in terms of a range of linguistic forms (e.g., *-s* affix; word order) and semantic meanings associated with these forms, either individually (e.g., plurality with a noun; time reference with a verb) or collectively (e.g., the overall literal meaning of the utterance). These forms and meanings occur at the subsentential, sentential, and suprasentential or discourse levels. Specifically, the forms and meanings can be categorized with respect to (1) phonology or graphology, (2) lexis, (3) morphosyntax, (4) cohesion, (5) information management (e.g., topic or comment), and (6) interaction (e.g., metadiscourse markers like “uh-huh”). In this conceptualization, the form–meaning mappings are assumed to provide fundamental resources for the ability to convey and understand the literal and intended meaning of utterances in L2 use situations. They also provide critical resources for conveying and understanding pragmatic meanings in L2 use, where context plays a major role in interpreting meanings expressed implicitly.

Consider, for example, the form and meaning dimensions of L2 proficiency. The plural *-s* affix added to a noun in English is a grammatical form associated with plurality—its semantic meaning. These two dimensions of the *-s* affix form may present challenges to learners whose L1s use different forms to convey plurality (e.g., Italian uses *-i* or *-e*) or whose L1s have different notions of plurality (e.g., plurality in Arabic treats two entities differently from more than two entities). As a result, English-speaking students learning Italian typically are assumed to have no problem understanding the notion of plurality in Italian, but may encounter challenges using plural forms correctly.

Given learning challenges relating to these two dimensions, it is important for testers to think about test content for grammar assessments in a systematic and principled way, so that specific assessments can be designed for different test purposes. Thus, as described above, we can think of grammar test content in terms of grammatical forms and meanings at the sub(sentential) level (i.e., phonology, lexis, morphosyntax) and at the suprasentential level (i.e., cohesion, information management, interaction). Such a view accommodates both sentence-level and discourse-level spoken and written grammar. Thus, drawing on a comprehensive framework of grammatical knowledge, a tester may choose to measure only the form dimension, understanding that without the meaning dimension, claims can only be made about knowledge of grammatical form, but not about grammatical knowledge in general. In other words, the ability to add the *-ed* affix to verbs does not necessarily mean a learner knows what the past tense verbs mean or how they can be used.

In developing the Oxford Online Placement Test, Purpura and his colleagues used the six categories described above as an organizational frame for creating a taxonomy of test content. They then surveyed English as a second language (ESL) textbooks and pedagogical grammars (e.g., Celce-Murcia & Larsen-Freeman,

Table 6.1 Taxonomy of grammatical forms

Nouns and noun phrases: <ul style="list-style-type: none"> • predeterminers, determiners, post-determiners • nouns (countability, affixation, compounding) 	Pronouns and reference (cohesion): <ul style="list-style-type: none"> • personal, demonstrative, reciprocal • relative, indefinite, interrogative
Verbs, verb phrases, tense and aspect: <ul style="list-style-type: none"> • tense—present, past; aspect—progressive • subject–verb agreement 	Questions and responses: <ul style="list-style-type: none"> • yes/no, <i>wh-</i>, negative, uninverted • tags
Modals and phrasal modals (<i>be able to</i>): <ul style="list-style-type: none"> • forms—present, past, future, perfective, progressive • obligation—<i>should</i>, <i>supposed to</i> 	Conditionals: <ul style="list-style-type: none"> • forms—present, past, future • factual, counterfactual
Phrasal verbs: <ul style="list-style-type: none"> • form—two-word, three-word • separability 	Passive voice: <ul style="list-style-type: none"> • form—present, past, future, perfective • other passives—<i>get something done</i>
Prepositions and prepositional phrases: <ul style="list-style-type: none"> • co-occurrence with verb, adjective or noun—<i>rely on</i>, <i>fond of</i> • spatial or temporal relationships—<i>at the store</i>, <i>at 5</i> 	Complements and complementation: <ul style="list-style-type: none"> • verb + noun phrase + (preposition) noun phrase • infinitive or gerund complements—<i>want (him) to</i>; <i>believe him to</i>; <i>get used to</i> + gerund
Adjectives and adjectival phrases: <ul style="list-style-type: none"> • formation (<i>-ous</i>, <i>-ive</i>) • adjective order—<i>the lovely, little, plastic Cher doll</i> 	Comparisons: <ul style="list-style-type: none"> • comparatives and superlatives • equatives—<i>as/so big as</i>
Logical connectors: <ul style="list-style-type: none"> • relationships of time, space, reason, and purpose • subordinating and coordinating conjunctions 	Adverbials and adverbial phrases: <ul style="list-style-type: none"> • forms—adverb phrase, clause, prepositional phrase • placement—sentence initial, medial, and final
Relative clauses: <ul style="list-style-type: none"> • forms—animate, inanimate, zero, place • subject noun phrase, (in)direct object noun phrase, genitive noun phrase 	Reported speech: <ul style="list-style-type: none"> • backshifting • indirect imperatives or questions
Nonreferential <i>It</i> and <i>There</i> : <ul style="list-style-type: none"> • time, distance, environment—<i>it's noisy in here</i> • existence—<i>there is/are</i> 	Focus and emphasis: <ul style="list-style-type: none"> • emphasis—emphatic <i>do</i> • marked word order—<i>him I see</i>

1999) for grammar points to include in the taxonomy. The resulting taxonomy allowed them to specify what features of grammatical knowledge they wanted on the test, and to balance the content across different categories, so that structures from all the categories could be represented in the test content. A simplified version of this taxonomy appears in Table 6.1.

Besides grammatical knowledge, Purpura's (2004) depiction of L2 proficiency specifies how grammatical forms and their semantic meanings provide resources

for conveying and understanding pragmatic meanings—that is, meanings that occur in language use that are not solely derivable from the literal meanings of words alone or arranged in syntax, but can only be interpreted from a concurrent understanding of the context. For example, the sentence *I'm Italian* changes meanings depending on the context in which it is used. If there were no further context than this sentence (as in many grammar tests), then one would default to the *literal* meaning based on the literal meanings of the words arranged in syntax. The utterance would, therefore, refer to an expression of one's nationality, and would be a plausible response to:

What's your nationality? → *I'm Italian.*

Where are you from? → *I'm Italian.*

The intended, functional meaning of the utterance would be to inform the interlocutor of the speaker's nationality.

In a different context, however, the same sentence could also be a response to:

Do you like red wine? → [smile] *I'm Italian.*

Do you lie about bad pizza? → [condescending look] *I'm Italian.*

In these cases, the response *I'm Italian* would obviously encode more than an expression of nationality. It would simultaneously convey a *sociocultural* association between Italian identity and the presupposition that Italians generally like red wine, or that they are not usually inclined to lie about substandard pizza. Such an utterance could also convey *sociolinguistic meanings* (e.g., informality between friends), and *psychological meanings* (e.g., playfulness). Thus, the utterance *I'm Italian* uses the same grammatical forms to convey literal meaning (i.e., nationality), intended meaning (i.e., to inform), and, other meanings derivable solely from context. Thus, pragmatic meanings are different from, but intrinsically linked to both a learner's grammatical resources and the contextual characteristics of the communicative event.

While this chapter is not specifically about pragmatic knowledge, it is important to distinguish how, in a comprehensive model of L2 proficiency, grammatical forms together with their literal and intended meanings (i.e., grammatical knowledge) provide the fundamental resources for communicating contextual implicatures; metaphor; poetry; social and cultural identity; social and cultural appropriateness—formality, politeness; affective stance—emotionality, irony, humor, sarcasm; and so forth.

Purpura's (2012) theoretical model of language knowledge appears in Figure 6.3.

In order to translate this theoretical model into an organizational framework that can be used flexibly in the design, development, scoring, and validation of grammatical assessments, Purpura proposed an operational model of language knowledge that specifies several types of grammatical forms together with their associated semantic meanings (grammatical knowledge), and a range of possible pragmatic meanings (pragmatic knowledge). The intention was to provide an organized list of features that could be used to design assessments specific to the assessment purpose. In other words, the model could be used to help design and

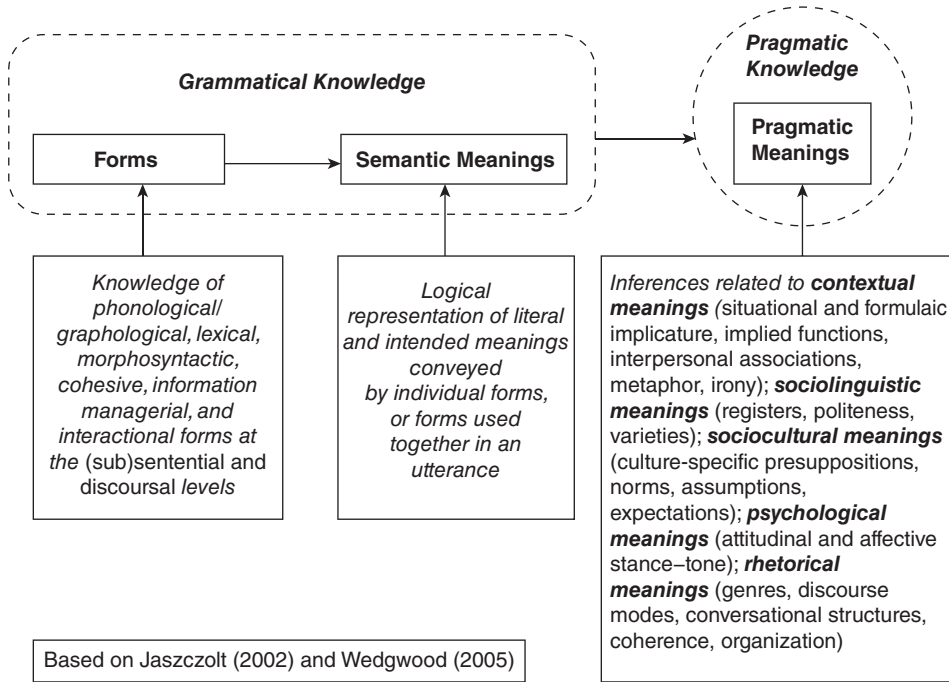

Figure 6.3 Purpura's theoretical model of language knowledge: the grammatical and pragmatic components (based on Purpura, 2012)

score assessments targeting discrete aspects of grammatical knowledge such as lexical forms (e.g., *get rid of*, *different from*) or cohesive meanings (e.g., *therefore*, *however*, *consequently*), should the assessment situation call for it. Or it could be used to design and score grammar assessments targeting the overall meaningfulness of one or more utterances (semantic meaning) and the precision of grammatical resources (forms) used to convey propositions in complex, language use tasks (e.g., the use of the active or passive voice in describing the desalination process). Finally, this model could also serve as a guide for specifying content related to the grammatical and semantic features of L2 production (e.g., accuracy, complexity, meaningfulness, and fluency), or the stages of L2 development (e.g., profiles of features characterizing beginning or advanced learners). Purpura's operational model of language knowledge is presented in Figure 6.4.

While the ultimate goal of grammar assessment is to ascertain a representation of grammatical knowledge in the learner's brain, we need to bear in mind that grammatical knowledge, as one component of language knowledge, combines with many other factors when learners have to use this knowledge to perform tasks involving the four skills. More specifically, grammatical and pragmatic knowledge in a learner's brain (i.e., L2 knowledge) combine with other internal factors (e.g., topical knowledge, sociocognitive ability, personal attributes) to provide the capacity to use this knowledge (L2 ability) to perform tasks (L2 use) involving receptive or productive modalities (L2 skills). The relationships between L2 knowledge, ability, and use appear in Figure 6.5.

Figure 6.4 Purpura’s (2012) operational model of language knowledge

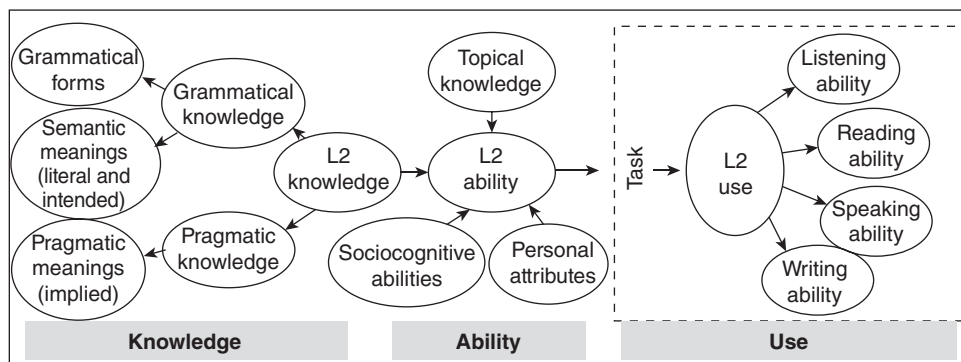

Figure 6.5 Grammatical knowledge as a resource for L2 use

Several studies (e.g., Chang, 2004; Ameriks, 2009; Grabowski, 2009; Kim, 2009; Liao, 2009; Dakin, 2010; Vafae Basheer, & Heitner, 2012) have used Purpura’s conceptualization of language knowledge to examine the nature of L2 grammatical ability in assessment contexts. Some of these studies have examined only the relationships between form and semantic meaning; most, however, have studied form–meaning resources in the context of L2 use. These studies consistently found that the learners’ knowledge of grammatical form was unsurprisingly related to their knowledge of the semantic meaning, and, more generally, that knowledge

of the forms is related to the ability to use them as resources for conveying literal and intended meanings (i.e., ideas, propositions, topics), as well as nuanced pragmatic meanings in context.

For example, Vafaei et al. (2012) examined the trait structure of the grammar section of a placement test, where grammatical knowledge was defined in terms of knowledge of form and meaning. The test consisted of 19 MC form and 12 semantic meaning items, constructed around four themes. The test was administered to 144 participants representing multiple proficiency levels. The results of a confirmatory factor analysis showed that the most plausible model of the test construct consisted of two traits (form and meaning) and four methods (the test themes). Interestingly, this study not only confirmed that the form and meaning traits were separate but highly related, as one would expect, but also showed a clear, empirical relationship between grammatical knowledge (defined in terms of form–meaning mappings) and the contexts of language use.

In a much more complex study, Liao (2009) investigated the factorial structure of the grammar, reading, and listening sections of the General English Placement Test—a high stakes test used in student admissions and job screening in Taiwan. The grammar test consisted of 11 MC form and 15 semantic meaning items, and was administered to 609 participants. Liao also found two distinct but highly correlated factors: knowledge of grammatical form and semantic meaning. Furthermore, she observed that while knowledge of grammatical form and semantic meaning in the grammar test provided strong predictors of the ability to understand semantic and pragmatic meanings encoded in the reading and listening texts, knowledge of semantic meaning influenced reading and listening ability to a much greater extent than did grammatical form.

In a beginning ESL program for adult immigrants studying to be US citizens, Dakin (2009) examined the relationships between grammatical knowledge (defined in terms of form and meaning) and knowledge of civics over the course of a semester. Administering a grammar and a civics test to 98 participants before and after instruction, she found a strong relationship between the learners' grammatical knowledge and their development of civics content knowledge, noting that over time, knowledge of semantic meaning was a better predictor of civics knowledge than was grammatical form.

Finally, Grabowski (2009) investigated the nature of grammatical and pragmatic knowledge by means of a high context, reciprocal test of speaking ability designed specifically to elicit grammatical knowledge along with contextually situated pragmatic meanings. She found that knowledge of grammatical form and meaning played a consistent and significant role in interactive speaking ability across all test contexts and at all proficiency levels, whereas the examinees' knowledge of pragmatic meanings was pretty much dependent upon the situation elicited by the task. Lastly, she found that while grammatical knowledge made the most important contribution to the examinees' overall speaking proficiency scores at all levels, this contribution decreased to some extent at the advanced level. She concluded that both grammatical and pragmatic knowledge should be explicitly measured in speaking proficiency assessments at all levels of proficiency.

In sum, these studies provide compelling evidence that grammatical knowledge involves more than a single focus on form, and that the measurement of both

dimensions of form and meaning are critical to a comprehensive assessment of L2 proficiency.

Current Approaches, Challenges, and Research Related to the Measurement of Grammatical Knowledge

Despite the form–meaning research, most L2 testers continue to conceptualize grammatical knowledge uniquely in terms of form, with little or no explicit attention to the measurement of meaning. While a form-focused approach to L2 assessment is certainly appropriate for some purposes, it provides only a partial representation of the grammar construct. As a result, important opportunities for supplying learners with information that could help them develop are missed. Therefore, I believe that grammar test development should be guided by a theoretical model of grammatical knowledge if for no other reason than to contextualize the actual test construct within the larger frame, and to help ensure that important aspects of the construct are represented in the test.

In the next section, I will first discuss some general considerations in the design of grammar assessment tasks. Then, I will discuss four methodological approaches to grammar assessment.

General Considerations in the Design of Grammar Test Tasks

Once we know the test purpose and what aspects of the construct to measure, we need to consider the contexts of target language use (TLU) so that we identify tasks that examinees are likely to encounter in real-life or instructional language use (Bachman & Palmer, 1996). This pool of target-like tasks can then be used for selecting test tasks. The degree to which the tasks on language tests correspond to the tasks in the TLU domain is referred to as *test authenticity* (Bachman & Palmer, 1996). This characteristic of assessment is critical for providing a basis to generalize score-based performance from assessment tasks to performance in the TLU domain.

Therefore, in an effort to maximize authenticity, grammar test development should probably begin with a consideration of the domains (i.e., situations) in which examinees will be likely to function linguistically, so that tasks within that domain can be identified and considered for test inclusion in light of the test purpose. We would also need to think about the grammar examinees would need to use to perform these tasks.

To illustrate, imagine we were designing a placement test in a university setting. Examinees in this context typically need to perform language tasks related to the following four domains: (1) the social-interpersonal (e.g., having a conversation in a café), (2) the social-transactional (e.g., resolving a course registration problem), (3) the academic (e.g., listening to a lecture), and (4) the professional (e.g., making a conference presentation). Within and across each domain, we can think of several features that could guide and control task development to ensure that test tasks align with TLU tasks. Table 6.2 provides an example of how tasks within these

Table 6.2 Linking test tasks with TLU tasks

Target domain	Social-interpersonal	Social-transactional	Academic	Professional
Setting	Business (café)	Business (pharmacy)	School (chemistry lab)	Conference (lecture hall)
Event	Socializing	Service encounter	Lab experiment and report	Conference presentation
Participant roles	Friend/friend	Customer/pharmacist	Student/student	Presenter/audience
Topic of communication	Subway event	Instructions for medicine	Litmus test experiment	Global warming
Goal of communication	Narrate a subway story	Understand prescription instructions	Report lab results	Explain and critique a new policy
Sociolinguistic features	Informal, close friends	Formal, businesslike	Formal, academic	Formal, professional
Sociocultural characteristics	New York City	USA	University	International association
Affective tone	Friendly/polite	Confused/helpful	Supportive/inquisitive	Collegial/supportive
Test input	Written prompt, role play	Instructions, listening text (dialogue), MC questions	Written prompt	Written prompt
Expected response	Extended production	Selected response	Extended production	Extended production
Communicative focus of assessment	Literal/intended meanings: narrate sequence of events	Literal/intended meanings: understand how to take medicine, side effects, and interactions	Literal/intended meanings: report: describe actions, observed results, and conclusions	Literal/intended meanings: provide a logical argument for topic: pros, cons
Linguistic focus of assessment	Grammatical (and pragmatic) resources: use a range of grammatical forms (e.g., simple past and past continuous tenses, logical connectors) accurately and meaningfully	Grammatical (and pragmatic) resources: use a range of grammatical forms to understand	Grammatical (and pragmatic) resources: use a range of grammatical forms (e.g., active and passive voice, <i>when</i> clauses, connectors) accurately and meaningfully	Grammatical (and pragmatic) resources: use a range of grammatical forms (e.g., formal registers, hedges) accurately, meaningfully, and appropriately

four domains can be generated, specified with respect to several features, and used to create grammar assessments.

In designing grammar tasks, we also need to consider how to elicit test performance so that examinees can display their grammatical knowledge. In other words, we need to consider the types of responses examinees might be expected to make in relation to the instructions and questions on the test—i.e., the *task input*. The type of *expected response* is critical since inferences about grammatical knowledge will be based on the scores associated with these responses. Test tasks can require examinees either to *select* a response from two or more options or to *construct* a response. Selected response tasks (SR) allow us to make inferences about the learners' receptive knowledge of the learning point; constructed response (CR) tasks allow us to make inferences about the examinee's language production. In constructing responses, examinees may need to produce a *limited* amount of language (i.e., anywhere from a word to a sentence) or an *extended* amount (i.e., more than a sentence). Limited production (LP) tasks allow us to make inferences about the learners' *emergent knowledge* of the learning point, while extended production (EP) tasks allow us to make inferences about learners' full production or their overall L2 performance. (For more information on writing items and tasks and on different response formats, see Chapter 48, *Writing Items and Tasks*, and Chapter 52, *Response Formats*.) Examples of SR, LP, and EP or *performance* tasks are presented in Table 6.3.

Table 6.3 Ways of eliciting grammatical performance (Purpura, 2012)

<i>Receptive</i>	<i>Emergent</i>	<i>Full production or overall L2 performance</i>		

In the next section, I will describe four common approaches to grammar assessment.

The Discrete-Point Approach to Grammar Assessment

Probably the most common way of assessing grammar is to use SR tasks to isolate and measure discrete units of grammatical knowledge. The assumption underlying this approach is that learning involves the acquisition of a discrete and finite set of predictable patterns. Discrete-point tasks are capable of measuring a wide range of individual forms, are relatively practical to administer and easy to score, and can be used to provide fine-grained information on grammatical knowledge. These tasks are also notoriously difficult to construct well, even if they do not appear so. (See Chapter 52, Response Formats, for more information on writing items and tasks.)

SR tasks of grammatical knowledge present test input in the form of an item and are designed to measure recognition or recall (i.e., receptive knowledge), usually involving one area of knowledge. These tasks are traditionally scored right or wrong for accuracy, that is, dichotomous scoring. (For more information on scoring, see Chapter 51, Writing Scoring Criteria and Score Reports, and Chapter 58, Administration, Scoring, and Reporting Scores.) The following item aims to measure lexical form by means of a co-occurrence restriction between an adjective and its associated preposition:

Example 1: Grammatical form: lexical form (co-occurrence restriction)

I am interested _____ history.

- a. at
- *b. in
- c. to
- d. of

(*correct response)

SR items can also be designed as “multittrak” items (Dávid, 2007), where examinees are presented with test input containing several potential choices for the context. In these items, examinees have to select the option that is *not* accurate, meaningful, appropriate, acceptable, natural, or conventional. The following multittrak item intends to measure the different meanings associated with modal auxiliaries (i.e., degrees of certainty). *Must* is the only option *not* semantically acceptable in this exchange.

Example 2: Semantic meaning: morphosyntactic meaning (degrees of certainty)

A: The evidence is still pretty unclear.

B: So then, it _____ be the butler or possibly someone else.

- a. may
- *b. must
- c. might
- d. could

SR items can also be designed to measure the overall semantic meaning of an utterance revolving around a specific form (Chang, 2004). The following item aims to measure the overall semantic meaning of an utterance containing a relative clause.

Example 3: Overall semantic meaning (relative clauses)

The woman in the corner who speaks Sicilian is my aunt.

My aunt speaks Sicilian.

*True

False

The obvious concern with discrete-point, SR tasks of grammatical knowledge is that knowledge of forms in isolation may not actually translate into the ability to use these forms meaningfully in communication; that is, these tasks fail to elicit responses capturing dynamic and complex understandings of the resources needed for communication. Nonetheless, this approach to grammar assessment is useful in situations where the goal is to observe the examinees' receptive knowledge of isolated language features.

In terms of research, several studies have examined the validity of using discrete-point, SR items as indicators of grammatical knowledge. Results from this research show that these tasks generally have high reliability and can be statistically plausible measures of grammatical knowledge. With regard to the effect of task format on the measurement of grammatical knowledge, Currie and Chiramanee (2010) examined the construct equivalence of using MC and CR tasks as measures of grammatical knowledge. They found that the MC format seems to elicit more format-related noise than the CR format, and that MC tasks do not reflect the same types of responses as those elicited in CR tasks. This study casts doubt on the validity of MC tasks as measures of grammatical form.

Finally, Purpura (2005) examined the convention of scoring MC grammar items dichotomously. He asked experienced teachers to judge the degree to which response options represented knowledge of grammatical form, meaning, or both. Teachers consistently agreed in their characterizations of how some options represented full knowledge, others represented some knowledge, and still others represented no knowledge of the targeted feature. These judgments were corroborated by student response data showing that the overall average scores of examinees selecting the different options corresponded to the expert judgments made by teachers regarding knowledge representation. Finally, when the responses were modeled in a partial credit statistical model, the number of thresholds observed for each item generally supported the results from the other two methods. Purpura concluded that there is seldom an empirical basis for scoring MC items dichotomously, and that doing so may underestimate the scores of those examinees who are still developing.

Another common way to assess grammar is by means of LP tasks designed to assess discrete units of grammatical knowledge. LP tasks present test input in the form of an item that requires examinees to produce a limited amount of language. LP tasks are based on the assumption that grammar learning transpires over time in developmental stages, represented by performance that is in variation on its

pathway to target-like proficiency. Discrete-point, LP tasks are also capable of measuring a wide range of individual forms. They are fairly easy to develop, relatively practical to administer, moderately easy to score, and can provide fine-grained, developmental information on grammatical knowledge—a major advantage over SR tasks.

The following LP item is designed to measure only one area of grammatical knowledge: morphosyntactic form of auxiliary verbs. Consequently, only one right response is possible. Scoring would be dichotomous, based on grammatical accuracy.

Example 4: Grammatical form: morphosyntactic form (auxiliary verbs)

If I (1) _____ known, I would (2) _____ done something.

Answers: (1) had; (2) have

The following LP item aims to measure more than one area of language knowledge, since the examinee needs to have knowledge of both grammatical form and lexical meaning in order to construct a correct response.

Example 5: Grammatical form and mean (future progressive)

Just think. This time next month, we _____ in the Mediterranean Sea.

Answer: will be swimming

If the examinee responds with *swimming*, this response would reflect knowledge of lexical meaning—that is, the verb “swim” for this context—but would show lack of knowledge of morphosyntactic form related to future progressives (i.e., the form dimension). Given the two dimensions, this item should probably be scored for semantic meaningfulness and grammatical accuracy. A score relating to only one dimension would underestimate the examinee’s grammatical knowledge, and potentially lose important developmental information for providing corrective feedback.

The following LP item aims to measure the morphosyntactic form of relative clauses. Examinees are first asked to judge the accuracy of the target structure. If it is wrong, they are asked to correct it.

Example 6: Grammatical form and meaning: recognition/correction (relative clauses)

A: Do you have a computer I can borrow it?

Circle one: Correct? Incorrect?

Correction: _____

Answers: incorrect; a computer I can borrow

Like SR tasks, LP tasks have been used as viable indicators of grammatical knowledge. Despite their widespread use, surprisingly little research has been published on the LP format relating to grammar assessment.

The Performance-Assessment Approach to Grammar Assessment

Many L2 testers believe that the assessment of grammatical ability is best accomplished through *performance tasks*, where examinees are presented with input in

the form of a prompt and required to produce extended amounts of spoken or written data, of which the quality and quantity can vary considerably among test takers. Performance tasks, a kind of EP task, are best designed when they reflect the tasks learners might encounter in the TLU domain (for a more detailed discussion of performance assessment, see Chapter 37, Performance Assessment in the Classroom). Because of the amount of data produced by these tasks, assessment involves multiple areas of L2 knowledge depending on the assessment goal. Speaking performance tasks are thought to be good measures of the learners' implicit knowledge of grammar, given the online nature of performance (Ellis, 2001). In sum, performance tasks provide an excellent means of eliciting the ability to use grammatical resources to convey a range of meanings during task completion. However, it is often difficult to fully control the type of grammar that a performance assessment will naturally elicit.

The performance-assessment approach is characterized not only by EP tasks, but also by the process for scoring performance data. Before discussing scoring, consider the following example of a speaking performance task.

Example 7: L2 performance task (complaints)

Imagine you were just on a long-distance bus trip, and several things went wrong. When you call the bus company to complain, you are asked to leave a voice mail message. Describe what happened and express your feelings about the service. Include in your message at least three things you would like the bus company to do. You have one minute to plan your response. Be polite but firm.

Performance samples elicited from the task above are likely to provide multiple assessment opportunities. As the primary goal of this task is to communicate a meaningful complaint, we might begin by evaluating the response for *semantic meaningfulness*, that is, for a voice mail message with complete and valid information for the context. Then we might evaluate the degree to which the response displays *grammatical precision*. Precision refers to how grammatically accurate the response is (*accuracy*), how varied the forms are (i.e., *range*), how the response displays late-learned, sophisticated grammatical forms (e.g., past passive modals) and complex constructions involving coordination and subordination (i.e., *complexity*), and automatic and effortless delivery of the response (i.e., *fluency*, with a minimum of disfluencies). Beyond these features, responses might also need to display pragmatic knowledge, such as *appropriate register (sociolinguistic meanings)* and *appropriate tone (psychological meanings)*, or even *sensitivity to the sociocultural conventions of complaining in a given culture (sociocultural meanings)*. In sum, performance assessments, if designed properly, elicit extremely rich grammatical (and pragmatic) data for assessment.

Finally, the performance-assessment approach is characterized by scoring procedures that involve human judges referring to a holistic or analytic rating scale. A *holistic* scoring rubric for the complaint task might minimally contain scaled descriptors characterizing the response's use of grammatical forms (the form dimension) to make a meaningful complaint (the meaning dimension). This would produce one overall score, perhaps on a scale from one (low performance) to five (high performance). An *analytic* scoring rubric might then contain two separate

components: one to characterize performance with respect to grammatical forms and the other with respect to the meaning dimension. This approach produces multiple scores that could be averaged or reported separately for formative feedback purposes.

Considerable research has been devoted to examining grammar performance by means of performance assessment. One early study performed by McNamara (1990) examined trained raters in the context of scoring the speaking section of the Operational English Test. Raters were asked to judge performance samples for resources of grammar and expression, fluency, intelligibility, appropriateness, comprehension, and overall task completion. The analyses showed that even though the raters had been trained to consider all components of speaking ability, they seemed to be making critical judgments about performance based on the resources of grammar and expression. McNamara concluded that the resources of grammar and expression seemed to provide the single best predictor of speaking ability in that test.

The L2 Production Features Approach to Grammar Assessment

Most SLA researchers and some testers maintain that the best way to understand what L2 resources learners have acquired is by asking them to engage in naturalistic (i.e., real-life) discussions, so that the features elicited by these discussions can be examined. However, these data are unrealistic for most assessment contexts. Therefore, a wide range of EP tasks have been successfully used to elicit production data containing many of the characteristics of naturalistic data.

In this approach, once performance is elicited, L2 knowledge can be inferred from the measurement of L2 production features thought to capture essential characteristics of speaking and writing performance, such as the percentage of error-free clauses or the length of the production. The claim underlying this approach is that if the linguistic characteristics of a learner's production are, in varying degrees, accurate, complex, fluent, meaningful, coherent, organized, conventional, and natural-sounding (to name a few), then this variability can be used to characterize and predict differences in speaking and writing proficiency. This approach differs from performance assessment in that it is concerned with characterizing performance in terms of production features in the data rather than judging specific L2 performance based on evidence in the data relating to a set of scaled descriptors.

While not necessarily framed this way, the L2 production features in these assessments revolve around the following knowledge components: (1) phonological, lexical, morphosyntactic, cohesive, and interactional forms and associated meanings (grammatical dimension); (2) propositions, topics, or idea units (semantic meaning dimension); and (3) markers of stance, coherence, and rhetorical or conversational organization (pragmatic dimension). In this section, I will describe three commonly examined features of L2 production (i.e., accuracy, complexity, and fluency) in this approach.

Wolfe-Quintero, Inagaki, and Kim (1998) defined *accuracy* as an error-free production unit (i.e., clause, t-unit). Several researchers (Skehan, 1998) have proposed measures of accuracy; some of the more common ones are the percentage of errors

per 100 words, the percentage of error-free clauses per total number of clauses, and the percentage of error-free t-units per total number of t-units.

Complexity is defined as the use of sophisticated forms (e.g., past passive modals), complex constructions (e.g., subordination), and various other late-learned production units. Ellis and Barkhuizen (2005) identified the following types of complexity depending on the feature being analyzed: (1) interactional (e.g., number of turns per speaker), (2) propositional (e.g., the density of the information unit), (3) functional (e.g., number of functions expressed), (4) grammatical (e.g., amount of subordination), and (5) lexical (e.g., number of academic words). Other complexity measures used to characterize L2 production include the total number of words uttered by a speaker per total number of speaker turns (*interactional complexity*); the frequency of major and minor propositions in a text (*propositional complexity*); the frequency of specific language functions (*functional complexity*); the number of words or clauses per t-unit (*grammatical complexity*); and the total number of different words used (type) per total number of words (token) (i.e., the type–token ratio) (*lexical complexity*).

Finally, *fluency* in oral production has been defined as the rapid production of language (Skehan, 1998) and operationalized by numerous measures. Ellis and Barkhuizen (2005) and Blake (2006) described fluency in terms of temporal variables (e.g., the number of syllables per second or minute on a task), hesitation variables (e.g., number of false starts, repetitions, reformulations, replacements, or other disfluencies), and the quantity of production (e.g., the response time or the number of syllables in a response).

While most of these measures come with serious caveats, many of the measures (or clusters of measures) have successfully predicted differences in L2 proficiency (Norris, 2006). As a result, serious research efforts are currently being devoted to understanding how these features relate to and even predict L2 oral and written proficiency, and what role these features might play in the development of automated scoring and feedback systems (Xi, 2010).

A growing body of research has been devoted to examining the grammatical features of L2 production in L2 assessments. Chapelle and Chung (2010) described how five automated scoring systems used measures of accuracy (e.g., agreement errors), complexity (e.g., average word length), fluency (e.g., essay length), topic relevance (e.g., topic-specific vocabulary usage), and diction (word length), to name a few, to examine relationships between these features and scores provided by human judges. Also, Ginther, Slobodanka, and Rui (2010) investigated how the automated scoring of 15 temporal measures of fluency (e.g., total response time, speech time) related to holistic ratings of speech quality. In the context of writing, Cumming et al. (2006) investigated the extent to which the features of L2 production for independent tasks differed from those for integrated tasks on the TOEFL writing exam. Examining lexical and syntactic complexity, grammatical accuracy, argument structure, orientations to evidence, and verbatim uses of source material, they found that in fact the discourse produced by examinees differed not only across tasks, but also across proficiency levels.

While these measures provide testers with a useful toolbox for characterizing L2 production within different assessment contexts, it remains unclear how these measures, individually or collectively, can be used to characterize what examinees

know or how the measures might be useful for characterizing performance for formative purposes.

The Developmental Approach to Grammar Assessment

Based on consistent findings in SLA that multiple structures seem to be acquired in a fixed developmental order and that the acquisition of single structures follows a fixed developmental sequence (see Ellis, 2008), some researchers (e.g., Piennemann, Johnston, & Brindley, 1988) have argued that grammatical assessments should be constructed, scored, and interpreted with developmental proficiency levels in mind. In fact, Ellis (2001) maintained that grammar test scores should be calculated to provide a measure of both target-like accuracy and acquisitional development; that is, a score linked to the different stages in the interlanguage continuum, so that information from these assessments could reflect both target-like and developmental criteria of specific grammatical forms.

Initial reactions to these intuitively appealing suggestions were strongly critical, arguing that the research relating to developmental orders and sequences was incomplete and at too early a stage to be used for assessment. Consequently, the use of development scores for anything more than research was discouraged.

Despite the caveats, Chang (2004) explored the degree to which scores on a relative clause test corresponded to scores on a developmental test designed to measure relative clause acquisition, based on Keenan and Comrie's (1977) accessibility hierarchy. The first section of his test included tasks aimed at measuring the forms, meanings, and pragmatic uses of relative clauses. The second consisted of two tasks developed to measure five types of relative clauses in the hierarchy. This section was designed to produce developmental scores. The first task in the developmental section asked examinees to indicate, on a scale of zero to five, how likely they were to use the targeted relative clauses in a dialogue. The responses were scored 1 for correct response, 0.5 for partially correct responses, and 0 for incorrect responses. The second task presented students with MC items designed to measure five types of relative clauses. Response options were based on the acquisitional characteristics of relative clauses and were scored as partial credit, similar to the scoring method Purpura (2005) used. Interestingly, Chang (2004) found that when form and meaning scores on a relative clause test were considered together, the observed order of difficulty for relative clauses strongly supported the noun phrase accessibility hierarchy, but when form alone was considered, the difficulty hierarchy was not fully supported.

More recently, Chapelle, Chung, Hegelheimer, Pendar, and Xu (2010) explored the potential of assessing productive ESL grammatical ability by targeting areas identified in SLA research, so that the items could be used on a computer-delivered and scored placement test. The test content was designed to measure structures on the morphosyntactic, syntactic, and functional levels (*forms and meanings*). The structures (rooted in SLA research) were putatively capable of predicting grammatical performance at the beginning, intermediate, and advanced levels. Examinees were presented with five LP tasks, where production ranged from a word to a sentence (as seen below), and one EP task, where they had to write a paragraph.

Example 8: Reorder jumbled word order (Level 3—subject–verb inversion with negative)

Complete the sentence using all the words given in the word list. Do NOT add more words or change the word forms.

seen, mess, a, they, have, such

Hardly ever _____

Answer: *have they seen such a mess*

(Chapelle et al., 2010, p. 455)

Responses were scored on a scale ranging from no evidence via partial evidence to evidence of knowledge of the targeted structure. The results showed that while the scores were indeed able to distinguish three proficiency levels, the LP tasks provided weak to moderate correlations with the EP task. Unfortunately, we have no information on whether the items themselves corresponded with the SLA level predictions. Finally, the scores from the entire productive grammar test produced expected moderate correlations with the TOEFL Internet-based test (iBT), suggesting that further research on the productive grammar test should be pursued.

Future Directions

Research and theory related to grammar assessment have made significant strides since the early 2000s, and this line of inquiry has become a vibrant area of scholarly endeavor and practical application. In the future, I believe that researchers will continue to explore the construct of grammatical ability and the resources that contribute to and predict the ability to convey meanings. Given the research in SLA on form–meaning connections and the recent research in L2 assessment on the role of meaning in grammatical knowledge, I believe that those interested in grammar assessment will move beyond the limitations of a uniquely syntactocentric approach to grammar assessment, especially when the data clearly warrant the assessment of more than one dimension.

I also believe that grammar assessment, in both large-scale and classroom-based assessment contexts, will be significantly impacted by advances in information technologies. These technologies will remove many of the constraints of pencil and paper assessments by allowing for innovative test formats that use multimedia and flash technologies, multimodal assessment, interactivity in real time, and flexibility in test formats, so that examinees can be presented with discrete-point tasks or cognitively complex tasks, depending on the goal of assessment. Advances in test delivery systems will also allow us to assess a much wider array of grammar in a greater number of domains using a larger variety of tasks. Fortunately, these technologies will enable us to implement new and innovative ways of scoring that can provide stakeholders not only with summative information, but also with formative information. Learners will have information for closing grammar learning gaps. Already advances have been made to give learners immediate feedback on a number of grammatical features in writing and speaking. In the future, I see much greater efforts to provide learners with concrete feedback associated with individually tailored instruction and further grammar assessment.

I believe that researchers will continue to try to characterize grammatical ability at different proficiency levels and in different language use domains. We are still far from understanding what grammatical features constitute the ability to perform at different levels of L2 proficiency. I also think that corpus linguistics research will make contributions to this endeavor.

Finally, grammar is the fundamental linguistic resource of communicative language ability. We have seen this over and over again in the research. I believe that in the future L2 educators will recognize that there are many ways to define and measure grammatical ability, not just the traditional discrete-point approach. The bottom line is that all learners at times need feedback on their grammar performance. This feedback comes from assessment. I believe that in the future L2 educators will continue to recognize the importance of grammar assessment both in large-scale and classroom-based contexts.

Assessing Pragmatics

Carsten Roever

University of Melbourne, Australia

Introduction

The assessment of second language (L2) learners' knowledge of target language pragmatics is a relatively new research area, with the first major project dating from the early 1990s. This chapter will review existing research in pragmatics assessment, and outline some future research directions.

Pragmatics is a large and unwieldy construct. In a commonly cited definition, Crystal (1997) conceptualizes it as "the study of language from the point of view of users, especially of the choices they make, the constraints they encounter in using language in social interaction and the effects their use of language has on other participants in the act of communication" (p. 301). This conceptualization of pragmatics as a research area focuses on investigating language use in social situations, and how such language use affects the relationships between interlocutors. Mey (2001) specifies some subareas of pragmatics, including implicature, speech acts, deixis, and extended discourse.

To conceptualize language users' pragmatic knowledge and ability for use, Leech (1983) distinguishes between sociopragmatics, the social rules of language use, and pragmalinguistics, the linguistic tools of such language use. Language users' sociopragmatic knowledge is their knowledge of social norms and conventions, social relationships, politeness and appropriateness levels, common ways of doing things, and mutual rights and obligations. A sociopragmatically competent language user understands the context factors of power, social distance, and imposition (Brown & Levinson, 1987) and knows what level of politeness is appropriate given different settings of context factors. Pragmalinguistics concerns linguistic tools, that is, a language user's linguistic knowledge that can be made available for pragmatic use. For example, a pragmalinguistically competent user can implement different levels of politeness, muster semantic

formulas to produce speech acts in conventional ways, employ situationally required routine formulas, express notions like tentativeness or assertiveness, or convey a stance. This clearly requires general target language proficiency, and the importance of general L2 knowledge and specifically grammatical knowledge has been discussed extensively in interlanguage pragmatics research (Kasper & Rose, 2002). Pragmatically competent language users need both sociopragmatic and pragmlinguistic knowledge. They need to map the two systems onto each other, and they need to be able to activate their knowledge within the time constraints of a communicative situation.

The above conceptualizations of pragmatics underlie much of the fundamental research in the area of interlanguage and crosscultural pragmatics, which in turn underpin the assessment of L2 pragmatics. Probably the most influential crosscultural pragmatics study was the Cross-Cultural Speech Act Realization Project (CCSARP) (Blum-Kulka, House, & Kasper, 1989). CCSARP collected first language (L1) data on the speech acts of request and apology from 1,946 participants representing seven native languages. It varied the social context factors of power, distance, and imposition, and compared L1 groups in terms of the semantic formulas chosen to implement the speech acts and of the politeness level expressed. The emphasis on speech acts in CCSARP characterizes much of the research in crosscultural and interlanguage pragmatics, which has had a distinct speech act orientation, with the speech act of request the most frequently investigated one, followed by apologies, with refusals and complaints far behind. Other speech acts such as compliments, advice, suggestions, and offers have also been occasionally researched.

Another distinguishing characteristic of this research area is the very common use of discourse completion tests (DCTs) as research instruments. A DCT consists minimally of a situation description (the prompt), a stimulus question (“What would you say in this situation?”), and a gap for participants to write their response, as exemplified in Figure 7.1.

Variations on this basic item type include opening utterances by the imaginary interlocutor (“Oh whoops”) or rejoinders by the interlocutor following the gap (“Don’t worry about it, I’ll just clean it up”). The advantage of DCT items is that they allow researchers to vary the situational context variables of power, distance, and imposition systematically, and in their typical written form, DCTs are fairly practical instruments: They can be administered to large groups of participants

<p>You are having dinner at a friend's house. As you are handing your friend the salt shaker you accidentally drop it. It breaks and spills salt all over the floor.</p> <p><i>What would you say?</i></p> <hr/> <hr/>
--

Figure 7.1 DCT item

simultaneously, they are easy to digitize, and while scoring is not as efficient as with one-word gap or multiple choice items, it is relatively efficient.

DCTs, however, are far from faithful emulations of actual conversation. There is no discourse-internal context, responses are not constructed under the time pressure of an online communicative situation, and respondents have been shown to write what they think they might say in the given situation, which is not necessarily what they actually do say in reality (Golato, 2003). So the range of conclusions that can be drawn from performances and scores obtained through DCTs is limited to test takers' offline knowledge of semantic formulas for implementing speech acts, and does not extend to their ability to perform them in real-world interaction.

Speech acts are not the only component of pragmatics, however, and other aspects have also been researched. Bouton (1999) investigated non-native speakers' comprehension of implicature, while Bardovi-Harlig (2009) looked at knowledge of routine formulas, and Cook (2008) analyzed the acquisition of speech styles (situation sensitive overall configurations of politeness and indexical features that encode the relationship with the interlocutor) in Japanese. Few studies have investigated extended discourse and most have used a speech act framework to do so (e.g., Gass & Houck, 1999) though recent studies by Pekarek Doehler and Pochon-Berger (2011) as well as Al-Gahtani and Roever (2012) use a conversation analytic approach to analyze extended interaction.

The assessment studies in L2 pragmatics reflect the strong traditional reliance on the speech act tradition apparent in pragmatics research but more recently have broadened to include other aspects of test takers' pragmatic ability.

Previous Conceptualization and Research

The first major test development project in the assessment of L2 pragmatics was Hudson, Detmer, and Brown's (1995) battery, which followed very much in the tradition of CCSARP. The authors focused on the three most commonly investigated speech acts, namely request, apology, and refusal, and designed the test contrastively for L1 Japanese-speaking learners of American English. The test consisted of four measures and two self-assessment questionnaires:

- 24 written DCT items administered as a paper and pencil test;
- 24 multiple choice DCT items as a paper and pencil test;
- 24 oral DCT items administered in a language lab;
- 8 role-play situations, each containing a request, an apology, and a refusal; and
- 2 self-assessment questionnaires, asking participants to rate how well they would perform in some of the DCT situations, and how well they thought they performed in the immediately preceding role play.

Hudson et al. (1995) trained native speaker (NS) raters to evaluate learner production using a five-point scale from "very unsatisfactory" to "completely appropriate" on six criteria: ability to use the correct speech act; formulaic expressions; amount of speech used and information given; and degrees of formality,

directness, and politeness. Hudson (2001) reports on a piloting of the battery with 25 Japanese English as a foreign language (EFL) students studying English in a pre-admission English as a second language (ESL) program at a US university. He found that the test was somewhat easy for his sample, with average scores on all three test sections at about 80%. The language lab DCT was the most difficult, at nearly one standard deviation more difficult than the role play, which was the easiest measure. Hudson found a high correlation between the oral and written DCT instruments, but low correlations between the DCT instruments and the role play. Inter-rater reliabilities ranged from .75 to .86.

Hudson et al.'s test sparked a number of subsequent test development projects. Yoshitake (1997) used the original battery in Japan with 25 EFL learners. Yamashita (1996) adapted the test for Japanese as a second language (JSL) and used it with 47 American English-speaking JSL learners in Japan. Ahn (2005) adapted the test for Korean as a foreign language (KFL), and ran it with 61 KFL learners in the US, though without the multiple choice DCT and the self-assessment on the DCT situations. Brown (2001) reviewed Yamashita's and Yoshitake's adaptations, and Brown (2008) did a generalizability analysis that additionally included Hudson's pilot data and Ahn's adaptation for Korean. Brown (2001) found much more shared variance between test sections in Yamashita's JSL data than in Yoshitake's EFL data, but in both cases, the multiple choice DCT had low reliabilities of .45 and .6 respectively, while other instruments in the JSL data had reliabilities around .9. Brown (2008) and Brown and Ahn (2011) added analyses of Ahn's instrument, which had high reliabilities of around .9 but did not include a multiple choice DCT. According to Yamashita (1996), the lack of reliability for the multiple choice DCT was due to the difficulty of creating incorrect responses that were clearly unacceptable to all NSs without being so extremely rude or nonconventional that they would never be chosen even by low ability test takers. This was an unfortunate outcome in that, as Brown (2001) argues, the multiple choice DCT was the most practical of all the test components.

To tackle the challenge of developing a reliable multiple choice DCT, Liu (2006) engaged in a concerted development effort to design a written DCT and multiple choice DCT for L1 Mandarin-speaking EFL learners. He asked learners to generate scenarios, which he then adapted into DCT items and gave to learners and a small group of NSs as a traditional written DCT. In designing his multiple choice DCT, he used learner responses as incorrect response options and NS responses as correct response options. He went through various iterations of NS benchmarking but it is notable that he accepted an NS agreement of 70% on the correct answer choices as a criterion for declaring the item suitable. When he ran the test with 200 native Mandarin-speaking students, he obtained high reliabilities of around .9 for his test sections.

In a final study in the same tradition, Tada (2005) developed a computer-based multiple choice DCT and an oral DCT with 24 items each, supported by video scenarios, and analyzed data from 48 Japanese EFL learners. He tested the speech acts of request, apology, and refusal, and varied the context variables of power and imposition. He obtained reliabilities of around .75 for both parts of his test but, like Brown (2001), Tada (2005) found a disjoint between the multiple choice and productive parts of the test, with little overlap between the two, indicating

that there is no clear and straightforward relationship between receptive and productive pragmatic ability.

The tests discussed so far were designed as standalone measures of learners' knowledge of speech acts and had a sociopragmatic focus, emphasizing appropriate politeness levels. In this tradition, a number of other assessment instruments have also been developed as part of research projects to investigate the effect of study abroad, learning setting, or instruction. For example, Matsumura (2001) used a multiple choice DCT on advice giving, and found that Japanese study-abroad students in Canada more closely approximated English native speaker judgments of social relationships over the course of an academic year than did their counterparts studying in Japan. Bardovi-Harlig and Dörnyei (1998) investigated the effect of learning setting (ESL vs. EFL) through a video-based judgment task, in which learners rated to what degree utterances containing a suggestion, apology, request, or refusal, or a response to these speech acts, were sociopragmatically appropriate, grammatically felicitous, or both. These researchers found that ESL learners' pragmatic awareness was greater than their grammatical awareness but the opposite was true of EFL learners. Takimoto (2009) investigated the effects of instruction using role plays and request DCTs scored by raters as well as receptive sociopragmatic judgment measures, and showed that ESL learners' requests had become more appropriate through targeted instruction.

While the overwhelming majority of tests were situated in the speech act tradition, there were some more sporadic developments of instruments testing other aspects of pragmatics for research purposes. For example, Bouton (1999) evaluated ESL learners' ability to interpret implicature through a multiple choice test and claimed to find an effect of exposure. Roever (1996) investigated the effect of residence on the knowledge of English routine formulas through a multiple choice instrument. Cook (2001) assessed Japanese as a foreign language (JFL) learners' recognition of appropriate speech styles in Japanese through a listening task, and found that most of her learners focused on the propositional content of an utterance and did not take into account the appropriateness of the speech style employed.

The speech act-oriented tests in the Hudson et al. (1995) tradition were an important first step toward assessing a part of the construct of communicative competence (Canale & Swain, 1980; Bachman & Palmer, 2010) that had not previously been systematically assessed. At the same time, these tests assessed only a relatively narrow part of an overall construct of "pragmatic competence," limiting the range of conclusions that can be drawn from the scores. The tests focused on speech acts to the exclusion of other aspects of pragmatics, and within speech acts, they focused on learners' sociopragmatic abilities, that is, their ability to recognize and display levels of politeness and situational appropriateness in accordance with NS norms. There was an underemphasis on pragmalinguistics, aspects of pragmatic competence like implicature, formulaic expressions, and extended discourse, and a highly deterministic understanding of context (for which Kasper [2006] criticizes the speech act tradition as a whole). This tradition also favored the use of paper and pencil testing, which did not harness the power of computers, for example in automatic scoring of multiple choice responses, automatic distribution of extended responses to scorers, automatic compilation of scores, and

automatic feedback to test takers, although Tada (2005) used computers for test delivery. The next generation of pragmatics tests differed from the previous one mainly in three major areas: It emphasized pragmalinguistics, it expanded the construct to areas of pragmatics beyond speech acts, and it used computer technology for testing pragmatics.

Current Conceptualization and Research

The first test battery that included multiple aspects of pragmatics was Roever's Web-based test of English pragmalinguistics (2005). Roever assessed three areas: comprehension of implicature; recognition of routine formulas; and knowledge of speech act strategies for the speech acts of request, apology, and refusal.

The implicature section was based on Bouton's (1999) work and tested learners' ability to interpret general conversational implicature (e.g., "Do you know where the blender is?" "Try the kitchen cabinet") and formulaic implicature (e.g., "Is the Pope Catholic?"). Figure 7.2 shows an example of an implicature item.

Darren does not respond directly to Jenny's question, which is designed to elicit a yes/no answer, but his response implies that the answer is evident given the month. February in Australia is a summer month and with Brisbane being subtropical, the weather is extremely unlikely to be cold, thus making option 3 the most likely one.

The routines section assessed recognition of situational routine formulas ("Can I get you anything else?"). Figure 7.3 shows an example of a routines item.

Both sections contained 12 items, and learners had 12 minutes to complete each section. The speech act section also consisted of 12 items, but learners were given 18 minutes to complete it. It included the speech acts of request, apology, and refusal, and varied only the context factor of imposition, keeping power and distance low. While the items were standard DCT items, they included rejoinders, which were not part of Hudson et al.'s DCT. Figure 7.4 shows a speech act item.

Please click the answer that says what the person means.	Time left: 11:25	Item: 4 /12
Jenny and her <u>flatmate</u> Darren go to university in Brisbane. They are talking one morning before going to lectures.		
Jenny: "Darren, is it cold out this morning?"		
Darren: "Jenny ,it's February!"		
What does Darren probably mean?		
<input type="radio"/> 1. It's surprisingly cold for February.		
<input type="radio"/> 2. It's so warm that it feels like February.		
<input checked="" type="radio"/> 3. It's warm like usual in February.		
<input type="radio"/> 4. It's hard to <u>predict</u> the temperature in February.		
End the test now!	Show instructions!	Next page >>

Please click on what the person would probably say. Time left: 9:52 Item: 4 /12

Tom ordered a meal in a restaurant and the waitress just brought it. She asks him if he wants to order additional items.

What would that waitress probably say?

1. "Would you like anything extra?"

2. "Is there more for you?"

3. "What can I do for you?"

4. "Can I get you anything else?"

Figure 7.3 Routines item (Australian version) © Carsten Roever

Please complete the conversation in a way that makes sense. Time left: 17:42 Item: 2 /12

Ella borrowed a recent copy of *TIME Magazine* from her friend Sean but she accidentally spill a cup of coffee all over it. She is returning the magazine to Sean.

Ella:

Sean: "No, don't worry about replacing it. I read it already."

Figure 7.4 Speech act item (Australian version) © Carsten Roever

In addition to the test sections, the instrument also included a background questionnaire and instructions for each of the sections. Test takers were able to request vocabulary assistance for any word not included in Longman's 2,000 word defining vocabulary (Longman, 2008), and they could also call up the section instructions at any time. The test system was written in HTML and Javascript and ran entirely client-side in a standard Web browser. The system recorded item answer times and scored responses to multiple choice items automatically. Upon completion it displayed scores for the implicature and routines section and submitted to the researcher a string of responses that were ready for analysis in the statistical software package SPSS. Speech act responses were scored by the researcher through a scoring interface, which also generated a detailed feedback report for test takers.

Roever ran the test with a total of 335 L2 learners of English in the US, Australia, Japan, and Germany, and 13 NSs of American English as a comparison group. His

section reliabilities were .71 for routines, .79 for implicature, and .89 for speech acts, with an overall reliability of .91. Roever (in press) shows that the routines section could be doubled in length to increase its reliability to .85 with only a very modest increase in time allowance, to 15 minutes. Through correlations between sections and a factor analysis of all items, Roever (2005) found a moderate degree of overlap between sections and a four-factor solution, accounting broadly for the three sections plus a distinct factor for difficult items. This finding supports a construct assumption of pragmalinguistic knowledge feeding from the same “pool” of pragmatic knowledge, with specific variance attributable to the individual subconstructs of implicature, routines, and speech acts. This in turn emphasizes the need for a comprehensive pragmatics assessment that covers various areas of the overall construct rather than just one subcomponent.

In contrast to Hudson et al. (1995), who had designed their test specifically for Japanese learners of English, Roever’s test was not contrastively designed, and Roever (2010) showed in a differential item functioning (DIF) analysis that neither test takers of Asian nor those of European language background had an advantage. Since his test-taker population included ESL and EFL learners, he was able to investigate the impact of exposure and proficiency on various aspects of pragmatic knowledge, and found a strong proficiency effect for speech acts and implicature, but a strong impact of exposure for routine formulas.

A second project very much in a similar tradition to Roever’s was Itomitsu’s (2009) test of the pragmatics of JFL. Itomitsu’s instrument consisted of four 12-item multiple choice sections, assessing recognition of situationally conventional routine formulas; recognition of the requisite illocutionary force in requests, suggestions, offers, and advice; recognition of the appropriate speech style for a social situation; and recognition of correct grammatical forms. Like Roever’s instrument, Itomitsu’s test focused on pragmalinguistics rather than sociopragmatics, but it differed from Roever’s in that no implicature section was included, and the speech act section was multiple choice based rather than productive. This test differed from other previous tests of pragmatics in that the speech acts section focused on test takers’ ability to recognize which response option actually conveyed the desired speech act rather than the appropriate level of politeness, as tested by Hudson et al. (1995) or Liu (2006). The speech styles section in Itomitsu’s test had a politeness focus but more in the sense of Japanese discernment politeness (Ide, 1989), which requires certain choices of linguistic form due to the relationship with the interlocutor and less as a result of strategic considerations, which underlie Brown and Levinson’s (1987) view of politeness.

Itomitsu delivered his test through a commercial Web site, and under unsupervised conditions. Each item was presented in written and spoken format to limit the effects of reading proficiency, and was illustrated with a picture. One hundred and ten learners of JFL at different proficiency levels participated in the test, and Itomitsu obtained reliabilities in the mid .6 to low .7 range, with an overall reliability of .89. The speech styles section was the most difficult and the routines section the easiest, with test takers’ scores increasing in step with their Japanese proficiency. Like Roever, Itomitsu found an overlap between sections ranging from 29% to 49%, with most sections overlapping by about 40%. Although a factor analysis

did not render interpretable results, due to low participant numbers, Itomitsu's correlational findings support the basic construct assumption of a shared pool of pragmatic resources for all three sections, and also indicate a strong relationship between pragmalinguistic and grammatical knowledge. Since Itomitsu's test-taker population was exclusively composed of JFL learners, he could not investigate the effects of exposure in contrast to proficiency on different aspects of pragmatic knowledge.

A remarkable feature of Itomitsu's study is the relatively high reliability, of .7, for the speech acts section, which is difficult to achieve with multiple choice speech act items. However, this might be because Itomitsu's speech act section tested recognition of conventional speech act implementation rather than politeness: It is arguably easier to determine whether a speech act has been realized in a comprehensible manner than to show that a certain level of politeness is "correct" or "incorrect." Itomitsu's study also continues Cook's (2001) work on speech styles, which are a common topic in Japanese pragmatics due to their clear connection to grammatical features, but not to the same extent in other languages.

Roever's and Itomitsu's tests can be seen as direct descendants of the battery developed by Hudson et al. (1995). Roever and Itomitsu extended the construct measured in the original battery to include other aspects of pragmatics while at the same time increasing practicality through the use of computer technology. However, their tests primarily elicited knowledge rather than online performance and did not allow conclusions to be drawn as to test takers' ability to produce routines, speech acts, implicatures, speech styles, or all of these under real-world conditions. Hudson et al.'s battery elicited more performance-based data through its role play but was otherwise limited to one aspect of pragmatic competence.

Some other tests have extended and elaborated various areas of L2 pragmatics and included different "value-adds" to gain a deeper and broader understanding of learners' pragmatic ability. Grabowski (2009), following Purpura's (2004) model of communicative language ability, investigated the relationship between pragmatics and grammar by having 102 ESL learners do four role plays, and rating their performance on two indicators of grammatical ability and three indicators of pragmatic ability. She found moderate to strong relationships between measures of pragmatic and grammatical ability, indicating that the constructs are related though distinct, as has been discussed in interlanguage pragmatics research (e.g., Kasper & Rose, 2002). Grabowski's test was billed as a "speaking test" rather than a test of L2 pragmatics, but the strong performance orientation of her role plays is an interesting innovation over the knowledge-oriented tests in the Hudson et al. (1995) tradition. At the same time, Grabowski's test is less practical than Roever's or Itomitsu's since it requires one-on-one administration and human scoring.

Walters (2007) designed his battery from a conversation analytic perspective. He developed a listening test, role play, and DCT to assess how learners comprehend and produce compliment responses as well as upgraded or downgraded assessments following an interlocutor assessment. Walters administered his test to 42 ESL learners in a fairly narrow proficiency range, which may help explain

the low reliabilities he obtained. However, his instrument was creative and innovative in that it assessed aspects of conversational ability, which none of the other tests did.

In a very different vein, Taguchi (2008) investigated comprehension of implicature in a series of studies, building on Bouton's (1999) work. In an advance on previous work, Taguchi employed computer-based test instruments which measured not only accuracy of response but also reaction time. This adds an interesting new psycholinguistic dimension to tests of pragmatics: Not only does accuracy distinguish learners at different proficiency levels and learners from NSs, but also the speed of comprehending pragmatic meanings is an indicator of pragmatic knowledge and ability.

Challenges

The greatest challenge for any research agenda on testing L2 pragmatics is the tension between ensuring broad coverage of the construct and maintaining practicality. The ideal test of L2 pragmatics is one that assesses learners' ability to use language in social settings and that can be delivered to large groups simultaneously while allowing automatic scoring. The need for practicality almost dictates a computer-based test, but the need for establishing a social situation makes this very challenging because social language use necessarily requires an interlocutor, and computers are not yet at a level of sophistication where they can carry on an interaction like a human interlocutor. Also, they cannot score spoken conversational production automatically without a trained human rater.

While practicality is a problem that might eventually be solved through advances in technology, there remain more fundamental construct issues. For one thing, it is not easy to score spoken production that has been elicited as part of a conversational interaction, since conversations are co-constructed and the conversational actors' productions are dependent on each other, due to the context-shaped and context-renewing nature of turns at talk (Heritage, 1984). An utterance or turn of a larger interaction is impacted by what preceded it, and it impacts what follows it. This makes it very difficult to judge one participant's production in isolation. Brown (2003) has shown for oral proficiency interviews that raters take the interlocutor's production into account when assigning a rating to a test taker, which affects tests with trained interlocutors just as much as paired role plays with two learners.

A further construct challenge is to determine the breadth of the construct to be tested and to benchmark it against an NS norm. What counts as "content" in testing pragmatics? Speech acts are a mainstay, but how much weight should they be given compared to routine formulas, implicature, or speech styles? And what about management of extended spoken or written discourse, implementation of argument structure, conventional sequential organization, expression of preference and dispreference, topic organization, and repair? Benchmarking such features of extended conversation with regard to NS norms is nearly impossible because there is no obligation on a speaker to organize discourse in a particular

way, produce a particular kind of repair at a particular time, or follow a standard formula in devising an argument. To put it simply, it is exceedingly difficult to judge conversational production as “right” or “wrong,” and it is not clear whether judgment on a rating scale would be easier.

Also, the test situation as a social situation affects test takers’ language use. This has been shown for oral proficiency interviews (OPIs) but is less of an issue there, as oral proficiency interviews are designed to test general language proficiency rather than pragmatic abilities. However, if a role play were conducted with the goal of assessing pragmatics, the language use that test takers are likely to show is affected by the social situation of being in a role play and being in a test, or in a broad sense, of being observed and judged. So it is unclear to what extent language use in role plays can be extrapolated to language use in the real world. For testing pragmatics, then, the testing situation itself might introduce construct-irrelevant variance.

Furthermore, the issue of the representativeness of the social situations under assessment looms large with regard to extrapolating from a universe score based on the universe of items (as reliability and generalizability theory might support) to a target score across the domain of interest. Even if a test effect could be limited or were found to be negligible, how representative are the situations tested of the full range of social situations learners might encounter? If someone can make a request in a service encounter, can they also make it in a casual situation? If someone can self-present in a job interview, can they also self-present to a new acquaintance?

Finally, social class and societal context are important variables in social interaction but most tests (and research studies) of L2 pragmatics focus on solidly middle-class interactional settings, like universities, university students interacting socially, or generic service encounters. There is no inclusion of interactions among working-class interlocutors or upper-class ones, or of interactions across class boundaries. This is probably due to most studies being conducted with university students, but it does distort the image of the social world as a whole.

Future Directions

Future developments in testing of L2 pragmatics will likely aim at making measures more comprehensive and thereby allowing larger construct coverage. They will also include a greater proportion of performance-based rather than knowledge-based measures, but it is not likely for the near future that both aspects could be tackled within the same project.

Roever’s (2005) and Itomitsu’s (2009) studies are good examples of extended content coverage, but this could go further in a number of ways. For example, written tasks could be part of the test with a test taker writing e-mail messages for different audiences and purposes, such as to a professor asking for a further extension of an (already extended) deadline to submit an assignment, to an old friend overseas informing him or her of an impending visit to their city and suggesting catching up for dinner, or to an employee denying their request for an

extended period of leave. Similar oral tasks might include a voice mail message left for a prospective landlord expressing interest in an apartment (and trying to make a good impression), a short speech thanking colleagues for coming to a surprise birthday party, or describing a recent travel experience to friends over dinner. Both written and spoken tasks would need to be scored by human raters at this point, but work could begin on extending speech recognition and essay-scoring engines to take pragmatic aspects into account.

While the monologic and written measures above would give pragmatics tests a stronger performance orientation, there is no avoiding the inclusion of extended spoken interaction in pragmatics tests if the construct of language use in social settings is to be truly reflected in the test. This could occur along a continuum from “more practical but less interactive” to “less practical but more interactive.” The former type could involve tasks like dialogue completion, where test takers are given one side of an interaction and fill in the other one, either in writing or orally. Such dialogue completion, which is basically a multi-turn DCT with rejoinders, does not assess turntaking, but it does assess receptive ability to comprehend discourse-internal context and implicature, as well as productive ability to react to the discourse-internal context created by the preceding utterances and to create a suitable context for the following utterances. Less practical but more interactive tasks would involve conversations with a human interlocutor in a role-play setting, which are notoriously impractical and difficult to control from a standardization perspective, but the practicality of these interactions could be increased by using computer-based face-to-face voice chat, so the interlocutors would not have to be physically present at the test site. This might introduce effects of the interaction medium, but what these effects are is an empirical question. The scoring of extended interaction from a pragmatics perspective deserves a great deal of research in its own right and an extension of scoring systems toward discourse abilities.

A final approach to expanding measurement of pragmatic ability would be to refine existing measures alongside the development of new ones. Taguchi’s (2008) work on reaction times is very interesting in that respect, and could be expanded to routine formulas and recognition of adequate illocutionary force as Itomitsu (2009) tested it in his speech act section (though without reaction time measures). Routine formulas lend themselves to productive testing in addition to receptive measures, and they are so highly constrained that productive tests of routines are likely first candidates for machine scoring. Cook’s (2001) test of speech styles for a specific situation is also a development that could be extended to other contexts and domains. Similarly, sociopragmatic judgment tasks like Bardovi-Harlig and Dörnyei’s (1998) could be given a productive component where test takers identify and repair the incorrect or inappropriate part of the target utterance.

In all new developments of measures in the area of L2 pragmatics assessment, the tension between practicality and comprehensive construct coverage will invariably be inherent, and both aspects must be addressed in the long run. Only if measures can be developed that are practical and informative for real-world decisions will testing pragmatics become a mainstream component of language testing as a whole.

Assessing Pronunciation

Talia Isaacs

University of Bristol, England

Introduction

Accents are one of the most perceptually salient aspects of spoken language. Previous research has shown that linguistically untrained listeners are able to distinguish between native and non-native speakers under nonoptimal experimental conditions, including when the speech is played backwards (Munro, Derwing, & Burgess, 2010) or when it is in a language that listeners do not understand (Major, 2007). In fact, one of the earliest documented examples of language testing, the biblical Shibboleth test described in the Book of Judges, involved testing the identity of members of warring tribes based on whether they pronounced the word *shibboleth* 'sheave of wheat' with a /ʃ/ or a /s/ sound at syllable onset, with fatal consequences if the "wrong" pronunciation betrayed their enemy status (Spolsky, 1995). In modern times, a less brutal but still high stakes example is the use of so-called experts' analyses of speech to determine the legitimacy of asylum seekers' claims based on their *perceived* group identity (Fraser, 2009). Of course, such identity tests are far from foolproof, can lead to erroneous conclusions that could inform high stakes decisions, and raise concerns about fairness. It is often unclear, for example, whether it is aspects of the speech signal that trigger unfavorable listener responses, or whether listener expectations that arise as a result of linguistic stereotyping lead listeners to assign qualities to the speech that are absent or distorted (Kang & Rubin, 2009).

Foreign accents tend to receive a disproportionate amount of attention precisely due to their perceptual salience. Despite the enduring reference to the native speaker as the "gold standard" of language knowledge (Levis, 2005), eradicating traces of a foreign accent is widely viewed by applied linguists as an unsuitable goal for L2 pronunciation instruction for several reasons. First, native-like attainment of phonology is an unrealistic goal for most adult L2 learners, not least

possibly an undesirable goal for L2 speakers, since accent and identity are intertwined (Gatbonton & Trofimovich, 2008). Second, L2 speakers do not need to sound like native speakers to fully integrate into society or successfully carry out their academic or professional tasks (Derwing & Munro, 2009). Third, the global spread of English and its emergence as the international lingua franca renders conformity to native speaker norms inappropriate in many EFL settings (Jenkins, 2002). In fact, many native English speakers themselves do not speak prestige (standard) varieties of English (e.g., Received Pronunciation, General American English). For all of these reasons, having a native-like accent is an unsuitable benchmark for pronunciation assessment in the vast majority of language use contexts.

The emerging consensus among applied linguists is that what really counts in oral communication is not accent reduction or attaining a native-like standard but rather simply being understandable to one's interlocutors and able to get the message across (Jenkins, 2002). In fact, over a decade of L2 pronunciation research has shown that having an L2 accent does not *necessarily* preclude L2 speech from being perfectly understandable, although it might. It is in cases when the presence of an L2 accent does impede listener understanding that explicit instruction is most needed to address learners' pronunciation difficulties (Derwing & Munro, 2009).

The theme of defining and operationalizing an appropriate assessment criterion for L2 pronunciation permeates this chapter. After providing reasons for the exclusion of pronunciation from L2 classrooms and its marginalization from mainstream L2 assessment research over the past several decades, the role of pronunciation in theoretical models of communicative competence and in L2 oral proficiency scales will be examined. Next, existing empirical evidence on the pronunciation features that should be taught and, by implication, tested will be considered, and research on individual differences in rater characteristics that could influence their judgments of L2 pronunciation will be discussed. The chapter will conclude with future directions in L2 pronunciation assessment research, with particular emphasis on technological innovations.

Previous Views or Conceptualization

In 1957, the English linguist J. R. Firth famously wrote, "you shall know a word by the company it keeps" (p. 11). A quick perusal of the past several decades of L2 pronunciation research reveals that "pronunciation" has kept close company with the term "neglect" (e.g., Derwing & Munro, 2009). This disparaging association generally refers to the devaluation of pronunciation by some communicative proponents and its resulting de-emphasis in ESL classrooms. One reason for the exclusion of pronunciation from L2 communicative teaching is the belief that an overt focus on pronunciation is extraneous to helping learners achieve communicative competence (Celce-Murcia, Brinton, Goodwin, & Griner, 2010). To counter this view, Morley (1991) argued that "intelligible pronunciation is an essential component of communicative competence" and that "ignoring students' pronunciation needs is an abrogation of professional responsibility" (pp. 488–9), since

poor pronunciation can be professionally and socially disadvantageous to L2 speakers. There is also evidence that adult L2 learners with “fossilized” pronunciation benefit from explicit pronunciation instruction (Derwing & Munro, 2009) and that a focus on pronunciation can be embedded in genuinely communicative activities (Trofimovich & Gatbonton, 2006).

Although the subject of L2 pronunciation *teaching* conjures up reference to neglect, there is at least a body of literature documenting this neglect. Not the same can be said about L2 pronunciation *assessment*, which, with the exception of literature on automated scoring, has been essentially dropped from the research agenda since the publication of Lado’s seminal book, *Language Testing*, over half a century ago (1961). In what remains the most comprehensive treatment of L2 pronunciation assessment to date, Lado devoted separate chapters to testing L2 learners’ perception and production of individual sounds, stress, and intonation, offering concrete guidelines on item construction and test administration. Some of Lado’s views on L2 pronunciation are timely, including challenges in defining a standard of intelligible (i.e., easily understandable) pronunciation. However, other ideas are clearly outdated. For example, operating under the premise that “language is a system of habits of communication” (p. 22), Lado held that where differences exist between sounds in the learner’s first language (L1) and the target language, there will be problems, and these need to be systematically tested. However, predicting learner difficulties appears to be more nuanced than a simple inventory of differences between the L1 and L2 can account for. There is growing evidence, for example, that the accurate perception and production of L2 segments (i.e., vowel or consonant sounds) is mediated by learners’ *perceptions* of how different a given sound is from their existing L1 sound categories (Flege, Schirru, & MacKay, 2003). In general, accurate perception/production is more likely if the learner does not perceptually identify an L2 sound with any L1 sounds. This is because, if no difference is perceived, the learner will simply substitute the L1 sound for the L2 sound. In addition, contextual factors such as phonetic environment and lexical frequency also contribute to learner performance (Flege et al., 2003). Clearly, Lado’s (1961) view that differences between L1 and L2 phoneme inventories should form the basis of L2 pronunciation tests oversimplifies the situation.

Due to advancements in language testing and speech sciences research, there is an urgent need for an updated guide on L2 pronunciation assessment and item writing. As reported above, Lado’s work is the only extensive treatment on the subject. Therefore, several decades later, this reference remains the starting point for any discussion on L2 pronunciation assessment and, thus, features prominently in this chapter.

Lado expressed concern about the subjective scoring of test takers’ speech and proposed the use of more objective paper and pencil tests as an alternative to assessing test takers’ L2 pronunciation production (e.g., using multiple choice). Such written tests have the advantage of facilitating the testing of large numbers of students without the added time or expense of recording and storing speech samples or double marking them. The National Centre Test in Japan, a gatekeeping test for university admissions, uses decontextualized written items of the sort that Lado proposed to test oral pronunciation skills (see <http://school.js88.com/>

sd_article/dai/dai_center_data/pdf/2010Eng.pdf). The pronunciation component of the 2010 version consists of (a) segmental items, in which the test taker selects the word where the underlined sound is pronounced differently from the others (e.g., *boot*, *goose*, *proof*, *wool*; the vowel sound in 'wool' /ʊ/ is different from the /u/ sound in the other choices); and (b) word stress items, in which the test taker selects the word that follows the same primary stress pattern as the item in the prompt (e.g., *fortunately* → *appreciate*, *elevator*, *manufacture*, *sympathetic*; both 'fortunately' and 'elevator' have primary stress on the first syllable).

In an empirical study on retired National Centre Test items entitled "Written Tests of Pronunciation: Do They Work?" conducted in a Japanese junior college, Buck (1989) found no evidence that they do. First, internal consistency coefficients (KR-20) for six pronunciation subtests were unacceptably low (range: $-.89$ to $.54$) as were correlations between scores on the written items and on test takers' oral productions of those items ($.25$ to $.50$). Correlations with read-aloud and extemporaneous speech task ratings were even lower ($.18$ to $.43$). Several decades after the publication of Lado's (1961) book and Buck's (1989) article, there is still no empirical evidence that written pronunciation items constitute a reliable or valid measure of L2 pronunciation speaking ability. In the absence of such evidence, the use of paper and pencil tests for oral production should be discontinued, particularly when they are being used for high stakes purposes.

Current Views or Conceptualization

Theoretical Conceptualization

The field of language testing has moved beyond Lado's (1961) focus on discrete-point testing and theoretical view of language as consisting of separate skills (speaking, reading, writing, listening) and components (e.g., vocabulary, grammar, pronunciation) toward expanded notions of communicative competence and communicative language ability. However, the assessment of L2 pronunciation has been left behind, with communicatively oriented theoretical frameworks not adequately accounting for the role of pronunciation. In Bachman's (1990) influential communicative language ability framework, for example "phonology/graphology" appears to be a carryover from the skills-and-components models of the early 1960s (Lado, 1961). However, the logic of pairing "phonology" with "graphology" (legibility of handwriting) is unclear. Notably, Bachman and Palmer's (1982) multitrait-multimethod study, which informed the development of Bachman's (1990) model, omitted the "phonology/graphology" variable from the analysis even though it was hypothesized to be an integral part of grammatical competence. This is because the authors claimed that phonology/graphology functions more as a channel than as a component, since pronunciation accuracy (and legibility) cannot be examined below a critical level at which communication breaks down. Bachman's reincorporation of phonology/graphology as a component in his 1990 model without explanation demonstrates the need for greater clarity on the role of pronunciation in communicative models.

In the L2 pronunciation literature, Levis has characterized two “competing ideologies” or “contradictory principles” that have long governed research and pedagogical practice (2005, p. 370). The first principle, the “nativeness principle,” holds that the aim of pronunciation instruction should be to help L2 learners achieve native-like pronunciation by reducing L1 traces from their speech. The construct of “accentedness” in the L2 pronunciation literature, defined as listeners’ *perceptions* of how different an L2 utterance sounds from the native-speaker norm (measured using rating scales), aligns with this principle. The second principle, the “intelligibility principle,” holds that the goal of L2 pronunciation instruction should simply be to help L2 learners be understandable to their interlocutors—a view that most L2 researchers endorse and which is also “key to pronunciation assessment” (Levis, 2006, p. 252). However, the issue that Lado (1961) raised of “intelligible to whom” still resonates. To complicate matters, some scholars have depicted intelligibility as interactional between the speaker and the listener, whereas others have underscored that intelligibility is principally “hearer-based,” or a property of the listener (Fayer & Krasinski, 1987, p. 313). Still others have criticized the burden that is implicitly placed on L2 speakers to achieve intelligibility, arguing that native speakers need to assume their share of the communicative responsibility (Lindemann, 2002).

Part of the problem is that intelligibility has been defined and measured in multifarious ways, which makes cross-study comparisons difficult (Isaacs, 2008). At least some of the confusion lies in the existence of broad and narrow definitions of the term. In its broad meaning, “intelligibility” refers to listeners’ ability to understand L2 speech and is synonymous with “comprehensibility” (Levis, 2006). Reference to intelligibility as the appropriate goal of L2 pronunciation instruction and assessment conforms to this broad meaning. In its narrower sense, Derwing and Munro’s (1997) conceptually clear definitional distinction between intelligibility and comprehensibility, which is increasingly pervasive in L2 pronunciation research, is useful to examine. Derwing and Munro define intelligibility as the amount of speech that listeners are able to understand (i.e., listeners’ *actual* understanding). This construct is most often operationalized by computing the proportion of an L2 learner’s utterance that the listener correctly orthographically transcribes. In contrast, comprehensibility, the more subjective measure, is defined as listeners’ *perceptions* of how easily they understand L2 speech. This construct is operationalized by having raters record the degree to which they can understand L2 speech on a rating scale. Thus, comprehensibility, in its narrow definition, is instrumentally defined in that it necessitates a scale (i.e., a measurement apparatus) in the same way that measuring temperature necessitates a thermometer. That is, what distinguishes narrowly defined intelligibility from comprehensibility is not theory but, rather, the way these constructs have been operationalized. Hereafter, the term “comprehensibility” will therefore be used in its narrow sense whenever the notion of understandability is evoked in rating scales, with the exception of when the original wording from a given rating descriptor is retained. The term “intelligibility” will be used in both its broad and its narrow senses in the remainder of this chapter and the sense in which it is being used will be specified. The role of pronunciation in general and comprehensibility and accentedness in particular in current L2 speaking scales is the subject of the next section.

The Role of Pronunciation in Current Rating Scales

Theory often informs rating scale development. Because the theoretical basis for L2 pronunciation in communicative frameworks is weak as is our understanding of major holistic constructs, it follows that there are numerous shortcomings in the way pronunciation has been modeled in existing rating scales. First, pronunciation is sometimes omitted as a rating criterion. For example, pronunciation was excluded from the Common European Framework of Reference benchmark levels due to the high misfit values (i.e., substantial unmodeled variance) obtained for the pronunciation descriptors (North, 2000). Other scales that do include pronunciation only incorporate this criterion haphazardly. For instance, in the 10-level ACTFL oral Proficiency Guidelines (1 = novice low, 10 = superior), pronunciation is referred to in levels 1, 3, 4, and 5 of the scale but is entirely omitted from level 2 (novice mid). It is unlikely that pronunciation does not contribute to L2 oral proficiency at this precise point of the scale (level 2) when it is relevant at both neighboring levels. The inconsistency of reference to pronunciation or its exclusion altogether implies that pronunciation is not an important component of L2 speaking proficiency, making it likely that “pronunciation will become a stealth factor in ratings and a source of unsystematic variation in the test” (Levis, 2006, p. 245).

Another limitation of current scales is that their descriptors are often too vague to articulate a coherent construct. For example, in the public version of the IELTS speaking scale, the band 4 level descriptor reads, “uses a limited range of pronunciation features; attempts to control features but lapses are frequent; mispronunciations are frequent and cause some difficulty for the listener” (http://www.ielts.org/PDF/UOBDS_SpeakingFinal.pdf). Similarly, the level 2 descriptor for the TOEFL iBT “Integrated Speaking Rubrics” (Educational Testing Service, 2009, p. 190) states, “speech is clear at times, though it exhibits problems with pronunciation, intonation, or pacing and so may require significant listener effort. . . . Problems with intelligibility may obscure meaning in places (but not throughout).” These descriptors only vaguely reference the error types that lead to listener difficulty. In addition, the use of the term “pronunciation” differs across the scales. In the IELTS scale, “pronunciation” could be interpreted as referring to both segmental (individual sounds) and suprasegmental phenomena (e.g., intonation, rhythm, word stress), although this is not specified. In contrast, in the TOEFL iBT, the juxtaposition of “pronunciation” with “intonation” suggests that “pronunciation” refers only to segmental features. Clarifying the meaning of “pronunciation” is necessary to convey what exactly is being measured and is crucial for score interpretation.

Scales that employ relativistic descriptors offer even less clarity about the focal construct. For example, Morley’s (1991) Speech Intelligibility Index makes reference to “basically unintelligible,” “largely unintelligible,” “reasonably intelligible,” “largely intelligible,” and “fully intelligible” speech (p. 502). However, these semantic differences do little to guide raters on how the qualities manifested in test takers’ performance samples align with the scale levels.

Finally, a major shortcoming in the way that pronunciation is modeled in current L2 oral proficiency scales is that some scales conflate the dimensions of

comprehensibility and accentedness. For example, the highest level of the Cambridge ESOL “Common Scale for Speaking” groups “easily understood” pronunciation with “native-like” control of “many features” (University of Cambridge ESOL Examinations, 2008, p. 70). Similarly, the Speech Intelligibility Index systematically equates increases in comprehensibility with decreases in the interference of accent until the highest level, when “near native” speech is achieved and “accent is virtually nonexistent” (Morley, 1991, p. 502). However, a large volume of L2 pronunciation research has shown that comprehensibility and accentedness, while related, are partially independent dimensions (Derwing & Munro, 2009). That is, L2 speakers with detectable L1 accents may be perfectly understandable to their listeners, whereas speech that is difficult to understand is almost always judged as being heavily accented. Clearly, there is a need for a greater understanding of the linguistic factors that underlie L2 comprehensibility ratings, particularly at high levels of ability, so that reference to accent or native-like speech can be left aside.

Current Research

Overview

Although the increased visibility and momentum of L2 pronunciation within the broader field of applied linguistics over the past few years is evidenced in pronunciation-specific journal special issues, invited symposia, special interest groups, and, most recently, in the establishment of the annual Pronunciation in Second Language Learning and Teaching conference, this momentum has yet to extend to L2 pronunciation assessment specifically. This notwithstanding, there are two areas in the L2 assessment literature in which discussions on pronunciation are noteworthy. One is in the North American literature on international teaching assistants (ITAs) in light of concerns about ITAs’ spoken proficiency; the other is in the growing body of research on automated scoring for L2 speaking—a subject that is likely to continue to inspire debate as speech recognition technologies become increasingly sophisticated and implementable in a variety of assessment contexts. Both areas will be discussed in the remainder of the chapter. In particular, research aimed at gaining a deeper understanding of major holistic constructs in L2 pronunciation research will be emphasized.

Linguistic Influences on L2 Intelligibility and Comprehensibility

In an increasingly globalized world with greater human mobility, a growing number of students face the challenge of conducting academic tasks in their L2. This includes international graduate students who bear instructional responsibilities in higher education settings in a medium of instruction that is different from their L1, referred to here as ITAs. ITAs’ pronunciation has been singled out as problematic by different university stakeholders, including undergraduate students, English for academic purposes experts, and ITAs themselves (Isaacs, 2008). However, “pronunciation” (or “accent”) sometimes serves as a scapegoat for

other linguistic or nonlinguistic barriers to communication that may be more difficult to identify (e.g., ITAs' acculturation issues or listeners' discriminatory attitudes toward accented speech; see Kang & Rubin, 2009). In cases where listener understanding is genuinely at stake, targeted training of the factors that are most consequential for achieving successful communication should be prioritized in ITA instruction and assessment while taking into account their teachability/learnability (e.g., for adult learners with "fossilized" pronunciation). Unless concrete, empirically substantiated guidelines on what matters most for intelligibility and comprehensibility are provided to teachers, there is a risk that pronunciation features that are perceptually salient (i.e., are noticeable or irritating) but that have little bearing on listener understanding will be targeted (e.g., English interdental fricatives) in lieu of features that have more communicative impact (Derwing & Munro, 2009).

Jenkins (2002) proposed a core set of pronunciation features that should be emphasized in instruction for a new, global variety of English—the "lingua franca core." Although her argument for a transnational standard of English that is an alternative to native speaker varieties is compelling, her recommendations are based on a limited data set. Further, the inclusion criteria for speech samples in the English as a lingua franca corpus that Jenkins and her colleagues frequently cite have not been clarified (e.g., Seidlhofer, 2010). Therefore, substantially more empirical evidence is needed before the lingua franca core can be generalized across instructional contexts or adopted as a standard for assessment.

To date, only a handful of empirical studies have examined which pronunciation features are most important for intelligibility and comprehensibility. Perhaps the most conclusive findings arise from controlled studies that have systematically isolated a particular pronunciation feature to examine its effect on intelligibility (narrowly defined; see above). Generally, different experimental conditions are created either through manipulating sound files using digital editing techniques (e.g., for syllable duration) or through having the same speaker record different renditions of an utterance (e.g., correct versus displaced primary stress placement). Taken together, the studies reveal that that prosodic (i.e., suprasegmental) aspects of pronunciation related to stress and timing have a direct effect on intelligibility (e.g., Hahn, 2004), although other features have yet to be methodically examined. This emerging evidence supports previously unsubstantiated claims about the negative effects of prosodic errors on communication.

As for segmental errors, the available evidence suggests that a nuanced approach to instruction and assessment is needed, since some segmental contrasts (e.g., /s/ vs. /ʃ/ in English) appear to be more detrimental to intelligibility and comprehensibility than others (e.g., /θ/ vs. /f/). This is dependent, in part, on the frequency of the contrast in distinguishing between lexical items (i.e., the so-called functional load principle; Munro & Derwing, 2006). It is likely that segmental errors are more problematic for learners from some L1 backgrounds than others and that the occurrence of segmental errors in conjunction with prosodic errors (e.g., word stress) can be particularly problematic (Zielinski, 2008). Overall, prosodic errors seem to be more crucial for listener understanding than segmental errors, although some segmental errors clearly lead to reduced intelligibility and comprehensibility and should be addressed (Munro & Derwing, 2006). In order

to target the problem, it is important to first diagnose whether the learner's difficulty lies in perception, production, orthographic influence (particularly in languages with poor sound-symbol correspondence), or a combination of these factors. In addition to systematically testing the perception and production of target features at the individual sound, word, and/or sentential levels, in the case of speech production, a diagnostic passage (read-aloud task crafted to elicit particular segmental or prosodic features that may not occur in natural speech) could be used in conjunction with a prompt eliciting an extemporaneous L2 speech sample (see Celce-Murcia et al., 2010).

Beyond diagnosing learner problem areas for pedagogical reasons, gaining a deeper understanding of the linguistic factors that most influence listeners' L2 comprehensibility ratings is crucial for adequately operationalizing the construct in assessment instruments. In low stakes research contexts, comprehensibility and accentedness are conventionally measured using nine-point numerical rating scales (1 = very difficult to understand, 9 = very easy to understand; 1 = very accented, 9 = not accented at all; e.g., Munro & Derwing, 2006). A minority of studies have instead used sliding scales (i.e., the rater places a cursor along a continuum to indicate his/her scoring decision) or Likert-type scales with a different number of scale levels. Such scales are appealing to L2 pronunciation researchers precisely due to their generic nature, since they can be used with L2 learners from virtually any L1 background and proficiency level. However, a caveat is that the raters receive no guidance on how to make level distinctions and, in the case of the conventionally used nine-point scales, are unlikely to converge on what the nine levels "mean" in terms of performance qualities, particularly between scalar extremes where no descriptors are provided (Isaacs & Thomson, in press). While these scales have been shown to work well for rank-ordering speakers, the lack of clarity on what is being measured at each scale level limits the precision of the instruments and raises questions about the validity of the ratings (e.g., it is unclear whether comprehensibility refers to comprehensibility of the overall message or of each individual word).

In a recent study examining the linguistic factors that underlie listeners' L2 comprehensibility ratings for the purpose of deriving a preliminary L2 comprehensibility scale for formative assessment purposes, Isaacs and Trofimovich (2012) analyzed speech samples of 40 Francophone learners of English on a picture narrative task using 19 speech measures drawn from a wide range of linguistic domains, including segmental, suprasegmental, temporal, lexicogrammatical, and discourse level measures. The speech measures were analyzed using both auditory and instrumental techniques. For example, in terms of suprasegmentals, "pitch contour" at clause boundaries was measured using listeners' perceptions of pitch patterns at the end of intonation phrases (auditory), whereas "pitch range" was measured using the pitch tracker function in the Praat speech analysis software (instrumental). The analyzed measures were then correlated with 60 raters' mean L2 comprehensibility ratings using the nine-point numerical comprehensibility scale. By bringing together statistical indices and raters' accounts of influences on their judgments, it was possible to identify a subset of measures that best distinguished between three different levels of L2 comprehensibility. Overall, lexical richness and fluency measures differentiated between low level learners,

grammatical and discourse level measures differentiated between high level learners, and word stress differentiated between learners at all levels. Such a formative assessment tool could help teachers integrate pronunciation with grammar and vocabulary teaching in communicative classrooms. However, follow-up validation studies are needed to refine the scale and clarify the range of tasks and settings that scale descriptors can be extrapolated to.

The Isaacs and Trofimovich (2012) study represents an initial step at “deconstructing” L2 comprehensibility by focusing on linguistic properties of speech. However, the scores that raters assign may also be influenced by individual differences in rater characteristics—factors that are external to the test takers’ performance that is the object of the assessment. This topic is examined in the next section.

The Influence of Rater Characteristics on Their Judgments of L2 Pronunciation

A growing body of L2 speaking assessment research has examined the influence of rater background characteristics on rater processes and scoring outcomes. Research focusing on L2 pronunciation specifically is a subset of this literature. In a recent study, Isaacs and Trofimovich (2010, 2011) examined the effects of three rater cognitive variables—phonological memory, attention control, and musical ability (aptitude)—on rater judgments of L2 comprehensibility, accentedness, and fluency. The rationale was that, if individual differences in rater cognitive abilities were found to influence raters’ scoring, then this could pose a threat to the validity of their ratings. There were two major findings. First, no significant effects were detected for phonological memory and attention control, which is reassuring because it removes these variables as a possible source of rater bias. Second, musical raters were overall more severe in their judgments of L2 comprehensibility and accentedness than their less musical peers. Follow-up analyses revealed that musical raters’ heightened sensitivity to melodic aspects of music and speech (i.e., pitch phenomena) likely accounted for these differences. Although these findings are intriguing from a research perspective, the statistical findings were relatively weak (e.g., yielded small effect sizes) and it is unclear how *practically* significant these findings are. Further evidence is needed before recommending, for example, that raters for high stakes speaking tests need to be screened for musical ability or that a homogeneous group of raters should be sought on the basis of their musical training. Therefore, until future research suggests otherwise, language testers need not be overly concerned by these findings.

Recent L2 pronunciation research has begun to establish a link between individual differences in L2 *learners’* sociolinguistic variables, such as ethnic group affiliation and willingness to communicate, and their L2 pronunciation attainment (e.g., Gatbonton & Trofimovich, 2008). Although not examined from an assessment angle, Lindemann (2002) observed that native speakers’ perceptions of how well they understood their non-native interlocutors was mediated by their attitudes toward their partners’ L1 (see also Kang & Rubin, 2009). Research on motivational and attitudinal factors in relation to pronunciation assessment bears further exploration.

Rater familiarity with a particular L2 accent is often not controlled for in L2 pronunciation research, and studies that have investigated this have produced inconsistent findings. Some studies have shown that greater rater familiarity is associated with a tendency toward higher scoring and better listener understanding, although other studies have found no facilitative effects (see Carey, Mannell, & Dunn, 2011; Isaacs & Thomson, in press). At least some of the difficulties can be accounted for by the multifarious ways in which familiarity, which is sometimes framed as listener experience or expertise, is defined (e.g., in terms of amount of exposure to a particular L2 accent, ESL/EFL teaching experience, or phonetic training) and the “novice,” “inexperienced,” or “lay” listener comparison group is defined (Isaacs & Thomson, in press). Clearly, greater consensus on the meaning of these terms in the context of L2 pronunciation research would be desirable.

Because subjective measures of pronunciation are contingent upon both the message sender and the message receiver, the effect of rater background characteristics on the rating processes and the scores assigned is important to examine. One way of removing rater idiosyncrasies from the scoring process is through automated (i.e., machine) scoring. This subject is discussed in the next section.

Automated Scoring

Lado’s (1961) concern about the reliability of subjective scoring of test takers’ L2 pronunciation productions can now be addressed through an alternative that was unavailable during Lado’s time—automated scoring. Because the machine scoring system (i.e., speech recognition algorithm) is trained on pooled ratings across a large cross-section of human raters, it has the effect of averaging out individual rater idiosyncrasies in a way that operational ratings of L2 speech involving two or three human raters do not. Research on Pearson’s fully automated Versant English Test (previously Phonepass) has revealed high correlations between machine-generated scores and human ratings (Bernstein, Van Moere, & Cheng, 2010) and has established criterion validity with traditional large-scale L2 speaking proficiency tests (e.g., TOEFL, IELTS). While this suggests that these tests are measuring a related construct, it is unlikely that the automated system is sensitive to the same properties of speech that human raters attend to when rating, which raises questions about the validity of the assessment. In fact, studies from the speech sciences literature have demonstrated that some aspects of listeners’ auditory perceptions conflict with acoustic facts obtained using instrumental measures. For example, human listeners often perceive stressed syllables to be higher than they are revealed to be in spectral analysis (Crystal, 2008). Further, because pattern matching is involved in automated scoring, controlled tasks that generate highly predictable test taker output (e.g., utterance repetition, sentence unscrambling) are much easier for automatic scoring systems to deal with than spontaneous speech arising from more communicative tasks (Xi, 2010). However, the use of such constrained tasks, which, at present, are necessary to replicate scores that human raters are likely to assign, has led to concerns about the narrowing of the construct of speaking ability. Finally, automated speaking tests may

claim to measure intelligibility in the broad sense of the term. However, much of the emphasis in the automated system is on pronunciation accuracy (e.g., of vowels and consonants). While automated feedback can inform the test user of the presence of mispronunciations, the type of mispronunciations, even if specified, will not likely all have the same impact on an interlocutor's ability to understand the utterance. Thus, the need to define the pronunciation features that most contribute to breakdowns in communication also applies to the automated scoring of speech.

Because human interlocutors involved in real-world communication are the ultimate arbiter of the qualities of speech that promote the successful exchange of information (and not machines), it is important not to lose sight of human raters as the gold standard to which automated assessments must conform. It is likely that, as speech recognition technology continues to improve, automated scoring will become increasingly prominent in the language testing research literature and testing products, albeit not to the extent that it ever supplants human ratings. There will always be constraints on what the automated system is able to do.

Challenges

This article has brought to the fore key issues in L2 pronunciation assessment. Numerous challenges have emerged thus far. Among the most salient are the need to:

- unpurse the role of pronunciation (i.e., "phonology/graphology") in theoretical models of communicative competence and communicative language ability;
- discontinue the use of pronunciation item types or assessment methods that do not meet high standards of reliability and validity (e.g., paper and pencil items purportedly testing pronunciation production) or that are methodologically unsound or of questionable fairness (e.g., speech analyses for asylum purposes by authorities who know little about language or linguistics), particularly when they are being used for high stakes purposes;
- clarify the role of pronunciation within the broader construct of L2 speaking ability;
- disambiguate terms in the L2 pronunciation research literature that are not used with consistency, such as intelligibility and comprehensibility or listener (rater) expertise, experience, and familiarity;
- recognize that intelligibility (broadly defined) is the appropriate goal of L2 pronunciation instruction and assessment in the vast majority of language use contexts but needs to be more clearly understood;
- prioritize empirical studies that isolate a particular segmental or suprasegmental feature to examine measurable effects of that feature on intelligibility or comprehensibility (narrowly defined), the findings of which can then be examined in conjunction with evidence from observational studies;
- develop a greater understanding of the linguistic factors that underlie listeners' perceptions of L2 comprehensibility for the purpose of operationalizing

comprehensibility more clearly in rating scales, including without resorting to a native speaker standard;

- examine systematic sources of variance (e.g., psycholinguistic, sociolinguistic, or experience-related rater variables) that have the potential to influence ratings of L2 pronunciation but that may be extraneous to the construct being measured (i.e., are possible sources of rater bias);
- provide L2 teachers with more precise information on the error types that most contribute to communication breakdowns so that these can be targeted in L2 speaking and listening instruction and assessment;
- continue to investigate the relationship between human-mediated and machine-mediated assessments of L2 pronunciation, including the extent to which automated speech recognition can predict human scoring on more communicatively oriented tasks and the quality of the feedback delivered to test users.

While these areas, both individually and as a unit, constitute major challenges, there is one challenge that underpins all of these points and that is fundamental to propelling L2 pronunciation assessment into a post-Lado era. That is, the most significant challenge in the area of pronunciation assessment research today is to reinvigorate the conversation on L2 pronunciation in L2 assessment circles. To say that the area of L2 pronunciation assessment has been under-researched over the past several decades would be an understatement, as repercussions of the view that pronunciation is incidental to L2 learning and is unessential for communicative competence still resonate. Although, in the minds of some applied linguists, pronunciation harkens back to tedious, mechanical drills and decontextualized discrete-point items of the past, the potential for communicatively oriented items is evident in some currently available teaching materials (e.g., Grant, 2009) if it has not yet infiltrated pronunciation assessments.

Although there is no mass reversal of the marginalization of L2 pronunciation from discussions on L2 assessment, a glimmer of hope is apparent in the publication of three articles on L2 pronunciation in the prominent assessment journal *Language Testing* since 2010 (as of the writing of this chapter). These articles, on the subjects of automated assessment and rater accent familiarity effects, are only the second, third, and fourth pronunciation-focused articles to have been published in the journal since its inception in 1984. Fruitful areas for future research are discussed in the final section of this chapter.

Future Directions

As the debate on automated scoring in relation to L2 speaking has gained increasing momentum with the recent launch of fully automated tests (e.g., the high stakes Pearson Test of English Academic or the low stakes SpeechRater, intended for TOEFL iBT training purposes), the topic of pronunciation has resurfaced in L2 assessment circles. However, this is only one area of research that merits attention. If we accept the argument that pronunciation (and, in particular, broadly defined intelligibility) needs to be assessed as part of the construct of L2 oral proficiency, then there is an urgent need to better define the constructs that we intend to

measure for assessment purposes, including filtering out accentedness from L2 proficiency scales. While accentedness is of substantive interest to L2 pronunciation researchers due to its potential to influence listeners' attitudes toward L2 speech (Kang & Rubin, 2009), intelligibility (broadly defined) is by far the more important construct for L2 pronunciation pedagogy and assessment (see above). It follows that operationalizing comprehensibility in more explicit terms in rating scales without resorting to the native speaker standard should be the focus of current L2 pronunciation scale development (Isaacs & Trofimovich, 2012). From a research perspective, this could be accomplished by triangulating statistical findings of the unique components of comprehensibility versus accentedness with raters' accounts of the linguistic aspects of the speech that they attend to when rating each construct. Drawing on Isaacs and Trofimovich's (2011) finding that musical raters, who are more attuned to certain aspects of the speech signal than their less musical counterparts, overall perceive comprehensibility and accentedness to be more independent dimensions, eliciting musicians' perceptions may be helpful in teasing these constructs apart.

One final substantive area not yet addressed in this chapter that needs to be flagged as a research priority relates to examining learners' L2 pronunciation performance on tasks that elicit a wider range of interactional patterns. Most of the pronunciation research cited above has involved native speakers' ratings of non-native speakers' performances on relatively inauthentic monologic tasks. Generally, this involves L2 learners (i.e., research participants) speaking into the microphone without the presence of an interlocutor, which does not foster genuine communication. To reflect the reality of English as a global language more closely, including the likelihood that L2 learners will need to interact not only with native speakers, but also with non-native interlocutors (depending, of course, on the context), performance on more collaborative tasks that bear greater resemblance to the real-world tasks that learners will be expected to carry out would be desirable. From an L2 assessment perspective, paired speaking tasks generally involve dyadic interactions among non-native interlocutors, although pairing procedures can be somewhat haphazard. Future research could, for example, investigate the effects of same versus different L1 group pairings on factors such as communicative efficiency and the production of target-like pronunciation.

Assessing Speaking

Barry O'Sullivan

British Council, England

Introduction

While there have been some significant advances in our understanding of spoken language, in terms of both production and interaction, over the past decades, there remain a number of areas of significant concern to the test writer. These are most notably construct definition (what exactly we are assessing), predictability of task response (task description), the effect of characteristics of the test taker on performance, the effect of characteristics associated with the interlocutor (the person with whom the candidate is interacting) on performance, and the appropriateness of the scoring system (i.e., rating scale validity and the reliability of the rating process). Before exploring these concerns, it is important to acknowledge the central role in test development of validation by first making explicit the model of validation that underpins this chapter.

Defining Speaking

In the 1970s, the field of psycholinguistics was most obviously associated with studies which focused on understanding and processing spoken language. The most important model of the psychological process of language production to emerge from early work in the area was that of Levelt (1999). This model (or blueprint, as Levelt called it) shows how the speech process is organized from the constraints on conversational appropriateness to articulation and self-monitoring. Levelt saw the speaker as an information processor, and proposed a blueprint in which message generation, grammatical encoding, phonological encoding, and articulation are seen as relatively autonomous processors. (Encoding here refers to the process by which the message is prepared for delivery.)

The Companion to Language Assessment, First Edition. Edited by Antony John Kunnan.

DOI: 10.1002/9781118411360.wbcla084

While Levelt's model stops largely at the point of utterance, he goes on to describe at length the three essential aspects of conversation in which the speaker plays the parts of both participant and interlocutor. Levelt saw conversation as being highly contextualized and purposeful, having a spatiotemporal setting. In addition, the basic mechanisms of speech processing are conceptualized in his model in an uncomplicated way: Speech is produced by first conceptualizing the message, then formulating its language representation (encoding), and finally articulating it. In terms of reception, speech is hypothesized as being perceived initially by an acoustic-phonetic processor, then linguistically encoded in the speech comprehension system (the parser), and finally interpreted by the conceptualizer.

Levelt's model continues to underpin research on speaking (e.g., Field, 2011; Weir, 2005) and informed a central element of the most significant and practical approach to test validation to emerge in recent years, that of Weir (2005). Weir's *theory-based validity*, more recently referred to as *cognitive validity* (Khalifa & Weir, 2009), marks the first real attempt to take into consideration, from the onset of test development, the cognitive processes that underlie language use. This is significant, as understanding the cognitive processing undertaken by a test taker allows the speaking test developer to do such things as

- make informed decisions about the amount and type of planning we build into our tasks (this planning might be teacher or developer led, student led, or unstructured);
- consider the impact on the scoring of a test taker's performance of the accent or pronunciation of his or her interlocutor; and
- ensure that lower level test takers are given some content support (e.g., bullet points indicating what they might talk about) so as to reduce the cognitive load.

While the view of speaking represented in the above model is of clear significance to test developers, who must ensure that candidates engage cognitive processes that reflect those of real-world communication, the social aspect of language use cannot be ignored. As will be shown below, there is ample evidence that a whole raft of variables can affect the linguistic performance of a test taker, from the topic to the task format (essentially cognitive in nature) and to the interlocutor or audience (essentially social in nature). The understanding that any test development model for speaking must reflect both cognitive and social aspects of language use was first proposed by O'Sullivan (2000, p. 277) and later formed the basis for the validation frameworks presented by Weir (2005), referred to above.

Weir (2005) argued that validation should be supported with evidence from a range of perspectives. These included:

- *test taker*, relating to the characteristics of the test taker suggested by O'Sullivan (2000) and categorized as physical, psychological, and experiential;
- *theory-based*, that is, the cognitive processes and resources brought to the test event by the test taker;
- *task-based*, considering task performance parameters (such as timing) as well as the linguistic demands of the task (which can relate to input and expected

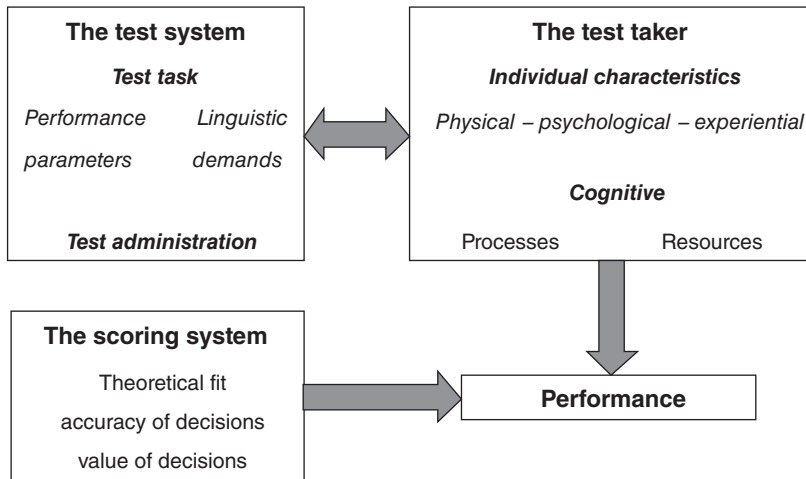

Figure 9.1 A reconceptualization of Weir's sociocognitive framework (from O'Sullivan, 2011) © Routledge

output), and also involving aspects of the administration of a test, from the delivery platform or format to security or room setup;

- *scoring*, relating to all aspects from rater recruitment, training, and monitoring to the rating scale and aspects of final grade awarding;
- *consequential*, seen by Weir as including such things as washback, social impact, and test bias; and
- *criterion-related*, that is, the traditional view of the value of a test score when compared to estimates obtained from other sources (e.g., teacher, self, peer, other tests).

O'Sullivan and Weir (2011) and O'Sullivan (2011) have updated the original Weir approach to reflect the extensive experience gained over recent years in applying the model to real test development and validation situations. The updated model (see Figure 9.1) takes a very similar perspective to the original, but moves away from the concept of consequence as an a posteriori aspect of validation (i.e., something that is investigated after the test has become operational) to one of consequence as an a priori aspect (seeing all decisions taken in the development process from the perspective of their impact on the test taker). This update also reflects concerns with the concept of consequential validity raised by Cizek (2011), who suggested that any decision to use a test must be supported by an evidence-based argument similar to that required for validation. Cizek also argued that the responsibility for developing this *test use* argument lies with the authorities who make the decision to use the test (though they would be expected to work with the test developer to build their argument). The other significant change to the model lies in the inclusion of criterion-based evidence (i.e., evidence of a candidate's ability gathered from alternative sources such as other tests or teacher estimations) in the scoring system. See O'Sullivan (2011) for a detailed overview of the revised model.

What follows in this chapter should be seen as a reflection of the validation model shown in Figure 9.1, as this chapter supports the contention of O'Sullivan and Weir (2011) that validation lies at the heart of test development.

Test Design

Speaking tests, like other direct tests of language performance, are designed to allow the test developer to make a claim or set of claims about an individual test taker's ability to use language under particular conditions. In a direct test, the candidate performs the skill being assessed; so to test speaking, we ask the candidate to speak. The nature of the claim is inextricably linked to both the ability model (i.e., the model or definition of the ability being assessed) upon which the test will be based and the test-taking population. This is because the test developer must take into account a whole series of variables (or characteristics) that are associated with the intended population in order to ensure that the resulting test is appropriate for use with that population. These have been categorized by O'Sullivan (2000) as physical, psychological, and experiential characteristics and are briefly discussed below.

The test task is then developed to reflect the ability model and the intended population, while the rating scale is devised to reflect the ability model in terms of both the criteria to be included and the level or amount of the ability expected of the successful test taker. When it comes to the administration phase of the development process, the test taker produces a performance (or set of performances) in response to the task (or tasks) which is then assessed by a rater who awards a score or grade.

It is likely that the test taker will be affected by a number of factors, including:

- the interlocutor, where this person is another candidate (e.g., O'Sullivan 2000);
- affective reactions to the examiner (e.g., Porter, 1991; O'Sullivan, 2000);
- examiner behavior (e.g., Brown & Lumley, 1997);
- the task topic (e.g., Lumley & O'Sullivan, 2005);
- the task format (e.g., Berry, 2007); and
- knowledge of the scoring (or rating) criteria, which will have an impact on how a typical candidate might approach a test task (e.g., by focusing on a particular aspect of the language they use to meet the perceived or actual expectations of an examiner).

On the other hand, it is equally possible that the rater will also be affected by a number of factors, including the test taker, the task, and the scoring system.

Once the final score or grade has been awarded, it is necessary to establish evidence of the value of the score in terms of the claim or claims upon which the test is based. In tests of speaking this typically includes evidence from sources such as performance on other tasks (e.g., performed in class), teacher estimates of each test taker's ability, or post-test longitudinal data of test-taker spoken performance. An example of this is in a test of language for immigration, where the developer or user will gather data through tracking studies of test takers' success

in using spoken language in the target country, though the limitation of tracking studies (since only successful test takers are typically tracked) must be acknowledged. It is also possible to look to test-taker performances to establish evidence that the language predicted by the test developer when the task was designed emerges in the test event (O'Sullivan, Weir, & Saville, 2002), or to compare test-taker language with descriptions of ability level in established standards such as the Common European Framework of Reference (CEFR), published by the Council of Europe (2001).

Issues in Testing Speaking

In this section of the chapter, I will focus on current issues of significance in the area of testing speaking and present these in terms of the model of validation shown in Figure 9.1.

The Test Taker

Physical Characteristics Building on earlier work, in which no evidence of any systematic effect for physical characteristics was found, O'Sullivan (2000) suggested that age may be a contributing factor to variation in performance when other variables, such as gender, perception of language ability, and personality, are included.

The evidence of a gender effect is quite mixed, with O'Sullivan (2000) finding significant differences in test performance where the examiner was female (irrespective of the gender of the test taker), and O'Loughlin (2002) reporting that there was no significant gender effect in the International English Language Testing System (IELTS) interviews, from the perspective of either test-taker language or scoring.

One very important aspect of test delivery is the availability of special measures (or accommodations) for test takers with physical disabilities. While most countries make such measures a legal requirement of all tests, there is a singular lack of empirical justification for the actual measures offered, with no published work in the area of language testing. Even when these measures are made available, there is quite a low uptake; for example, Taylor (2003, p. 2) reports that despite a population of over one million test takers in 2001, Cambridge English for speakers of other languages (ESOL) in the UK had only seven requests for special measures in the speaking tests across all levels. Even though O'Sullivan and Green (2011) record a significant increase in the number of requests over the following decade, this still amounts to little more than 0.01% of the test population.

Psychological Characteristics Berry (2007) explored the effect on performance of characteristics associated with learners' psychological profiles. Using the Eysenck Personality Questionnaire to classify test takers as either extremely extraverted or extremely introverted, Berry was able to establish convincing evidence of significant differences in the performances of the two groups under different test conditions. Her results suggested, for example, that introverts performed

significantly better than extraverts under the solo condition, while there were no significant differences in performance in either of the paired conditions for either the introverts or the extraverts. This work was built upon by Ockey (2009), who found that assertive test takers scored higher than expected when grouped with nonassertive test takers and lower than expected when grouped with other assertive test takers. O'Sullivan (2000) took a different perspective, looking at the impact on a test taker's performance of their perception of the relative personality (in terms of introversion/extraversion) of their partner in a paired test. O'Sullivan found that a candidate's perception of their partner's personality (relative to their perception of their own personality, e.g., "he seems more outgoing than me") had an effect on performance in interaction with that of the other variables studied.

Other psychological characteristics have been explored in the broader language-learning domain include motivation and anxiety, though only the latter has received systematic attention in the area of assessment. Young (1986) found no evidence of anxiety impacting on oral proficiency test performance, though she acknowledged that the tests in her study were not taken under operational conditions.

Experiential Characteristics Experiential characteristics can refer to education, both formal and informal, and background knowledge, both general and test specific. There is evidence that test performance will be positively affected by education, that is, exposure to the language in formal and informal settings (e.g., Spurling & Illyin, 1985), though this has not been established specifically for speaking. While test preparation courses comprise a major segment of the language-learning industry worldwide, and it is intuitively clear that knowledge of a test format (in the case of speaking) would be of significant benefit to a test taker, there is no empirical evidence that this is in fact the case. In terms of task topic, there appears to be some evidence that choice of topic is unlikely to impact on performance (e.g. Lumley & O'Sullivan, 2005), though it may well be that the nature of the scoring system means that the instrument is simply neither finely tuned nor focused enough to allow for differences in performance to be identified.

Cognitive Aspects As Figure 9.1 suggests, test developers should take into consideration those cognitive processes associated with the ability or abilities being tested as well as those characteristics of the proposed population that are found to be appropriate within the current test development (e.g., by taking into account the age of the intended population when developing a school-leaving language test). While Khalifa and Weir (2009) have investigated the cognitive perspective of writing and reading respectively, little significant work has been done to date on the subject of speaking, though see Field (2011) for a notable exception.

Another important aspect of cognition in language use is that it is within this part of the model that we look to the linguistic resources brought to the test by the test taker; in other words, the model of language use which will be used to drive the test. To date, few test developers explicitly define these models (though see, among others, Galaczi & French, 2011), and the implications of research in applied linguistics since the early 2000s call into question the way at least some

components of language are assessed. The work of Carter and McCarthy (e.g., 2006) and others in their research circle suggests, for example, that the traditional descriptors of grammar used in rating scales, which are typically focused on accuracy and range, are unlikely to result in meaningful measures due to the often significant differences between spoken and written grammar. It may be that more formal, monologic, or individual long-turn or presentation tasks are more likely to reflect the expectations of a written grammar, while more interactive tasks may require descriptors which are more systematically based on grammars of spoken discourse. A second area for concern is that of fluency. McCarthy (2010) argues convincingly that fluency should be regarded in a different way for monologic discourse (the traditional view) and interactive discourse, where he has shown it to be co-constructed by the participants. This again suggests that current practice, in which descriptions of fluency are based on the monologic model, are likely to result in misleading claims and as such are in need of revision.

The Test System

The test system includes those aspects of the test that relate to the performance parameters, the linguistic demands, and the administration conditions through which the test is delivered.

Performance Parameters The most often researched aspect of task performance has been that of planning time (see, among others, Foster & Skehan, 1997), and it is now well accepted that the appropriate inclusion of planning time is likely to result in significantly improved performance on speaking test tasks. Other parameters that might benefit from more extensive research include the way in which knowledge of how the performance will be assessed (i.e., knowing the rating criteria) will affect subsequent test performance and how the amount of language output expected or the degree of support offered will impact the performance (Weir, O'Sullivan, & Horai, 2004). The way in which the test is delivered to the candidate should also be considered. The test formats currently used are:

- *live*, where the test taker responds to a series of language elicitation tasks (LETS) in the presence of an examiner (or examiners), who award(s) a score or grade using a pre-established rating scale;
- *recorded*, where the performance is recorded for later scoring by human raters, who again use a pre-established rating scale. Here, the event can be exactly the same as the live event (i.e., with an examiner present) or the recordings can be made of a test taker's responses to recorded, written, or visual prompts; and
- *automated*, where test taker responses to a series of LETS are automatically scored by a computer program using either voice recognition technology or sound production comparisons.

All of these methods have strengths and weaknesses, which are summarized in Table 9.1. It is clear from these brief descriptions that the different formats access different aspects of language and award scores or grades based on different

Table 9.1 Overview of test methods

<i>Format</i>	<i>Variant</i>	<i>Gloss</i>	<i>Advantages</i>	<i>Disadvantages</i>
Live	1. One-to-one interview	A single test taker responds to questions or tasks presented by a single examiner	Perceived as valid since the candidate's performance is affected only by an interaction between his or her language ability, the task, and the examiner	Heavily reliant on the examiner/interlocutor Training required for both examiner and rater roles Without additional ratings, reliability is suspect Accesses a narrow range of language functions (mainly informational; O'Sullivan et al., 2002)
	2. Pair/small group	Two or three test takers interact in response to a prompt	Potential to access full range of functions (informational, interactional, and discourse management)	Individual test takers (e.g., introverted) may be disadvantaged (Berry, 2007; Ockey, 2009). Affective reactions to one's interlocutor may significantly affect performance (O'Sullivan, 2000) Co-construction of discourse means that score awarding can be compromised as it is difficult to decide how to assess test takers based on their contribution to the discourse (McNamara, 1997)
	3. Group	Four or more test takers interact in response to a prompt	Potential to access full range of functions (informational, interactional, and discourse management)	Individual test takers may again be disadvantaged and affective reactions to fellow group members may impact on performance Can appear staged, with no real interaction generated Co-construction of discourse may also be an issue

Recorded	<p>1. Based on live event</p> <p>2. Based on recordings</p>	<p>A recording of the live test event is rated by a remote human rater</p> <p>The test taker responds to prompts that can be recorded, read, or visual (or a combination of these), as in, for example, the Simulated Oral Proficiency Interview (SOPI)</p>	<p>Useful method of gaining additional scores, so reliability of test is likely to be positively affected</p> <p>Allows for a record of the event to be archived in case of any future test-taker request for rescoring</p> <p>Can be used to test a large number of students within a short period of time</p> <p>All input controlled, so the event is the same for all test takers</p> <p>Task performances can be separated (i.e., no single rater scores all tasks), thus eliminating any halo effect (where the rater awards the same score for all performances, possibly based on performance of a single task)</p>	<p>Some danger that the score awarded for the recorded performance will be lower than that awarded for the live event (McNamara & Lumley, 1997)</p> <p>Where the recording is audio, any nonverbal communication strategies are invisible to the rater, which may affect the score negatively</p> <p>With current technology, tasks are limited to production, though newly emerging technology allows for interactive tasks through random assignment into pairs or small groups.</p>
Automated	<p>1. Voice recognition based</p> <p>2. Sound recognition based</p>	<p>Similar to recorded variant (2) in data collection, but scoring is done automatically by computer</p> <p>As automated variant (1)</p>	<p>No human intervention required, so tests likely to be cheap to administer once the system has been developed</p> <p>Fast response</p> <p>No human intervention required, so tests likely to be cheap to administer once the system has been developed</p> <p>Fast and relatively consistent response</p>	<p>High development costs</p> <p>Level of accuracy is not high enough to allow for high stakes use as yet</p> <p>Limited aspect of spoken language assessed</p> <p>High development costs</p> <p>Unclear exactly what is being tested</p> <p>Limited aspect of spoken language assessed (Bernstein, Van Moere, & Cheng, 2010)</p>

criteria. While the automated tests have been shown to be highly consistent (Bernstein et al., 2010), they have yet to receive widespread acceptance, due at least in part to the apparent lack of validity of the contents and scoring system. The issue of what is being tested is not, of course, confined to automated tests.

In comparing test-taker performance on an Oral Proficiency Interview (OPI) and a Simulated Oral Proficiency Interview (SOPI), Stansfield and Kenyon (1992, p. 363) concluded that “both tests are highly comparable as measures of the same construct—oral language proficiency.” However, this finding was not supported by Shohamy (1994), whose qualitative analysis of the language associated with performance on both formats highlighted a series of significant differences between the two. This was also the deduction of Wigglesworth and O’Loughlin (1993), who reported that approximately 12% of the candidates received different overall classifications for the two tests. In a follow-up study, O’Loughlin (1995) explored differences in the lexical density of output on the two formats, again highlighting significant differences and concluding “that the tape-based version taps a slightly more literate kind of language than the live version” (O’Loughlin, 1995, p. 236), a finding that mirrors that of Shohamy (1994). These early studies are interesting in that test developers continue to explore the use of different delivery platforms (e.g., computer and phone) though they have yet to systematically explore the language used by test takers under the different conditions or the impact of delivery format on rater behavior.

We have seen, above, how manipulation of task variables (such as planning time, amount of expected output, and amount of support) can affect task performance. Similarly, research suggests that different tasks will result in different language output (e.g., O’Sullivan et al., 2002). Topic bias was addressed by Lumley and O’Sullivan (2005), who found little empirical evidence that topics which were expected to result in one group of test takers (based on gender) achieving higher test scores or grades actually did so, and even where a significant effect was found it appeared to be very small and was likely to be meaningless in terms of test score. It would appear that for a test to offer a broad enough sample of a test taker’s language, a range of tasks, each designed to elicit a particular output, should be used, while the topic may not be as significant a factor as once thought. It would also appear sensible (particularly in light of the suggestions regarding grammar and fluency outlined above) that these tasks should be individually scored.

The negative impact of examiner domination of the test event was, at one time, exacerbated by the wayward behavior of examiners in tests of speaking (in terms of variability in topic, interaction style, and questioning). This was addressed by the introduction of so-called *interlocutor frames* (or scripts) through which the test developers attempted to control test input as much as possible. While this approach was certainly successful in ensuring that the input to all candidates was consistent, there were a number of criticisms of the practice as it was felt that the natural flow of communication between examiner and test taker was compromised (e.g., Foot, 1999). In fact, the real danger lay in the possibility that in removing any opportunity for genuine interaction, the test might come to elicit the sort of language typical of a recorded test such as a SOPI, where the tasks or questions are delivered aurally and the responses recorded for later scoring by trained raters; in other words, where the language is monologic rather than interactive in nature.

O'Sullivan and Yang (2006) examined the language produced by test takers in an IELTS speaking test on both sides of all variations from the interlocutor frame by their examiners. These authors found that there were no systematic points during the interviews at which variation from the interlocutor frame tended to occur and no significant difference in the language produced either side of any variations that were found. This suggests that, while an interlocutor frame is of value (in keeping the test event consistent for all test takers), it is not necessary that it should be overly prescriptive.

Linguistic Demands Skehan (1998) hypothesized that the amount, complexity, and degree of concreteness of the language of the task prompt will impact on the complexity of the task. While Norris, Brown, Hudson, and Yoshioka (1998) have made a systematic attempt to develop a task development matrix based on the work of Skehan, there is, as yet, no empirical support for the approach. With regard to the lexical demands of a speaking test, there has been some debate over the amount of vocabulary expected of a test taker at any specific level of ability. Khalifa and Weir (2009), for example, argue that it is difficult to specify with any real precision what words a test taker might need to respond successfully to a task. Galaczi and French (2011, pp. 153–4) point to the idea originally proposed for writing by Khalifa and Weir (2009) that an attempt be used to link productive vocabulary to the language functions typically associated with performance of particular tasks. While this is an interesting idea, it remains doubtful where it could be used to sufficiently define successful performance in terms of vocabulary. It would appear that it is difficult to move away from the current practice of the rater or marker making a subjective decision on the appropriateness of a test taker's vocabulary within the context of a particular performance.

With regard to the language of the prompt (i.e., the task input, as opposed to the task output produced by the test taker), Galaczi and French (2011, pp. 155–7) show how a very basic analysis of the vocabulary can highlight inconsistencies in a suite of examinations. They found that the lowest level test they analyzed contained fewer words from the 2,000 most frequently occurring English words than the highest level test. It would appear, therefore, that as well as looking at the language of the expected output (i.e., test-taker performance), the test developer should consider the language of the input. General practice is to ensure that the language of the input is at a level below that of the language of the intended output. This ensures that the test taker's performance is unlikely to be affected by their not understanding the language of the input. There is also a need to explore the impact on task performance under test conditions of a range of input-related variables, including language or visual stimuli or both (as has been done for listening by Ginther, 2002).

Test Administration Though it is obvious that differences in test administration can result in meaningful variation in test performance (e.g., with regard to setting, security, timing, and so forth), this is not an area that has received any significant exploration in the language testing literature. For a clear and comprehensive description of one approach to the area of administration of a speaking test, see

Taylor (2011, Appendix D). This impressive piece offers the reader a broad overview of the main issues and also an insight into how one major examination board addresses them.

The Scoring System

The scoring system includes everything that is done to transform a test performance into a test score. Limitations of space mean that only some key aspects of this very complex system can be addressed in this chapter.

Theoretical Fit The most obvious aspect of this is the fit between the underlying ability model and the rating scale. We have already seen that there are some serious issues related to the way in which grammar and fluency are defined in typical scale descriptors. Whether the scales are holistic (where there is a single global score), analytic (where the overall score is comprised of a number of scores awarded on a set of predetermined criteria), or boundary recognition (essentially a series of yes/no distinctions based on a series of task-specific questions or statements; see Upshur & Turner, 1999), it is vital that a clearly defined link can be made between the content and format of the scale and the ability model. Without this any resulting score is clearly meaningless in relation to the claims the developer wishes to make.

Theoretical fit also refers to the selection and training of the raters. The developer must maintain the integrity of the scoring system by ensuring that the raters are appropriately qualified and trained. A typical issue here is that of bias. While Lumley and McNamara (1995, p. 69) conclude “that judge differences survive training,” it is important that training is offered, though it should probably focus on things like intra-rater consistency (i.e., whether the person himself or herself is consistent) and critical boundary internalization (whether the rater automatically recognizes a passing or failing performance). It is also important that training should focus on acquainting raters not just with the scale and the tasks, but with the rationale that lies behind these.

Where the rater is also the interlocutor, it is very important to ensure too that participants are trained for their role as interlocutor and not just in the management of the event, for example in score recording and time keeping. This training would benefit as well from a focus on affect, similar to the behavioral observation training offered to medical professionals and counselors, highlighting how this can impact on their rating. The contribution of raters with different behavior patterns to the co-construction of the live test event and test-taker proficiency, explored by Brown (2003), highlights the importance of this aspect of training.

A final comment here on the rater: Much has been made over the years of differences between native and non-native speakers as raters. Recent studies seem to demonstrate that there is no significant difference in the consistency of raters from the two groups, though they may well be assessing different aspects of test-taker language (Zhang & Elder, 2011). This is clearly an area that is in need of further exploration, though it is not always an easy matter to make a definitive distinction between a native and a non-native speaker, as it is not necessarily a matter of dichotomy but one of degree.

Accuracy of Decisions The accuracy of the decisions made by the rater, or by the machine for that matter, is one of the central elements of the scoring system. It is clear from writing assessment research that training is a key contributor to accuracy and consistency (Weigle, 2000), though as pointed out by Lumley and McNamara (1995), training is unlikely to eradicate all differences between raters. However, little empirical work has been reported for the impact of training on raters of speaking tests (though see O'Sullivan & Rignall, 2007), and we can assume that the impact of training in both areas will be similar (though, as pointed out above, it is important that raters in live events are also trained for their role as interlocutor).

Multifaceted Rasch analysis has been used to explore rater error and other aspects of the rating process (e.g., Lumley & O'Sullivan, 2005; Ockey, 2009) and offers a valuable tool for taking rater harshness or leniency into account when calculating test scores (Lumley & McNamara, 1995). The broader use of probability-based (or alternative) statistical procedures to estimate ability level is clearly an area worth further exploration, as is the use of technology such as voice recognition or artificial intelligence to refine automated scoring engines. It is also important to investigate how technology can support human rating by looking at a more collaborative model of rating in which each plays a role.

Value of Decisions While this aspect of validation can include the collection of evidence from sources such as other tests or from teacher, peer, or self-assessments, I would like to focus here on the concept of establishing evidence of the value, or meaning, of test scores in contexts outside of the testing arena. The most commonly referenced standard these days is the CEFR, with test developers around the world working to establish empirical evidence of the link between their tests and the standard (Martyniuk, 2010). In terms of speaking, certainly in comparison with the other skills, the CEFR offers perhaps the most valuable descriptors, though it is obvious to those who have used the CEFR and the manual produced by the Council of Europe (2009), which sets out procedures for establishing an empirical link between a test and the CEFR, that we are still some way away from fully understanding language development (e.g., O'Sullivan, 2009). In an attempt to broaden our understanding of the criterial features of specific language ability levels, the English Profile Project (www.englishprofile.org) was established in the UK. While the work has already begun to pay dividends, there is some concern that the data upon which it is based is limited. This is particularly the case with the speaking test data, which appears to come from a single source. Were this to continue, it would severely limit the value of the project, so it is important that both the project managers and the broader testing community collaborate to broaden its scope by providing data from multiple sources (from classrooms and assessment events).

Conclusion

In this chapter, I have outlined a view of testing speaking that is based on a model of test validation. Despite the growing use of speaking tests worldwide, the area

is really quite under-researched. This may well be due to the fact that most speaking tests are essentially local in nature, meaning that there is a distinct likelihood that factors such as familiarity with the language and culture of the population play a greater part in the test, from its inception through to administration, than is the case with other skills. The discussion presented here is intended to provide the interested reader or researcher with a basis for developing a research agenda that can systematically broaden our knowledge and understanding of this fascinating area, by hinting at the tremendous opportunities for inter- and intra-disciplinary collaboration that exist for speaking test developers and theorists.

Assessing Vocabulary

David Beglar

Temple University, Japan

Paul Nation

Victoria University of Wellington, New Zealand

Introduction

In recent decades, the amount of research into second language vocabulary acquisition has increased tremendously, and for good reason: Lexical knowledge is a crucial, and arguably the central, component of communicative language proficiency. Though there are many questions still surrounding the nature of the relationship between vocabulary knowledge and language reception and production, a multitude of empirical studies have shown that the relationship is a strong one. Closely related to the work on lexical acquisition and use is the issue of vocabulary assessment, which plays an important role both in empirical research and in classroom assessment. Without an ability to accurately measure different aspects of vocabulary knowledge, it is not possible for researchers to assess the results of various treatments, model the effects of lexical knowledge, clarify the relationships among various types of lexical knowledge, and estimate lexical growth over time, or for teachers to judge the efficacy of pedagogical interventions and learners to clearly understand their lexical strengths and weaknesses.

In this chapter, we focus on three areas of vocabulary assessment—measures of receptive vocabulary size, productive vocabulary size, and depth of lexical knowledge—comment briefly on vocabulary assessment in foreign language classrooms, and suggest eight areas where further research is needed.

Measuring Written Receptive Vocabulary Size

Vocabulary size is arguably the most basic dimension of lexical competence, particularly for learners at lower levels of proficiency. Receptive knowledge normally precedes productive knowledge both in L1 and in L2 acquisition, in part because

a variety of linguistic and nonlinguistic cueing systems, such as textual and contextual information, are available during reading and listening but absent during speaking and writing. Receptive lexical knowledge is crucial in all academic contexts because it is the pathway through which learners gain the majority of new knowledge; thus, learners who are unable to fully comprehend oral and written texts find themselves at a distinct disadvantage in terms of access to information. Recent research has indicated that a 4,000 to 5,000 word family (i.e., a base word and inflected forms as well as derived forms that share a common meaning with the base form) vocabulary is needed to achieve 95% lexical coverage of written text (Laufer & Ravenhorst-Kalovski, 2010) and an 8,000 to 9,000 word family vocabulary is needed to gain 98% lexical coverage of a written text (i.e., the figure needed for unassisted comprehension) (Nation, 2006).

Yes/No Test

Meara's yes/no test of written receptive vocabulary size has probably been the focus of more published studies than any other second language vocabulary size test and has received a good deal of empirical support. Early research on the test was focused on developing a computerized version for use as a placement test. This resulted in the production of the Eurocenters Vocabulary Size Test, which is a 150 word instrument that produces an estimate of learners' knowledge of the most frequent 10,000 lemmas of English as found in Thorndike and Lorge's (1944) frequency count of English words.

The yes/no test is made up of a combination of real words and nonwords, the latter of which are added to make an adjustment for guessing. Example items are as follows:

Tick the words you know the meaning of, e.g., milk ✓

gathering	forecast	descent	revenge
strap	conscious	wodesome	heartless
untamed	mudge	topical	mere
loyalment	crope	robber	awkward

The yes/no test uses the simplest possible format for assessing receptive lexical knowledge, and, although reservations have been voiced regarding the possibility that some words might be simply recognized but not understood (Read, 2000), the simplicity of the test has advantages, as it allows the lexical knowledge of low proficiency and young learners to be measured and it presumably eliminates variance from factors such as inferencing ability. The extensive use of the yes/no test in a large number of empirical studies has established it as an important test of written receptive vocabulary size in the field of second language vocabulary testing.

Vocabulary Levels Test

Nation's Vocabulary Levels Test (Nation, 1990, pp. 261–72) has been termed "the nearest thing we have to a standard test in vocabulary" (Meara, 1996, p. 38), an

evaluation that is correct if frequency of use in empirical studies is an indication of its acceptance. Though frequently used as a test of written receptive vocabulary size, the Vocabulary Levels Test was originally conceptualized as a diagnostic test that measures knowledge of words at the 2,000, 3,000, 5,000, and 10,000 word frequency levels as well as academic lexis.

The test requires test takers to match words with short definitions. As the distractors have no semantic relationship with the correct response, the test is sensitive to partial knowledge of the target words. An example item is as follows (Nation, 1990, p. 265):

1. original
2. private _____ complete
3. royal _____ first
4. slow _____ not public
5. sorry
6. total

In an initial investigation of the Vocabulary Levels Test, Read (1988) reported that the test performed as expected with higher frequency items being easier than lower ones. Beglar and Hunt (1999) examined multiple forms of the 2,000 and university word levels. They found that the test forms were reliable, the items were strongly unidimensional, and intercorrelations between the 2,000 word level and University Word List forms ranged between .39 and .72, indicating that the type of lexical knowledge measured by the test was significantly correlated with the skills measured by the TOEFL. The third evaluation of the Vocabulary Levels Test (Schmitt, Schmitt, & Clapham, 2001) involved all five levels of the test and provided further confirmation of Read's finding that the different levels of the test are highly scalable, and the results presented by Beglar and Hunt that individual items worked effectively and the items formed a strongly unidimensional scale. The test forms produced in the Schmitt et al. study were used by many subsequent researchers as measures of written receptive vocabulary size.

Vocabulary Size Test

Nation's Vocabulary Size Test (see Nation & Beglar, 2007, for a description of the test) was designed as a test of written receptive vocabulary size. The test is made up of items that range from the first to the 20th 1,000 word families of English based on the British National Corpus; thus, the first contribution of this test is that it greatly extends the range of measurement compared with previous tests of written receptive vocabulary size. Multiple versions of the English language test as well as bilingual versions in various languages are available at <http://www.victoria.ac.nz/lals/staff/paul-nation.aspx>

Like the Vocabulary Levels Test, a multiple choice format is used; however, because the correct answer and the distractors usually share elements of meaning, the items that make up the Vocabulary Size Test are somewhat more difficult compared to those on the Vocabulary Levels Test. The target words on the Vocabulary Size Test are placed in a short, nondefining context that orients the test takers

to the part of speech of the word and sometimes provides slight associational cues. An example item is as follows:

innocuous: This is **innocuous**.

- a. cheap and poor in quality
- b. harmless
- c. not believable
- d. very attractive-looking

The test items are based on the notion of word family, which is more appropriate for receptive vocabulary tests than lemma-based counts given that even learners at relatively low proficiency levels can recognize formal and semantic relationships among regularly affixed members of the same word family.

To date only one validation study has been published. Beglar (2010) investigated six aspects of construct validity and reported that the items at higher frequency bands were easier than those at lower frequency bands, the test clearly distinguished learners at different proficiency levels, the items displayed a high degree of unidimensionality and invariance, and various combinations of items produced precise person ability estimates. The Vocabulary Size Test is an important addition to the current battery of written receptive vocabulary size tests.

Measuring Aural Receptive Vocabulary Size

Empirical studies indicate that lexical knowledge plays a key role in the processing of aural input in a foreign language. In an important study, Nation (2006) determined that a 6,000 to 7,000 word family vocabulary is needed if listeners are to consistently achieve 98% comprehension of authentic spoken texts. This figure provides a clear goal for all second language learners of English who aspire to comprehend most of the spoken lexis they will encounter and indicates that tests of aural vocabulary size generally need to extend at least to the 7,000 word frequency level. Despite the importance of developing measures of aural vocabulary size, very little empirical work on tests designed to measure this construct exists.

Fountain and Nation (2000) produced a lexically graded dictation test based on five word frequency levels: the first 500 words from the Thorndike and Lorge (1944) list, the second 500 words, the second 1,000 words, the third 1,000 words, and the fourth to sixth 1,000 words. The test can be administered in a short amount of time, as test takers hear the text only once, and because there is one correct answer for each item, scoring can be done quickly. An example item is as follows:

Every year a large number of young people leave school and begin work.

Test takers write the dictated text and the underlined words are tallied to provide estimates of knowledge of the five frequency bands. In the only published report of the test, Fountain and Nation (2000) reported that the test displayed high internal reliability estimates and four forms of the test correlated at .95 or above, indicating that they likely measure the same construct. In addition, the dictation

test correlated with a version of the Vocabulary Levels Test at .78, suggesting that they are both measuring a similar construct, presumably receptive vocabulary size.

A second test of aural receptive vocabulary size is AuralLex (Milton & Hopkins, 2005). This test is based on X-Lex, which uses the yes/no format to assess knowledge of written receptive vocabulary. The difference between the two tests is that, with AuralLex, test takers hear rather than read words from the first five 1,000 lemmatized word frequency levels. In an empirical study with 126 native speakers of Arabic and Greek, Milton and Hopkins (2006) reported that AuralLex provided reliable estimates of aural vocabulary size.

Measuring Written Productive Vocabulary Size

Productive vocabulary size has been shown to be an important element in writing given that higher proficiency second language learners and native speakers use a wider variety of vocabulary and more low frequency words than less proficient second language writers (e.g., Laufer & Nation, 1995), and breadth of vocabulary accounts for a large amount of variance in assessments of writing samples.

Productive vocabulary size is also a key factor underlying speaking proficiency, and speaking effectively requires a vocabulary of several thousand words. Larger vocabularies have been found to have a positive relationship with greater spoken fluency, and there is evidence that the majority of oral disfluencies can be attributed to lexical errors and lexical searches.

The Controlled Productive Vocabulary Test

The Controlled Productive Vocabulary Test (Laufer & Nation, 1999) is designed to diagnose test takers' written productive vocabulary knowledge. The test is based on the Vocabulary Levels Test (Nation, 1990) and is made up of 18 items at the 2,000, 3,000, 5,000, and 10,000 word frequency levels, as well as words from the University Word List (Xue & Nation, 1984).

Test takers are provided with a meaningful sentence context and with the first few letters of each target word, both of which act as cues to elicit specific vocabulary. This format is similar to a C-test (Klein-Braley & Raatz, 1984), though fewer initial letters are generally provided on the Controlled Productive Vocabulary Test. An example item designed to elicit the word *opportunity* is as follows:

I'm glad we had this opp_____ to talk.

Laufer and Nation (1999) reported that the test was sensitive to proficiency differences, as students at higher proficiency levels scored higher on the various frequency levels measured by the test. The primary concern with the instrument is that the construct measured by the test is not unequivocally clear. Because answering the items requires considerable use of information embedded in the surrounding context, it is possible that the test taps receptive vocabulary knowledge to some extent. This possibility received some support from the fairly high

correlations reported by Laufer (1998) between the Vocabulary Levels Test, a test of written receptive vocabulary, and the Controlled Productive Vocabulary Test. An alternative interpretation of the high correlation coefficient, however, is that learners with larger receptive vocabularies also tend to have larger productive vocabularies.

Lex30

The Lex30 test (Meara & Fitzpatrick, 2000) uses a word association task to elicit a small sample of test takers' written productive vocabulary in a short amount of time. The test typically uses 30 cue words (e.g., *attack*, *beard*, *dirty*, *experience*, and *habit*) taken from the first 1,000 high frequency words of English, an approach that allows even low proficiency learners to sit the test. Test takers are asked to produce up to four responses to each cue word and each response not in the first 1,000 high frequency words of English is awarded one point. Stimulus words that elicit a variety of responses and that generate responses that are not among the high frequency 1,000 words of English were selected based on piloting. Test takers typically produce approximately 90 words and scores of around 60 are typical for many native speakers of English.

Lex30 is easy to administer and test takers can complete it quickly. A computerized version is available (see Meara, 2009, for details about the test and information concerning the Lex30 software and chap. 4 in the same book regarding validation efforts). Lex30 can also be used as a test of spoken productive vocabulary.

Lexical Frequency Profile

The lexical frequency profile (Laufer & Nation, 1995) is designed to measure free productive vocabulary produced in three lexical categories in written compositions: the high frequency 2000 word family level, academic words from the Academic Word List (Coxhead, 2000), and all other words in the text. As such, this test is also a diagnostic test rather than a test of productive vocabulary size. This assessment is conducted with the computer program Range (freely available from www.victoria.ac.nz/lals/staff/paul-nation.aspx).

Research has indicated that the lexical frequency profile is sensitive to changes in vocabulary use over time, can be used as a predictor of academic performance and to identify at-risk students in academic settings, and provides reliable estimates of written productive knowledge.

In a recent study, Edwards and Collins (2011) reported that the lexical frequency profiles produced by this analysis effectively distinguish between groups of learners with different vocabulary sizes, but that their ability to do so decreases as learners' vocabulary sizes increase. The lexical frequency profile produced by the Range program can also be applied to the analysis of spoken texts.

Lexical Diversity

Measures of lexical diversity are attractive as estimates of productive vocabulary size because they account for all of the vocabulary produced in a given text and

they can be used with both written and spoken texts. However, the problem with such measures is their dependence on text length. Although this problem has most frequently been associated with the type–token ratio, none of the numerous alternatives to the type–token ratio have proven immune to the effects of text length.

Two recent studies by Jarvis (2002) and McCarthy and Jarvis (2007) have shed light on the strengths and weaknesses of rival indexes. Jarvis reported that the D and U indexes were most accurate for measuring lexical diversity in whole texts, and that U was equally effective when used with only content words. In recent years, D and *vocd*, a computer program that uses D to estimate lexical diversity, have enjoyed widespread acceptance; however, McCarthy and Jarvis reported that, while D is also affected by text length, the most stable results are produced by texts between 250 and 666 tokens, which is a typical length for many writing assessments. In sum, the results produced by D and other estimates of lexical diversity must be treated with caution, and, despite the progress that has been made, more accurate formulas for estimating lexical diversity need to be developed.

Measuring Depth of Lexical Knowledge

While vocabulary size and depth of knowledge have been distinguished by a number of authorities (e.g., Meara, 1996, p. 49), the distinction is not universally accepted. The relationship between vocabulary size and depth, as estimated by correlation coefficients, is reasonably consistent, as they have varied between approximately .61 and .82. However, when participants are divided into two or more proficiency levels, the correlation between tests of size and depth are far lower for low proficiency students compared with high proficiency learners. These findings support the idea that learning the primary meaning of a word precedes the acquisition of further knowledge about the word or placing the new word in a semantic network.

The Word Associates Test

The most well known test of vocabulary depth is Read's (1993) Word Associates Test. On the test, a target word and eight options, four of which are semantically related to the target word, are shown to test takers. An example item is as follows:

sudden
| beautiful quick surprising thirsty || change doctor noise school |

As shown in the example, the test takers' task is to identify words on the left that have a paradigmatic relationship with the target word (e.g., *quick* is a synonym of *sudden*) and words on the right that have a syntagmatic (i.e., collocational) relationship with the target word (e.g., *sudden change*). Interesting variants of the original Word Associates Test have also been developed. For instance, Schoonen and Verhallen (2008) adapted Read's Word Associates Test by using one stimulus word and six associates. The test takers had to identify three words representing

paradigmatic, partonomic, decontextualized syntagmatic, perceptual features, inherent characteristics, or means–aim relations. The researchers reported that the new test was sufficiently reliable and it met a number of validity criteria.

Although the Word Associates Test has been used in a number of studies, a number of basic questions about the test remain unanswered, as it has yet to be subjected to stringent validation efforts. In a recent study, Schmitt, Ng, and Garras (2011) concluded that the test works well overall, but overestimates of lexical knowledge can occur due to successful guessing. However, most of the problems identified by Schmitt et al. indicate that the format itself is workable and that the primary challenge lies in writing effective items that reduce the probability of guessing.

The Vocabulary Knowledge Scale

Wesche and Paribakht (1996) produced the Vocabulary Knowledge Scale (VKS) based on an approach first proposed by Dale (1965). The primary purpose of the VKS is to track the development of the knowledge of new words from reading texts on the following five-point self-report scale that is supposed to represent the depth to which a word has been acquired:

- I. I don't remember having seen this word before.
- II. I have seen this word before, but I don't know what it means.
- III. I have seen this word before, and I think it means _____ (synonym or translation).
- IV. I know this word means _____ (synonym or translation).
- V. I can use this word in a sentence: _____ (Write a sentence.)

Although the scale has been used by a number of second language vocabulary researchers, relatively little is known about its functioning, and many questions remain about the validity of the scale as no extensive validation effort has taken place. For instance, one concern is that the original form of the VKS mixes receptive and productive vocabulary knowledge; however, reformulating the scale into separate receptive and productive measures is possible. Although the best way to score test takers' responses has yet to be established, one way in which the scale can be used profitably is to investigate changes in learners' lexical knowledge of specific lexis by tracking changes in the ratings on the five-point scale over time.

Vocabulary Networks

Meara (1996, 2009) has proposed that lexical knowledge should be conceptualized as a network of lexical items connected by a multitude of links. Thus, Meara's approach is to use the concept of organization rather than depth of knowledge. He has attempted to instantiate this idea with the software program *V_Links* (see Meara, 2009, chap. 6 for an introduction to the program). To date, research in this area is just getting under way and more sophisticated, large-scale studies are needed to determine whether the initial promise of the approach can be fully realized. One strength of this approach is that it aims to provide information about

a fairly large part of learners' lexicons as opposed to information about the knowledge of single words (Meara, 2009, p. 75).

Classroom Vocabulary Assessment

Classroom vocabulary assessment often takes three main forms. The first, which is primarily the concern of administrators and teachers, is designed to determine how a class, school, or district compares with other classes, schools, and districts. This type of assessment is focused on the long-term performance of a program. The second form involves identifying gaps in students' knowledge and determining lexical learning goals. This often takes place at the beginning of a course of instruction. The third form of assessment involves determining the degree to which instruction is effective. In this case, the focus is on student achievement.

Classroom teachers should keep in mind that the most basic aspect of lexical knowledge, particularly for lower proficiency learners, is vocabulary size. Measuring learners' vocabulary size is important, as this information can tell both learners and instructors what lexis to focus on. For instance, given the great importance of the high frequency words of English for both receptive and productive language use, any gaps identified in this area should be addressed first.

After vocabulary size, there is no clear consensus on what aspects of lexical knowledge should be assessed next, but one reasonable approach is for instructors to consider the needs of the students when making this decision. For instance, students who need to read in academic contexts might focus on developing more detailed knowledge (e.g., collocational and associational knowledge) of the vocabulary on the Academic Word List.

Teachers should also be aware of the idea of washback when assessing vocabulary: The way in which words are tested potentially influences multiple aspects of the curriculum, including how students study. Thus, in some instances, vocabulary assessments that place words in meaningful, communicative contexts might be seen as more desirable than those that assess words in a decontextualized fashion.

While the vocabulary test formats described in this chapter can be used for classroom assessment, teachers might wish to base some or all of the lexis included in a classroom test on the course materials in order to make the test more sensitive to instruction and to provide a more accurate indication of students' achievement.

Directions for Future Research

While considerable progress has been made in the field of second language vocabulary assessment in the past three decades, a great deal of research remains to be done. If pursued, the following eight ideas would increase knowledge of this area.

The area most in need of further research is the theoretical underpinnings of vocabulary assessment, as measures of lexical competence must ultimately be in accord with empirically supported aspects of lexical competence. This issue is

particularly important for the measurement of depth of knowledge, which is currently a cover term for a multitude of aspects of lexical knowledge. Progress in this area will provide answers to questions such as: To what degree are assessments of separate aspects of lexical competence needed? How are different types of lexical knowledge related to one another in the same individual? How do the relationships among different types of lexical knowledge interact and change over time? Is there a general order of acquisition for L2 knowledge?

A greater understanding and use of item-banking and item-anchoring techniques can play an important role in longitudinal studies. For instance, understanding how lexical knowledge develops over time is important because any complete understanding of vocabulary acquisition requires knowledge of the types and rates of lexical growth that occur in different learning contexts. In addition, little is known about norms for lexical growth for foreign language learners. Investigations in this area must be conducted over a period of years to be of benefit.

More research into criterion-referenced testing of vocabulary would be welcome, as not enough is known about vocabulary learning in various classroom contexts. What we do know is that many English as a foreign language (EFL) learners have vocabulary sizes that are inadequate for many real-world communicative tasks and that learning rates for many EFL students are too slow and will not permit the development of sufficiently large vocabularies in reasonable time frames.

Little is known about how fluent access to known vocabulary develops and how it can best be measured. Approaches to assessing fluency used in first language contexts (e.g., the Word Use Fluency Test; dibels.uoregon.edu/measures/wuf.php) might be usable with second language learners, but second language researchers will also want to develop original instruments (e.g., the Written Productive Translation Task, which is designed to measure speed of written lexical retrieval; Snellings, van Gelderen, & de Glopper, 2004).

Read's (2000) call for a greater use of embedded, comprehensive, and context-dependent assessments of lexical knowledge using performance tasks remains largely unanswered; however, researchers in favor of such assessments must show that such tests provide real advantages over discrete, decontextualized tests. It is plausible that both types of assessment are needed, but they are appropriate in different assessment contexts.

Computer-delivered and computer-adaptive assessments of vocabulary have yet to be used widely. However, such tests are important as they can be focused on a wide variety of areas such as assessing learners' knowledge of specific word frequency levels, high frequency affixes, or specific types of academic or technical vocabulary.

Although English for specific purposes (ESP) vocabulary assessment is an important area in many English language education contexts, little work has been conducted in this area. Given the importance of technical vocabulary in most academic and professional contexts, high quality vocabulary assessment tools would be useful in diagnosing gaps in lexical knowledge and measuring learners' progress in acquiring technical vocabulary.

Vocabulary assessment specialists would benefit from becoming better acquainted with measurement theory and attendant issues such as interval

measurement and fit to measurement models, as approaches to scoring are not well aligned with modern psychometric theory and practice.

Conclusion

Vocabulary assessment has been a vibrant area for a number of years, and the distinctly different lines of inquiry are indicators of the fundamental health of the field. Because of the complexity of the mental lexicon and lexical acquisition, much work remains to be done on two fundamental levels: understanding what to measure and then measuring it in efficient, reliable, and valid ways that lead to useful interpretations of learners' performances and state of knowledge.

While the tests reviewed in this chapter are used frequently by researchers, none of them have been incorporated into a large-scale, standardized, high stakes test, despite the fact that lexical knowledge underpins all language skills. In addition, reports of how well the tests function as diagnostic or achievement measures in classroom settings are lacking. While the coming years should see a plethora of new developments and approaches to second language vocabulary assessment, we would hope that some of that work will be directed at improving the measurement of lexical knowledge in ways that directly benefit materials developers, course designers, and the students they serve.

Assessing Reading

William Grabe

Northern Arizona University, USA

Xiangying Jiang

West Virginia University, USA

Introduction

In this chapter, we discuss the construct of reading comprehension abilities in relation to reading assessment, examine prior and current conceptualizations of reading abilities in assessment contexts, and describe why and how reading abilities are assessed. From a historical perspective, the “construct of reading” is a concept that has followed far behind the formal assessment of reading abilities (leaving aside for the moment the issue of classroom assessment of reading abilities). In fact, the construct of reading comprehension abilities, as well as all the relevant component subskills, knowledge bases, and cognitive processes (hereafter “component skills”), had not been well thought out and convincingly described in assessment contexts until the 1990s. It is interesting to note, in light of this point, a quote by Clapham (1996) on efforts to develop the IELTS reading modules:

We had asked applied linguists for advice on current theories of language proficiency on which we might base the IELTS test battery. However, the applied linguists’ responses were varied, contradictory and inconclusive, and provided little evidence for a construct for EAP tests on which we could base the test. (p. 76)

Similar limitations can be noted for the TOEFL of the 1980s (Taylor & Angelis, 2008) and the earlier versions of the Cambridge ESOL suite of tests (see Weir & Milanovic, 2003; Hawkey, 2009; Khalifa & Weir, 2009). Parallel limitations with classroom-based assessments in second language contexts were evident until fairly recently with the relatively narrow range of reading assessment options typically used (often limited to multiple choice items, true/false items, matching items, and brief open-ended response items). Fortunately, this situation has changed remarkably in the past 15 years, and very useful construct research (and

construct statements for assessment purposes) is now available to help conceptualize reading assessment.

The transition from reliability to validity as the driving force behind standardized reading assessment development in the past 20 years has focused on efforts to reconceptualize reading assessment practices. Most importantly, this reconceptualization reflects a more empirically supported reading construct, one that has also led to a wider interpretation of reading purposes generally (Grabe, 2009) and in reading assessment contexts more specifically, for instance reading to learn and expeditious reading (Enright et al., 2000; Khalifa & Weir, 2009).

Reading assessment itself involves a range of purposes that reflect multiple assessment contexts: standardized proficiency assessment, classroom-based formative and achievement testing, placement and diagnostic testing, assessment for reading research purposes (Grabe, 2009), and assessment-for-learning purposes (Black & Wiliam, 2006). The first two of these contexts take up the large part of this chapter (see Grabe, 2009, for discussion of all five purposes for reading assessment).

In the process of discussing these purposes for reading assessment, questions related to how reading assessments should be carried out are also addressed. The changing discussions of the reading construct, the redesign of standardized assessments for second language learners, and the need to assess aspects of the reading construct that were previously ignored have led to a wide range of assessment task types, some of which had not been given serious consideration until the late 1990s.

Previous Conceptualizations

Reading comprehension ability has a more intriguing history than is commonly recognized, and it is a history that has profoundly affected how reading comprehension is assessed. Before the 20th century, most people did not read large amounts of material silently for comprehension. For the much smaller percentage of test takers in academic settings, assessment emphases were placed on literature, culture, and interpretation involving more subjectively measured items. The 20th century, in its turn, combined a growing need for many more people capable of reading large amounts of text information for comprehension with many more uses of this information in academic and work contexts. In the USA, for example, while functional literacy was estimated at 90% at the turn of the 20th century, this may have been defined simply as completing one or two years of schooling. In the 1930s, functional literacy in the USA was placed at 88%, being defined as a third grade completion rate (Stedman & Kaestle, 1991). The pressure to educate a much larger percentage of the population in informational literacy skills, and silent reading comprehension skills in particular, was driven, in part, by the need for more literate soldiers in World Wars I and II, more literate industrial workers, and increasingly higher demands placed on student performance in educational settings (Pearson & Goodin, 2010).

Within academic settings, the rise of objective testing practices from a rapidly developing field of educational psychology and psychological measurement

spurred on large-scale comprehension assessment. However, for the US context, it was only in 1970 that comprehension assessments provided a reliable national picture of English first language (L1) reading abilities, and their patterns of variation, through the NAEP (National Assessment of Educational Progress) testing program and public reports. If broad-based reading comprehension skills assessment has been a relatively recent development, so also has been the development of reading assessment measures that reflect an empirically derived construct of reading abilities.

During the period from the 1920s to the 1960s, objective assessment practices built on psychometric principles were powerful shaping forces for reading assessment in US contexts. In line with these pressures for more objective measurement, L2 contexts were not completely ignored. The first objectively measured foreign language reading test was developed in 1919 (Spolsky, 1995). In the UK, in contrast, there was a strong counterbalancing emphasis on expert validity. In the first half of the 20th century, this traditional validity emphasis sometimes led to more interesting reading assessment tasks (e.g., summarizing, paraphrasing, text interpretation), but also sometimes led to relatively weak assessment reliability (Weir & Milanovic, 2003).

By the 1960s and 1970s, the pressure to deliver objective test items led to the development of the TOEFL as a multiple choice test and led to changes in assessment practices with the Cambridge ESOL suite as well as the precursor of the IELTS (i.e., ELTS and the earlier EPTB, the English Proficiency Test Battery) (Clapham, 1996; Weir & Milanovic, 2003). At the same time, the constraints of using multiple choice and matching items also limited which aspects of reading abilities could be reliably measured. Starting in the 1970s, the pressures of communicative competence and communicative language teaching led to strong claims for the appropriateness of integrative reading assessments (primarily cloze testing). However, from 1980 onwards, the overwhelming output of cognitive research on reading abilities led to a much broader interpretation of reading abilities, one that was built from several component subskills and knowledge bases. From 1990 onward, research on reading comprehension has been characterized by the roles of various component subskills on reading performance, and on reading for different purposes (reading to learn, reading for general comprehension, expeditious reading, etc.). This expansion of reading research has also led to more recent conceptualizations of the reading construct as the driving force behind current standardized reading assessment practices.

Current Conceptualizations

In considering current views on reading assessment, we focus primarily on standardized assessment and classroom-based assessment practices. These are the two most widespread uses of reading assessment, and the two purposes that have the greatest impact on test takers. In both cases, the construct of reading abilities is a central issue. The construct of reading has been described recently in a number of ways, mostly with considerable overlap (see Alderson, 2000; Grabe, 2009; Khalifa & Weir, 2009; Adlof, Perfetti, & Catts, 2011). Based on what can now be classified

as thousands of empirical research studies on reading comprehension abilities, the consensus that has emerged is that reading comprehension comprises several component language skills, knowledge resources, and general cognitive abilities. The use of these component abilities in combinations varies by proficiency, overall reading purpose, and specific task.

Research in both L1 and L2 contexts has highlighted those factors that strongly impact reading abilities and account for individual differences in reading comprehension performance:

1. efficient word recognition processes (phonological, orthographic, morphological, and semantic processing);
2. a large recognition vocabulary (vocabulary knowledge);
3. efficient grammatical parsing skills (grammar knowledge under time constraints);
4. the ability to formulate the main ideas of a text (formulate and combine appropriate semantic propositions);
5. the ability to engage in a range of strategic processes while reading more challenging texts (including goal setting, academic inferencing, monitoring);
6. the ability to recognize discourse structuring and genre patterns, and use this knowledge to support comprehension;
7. the ability to use background knowledge appropriately;
8. the ability to interpret text meaning critically in line with reading purposes;
9. the efficient use of working memory abilities;
10. the efficient use of reading fluency skills;
11. extensive amounts of exposure to L2 print (massive experience with L2 reading);
12. the ability to engage in reading, to expend effort, to persist in reading without distraction, and achieve some level of success with reading (reading motivation).

These factors, in various combinations, explain reading abilities for groups of readers reading for different purposes and at different reading proficiency levels. Given this array of possible factors influencing (and explaining) reading comprehension abilities, the major problems facing current L2 assessment development are (a) how to explain these abilities to wider audiences, (b) how best to measure these component skills within constrained assessment contexts, and (c) how to develop assessment tasks that reflect these component skills and reading comprehension abilities more generally.

Standardized Reading Assessment

Major standardized reading assessment programs consider the construct of reading in multiple ways. It is possible to describe the reading construct in terms of purposes for reading, representative reading tasks, or cognitive processes that support comprehension. To elaborate, a number of purposes for engaging in reading can be identified, a number of representative reading tasks can be

identified, and a set of cognitive processes and knowledge bases can be considered as constitutive of reading comprehension abilities. Of the three alternative descriptive possibilities, reading purpose provides the most transparent explanation to a more general public as well as to test takers, text users, and other stakeholders. Most people can grasp intuitively the idea of reading to learn, reading for general comprehension, reading to evaluate, expeditious reading, and so on. Moreover, these purposes incorporate several key reading tasks and major component skills (many of which vary in importance depending on the specific purpose), thus providing a useful overarching framework for the “construct of reading” (see Clapham, 1996; Enright et al., 2000; Grabe, 2009; Khalifa & Weir, 2009). This depiction of reading abilities, developed in the past two decades, has also led to a reconsideration of how to assess reading abilities within well recognized assessment constraints. It has also led to several innovations in test tasks in standardized assessments. This trend is exemplified by new revisions to the Cambridge ESOL suite of exams, the IELTS, and the iBT TOEFL.

The Cambridge ESOL suite of exams (KET, PET, FCE, CAE, CPE) has undergone important changes in its conceptualization of reading assessment (see Weir & Milanovic, 2003; Hawkey, 2009; Khalifa & Weir, 2009). As part of the process, the FCE, CAE, and CPE have introduced reading assessment tests and tasks that require greater recognition of the discourse structure of texts, recognition of main ideas, careful reading abilities, facility in reading multiple text genres, and a larger amount of reading itself. Reading assessment tasks now include complex matching tasks of various types, multiple choice items, short response items, and summary writing (once again).

IELTS (the International English Language Testing System) similarly expanded its coverage of the purposes for reading to include reading for specific information, reading for main ideas, reading to evaluate, and reading to identify a topic or theme. Recent versions of the IELTS include an academic version and a general training version. The IELTS academic version increased the amount of reading required, and it includes short response items of multiple types, matching of various types, several complex readings with diagrams and figures, and innovative fill-in summary tasks.

The iBT TOEFL has similarly revised its reading section based on the framework of reader purpose. Four reading purposes were initially considered in the design of iBT TOEFL reading assessment: reading to find information, reading for basic comprehension, reading to learn, and reading to integrate (Chapelle, Enright, & Jamieson, 2008), although reading to integrate was not pursued after the pilot study. iBT TOEFL uses three general item types to evaluate readers’ academic reading proficiency: basic comprehension items, inferencing items, and reading-to-learn items. Reading to learn has been defined as “developing an organized understanding of how the main ideas, supporting information, and factual details of the text form a coherent whole” (Chapelle et al., 2008, p. 111), for which two new tasks, prose summary and schematic table, were included. In addition, the iBT TOEFL uses longer, more complex texts than the ones used in the traditional TOEFL.

In all three of these standardized test systems, revisions drew upon well articulated and empirically supported constructs of reading abilities as they apply to academic contexts. In all three cases, greater attention has been given to longer

reading passages, to discourse organization, and to an expanded concept of reading to learn or reading to evaluate. At the same time, a number of component reading abilities are obviously absent, reflecting the limitations of international standardized reading assessment imposed by cost, time, reliability demands, and fairness across many country settings. (Standardized English L1 reading assessment practices are far more complex.) These limited operationalizations of L2 reading abilities are noted by Alderson (2000), Weir and Milanovic (2003), Grabe (2009), and Khalifa and Weir (2009).

Among the abilities that the new iBT TOEFL did not pursue are word recognition efficiency, reading to scan for information, summarizing, and reading to integrate information from multiple texts. Khalifa and Weir (2009) note that the Cambridge suite did not pursue reading to scan, reading to skim, or reading rate (fluency). All three come under the umbrella term “expeditious reading” and, for their analysis, this gap represents a limitation in the way the reading construct has been operationalized in the Cambridge suite (and in IELTS). IELTS revisions had considered including short response items and summary writing. In recent versions, it has settled for a more limited but still innovative cloze summary task.

Returning to the list of component skills noted earlier, current standardized reading assessment has yet to measure a full range of component abilities of reading comprehension (and may not be able to do so in the near future). Nonetheless, an assessment of reading abilities should reflect, as far as possible, the abilities a skilled reader engages in when reading for academic purposes (leaving aside adult basic literacy assessments and early child reading assessments). The following is a list of the component abilities of reading comprehension that are not yet well incorporated into L2 standardized reading assessment (from Grabe, 2009, p. 357):

1. passage reading fluency and reading rate,
2. automaticity and rapid word recognition,
3. search processes,
4. morphological knowledge,
5. text structure awareness and discourse organization,
6. strategic processing abilities,
7. summarization abilities (and paraphrasing),
8. synthesis skills,
9. complex evaluation and critical reading.

How select aspects of these abilities find their ways into standardized L2 reading assessment practices is an important challenge for the future.

Although researchers working with standardized reading tests have made a serious effort to capture crucial aspects of the component abilities of reading comprehension (e.g., Khalifa & Weir, 2009; Chapelle et al., 2008; Hawkey, 2009), construct validity still represents a major challenge for L2 reading assessment because the number and the types of assessment tasks are strictly constrained in the context of standardized testing. If the construct is underrepresented by the test, it is difficult to claim that reading comprehension abilities are being fully measured. This difficulty also suggests that efforts to develop an explanation of the reading construct *from* L2 reading tests face the challenge of construct

underrepresentation in the very tests being used to develop the construct (a fairly common problem until recently). Perhaps with greater uses of computer technology in testing, the control over time for individual items or sections can be better managed, and innovative item types can be incorporated without disrupting assessment procedures. In addition, as suggested by Shiotsu (2010), test taker performance information recorded by computers may not only assist decision making but might also be used for diagnostic purposes. One of the most obvious potential applications of the computer is to more easily incorporate skimming, reading-to-search, reading fluency, and reading rate measures. Such an extension in the future would be welcome.

Classroom-Based Reading Assessment

Moving on from standardized assessments, the second major use of L2 reading assessments takes place in classroom contexts. In certain respects, classroom-based assessment provides a complement to standardized assessment in that aspects of the reading construct not accounted for by the latter can easily be included in the former. In many classroom-based assessment contexts, teachers observe, note, and chart students' reading rates, reading fluency, summarizing skills, use of reading information in multistep tasks, critical evaluation skills, and motivation and persistence to read.

Reading assessment in these contexts is primarily used to measure student learning (and presumably to improve student learning). This type of assessment usually involves the measurement of skills and knowledge gained over a period of time based on course content and specific skills practiced. Typically, classroom teachers or teacher groups are responsible for developing the tests and deciding how the scores should be interpreted and what steps to take as a result of the assessment outcomes (Jamieson, 2011). Classroom learning can be assessed at multiple points in any semester and some commonly used classroom assessments include unit achievement tests, quizzes of various types, and midterm and final exams. In addition to the use of tests, informal and alternative assessment options are also useful for the effective assessment of student learning, using, for example, student observations, self-reporting measures, and portfolios. A key issue for informal reading assessment is the need for multiple assessment formats (and multiple assessment points) to evaluate a wide range of student performances for any decisions about student abilities or student progress. The many small assessments across many tasks helps overcome the subjectivity of informal assessment and strengthens the effectiveness and fairness of informal assessments.

Classroom-based assessment makes use of the array of test task types found in standardized assessments (e.g., cloze, gap-filling formats [rational cloze formats], text segment ordering, text gaps, multiple choice questions, short answer responses, summary writing, matching items, true/false/not stated questions, editing, information transfer, skimming, scanning). Much more important for the validity of classroom assessment, though less commonly recognized, are the day-to-day informal assessments and feedback that teachers regularly provide to students. Grabe (2009) identifies six categories of classroom-based assessment practices and notes 25 specific informal assessment activities that can be, and often are, carried out by

teachers. These informal activities include (a) having students read aloud in class and evaluating their reading, (b) keeping a record of student responses to questions in class after a reading, (c) observing how much time students spend on task during free reading or sustained silent reading (SSR), (d) observing students reading with an audiotape or listening to an audiotaped reading, (e) having students list words they want to know after reading and why, (f) having students write simple book reports and recommend books to others, (g) keeping charts of student reading rate growth, (h) having a student read aloud for the teacher/tester and making notes, or using a checklist, or noting miscues on the text, (i) noting students' uses of texts in a multistep project and discussing these uses, and (j) creating student portfolios of reading activities or progress indicators.

Among these informal assessment activities, it is worth pointing out that oral reading fluency (reading aloud) assessment has attracted much research interest in L1 contexts. Oral reading fluency has been found to serve as a strong predictor of general comprehension (Shinn, Knutson, Good, Tilly, & Collins, 1992; Fuchs, Fuchs, Hosp, & Jenkins, 2001; Valencia et al., 2010). Even with a one-minute oral reading measure, teachers can look into multiple indicators of oral reading fluency (e.g., rate, accuracy, prosody, and comprehension) and obtain a fine-grained understanding of students' reading ability, particularly if multiple aspects of student reading performances are assessed (Kuhn, Schwanenflugel, & Meisinger, 2010; Valencia et al., 2010). However, research on fluency assessment has not been carried out in L2 reading contexts. Practices of reading aloud as an L2 reading assessment tool will benefit from research on the validity of oral reading fluency assessment in the L2 context.

Another aspect of classroom-based assessment that is gaining in recognition is the concept of assessment for learning (Black & Wiliam, 2006; Wiliam, 2010). This approach draws on explicit classroom tests, informal assessment practices, and opportunities for feedback from students to teachers that indicate a need for assistance or support. The critical goal of this assessment approach is to provide immediate feedback on tasks and to teach students to engage in more effective learning instead of evaluation of their performance. An important element of assessment for learning is the follow-up feedback and interaction between the teacher and the students. Through this feedback, teachers respond with ongoing remediation and fine-tuning of instruction when they observe non-understanding or weak student performances. The key is not to provide answers, but to enhance learning, work through misunderstandings that are apparent from student performance, develop effective learning strategies, and encourage student self-awareness and motivation to improve. Grabe (2009) notes 15 ideas and techniques for assessment for learning. Although these ideas and techniques apply to any learning and assessment context, they are ideally suited to reading tasks and reading comprehension development.

Current L2 Reading Assessment Research

In addition to the volume-length publications on assessment development and validation with three large-scale standardized L2 tests (e.g., Clapham, 1996; Weir & Milanovic, 2003; Chapelle et al., 2008; Hawkey, 2009; Khalifa & Weir, 2009)

reviewed above, this section will focus on recent journal publications related to reading assessment. We searched through two of the most important assessment journals, *Language Testing* and *Language Assessment Quarterly*, for their publications in the past 10 years and found that the recent research on reading assessment focused mainly on the topics of test tasks, reading texts, and reading strategies.

We note here seven studies relevant to conceptualizations of the L2 reading construct and ways to assess the reading construct. The first four studies focus on aspects of discourse structure awareness, complex text analysis tasks, and the role of the texts themselves. Two subsequent studies focus on the role of reading strategies and reading processes in testing contexts. At issue is whether or not multiple choice questions bias text reading in unintended ways. The final study examines the role of memory on reading assessment as a further possible source of bias. Overall, it is important to note that research articles on L2 reading assessment are relatively uncommon in comparison with research on speaking and writing assessment (and performance scoring issues).

Kobayashi (2002) examined the impact of discourse organization awareness on reading performance. Specifically, she investigated whether text organization (association, description, causation, and problem-solution) and response format (cloze, open-ended questions, and summary writing) have a systematic influence on test results of learners at different proficiency levels (high, middle, and low). She found that text organization did not lead to strong performance differences for test formats that measured less integrative comprehension such as cloze tests or for learners of limited L2 proficiency. On the contrary, stronger performance differences due to organizational differences in texts were observed for testing formats that measure more integrative forms of comprehension tasks (open-ended questions and summary writing), especially for learners with higher levels of L2 proficiency. The more proficient students benefited from texts with a clear structure for summary writing and open-ended questions. She suggested that "it is essential to know in advance what type of text organization is involved in passages used for reading comprehension tests, especially in summary writing with learners of higher language proficiency" (p. 210). The study confirms previous findings that different test formats seem to measure different aspects of reading comprehension and that text organization can influence reading comprehension based on more complex reading tasks.

Yu (2008) also contributed to issues in discourse processing by exploring the use of summaries for reading assessment with 157 Chinese university students in an undergraduate EFL program. The study looked at the relationships between summarizing an L2 text in the L2 versus in the L1, as well as relationships among both summaries (L1 and L2) and an L2 reading measure, an L2 writing measure, and a translation measure. Findings showed that test takers wrote longer summaries in the L1 (Chinese) but were judged to have written better summaries in their L2 (English). Perhaps more importantly, summary writing in Chinese and English only correlated with L2 reading measures at .30 and .26 (r^2 of .09 and .07 respectively, for only the stronger of two summary quality measures). These weak correlations suggest that summary writing measures something quite different from the TOEFL reading and writing measures used. Yu found no relationships between summary-writing quality and the TOEFL writing or translation

measures. In a questionnaire and follow-up interviews, test takers also felt that summary writing was a better indicator of their comprehension abilities than of their writing abilities. While this is only one study in one context, it raises interesting questions about the role of summarizing in reading assessment, which needs to be examined further.

Trites and McGroarty (2005) addressed the potential impact of more complex reading tasks that go beyond only measures of basic comprehension. The authors reported the design and use of new measures to assess the more complex reading purposes of reading to learn and reading to integrate (see Enright et al., 2000). Based on the analyses of data from both native and non-native speakers, the authors found that new tasks requiring information synthesis assessed something different from basic comprehension, after a lower level of basic academic English proficiency had been achieved. The authors speculated that “the new measures tap additional skills such as sophisticated discourse processes and critical thinking skills in addition to language proficiency” (p. 199).

Green, Unaldi, and Weir (2010) focused on the role of texts, and especially disciplinary text types, for testing purposes. They examined the authenticity of reading texts used in IELTS by comparing IELTS Academic Reading texts with the texts that first year undergraduates most needed to read and understand once enrolled at their universities. The textual features examined in the study included vocabulary and grammar, cohesion and rhetorical organization, genre and rhetorical task, subject and cultural knowledge, and text abstractness. The authors found that the IELTS texts have many of the features of the kinds of text encountered by first year undergraduates and there are few fundamental differences between them. The findings support arguments made by Clapham (1996) that nonspecialist texts of the kind employed in IELTS can serve as a reasonable substitute for testing purposes.

Rupp, Ferne, and Choi (2006) explored whether or not test takers read in similar ways when reading texts in a multiple choice testing context and when reading texts in non-testing contexts. Using qualitative analyses of data from introspective interviews, Rupp et al. (2006) found that asking test takers to respond to text passages with multiple choice questions induced response processes that are strikingly different from those that respondents would draw on when reading in non-testing contexts. The test takers in their study were found to “often segment a text into chunks that were aligned with individual questions and focused predominantly on the microstructure representation of a text base rather than the macrostructure of a situation model” (p. 469). The authors speculated that “higher-order inferences that may lead to an integrated macrostructure situation model in a non-testing context are often suppressed or are limited to grasping the main idea of a text” (p. 469). The construct of reading comprehension that is assessed and the processes that learners engage in seem to have changed as a result of the testing format and text types used. The authors assert that the construct of reading comprehension turns out to be assessment specific and is fundamentally determined through item design and text selection. (This issue of test variability in reading assessments has also been the focus of L1 reading research, with considerable variability revealed across a number of standardized tests; see Keenan, Betjemann & Olson, 2008.)

Cohen and Upton (2007) described reading and test-taking strategies that test takers use to complete reading tasks in the reading sections of the LanguEdge Courseware (2002) materials developed to introduce the design of the new TOEFL (iBT TOEFL). The study sought to determine if there is variation in the types of strategies used when answering three broad categories of question types: basic comprehension item types, inferencing item types, and reading-to-learn item types. Think-aloud protocols were collected as the participants worked through these various item types. The authors reported two main findings: (a) participants approached the reading section of the test as a test-taking task with a primary goal of getting the answers right, and (b) "the strategies deployed were generally consistent with TOEFL's claims that the successful completion of this test section requires academic reading-like abilities" (p. 237). Unlike those in Rupp et al. (2006), the participants in this study were found to draw on their understanding and interpretation of the passage to answer the questions, except when responding to certain item formats like basic comprehension vocabulary. However, their subjects used 17 out of 28 test-taking strategies regularly, but only 3 out of 28 reading strategies regularly. So, while subjects may be reading for understanding in academic ways, they are probably not reading academic texts in ways in which they would read these texts in non-testing contexts. In this way, at least, the results of Cohen and Upton (2007) converge with the findings of Rupp et al. (2006).

Finally, Chang (2006) examined whether and how the requirement of memory biases our understanding of readers' comprehension. The study compared L2 readers' performance on an immediate recall protocol (a task requiring memory) and on a translation task (a task without the requirement of memory). The study revealed that the translation task yielded significantly more evidence of comprehension than did the immediate recall task, which indicates that the requirement of memory in the recall task may hinder test takers' abilities to demonstrate fully their comprehension of the reading passage. The results also showed that the significant difference found in learners' performance between the immediate recall and the translation task spanned the effect of topics and proficiency levels. This study provides evidence that immediate free recall tasks might have limited validity as a comprehension measure due to its memory-related complication. Certainly, more research is needed on the role and relevance of memory processes as part of reading comprehension abilities.

Challenges

A number of important challenges face reading assessment practices. One of the most important challenges for reading assessment stems from the complexity of the construct of reading ability itself. Reading comprehension is a multicomponent construct which involves many skills and subskills (at least the 12 listed above). The question remains how such an array of component abilities can best be captured within the operational constraints of standardized testing, what new assessment tasks might be developed, and what component abilities might best be assessed indirectly (Grabe, 2009). In standardized assessment contexts, practices that might expand the reading assessment construct are constrained by

concerns of validity, reliability, time, cost, usability, and consequence, which limit the types of reading assessment tasks that can be used. In classroom-based contexts, effective reading assessments are often constrained by relatively minimal awareness among teachers that a range of reading abilities, reflecting the reading construct, need to be assessed.

A second challenge is the need to reconcile the connection between reading in a testing context and reading in non-testing contexts. Whether or not a text or task has similar linguistic and textual features in a testing context to texts in non-test uses (that is, how authentic the text is) does not address what test takers actually do when encountering these texts in a high stakes testing situation. When students read a text as part of standardized assessment, they know that they are reading for an assessment purpose. So, for example, although the characteristics of the academic reading texts used in IELTS were said to share most of the textual characteristics of first year undergraduate textbook materials (Green et al., 2010), the context for standardized assessment may preclude any strong assumption of a match to authentic reading in the “real world” (see, e.g., Rupp et al., 2006; Cohen & Upton, 2007). One outcome is that it is probably not reasonable to demand that the reading done in reading assessments exactly replicate “real world” reading experiences. However, the use of realistic texts, tasks, and contexts should be expected because it supports positive washback for reading instruction; that is to say, texts being used in testing and language instruction are realistic approximations for what test takers will need to read in subsequent academic settings.

A third challenge is how to assess reading strategies, or “the strategic reader.” Rupp et al. (2006) found that the strategies readers use in assessment contexts were different from the ones they use in real reading contexts and even the construct of reading comprehension is assessment-specific and determined by the test design and text format. On the other hand, Cohen and Upton (2007) found that, although the participants approached the reading test as a test-taking task, the successful completion of the test requires both local and general understanding of the texts, which reflects academic-like reading abilities. This debate leaves open a key question: If readers use strategies differently in non-testing contexts and in testing contexts, how should we view the validity of reading assessments (assuming strategy use is a part of the reading construct)? Clearly, more research is needed on the use of, and assessment of, reading strategies in testing contexts.

A fourth challenge is the possible need to develop a notion of the reading construct that varies with growing proficiency in reading. In many L2 reading assessment situations, this issue is minimized (except for the Cambridge ESOL suite of language assessments). Because English L2 assessment contexts are so often focused on EAP contexts, there is relatively little discussion of how reading assessments should reflect a low-proficiency interpretation of the L2 reading construct (whether for children, or beginning L2 learners, or for basic adult literacy populations). It is clear that different proficiency levels require distinct types of reading assessments, especially when considering research in L1 reading contexts (Paris, 2005; Adlof et al., 2011). In L2 contexts, Kobayashi (2002) found that text organization and response format have an impact on the performance of readers at different proficiency levels. The implication of this finding is that different texts, tasks, and task types are appropriate at different proficiency levels. In light of this finding, how should reading assessment tasks and task types change with growing

L2 proficiency? Can systematic statements be made in this regard? Should proficiency variability be reflected at the level of the L2 reading construct and, if so, how?

Future Directions

In some respects, the challenges to L2 reading assessment and future directions for reading assessment are two sides of the same coin. In closing this chapter, we suggest five future directions as a set of issues that L2 reading assessment research and practice should give more attention to. These directions do not necessarily reflect current conflicts in research findings or immediate challenges to the validity of reading assessment, but they do need to be considered carefully and acted upon in the future.

First, different L2 reading tests likely measure students differently. This is not news to reading assessment researchers, but this needs to be explored more explicitly and systematically in L2 reading contexts. Standardized assessment programs may not want to know how their reading tests compare with other reading tests, so this is work that might not be carried out by testing corporations. At the same time, such work can be expensive and quite demanding on test takers. Nonetheless, with applied linguists regularly using one or another standardized test for research purposes, it is important to know how reading measures vary. One research study in L1 contexts (Keenan et al., 2008) has demonstrated that widely used L1 reading measures give different sets of results for the same group of test takers. Work of this type would be very useful for researchers studying many aspects of language learning.

Second, the reading construct is most likely underrepresented by all well-known standardized reading assessment systems. A longer-term goal of reading assessment research should be to try to expand reading measures to more accurately reflect the L2 reading construct. Perhaps this work can be most usefully carried out as part of recent efforts to develop diagnostic assessment measures for L2 reading because much more detailed information could be collected in this way. Such work would, in turn, improve research on the L2 reading construct itself. At issue is the extent to which we can (and should) measure reading passage fluency, main idea summarizing skills, information synthesis from multiple text sources, strategic reading abilities, morphological knowledge, and possibly other abilities.

Third, L2 readers are not a homogeneous group and they bring different background knowledge when reading L2 texts. They vary in many ways in areas such as cultural experiences, topic interest, print environment, knowledge of genre and text structures, and disciplinary knowledge. In order to control for unnecessary confounding factors related to these differences in prior knowledge, more attention should be paid to issues of individual variation, especially in classroom-based assessments, so no test takers are advantaged or disadvantaged due to these differences.

Fourth, computers and new media are likely to alter how reading tests and reading tasks evolve. Although we believe that students in reading for academic purposes contexts are not going to magically bypass the need to read print materials and books for at least the near future, we need to recognize that the ability to

read online texts is becoming an important part of the general construct of reading ability. As a result, more attention needs to be paid to issues of reading assessment tied to reading of online texts, especially when research has indicated a low correlation between students who are effective print readers versus students who are effective online readers (Coiro & Dobler, 2007). At the same time, reading assessment research will need to examine the uses of computer-based assessments and assessments involving new media. A major issue is how to carry out research that is fair, rigorous, and relatively free of enthusiastic endorsements or the selling of the “new” simply because it is novel.

Finally, teachers need to be trained more effectively to understand appropriate assessment practices. A large number of teachers still have negative attitudes to the value of assessment measures for student evaluation, student placement, and student learning. In many cases, L2 training programs do not require an assessment course, or the course is taught in a way that seems to turn off future teachers. As a consequence, teachers allow themselves to be powerless to influence assessment practices and outcomes. In such settings, teachers, in effect, cheat themselves by being excluded from the assessment process, and they are not good advocates for their students. Perhaps most importantly, teachers lose a powerful tool to support student learning and to motivate students more effectively. The problem of teachers being poorly trained in assessment practices is a growing area of attention in L1 contexts; it should also be a more urgent topic of discussion in L2 teacher-training contexts.

Assessing Writing

Deborah Crusan

Wright State University, USA

Introduction

Over the last few decades, investigators have identified and studied many of the components of and issues associated with writing assessment. However, the inherent complexity of myriad interacting philosophical and pragmatic components of both writing and writing assessment coupled with the lack of consensus about the best way to address these issues leave the field of writing assessment still facing most of the same problems. It is my hope that by identifying and discussing cutting-edge issues and controversies, teachers, program administrators, and test developers will develop a better understanding of the field and the options available to assess student writing for a variety of purposes.

Previous Views

The history of writing assessment documents shifting responsibilities, foci, and methodology (Cumming, 2009). Second language writing, writing assessment, and measurement histories connect with the history of writing and writing assessment in English. Certain parallel metaphors appear in the literature; note the similarities between Yancey's (1999) waves (objective, holistic, and portfolio and program assessment), Hamp-Lyons's (2001) four generations (direct [essays]; indirect [multiple choice]; portfolio; humanistic, technological, political), and Spolsky's (Cumming, 2009) three periods (pre-scientific, psychometric-structuralist, integrative-sociolinguistic). Throughout the history of the field of writing assessment, we can see shifts from oral tests to written exams to objective tests and back again.

While the history of *writing* traditionally traces its roots internationally (from cuneiform in Mesopotamia to hieroglyphs and papyrus in Egypt, Chinese characters, phonetics and the alphabet, the Arabic script and so on), research into the history of *writing assessment* has been, at least for now, largely concentrated in the USA. Consequently, the following history focuses primarily on US contexts; more research is necessary to tell the story of writing assessment in other contexts.

In the late 19th century, Harvard impacted writing assessment in the USA by shifting to “dispassionate scientific systemization” (Elliot, 2005, p. 9) and failing 157 out of 316 students on its first composition test. Failure was based on mechanical errors and, in turn, led to a national fixation on linguistic correctness. Following this, the College Entrance Examination Board (CEEB) introduced standardized testing and the accountability movement. The accountability movement, particularly in the USA, is an assessment of the effectiveness and efficiency of instructional programs regarding student learning and involves punitive and reward mechanisms; the failures and successes of the instructional program are the responsibility of educators.

In 1912, Thorndike and Hillegas, in response to the desire for standardization (Elliot, 2005), designed a scoring guide for composition, which promised to eliminate errors of comparison between essays. Even though standardization was a central component in these examples, writing was still being assessed through actual writing.

Multiple choice standardized testing was first developed because of the need to assign massive numbers of soldiers to jobs during World War I, followed closely by the development of objective tests for college admission. These tests were valued for their purported abolition of favoritism as well as their easy and economical scoring. With these developments, large-scale writing assessment dramatically redirected testing and writing research in the United States. Research and teaching began to be driven by the dogma of deficit theory, in which educators approach students based on their deficits rather than their strengths and automatically assume that some students are more likely to succeed academically than others. Because it was widely believed at the time that deficits needed to be remediated before learning could occur, research and teaching focused on the impact of grammar instruction on the production of error-free writing.

In the 1960s and 1970s, a major shift resulted from work on the writing process. This work helped displace the focus on correctness with a focus on how meaning is made when people write. However, although this period of process work in the USA and its accompanying focus on performance assessment (actual writing to assess writing) suggests that second language writing was *first* assessed through writing at this same time in history, it is far from true. Cambridge English for speakers of other languages (ESOL) examinations have included an essay writing task since 1913 (Shaw & Weir, 2007, p. 11).

Around this time, the Educational Testing Service (ETS) developed the traditional five-point rubric and experimented with holistic scoring. This development marked an important landmark in writing assessment as the claim was made that validity and reliability were somewhat improved by the addition of a short, holistically scored essay. Direct measures were once again being used to assess writing. Although in subsequent years the use of a single essay as sole indicator of writing

ability would fall into relative disfavor, the work done at ETS vastly improved writing assessment, both for large-scale and in-class purposes, as it focused on the assessment of actual writing rather than the subskills of writing.

This brief history demonstrates the vacillation of method in writing assessment and the rationale for changes made in writing assessment. In recent years, the course of the history of writing assessment has broadened to include a wider array of topics, more ways of assessing writing for different purposes (e.g., the portfolio), and an investigation of other aspects of writing assessment, such as feedback, assessment literacy, writing placement, rating/raters, and machine scoring.

In the subsequent sections of this chapter, in an effort to provide the state of the art of the field of writing assessment, I will examine more contemporary issues at work in writing assessment.

Current Views

Writing assessment is a relatively new discipline, gradually emerging as a field in the late 20th century (Behizadeh & Engelhard, 2011). Current views in writing assessment, rather than considering only the methods by which writing is assessed, see the people involved as an important aspect. Prevalent questions include when to assess, what to assess, and how to assess writing. They examine the teacher, the rater, and the writer. Because feedback in writing, often termed a “problematic practice” (Parr & Timperley, 2010, p. 69), involves all of these participants, it occupies a significant place in the assessment literature.

Feedback

Zhao (2010) examined the ways Chinese university English learners used and understood feedback from both peers and teachers. Using content analyses, stimulated recall, and interviews, Zhao found that writers rely more on teacher feedback than on the feedback from their peers although interviews revealed that writers did not understand the significance of the feedback. Writers passively accepted teacher feedback. The researcher concluded that a teacher-driven classroom “induced . . . biased views of peer and teacher feedback” (p. 14) and called for both peer and teacher feedback to be integrated into the English as a second language/English as a foreign language (ESL/EFL) writing classroom.

In New Zealand, Parr and Timperley (2010) assessed the quality of teacher feedback in the writing classroom in which assessment for learning (AFL) was used. They found a “strong relationship . . . between teacher ability to give quality assessment for learning feedback and student progress” (p. 80) and suggest that this ability could possibly be a marker of teacher pedagogical knowledge. When content knowledge was strong, teachers were more able to provide quality assessment for learning to their students.

Peterson and McClay (2010) recorded telephone interviews from 216 Canadian 4th to 8th grade teachers currently teaching to assess their awareness of the value of feedback. Teachers in the study recognized that feedback is a valuable addition to their pedagogy. They were reliant on oral feedback as they saw it as a way to

nurture their students. Interesting was the fact that although teachers in this study regarded portfolios highly (see Chapter 40, Portfolio Assessment in the Classroom), they did not use them, indicating that they might not value self-assessment or found it difficult to encourage students in assessing their own writing. Teachers noted the “competing demands that teachers face every hour in their classrooms and in their planning for teaching” (p. 97), which keep them from implementing more in the way of feedback. To answer those time constraints, the authors recommend using computer recording devices to provide feedback in a more manageable way.

Chiefly in the USA, there remains a divide between mainstream composition teachers and second language writing teachers, particularly when compositionists meet second language writers in their classrooms. That divide is studied in Ferris, Brown, Liu, and Stine (2011). In this study, researchers surveyed and interviewed first language (L1) and second language (L2) US college writing instructors regarding their training, experience, and practices concerning teacher feedback to student writers. Instructors proved proficient in adapting their feedback approaches when working with L2 writers, but the adaptations made were wildly different, as were their positions about responding to L2 writers. In fact, some teachers “firmly believed that these students ‘do not belong’ in their classes and expressed resentment of the perceived extra burdens L2 writers might bring” (Ferris et al., 2011, p. 220). Noting this less than enthusiastic welcome by mainstream compositionists to L2 writers in their classrooms, the researchers call for collaboration between writing teachers and training for L1 teachers who work with second language writers.

Assessment Literacy

As is apparent from the studies above, teacher cognition and teacher training are vital. One aspect of teacher cognition is assessment literacy, defined as an understanding of the principles of sound assessment. Mertler (2009) argues that teachers feel inadequate where assessment (all kinds) is concerned and reports that teachers claim their assessment training received during undergraduate teacher training programs “did not prepare them to feel comfortable with the decisions they are routinely charged to make” (p. 101).

Assessment is one of the most difficult of teacher tasks. Teachers approach writing assessment with more than a little anxiety. Although teachers often report an intense dislike for assessment, they cannot shirk their responsibilities (Weigle, 2007). Because assessment is an issue for teachers every day, it is vital that they learn about the assessment of writing and become involved in the design and implementation of writing assessment at their institutions. There is a critical need for careful teaching of the assessment of writing in courses that prepare second language writing teachers at all levels. Regrettably, many graduate programs in teaching English to speakers of other languages (TESOL) and composition and rhetoric fail to prepare teachers to assess writing (Weigle, 2007).

Teachers need to be cognizant of many issues regarding writing assessment, which is tied inextricably to the teaching of writing for “responsibly teaching writing requires consistent engagement in the practice of writing assessment”

(Crusan, 2010, p. 12). Teachers need to be aware of assessment research and theory to drive their assessment choices both locally in their classes and, more globally, in their institutions (Crusan, 2010). This knowledge will serve them as they teach and assess writing, administer writing programs, and advocate for specific forms of assessment.

Weigle (2007) outlined what teachers need to know about assessment. Specifically, teachers need to:

- understand classroom writing assessment methods;
- recognize what good assessment is;
- comprehend the concepts of formative and summative writing assessment;
- grasp concepts of reliability, validity, and practicality in test development;
- understand the test development process;
- recognize good writing;
- recognize the components of a good paper;
- realize that the concept of good writing is highly individualized and conceptualized;
- understand goal and objective setting;
- create and use fair and effective assessment tools for their students; and
- be conscious of externally mandated tests, their uses, and what scores mean.

(For a more in-depth and conclusive summary of what teachers should know, see Weigle, 2007.)

Current Research

Although many topics are currently at the forefront of the field, a search of several academic journals over the last five years yielded areas of primary research interest: writing placement; rating, raters, and rating scales; and machine scoring.

Placement

Of the purposes for writing assessment, placement is perhaps most problematic. In fact, White (2008) calls it the “knottiest of our assessment problems” (p. 141). Little has been written about placement in EFL contexts and when it has, the focus is general placement. For example, Cornwell, Simon-Maeda, and Churchill (2007) reviewed literature regarding university placement decisions; however, the placement they described was testing to assign students (to general English classes) based on proficiency levels. Among other issues, the authors recommend that locally developed placement tests might provide better results for Japanese universities than commercially produced tests. Likewise, Barber (2007) examined Japanese (conversation school) placement tests and maintained that standardized tests seldom match curriculum; he then provided a model for constructing a valid and reliable criterion-referenced placement test more aligned with school curriculum.

Placement is a classification system in which a test (SAT [Scholastic Aptitude Test], ACT [American College Testing], Test of English as a Foreign Language

[TOEFL], locally developed instrument) is used to categorize and sort students into appropriate writing courses. Often-employed placement methods include single essay, multiple choice (indirect) test (both paper and pencil and electronic), and, to a lesser extent, portfolio. The essay test is sometimes given as a reading and response test and, even more often, the writer responds to a single prompt. These tests are usually given onsite and are most often timed. Of course, when writing is timed, students often do not produce their best work. Additionally, scoring is costly and time consuming. Further, long-held beliefs concerning the impromptu essay (e.g., that it is criterion-referenced, that it reflects generalizable information about a writer's ability) have been called into question (Cho, 2003).

Multiple choice (indirect) testing is generally testing writing without producing any writing; in fact, indirect testing is more an assessment of the subskills involved in writing—mechanics, usage, grammar, and spelling. Its use in higher education for placement is prevalent (Yancey, 1999; Crusan, 2010). When examined, reliance on indirect assessment (at least for placement purposes) makes administrative sense. Efficiency, low cost, and quantification make standardized tests attractive. It is difficult to resist the promise of reliable and valid writing assessment for a fraction of the time, money, and energy. However, we must consider the weaknesses of indirect testing of writing ability. One weakness is the lack of face validity. If a test does not look like it will measure what it is supposed to measure (especially to the test taker), it lacks face validity. Another problem is the possibility of less valid interpretations of test scores because of construct-irrelevant variance (Messick, 1989) from use of test-taking strategies; for example, a high score on a grammar or mechanics multiple choice test does not automatically guarantee that the test taker is good at writing.

Although difficult and possibly unwieldy for placement, “the portfolio and its subsequent withholding of summative assessment (an actual grade rather than formative feedback on a series of drafts) is now a central notion in many L1 and L2 writing classrooms” (Crusan, 2010, p. 41) so it makes theoretical sense for placement as it mirrors classroom practice. However, while authentic, its drawbacks include time, energy, and money, coupled with increased risk of plagiarism. Further, the reliability of the portfolio as a testing method has yet to be established (White, 2008).

One of the newer methods used for placement is directed self-placement (DSP), developed and first implemented by Royer and Gilles (1998). DSP comes in many forms (face-to-face, online, including writing or not including writing), but its basic tenet concerns student autonomy. In DSP, *students* select their beginning writing course. DSP offers *agency* to students (Royer & Gilles, 1998; Blakesley, 2002; White, 2008)—they know their abilities and should be included in high stakes decisions (for more details on directed self-placement, see Royer & Gilles, 1998).

Not surprisingly, there is opposition to DSP, particularly as a placement method for second language writers. A concern is a student's ability to self-assess. However, when students are guided through the process and understand the responsibility of DSP, they generally select courses appropriately (Royer & Gilles, 1998).

Statements in favor of DSP include Blakesley (2002) and White (2008); for native speakers of English, both scholars believe that DSP holds great promise. White

argues that a test causes more problems than it solves and that placement testing is far from neutral but rather “a political and economic rather than an academic activity” (2008, p. 137), so he sees the move toward DSP as metaphorically stepping away from the politics inherent in assessment. Blakesley reports that adopting DSP has resulted in improved student performance and retention at his institution. And for second language writers, the Conference on College Composition and Communication (CCCC) statement on second language writing and writers (2009) supports the use of DSP for placement of second language writers into composition courses.

In contrast, Gere, Aull, Green, and Porter (2010) explored the validity of DSP at their university. They drew upon academic records, course materials, the questions used for DSP, and conducted interviews with students. They found that DSP lacked strong validity in their context and called for further investigations of DSP’s validity at other universities. Along the same lines, Lewiecki-Wilson, Sommers, and Tassoni (2000) examined placement as a rhetorical act and concluded, “The forms of assessment we use contribute to public debate about proper uses of writing” (p. 172). When assessment is viewed in this manner, Lewiecki-Wilson et al. believe that DSP sends the wrong message about writing at their institution—that college writing is about self-inventory checklists and filling in the blanks. They were also worried that students at their institution, because of “a long history of test failure and test anxiety . . . might misplace themselves out of reticence, fear, or anxiety” (2000, p. 169).

The decision to use DSP for placement must be made after careful examination of individual writing programs. It is inappropriate to make a blanket statement that DSP is suitable for all programs or is the only valid placement method. Programmatic goals, course requirements, and institutional constraints must be weighed carefully. The placement debate will no doubt continue, but DSP’s intrinsic advantages cannot be overlooked.

Raters

The topic of rating is addressed more comprehensively in Chapter 80, *Raters and Ratings*; however, because it is an important aspect of writing assessment, several issues regarding the rating of writing in test situations are considered here. In short, novice raters discover rating strategies fairly quickly; raters tend to be consistent, even over time and even in light of feedback, but test consequences and amount of rating required may influence rater consistency.

One issue is rater inconsistency. Baker (2010) investigated variability of rater behavior in a high stakes writing assessment and a low stakes writing assessment undertaken by the same raters. Baker attempted to answer the question about variability among tasks—that is, do raters rate differently according to the consequences of the test when all else (rating scale, training) remains the same? In interviews after rating the low stakes assessment, raters were asked if their rating was different from their previous rating of a high stakes writing task. All raters were considered to be consistent raters, and all raters appeared to be very concerned with remembering their ratings to demonstrate that consistency; however, “post-rating comments suggest that the difference in the stakes involved for test

takers from one condition to the next was a salient focus for two of the raters, but not all four” (p. 145).

Knoch (2011) examined 19 individuals rating the Occupational English Test (OET) given in Australia to immigrating health-care professionals. Raters were provided with various kinds of feedback in the form of detailed performance profiles of their rating behavior following each rating experience; raters responded positively to the feedback but rating was not affected either positively or negatively because of the feedback, leading the researcher to question whether the time invested in creating rater profiles was worth the effort.

In another study of rater performance, Lim (2011), using data from the Michigan English Language Assessment Battery (MELAB), investigated the performance of new and experienced raters over three time periods of 12 to 21 months. Examining rater severity and consistency, Lim found that inexperienced raters discover appropriate rating strategies fairly rapidly, that raters are able to preserve the quality of their performance over time, and the amount of rating a rater performs has an effect on the quality of the rating.

Machine Scoring

Another aspect of writing assessment that is gaining recognition is automated scoring and feedback. Machine scoring has a relatively long history. Ellis Page developed the first recognized essay scoring machine—Project Essay Grader (PEG)—in 1966 (Page, 2003). Currently referred to as automated essay evaluation (AEE), automated essay scoring (AES), automated writing evaluation (AWE), or the machine scoring of essays (Ericsson & Haswell, 2006), it is “designed to provide instant computer-generated scores for a submitted essay along with diagnostic feedback” (Chen & Cheng, 2008, p. 94). These scoring platforms use natural language processing, latent semantic processing, or artificial intelligence technologies.

While machine scoring was predominately developed outside of language testing, in recent years, as Xi (2010) points out, applied and computational linguists have become increasingly involved in the development and implementation of platforms especially for scoring standardized writing assessments. To strengthen these platforms, Chapelle and Chung (2010) call for more collaboration among academics and commercial purveyors involved in machine scoring “to construct systems, conduct research and provide feedback to future research and development” (p. 312).

Although machine scoring is used primarily for large-scale writing assessment scoring, classroom instructional tools (My Access![®], Criterion[®], WriteToLearn[®]) are available for grades K-12 and first year composition. Programs feature grade books, portfolios, and email capability. Teachers can select from a database of prompts graded to either a four- or six-point rubric; grading criteria are controlled by the program since the machine is trained with hundreds of example essays. Students write essays, submit them, and almost instantaneously receive a score and detailed feedback. Students make revisions accordingly; however, currently, feedback concerns mostly grammatical and mechanical facets of students’ writing.

Enright and Quinlan (2010) compared human scores with those of ETS's e-rater® as well as other components (reliability, fairness, relationship between external criterion writing measures, consequences). They argue that machines and humans complement each other—that the combination of human and machine increases efficiency and score quality. On the other hand, McCurry (2010) argues that machine scores, while highly correlated with human raters on constrained writing tasks, do not as reliably rate essays on an open writing task. Unsure of the consequences of machine scoring, Enright and Quinlan (2010) suggest the need for a study investigating if writers are affected when they know how (by machine, by human, a combination) their writing will be being scored.

Unfortunately, administrators and second language writing teachers often seem at odds regarding machine scoring. Administrators appreciate the score generation for large numbers of essays in a short time, quick feedback to writers, and increased student text production. Teachers, on the other hand, worry about the technology's possible encroachment on their jobs; students ignoring their teachers in favor of gaming the machine; and the narrowing of students' writing and the resultant loss of imagination and creativity. However, some of these concerns might be the result of unfounded fears due to too limited information about machine scoring. Since machine scoring has not developed to the point that meaning is understood (McCurry, 2010; Xi, 2010), current classroom programs are best viewed as an additional tool in the arsenal of the writing teacher, albeit one that should be used with care.

Machine scoring of essays is destined to play a larger role in writing assessment. As computer hardware and software evolve in sophistication, we can expect more complexity and greater innovation. However, programs that truly understand meaning are still a distant prospect. More research is needed to provide evidence of the effectiveness of machine scoring platforms.

Challenges

A number of important challenges face writing assessment practice. Fraught with ethical dilemmas (Cumming, 2002), writing assessment has been called a thorny and perennial problem by writing teachers and writing assessment theorists (Hamp-Lyons, 2001; Crusan, 2010).

Construct

One challenge in the field of writing assessment is construct, for the field does not "share a construct of writing quality" (Hamp-Lyons, 1990, p. 80). If this is so, then it stands to reason that difficulties arise when discussing ways to assess writing. Teachers can identify good writing—they can point to a paper that contains what they consider to be good writing; however, when pressed, they are often unable to define it or describe it, or both. The construct of good writing, and thus writing assessment, is also highly contextualized. For example, Cumming (2001) examined the assessment practices of teachers working in Australia, Canada, New Zealand, Hong Kong, Japan, and Thailand. Admitting that context is a key factor,

he expected to find differences in assessment practices between ESL and EFL settings but instead discovered that instructors' perceptions of curriculum affected their assessment of student writing. When teaching in an English for specific purposes setting, teachers' assessments were much more form-focused while those teaching in English for general purposes courses focused on a wider variety of performance indicators. Clearly, one's notion of the construct of writing is an issue in writing assessment and potential source of bias.

Cumming (2009) explored ethical issues surrounding the definition of the construct of writing in high stakes writing assessment in the development of new TOEFL task types. On the TOEFL, the construct of writing is represented as follows. The test taker must complete two writing tasks in a time limit of 50 minutes; one task is to write an essay in response to reading and listening tasks; the other is a task wherein the writer supports an opinion in writing in response to a prompt. We might ask if this is the way writing is represented in the real world. Is this an authentic representation of the construct of writing? Cumming (2009) claims that alternative constructs of writing might not be assessed in high stakes situations because of the ethical dilemmas posed when assessing "writing as a mode of learning, the expression of identity, or a medium for political action" (p. 73).

Beck and Jeffrey (2007) examined both prompts and high-scoring benchmark papers written in response to these prompts on high stakes writing assessments in three states in the USA to determine, among other factors, the uniformity of the construct of writing in each of the tests. Their findings reveal a "lack of alignment between the genres of the benchmark papers designated as exemplary and the genre demands of the prompts to which they were written" (p. 60). They call for more construct uniformity in the design of assessment of writing and for better representation of discipline-specific forms of writing.

Scoring

A further challenge in writing assessment has always been the method by which writing is scored for a variety of purposes. In many cases, both for high stakes standardized tests of writing and for in-class writing assessment, rubrics are used to score writing products. A rubric is a scoring scale used to assess performance along a task-specific set of criteria. Rubrics focus on measuring stated objectives or outcomes, rating student performance using a range, and include a series of explicit performance characteristics for each grade, benchmarked to the degree to which a standard has been met.

There are many advantages of using rubrics for the assessment of writing. First, rubrics allow for more objective and consistent evaluation. Once developed for a specific assignment, the rubric can guide both students and teacher in completion and assessment of the task. In the same vein, rubrics clearly illustrate to students the ways in which their work will be evaluated and what is expected of them, probably one of the most important aspects of using rubrics. Moreover, particularly for the classroom, rubrics aid in making writing assessment "transparent" (Crusan, 2010, p. 33); that is, the criteria upon which students' writing will be assessed are not a secret. Instead, information concerning assignments is fronted (introduced at the beginning of each assignment) and unambiguous. Additionally,

rubrics provide feedback to teachers regarding the effectiveness of their instruction and provide benchmarks upon which to measure and document progress. Finally, rubrics provide all students with an opportunity to succeed at some level.

Those who view the use of rubrics in a less favorable light do so because they believe that rubrics are limiting, that they lead to standardization of the curriculum (Wilson, 2006; see also Broad, 2003). When allowed to drive instruction, rubrics can be less than ideal, but when teachers follow good assessment practices, developing criteria and rubrics for every task rather than using the same rubric for every assignment, these problems can be avoided (Crusan, 2010).

The three main types of rubrics are holistic, analytic, or primary trait (Hamp-Lyons, 1990). Holistic rubrics generally have a four-, five-, or six-point scale, which involves ranking an essay in relation to a benchmark essay. Holistic rubrics are used when a general impression of a student's writing is needed, as is the case of large-scale writing assessment in standardized tests like ACT, SAT, or TOEFL. While holistic rubrics are an excellent option when fast evaluation is needed, their delivery of a single score might not provide enough information for some assessment purposes, particularly in-class writing, nor are holistic rubrics the most effective tool for every genre of writing.

An analytic rubric is a more detailed scoring instrument, which often includes categories such as content, organization, vocabulary, language use, and mechanics. Categories can be weighted. Teachers can assign a greater number of points to features such as content and organization and fewer points to mechanics. Much is accomplished in using an analytic rubric. First it shows students what the teacher considers the more important aspects of writing. Further, it provides students with a breakdown of their strengths and weaknesses in writing in general and in each paper. The strongest appeal of the analytic rubric is the positive washback it provides (Hamp-Lyons, 1990; Crusan, 2010). Washback, an important testing concept, is the influence of testing on teaching and learning (Cumming, 2002). For students, washback is positive when it affords the opportunity to learn what they have done well and what they can improve upon. For examples of holistic and analytic rubrics, see "Rubrics" (*n.d.*).

The final type of rubric, the primary trait rubric (presented in Table 12.1), is an assessment instrument that focuses on one specific aspect of student writing. Primary trait rubrics are especially useful in the second language writing classroom (Hamp-Lyons, 1990, 2001) as they can be used to pinpoint issues such as grammar, vocabulary, or organization. Students appreciate the freedom to focus on one feature in their writing to the exclusion of others as it frees them from worry and raises awareness of that one issue and ways to combat it.

Stakeholder Perspectives

A final challenge within the field of writing assessment is the tension between various stakeholders in writing assessment. The stakeholders in writing assessment are students, teachers, researchers, and members of the measurement community. It is clear: stakeholders see writing assessment from their own vantage point. This clash of perspectives has always been problematic and is clearly at work in the field of writing assessment today (Huot, O'Neill, & Moore, 2010). The

Table 12.1 Example of primary trait rubric assessing use of past tense

<i>Criteria</i>	<i>Points possible</i>	<i>Score</i>
Excellent to Very good The paragraph shows sophisticated and effective past tense usage. It shows mastery and appropriate choice of the past tense.	20–18	
Good to Average The paragraph shows adequate usage with occasional errors in past tense choice and usage but meaning not obscured.	17–14	
Fair to Poor The paragraph shows limited understanding of the past tense with frequent errors in past tense usage. Meaning is confused or obscured.	13–10	
Very poor The paragraph is essentially a translation. It shows little knowledge of verb forms in English.	9–1	
Comments		
Total score		

discord concerns viewpoints taken by various communities, which position them philosophically. For example, tests can be viewed through the lens of “efficiency and problem solving” (Huot et al., 2010, p. 497) in which tests are used by institutions for decisions such as college admission. When viewed in this way, the teacher, the student, and perhaps parents are often absent from the assessment loop. It is clear that some see assessment through the lens of efficiency while others see assessment through a pedagogical lens. Neither is right or wrong.

In a study investigating the connections between measurement theories, writing theories, and writing assessments, Behizadeh and Engelhard (2011) found that “measurement theory has had a strong influence on writing assessments, while writing theory has had minimal influence on writing assessments” (p. 189). Claiming writing assessment as an emerging discipline, the authors describe the field as a combination of the writing, composition, and measurement communities of scholars and call for collaboration among these groups.

Future Directions

Most research in writing assessment is focused on US contexts, so a call for more research in EFL contexts is a consideration. Additionally, research into assessing writing in languages other than English certainly deserves attention.

Looking to the future, it is clear that the field of writing assessment will continue to flourish, enjoying an influx of attention in the form of dissertations, conference presentations, journal articles, and scholarly books (Cumming, 2009; Huot et al. 2010). In fact, journals report that the number and quality of articles addressing writing assessment continue to rise. Additionally, conferences whose topic is writing assessment are beginning to appear; for example, a two-day international

symposium, "Writing Assessment in Higher Education: Making the Framework Work," was held in Amsterdam in late 2011. Additionally, while still somewhat limited, presentations regarding writing assessment are becoming more prominent at conferences such as TESOL and Conference on College Composition and Communication (CCCC). And even though there has been a burst of robust research, many questions about writing assessment have yet to be answered. Always at issue will be the reliability, validity, and practicality of various methods along with questions about tests' effects on students, institutions, and society in general (Crusan, 2010; Huot et al., 2010).

The assessment of writing in English will occupy a place of importance because of the scope of English. English has been called the lingua franca. "Most of the scientific, technological, and academic information in the world is expressed in English and over 80% of all the information stored in electronic retrieval systems is in English" (Crystal, 1997, p. 106). These statistics translate into a rise in the number of persons who, for employment and/or education purposes, will be English language learners and users of oral and written English. Of course, this increase in users of English should set the assessment world on its head as it considers questions of linguistic imperialism and World Englishes, for what is considered good writing is no longer dominated by one elite variety. Instead, we must as best we can assess a language that is constantly changing. What should *standard* mean? Who makes the decisions to endorse one form of English over another form? These questions will ultimately affect writing assessment.

Regarding technology, machine scoring will continue its quest to grapple with meaning in text. There may come a day when this technology is more common in the classroom, but that decision to include such technologies should always be made by the informed teacher. To that end, much research is still needed in order to answer the many questions provoked by machine scoring; however, machine scoring is, in the eyes of many, a viable option for the writing classroom, so teachers must develop logical arguments to support their decisions to use (or not use) this technology.

In summary, writing assessment is a highly complex and consistently evolving topic. It has been my purpose to provide an overview of the field, highlighting emerging innovations and perhaps offering another perspective regarding some of the major issues at play in the field of writing assessment.

Assessing Integrated Skills

Alister Cumming

University of Toronto, Canada

Introduction

It is rare to write extended texts without reference to some source reading or to some audio or visual material—or to both—just as it is unusual to speak a language without interacting with some other speakers and engaging in ideas. In academic and many workplace contexts, the fundamental purpose of extended writing or speaking is usually to display one's knowledge appropriately with reference to the relevant source information—be that, in academic settings, from course assignments or lectures, required readings, or textbooks or, in workplace settings, from relevant policies, communications, data, or authorities.

Language tests have taken a while to address this fundamental dimension of literate human communication and, particularly, to establish how to evaluate it systematically, through writing and speaking tasks that integrate language production with the interpretation of source content from reading and listening material. Conventionally, language tests have assessed—in separate test components and with separate scores—individuals' abilities to speak, listen to, read, or write a language or their knowledge of its grammar or vocabulary. All these elements of language are, of course, interrelated to some extent, but tests have typically sought to separate them as objects of measurement rather than to address them as fundamentally integrated wholes. Over the last decades, however, an increasing number of language tests, particularly for academic or vocational purposes, have been designed to require examinees to demonstrate their writing and/or speaking abilities not as isolated or separate skills, but rather as the ability to write or speak appropriately, in an integrated manner, about source content, ideas, and texts. The guiding rationale for these initiatives in language test design is that abilities to write or speak coherently about relevant ideas, to handle source documents appropriately, and to display knowledge in relevant ways are primary

abilities required for successful performance in universities, colleges, and high schools, and also in many workplaces. This chapter describes the development of concepts about assessing integrated language skills over recent decades; the current state of understanding, practices, and research in this field; and the particular challenges and future directions faced in the assessment of integrated language skills.

Previous Views

The impetus to assess language abilities in an integrated rather than separate or componential manner arose from a variety of concerns. Most generally, from the 1970s onwards educators argued that assessments of language proficiency needed to focus on students' abilities to communicate purposefully in a language rather than merely to demonstrate knowledge of its grammar, vocabulary, or single skills—which had become the primary, conventional basis for designing language tests (since, e.g., Lado, 1961). Concerted research attempts were made to develop assessments that expanded the range of competencies evaluated in language tests to those considered to be fundamental to communicating in a second or foreign language (e.g., Bachman, 1990; Harley, Allen, Cummins & Swain, 1990; Hawkey, 2004; Davies, 2008). These efforts retained, however, the conventional distinction—articulated influentially through Carroll (1975) and subsequently instantiated in most educational curricula around the world—that language abilities can be distinguished, and hence comprehensively assessed, as four separate “skills,” namely those of reading, writing, listening, and speaking.

The autonomy and categorical separation of these so-called four skills have been challenged for a number of reasons. First, the word “skill” is too broad a term to apply to modes of communication such as writing, speaking, listening, and reading, as is shown by theories and by empirical evidence about skill learning in domains of human activity other than languages (e.g., Anderson, 1995). Koda (2007), for instance, reviewed the substantial theories and research about reading that have accumulated in order to show that (just) reading in a second language requires the development and integration of a large number of distinct but inter-related componential subskills. That is, reading is not a single skill, but rather comprises many inter-related subskills; and the same can certainly be said of other modes of communication such as writing, speaking, and listening. Abilities to produce or interpret languages inherently involve many interdependent rather than separate skills and modes of interaction: in ordinary interactions, for example, people are compelled to talk about what they have read or listened to, and extended texts are usually written about things people have read, heard, or done. Moreover, the particular skills that are called upon for the specific tasks of reading, writing, listening, or speaking vary greatly according to such situational factors as the context, purpose, and age and status of participants.

In academic contexts in particular, educators criticized the types of tasks that conventionally appeared in tests of second language writing (a) for lacking authenticity with respect to the abilities that are really required for academic performance (Morrow, 1977; Lewkowicz, 2000); and (b), as a consequence, for

negatively affecting teaching and learning by reducing them to the practice of simple, rhetorically formulaic types of writing in preparation for such tests (Raimes, 1990). These criticisms, which are directed at the tendency for tests to under-represent the construct of writing for academic purposes, are even more predominant and worrying now, as formal testing has assumed greater importance and impact in educational policies (Hillocks, 2002). Parallel concerns about lack of authenticity appeared in criticisms of oral interviews as a conventional means of assessing speaking abilities (e.g., van Lier, 1989). As Peirce (1992) observed, high stakes language tests tended to establish certain genres of communication that were unique to test formats, because they facilitated objective measurement; but these genres required in tests were scarcely representative of how people really use language to interact in their ordinary lives.

Performance assessments were designed to address and counter these kinds of concerns: examinees perform tasks that represent realistically the complex types of communication and the knowledge demands imposed by university or workplace activities—for instance extended writing and speaking with reference to source information. Morrow (1977) articulated an influential conceptualization of communication assessment on the basis of ideas emerging at the University of Reading and from the Council of Europe's notional–functional syllabi and leading to innovative, integrated language tests for the Royal Society of Arts (Hawkey, 2004, chap. 3). Davies (2008, chap. 2) documented how the English Language Testing System attempted in the 1980s to integrate academic language skills in a systematic way, as well as to distinguish between macro- and micro-levels of skills. Wesche (1987) documented a notable example following from these ideas in the Ontario Test of ESL (English as a second language), a post-admissions university test that involved examinees writing and speaking critically about lengthy source texts they had to read and interpret as they would for an assignment in a university course.

Current Views

Assessments of integrated language skills follow interactionist conceptualizations of assessment; evaluating examinees' "capability to use language in a specified space of contexts, and demonstrating that capability jointly requires knowledge of substance, practices, conventions, and modes of interaction in those contexts" (Mislevy & Yin, 2009, p. 263; see Chalhoub-Deville, 2003). The interactionist view of assessment differs from traditional views, which conceive of language ability as a fixed set of traits (such as grammar or vocabulary) that people have—or have not—acquired, irrespective of situational contexts. Instead of evaluating or scoring acquired traits, interactionist-oriented assessments make claims about examinees' abilities to perform specific types of complex tasks, which represent crucial activities, skills, and strategies in a target domain of language use. This interactionist orientation puts integrated skills assessment in sync with recent trends, in education, work, and multimedia communications, to promote multiliteracies rather than traditional assessments that conceive of reading, writing, listening, speaking, or visual representations as autonomous skills (Cope & Kalantzis, 2000). From a

psychological perspective, too, integrated skills assessments take an orientation toward literate task performance, which realizes constructivist principles of knowledge integration and synthesis, as articulated in the theories of Kintsch (1998) or Bereiter (2002).

For example, integrated skills assessments may involve writing or speaking tasks that require examinees to interpret source information on a particular topic and then to write or speak about the information for a specified purpose. Examinees' writing or speaking is then later rated holistically or analytically, on scales that specify criteria for gradations of more or less effective performance. The integrated writing tasks on the Test of English as a Foreign Language, Internet-based test (TOEFL iBT) exemplify this kind of task, and (as described below) have been widely researched; see samples at Educational Testing Service (2005). These tasks emulate the kinds of behaviors expected of students writing exams on a particular academic topic, under timed conditions, at university. Justification for assessing these behaviors in language tests for admissions to programs of higher education follows from a considerable amount of research showing that students' writing for courses at universities or colleges mostly involves their displaying knowledge—gained from source readings, lectures, and discussions—in ways that are “responsible” to the relevant content and in appropriate genres and academic conventions (Leki & Carson, 1997; Sternglass, 1997; Rosenfeld, Leung, & Oltman, 2001; Leki, 2007; Byrnes, 2008). In brief, university students require abilities to integrate reading, listening, and writing in order to be able to perform competently in and learn from academic courses, so these language abilities need to be assessed in order for assessments to be able to fulfill the purpose of establishing individuals' preparedness for university studies.

Akin to the integrated writing and speaking tasks on the TOEFL iBT, integrated skills assessments feature internationally in various other established English tests for university admissions. In Canada, the Canadian Academic English Language (CAEL) Assessment (Carleton University, *n.d.*) features refined and elaborated versions of the task types established initially in the Ontario Test of ESL (Wesche, 1987), requiring examinees to read a lengthy text on a certain topic, hear segments of a lecture or other discussion about it, and then write and speak about the information from the source materials. In New Zealand, the Diagnostic English Language Needs Assessment (DELNA) (University of Auckland, *n.d.*) asks doctoral students to read several short excerpts from varied sources about a topic, then to write an essay in answer to a specific question about the topic by referring to the statements read.

A cline can be distinguished between weak and strong versions of integrated skills assessments. A weaker version appears, for example, in the writing component of the Cambridge First Certificate in English, which requires examinees to read a letter or email of about 160 words and then to compose a reply to it of 120 to 150 words (Cambridge ESOL [English for Speakers of Other Languages], 2012). Expectations for both reading and writing performances are pitched within the intended ability level of the examinees, at CEFR (Common European Framework of Reference for Languages) B or pre-academic, intermediate proficiency, and only writing performance is scored. A middle-range version of skills integration appears in the TOEFL iBT (described above), which requires all test takers, regardless of

English proficiency levels, to integrate and synthesize material from relatively lengthy reading and listening source materials to answer specific academic-type questions in both written and oral production. A strong version of skills integration appears in task-based assessments, which may involve the integration of information and language production across a range of media and task conditions, as these have been determined (e.g., from needs analyses) to represent authentic communication tasks in target domains (Norris, 2002; Hawkey, 2004; Colpin & Gysen, 2006; Deane, 2011).

Current Research

Cumming's (2013) review of recent research on integrated writing assessments for academic purposes highlights five of their widely acknowledged benefits. Integrated skills assessments (a) provide realistic, challenging literacy activities; (b) engage examinees in writing that is responsible to specific ideas and content; (c) counter test method or practice effects associated with conventional item types on writing tests; (d) evaluate language abilities in accordance with construction integration or multiliteracies models of literacy; and (e) offer diagnostic value for instruction or self-assessment. Four approaches to research have been taken in the studies leading up to these claims.

One approach has been to document and analyze the processes or strategies that examinees use during integrated skills assessment tasks that involve writing (Cumming, Rebuffot, & Ledwell, 1989; Esmaeili, 2002; Fraser, 2002; Plakans, 2008; Plakans & Gebril, 2012; Yang & Plakans, 2012) or speaking (Swain, Huang, Barkaoui, Brooks, & Lapkin, 2009). These studies have shown that integrated skills tasks elicit from examinees a broad variety of relevant interpretive, analytic, self-monitoring, and composing strategies, seemingly (a) surpassing the range and depth of strategies observed in less complex writing or speaking tasks, on assessments that do not require reference to source material; (b) approximating the cognitive demands of writing or speaking for academic purposes in the ordinary situations of studying and learning in university or in college courses; and (c) being welcomed by participating students as more authentic, interactive, and challenging than conventional writing tasks tend to be on language tests. However, this line of inquiry, like the other approaches described below, has been primarily descriptive, confined to performance on limited sets of integrated tasks and populations, and it has produced a range of individual differences among participating students, so that any assertions about the value of, and specific outcomes from, integrated skills assessment tasks—for example, by comparison with other types of complex writing or speaking tasks—remain to be verified.

A second approach to research has been to analyze the discourse features of written or spoken texts produced under conditions that involve summarizing or interpreting source reading or listening material. Most of these studies have compared a range of text features that appear in compositions written for assessment purposes (a) with reference to source documents and (b) without reference to source material. Studies by Cumming et al. (2005), Knoch (2009), Plakans (2009), and Yu (2009) have showed that the written compositions that university level

learners of English produce in integrated skills tasks tend to display more complex lexical, syntactic, rhetorical, and pragmatic features (in contrast to comparable compositions written for tasks that do not require source information). Frost, Elder and Wigglesworth (2012) analyzed the content dimensions of the spoken discourse produced in listening–speaking tasks in Oxford English tests, establishing that the quantity and quality of the content conveyed by examinees from source materials corresponded to their speaking proficiency scores. These studies have also revealed numerous points of variability in integrated skills tasks—points related to such factors as the length, the topic, or other qualities of the source texts, the levels of language proficiency, the individual writers’ skills at synthesizing or citing source material, their comprehension of source texts, or their interpretation of task instructions.

A third approach to research has been to investigate instructors’ or raters’ perceptions of integrated skills assessment tasks. Findings from research by Cumming, Grant, Mulcahy-Ernt, and Powers (2004); Brown, Iwashita, and McNamara (2005); Wall and Horak (2008); and Knoch (2009) indicate that experienced instructors or raters are positively impressed by innovative assessment tasks for writing and speaking, which require students or examinees to integrate source materials from reading or listening sources, because these integrated tasks seem to be more authentic representations of abilities required for academic performance, are intellectually more complex and challenging, and produce opportunities for language learning.

The fourth approach to research has considered integrated skills assessments for their diagnostic value, either (a) for purposes of assisting instructors to identify needs for students to learn or improve their abilities, or (b) for purposes of learners’ own self-assessments and self-guided learning. The contexts, issues, and assessments investigated in these studies vary greatly, constraining any general conclusions other than to affirm that the researchers assert the particular value of integrated skills assessments for diagnostic purposes in diverse educational settings. The contexts investigated include the DELNA (Knoch, 2009), described above, which is aimed specifically at eliciting diagnostic information relevant to the teaching and learning of writing among university students; the TOEFL iBT integrated writing tasks, which Sawaki, Quinlan, and Lee (2013) show to be potentially useful for profiling differences among English language learners with varied needs for instruction according to their proficiency levels and writing abilities; and Artemeva and Fox’s (2010) inquiry into how university students of engineering and their instructors can benefit alike from analyzing their existing knowledge of the genre and their intended aims for writing improvement in relation to integrated skills tasks and assessments.

Challenges

Integrated skills tasks do, nonetheless, pose several challenges when used for assessment purposes. Cumming (2013), in describing the benefits of integrated skills assessments, also observed the following five constraints, which are also documented in most of the publications cited above. Integrated skills

assessments confound the measurement of writing or speaking abilities with the measurement of abilities to comprehend source materials; they muddle assessment and diagnostic information together; they involve genres that are ill defined, and hence difficult to score; they require threshold levels of abilities for competent performance, producing results for examinees that may not compare neatly across different ability levels; and they elicit texts in which the language from source materials is hard to distinguish from the examinees' own language production.

The major constraint on complex integrated tasks arises from their involving, together, both comprehension (i.e., of source information from reading and/or listening) and production (of either writing or speaking); so they require a threshold level of language proficiency for examinees to perform on them competently. In order to write or speak about source information, examinees have to be able to understand it—at least partially, and perhaps even fully in terms of a source text's verbatim, propositional, and situational representations (to use Kintsch's terms for the construction of comprehension: see Kintsch, 1998). Comprehension and production are inextricably linked in integrated skills tasks, and so they are impossible to separate for assessment purposes. Technically, assessment experts call this a problem of task dependencies. The practical consequence, however, is that examinees who cannot comprehend source materials are not able to write or speak about them effectively. For this reason most of the research cited above has concluded that integrated skills assessments tend to produce meaningful results only for learners who have attained an intermediate or advanced proficiency in a second language. Cumming (2013) and Sawaki et al. (2013) have suggested that this requirement of integrated skills tasks makes them especially suitable for university admissions tests, because the threshold level of comprehension they require appears to be what actually demarcates the language abilities of students who are prepared to begin academic studies in a second language from those of students who are not. But, also for this reason, as Charge and Taylor (1997) explained, at least one major English test, the IELTS (International English Language Testing System), decided to exclude integrated skills tasks so as to be able to provide score reports that are meaningful and comparable across a full range of language proficiency and that do distinguish consistently between language comprehension and production abilities.

A further implication from the inherent combination of language comprehension and production in integrated tasks is that interpreting their results can be tricky for diagnostic purposes. What, on the basis of results from an integrated skills assessment, are the specific abilities that students should be taught, or should focus on in self-study? Comprehension? Writing? Speaking? Or all combined? And, if the latter, how can one separate or isolate appropriately teachable elements? A response could reasonably be that in general people learn to write or speak from reading or listening, particularly for academic or professional purposes. However, other perspectives on this complex issue have emerged from research. Knoch (2009) provided evidence that, for advanced writers, in academic contexts it may be only complex integrated skills tasks that can produce the kinds of relevant information needed in order to reveal the abilities that such learners truly need to acquire or have already mastered. Likewise, Sawaki et al. (2013)

demonstrated that there are certain indicators of language proficiency (i.e., comprehension of source material, productive vocabulary, and sentence conventions) that emerge from the TOEFL iBT's integrated tasks and are especially robust and sensitive in demarcating between students who need further English study or are prepared to engage in literate academic tasks in higher education. Powers (2010) too has offered a spirited defense of language assessments that assess a broad range of language abilities comprehensively, recognizing that language abilities are at once integrated as well as distinct.

Another challenge for integrated skills assessment is that there are no fixed—or even conventional—genres for tasks such as summarization, *précis*, synthesis, or responses on academic-type exams. On the contrary, such text forms, either written or spoken, are highly variable according to context, purpose, and intended audience. This constraint has long been recognized in research on writing in first language education; it involves not just expectations for written text forms but also the cognitive and other self-control strategies adopted by examinees or students in performing integrated skills tasks (Hidi & Anderson, 1986). Yu (2009, 2013) has shown how this variability in expectations for integrated skills tasks has profound implications on the quality of the information about people's abilities that arises from their performance on such tasks. The obvious implications for test designers and for educators preparing students for assessments are to specify precisely the expectations for performance on integrated skills tasks, to ensure that examinees are oriented to and familiar with these expectations, and to pilot assessment tasks carefully, so as to determine if the tasks produced any unintended, irrelevant sources of variance.

A final, related challenge for integrated skills assessment concerns the state of knowledge about how people learn to write from sources. Systematic scholarly inquiry into this matter has only emerged over the past decade and a broad range of novel findings and conceptualizations have developed from it, shifting perspectives from naive, alarmist concerns over plagiarism to a substantial appreciation of the complex challenges and contextual variability associated with learning how to cite information appropriately from source texts while at the same time displaying one's own knowledge in written texts, particularly in a second language and unfamiliar discourse domains (Flowerdew & Li, 2007; Shi, 2004, 2010; Harwood & Petric, 2012). For examinees performing integrated skills tasks as well as for raters of the written compositions or spoken texts that arise from them, demarcations are difficult to discern between what are—or are not—appropriate citation practices, learning strategies, expressions of individual viewpoints, and practiced formulaic routines. Considerably more research on this matter is needed to inform both the preparation of instructions for integrated skills assessments and the guidelines for scoring them.

Future Directions

Among the many possible directions for the future development of integrated language skills assessment, the most fundamental is to refine the constructs and purposes that define language tests for academic and professional purposes.

Integrated skills assessment presupposes an interactionist theory of human communication in which knowledge is constructed through the interpretation and expression of relevant ideas through multiple media. These abilities are fundamental to being able to use language effectively for extensive writing and speaking in academic and professional contexts; so they need to be the guiding principles in language assessments made for these purposes. For assessments in other types of contexts, conventional models of language as four separate skills or as componential knowledge may suffice—for example, in courses where accumulating knowledge about the vocabulary of grammar may be a goal of education; or for limited purposes such as reading abilities or sojourning travel. However, considerable work needs to be done to understand and define the constructs that are essential to performing integrated writing and speaking tasks for academic or professional purposes. Moreover, these abilities are highly complex, and so they require extensive, interactive assessments, as Deane (2011) has shown in pioneering studies of multiliteracies assessments for adolescents writing in English as a mother tongue.

Most research and test developments involving integrated skills assessments have, to date, focused on contexts related to English for academic purposes with populations of international or migrant students. But examples of inquiry and assessment practices have also appeared in relation to other languages, taught and studied to advanced levels of proficiency (e.g., German at a US university: Byrnes, Maxim, & Norris, 2010; Dutch for occupational purposes internationally: *Certificaat Nederlands als Vreemde Taal*, 2012), or in English competency tests for secondary school completion (Part 3 of New York State's *Regents Examination*: New York State Education Department, 2012—but curiously not in these schools' tests of various foreign languages). These and many other assessment contexts and purposes need to be developed and analyzed further to determine if the benefits and challenges described above obtain as they do in tests of English for university admission. Innovative uses of new technologies also hold promise, not only for providing modes of assessment delivery that capitalize on and evaluate the increasing uses of new multimedia for communications, but also for overcoming certain challenges that have beset integrated skills tests in the past—particularly for managing test materials, for disentangling the focus and components of assessment, and for monitoring the processes of test takers responding to tasks in ways that may reveal how they integrate language and content appropriately to achieve communicative goals.

At the practical level of designing language assessments, an important future direction is to specify clearly the purpose, context, audience, and evaluation criteria of tasks that involve integrated skills. To whom, where, how, and why exactly is an examinee expected to write or speak? As Yu (2013) has demonstrated, a summary can involve many different forms, genres, or purposes; so expectations for writing summary-type tasks vary greatly in the instructions given on major English language tests, ranging from (a) a single sentence about a reading passage in the Pearson Test of English (Academic), to (b) summaries that involve interpreting pictorial or schematic information rather than extended source texts in the IELTS, and to (c) complex, open-ended writing and speaking tasks, judged on multiple criteria, in the TOEFL iBT. Likewise, for integrated

speaking tasks, this range and ambiguity in expectations may be a reason why studies such as Xi, Higgins, Zechner, and Williamson (2008) have found distinct variation in interpretations, both in raters' scoring and in examinees' performances, on these kinds of tasks, posing a difficult challenge for modeling these performance criteria precisely through automated scoring by computer programs.

A final direction for future research and development is to establish if and how integrated skills assessments really do produce a positive impact on teaching and learning. Wall and Horak (2008) have shown that the introduction of the integrated writing and speaking tasks on the TOEFL iBT had a distinct, positive washback effect on the teaching practices and classroom activities of a small sample of teachers in Central and Eastern Europe. Much of this impact appears to have occurred through changes in the textbooks that adopted integrated tasks and in their classroom uses to prepare students for the new version of the test. More studies of this kind need to be conducted on a broader basis and in a variety of contexts in relation to major language tests, particularly to establish exactly how integrated language tasks can promote effective teaching, learning, and instructional materials, and further to demonstrate how these processes can be most productively acted upon in educational practices. Such research, however, may be dependent (as suggested above) on further refinements in the construct definitions of integrated skills assessment so as to know precisely what abilities they involve, and consequently how they can be taught, studied, learned, and assessed.

Assessing Language and Content

Marguerite Ann Snow

California State University, Los Angeles, USA

Anne M. Katz

The New School, New York, USA

Introduction

The relationship between language and content in the classroom and its implications for assessment depend largely on the educational context. Courses focused on language proficiency provide one kind of context, while courses centered on content—such as specific purpose courses, in which students study the language needed for a particular discipline or vocation—represent another set of assessment considerations. This chapter investigates the role of language and content knowledge in different types of instructional programs and examines the role of language assessment in the classroom and in large-scale testing, when language and content are interrelated.

The context selected as the focus of this chapter is K-12 education in the USA, where population shifts have brought increasing numbers of second language students into mainstream classes. Schools serving these students function under accountability mandates that require all students to achieve high academic standards. Their success is measured by means of high stakes, standards-based assessments in English. These English learners (ELs) who are at various stages of acquiring English as a second language need to develop English for all communicative purposes and, more specifically, be able to access academic content in classrooms conducted primarily in English. They must acquire language skills including listening, speaking, reading, and writing, and related grammar, vocabulary, and phonology. The ultimate goal is for these students to develop the levels of English proficiency needed to succeed academically. To do so, ELs must learn the grade level content of the curriculum while concurrently developing English language proficiency. ELs must also acquire the language underpinning social skills for everyday uses of language both in school and outside of school.

This chapter will explore the theoretical and practical implications of assessment practices in settings where students are expected to learn both language and content, and, hence, where assessment must account for language knowledge and topical knowledge in a reliable and valid manner. As noted, while the chapter explores the intersection of language and content in US-based K-12 programs, the expanding global interest in integrating content and language in educational settings suggests the chapter may have useful implications in this wider arena (Stoller, 2004).

Previous Conceptualizations

Until recently, the assessment literature has provided little guidance in understanding the relationship between content and language. Instead, it has centered primarily on the use of language tests for making inferences about communicative language ability, defined as consisting of language knowledge and strategic competence, or metacognitive strategies (Bachman & Palmer, 1996). This focus on language rather than content is in line with the emphasis in second/foreign language education on formal features of language for teaching and assessment (Byrnes, 2008). In the design of language instruction, the choice of target language forms, functions, and skills has preceded decisions about the content learners will use as a medium for developing language proficiency. In language assessment, test construction has reflected a similar focus on linguistic aspects of communication rather than content ones. In fact, content, or topical knowledge, has often been viewed as a potential source of test bias (Clapham, 1996; Douglas, 2000). The concern is that either the presence or the lack of background or content knowledge may interact with test takers' performance on tasks designed to assess language knowledge, making it problematic to make inferences about language ability. It is not surprising, then, that assessment tools such as rubrics and scoring guides typically examine language users' facility with language features rather than whether the content is true or accurate.

Bachman and Palmer (1996), however, argue that topical knowledge is an integral part of authentic language use and, thus, a component in test performance. Although they consider several options for dealing with topical knowledge in test construction depending on the test-taking situation, they note that, when information about both content and language knowledge is needed—as, for example, in language for specific purposes situations, when language and content are both the target for learning—the preferable option is to define language ability and topical knowledge as separate constructs, to be tested separately.

When language learning takes place in instructional settings focused primarily on language development and language skills, such as reading and conversation, the separation of language and content makes good sense. However, with classrooms filled with language learners needing to acquire language proficiency alongside content knowledge, the intersection of language and content has become more relevant and questions about how to assess language development in academic settings more critical. In these contexts, the separation of language and content in assessment is no longer sustainable.

Current Conceptualizations

Dual Role of Language and Content

With the advent of specific purposes courses (Douglas, 2000) in postsecondary contexts and content integrated language models (Mohan, 1986; Brinton, Snow, & Wesche, 2003) at all educational levels, separation of language knowledge and topical or content knowledge is no longer possible, or even appropriate. As Douglas (2000) notes, “the definition of specific purpose language ability is that the construct contains, by definition, specific purpose background knowledge” (p. 39). Assessment practices have necessarily broadened, as the goals of integrated language and content courses include both language development and subject matter learning. Specific purpose or content-based approaches do not view content as primarily a vehicle for language practice, but rather as an integral component of instruction, and, by extension, of assessment. The challenge of assessment in specific purpose and content-based instruction is the interface between language and content objectives. Weigle and Jensen (1997) point out that content-based assessment plays an essential role in making decisions about individual students and in evaluating the effectiveness of the program.

The Importance of Academic Language in Success in the Content Areas

A major consideration for the interface between language and content assessment is the role of academic language. Cummins (1981) was one of the first to draw the distinction between the type of language used in conversation—*basic interpersonal communication skills*—and language needed for school success—*cognitive academic language proficiency*. Chamot and O’Malley (1987) defined academic language as “the language that is used by teachers and students for the purposes of acquiring new knowledge and skills . . . imparting new information, describing abstract ideas, and developing students’ conceptual understanding” (p. 40). A K-12 program coordinator, responding to a survey aimed at defining academic language, noted that it can only be acquired at school: “Academic language is the language of lecture and textbooks. It is filled with expectations of prior knowledge and background and uniformity” (Solomon & Rhodes, 1996, p. 6). Gibbons (1998) characterizes academic language as “intertextual”—that is, involving all language modalities, listening, speaking, reading, and writing. Students must integrate these modalities in oral and written academic tasks.

Schleppegrell (2004) argues that conversational language and academic language should not be viewed as a dichotomy since interactional spoken language can be both complex and cognitively demanding. Continuing in this vein, Bailey (2007) takes the position that it is more accurate to speak of the differences between social and academic language in terms of the frequency of complex grammatical structures, specialized terminology, and academic language functions.

In their review of the literature on academic language, Anstrom et al. (2010) characterized it as a “variety of English, as a register, or as a style, and is typically used within specific sociocultural academic settings” (pp. iv–v). Snow (2005)

emphasized the importance of language functions, distinguishing between social language functions (e.g., inviting or complimenting) and academic language functions, in which students have to use language, for example, to define, classify, and sequence. In addition, ELs must be exposed to the common discourse patterns in the content areas. Carr, Sexton, and Lagunoff (2006), for instance, presented discourse patterns of science such as *formulate*, *hypothesize*, *infer*, and *predict*, and common function words in science like connectors used to show cause and effect such as *because*, *since*, *consequently*, *as a result of*, and *so that*. To Saunders and Goldberg (2010), academic language entails all aspects of language, from grammatical elements to vocabulary and discourse structures and conventions.

While there is no complete consensus on the evolving construct of academic language, all conceptualizations suggest that it is necessary to broaden the discussion to include academic content in any definition of academic language. Linguistic analyses of different academic registers have uncovered the distinctive language patterns and discourse features of different content disciplines (Anstrom et al., 2010). Schleppegrell (2004) notes that the academic language needed in order to read, write, and talk about science is different from the language required in mathematics. Moreover, Gee (2005) identifies patterns of language use at the level of subdisciplines, for example in geometry within mathematics, noting that “different patterns or co-relations of grammatical elements . . . are associated with or map to particular social languages . . . associated with specific socially situated identities and activities” (p. 20). More recently, Bailey and Heritage (2008) broaden the conceptualization of school language use, breaking down academic language into “school navigational language” and “curriculum content language.” In their terms, school navigational language is the language students use “to communicate with teachers and peers in the school setting in a very broad sense,” and curriculum content language is “the language used in the process of teaching and learning content material” (p. 15). Their conceptualization is meant to capture the range and variety of academic language acquisition situations for both native English speakers and ELs.

Standards for Language Proficiency

Standards, or levels of proficiency, have been a part of discussions about language proficiency for some time now. Two scales have been used widely in describing language proficiency across multiple languages and situations. In Europe, the Common European Framework of Reference (CEFR) (Council of Europe, 2001) describes what learners need to know about and do with language in order to use it effectively for communication. The framework is designed to inform a range of language-learning components, such as curriculum design, instructional objectives, textbook development, and assessment, although the most frequently used portion of the document is centered on the language proficiency scales that describe what language learners can do at each of six reference levels of communicative competence. In the United States, the American Council on the Teaching of Foreign Languages (ACTFL) proficiency guidelines (2012) serve a purpose similar to that of the CEFR by describing what language learners in K-12 and postsecondary foreign language programs can do at five levels of proficiency. The

guidelines include tasks for learners at each level, along with descriptors for other components of language tasks such as context, accuracy, and discourse types.

Neither of these scales includes academic content as a feature of language proficiency. The scales in both the CEFR and the ACTFL proficiency guidelines were developed as descriptions of general language proficiency, external to the instructional settings in which language proficiency may be developed. Both emphasize the ability of the language user to engage in communicative tasks; language performances are referenced to fixed levels for use across different settings and multiple languages. And, with both, content is addressed via suggestions that instruction and assessment tasks utilize general themes organized around contexts that are accessible to learners, such as daily life, personal interests, and current events.

A different approach to the development of language standards took place in the USA in response to a perceived need to raise academic standards across the nation's schools (Gomez, 2000). As cornerstones in this national school reform effort, standards were developed for school content areas such as mathematics, science, language arts, and social studies. To ensure that the needs of ELs were represented in the national discussion about what students in K-12 classrooms were learning, the Teachers of English to Speakers of Other Languages (TESOL) professional association assumed the task of developing a model for English language standards, which were published in 1997. In 2001 Congress passed legislation known as No Child Left Behind (NCLB), requiring that each state have English language proficiency standards and measure English learners' progress toward meeting those standards, and that all children, including ELs, work to achieve grade level proficiency in two content areas: English language arts and mathematics. Following the NCLB mandate, TESOL published a second set of standards in 2006. TESOL's two versions of English language standards illustrate the impact of the changing educational context for K-12 schooling on the design of language standards and, specifically, the increasing attention paid to content integrated with language in standards-based instruction and assessment for ELs.

The first version of TESOL's standards, *ESL Standards for Pre-K-12 Students* (TESOL, 1997), describes the language skills needed by K-12 students in order to become proficient in English for both social and academic purposes. While the target for immediate use was to ensure grade-appropriate instruction, the aim included a broader purpose: that of helping students develop language proficiency that would lead to "rich and productive lives" (p. 2). The standards were grouped according to three broad goals that illustrate the breadth of vision for language proficiency:

- Goal 1: to use English to communicate in social settings;
- Goal 2: to use English to achieve academically in all content areas;
- Goal 3: to use English in socially and culturally appropriate ways.

The content standards presented in the 1997 version offered educators targeted outcomes that could be used for designing the delivery of instruction. The next step was to articulate an approach to assessment that would ensure that students

were on the road to developing needed levels of English language proficiency. In 2001 TESOL published an accompanying volume entitled *Scenarios for ESL Standards-Based Assessment* (TESOL, 2001), which contained a model for the assessment process, along with a series of scenarios illustrating how each standard could be implemented and assessed in the classroom. The scenarios are constructed around sample progress indicators (SPIs) and provide examples of assessable, observable behaviors related to each standard within each of three grade level spans: pre-K–3, 4–8, and 9–12.

Here is an example from a scenario constructed to illustrate how teachers can organize assessments around Goal 2, Standard 2, which reads: “To use English to achieve academically in all content areas: Students will use English to obtain, process, construct, and provide subject matter information in spoken and written form.” The scenario is set in a 4th/5th grade mainstream class, with ELs at high beginning to high intermediate levels, and the focus of instruction is on science and language arts. Below are several SPIs:

- gather and organize the appropriate materials needed to complete a task;
- synthesize, analyze, and evaluate information;
- ask and answer authentic questions;
- explain change.

The SPIs span both content and language objectives, and the assessment tools included in the scenario illustrate a variety of methods to collect and record information about student performances in reaching those objectives. For example, a teacher observation guide is provided that focuses on whether students can carry out certain activities, such as developing relevant inquiry questions and following directions.

The second version of TESOL’s standards, *PreK-12 English Language Proficiency Standards* (TESOL, 2006), was published nearly ten years later, after the enactment of NCLB. These revised standards, an augmentation of the World-Class Instructional Design and Assessment Consortium (WIDA) English language proficiency standards (WIDA, 2007), reflect an increasingly explicit focus on academic uses of language in the classroom.¹ Below are the five standards:

Standard 1: English language learners *communicate* for social, intercultural, and instructional purposes within the school setting.

Standard 2: English language learners *communicate* information, ideas, and concepts necessary for academic success in the area of *language arts*.

Standard 3: English language learners *communicate* information, ideas, and concepts necessary for academic success in the area of *mathematics*.

Standard 4: English language learners *communicate* information, ideas, and concepts necessary for academic success in the area of *science*.

Standard 5: English language learners *communicate* information, ideas, and concepts necessary for academic success in the area of *social studies*.

In effect, the 2006 standards build on Goal 2 of the 1997 standards and expand it to explicitly address the language needs of four key content areas, while Goals

Topic	Level 1	Level 2	Level 3	Level 4	Level 5
Immigration	List family members or historical figures with countries of origin, using maps or charts.	Create personal or historical family trees using graphic organizers and photographs.	Produce illustrated family or group histories through albums, journals, diaries, or travelogues.	Research (e.g., by conducting interviews) and report family or historical journeys.	Discuss, in paragraph form, cause/effect, historical patterns, or impact of movement of peoples from nation to nation.

Figure 14.1 Examples of behaviors at five levels of proficiency for Standard 5, grade level 4–5. Adapted from *PreK-12 English Language Proficiency Standards* (TESOL, 2006)

1 and 3 are addressed in Standard 1. Just as the 1997 standards used SPIs couched in detailed language to illustrate how educators could design instruction and assessment to support student learning, the 2006 standards utilize a series of matrices illustrating language development within each standard, at specific grade level spans, and for each of the four language skills, here called domains. These matrices provide examples of specific, observable behaviors at each of five levels of proficiency. Topics for the matrices were culled from an analysis of state and national academic content standards. Figure 14.1 is an example from a matrix designed to address Standard 5, grade level 4–5, and the domain of writing.

An accompanying volume, *Paper to Practice: Using the TESOL English Language Proficiency Standards in PreK-12 Classrooms* (Gottlieb, Katz, & Ernst-Slavit, 2009), provides examples of how to use the standards in a variety of contexts for both instruction and assessment. Sample assessments, suitable for the language proficiency level of the students, are provided; these tools focus on the academic language needed to carry out academic tasks. Figure 14.2 is an example of a Peer Review Guide used by 4th/5th grade students to look over the first draft of interview questions for an assignment based on the immigration topic presented in Figure 14.1.

Critiques of English language proficiency standards focus on the lack of an empirical foundation, noting that some documents provide little clarity or internal coherence in describing classroom progress (McKay, 2007). Llosa (2011) identifies another key issue that is particularly challenging for newer English language proficiency standards like the 2006 TESOL standards, namely separating out language proficiency from content area knowledge—which takes us back to the dilemma posed in previous conceptualizations of assessing language and content. Bailey and Huang (2011) further question the relationship between English

Peer Review Guide			
	Yes	No	Not Sure
The questions ask for useful information.			
The questions are in the correct form.			
Immigration vocabulary is used correctly.			
Suggestions for improvement:

language proficiency standards and the construct of academic English, in particular examining how closely such standards represent the actual language demands found in content classrooms.

Current Research

Much of the testing research on the intersection of English language proficiency and content in US classrooms has centered on EL student performances on large-scale assessments in content areas. With the growing use of such assessments since the implementation of legislation under NCLB to monitor the academic progress of all students, including ELs, questions have arisen as to whether tests in English can provide accurate information about what EL students know and can do in subject areas such as science, mathematics, and language arts.

The Role of Language in Large-Scale Content Assessments

Language proficiency has long been recognized as playing an important role in how ELs perform on assessments designed to gauge their knowledge in content areas. When students lack sufficient English language skills to follow test directions, to understand test items, and to carry out required academic operations, their performances cannot provide trustworthy information about what students know and can do in those content areas. One strand of research addressing this issue has focused on determining how long it takes EL students to reach the average academic achievement level of native speakers. Findings have varied

somewhat, though all suggest that it takes a substantial amount of time for ELs to develop the academic language skills necessary to support their performances on content assessments in English. Examining the average length of the time in which immigrants reach native speaker norms on standardized tests, Collier (1987), for example, found that this process took four to eight years. In a study of the language proficiency and achievement of Japanese students in Toronto, Cummins and Nakajima (1987) found that four years of instruction were needed for them to attain grade level norms. Analyzing data from both Spanish- and Chinese-speaking cohorts on state mathematics assessments, Tsang, Katz, and Stack (2008) determined that it would take five to six years for the achievement patterns of EL students to match those in the national norm sample—a result that was true for both language groups. Taking a different approach, other studies have examined the effect of the language load found on large-scale assessments. Abedi, Leon, and Mirocha (2000) noted that, as the language load in assessments increased, so did the gap between ELs and non-ELs.

Given the importance of ELs acquiring sufficient English language proficiency to be able to demonstrate their content area knowledge and skills on large-scale assessments, another strand of research has explored whether English language proficiency tests adequately predict ELs' readiness to take content assessments in English. Butler, Stevens, and Castellon (2007) examined the relationship between language and content assessments, in part to gain a better understanding of the language measured by then current language proficiency instruments. One of the studies they reviewed compared the language used on the Language Assessment Scales (LAS) (Duncan & De Avila, 1990) and on the Iowa Test of Basic Skills (ITBS) Social Studies Test for Seventh Grade (level 13), Form L (*Iowa Test of Basic Skills Norms and Score Conversation*, 1993) and found "a limited relationship" (p. 32), thus making the language proficiency test an inadequate predictor of whether students would have sufficient English skills to deal with items on standardized content assessments. This work emphasizes the need to ensure that tests of English language proficiency yield information about the academic English skills needed not only for taking content assessments but, importantly, for engaging in content area instruction and learning activities in school.

The Use of Accommodations

Although research strongly suggests that it takes a number of years for ELs to acquire academic English proficiency, accountability schemes that ensure all students are meeting grade level expectations for academic achievement in content areas such as reading/language arts and mathematics mean that ELs are regularly tested in English before reaching fully proficient levels of language ability. Given this situation, accommodations or modifications of some aspect of the test format or test conditions are intended to provide ELs with equitable access to the content of large-scale assessments and educators with a more accurate picture of students' knowledge of that content. This assumes that it is feasible to separate linguistic and content demands, whereas current thinking would suggest otherwise. While numerous accommodations for ELs have been included in assessment policies across all states in the US, these policies provide little specific direction to guide

decision making or to monitor local practices; nor have many of those policies included much attention to the linguistic needs of ELs. Only two accommodations frequently allowed in state policies—commercial word-to-word dual language dictionaries and extended time—were described as having a research base to support claims of their effectiveness with ELs (Willner, Rivera, & Acosta, 2008). In making recommendations for ways to improve state policies regarding accommodations for ELs, Willner and colleagues emphasize the need to move away from a “one size fits all” approach, which ignores the diverse needs of the EL community, and to focus not only on effective use of accommodations but also on clearer procedures in implementing them in a systematic way.

Taking the position that accommodation strategies may need to vary according to a range of factors, Abedi, Courtney, Mirocha, Leon, and Goldberg (2005) examined the use of accommodations with EL students in grade 4 and grade 8, in order to explore how effective these accommodations were in reducing the gap in test performance between ELs and non-ELs. The study’s results suggest that effectiveness may vary by grade level. In grade 4 the English dictionary was an effective accommodation, while in grade 8, where students face linguistically more complex assessments, a more effective accommodation seemed to be linguistic modification of test items.

It is important to note that other accommodations for ELs may provide effective support; however, research in this area is still emerging. In their meta-analysis of accommodations for ELs, Kieffer, Lesaux, Rivera, and Francis (2009) note that a variety of accommodations are being used with ELs, though not always appropriately. They suggest that appropriate support would “provide direct or indirect linguistic support to minimize the negative impact of irrelevant language demands on students’ performance so that the students can demonstrate their content knowledge and academic skills to the greatest extent possible” (p. 1171). The one accommodation found to have a small but statistically significant and positive average effect size was the use of “customized English language dictionaries or glossaries” (p. 1181). While Kieffer et al. (2009) point out that future research may uncover additional effective accommodations, they caution that such an approach is “largely ineffective in improving the performance of the majority of ELLs on large-scale assessments” (p. 1190). Instead they suggest that, by focusing instruction on the academic English language skills that ELs need in order to carry out academic tasks across subject areas, educators have a greater chance of improving students’ performances on large-scale assessments.

Investigations of Academic Language

Recent research seeks to describe features of academic language with the goal of illuminating issues of instruction and assessment. Schleppegrell (2004) proposed a functional linguistics approach as a means to identify the linguistic features of school tasks and of genres of different school disciplines. Using a language-based approach, Schleppegrell and de Oliveira (2006) reported on a professional development project in which high school history teachers learned language analysis tools to analyze the meaning of history texts. The teachers then developed instructional materials that assisted their struggling students to analyze how historians

construct content by using language features such as time markers, complex nominal groups, and reference devices. Students enrolled in the classes of project teachers performed better than students of non-project teachers on a history essay writing task in which they had to develop a thesis and support it with evidence and analysis.

Mohan and Slater (2006) also applied a functional view of language in observing how students connected theory and practice in a grade 9 high school science class. Using knowledge structures of classification, principles, and values, together with the corresponding action levels of description, sequence, and choice, Mohan and Slater found that the science teacher they studied used language as a resource to link the abstract and general taxonomy of physical properties he had built up in his lessons to the specific, practical actions students took as they participated in class discussions, using language as a resource for meaning in their decision making and reasoning. Similar methodology has been applied to mathematics, science, and literature (Fang & Schleppegrell, 2008). From the functional linguistics perspective, "students are active language users who require explicit knowledge about language use in different contexts and for varying purposes in order to be effective in completing academic tasks in the school environment" (Anstrom et al., 2010, p. 10).

Another approach to conceptualizing academic language can be found in the work of Bailey and Butler (2007) who developed an evidentiary framework for operationalizing academic language proficiency. The framework has six bases of evidence: (1) empirical studies of EL/English Only student performance and language demands related to content and English language development assessments; (2) the language demands assumed in national content standards (e.g., science standards); (3) the language demands assumed in state content standards (e.g., science standards); (4) the language demands assumed in ESL standards; (5) teacher expectations for language comprehension and production; and (6) classroom observations, including teacher talk and textbook analyses. In the operationalization of the academic language construct, example test specifications, task prototypes, and guidelines for teachers, agencies, and organizations seeking to develop assessments for academic language were developed (Bailey, Stevens, Butler, Huang, & Miyoshi, 2005).

Content-Focused Instruction and Assessment

One of the strongest research bases of integrated language and content instruction and assessment is the Sheltered Instruction Observation Protocol (SIOP) model (Echevarria & Short, 2010). Sheltered instruction is one type of content-based language instruction, generally offered by content specialists who focus on providing ELs with access to academic content by helping to develop their academic language skills. SIOP components include: lesson preparation; building background; comprehensible input; strategies; interaction; practice and application; lesson delivery; and review and assessment. Research on the SIOP includes validation of the SIOP rating instrument and impact on student achievement.

Numerous professional development programs in elementary school, middle school, and high school, in districts across the USA serving large numbers of ELs,

have adopted the SIOP, with positive results that have translated into gains on large-scale assessments (Short, Fidelman, & Louguit, 2012). For example, after a two-year program of SIOP staff development in a low performing school in Arizona, a study of elementary ELs revealed gains in achievement on the reading, mathematics, and writing tests of the state standardized assessment. In addition, students outperformed students at similar schools whose teachers did not participate in SIOP training. In another study, middle school ELs in Illinois improved their writing skills and outperformed comparison classes on three of five subtests (language production, organization, and mechanics) on the state test of annual progress in English. Other SIOP studies have looked at implementation data to assess the teachers' levels of sheltered instruction, which are considered a major factor in the success of the model. An ongoing study is taking place to develop science curricula and to investigate its impact on both ELs and native English speakers exposed to enhanced science instruction (Echevarria & Short, 2010).

Implications for Teachers

The need for ELs in K-12 classrooms to develop the necessary academic language skills to be successful in accessing the core curriculum at each grade level requires teachers to incorporate both language and content aims into their teaching. Several resources provide suggestions for how to plan instruction and assessment that reflects this dual focus. The SIOP instructional model for ensuring that the academic content in lessons is comprehensible to ELs, discussed in the previous section, presents a step by step process for preparing and delivering lessons on the basis of both content and language objectives. Assessment occurs during lessons, as teachers conduct comprehension checks to gather feedback about students' understanding of the material, and then at the end, as they attempt to determine whether students are developing the language skills and knowledge required to engage with the lesson's content (Echevarria, Vogt, & Short, 2007).

Snow and Katz (2010) describe a process for situating instruction and assessment plans into a dynamic four-step framework. The four steps are:

- identify the learners' language proficiency levels;
- select standards-based language objectives for English language development;
- design and enact activities;
- assess learning through standards-referenced assessments.

English language proficiency and content standards are used in this framework to ensure that grade level content forms the basis for designing targets for language learning. In the assessment step, teachers collect information that can help them determine whether students are meeting lesson objectives.

Both the SIOP model and the four-step assessment framework highlight the importance of collecting assessment information during and at the end of instruction to monitor and document student learning. What follows is a two-part sample assessment from a commercial textbook for ELs (*High Point* Level B, Selection Test

<p>DIRECTIONS: Read the paragraph about Anne Frank. Then make a time line that shows the order of the events. Write 8 events on the time line. (16 points)</p> <p>Anne Frank was born on June 12, 1929. She was just ten years old when World War II began. In July 1942, she and her family were forced into hiding. On August 4, 1944, the Nazis found their hiding place and sent Anne and her family to concentration camps. Less than a year later, Anne died. Her diary was published in Europe two years after her death. In 1952, the diary was published in the United States as <i>Anne Frank Diary of a Young Girl</i>. It was made into a movie seven years later.</p> <p>Time Line:</p> 
<p>LANGUAGE FUNCTIONS: Define and explain</p> <p>(Have students review the time line before explaining the event. As students define and explain, check the box that most closely matches your observation.)</p> <p><input type="checkbox"/> Beginning – nonverbal (gesturing or drawing), fragments (dictator control), or simple sentences with errors (Dictators control people. They make people wear stars.)</p> <p><input type="checkbox"/> Intermediate – simple sentences (Dictators control people. Hitler made Jewish people wear a star.) or more detailed sentences with errors (Dictators control people. By 1935, Hitler taken away many freedoms.)</p> <p><input type="checkbox"/> Advanced – comparable to native speaker (A dictator is a leader who controls people's lives. Hitler and many other dictators have taken away many freedoms.)</p>

Figure 14.3 Sample assessment to assess oral language functions of *define* and *explain*. Adapted from *High Point Assessment Handbook, Level B (n.d.)*

15). In Figure 14.3, notice how the language demands of the first task are scaffolded through the use of a graphic organizer to provide access to ELs with developing language proficiency in social studies, and how, in the next one, the oral language functions of *define* and *explain* build on the text and time line. This sample assessment shows how teachers can use language and content objectives, along with scaffolds, to allow ELs to demonstrate their knowledge.

Challenges and Future Directions

As this review suggests, the connection between language and content is pivotal in understanding the role of assessment in educational contexts. Many challenges remain:

- *The research agenda needs to be expanded to include more varied settings.* As noted throughout this review, there is a paucity of research in several important areas, notably on the use of academic language across ages, grade levels, and content areas. While useful models of the kind of data needed can be found in studies investigating school language (e.g., Schleppegrell,

2004; Gee, 2005; Bailey, 2007; Bailey, Butler, Stevens, & Lord, 2007), additional research and discussion are needed to develop a more complete picture of language development across a range of instructional contexts and learner differences. For example, Hawkins (2005) notes that most work in academic literacy to date has focused on adolescent, college, or adult learners despite the fact that the high stakes environment of schooling in the USA demands that young learners learn “ways of using language that are specific to the institution and practices of schooling” (p. 63). Careful documentation of academic language use would be useful in shaping agendas for instruction and assessment. Moreover, while this chapter has focused specifically on ELs in the US context, many of the considerations discussed are also relevant to learners of additional languages in bilingual education programs around the world.

- *The use of alternative and performance assessments can offer insight into ELs’ developing academic language competence.* While large-scale content assessments are mandated under school accountability requirements, they present a number of challenges related to the degree to which ELs with developing language proficiency can access the content of such tests and demonstrate their competency. In addition, since such tests are not tied to a specific school curriculum, they offer little guidance to classroom teachers or students about the learning that takes place within that curriculum. Other options, such as classroom-based assessments, need to be considered, so that students may become able to demonstrate their learning. It should be noted that the introduction of any form of assessment requires careful planning in order to ensure that such tools are designed and implemented appropriately.
- *Professional development is an important component in ensuring that teachers can participate effectively in assessment.* As noted above, teachers need to be supported when implementing assessments to describe language learning. They need to be familiar with key principles of effective assessment, such as constructs of reliability and validity. They need exposure to and practice with a variety of classroom-based assessments, so that they may use multiple measures to assess language and content development. And they need to be able to understand the results of their EL students on large-scale assessments, in order to make appropriate instructional decisions in their classes and to participate in data-driven decision making in their programs, schools, and districts. Staff development can provide teachers with these critical assessment skills.

This chapter has raised issues relating to the assessment of language and content in educational contexts where second language students must develop English language proficiency and master the content of the school curriculum simultaneously. We explored the critical variable of academic language and the role of standards in language and content assessment, and we presented several models that integrate instruction and assessment. Most importantly, we underscored the staggering challenges that teachers face in language and content assessment in educational contexts where the stakes for their English learners are very high.

Assessing Translation

Juliane House

Hamburg University, Germany

Introduction

One of the most intriguing questions asked about translation is how one can tell whether a translation is good or bad. This question cannot (and should not) be answered in any simple way, because any statement about the quality of a translation implies a conception of the nature of translation. In other words, it presupposes a theory of translation. Different theoretical stances lead to different concepts of translational quality, different ways of going about assessing (retrospectively) the quality of a translation, and different ways of ensuring (prospectively) the production of a translation of specified qualities. These theoretical stances can be grouped and subjected to a “meta-analysis” by examining how they take account of, and formulate rigorous statements about, (at least) the following issues: (1) the relation between the source text and its translation(s); (2) the relationship between (features) of the text(s) and how they are perceived by the author, the translator, and the recipient(s); and (3) the consequences that views about these relationships have when one wants or has to distinguish a translation from other types of multilingual text production.

In the following, I will first review various approaches related to translation evaluation. This will be done with a view to whether and how they are able to throw light on the three questions formulated above. I will devote much more space to the description of House’s model of translation quality assessment (1977, 1997). This is justified by the fact that this model is to date the only one of its kind, and the only one that is informed by linguistic theory. Following the description of this model, I briefly describe recent developments of tests of translation quality. Finally, a crucial distinction between analysis and evaluation is suggested.

Different Approaches to Translation Criticism

Psychosocial Approaches

Mentalist Views Mentalist views are reflected in the centuries-old subjective, intuitive, and anecdotal judgments of “how good or how bad somebody finds a translation.” In the vast majority of cases, these judgments are not based on any explicit set of criteria, but rest entirely on impressions and feelings, and as such they lead to global, undifferentiated valuations like “The tone of the original is somehow lost in the translation.” In recent times, this type of vague valuation is replayed by neo-hermeneutic scholars, who believe in the legitimacy of subjective interpretations of the worth of a translation (e.g., Stolze, 2003). Instead of striving to develop criteria with which to evaluate a translation in an intersubjectively reliable manner, propagators of this approach believe that the quality of a translated text is intimately linked to the translator, whose interpretation of the original is regarded as rooted in her intuition, empathy, and interpretive experience. Translating is here regarded as an individual creative act, where the “meaning” of a text is also “created” anew. There is no meaning in the text itself; the meaning is, as it were, in the “eye of the beholder.” Such a relativizing and individualizing position as is promulgated in much hermeneutic work seems to me to be inappropriate, if one considers that evaluating translations is often not conducted in free-floating, inconsequential, aesthetic-artistic environments but in responsible social and cultural environments, in all of which assessment can have serious consequences.

To sum up, mentalist approaches to translation assessment emphasize the belief that the quality of a translation depends largely on the translator’s subjective interpretation, based on her intuition. With respect to the three questions above, the subjective and neo-hermeneutic approach to translation evaluation can only shed light on what occurs between the translator and (features of) the original text. This is a selective view of translation one-sidedly emphasizing processes of interpretation. In concentrating on the translator’s mental processes, the original text, the relation between original and translation, and the expectations of the target text readers are disregarded, and the problem of distinguishing between a translation and other multilingual operations is not recognized. The aversion to any kind of objectivization, systematization, and rule hypothesizing in translation procedures inherent in this approach leads to a reduction of translation evaluation research to examining each act of translation as an individual creative endeavor.

Response-Based Approaches In contrast to followers of the above subjective-hermeneutic approach, proponents of response-based approaches believe it is necessary to have some more reliable way of assessing translations. One can distinguish at least the following two variants of such approaches, which we will discuss in turn.

Behavioristic views: This tradition was first influenced by American structuralism and behaviorism, and it is associated with Nida’s (1964; Nida & Taber, 1969) seminal work on translation and his suggestion of behavioral tests. These tests

used broad behavioral criteria such as a translation's "intelligibility" and "informativeness." They were based on the belief that a "good" translation would have to lead to an "equivalent response," a criterion linked to Nida's famous principle of "dynamic equivalence"; that is, the manner in which the receptors of a translation respond to the translation is to be equivalent to the manner in which the source text's receptors respond to the source text. In the heyday of behaviorism, a number of imaginative tests were proposed: reading-aloud techniques and various cloze and rating tasks, all of which took observable responses to a translation as criteria of its quality. However, with hindsight, it is safe to say that these tests ultimately failed because they were critically unable to capture something as intricate and complex as the "overall quality of a translation." Even if one accepts the assumption that a translation of optimal quality should elicit an equivalent response, one must still face the awkward question whether it is at all possible to operationalize such grand concepts as "intelligibility" or "informativeness" and how one can measure an "equivalent response" in a valid and reliable manner. If one cannot do this, then it is futile to posit such behavioral criteria. Further, in the behavioral approach to translation assessment, the source text is largely ignored. So nothing can be said about the relationship between the original and texts resulting from different multilingual operations.

Functionalistic, "skopos"-related views: Proponents of this approach (most notably Reiss & Vermeer, 1984) maintain that it is the "skopos" (purpose) of a translation, and the manner and degree to which target culture norms are heeded in a translation, that are of overriding importance for translation evaluation. And it is the translator, or more frequently the translation brief the translator is given by the commissioner of the translation, that decides on the function the translation is to fulfill in its new context. The notion of function, critical in this theory, is, however, never made explicit let alone operationalized, so one can only hypothesize that "function" is here meant to be something similar to the real-world effect of a text, that is, an extralinguistically derived entity. Exactly how a text's global skopos is realized *linguistically*, and how one can determine whether a given translation is adequate vis-à-vis this skopos, remain unclear. Given the crucial role assigned to a translation's purpose and the concomitant reduction of the original text to an "offer of information," which the translator is licensed to change, reject, or "improve upon," one can see the closeness of this approach to the mentalistic, subjective-hermeneutic approach, where the translator is also given enormous power in the translation process. What is ignored in approaches that "upgrade" the "human factor" in the translation process is the undeniable fact that a translation qua translation is never an "independent" text but in principle a "dependent" one. By its very nature, a translation is bound to its source text *and* to the conditions governing its reception in the target linguacultural context. To stress only the latter factor, as is done in the functionalistic approach to translation, is unwarranted. What is needed is a definition of what exactly a translation is; a definition of when a text is no longer a translation, but a text derived from a different multilingual textual operation; and a making explicit of the constraints governing the translation process. With regard to the three questions, we can say that it is particularly with reference to the issue of distinguishing a translation from other forms of texts that the functionalistic approach seems inadequate.

Text- and Discourse-Oriented Approaches

These are descriptive translation studies, postmodernist and deconstructionist views, and linguistically oriented approaches to translation quality assessment. They will now be briefly discussed.

Descriptive Translation Studies In this descriptive-historical approach, associated primarily with the work of Toury (e.g., Toury, 1995), a translation is evaluated retrospectively (from the viewpoint of its receptors) in terms of its forms and functions inside the system of the receiving culture and literature. As with the approaches described above, here, too, the original is of subordinate importance: The focus in descriptive translation studies is on “actual translations,” that is, those that are, in the context of the receiving culture, regarded *prima facie* as belonging to the (often literary) genre of translation, and on the textual phenomena that have come to be known in the target culture as connected with translations. The procedure followed in this paradigm is thus a retrospective one: from a translation to its original text. The concept of equivalence is retained, but it does not refer to a one-to-one relationship between original and translation. Rather it is seen as sets of relationships found to characterize translations under specified circumstances. Translation equivalence is never a relationship between original and translation, but a “functional-relational notion”: a number of relationships established as distinguishing appropriate modes of translation performance for the particular culture in which the translation operates.

The characteristic features of a translation are “neutrally described” according to the way these features are perceived on the basis of native culture members’ tacit knowledge of comparable textual specimens in the genre into which the translation is inserted. They are not to be “prescriptively prejudged” in their correspondence to, or deviation from, features of the original. However, if one wants to evaluate a particular translation, which is never an independent new text in a new culture alone, but is related to a pre-existing entity, then such a view of translation (quality assessment) seems strangely skewed. With respect to the three criteria, we can state that this theory is deficient with regard to its capacity to illuminate the relationship between original and translation.

Postmodernist and Deconstructionist Approaches Proponents of this approach, such as Venuti (1995), attempt to critically investigate originals and translations from a psycho-philosophical, sociopolitical, and ideological stance in order to reveal unequal power relations and manipulations. In a plea for making translations and translators more “visible,” adherents of this “politically correct” approach try to make a point of unmasking the “hidden persuaders” in texts whose potentially ulterior, often power-related, motives are to be made transparent. Emphasis is also placed on what types of texts get translated in the first place, and exactly how and why an original text is skewed in the interests of powerful ideologies and interests. However laudable such an approach may be, when it comes to tracing the often neglected agendas behind translations and documenting the influence translations exert on recipient national literatures and their canons as “loci of difference,” one wonders whether it is wise to be so one-sidedly concerned with ideological

constraints, power structures, and external pressure. Surely, one may argue that translation is first and foremost a *linguistic* procedure, however susceptible it may be to ideological influences. Before adopting a critical stance vis-à-vis translations emphasizing the importance of a macro-perspective, one needs to engage in a more modest micro-perspective, that is, to conduct detailed, theoretically informed analyses of the choices of linguistic forms in originals and their translations as well as the consequences of these choices.

With respect to the three questions posed above, the critical, postmodern approaches are most relevant in their attempts to find answers to the first question, and also to the second one. However, no answers are sought for the question of when a text is a translation and when it results from a different multilingual textual operation.

Linguistically Oriented Approaches A pioneering approach to evaluating translations in this paradigm is Reiss's (1971) text typology deemed relevant for translation evaluation. She assumed that it is the text type (expressive, informative, operative) to which the original belongs that predetermines all subsequent translational decisions. Unfortunately, Reiss failed to give precise indications as to how one might go about conducting an assessment of whether and how original and translation are equivalent in terms of textual type. In other words, the same type of criticism applies here as to skopos-oriented translation theory.

Other seminal early work include Catford's (1965) translation theory and the work of the "Leipzig school" (Neubert, 1968) and Koller's (2011) authoritative (German) overview of *Übersetzungswissenschaft* (translation science). In more recent times, many more linguistically oriented works on translation and translation evaluation have appeared, such as Hatim and Mason (1997), Baker (2011), Hatim and Munday (2004), Steiner (2004), Teich (2003), and others. They all widened the scope of translation studies to include developments in linguistics such as speech act theory, discourse analysis, pragmatics, and corpus linguistics.

Linguistic approaches take the relationship between source and translation texts seriously, attempting to explicate the relationship between (features of) the text and how these are perceived by authors, translators, and readers, but they differ in their capacity to provide detailed procedures for analysis and evaluation. Most promising are approaches that explicitly account for the interconnectedness of context and text, because the inextricable link between language and the real world is definitive both in meaning making and in translation. Such a view of translation as recontextualization is taken by House in a linguistic model of translation criticism first developed in the late 1970s and recently revised (House, 1977, 1997, 2009).

A Linguistic Model of Translation Quality Assessment

Equivalence and "Meaning" in Translation

So far I have discussed approaches to translation criticism with a view to their stances on the relationships between texts and human agents involved in translation and between translations and other textual operations. These relationships

implicitly touch upon a crucial concept in translation: “equivalence.” Equivalence is rooted in folk linguistic understanding of translation as a “reproduction” of something originally produced in another language, and it is this everyday view of what makes a translation a translation that legitimizes a view of translation as being in a “double-bind” relationship. Over and above its role as a concept constitutive of translation, equivalence is also a fundamental notion for translation quality assessment. The linguistic, functional-pragmatic model of translation criticism developed by House (1977, 1997, 2009) is therefore firmly based on equivalence. Translations are here conceived as texts that are doubly constrained: by their originals and by the new recipient’s communicative conditions. This is the basis of the “equivalence relation,” that is, the relation between an original and its translation. Equivalence is the fundamental criterion of translation quality. One of the aims of a descriptively and explanatorily adequate theory of translation quality assessment is, then, to specify and operationalize the equivalence relation by differentiating between different equivalence frameworks, such as extralinguistic circumstances, connotative and aesthetic values, audience design, and textual norms of usage, that have emerged from empirical investigations of parallel texts and contrastive pragmatic analyses.

Equivalence is not an absolute, but a relative concept that emerges from the texts and the context of situation as defined by the interplay of many different factors. Equivalence is a relative concept in several aspects. It is determined by the sociohistorical conditions in which the translation act is embedded, and by the range of often irreconcilable linguistic and contextual factors, among them at least the following: source and target languages with their specific structural constraints; the extralinguistic world and the way it is “cut up” by the two languages, resulting in different representations of reality; the original text’s reflection of particular linguistic and stylistic source language norms; the linguistic and stylistic norms of the translator and of the target language and culture; structural features of the original; target language receptors’ expectation norms; the translator’s comprehension and interpretation of the original and his “creativity”; the translator’s explicit or implicit theory of translation, or both; translation tradition in the target culture; and interpretation of the original by its author.

Koller (1995, p. 216) posits different equivalence types according to different frames of reference:

1. *denotative* equivalence, according to the extralinguistic referents to which the text relates;
2. *connotative* equivalence, according to the connotations conveyed through the specific means of the verbalizations present in the text;
3. *text normative* equivalence, according to the linguistic and textual norms of usage that characterize a particular text;
4. *pragmatic* equivalence, according to the recipient of the translation, for whom the translation is “specially designed,” such that it can fulfill its communicative function; and
5. *formal-aesthetic* equivalence, according to certain aesthetic, formal, and idiosyncratic characteristics of the source text.

Given these types of equivalence in translation, it is obvious that not all five can be aimed at in translation. Rather, the translator must set up a hierarchy of demands on equivalence that he wants to follow. Definitions of equivalence as based on formal, lexicogrammatical similarities alone have long been criticized, not least because any two linguistic items in two different languages are multiply ambiguous. Further, purely formal definitions of equivalence are deficient in that they cannot explain appropriate language use in communicative performance. This is why functional-pragmatic equivalence has been an accredited concept in contrastive linguistics for a long time, focusing on language use rather than language as a formal system. It is this type of equivalence that is also most relevant for translation. This is reflected in House's functional-pragmatic model, where equivalence is related to the preservation of "meaning" across two different linguacultures. Three aspects of that "meaning" are particularly important for translation: a semantic, a pragmatic, and a textual aspect. Translation is then defined as the replacement of a source text by a semantically and pragmatically equivalent target text, and an adequate translation is a pragmatically and semantically equivalent one. As a first requirement for this equivalence, it is posited that a translation has a function equivalent to that of its original. However, this requirement will have to be differentiated given the existence of an empirically derived distinction into *overt* and *covert* translation, to be discussed below in detail.

The use of the concept of "function" presupposes that there are elements in a text that, given appropriate tools, *can* reveal that text's function. The use of the concept of function is here not to be equated with "functions of language." Different language functions always coexist inside any text, and a simple equation of language function with textual function or textual type is simplistic. Rather, a text's function, consisting of an ideational and an interpersonal functional component in Halliday's (1989) sense, is defined as the application of the text in a particular context of situation. Text and "context of situation" should thus not be viewed as separate entities; rather, the context of situation in which a text unfolds "is encapsulated in the text . . . through a systematic relationship between the social environment on the one hand and the functional organization of language on the other" (Halliday, 1989, p. 11). This means that the text is to be referred to the particular situation enveloping it, and for this a way must be found of breaking down the notion of "context of situation" into manageable parts, that is, particular "situational dimensions."

Inside British systemic-functional linguistics, many different systems have been suggested featuring situational dimensions as abstract components of the context of situation. The original translation quality assessment model by House (1977) used three dimensions characterizing the text's author according to her temporal, geographical, and social provenance, and five dimensions of language use elaborating on the text's topic and the interaction of, and relationship between, author and recipients in terms of their social role relationship, the social attitude obtaining, the degree of participant involvement, and the degree of written-ness or orality. The operation of the model involves initially an analysis of the original according to this set of situational dimensions, for which linguistic correlates were established. These linguistic correlates are the means by which the textual function is realized, and this function is the result of a linguistic-pragmatic analysis along

the dimensions, with each dimension contributing to the two functional components: the ideational and the interpersonal. Opening up the text with these dimensions yields a specific textual profile that characterizes its function, which is then taken as the individual textual norm against which the translated text is measured. The degree to which the textual profile and function of the translation (as derived from an analogous analysis) match the profile and function of the original is, then, the degree to which the translation is adequate in quality.

The set of situational dimensions acts thus as a kind of *tertium comparationis*, or quality that two things that are being compared have in common. In evaluating the relative match between original and translation, a distinction is made between “dimensional mismatches” and “nondimensional mismatches.” Dimensional mismatches are pragmatic errors to do with language users and language use, while nondimensional mismatches are errors involving denotative meanings of original and translation elements, and breaches of the target language system at various levels. The final qualitative judgment of the translation consists, then, of a listing of both error types and of a statement of the relative match of the two functional components.

In House’s revised model (1997, 2009), the classic Hallidayan register concepts of “field,” “tenor,” and “mode” are used. *Field* captures the topic of the text, its subject matter and social action, with differentiations of degrees of generality, specificity, or “granularity” in lexical items analyzed. *Field* also captures different “processes,” such as material processes (verbs of doing) or mental processes (verbs of thinking, believing, and feeling). *Tenor* refers to the nature of the participants, the addresser and the addressees, and the relationship between them in terms of social power and social distance, as well as degree of “emotional charge.” Included here are the text producer’s temporal, geographical, and social provenance and his intellectual or affective stance (his viewpoint) vis-à-vis the content he is portraying and the communicative task he is engaged in. Further, *tenor* captures “social attitude,” that is, different styles (formal, consultative, and informal). Linguistic indexes along *tenor* are mood and modality. *Mode* refers to both the channel—spoken or written (which can be “simple,” i.e., “written to be read,” or “complex,” e.g., “written to be spoken as if not written”)—and the degree to which potential or real participation is allowed for between writer and reader. Participation can also be “simple,” that is, be a monologue with no addressee participation built into the text, or “complex,” with various addressee-involving linguistic mechanisms characterizing the text. In taking account of (linguistically documentable) differences in texts between the spoken and written medium, reference is also made to the empirically established (corpus-based) oral–literate dimensions as, for example, hypothesized by Biber (1988). He suggests dimensions along which linguistic choices may reflect medium, namely involved versus informational text production, explicit versus situation-dependent reference, and abstract versus nonabstract presentation of information.

The type of textual analysis in which linguistic features discovered in the original and the translation are correlated with the categories of field, tenor, and mode does not, however, as in the original model, directly lead to a statement of the individual textual function (and its interpersonal and ideational components). Rather, the concept of “genre” is newly incorporated into the analytic scheme, “in

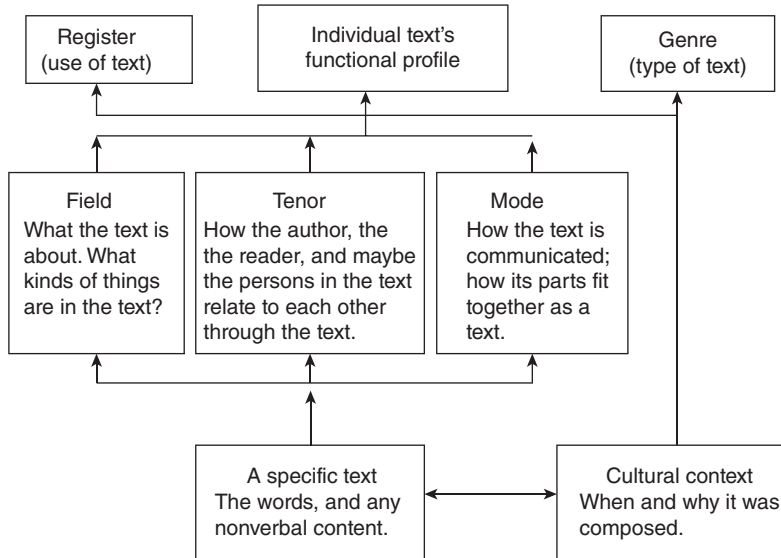

Figure 15.1 A system for analyzing and evaluating texts for translation purposes. Adapted from House (2009) © Oxford University Press. Reprinted with permission

between,” as it were, the register categories field, tenor, and mode. *Genre* enables one to refer any single textual exemplar to the class of texts with which it shares a common purpose or function. Genre is a category superordinate to that of register. While register captures the connection between texts and their “micro-context,” genre connects texts with the “macro-context” of the linguacultural community in which the text is embedded. Register and genre are both semiotic systems realized by language such that the relationship between genre, register, and language or text is one between semiotic planes that relate to one another in a Hjelmslevian “content-expression” type; that is, genre is the content plane of register, and register is the expression plane of genre. Register in turn is the content plane of language, with language being the expression plane of register. The resultant scheme for textual analysis, comparison, and assessment is shown in Figure 15.1.

Taken together, the analysis provided in this assessment model along the levels of the individual text, register, and genre, building one on the other in a systematic way, yields a textual profile that characterizes the individual textual function. But as mentioned above, whether and how this textual function can in fact be kept up depends on the type of translation sought for the original. In the following section, the nature of the different types of translation and versions are discussed.

Overt and Covert Translation

In an overt translation, the receptors of the translation are quite “overtly” not being addressed; an overt translation is thus one that must overtly be a translation, not a “second original.” The source text is tied in a specific manner to the source

linguaculture. The original is specifically directed at source culture addressees but at the same time points beyond it because it is also of general human interest. Source texts that call for an overt translation have an established worth in the source language community; either they are historically source texts, such as those tied to a specific occasion when a precisely specified source language audience is or was being addressed, or they may be timeless source texts, that is, those transcending as works of art and aesthetic creations a distinct historical meaning.

A covert translation is a translation that enjoys the status of an original source text in the target culture. The translation is covert because it is not marked pragmatically as a translation text of a source text but might, conceivably, have been created in its own right. A covert translation is thus a translation whose source text is not specifically addressed to a particular source culture audience; that is, it is not firmly tied to the source linguaculture. A source text and its covert translation are pragmatically of equal concern for source and target language addressees. Both are, as it were, equally directly addressed. A source text and its covert translation have equivalent purposes. They are based on contemporary equivalent needs of a comparable audience in the source and target language communities. In the case of covert translation texts, it is thus both possible and desirable to keep the function of the source text equivalent in the translation text. This can be done by inserting a "cultural filter" (see below for details) between original and translation with which to account for cultural differences between the two linguistic communities.

The distinction between overt and covert translation can be given greater explanatory adequacy by relating it to the concepts of "frame" and "discourse world." Translation involves a transfer of texts across time and space, and whenever texts move, they also shift cognitive frames and discourse worlds. *Frame* delimits a class of meaningful actions. A frame often operates unconsciously as an explanatory principle; that is, any message that defines a frame gives the receiver instructions in his interpretation of the message included in the frame. Similarly, the notion of a *discourse world* (Edmondson, 1981) refers to a superordinate structure for interpreting meaning in a certain way, for instance when a locutionary act acquires an illocutionary value by reference to a newly operant discourse world.

Applying these concepts to overt and covert translation, we can state the following: In overt translation, the translation text is embedded in a new speech event, which gives it also a new frame. An overt translation is a case of "language mention," similar to a quotation. Relating the concept of overt translation to the four-tiered analytical model (function, genre, register, and language or text), we can state that an original and its overt translation can be equivalent at the level of language or text and register as well as genre. At the level of the individual textual function, however, functional equivalence, while still possible, is of a different nature: It can be described as merely enabling access to the function the original has in its discourse world or frame. As this access is to be realized in a different language and in the target linguacultural community, a switch in discourse world and frame becomes necessary; that is, the translation will have to be differently framed, will operate in its own frame and discourse world, and can thus reach at best "second-level functional equivalence." As this type of equivalence is, however,

achieved though equivalence at the levels of language or text, register, and genre, the original's frame and discourse world will be coactivated, such that members of the target culture may eavesdrop, as it were; that is, be enabled to appreciate the original textual function, albeit at a distance. In overt translation, the work of the translator is important and clearly visible. Since it is the translator's task to permit target culture members to gain access to the original text and its cultural impact on source culture members, the translator puts target culture members in a position to observe or judge this text, or do both, "from outside."

In covert translation, on the other hand, the translator will attempt to re-create an equivalent speech event. Consequently, the function of a covert translation is to reproduce in the target text the function the original has in its frame and discourse world. A covert translation operates quite "overtly" in the frame and discourse world provided by the target culture. No attempt is made to coactivate the discourse world in which the original unfolded. Covert translation is both psycholinguistically less complex than overt translation and more deceptive. The translator's task is to betray the original, to hide behind the transformation of the original. The translator is clearly less visible, if not totally absent. Since true functional equivalence is aimed at, the original may be legitimately manipulated at the levels of language or text and register using a "cultural filter" (see below). The result may be at a very real distance from the original. While the original and its covert translation need thus not be equivalent at the levels of language or text and register, they will be equivalent at the level of genre and the individual textual function.

In assessing the quality of a translation, it is essential that the fundamental differences between these two types of translation be taken into account. Overt and covert translation make different demands on translation quality assessment. The difficulty of evaluating an overt translation is reduced in that considerations of cultural filtering can be omitted. Overt translations are "more straightforward," the originals being taken over "unfiltered" and "simply" transposed from the source to the target culture in the medium of a new language. The major difficulty in translating overtly is, of course, finding *linguistic-cultural* "equivalents," particularly along the dimension of tenor and its characterizations of the author's temporal, social, and geographical provenance. However, here we deal with *overt* manifestations of cultural phenomena that must be transferred only because they happen to be manifest linguistically in the original. A judgment whether a "translation" of, for instance, a dialect is adequate in overt translation can ultimately not be objectively given: The degree of correspondence in terms of social prestige and status cannot be measured in the absence of complete contrastive ethnographic studies—if, indeed, there will ever be such studies. In other words, such an evaluation will necessarily remain to a certain degree a subjective matter. However, as compared with the difficulty of evaluating differences in cultural presuppositions and communicative preferences between text production in the source and target cultures, which characterizes the evaluation of covert translation, the explicit overt transference in an overt translation is still easier to judge.

In connection with assessing the quality of a covert translation, it is necessary to consider the application of a "cultural filter" in order to differentiate between

a covert translation and a covert version. In the following section, I will therefore discuss the concept and function of the cultural filter in more detail.

The “Cultural Filter”

The concept of a “cultural filter” was first suggested by House (1977) as a means of capturing sociocultural differences in expectation norms and stylistic conventions between the source and target linguacultural communities. The concept was used to emphasize the need for an empirical basis for “manipulations” of the original undertaken by the translator. Whether or not there is an empirical basis for changes of the original text would need to be reflected in the assessment of the translation. Further, given the goal of achieving functional equivalence in a covert translation, assumptions of cultural difference should be carefully examined before any change in the source text is undertaken. In cases of unproven assumptions of cultural difference, the translator might apply a cultural filter whose application, resulting in possibly deliberate mismatches between original and translation along several situational parameters, might be unjustified. The unmarked assumption is one of cultural compatibility, unless there is evidence to the contrary. In the case of, for example, the German and Anglophone linguistic and cultural communities such evidence seems now to be available, with important consequences for cultural filtering in the case of this language pair. Since its first proposal, the concept of cultural filter has gained substance through contrastive-pragmatic studies, in which Anglophone and German communicative preferences were hypothesized. Converging evidence from these studies conducted with many different data, subjects, and methodologies suggests that there are German communicative preferences that differ from Anglophone ones along a set of dimensions, among them directness, content focus, explicitness, and routine reliance (House 2006).

For the comparative analysis of source and target texts and the evaluation of a covert translation, it is essential to take into account whatever knowledge there is about linguacultural differences between source and target linguacultures. There is a research desideratum in this field, because there are to date very few language-pair-specific crosslinguistic and crosscultural analyses.

Distinguishing Between Different Types of Translations and Versions

Over and above distinguishing between covert and overt translation in translation assessment, it is necessary to make another distinction: between translations and versions. Covert versions can be differentiated from overt versions. Overt versions are produced whenever a special function is (overtly) added to a translation. There are two different types of overt versions.

1. The “translation” is to reach a particular audience. Examples are special editions for children featuring omissions, additions, simplifications, or different accentuations of certain features of the original, or popularizations of specialist works (newly) designed for a lay audience.

2. The “translation” is given a special added purpose. Examples are interlingual versions or “linguistic translations,” *résumés*, and abstracts, where it is the express purpose of the version producer to pass on only the most essential facts of the original.

A covert version results whenever the translator, in order to preserve the function of the source text, has applied a cultural filter randomly manipulating the original where such a manipulation has not been substantiated by research or a body of knowledge.

In discussing different types of translations and versions, there is an implicit assumption that a particular text may be adequately translated in only one particular way. The assumption that a particular text necessitates either a covert or an overt translation does not, however, hold in any simple way. Thus any text may, for a specific purpose, require an overt translation. The text may be viewed as a document that “has an independent value” existing in its own right—for example, when its author has become, in the course of time, a distinguished figure—and then the translation may need to be an overt one. Further, there may well be source texts for which the choice between overt and covert translations is necessarily a subjective one. For example, fairy tales may be viewed as products of a particular culture, which would predispose the translator to opt for an overt translation, or as non-culture-specific texts, anonymously produced, with the general function of entertaining and educating the young, which would suggest a covert translation. Or consider the case of the Bible, which may be treated either as a collection of historical literary documents, in which case an overt translation would be called for, or as a collection of human truths directly relevant to all human beings, in which case a covert translation might seem appropriate.

Further, the specific purpose for which a “translation” is produced will, of course, determine whether a translation or an overt version is to be aimed at. That is, just as the decision as to whether an overt or a covert translation is appropriate for a particular source text may depend on factors such as the changeable status of the text author, so clearly the initial choice between translating or producing a version cannot be made on the basis of features of the text alone, but may depend on the arbitrarily determined purpose for which the translation or version is required.

Returning to the three basic questions of relationship between original and translation, relationship between texts and human agents, and distinction between translation and other secondary textual operations, the assessment model presented here is firmly based on a view of translation as a double-linkage operation. As opposed to views that show a one-sided concern with the translation’s reception in the target culture, the model takes account of both original and translation. It posits a cline along which it can be shown which tie of the double linkage has priority in any particular translation case, the two end points of the cline being marked by the concepts of overt translation and covert translation. The relationship between (features of) the text(s) and the human agents involved (as author, translator, and recipient) is explicitly accounted for through the provision of an elaborate system of pragmatic-functional analysis of original and translation, with the overt-covert cline on which a translation is to be placed determining the type

of reception sought and likely to be achieved. Finally, explicit means are provided for distinguishing a translation from other types of textual operation by specifying the conditions holding for a translation to turn into a version.

Integrating empirically verified cultural filters into the assessment process can be taken to mean that there is greater certainty as to when a translation is judged to be no longer a translation but a version. However, given the dynamic nature of communicative norms and the way research tends to lag behind, translation critics will still have to struggle to remain abreast of new developments that will enable them to judge the appropriateness of changes through the application of a cultural filter in any given language pair.

Some Recent Developments in Testing Translation Quality

Since Carroll's (1966) early proposals of tests of translation quality followed by response-based tests (see above) in the form of comprehension, readability, and naturalness checks, more recent progress in computer and communication technology, coupled with an ever increasing demand in a globalized world for fast and inexpensive translations, has led to the development of formalized approaches to translation quality assurance, including quality assurance software such as TRADOS, WF, or QAD. These programs are mainly used to verify terminology, compare source and target text segments, and detect (mostly formal and terminology related) errors. Such software does not replace human translators; it assists them. And it cannot detect stylistic and register infelicities resulting from faulty understanding of the source text. An important new field is the assessment of software localization, localization being similar to the notion of linguistic-cultural filtering mentioned above.

In addition to translation quality assurance software and metrics following the demand for repeatable, reproducible, and objective measures, the availability of large, multilingual parallel corpora adds important knowledge sources for tests of both automatic and human translation quality. Many automatic evaluation methods using translation quality metrics such as Bilingual Evaluation Understudy (BLEU) now compare machine translation output with reference translations, trying to correlate automatic translations with judgments by expert human translators or quality panels for validation and the generation of similar scores.

Linguistic Analysis Versus Social Evaluation

In translation quality assessment, it is important to be maximally aware of the difference between (scientifically based) analysis and (social) judgment in evaluating a translation. In other words, there is a difference between comparing textual profiles, describing and explaining differences established in linguistic-textual analysis, and evaluating the quality of a translation. "Absolute evaluation" is an illusion, and all a linguistic model of translation quality assessment can do is provide a basis for systematic comparison, making explicit the many factors that

might theoretically have influenced the translator in making certain decisions and rejecting others, thus providing the basis for evaluating a particular case.

Instead of taking the complex psychological categories of translation receptors' intuitions, feelings, reactions, or beliefs as a cornerstone for translation criticism, a linguistic, functional-pragmatic approach that takes account of language in its sociocultural context focuses on texts, the products of (often unfathomable) human decision processes that are most tangible and least ambiguously analyzable entities. Such an approach, however, does not enable the evaluator to pass judgments on what is a "good" or a "bad" translation. All a linguistic approach can do is, generally, to prepare the ground for the analysis of a large number of evaluation cases that would, in each individual case, not be totally predictable. In the last analysis, then, any evaluation depends on a large variety of factors that necessarily enter into a social evaluative judgment. Such a judgment emanates from the analytic, comparative process of translation criticism; that is, the linguistic analysis provides grounds for arguing an evaluative judgment. As intimated above, the choice of an overt or a covert translation depends not on the translator alone or on the text to be translated, or only on the translator's subjective interpretation of the text, but also on the reasons for the translation, on the implied readers, and on publishing and marketing policies, all of which means that there are many factors that have nothing to do with translation as a linguistic procedure. Such factors are social factors that concern human agents and sociocultural, political, or ideological constraints that tend to be far more influential than linguistic considerations or the translator herself.

I hasten to add, however, that despite all these "external" influences, translation is also a linguistic-textual phenomenon, and it can be legitimately described, analyzed, and evaluated as such. More forcefully argued, the primary concern for translation assessors remains linguistic-textual analysis and comparison. Consideration of social factors is, if divorced from textual analysis, of secondary relevance. Linguistic description and explanation provided by a model of translation quality assessment must not be confused with evaluative assertions made on the basis of social, political, ethical, or individual grounds. It is important to emphasize this distinction given the current climate, in which the criteria of scientific validity and reliability are often usurped by factors such as social acceptability, political correctness, vague emotional commitment, or fleeting "Zeitgeist" fashions. Translation as a phenomenon in its own right, as a linguistic-textual operation, should not be confused with issues such as what the translation is for, or what it should, might, or must be for. One of the drawbacks of an overriding concern with the covert end of the translation cline is that the borders between a translation and other multilingual textual operations become blurred. In view of this confusion, some conceptual clarity can be reached by theoretically distinguishing between translations and versions and by positing functional equivalence ("real" or second level) as a *sine qua non* in translation.

The core concept of translation quality assessment is translation quality. This is a problematical concept if it is taken to involve individual value judgments alone. It is difficult to pass any "final judgment" on the quality of a translation that fulfills the demands of scientific objectivity. This should not, however, be taken to mean that translation quality assessment as a field of inquiry is worthless.

But one should be aware that in translation quality assessment one will always be forced to move from a macro-analytical focus to a micro-analytical one; from considerations of ideology, function, genre, and register to the communicative value of individual linguistic items. In taking this dual, complementary perspective, the translation critic will be enabled to approximate the reconstruction of the translator's choices and to throw some light on his decision processes in as objective and intersubjectively reliable a manner as possible. That this is a complex undertaking that, in the end, yields but probabilistic outcomes should not detract from its usefulness. In translation criticism, one should reveal, in any individual case, exactly where and with what precise consequences and (possibly) for what reasons a translation is what it is in relation to its "primary text." Such a modest precision, evolving from attempts to make explicit the grounds of one's (preliminary) judgments on the basis of an argued set of procedures, might guard against making prescriptive, apodictic, and global judgments (of the "good" vs. "bad" type), which can never be intersubjectively verifiable.

In summary, translation quality assessment, like language itself, has two functional components—an ideational and an interpersonal one—which lead to two separable steps: the first and primary one referring to linguistic analysis, description, and explanation based on knowledge and research; the second and secondary one referring to value judgments, social and ethical questions of relevance, and personal taste. In the study of translation, we need both. Judging without analyzing is irresponsible, and analyzing without judging is pointless. To judge is easy; to understand is less so. If we can make explicit the grounds of our judgment on the basis of an argued set of procedures such as the one developed in the assessment model presented above, we can discuss and refine them. If we do not, we can merely disagree.

Assessing Language Varieties

Mingwei Pan

Hong Kong Polytechnic University, Hong Kong

David D. Qian

Hong Kong Polytechnic University, Hong Kong

Introduction

The evolution of language is an interesting phenomenon. Largely out of political, historical, or social reasons, some languages have witnessed their own development in the form of branching out, with a “standard” or high level variety as an umbrella (Spolsky, 1993; Seidlhofer, 2001) below which a number of varieties would evolve and coexist, with either slight or substantial variation at multiple levels—such as pronunciation, vocabulary, syntax, and so on. Take English, for example: the umbrella variety is generally known as British or American English. From a sociolinguistic point of view, such a variety can sometimes be referred to as “received pronunciation” or “general American” in the Inner Circle (Kachru, 1985, 1986, 1992), where English is used as the first language. Following this notion, there emerged a view of international English (IE) that claims that the only acceptable standards for the English language should be those given by the language produced by, or expected of, educated native speakers of English in the Inner Circle (Kachru, 1992).

However, a number of good reasons also gave rise to Outer Circle English varieties (Kachru, 1986, 1992), such as Singapore English and Indian English, which enjoy equal institutional, legal, and official status with other native languages in the same speech communities. Other postcolonial countries that belong to this Outer Circle include Bangladesh, Kenya, Malaysia, Nigeria, Pakistan, and the Philippines. Given the diversity of the changes accommodated by these postcolonial English-speaking communities, such varieties of English are characterized by many discernible features, especially at the phonetic and lexical levels, which are due to historical, geographical, political and social variations. A further extension of the development of English varieties has been the Expanding Circle, where

“members are more likely to communicate in English with non-native speakers (NNSs) from other first languages than their own, than with either native speakers (NSs) of English or with people who share their first language” (Jenkins, 2006, p. 42). The proposal and popularization of the notion of Outer and Expanding Circles led to a proposal of World Englishes (WE) as opposed to IE, as mentioned above (Kachru, 1992). The concept of WE argues that the use of Inner Circle English should not be discriminatorily imposed on NNSs, whose Englishes, belonging either to the Outer Circle or to the Expanding Circle, should be regarded as legitimate varieties of English because they are already established in their own speech communities.

The evolution of English, as described above, has eventually resulted in a large number of varieties. However, such variation within a language often poses a challenge to language testing professionals as to what standardization and codification or what variety, or even dialect, of this particular language should be benchmarked in assessment settings (Kachru, 1985; Lowenberg, 1992; Taylor, 2009a, 2009b). This can become particularly controversial when candidates’ written and spoken outputs are supposed to be measured against a rubber rule (Douglas, 2010) supposedly made with the Inner Circle speakers’ standard. Nevertheless, it is reassuring to note that a consensus seems to have been reached between the schools of IE and WE that what should be at the heart of the discussion is the status of language norms rather than the debate of whether or not IE and WE exist (Davies, 1999).

The present chapter, therefore, mainly dwells upon the complex issue of the effects of English language varieties on the assessment of language proficiency, with a specific view to understanding how the depiction of language varieties might affect the benchmarking for language assessment. After a discussion of varieties of English, the authors will discuss the assessment situations of other languages, especially those with a large speaking population and well-established variation in their written or spoken form, so that the challenge of assessing language varieties may be better understood.

The chapter will conclude with a note on desirable directions for future research, particularly for test development, design, and use. Toward the end of the chapter, a tentative model of reference will be proposed for language-testing professionals, on the consideration of fostering pragmatic competence and expanding the construct of communicative competence to include the awareness and capability of accommodating context-specific language varieties.

English as a Lingua Franca (ELF): A Brief Overview

In terms of terminology, many a name has emerged in referring to the use of English in an international speech community. For example, the generic concept *English as an international language* (EIL) has spanned the Inner, Outer and Expanding Circles (Kachru, 1992); English as a lingua franca (ELF) appears to be a more specific reference (Seidlhofer, 2005; Jenkins, 2006), which might or might not overlap with other concepts, such as *English as a global language* (Crystal, 2003), *English as a world language* (Mair, 2003) and *World English* (Brutt-Griffler, 2002).

Existing research is more oriented toward describing the English varieties in the Outer and Expanding Circles, where English is seen as a second language, for instance Hong Kong English and Singapore English, or English as a foreign language, for instance China English and Japan English; but before we engage a further discussion of English varieties, four pertinent pairs of opposing notions are introduced below.

Monocentrists Versus Pluricentrists

The opposition of the concepts of monocentrism and pluricentrism mainly arose from the argument as to whether there should be a “one version English,” inclusive of various social diversities, a view firmly upheld by monocentrists, or a “multiple versions English,” characterized by “autonomous or semi-autonomous varieties of the language” (Bolton, 2004, p. 368), a position enthusiastically supported by pluricentrists. In particular, the pluricentricists argue that various speech communities should become “norm-providing in their own right and are capable of developing in their own distinct ways” (Ooi, 2001, p. 186), because “the mere fact of having an earlier place in the chronological development of the English language does not confer everlasting rights of ownership” (Jenkins, 2006, p. 44).

World English Versus World Englishes

The second pair of mutually opposing concepts features World English versus World Englishes. This opposition can be characterized as a scale with a different force at each end, one being centrifugal and the other centripetal. At the end of the centrifugal force, English in various contexts is deemed to be different versions of the same language, and Standard English is regarded as an outside pressure sweeping the English-speaking world through various channels, including the Internet and the media; at the end of the centripetal force, the use of English is extended, as established practices, to various nativized speech communities where World Englishes are viewed as almost purely regional English varieties. Not only are such varieties contextualized, but in many cases they have even taken root in the local culture, a particular local identity being attached to each one.

Exonormative Versus Endonormative

These two opposing concepts are more concerned with the issue of whose standards should be referred to when the benchmark of language assessment is determined (see Taylor, 2009b, for an extensive discussion). The exonormative model argues that the benchmark supposedly originates from outside the place where English is spoken. In other words, the standards by which the correctness of English is judged should be proposed and maintained by the native speakers of Standard English. This conventional model is widely adopted, given the fact that the norms of Outer and Expanding Circle English varieties have not yet been properly and fully codified. By contrast, the endonormative model refers to a self-growing variety, where the standards of English have been localized in a

particular speech community. Brown and Lumley's (1998) study is a case in point: the test they developed for English teachers in Indonesia featured local situations, raters, and norms for assessing English proficiency. The validity argument for such an English test would be that, since the local English teachers were prepared for the communicative functions largely expected of the local speech contexts, the norms of the assessment should be made to accord with and accommodate local features, even though such an uncodified variety of English contains ungrammaticality (Canagarajah, 2006).

Native Speakers Versus Non-Native Speakers

The arguments over the three pairs of concepts presented above are followed by the debate over who is a native speaker and what should be the benchmark against which native speakers can be evaluated (Davies, 2003). Kirkpatrick (2007) postulates that it does not make any sense to distinguish between native and non-native speakers, and he does so on the basis of three considerations. First, challenges will be encountered in differentiating the linguistic ability of a near-native speaker from that of an Inner Circle native speaker. Second, even though a speaker is native to one Inner Circle English-speaking country, such as the USA, that person may lack communicative competence in the speech community of another Inner Circle English-speaking country, such as Australia. Third, provided that speakers are motivated to use their own varieties for emphasizing their societal or cultural identity, many varieties of the Outer and Expanding Circle English are likely to be mutually unintelligible. Mauranen (2003, p. 517) warns that "holding up an NS model as the target for international users of English is counterproductive because it sets up a standard that by definition is unachievable." Consequently, the debate over "nativeness" leads to a total avoidance of deploying the concept of *native speaker* (Kirkpatrick, 2007) in the benchmarking of some language tests; *expert user* is a suggested alternative (see, e.g., Rampton, 1990).

Identifying Different English Varieties

After this review of four pairs of opposing notions centering upon language varieties, the ensuing text briefly describes existing research on understanding different English varieties. In most investigations two approaches were adopted: a descriptive approach and a corpus-based approach. The former chiefly captures one linguistic aspect of a particular English variety, such as the pronunciation of East Asian ELF (e.g., Deterding, 1994; Deterding, Wong, & Kirkpatrick, 2008), ELF phonology (e.g., Jenkins, 2000), and pragmatics (e.g., House, 1999). The latter approach features a number of corpus-related projects, such as the International Corpus of English (ICE) (Greenbaum & Nelson, 1996), Vienna Oxford International Corpus of English (VOICE) (Seidlhofer, 2001, 2005) and the corpus of ELF in Academic Settings (ELFA) (Mauranen, 2003), all of which were compiled for identifying linguistic features of certain expressions that are discrepant from the perspective of Inner Circle English speakers' production but without communication breakdowns. Nevertheless, it has to be admitted that, whichever approach is adopted, the main purpose of the above studies was to build a further argument

to the effect that the standards of English language assessment should not be solely confined to Inner Circle English; rather, the features distinguishable in those established English varieties should not be regarded as errors, as pinpointed by Jenkins (2006, p. 43), because it is “unreasonable to expect NNSs to produce a more rigidly consistent kind of English than is typical or expected of NSs.”

Variation Across English Varieties: An Overview

Research shows that there is considerable variation at multiple levels among different varieties of English, even within the Inner Circle English. By comparing British and American English with other Inner Circle English varieties, McArthur (1992) notes that, while Canadian English differs in grammar from British English, it is more likely to conform to American English, whereas New Zealand English is to all intents and purposes similar to British English. Therefore, pinning its hope on depicting a microscopic picture of the possible variation, this section takes a glance at some variation across different varieties of English from the perspectives of phonology, vocabulary, morphology, syntax, and pragmatics (see Kirkpatrick, 2007).

At the level of phonology, two salient aspects of variation can be perceived. One aspect is the possible deletion of consonant sounds at the end of a syllabic cluster in some Outer Circle English varieties—for example, *film*, *known*, *worked*. The other aspect is that speakers of the Outer and Expanding Circle Englishes might transfer the feature of their syllable-timed (Platt, Webber, & Ho, 1984) mother tongue to English, which is intrinsically stress-timed. Variation at the vocabulary level can be even more salient, as the change of vocabulary is often accompanied by rapid vicissitudes in society and culture. Some words can carry different meanings across English varieties. Take the word *sake* as an example. With the same spelling, the word can mean *purpose*, *end* (in a general sense) within the Inner Circle English, while it can also be a loan word referring to a Japanese alcohol made from rice. On the other hand, some meanings are expressed by different lexical items in different English varieties, even within the same Inner Circle. For instance, *a test invigilator* in the UK would become *a test proctor* in the USA. In addition, some words are exclusively used in certain varieties. For example, *reffo* is a derogatory ethnic slur typically applied in Australian English to *refugee*.

At the morphological and syntactic levels there are variations as well. When the use of tenses is taken into account, Kirkpatrick's (2007) illustration is a fitting example to demonstrate variation in this regard: where an Inner Circle speaker of British English would say *I know very well*, a speaker of Indian English may say *I'm knowing very well*, which might be judged as unacceptable by the Inner Circle standards. Well above syntax is the level of pragmatics, where the roles of speech settings and cultural contexts in communication are considered. Even within the Inner Circle, American, British, and Australian English can be remarkably different with regard to greeting manners, the violation of which might trigger “pragmatic dissonance” (Li, 2002, p. 587), as illustrated by the following example.

Example 1: Comparison of greeting manners in Inner Circle varieties of English

English variety	Greeting	Response
<i>British English</i>	<i>How are you?</i>	<i>Fine, thanks.</i>
<i>American English</i>	<i>How are you doing?</i>	<i>(Just) Great (thanks).</i>
<i>Australian English</i>	<i>How are you going?</i>	<i>Good, thanks.</i>

Given what has been said above about certain linguistic features in the Outer and Expanding Circle Englishes, it is arguable whether Inner Circle English should or should not be the only provider of English language norms for assessment purposes. An argument can be made that, subject to the purpose of a specific assessment, the benchmarking for an assessment should be set so as to take into consideration all pertinent English varieties, including the Englishes used in the Outer and Expanding Circles.

Assessing Varieties of English

This section considers how the present state of affairs concerning English language varieties might affect assessment practice. More exactly, what should the yardstick be for assessing the English proficiency of second and foreign language learners in today's globalized context? Before a discussion of the criteria of assessment, a priori considerations relating to why a second or a foreign language is learned should be taken into account. The first consideration should be given to understanding the reason, or the motivation, for learning a second or a foreign language. Jenkins (2007) argues that people learn a foreign language mainly out of the need to communicate in various settings, improve their job prospects, or further their education abroad. This, however, does not necessarily mean that all English learners need or use English in Inner Circle settings. In fact most learners are likely to use the English language largely in non-native speaker settings or in countries where an Outer or Expanding Circle variety predominates. Taking as their example a test candidate who is being assessed for his or her spoken English proficiency as the threshold for communication in English in India, Trudgill and Hannah (2002) point out that in Indian English dental fricatives are usually replaced with /t/ or /d/. Therefore, if all that is expected is received pronunciation, which is "unlikely ever to have been spoken by more than 3–4% of the British population" (McArthur, 1992, p. 15), such benchmark setting cannot really be justifiable from a practical point of view. Thus the environment where English learners will use English might determine that test takers should not be expected to produce the type of language used in the Inner Circle.

Another important consideration is the purpose of various English language assessments. If an English language test is specifically intended to prepare test takers for further academic studies in an Inner Circle English-speaking country, there might be a need to uphold the standard of Inner Circle English, without which such candidates might be disadvantaged in their future studies in the Inner Circle countries. On the other hand, language professionals also need to be aware

that language tests might be used for some other purposes, such as assessing language proficiency for occupation-related or business-related communication. For instance, when customer service workers in an international organization are assessed for their English proficiency, their understanding of and sensitivity to various English varieties may become part of the construct for measurement, in addition to the need to measure many other aspects. Otherwise communication breakdowns may happen due to misunderstandings caused by the inability to comprehend the varieties of the English language used between the customer and the service provider.

Mainly because of the two foregoing considerations, researchers have come to be aware of the necessity of empirically querying whether the rationale for using the standards of the Inner Circle English is still valid in language test development in the Outer and Expanding Circles. One important issue under debate is to what extent tolerance, or accommodation, should be given in assessing the written and spoken output of ELF or English as a foreign language (EFL) learners. Lowenberg (1992) vehemently challenges the traditional concept that the "one version" Inner Circle English should be upheld as the benchmark in international English language tests. Based on a critical analysis of the Test of English for International Communication (TOEIC), Lowenberg (1993) points out that an overwhelming number of test items he has inspected were actually developed on the basis of a common core of Standard English norms. He therefore questions whether "certain features of English posited as being globally normative in tests of English as an international language" (p. 104) were actually valid and whether materials were properly selected for developing these tests. Given a broad range of international domains where communication in English might take place without the presence of Inner Circle native speakers, it is reasonable that the norms established in other English varieties should also be accepted. This is tantamount to anticipating that, if a language test is designed for assessing testees' English proficiency for international communication, features representing various English varieties should be incorporated into the testing materials. However, this anticipation cannot be easily realized, due to the fact that the demarcation between an error and an established version of Expanding Circle English is still rather blurred. For instance, departing from the point of creative processes of linguistic development, Jenkins (2006) contends that, even though a former "error" produced by native speakers might have evolved into an accepted expression in an English variety (e.g., the use of *data* as singular, in place of *datum*), in the Inner Circle the expression could still be judged as erroneous instead of being tolerated as a new standard expression in a language variety.

It is apparent that advocates of embedding features of Outer and Expanding Circle Englishes into language tests are still facing an uphill battle in their effort to strike a balance among various versions of English, so that a test construct can capture test takers' sensitivity to language varieties, or their language awareness. Jenkins (2006) makes two pertinent observations. First, she believes that, if a test contains exclusively Inner Circle English, the test takers' motivation and teaching guidance may gear naturally toward the "one version" English, which would run counter to the de facto use of English in today's globalized world. Second, because norms of different varieties of English are not yet sufficiently described, it is likely

that test developers are still unaware of many important characteristics of a relevant variety of English. To a great extent, many existing English language tests may still follow the norms of colonial Standard English. Qian (2008) corroborates this argument as he points out that the rubrics for benchmarking the spoken English assessment in a high stakes local test, Language Proficiency Assessment for Teachers of English, clearly find the local accent as a deficit that deserves a score deduction (Government of the Hong Kong Special Administrative Region, 2000; Qian, 2008).

Nonetheless, even though some English language tests are criticized for not being representative of the subject language, or not even fair in assessing English proficiency in the ELF context, nowadays developers of large-scale tests tend to be more aware of the need to accommodate NNS English in building their validity argument and to respond positively in this area. Taylor (2002, 2006), for example, notes that the recent dramatic change of landscape in English language has led to an increasing number of English varieties and, as a result, Cambridge ESOL (English for speakers of other languages) is making unremitting efforts to respond, for instance by developing *can-do* statements instead of using a *deficit* description in the score report, and by promoting a performance-based assessment that incorporates features of regional English varieties. From the perspectives of test purpose, validity, reliability, impact, and practicality, it is arguable that international language tests, while needing to incorporate ELF features, can always be on the way to being “the art of the possible” (Taylor, 2006, p. 58) and can be amenable to embracing new changes in the interest of stakeholders of various parties in order to achieve quality and fairness (Weir, 2005).

In fact, at the operational level, the accommodation of English varieties in language assessment cannot be accomplished with ease. Obstacles are multifaceted. First, as already mentioned, not every English variety is fully described, which poses difficulty for the inclusion of different English varieties in tests. Second, even with sufficient information on English varieties, test developers are still confronted with the issue of how to balance the features of various Outer and Expanding Circle Englishes. Third, thorny problems also arise as to whether test materials such as reading comprehension passages, or intended test takers’ output such as their utterances in a paired discussion, should be aligned with the Outer or with the Expanding Circle Englishes. In the final analysis, the extent to which Outer and Expanding Circle Englishes should be introduced into international language tests needs to be handled cautiously. Therefore the controversy no longer seems to turn on whether or not English varieties should be considered in assessment practices, but rather on how, and to what extent, features of such varieties should be incorporated. In response to the above challenges, a tentative model is proposed here with a view to facilitating test construction in the context of the increasing need to accommodate features of ELF in developing international English language tests.

Before this model is unfolded, an elaboration is due on the interaction between the choice of English varieties for learning and the learning stages. As is illustrated in Figure 16.1, one of the primary aims for English learning should be to foster the learner’s pragmatic competence, which is an indispensable part of their communicative ability (Bachman, 1990; Bachman & Palmer, 1996). In particular, it is

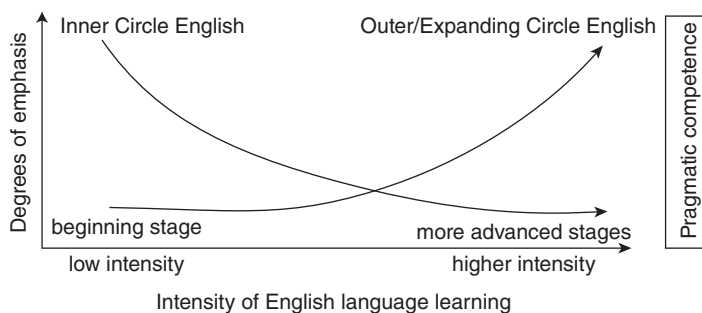

Figure 16.1 Interaction between English learning intensity and varieties of English

important for English learners to be equipped with the necessary sensitivity to dialect, language variety, and register (see Bachman, 1990, pp. 94–7, for details). Therefore, from the outset of learning English, it would be helpful to place more emphasis on the Inner Circle English, while Outer and Expanding English should be downplayed. This is because, if, at the very beginning of learning a new language, learners are given too much freedom with regard to “error” tolerance, the outcome might be an inability to distinguish English variety features from real errors. It is the same with first language acquisition, in the sense that, if an infant’s utterances are not properly monitored and guided by adults, errors may stabilize in the early stage of learning, eventually leading to fossilization.

Therefore, at this initial stage of language learning, strictness with real errors should be accorded top priority, even though some “variety features” can be tentatively left aside. Nevertheless, as learning increases in intensity, learners at more advanced levels can be exposed to more English varieties, including Outer and Expanding Circle Englishes, so that their pragmatic competence can thus develop better. In addition, this training will also improve their ability to accommodate different English varieties under various circumstances of communication. The curve representing Inner Circle English in Figure 16.1 smoothly glides down, suggesting a gradual reduction of Inner Circle English, to make room for input from other English varieties where applicable; on the other hand the other curve, which represents Outer and Expanding Circle Englishes, moves up, indicating that, as a learner becomes more advanced, the learning input may be embedded in an increasing amount of elements from Outer and Expanding Circles varieties of English, in order to foster the learner’s pragmatic competence.

Now that this model has been expounded, it is time to discuss how features of language varieties can be accommodated in language assessment. As is shown in Figure 16.2, the factors and variables within the square with dotted borders can all contribute to determining whether, and if so how, features of English varieties should be incorporated into a language proficiency test. A number of factors need to be considered before a decision is made as to how features from one or more varieties of English might be “incidentally” or “deliberately” embedded in the test.

First, among many possible factors, test purposes should be a primary concern. For instance, if an English language test is intended for measuring candidates’ language proficiency in academic writing for the purpose of study in an Inner

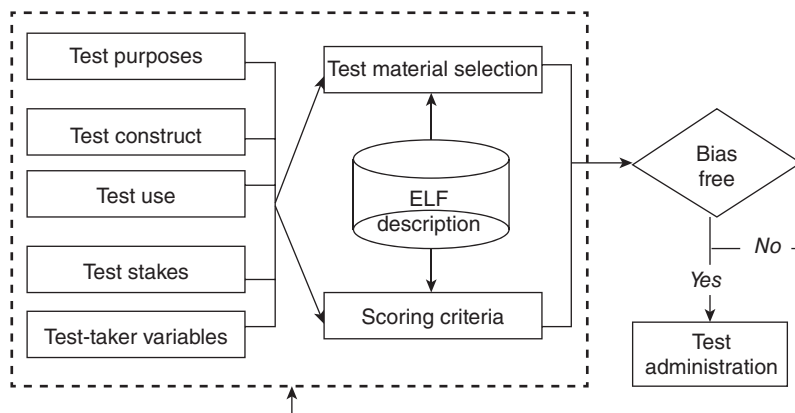

Figure 16.2 Accommodating varieties of English in test construction

Circle country, it is naturally justifiable that the manifestation of proficiency should be supported by the candidates' language output conforming to norms of conventional English academic writing. Therefore determining test purposes should be one of the top priorities in encompassing the features of English language varieties that are relevant for such an assessment. However, if a test is to prepare new immigrants to have survival English proficiency in an English-speaking country where multiculturalism prevails, there is a need to accommodate an ELF paradigm in the test construction, since the nature of the linguistic community determines that the targeted candidates are expected to demonstrate awareness of the varieties of English used there.

In a similar vein, test construct and test use should also contribute to deciding how varieties of English might be incorporated into test construction. For instance, if an English proficiency test is developed to assess would-be hotel receptionists' communicative competence, the construct should include a measurement of whether or not the candidates can respond sensitively to the diversity of English idioms used in various hotel situations, given that hotel guests might have different social and educational backgrounds. If candidates are able to communicate effectively in such contexts, the test score can then be deemed valid for helping make decisions on the selection of qualified hotel receptionists.

The quality of test stakes is another factor. For example, aviation English tests, normally considered tests with extremely high stakes, should exercise a high degree of caution as to which varieties of English are to be included. In addition to the technical terms expected of pilot tower communication, all the main English accents that the would-be pilots will possibly encounter should also (ideally) be covered in the test, so that potential risks caused by communication breakdowns are minimized.

Last but not least, test-taker variables are also worth considering. In particular, the proficiency level of the target test takers should be a primary factor in designing a good language test, because the need for assessing pragmatic competence will vary with test takers of different language proficiency levels. For example, an advanced level test may focus more on pragmatic competence, while a test of

lower proficiency level may concentrate more on linguistic competence. Therefore test developers should be aware of this need.

Nevertheless, the above considerations are closely associated with two aspects on the side of test development: test material selection and scoring criteria. The former is more concerned with what information, or test input, test takers receive from the test. As mentioned before, if a test measures pilots' English proficiency in communications with control tower staff in South America, the materials for listening comprehension should reflect the accent(s) of South American English speakers, because qualified pilots from other countries and regions should be able to understand the accent of the control tower staff in real situations.

The latter aspect deals with how test takers' own output, either written or spoken, will be evaluated. In other words, how should the scoring criteria reflect an accommodation of varieties of English? Take again the example of aviation English. It would be unfair to downgrade a candidate's score on the basis of his or her accent; if a test candidate who speaks with an easily detectable L1 accent is able to communicate in English effectively, there is no reason why such performance should be downgraded on account of his or her L1 accent.

Therefore both aspects, namely test material selection and scoring criteria, should be suitably informed by a proper description of the ELF, as is illustrated in Figure 16.2. To achieve this objective, more ELF corpora need to be compiled with a special view to informing the test construction. By constantly checking these corpora, or by being informed through ELF descriptions, test developers will (hopefully) still be capable of incorporating at an appropriate level selected features of the desired varieties of English into the assessment, even if they themselves may have a limited knowledge of the ELF characteristics.

Furthermore, after being constructed, the test still needs to undergo an a priori validation (Weir, 2005), in particular content validation, to ensure absence of bias before that test is administered to the targeted candidates. If any bias or content under-representation due to the incorporation or exclusion of the features of a regional variety of English is detected, the test construction process may have to be regressed to the dotted square, as illustrated in Figure 16.2, for further moderation, so that a part of the test may be revised, or items rewritten. In spite of its tentativeness, this model at least gives test developers some basic guidance on how to accommodate desired features of target English language varieties in language assessment. In particular, different factors (not just those listed in Figure 16.2) should cofunction for a decision on (a) what features of a variety of English, and how many varieties, need to be incorporated; (b) how this incorporation should be performed at the operational level; and (c) what proportions of each desired variety of English should be represented in the test, if a test needs to reflect more than one variety in the measurement of the language proficiency.

Assessing Varieties of Other Languages

In comparison with varieties of English, the assessment of which is relatively well documented and evidenced, other languages do not seem to have attracted as much attention. Taylor (2009a) investigates language varieties and assessment

practice across a few European languages and across different European test providers. In order to further triangulate the consideration that the varieties of other languages should also be justified in the process of assessment benchmarking, this section briefly reviews the major varieties of Chinese, Spanish, and Portuguese within the context of language assessment, so that a broader contour of language variety assessment can be captured.

Chinese

One example of language variation is offered by the Chinese language, which boasts a large number of dialects all over China. However, with respect to the assessment of Chinese proficiency, Cantonese is probably the only exception, in that it actually has an established assessment system in Hong Kong in its own right. As Cantonese is supposedly the native spoken language of the majority of Hong Kong residents, such an assessment is actually oriented more toward first language testing; therefore the benchmarking seems stricter and more emphasis is laid on the pronunciation of certain consonants in Cantonese—consonants that are believed to require greater sound-producing effort, or *lazy sound* in local terms. For example, in the Reading Aloud section of the Chinese (Cantonese) Speaking Test of the Hong Kong Certificate of Education Examination (HKCEE), the rating dimensions include (1) pronunciation; (2) speaking rate and intonation; and (3) fluency (Hong Kong Examinations and Assessment Authority, 2007). In particular, when the dimension of pronunciation, with a full score of 9, is assessed in this section, there are usually 9 individual Chinese characters (9 spots) contextualized in a short passage. When candidates are assessed, examiners, in reaching the final score, would pay special attention to each of these nine spots.

Example 2: An item in Cantonese assessment

Chinese: 餐桌的禮儀要重視，不過(*gwo³*)也不能太重視。

English: Table manners are important but should not be overemphasized.

Example 2 was extracted from the Reading Aloud section of a past test paper of the HKCEE Chinese (Cantonese) Speaking Test. The assessment point in this context is the pronunciation of the Chinese character 過 (*gwo³*), which could be mispronounced as 過 (*go³*) with less articulating effort. Since the assessment measures candidates' proficiency in their first language, such strictness makes sense, but the expectation would be different if the assessment were for a second language: in that case leniency about accuracy and focus on intelligibility would take priority.

Spanish

Spanish is spoken not only in Spain, but also in many Central and South American—or Latin American—countries as an official language. Therefore, for political and historical reasons, Spanish has naturally branched out into different varieties. Nevertheless, the linguistic norms of Spanish, unlike those of English,

are strictly maintained—namely by the Royal Spanish Academy, whose efforts involve mainly the publication of Spanish dictionaries and some widely respected guides on Spanish grammar and styles (Batchelor, 1992).

The variation among different varieties of Spanish spans a number of aspects, from phonetics and lexis to syntax. Differences in Spanish vocabulary can be a good start, as many a word used in Latin American countries somehow are not recognized in Spain. The everyday Spanish word *coger* (*to take*) is, for example, considered extremely rude in some parts of Latin America, where the same word may mean *to have sex*. Another well recognized variation is evidenced in the use of the second person pronoun in Spanish. On the one hand, in most Spanish-speaking communities there is a certain distinction between a formal (*usted*) and an informal (either *tú* or *vos*) register for using a second person singular pronoun. On the other hand, even though the word is still not much used in Spain, *vos* now appears in some formal Spanish writing in Central America, in addition to being the primary spoken form of the second person singular that shows intimacy.

Thus a question arises as to what standards should be referred to in an assessment context. The Cervantes Institute, an organization founded by the Spanish government, is responsible for promoting Spanish culture and education, including Spanish language assessment. The Spanish proficiency test that the Institute regularly administers still adheres to European Spanish and is aligned with the proficiency levels of the Common European Framework of Reference for Languages. The practice might be fairly acceptable for Spanish learners in Spain; however, among those in other parts of the Spanish-speaking world, a controversy might arise, because what is being taught (e.g., Spanish as taught by Mexican teachers) might not be entirely consistent with what is assessed by this test, given that only the Spanish language used in Spain is referred to as the standard for the assessment.

Portuguese

Portuguese is spoken as the official or subofficial language in Portugal and in former Portuguese colonies in South America and Africa. Apart from Portugal (where of course Portuguese originated), the country where this language is spoken by a large population, as an official language, is Brazil. In a phenomenon akin to the evolution of varieties of English and Spanish over the years, Brazilian Portuguese has also been established as a variety of Portuguese with features that distinguish it from European Portuguese. From the perspective of language assessment, there are a number of Portuguese language tests that measure candidates' proficiency in Portuguese for immigration or professional purposes.

For instance, Celpe-Bras (Certificate of Proficiency in Portuguese Language for Foreigners) is officially recognized by the Brazilian government for assessing non-Portuguese speakers' proficiency in Portuguese. In this test battery, particularly in the reading section, one may find some vocabulary that is different from that of European Portuguese. This is because the reading materials for the test are generally selected from Brazilian Portuguese sources. As is illustrated in Example

3, there is a clear discrepancy between European Portuguese and Brazilian Portuguese in certain lexical items that are commonly used. Although both varieties share the word *desjejum* for *breakfast*, there are also other expressions for it in each. In addition, the same meaning can be rendered through different words or phrases in each variety of Portuguese. For example, *estação de trem* and *ônibus* in Brazilian Portuguese are equivalent to *estação* and *autocarro* in European Portuguese, meaning *train station* and *bus* respectively.

Example 3: Lexical differences between European and Brazilian Portuguese

<i>European Portuguese</i>	<i>Brazilian Portuguese</i>	<i>English</i>
pequeno almoço, <i>desjejum</i>	café da manhã, <i>desjejum</i> , parva	breakfast
gare, estação	estação de trem	train station
autocarro	ônibus	bus

The variation in European and Brazilian Portuguese is also reflected at the syntactic level. As is shown in Example 4, on a conventional interpretation, the Brazilian version does not conform to grammatical rules, as the receiver *me* should be placed after the subject and predicative *mostrou*. However, as an element in an established variety of Portuguese, the pre-placement of *me* is quite common and acceptable, since the original meaning is still conveyed.

Example 4: Syntactic differences between European and Brazilian Portuguese

<i>Language variety</i>	<i>Sentence (with the same meaning)</i>
European Portuguese	Mostrou-me a casa tocta.
Brazilian Portuguese	Me mostrou a casa tocta.
English	She showed me the whole house

Challenges and Future Directions

This section focuses on challenges and future directions for assessing English language varieties; but the discussion should also have implications for the assessment of other language varieties.

Research on World Englishes has come a long way in the last two decades. Today, with the wide spreading of English as a global lingua franca and the increasing popularity of such concepts as World Englishes and concentric circles for varieties of English, the recognition of the existence of World Englishes no longer seems to be a major issue. However, challenges still remain concerning at least four other issues:

- 1 Is there already a generally accepted set of criteria capable of identifying and of systematically describing a new English variety? In particular, can such

criteria be sufficiently robust to determine when an error in the Inner Circle English would become a new feature in an emerging language variety? Are existing criteria (e.g., Butler, 1997) or models (e.g., Schneider, 2007) sufficiently powerful to perform this function?

- 2 How can research outcomes on World Englishes facilitate the advancement of language assessment?
- 3 How and to what extent should language assessment professionals accommodate features of targeted language varieties in language proficiency tests in various assessment contexts, such as those for EFL learners and those for immigrants?
- 4 How will the incorporation of features of ELF and regional English varieties into a given assessment contribute to the validity argument for that assessment, since the effects of such incorporation may go beyond content validity?

While these are all challenging issues, the first appears to be the most daunting one among the four, because a solution to this issue will provide a useful basis for addressing the second issue, which calls for an interface between research on World Englishes and on language assessment. It is apparent that an appropriate accommodation of varieties of English in language assessment needs to be informed by sociolinguistic research. In this respect, especially meaningful will be the identification and detailed description of the ELF core (Mauranen, 2003), the importance of which is obvious. In addition, thick descriptions of representative and distinctive features of English varieties of the Outer Circle, which are still under-documented, are also highly desirable. As most of these varieties have already had a long history with unique linguistic features, they certainly constitute important parts of ELF. Without such descriptions, it is basically impossible for assessment professionals to identify and accommodate important features of pertinent varieties of English in the assessment design, including the development of test items and rating scales and the selection of test materials.

At the same time there is a great need to raise the awareness of language assessment professionals, so that staff responsible for assessment development at all levels will realize the importance of accommodating the representative features of varieties of English in all the phases of their work on the assessment, including test development, administration of the oral test, and rating of the test response data.

The authors would like to acknowledge the generous help received from Renia Lopez and Elaine Espindola of the Department of English, Hong Kong Polytechnic University, who provided valuable sources as well as insights on the assessment of varieties of Spanish and Portuguese.

International Assessments

University of Barcelona, Spain

Introduction

Assessment and evaluation are pervasive features of human activity: We evaluate everything and are being evaluated all the time. Education is no exception. While education generally aspires to goals of individual growth and development, it is also expected to serve social, cultural, and economic policies. One of the present top policy priorities is to enable the nations and their citizens to take full advantage of an increasingly globalized economy. This requires provision of high quality and sustainable education, with an acceptable degree of equity in the distribution of opportunities to learn (OTL) and with clear incentives for achieving greater efficiency in schooling.

Successful educational policy and well-informed planning and implementation depend on indicators showing how well the educational systems are functioning. During recent decades, many countries have set up monitoring systems of various kinds: revised national examinations or sample-based national assessment to monitor students' learning and the performance of schools (e.g., National Assessment of Educational Progress [NAEP], designed in the late 1960s). In addition to national assessments, international yardsticks were called for. Systematic international assessments emerged in 1958 when the International Association for the Evaluation of Educational Achievement (IEA) was set up, and expanded when the Organization for Economic Cooperation and Development (OECD) launched the intergovernmental Programme for International Student Assessment (PISA) project. International assessments have since proliferated. As indicated above, international assessment is understood here to refer to assessments undertaken by an international team or organization to obtain comparative

information on educational performance through a jointly planned approach and methodology. This means that, for example, widely used international tests are not covered in this chapter.

Previous Views or Conceptualization

Descriptive Phase in International Comparisons

Throughout the long history of formal education and long before the emergence of the IEA and PISA international assessments, the quality of education had been of interest and an object of comparison to students, parents, and scholars. As a consequence, many students chose to study abroad in well-reputed international educational institutions. When national educational systems were being developed, it was common for educationalists to visit other countries to observe how education was conducted elsewhere and what appeared to be the outcomes. Such visits to “educational laboratories” provided useful stimuli, although data were not gathered in a consistent and standardized fashion.

This comparative approach was often ethnographic (in a broad sense), setting the descriptive national case studies in a cultural context, paying particular attention to the curricular arrangements (what was being taught), the organization of the educational system, teacher education, and teaching methods. Successful pedagogic approaches were copied and adapted (Pestalozzi, Herbart, Montessori, Waldorf, and so forth). Occasionally a more explicit exploration followed, when it was perceived that some particular country was doing particularly well in a subject. For instance, Brown (in 1915) reported to his interested American readers “how the French boy learns to write.”

Comparative education developed also as a discipline (e.g., Noah, 1973) and acquired special journals, the flagship of which, *Comparative Education Review*, started in 1957.

From early on, examinations had been a burning pedagogical problem in many countries. At a world congress in 1927, a committee was set up to study the question. This committee met five times from 1931 to 1938. At the final conference in 1938, members from the participating countries, namely England, Finland, France, Germany Norway, Scotland, Sweden, Switzerland, and the United States, presented reports confirming problems concerning the marking of essays, highlighting the common inadequacies of the prevailing examinations in all countries, and stressing the need for intensive research to improve such measures (see Spolsky, 1995, pp. 66–73 for a succinct review). In spite of such activity, empirical comparative education was in short supply.

Emergence of a Systematic Approach: IEA

In the late 1950s, a group of internationally minded scholars initiated discussions within the IEA on the idea that doing systematic empirical research on educational achievement in a comparative perspective and using the same data collection methods and instruments might provide useful theoretical and practical

information on patterns of variables related to the levels of achievement across countries. The variation in educational systems was seen to provide a “natural laboratory,” a natural “experimental setting.”

The IEA studies, the main focus of this section, measure performance among students of different countries and thereby indirectly highlight the question of whether certain policies in a particular educational system have a positive or negative impact on learning.

Through its comparative research and assessment projects, IEA aims to:

1. provide international benchmarks to assist policy-makers in identifying the relative strength and weaknesses of their education systems
2. provide high-quality data to increase policy-makers’ understanding of key school- and non-school-based factors that influence teaching and learning
3. provide high-quality data that will serve as a resource for identifying areas of concern and action, and for preparing and evaluating educational reforms
4. develop and improve the capacity of education systems to engage in national strategies for educational monitoring and improvement
5. contribute to the development of a worldwide community of researchers in educational evaluation. (IEA, *n.d.*)

The early IEA international assessments reflected the influential views of Ralph W. Tyler, and the Chicago measurement school more generally, on the triangular relationship between goals of education (curriculum), modes of instruction, and the assessment of outcomes. In the assessments conducted in the 1980s, a distinction between the intended curriculum, the implemented curriculum, and the realized curriculum (systemic, instructional, and student levels, respectively) became an important design feature.

Since 1958, IEA has conducted more than twenty comparative surveys focusing on student performance (see Papanastasiou, Plomp, & Papanastasiou, 2011). The main purpose of the massive Six Subject Survey (Walker, 1976), including a quarter of a million students in about 10,000 schools and stretching from the late 1960s to the mid-1970s, was to study the relationship between *input* factors in the social, economic, and instructional domains and *output* as measured by international tests covering both cognitive (student performance) and affective behavior (questionnaires on student attitudes and motivation). These relationships were studied in some twenty national systems of education and, as a rule, at three different levels (populations) within each educational system, aiming at generalizable findings.

The IEA studies used a common design (see Table 17.1) where achievement (dependent variable) was predicted by a variety of societal, institutional, instructional, and personal characteristics, using multivariate methods such as regression analysis and path analysis. The independent variables were arranged in “blocks” with the home background entered as the first block in analyses, followed by type of school or program (degree of selectivity) and school instruction variables. This order was considered to reflect the causal sequence in influencing school achievement (see also Figure 17.1). Walker (1976) provides an informative summary of the six studies.

Table 17.1 A summary of early IEA language-related surveys, late 1960s to early 1990s

<i>Study</i>	<i>Target populations</i>	<i>Participants</i>	<i>Tests</i>	<i>Questionnaires</i>	<i>Reports</i>
Reading Comprehension (1968–72)	* 14-year-olds * Final grade of secondary school	Belgium, Chile, England, Finland, Hungary, India, Italy, Netherlands, New Zealand, Scotland, Sweden, United States	* Verbal ability * Reading comprehension * Speed of reading * Word knowledge	* Out-of-school literacy environment * Educational practices * Size and type of school * Interests, attitudes * Study and reading habits	Thorndike (1973)
Literature Education (1968–73)	* 14-year-olds * Final grade of secondary school	Belgium, Chile, England, Finland, Hungary, Italy, New Zealand, Sweden, United States	* Measures of literary response * Literary comprehension	* Attitudes to literature * Interest in literature	Purves (1973)
French as a Foreign Language (1968–73)	* 14-year-olds * Final grade of secondary school	Chile, England, Netherlands, New Zealand, Romania, Scotland, Sweden, United States	* Reading * Listening * Speaking * Two writing tests (“objective” and directed composition)	* Student * Teacher * School	Carroll (1975)
English as a Foreign Language (1968–73)	* 14-year-olds * Final grade of secondary school	Belgium, Chile, Finland, Germany (FRG), Hungary, Israel, Netherlands, Sweden, Thailand	* Reading (six subtests, including vocabulary and grammar) * Listening (sound discrimination, sentence comprehension, dictation)	* Place of English in the educational system * Student * Teacher * School * Context	Lewis and Massad (1975)
Written Composition (1983–9)	Students: * near the end of primary schooling (A) * near the end of compulsory schooling (B) * near the end of academic secondary school (C)	Chile, England, Finland, Germany (FRG), Hungary, Indonesia, Italy, Netherlands, New Zealand, Nigeria, Sweden, Thailand, United States, Wales	See Figures 17.1 and 17.2	See Figures 17.1 and 17.2	Gorman, Purves, and Degenhart (1988); Purves (1992)

Language Education (1993–6)	<p>* End of compulsory schooling (ages 15/16)</p> <p>* End of upper secondary schooling (ages 17/ 18)</p> <p>Planned as a three-phase project ending up with testing of performance, but lack of funding limited information gathering to phase 1</p>	<p>Austria, Cyprus, Czech Republic, Denmark, England, Finland, France, Hong Kong, Hungary, Iran, Israel, Italy, Latvia, Netherlands, Norway, Philippines, Portugal, Russian Federation, Slovenia, South Africa, Spain, Sweden, Switzerland, Thailand, United States</p>	<p>* Data for four languages commonly taught as a school subject (English, French, German, and Spanish) collected in 1995</p>	<p>* Language education (sociolinguistic context, language policy, curriculum and assessment)</p> <p>* Language teaching and professional support)</p> <p>* School level (characteristics of schools and teachers)</p> <p>* Student level (proficiency, attitudes, and aspirations)</p>	<p>Dickson and Cumming (1996)</p>
Reading Literacy (1985–94)	<p>* 9-year-olds</p> <p>* 14-year-olds</p>	<p>Belgium (French), Botswana, Canada (British Columbia), Cyprus, Denmark, Finland, France, Germany (FRG), Germany (GDR), Greece, Hong Kong, Hungary, Iceland, Indonesia, Ireland, Italy, Netherlands, New Zealand, Nigeria, Norway, Philippines, Portugal, Singapore, Slovenia, Spain, Sweden, Switzerland, Thailand, Trinidad & Tobago, United States, Venezuela, Zimbabwe</p>	<p>* Word recognition (only 9-year-olds)</p> <p>* Narrative</p> <p>* Expository</p> <p>* Documents</p>	<p>* Student</p> <p>* Teacher</p> <p>* School</p> <p>* National case study</p>	<p>Elley (1994)</p>

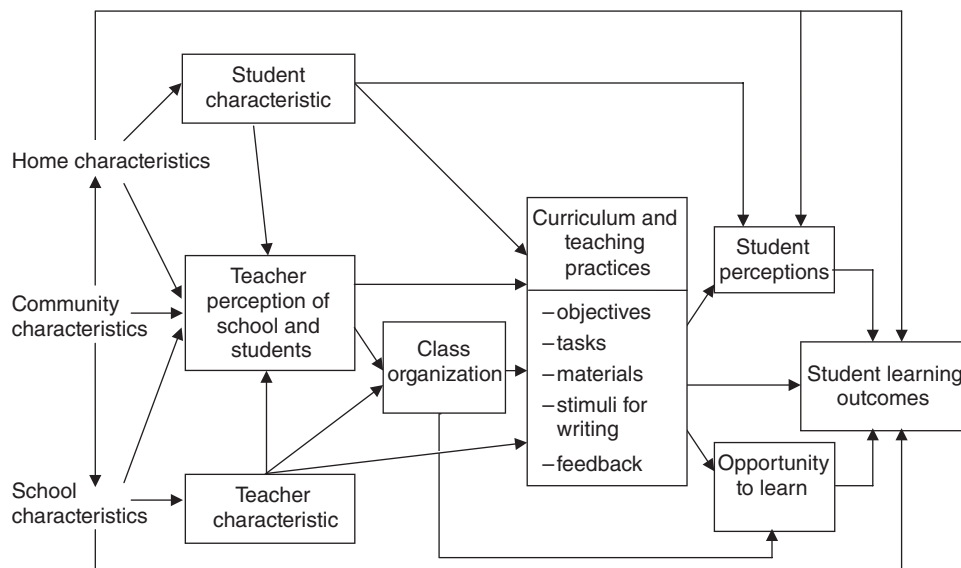

Figure 17.1 The design of the IEA Study of Written Composition (adapted from Gorman, Purves, & Degenhart, 1988, p. 10) © Elsevier

Figure 17.1, based on a design used in the Study of Written Composition, illustrates the approach to the IEA study designs. This kind of model is still basically applied in broad outline. For an up-to-date conceptualization in the Progress in International Literacy Study (PIRLS), consult http://timss.bc.edu/pirls2011/downloads/PIRLS2011_Framework.pdf

In addition to the prioritized international studies of mathematics and sciences, the IEA carried out studies of English and French as a foreign language and of reading and literature, published in the early 1970s, and of writing in the late 1980s. Studies of reading have continued, focusing on 10–11-year-olds (PIRLS) with a cycle of five years (2001, 2006, and 2011).

The language-related IEA studies are presented in Table 17.1.

The wealth of results cannot be reported in any detail (see Walker, 1976). Therefore, only two studies are discussed briefly below: the study of French (second language [L2]) and the study of written composition (first language [L1]) as summarized on the IEA website (http://www.iea.nl/completed_studies.html). As a prominent psychometric expert, Carroll (1975) was able to apply state-of-the-art methodology and, incidentally, also explore the validity of his 1973 model of school learning. The main findings were these:

- General proficiency in learning French was strongly related to performance on a word knowledge test in the student's mother tongue, which was used as a measure of verbal ability.
- The student's aspiration to understand spoken French contributed more to listening achievement than to reading achievement. Aspiration to learn to read French contributed more to reading scores than to listening scores.

- In all four fields of performance (reading, listening, speaking, and writing) there was a strong linear relationship between country mean score and the average number of years the students had studied French.
- Time spent on homework had an influence on reading scores, but much less effect on listening scores, which were only indirectly influenced by amount of homework. Classroom activities were much more important for listening. Students achieved higher scores when French was used for a substantial part of the time in the classroom, and when the use of the mother tongue was reduced but not eliminated.
- Neither the amount of university training nor the amount of travel or residence in a French-speaking country by the teacher led to any differences in students' French achievement.

Carroll found that the French study was very successful in identifying predictors of achievement in French. As an innovation in methodology, he pooled the data across countries and used canonical regression analyses to explore the "international French classroom." He estimated, among other things, that 5–6 years with three or four weekly lessons were required to achieve a satisfactory level of reading comprehension (Carroll, 1975, pp. 227–64).

The domain specification and the sampling of tasks for the three populations (A, B, and C) of the Study of Written Composition are presented in Table 17.2.

The key findings of the study of written composition, again as summarized on the IEA website, were as follows:

- The construct "written composition" was found to be sited in a cultural context and so cannot be considered a general cognitive capacity or activity. Marked variation across the countries existed both in the ideology of the teachers and in instructional practices. Written performance was also found to be task dependent.
- Good compositions from different countries shared common qualities of handling of content and appropriateness of style, but these qualities had their national or local characteristics in organization, use of detail, and other aspects of rhetoric.
- Students across educational systems had in common a sense of the importance of the written product and its surface features. Beneath that commonality, however, there was national variation in the perception of what is valued.
- In most countries, girls were treated differently than boys in the provision of writing instruction and in the rating of writing performance, particularly at the primary and lower secondary school levels, where women largely provided instruction. In such a milieu, the most successful students were girls, and gender itself, or gender in combination with certain home variables, was the most powerful predictor of successful performance, particularly on the more "academic" tasks.
- Differences between the ratings of student writing were not explained by differences in instruction. They were, however, accounted for by factors involving the characteristics of the home, the reinforcement provided by parents, and the cultural values of the community.

Table 17.2 Domain specification and distribution of tasks among the three populations in the IEA Study of Written Composition

<i>Dominant intention/ Purpose</i>	<i>Primary cognitive demand</i>		
	<i>Reproduce</i>	<i>Organize/Reorganize</i>	<i>Invent/Generate</i>
1. To learn (metalingual/ mathetic)		* Summary (B, C) * Paraphrasing (A)	
2. To convey emotions (emotive)		* Narrative/personal story (A, B)	* Open essay (B, C)
3. To inform (referential)		* Letter to uncle describing a bike (A, B) * Self-description in a letter to pen-pal (A, B) * Formal note to head of school (A, B) * Message to family (A) * Application letter (B, C) * Letter of advice to a younger student (B, C) * Describing an object (B, C) * Describing a process (B, C)	* Reflective essay (B, C)
4. To convince/persuade (conative)		* Application letter (B, C) * Letter of advice to a younger student (B, C)	* Persuasive/ argumentative essay (A, B, C)
5. To entertain (poetic)			* Open essay (B, C)

Note. Several tasks were common for two populations and one task for all three populations.

The IEA studies have been, and continue to be, an important source for considering how to enhance students' learning at the international, national, and local levels. By reporting on a wide range of topics and subject matters, the studies contribute to a deeper understanding of educational processes within individual countries, and across a broad international context.

Current Views or Conceptualization

When the IEA Six Subject Survey was conducted, several participating countries had no prior experience in large-scale assessment. For this reason, national centers were provided with very detailed instructions on sampling and test administration. The order for the actions by test administration instructions were spelled out in minute detail. In fact, the survey served as an effective hands-on training in large-scale assessment methodology.

Since then, there has been considerable methodological progress in international assessments ranging across the whole process: conceptualization (assess-

ment frameworks), domain specification, sampling and design of task rotation, scoring guides, scorer training, data analysis methods, and presentation of results.

By administering different subsets of items to different subsamples of students, broad coverage can be achieved with a reasonable amount of testing time for each student. Such matrix sampling designs have been used in most of the international studies, and they have been implemented in several different ways, such as administration of different forms to different subsamples, and administration of a common core of items to all students along with different forms to different subsamples (Linn, 2002). Current studies, such as the Trends in International Mathematics and Science Study (TIMSS) and PISA, use different versions of balanced incomplete block designs, in which blocks of items are combined into booklets to obtain a balanced order of presentation and to obtain links among the different blocks.

Results of early international assessments were reported in terms of total number of correct scores or average percentage of correct scores until the late 1980s. However, when matrix sampling designs are used such reporting tends to be complicated and inefficient. Starting with the TIMSS 1995 study, the international studies have relied on item response theory (IRT) techniques to put results obtained by students taking different combinations of items onto a common scale. These techniques model the probability of a correct answer in terms of invariant item characteristics such as difficulty and discrimination, along with student ability, and they provide a basis for estimating performance on a common scale even when students have been given different subsets of items. Given that there is an overlap of items in successive assessments, IRT can also be used to put these onto the same scale, thereby allowing investigations of trends in performance.

Starting with the IEA Reading Literacy Study (Elley, 1994) the international studies reported their results on a scale with a mean of 500 and a standard deviation of 100. This study did not use a matrix sampling design, but it was the first international study that relied on IRT techniques (the Rasch model) to scale the data. Such scaling results in both positive and negative scores, and before publication these results needed to be transformed into more meaningful numbers. While the choice of the mean of 500 and standard deviation of 100 was arbitrary, it carries the advantage that results can be reported in terms of integer values without any decimals, and it has been adopted as a standard scale for reporting results from international studies.

Much of the reporting of international studies focuses on means, but there is also great interest in measures of variability, and in levels of performance at different percentiles. All this information can be obtained with the IRT-based scales, and it is regularly provided in the international reports. However, the simplicity and accessibility of the reporting are somewhat deceptive, because it is based on complex techniques that are not easy to apply in secondary analyses. Thus, the estimation of different statistics computed from matrix sampling designs requires the use of several so called "plausible values" computed for each student, and user-friendly software to support such analyses has only recently become available.

While the main emphasis in reporting is typically put on a single score representing the general level of performance in the domain under investigation, the international studies generally also report separate scores for different subdomains.

This information can, for example, be used to describe achievement profiles within countries in relation to different curricular emphases.

Both PISA and PIRLS have devoted a lot of attention to the scoring of constructed response answers. For instance, PIRLS provides, for each constructed response item, an analysis of what aspect of the construct it measures and what characterizes an acceptable, unacceptable, partial, or complete answer. In addition, authentic examples are provided to further clarify the qualitative differentiation between different responses. Such procedures have improved the reliability of scoring in international assessments.

Translation has also become a topic of growing priority. This will be discussed in more detail below.

Current Research

Summary of Current International Assessments

This section presents the main features of the current PISA, PIRLS, and the European Survey on Language Competences (ESLC), mandated by the European Council of the EU. For economy and comparability, these most recent large-scale international assessments in the domain of languages are presented in Table 17.3. Several new aspects will be discussed below.

Recent European Studies of Foreign Language Proficiency

Over the years, compared to other subjects, international surveys of foreign language proficiency have been sparse. Among them, a few should be mentioned.

The Assessment of Pupils' Skills in English in Eight European Countries In 2002, a European survey of English proficiency at the end of compulsory education was performed in eight countries: Denmark, Finland, France, Germany (partly), the Netherlands, Norway, Spain, and Sweden. The survey was initiated by the European Network of Policymakers for the Evaluation of Education Systems and was an expanded repeat of a 1996 study. All in all, around 12,000 students took part in the 2002 study, which comprised tests, a set of self-assessment questions, an extensive student questionnaire, and a questionnaire for teachers (Bonnet, 2004). In spite of certain problems with construct coverage and student representativeness, the study generated data of considerable interest, most of all for national analyses. As for international comparisons, the report emphasizes that the approach taken was to provide broad indications about pupils' performance, and it was not attempted to benchmark countries. Consequently, the comparative perspective was toned down (see http://www.reva-education.eu/spip.php?page=article&id_rubrique=213&id_article=203&lang=en).

The EBAFLS Project In 2002, a decision was taken by the European Council to develop a linguistic competence indicator for foreign language learning. This decision brought about an initiative by institutions in eight EU countries (France,

Table 17.3 Current major international assessments: PISA, PIRLS, and ESLS

Feature	PISA: Reading literacy (OECD)	PIRLS (IEA)	ESLS (EU)
Construct definition	<p>"An individual's capacity to understand, use, reflect on and engage with written texts, in order to achieve one's goals, to develop one's knowledge and potential, and to participate in society" (OECD, 2009a).</p>	<p>Reading literacy is defined as the ability to understand and use those written language forms required by society, valued by the individual, or both. Young readers can construct meaning from a variety of texts. They read to learn, to participate in communities of readers in school and everyday life, and for enjoyment.</p>	<p>The Common European Framework of Reference for Languages (CEFR) serves as the framework for the Survey. A sociocognitive model based on the CEFR's model of language use and learning has been adopted, identifying two dimensions: <i>the social</i> (functional language use in real life) and <i>the cognitive</i> (language as a developing set of competences, skills and knowledge).</p>
Target groups	<ul style="list-style-type: none"> * 15-year-old students * OECD members and several non-members participate 	<ul style="list-style-type: none"> * Students in their fourth year in school, at least 9.5 years old * Approximately 50 countries participate 	<ul style="list-style-type: none"> * Final year of lower secondary education (15–16-year-olds) * Two most popular foreign languages studied (English, French, German, Italian, Spanish) * Approximately 1,500 per language or country; 14 EU member states
Skills and domains tested	<ul style="list-style-type: none"> * Continuous * Noncontinuous * Also: mixed texts and multiple texts 	<p>Two overarching purposes for reading:</p> <ul style="list-style-type: none"> * reading for literary experience * reading to acquire and use information <p>Four types of comprehension processes:</p> <ul style="list-style-type: none"> * focus on and retrieve explicitly stated information * make straightforward inferences * interpret and integrate ideas and information * examine and evaluate content, language, and textual elements 	<ul style="list-style-type: none"> * Listening, reading, writing * Short routing test to select the appropriate test booklet level.
Background	Questionnaires	Questionnaires	Questionnaires
Result reporting	<p>Five processes or aspects of comprehension or reading literacy, condensed in 2009 into three broad categories:</p> <ul style="list-style-type: none"> * access and retrieve * integrate and interpret * reflect and evaluate 	<ul style="list-style-type: none"> * Continuous texts * Noncontinuous texts 	<p>Related to the CEFR levels, using standard-setting procedures.</p>

Germany, Hungary, Luxembourg, the Netherlands, Scotland, Spain, and Sweden) to seek funding for a project aimed to investigate the possibility of producing banks of calibrated anchor items. The project, referred to as Building a European Bank of Anchor Items for Foreign Language Skills (EBAFLS), was granted financial support by the EU for three years (2004–7) and was organized on a cooperative basis, coordinated by Cito in the Netherlands. The project undertook to provide items focusing on reading and listening comprehension in English, French, and German. A large number of items from existing tests in the participating countries were collected, scrutinized, pretested, standard-set, and analyzed. Considerable differential item functioning (DIF) was found, meaning that item difficulties tended to vary considerably among the participating countries. Thus, one of the conclusions of the project was that identical test items could not automatically be used across countries and contexts (www.cito.com/research_and_development/participation_international_research/ebafls.aspx).

Challenges

International assessments have faced and are facing many challenges requiring critical analyses, solid research, and continuous development work.

Translation

Translation guidelines have been an essential part of international assessments. In the late 1960s, the IEA Six Subject survey established a methodology that has been followed and adapted in subsequent assessments. It recommended that two translators be employed who were to be specialists in the subject matter and experienced in item writing. In case of disagreement, a third opinion was to be heard. If possible, back translation was recommended. Literature survey texts were to be translated by a literary translator.

In PISA, high requirements are set for the translators. They are to be professional translators with a good command of the two source languages and cultures (English or French), and to be familiar with the educational systems and cultures of the countries involved and with the topics covered in the assessment.

The translation process recommended by PISA is double (forward) translation but from two parallel source texts, followed by national and international verification (Grisay, 2003; see Figure 17.2). Two calibrated source versions (source texts, STs), English and French, are used. Two translators produce two independent versions (TT₁ and TT₂) in the target language. These are reconciled by a third translator into one national version, verified by still a fourth, independent translator from the International Project Centre. Test booklets are sent to the International Project Centre for a final optical check of the layout of the texts.

Specific instructions are given concerning layout, choice of vocabulary and syntax, and avoidance of irrelevant clues. The translators are reminded that the guidelines provide advice and that cumbersome translations are avoided. The translators are also provided with specific translation notes attached to the texts. For every question item, it is explained whether answering the item requires

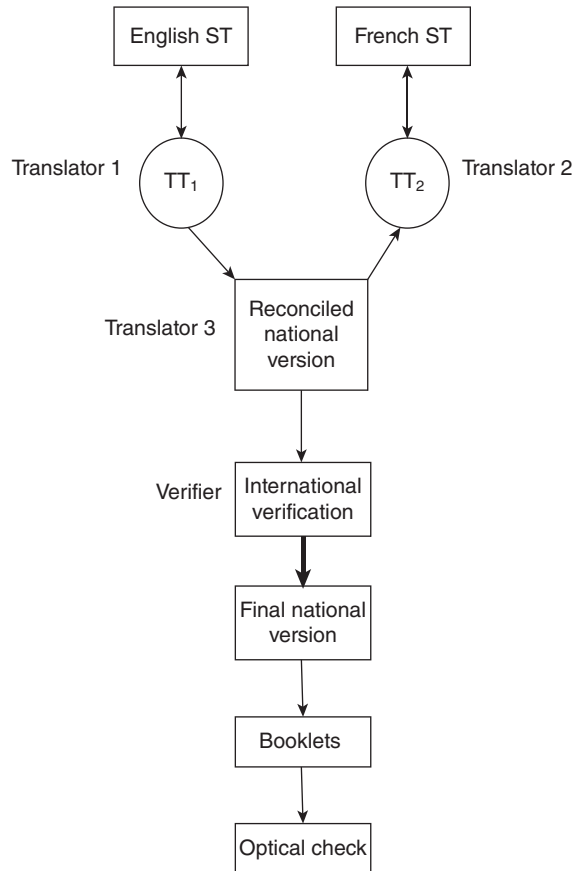

Figure 17.2 PISA translation and verification process (Arffman, 2007, p. 107) © University of Jyväskylä, Institute for Educational Research. Reprinted with permission

general understanding, retrieving information, developing an interpretation, reflecting on the content of the text, or reflecting on the form of the text. This is to avoid changing the nature of the questions and the strategies required to answer them correctly, because such modifications have been found to be one of the most typical reasons leading to shifts in difficulty (see Bechger, van Schooten, de Glopper, & Hox, 1998).

Valid results presuppose that all the different-language texts and translations are equivalent with each other, and hence equally easy or difficult to understand. Given this, it is unexpected that Arffman's (2007) linguistic analysis appears to be the first to explore in depth the equivalence of translations (PISA 2000 reading texts in Finnish). Statistical analyses of item "behavior" across countries have usually been considered sufficient. Another technique used extensively up to the early 1990s is back translation. If the original and the back-translated versions are similar, the target text is deemed to be of high quality and equivalent with the source text. This technique is relatively effective in detecting, for example, miscomprehensions and mistranslations. However, it may put too much weight on

the source text, surface structure phenomena, and literal translation (Grisay, 2003, pp. 227–8), as a back-translated text that is formally equivalent may sound strange and awkward and be difficult to understand. Thus back translation alone cannot guarantee high quality and equivalence with the source text (Brislin, 1986), and more recent reading literacy studies have not utilized it.

Some critical studies have been reported on recent international assessments (e.g., Bechger et al., 1998; Bonnet, 2002). They have pointed out significant shortcomings in the implementation of the studies and cited translations as one potential source of error, bias, and invalidity. This criticism has mainly concerned differences between languages and cultures, and claims that, due to these differences, translations will never be able to ensure full linguistic and cultural comparability. While the critics acknowledge that international reading literacy studies have improved during the last few years, they maintain that the distortions, including defects in the translations, still jeopardize the validity of the assessments.

Scaling Models and DIF

One problem is the effect of the aforementioned DIF on the interpretation of results. Kreiner (2011) claims that the fit of item responses to PISA's scaling model is often inadequate and that the ranking of countries is confounded by this. He offers two ways of dealing with the problem: (1) modeling departures from the scaling model so that measurement can be adjusted for DIF and other problems before countries are compared, and (2) purification by elimination of items that do not agree with the scaling model. Kreiner's criticism was promptly countered by the OECD (Adams, 2011), claiming that the fundamental flaw in Kreiner's argumentation is that he confounds two primary issues: (1) Do the outcomes of PISA depend upon the set of items that are developed and chosen, and (2) does the use of the Rasch model provide misleading results because the data do not *fit* the Rasch model? The conclusion drawn by the OECD is that Kreiner's analyses do not offer a better and more viable alternative than the one used in the regular PISA analyses.

Use of Computer Technology

The use of computer technology at the national and international levels offers great potentials for using a greater variety of more real-life tasks and achieving better cost-effectiveness. However, a certain cautious reflectiveness is called for, concerning theoretical as well as practical implications. Examples of matters to be considered thus range from construct definition to format effects and student computer literacy. Moreover, conducting technology-based assessments internationally poses formidable challenges due to variations in the level of infrastructure and the technological competence of the school staff. All these aspects are related to validity in an expanded sense and need to be discussed and analyzed as such (e.g., Björnsson, 2008).

Several computer-based studies have been conducted as part of large international surveys, e.g., within PISA (the Computer-Based Assessment of Science

[CBAS] in 2006 and the digital reading study in 2009), with full-scale studies being planned for the near future. Thus, it will be of considerable interest to see what the experiences of the IEA 2013 International Computer and Information Literacy Study (ICILS) project and PISA's plan to extend the use of computer-based assessment dramatically in all aspects of the 2015 survey will yield. Furthermore, the ESLC, conducted in 2011 and with a final report delivered in 2012, was offered in both print and digital versions, thereby generating data for interesting analyses.

Volume VI of *PISA 2009 Results* (OECD, 2009b) reports the experiences and results of the digital reading component of the reading literacy study.

Future Directions

As in all types of assessment, at least five fundamental questions need to be continuously addressed, namely *Why, What, How, Who, and And . . . ?* This means that the different aims of international studies must be clarified and modified, constructs analyzed and problematized, and rubrics scrutinized and elaborated on; the same obviously goes for methodology at all stages of the process, for example test development, translation, and analyses of results. The role of different stakeholders is another crucial aspect of the assessment process. However, what may need the most intense attention is the interpretation and use of the results, and, in a wide sense, the various consequences—the impact—that they may have at different educational and societal levels, and perhaps even for individual students and teachers (e.g., Simola, 2005; Novóa & Yariv-Mashal, 2003; Hopmann, Brinek, & Retzl, 2007).

The alignment of content with assessment is likely to be one of the strongest priorities in both national and international assessments. Porter, McMalen, Hwang, and Yang (2011) is a good example of this trend, as it discusses the US core curriculum in mathematics and language arts and compares the results with three “international benchmark countries” with high student achievement: Finland, New Zealand, and Sweden.

As in all assessment, the definition of the constructs and their credible representation is a perennial challenge in international assessments. The breadth and depth of construct coverage are an obvious challenge, but the increased use of computer technology may ameliorate the situation in the future. Noncognitive factors may be expected to receive considerably more attention in national and international assessments. Motivation, liking of school, attitudes, interests, and so forth have been part of many designs in the past, but it is likely that there will be clear progress in doing a better job in future assessments.

Another probable trend is an increase in elaborative studies using the national and international assessment databases. Verhelst (2012) can be cited as an illustrative example. Using a newly developed method of profile analysis, he takes a closer look at the PISA 2000 Reading Data and reports interesting new findings. Sophisticated analyses such as structural equation modeling (SEM) are being used, but it is probable that new approaches will be further elaborated. Increasing attention will most probably be paid to the description and analyses of trends over

time in individual countries, thereby perhaps, to some extent, decreasing the interest shown in international comparisons that, so far, has often been the focal point of many comments and analyses. It can also be expected that there will be closer links to the educational effectiveness research (EER), which can be expected to have a positive impact on international assessments.

Large-scale assessments, both national and international, are here to stay. If the past fifty-odd years are anything to go by, the number of both assessments and participants will increase. International assessment is a “growth industry” (see ETS, 2011).

In spite of the growth of the international assessments and the increasing interest in the outcomes at many levels of stakeholders, there has been an undercurrent of critical response. As expected, the research community has found several grounds for critical views, especially concerning the methodology used and the validity of the findings. There has been hand-wringing and occasionally some drastic policy measures in countries that have done less well than expected, and admiration and envy of the high achieving countries, but it would appear that there has been little complacency in the latter. For instance in Finland, which has done well in PISA, the good results have caused a pleasant surprise but the dangers of complacency have often been voiced. It has been pointed out that the educational system has a number of problems to cope with, requiring continuous and consistent development work. Indeed, it would be useful to conduct systematic analyses of what discussions have emerged and what actions have been taken in well-performing and especially in less well-performing countries. Are there any signs of adapting teaching, testing, and examinations, and even national curricula, to be aligned with the PISA approach—“teaching to the test” in order to obtain a higher ranking? In other words, what is the inevitable impact of large-scale, comparative studies, whether perceived as positive or as negative?

There is widespread agreement that international assessments are extremely challenging and complex, posing questions about validity ranging from construct definition and coverage to interpretation, use, and consequences. Since large-scale assessments of the kind dealt with in this chapter have considerable influence at pedagogical, political, and personal levels, issues of impact must be given continuous attention. Equally important, however, is the fact that viewing the world as an “educational laboratory” or “educational experiment” holds promise for exploring and generating hypotheses, testing them, and gaining a better understanding of systemic and cultural effects. This means that, at best, international assessments can inform policy in positive directions concerning the learning of students as well as teachers, decision makers, and politicians.

The authors wish to acknowledge the valuable comments and suggestions by Professor Jan-Eric Gustafsson, University of Gothenburg, on the methodological discussion.

English Language Proficiency Assessments as an Exit Criterion for English Learners

Mikyung Kim Wolf
Educational Testing Service, USA

Timothy Farnsworth
CUNY Hunter College, USA

Introduction

It is increasingly common in English-speaking countries that K-12 school populations include students for whom English is a second language. These students are very diverse in terms of their cultural and language background as well as in their formal schooling experiences. The students may be new immigrants, or may have grown up in English-speaking countries but be from homes where another language is spoken. The English and home language proficiencies of these students therefore vary widely. Some students' home language might not be fully developed, in particular in terms of literacy, while they simultaneously learn English. Students who have grown up in English-speaking countries may have oral proficiency for communicating in daily life, but lack English literacy skills for performing academic tasks in school.

The terminology to refer to these students in K-12 schools is also varied across countries, although *English as a second language (ESL) students* has been the term most used in the literature. In the USA, *English language learner (ELL)* or *English learner (EL)* is an emerging term in official documents and literature, moving away from the term *limited English proficient (LEP)* students. In England, the term *English as an additional language (EAL) students* is officially used to encompass both newcomers and students who have been in the country for longer but whose home language is not English. In Ontario, Canada, the term *English literacy development (ELD) students* also appears in K-12 official documents. In this chapter, we will use ELL, as we will primarily focus on the US context in discussing the exit assessment issues of this population.

In this chapter, we focus on the assessment of English language proficiency (ELP) of ELL students in K-12 schools. As this chapter contributes to the theme of

assessment contexts, particularly for exit examinations, in this book, we highlight the use of ELP assessments to exit students from ELL designation or ESL programs and move them into English-only mainstream classrooms. We present an overview of the contexts in which ELP assessments are used for this specific purpose for ELL students and discuss how the contexts or policies are tied to the design and development of the assessments. We also discuss a set of general, but essential, issues to consider in validating an ELP assessment for making exit decisions about K-12 school-aged ELLs. We anticipate that the issues discussed here will be relevant across many countries where ELL identification and reclassification decisions are partly based on ELP assessment results.

This chapter is structured as follows: We provide a brief overview of large-scale ELP assessment practice for ELL students in US K-12 schools. Then we discuss three points: (1) issues in ELP assessment constructs, (2) issues in developing and using ELP assessments for an exit decision, and (3) validation considerations including technical qualities and consequences. Throughout the chapter, we use examples of sample assessments and standards from the USA in order to facilitate our discussion.

The Composition of ELL Students

Understanding the diversity of the ELL population is crucial for these students' instruction and assessment. In US K-12 public schools, there are over 5 million students officially designated as ELL, comprising nearly 11% of the total public school enrollment in the school year of 2008/9 (Office of English Language Acquisition, Language Enhancement, and Academic Achievement for Limited English Proficient Students [OELA], 2011). These figures do not include all students who are non-native speakers of English, only those who are officially designated as ELL to receive specific ESL services. The pace of this population growth is very rapid. Over the 10-year period from the 1997/8 to the 2007/8 school year, the ELL population grew by over 51%, while the total K-12 population growth was just over 7% in the USA (OELA, 2011). This substantial growth in the ELL population is also a trend in other English-speaking countries due to increasing immigration and the globalized economy. For instance, over 20% of the total school population was reported as ELL in Ontario, Canada (Jang, Wagner, & Stille, 2011).

US ELLs' home language backgrounds are tremendously diverse. Although Spanish is reported as a home language for 75%, over 400 home languages are reported for K-12 ELL students (Kindler, 2002). Time of entry to US schools is another important factor to consider with respect to student diversity. Interestingly, about 50% of ELL students were born in the USA, starting their schooling there from kindergarten (Capps et al., 2005). There are many students who enter US schools with high quality formal schooling experience in their native countries, while others such as refugee students have had limited formal schooling experiences previously. These factors signify the complexities of developing and utilizing the assessment of ELP appropriate for this diverse group of students.

Policies and Contexts for the Use of ELP Assessments

The use of ELP assessments for K-12 ELL students is closely tied to educational reform policies. For example, federal legislation in the USA (known as the No Child Left Behind Act, or NCLB) mandated that all states annually measure ELL students' attainment of ELP, based on their ELP standards for accountability purposes (US Congress, 2002). The Act also required states to set an objective of annually increasing the number of ELL students meeting English proficiency standards (the standards themselves were left to states to determine). This policy led states to develop or adopt ELP standards and align new ELP assessments with the standards. Further, it increased the importance of ELL identification and reclassification procedures as states determined the target population that should be reported. Once the students are identified as ELLs, primarily based on an ELP assessment, they are placed into appropriate instructional programs such as bilingual instruction or ESL programs. With the federal mandate, the ELL students are given an ELP assessment toward the end of the school year to measure progress in their English attainment. The test results are used as a primary criterion for reclassification decisions, in conjunction with other criteria such as subject matter test results and the inputs from school personnel and parents, depending on each state's policy (Wolf, Kao, et al., 2008). It is important to note that state policies regarding exit criteria vary widely, as the examples below demonstrate. As the ELP assessments involve high stakes decisions including ELL designation, instructional placement, and further school and district evaluation, the validation of test quality and uses is of great significance.

To illustrate these issues, we discuss two examples of ELP assessments being used to identify and exit ELL students in two states with large ELL populations: California¹ and New York. Then we discuss specific issues to consider in developing appropriate ELP assessments to be utilized for making ELL exit decisions.

ELP Assessment Examples

Example 1: California English Language Development Test (CELDT)

California has the largest number of ELL students: as of 2009, approximately 1.5 million children, or 24% of total school enrollment (California Department of Education, 2010). The state uses a test called the California English Language Development Test (CELDT) as its standards-based large-scale ELP assessment. This was developed by a test publisher in conjunction with the state department of education. The state's guideline document describes the CELDT as used for three purposes: (1) identifying and reclassifying ELLs, (2) determining ELL students' ELP, and (3) monitoring the progress of ELLs in their English language development (California Department of Education, 2011).

When students enter a new school for the first time, a home language survey is administered. If this indicates that the student does not primarily speak English in the home, the CELDT is administered within 30 days. If they do not initially

meet the cut score designation for “fluent” English users, they are designated as ELLs and receive services which range from intensive standalone ESL coursework via after-school programs to tutoring centers within the school. Thereafter, students are assessed yearly using this test. The test is also used as a primary exit criterion from ELL designation; cut scores for “fluent” designation depend on grade level within a test version. CELDT scores are used in conjunction with the state’s English language arts (ELA) assessment (where ELL students must meet a “basic” proficiency level designation), a formal teacher observation, and consultation with parents to remove the ELL designation and transition the student out of ESL-specific services.

The CELDT has different forms for separate grade bands: K-2 (K-1, 2), 3–5, 6–8, and 9–12, assessing all four modalities of reading, writing, speaking, and listening. Until 2010, the K-1 version of the test did not include a writing component. The CELDT was designed to align with California state standards for English language development, which provide a five-level description across grade spans, and are linked explicitly to state ELA standards. Thus California’s English Language Development (ELD) Standards explicitly discuss skills such as responding to literary works. However, they are not aligned with or explicitly linked to other content area standards such as science. As a result, the construct and content of the CELDT tend to reflect the content focus of the ELA standards in addition to language skills delineated in the different levels of the ELD Standards.

Questions for each language modality are organized into subsections. For the listening section, these are “following oral directions,” “teacher talk,” and “extended listening comprehension.” The reading section contains “word analysis,” “fluency and vocabulary,” and “reading comprehension” items. The speaking section includes “oral vocabulary,” “speech function,” “choose and give reasons,” and “picture narrative.” Lastly, the writing section has “grammar and structure,” “sentences,” and “short compositions.” Speaking is measured using an interview format by qualified local school personnel. Simple holistic scoring rubrics are used to score the speaking and writing sections.

Scores are reported as separate scaled scores for each of the four modalities along with an overall combined score. To be exited from their ELL designation, students’ overall combined score must meet at least the “early-advanced” level (level 4 out of 5) and their performance on each modality section should reach at least the “intermediate” level (level 3 out of 5).

Example 2: New York State English as a Second Language Achievement Test (NYSESLAT)

New York is another state with a large number of ELLs, particularly in New York City, the nation’s largest school district. As of 2008, there were about 150,000 ELLs in city schools, or about 14% of total school district enrollment, and about 200,000 ELLs in the state overall (Hayes, 2009). The New York State English as a Second Language Achievement Test (NYSESLAT) was developed by the state department of education to assess these students’ proficiency in English language development. Like the CELDT, the NYSESLAT is a single assessment serving multiple purposes: determining proficiency in English, monitoring

progress and determining ELL exit, but not for initial identification of ELLs. This identification is achieved by administering a test called Language Assessment Battery-Revised (LAB-R) to students who indicate on a home language survey that a language other than English is spoken at home. Students designated as ELL are thereafter assessed yearly using the NYSESLAT. Services these students receive mirror the California services, with the addition, in many schools, of bilingual education programs which parents can opt into or out of for their children. New York, in contrast to California, uses the NYSESLAT as the sole criterion on which to make an ELL exit decision. Other information, such as input from teachers and parents, and school performance in content area subjects or on other standardized tests, is not used to make this determination (New York State Education Department, 2011).

There are multiple forms of the NYSESLAT, each covering a band of two to three school years (i.e., grades K-1, 2-4, 5-6, 7-8, and 9-12). Every form of the NYSESLAT tests all four modalities. The test is designed to measure the constructs described in the New York State ESL standards. As in California, the ESL standards are expected to link with the state's ELA standards. In the case of New York, ESL standards were written by restating the ELA standards. For example, standard 1 of the New York State ELA standards states "Students will read, write, listen, and speak for information and understanding." The ESL version of this standard states "Students will read, write, listen, and speak for information and understanding *in English*." This view of English language development standards as essentially a parallel version of ELA standards is reflected in the content of the NYSESLAT test items.

Questions for each modality are again, organized into subsections. The listening section includes "word cluster comprehension," "comprehension of conversational language," and "task-based listening." The speaking section contains "sentence completion," "story telling," and "picture description." The speaking section is administered and scored by qualified school personnel, typically the students' teacher. In addition to writing convention items, the writing section requires the students to prewrite and then compose a short essay. Both the prewriting and the writing are scored. Essays have assigned topics which have included themes in social studies, health (nutrition), and literature.

Scores are reported as two separate scaled scores: one based on a combination of listening and speaking, and the other on a combination of reading and writing. The exit criterion for ELL designation in New York is achievement of a "proficient" level (level 4 out of 4) on both the listening and speaking and the reading and writing subscores.

Due to the different nature of the language construct measured on the CELDT and the NYSESLAT tests, it is difficult to determine to what extent a California ELL designation and a New York ELL designation are comparable. From the two states' ELP test examples, several questions emerge regarding the development and validation of ELP tests for the use of exiting ELL students. Do the ELP test constructs include the language skills needed to handle academic materials in school settings, in addition to the social language demands of school and society? Are the students who pass the ELP test truly ready to be in mainstream classes without ESL support? Considering the variation among states' standards, which

standards best reflect students' progress toward language proficiency? Is the cut-off score for the "early-advanced" or "proficient" levels adequately established? Do the students have the opportunity to learn language skills measured in the tests throughout the school year? In what follows, our discussion is primarily concerned with the construct and content of the ELP tests, the levels of proficiency and their corresponding cut-off scores, and types of validity evidence to support the ELP tests uses for exiting ELL students.

Constructs of ELP Tests: Language Proficiency for Academic Contexts

One of the consequences of exiting ELL students from the ELL designation is that the students will no longer be entitled to language support in their academic learning in most cases (e.g., no ESL classes, no ESL teacher support in mainstream classes, and no testing accommodations). Thus it is critical that ELP tests measure students' language proficiency needed for academic contexts. In turn, the students' ELP test scores and the levels associated with the scores should indicate that the students possess ELP to handle academic materials and tasks in school settings. A substantial body of literature has promoted the importance of assessing students' academic language proficiency as well as social language proficiency for school settings (e.g., Bailey & Butler, 2003; Francis, Rivera, Lesaux, Kieffer, & Rivera, 2006; Butler, Steven, & Castellon-Wellington, 2007; Snow, 2008). Researchers assert that traditional ELP assessments tend to focus primarily on social language, with little attention to the academic language skills the ELL students need to be successfully engaged in school settings. That is, due to the limited construct being measured, the results of the traditional ELP tests are criticized for not reflecting whether the ELL student is at the level of readiness or competency to perform in an academic setting. The problems in the construct being measured and therefore in the reliability of the ELL classifications results from those ELP tests have been noted in prior literature (Del Vecchio & Guerrero, 1995).

As a result, there was a movement toward the development of ELP tests to measure both academic and social language skills for ELL students. One of the challenges in developing ELP tests for ELL classification and exit decisions lies in establishing a common, operational definition of academic English to put into assessment. Since Cummins (1981) introduced the notion of cognitive academic language proficiency (CALP) and basic interpersonal communicative skills (BICS), based on the cognitive and context-based demands of language use, much research has been conducted to advance our understanding of academic English language beyond this dichotomous classification. Bailey, Butler, LaFramenta, and Ong (2004), for example, examined school standards, curricula, and academic texts in order to identify academic English language characteristics and develop an operational framework of academic English for K-12 ELL students for assessment. The researchers particularly focused upon two complementary academic language features: linguistic forms and academic language functions. These two features have been elaborated in other literature as well. For example, Schleppegrell (2004)

points out that certain linguistic forms are more frequently encountered in academic texts. For instance, to explain a concept in a succinct manner, a science text often has sentence structures with a nominalization (e.g., “a *chemical reaction* of X and Y is a common phenomenon,” instead of saying that X and Y react chemically and it is a common phenomenon).

Chamot and O’Malley (1994) identify specific academic language functions including *analyzing, comparing, predicting, persuading, solving problems, and evaluating*, and suggest specific linguistic features used to perform these language functions. Gottlieb, Katz, and Ernst-Slavit (2009) further delineate the academic language skills needed for specific subject matters including social studies, science, and mathematics.

This emerging research on academic English language has been incorporated into the current ELP assessment development to varying degrees. Wolf, Wang, and Holtzman (2011) compared the language demands and language characteristics across a sample of the current ELP tests. The researchers found that there were different degrees and types of academic language features in the tests they examined. For instance, one test contained more subject matter-specific items (e.g., mathematics and science), focusing on the academic language uses in learning content materials, while another test tended to include more general academic English items and more social contexts. The findings indicate that, depending on the test a student takes, the inference that can be made about a student’s ability would be quite different. Moreover, it may take longer to exit from ELL designation depending on the test construct. If indeed academic language for school success takes longer to acquire, tests which measure it will likely exit students later than tests which focus on social language. While it is inarguably important to include the academic language construct in ELP assessments for K-12 ELL students, a common framework for defining the construct of both social and academic language would be beneficial in order to make fair and valid ELL exit decisions.

Alignment with Standards: Challenges in Operationalizing the Standards into Assessment

Another important factor to consider in developing and using ELP assessments for an ELL exit decision is how to incorporate the standards into the construct of the assessment. In K-12 schools, standards-based education is commonplace. The standards guide the content of instruction, and in turn, that of the assessment. With respect to the impact of standards on ESL classrooms in schools, Breen et al. (1997) conducted a large-scale teacher survey and found that teachers were generally influenced by the standards in their professional understanding and in their instructional planning. The researchers report that the ESL teachers highly valued an assessment framework which informed their students’ development processes in English and offered information on specific teaching strategies and curriculum support.

ELP standards typically contain language proficiency levels to illustrate language development stages and reasonable expectations for ELL students at

different levels of proficiency. The prior literature illustrates the need for deep understanding and consideration of different learning contexts in the development of an English assessment for this population. As North and Schneider (1998) note, when defining proficiency levels, the extent to which the levels are distinguishable and supported based upon second language acquisition (SLA) theory is also an important aspect to be considered.

Some well-known ELP standards include the Common European Framework of Reference for Languages (CEFR) (Council of Europe, 2001) and the International Second Language Proficiency Ratings (ISLPR) (Ingram & Wylie, 1997/1999), formerly known as Australian Second Language Proficiency Ratings. England also has national standards for students of English as an additional language. These standards tend to be general to be applied in any context of language learning, with focus on the communicative use of language. Jang et al. (2011) point out that ELP standards for K-12 ELLs should consider curricular learning in addition to language learning itself. That is, language proficiency specific to school contexts needs to be integrated into the standards.

One reason for the difficulty of direct assessment of standards is that they are not written for the assessment development, but for other various purposes. McKay's (2000) review on ESL standards for school-aged learners in a few countries (e.g., Australia, England, the USA) provides insights into the different types of standards and their potential impact on English curricula and assessments. McKay notes that there were different natures and purposes in the standards across and sometimes even within countries. For instance, some standards reviewed in her study were constructed for the purpose of "planning" instruction. Other standards were designed for the purpose of "professional understanding" of stages of learning. As the standards are not necessarily written for the assessment development, identifying language skills embedded in them and sampling the language skills to be measured in the limited assessment context is an important step to take for the assessment development. McKay also points out that standards are structured to varying degrees for describing a proficiency scale. Some standards contained two separate descriptor levels: one for the primary grades and the other for the upper grades. On the other hand, some standards delineated one proficiency scale for all school-aged students (i.e., K-12). These various levels of proficiency also add a complexity to developing appropriate ELP assessments for K-12 ELL students.

In the USA, all states have developed or adopted ELP standards for ELL students due to federal policy requirements. Unlike general ELP standards in some countries, states' ELP standards in US K-12 schools are to be aligned with academic content standards (e.g., ELA, mathematics, science, and social studies) in terms of language and cognitive demands. The underlying rationale for this requirement is that ELP standards are employed to help ELL students achieve better access to content-area learning. Thus, special attention was paid to the characteristics of academic language needed for ELL students. As research on the academic language characteristics for K-12 school settings is an emerging area, the content of states' ELP standards varies considerably with regard to the details and expectations at each level of proficiency. For instance, California's ELD

Standards have five levels for each domain of reading, writing, and listening and speaking. New York's ESL standards include overall descriptors for elementary, middle, and high school grades. The New York standards document does not include descriptors for the levels of proficiency. Instead, it gives examples of tasks and performance indicators at three proficiency levels of beginning, intermediate, and advanced. The following examples are from the highest level for the domain of reading comprehension in the standards from California and New York states, respectively.

California, comprehension and analysis of grade-level-appropriate text: advanced level (California Department of Education, 2002, p. 8):

- Read and orally respond to familiar stories and other texts by answering factual comprehension questions about cause-and-effect relationships.
- Read and orally respond to stories and texts from content areas by restating facts and details to clarify ideas.
- Explain how understanding of text is affected by patterns of organization, repetition of main ideas, syntax, and word choice.
- Write a brief summary (two or three paragraphs) of a story.

New York, standard 1 for intermediate grades 5–8 (New York State Education Department, 2004, p. 60):

- Students will listen, speak, read, and write in English for information and understanding.
- Students learning English as a second language will use English to acquire, interpret, apply, and transmit information for content area learning and personal use. They will develop and use skills and strategies appropriate to their level of English proficiency to collect data, facts, and ideas; discover relationships, concepts, and generalizations; and use knowledge generated from oral, written, and electronically produced texts.

Clearly, these examples indicate the different nature of standards employed in practice. California's standards distinguish the modalities of reading, writing, speaking, and listening, with specific descriptors for different levels of proficiency per modality. On the other hand, New York's standards focus more on the instructional perspectives by integrating all modalities into one standard and describing example tasks and performance indicators. As a result, California's example includes more detailed description of reading skills whereas New York's example contains general tasks involved in any language modalities. It is also notable that both states' standards list tasks that students would encounter in academic contexts.

Assuming that students receive instruction based on these standards, it is critical that ELP assessments used for an ELL exit decision should measure the students' proficiency reflecting these standards. In the case of the US schools, states must ensure that their ELP assessments are aligned with their states' standards to warrant a fair decision for students.

Establishing the Levels of Proficiency and Cut Scores

Our discussion has been concerned so far with the construct and content of ELP assessment for an exit use. Once it is established that the assessment covers the appropriate construct and content for the context of students' language uses and specific standards of instruction, the test scores must be mapped to different levels of proficiency. The next crucial aspect of developing and using an ELP test for an exit decision is to establish the cut scores for each proficiency level. Determining the cut score, or the level that students should achieve to exit ELL status, requires rigorous standard-setting procedures. As exit tests typically entail a high stakes decision, it is critical to provide empirical evidence to support cut score decisions for each proficiency level.

A common standard-setting procedure involves experts' judgments. For instance, in bookmarking, a panel of qualified content experts (e.g., teachers, curriculum specialists) reviews a booklet of items that have been ordered by difficulty, and judges the difficulty level of each item for each proficiency level. The results provide quantifiable data to determine cut scores. Having an appropriate panel and a high level of rater reliability is thus of tremendous importance.

Another factor to consider in determining the proficiency level for an exit criterion is the consequences for the students and schools. Suppose that an ELP test divides scores into five levels of proficiency and that the exit criterion is attainment of the highest level, level 5. It is then likely that fewer students will meet the criterion and more will stay as ELLs; that is, it may take longer for an ELL student to exit from ESL service, which will lead to more long-term ELL students and the need for more resources to support them. This is even more likely to be the case when exit decisions depend on information about the students' overall academic achievement in addition to the test scores. On the other hand, if the exit criterion is lower, say level 4, it may take less time for a student to exit from the ESL service and move to a mainstream class. Depending on the context (e.g., high school ELL students), it may be desirable for ELL students to be placed in mainstream classes sooner so that they have more time to keep up with mainstream work. Kim and Herman (2009) examined the academic performance of exited ELL students on content-area tests such as ELA, reading, and mathematics. The researchers found that students recently exited on a high criterion performed as well as or better than their non-ELL peers, while students exited on a lower criterion generally performed less well than their non-ELL counterparts. However, a closer examination of students exited earlier indicated that both criterion groups performed comparably to their non-ELL peers after two years. The researchers suggest that the optimal level of exit criterion should consider not only students' academic performance but also school and policy factors to best serve students' needs.

Validation Considerations: Technical Qualities and Consequences

Validation is an ongoing process to ensure that the assessment results are appropriate for their intended uses. In using an ELP test for exit purposes in public

schools, the stakes are high, impacting individual students' academic paths and school or program evaluation. It is thus critical to continuously examine the validity of assessment uses as new groups of students take the test and programs or instruction change over time. In this section, we highlight important issues and considerations in validating ELP tests for making ELL exit decisions.

As a framework to organize the test score-based interpretations and their supportive evidence, an argument-based approach to validation has been useful in language testing (Kane, 2002; Bachman, 2005). In articulating a validity argument, not only interpretations about students' abilities based on the test scores but also decisions or uses of test results are an essential piece to be included in the argument. Kane (2002) describes the former as a descriptive interpretation and the latter as a decision-based interpretation. Bachman attempts to capture this notion as an interpretative argument and a utilization argument. In making utilization arguments, both intended and unintended consequences of the test use should be examined (Bachman, 2005). These concepts provide valuable insight into examining validity evidence.

To support these test score interpretations and exit decisions, evidence to be collected can be organized according to two perspectives: technical qualities of test scores and consequences of the test use. As the consequences of an exit test are substantial, ensuring that the test scores demonstrate high technical quality is an essential piece of evidence. Among various types of evidence, we consider the following areas the most pertinent and critical.

Reliability evidence: Validity of interpretations based on test scores would be unwarranted without reliability evidence. Internal consistency and inter-rater reliability for the constructed response items must be examined and an acceptable level of reliability estimates should be obtained. Reliability evidence should also include consistency in decisions about students' ability and ELL classification.

Construct validity evidence: As discussed earlier, the construct of language abilities included in ELP tests can vary depending on what standards and academic language frameworks the tests were based upon. In order for test users to support the claim of passing students being ready to exit ELL status, it is crucial to examine what types of language ability are measured in the test. It is equally important that the construct and content of the tests are aligned with those in the standards. A central concern should be the degree to which the language demands of the ELP test are aligned to those delineated in both ELP and content standards. In other words, ELP tests' construct and content should reflect the language demands and skills that students would need to successfully engage in content-area classes. A finding of strong alignment would provide validity evidence to support the use of ELP tests to make a decision about exiting ELL students.

Consequential validity evidence: Linqunti (2001) stresses that ELL exit decisions have tremendous consequences for students and the schools. He asserts that a clear understanding of what ELL students should demonstrate in order to exit from the ELL designation needs to be obtained across policy makers, educators, and test developers. This concern requires broader validation work for exit tests, including an investigation of the policies and consequences of the decisions. One crucial area is how exited students perform in mainstream classes without ESL support, compared to their non-ELL peers. This should be examined longitudinally since some

early-exited students may need transition time to adjust themselves to new instructional programs. The exit level or cut scores should also be carefully examined in terms of the test content and standard-setting procedures. In the process, the credibility of validity arguments and evidence may be accepted to different degrees in different contexts. As seen in a study by Kim and Herman (2009), different cut scores to exit ELL programs may be valid depending upon the resources available to serve exited or non-exited ELL students.

Instructional validity evidence: An exit test cannot in fact be fair if students are not provided with appropriate opportunities to learn the knowledge and skills that will be assessed. Inadequate opportunity to learn, or instructional validity, is a serious threat to the validity of exit tests (Garcia, 2003). Although it is usually ignored by validity researchers, an investigation of instructional programs and the content provided to ELLs is an important component of a validity argument.

Conclusion

In this chapter, we have reviewed some sample ELP standards, policies, and assessments used for making exit decisions about ELL students in K-12 schools. We have also discussed a few key issues in developing appropriate ELP assessments for this particular purpose: defining constructs, being aligned with standards, and establishing an exit proficiency level. Additionally, we have highlighted critical validation considerations including the technical qualities and consequences of the test use. At this time, there is a critical need for more, and more public, validation work in these areas (Wolf, Farnsworth, & Herman, 2008).

Our discussion illustrates the fact that educational policies and contexts are intertwined with and dependent upon assessment development and valid test uses. In developing tests for making exit decisions about students, it is important to identify the contexts or domains which are most critical to student achievement outside of ESL education contexts, and then to design tests which target this construct. Finally, we have discussed some unique challenges in developing and validating ELP assessments for making decisions about exit from ESL services. Not enough is known about critical questions such as the level of academic language ability needed to succeed in school as a second language learner, the relative importance of oral versus print modalities, and other issues. The lack of agreement among states as to what constitutes evidence of ESL language proficiency—in some states the ELP tests alone, in most others a combination of evidence—illustrates the overall lack of knowledge in this area. As Chalhoub-Deville (2009) notes, validation efforts should be the shared and negotiated responsibilities of test developers and users when assessment uses are driven by policies. In the case of ELP assessments for K-12 ELLs, it is crucial for test developers and language-testing researchers to work together closely to increase the valid use of tests for exit decisions.

Tests of English for Academic Purposes in University Admissions

Cathy Wendler

Educational Testing Service, USA

Introduction

For more than a century, applicants to universities have been tested to gauge their level of subject matter knowledge, their reasoning ability, and their level of proficiency in specific areas deemed important by the university. Tests given at the college or university level are generally of two types: *placement* and *admissions*. *Placement* tests are used to determine whether students are in need of particular resources, such as English or mathematics support, and to place them into classes of the appropriate level. *Admissions* tests are used to determine whether applicants have the requisite level of certain knowledge, skills, and abilities (such as English proficiency) deemed necessary for success at the institution.

In this chapter we first present a brief historical overview of the origins and development of tests of English for academic purposes (EAP) used in admissions decision making. This overview is followed by a discussion of current trends in EAP tests in the areas of defining and operationalizing test constructs, test delivery methods, scoring methods and technologies, and score reporting and interpretation. In this discussion, emphasis is placed on validation research associated with major EAP tests for admissions. Finally, we conclude with a discussion of research and development issues and future trends.

The History and Growth of EAP Tests in Higher Education Admissions

Measuring language proficiency in applicants to postsecondary institutions is now a well-established practice. Typically, a minimum cut score on English language

tests is established to screen applicants who are non-native speakers of English, and this information is used along with other indicators of their potential for academic success to make admissions decisions, such as their high school or college grade point average (GPA) and scores on standardized aptitude tests. One of the earliest admissions tests for speakers of other languages was introduced in 1913 by the University of Cambridge. This examination, the Cambridge English Proficiency Exam, was for entrance into the university. However, given the relatively small number of students applying from other countries, few other universities or colleges screened non-native English speakers at that time.

In the early days of admissions testing in the United States, admissions tests were unique to the institutions that created them. Due to disparities across tests at different colleges and universities, the College Entrance Examination Board was formed in 1900, with the goal of establishing more uniform standards for admission to American colleges. The development and use of standard admissions tests continued to expand during the 20th century, focusing on applicants' knowledge in specific subjects and on verbal and quantitative reasoning skills. The SAT® and its derivatives were administered beginning in 1926, the American College Test (ACT®) in 1959, and the Graduate Record Examinations (GRE®) in 1949. The 20th century also saw continued growth in student diversity in higher education, with more and more individuals from non-English-speaking countries seeking admissions into postsecondary institutions in the United States.

In 1961, the National Council on the Testing of English as a Foreign Language, comprised of representatives from 30 governmental and private organizations, was formed to address the issue of English proficiency for non-native speakers of English applying to US institutions of higher education. Ultimately, the Council recommended the creation of an English proficiency examination that would be used in conjunction with other criteria for university admissions. In 1964, the first large-scale assessment measuring the English proficiency of English as a second language (ESL) and English as a foreign language (EFL) students, the Test of English as a Foreign Language (TOEFL®), was introduced.

Since the late 1970s, with gradually increasing numbers of graduate students seeking university education in English-speaking contexts, the landscape of EAP testing at the tertiary level has changed significantly. The TOEFL test has gone through several major revisions in response to test-user demands and continuing developments in the theories and practices of language learning, teaching, and testing. Until 1979, the TOEFL test included three sections: reading, listening, and structure and written expression. With the emergence of communicative language teaching (CLT) in the 1980s, the Test of Spoken English (TSE) was introduced into the TOEFL suite in 1979, and the Test of Written English (TWE) was added to the TOEFL test in 1986. A computer-based version of the TOEFL was created in 1998 that included reading, listening, and writing sections. In 2005, a completely redesigned TOEFL Internet-based test (iBT™) debuted. The TOEFL iBT tasks assess reading, writing, listening, and speaking in more authentic communication contexts that require the ability to use multiple language skills in an integrated fashion to communicate.

Universities and colleges in other English-speaking countries also called for English proficiency tests for non-native students in the 20th century. In the

mid-1960s, the English Proficiency Test Battery (EPTB) was introduced for screening applicants to institutions in the United Kingdom. In 1980, the EPTB was replaced by the English Language Testing Service (ELTS), and in 1989 the ELTS was replaced by the International English Language Testing System (IELTS). Changes to the content, format, and delivery mode were also introduced to IELTS during its growth spurts between 1995 and 2005. In 1995, the three field-specific reading and writing modules were replaced by one academic reading module and one academic writing module (Clapham, 1996; Charge & Taylor, 1997). The revised IELTS Speaking Test was introduced in 2001, and a computer-based IELTS test for reading, listening, and writing was piloted in 2005 at a number of test centers.

The Cambridge English: Advanced, also known as Certificate in Advanced English (CAE), was introduced in 1991, and has been used for admissions into institutions of higher education in addition to professional purposes. It includes reading, listening, speaking, writing, and use of English, and is offered in a paper-based or a computer-based format. The content of the test involves a variety of topics such as school, professional, business, and social topics.

The Michigan English Language Assessment Battery (MELAB) has also been used for individuals applying to English-medium educational institutions, and to evaluate English language ability of professionals who need English for work or training reasons. It is a paper-based test that contains grammar, cloze, vocabulary and reading, listening, writing, and an optional speaking section that takes the form of a conversation with an examiner.

The most recent addition to the community of standardized EAP tests for admissions is the Pearson Test of English (PTE) Academic, introduced in 2010. It is a computer-based test (CBT) that assesses reading, listening, speaking, and writing, and all four sections are scored using automated scoring engines exclusively.

Since its introduction in 1989 IELTS has been used primarily in the UK, Australia and New Zealand while TOEFL was dominant in the USA; today all of the EAP tests are positioned as global measures of academic English proficiency for admissions into English-medium institutions of higher education across the globe.

Current Trends of EAP Testing in Higher Education Admissions

This section discusses current trends associated with three major EAP tests for higher education admissions: TOEFL iBT, IELTS, and PTE Academic. It focuses on approaches to operationalizing test constructs, test delivery mode, scoring methods and technologies, and score reporting and interpretation.

Test Constructs and Approaches to Operationalization

The definition of constructs for academic English proficiency tests, which can be considered tests for specific purposes, should draw on analysis of the target language use domain of English-medium colleges and universities. Based on

analyses of the English language knowledge, skills, and abilities required for success in academic studies and typically encountered instructional tasks and materials (Bridgeman & Carlson, 1984; Hale et al., 1996; Rosenfeld, Leung, & Oltman, 2001), the TOEFL iBT captures three subdomains of English language use: *general academic*, *navigational*, and *social/interpersonal*, with emphasis on general academic use contexts. The reading and writing sections of the test primarily make use of materials on general academic course content, and argumentative texts are used as stimulus materials, whereas the listening and speaking sections include both tasks that require comprehension or responding in writing to materials on academic course content and tasks that reflect language use contexts of navigating a university environment, such as interactions in the library and cafeteria. The speaking section also includes tasks that require examinees to speak about familiar topics as well as academic content and navigational topics. The IELTS academic module includes academic reading, academic writing, general listening, and general speaking. The materials used in academic reading are for a nonspecialist audience and written in narrative, descriptive, or argumentative styles (at least one of the texts is argumentative). Academic writing focuses on general academic materials such as describing a chart or a graph and writing an argumentative essay. General listening uses materials on everyday social situations and general educational and training contexts. General speaking elicits conversations, presentations, and discussions about everyday familiar topics. The listening and speaking sections are shared between the IELTS academic module and the general module, which measures English skills in broad social, educational, and workplace contexts. Overall, academic reading, general listening, and general speaking in the IELTS academic module put less of an emphasis on using academic content materials, which are predominantly argumentative, or on academic language use situations. The PTE Academic uses reading and listening materials for both academic work and extracurricular activities on a university campus (e.g., dealing with university administration).

It is now common practice for communicative language tests to assess all four modalities of reading, listening, speaking, and writing, but a growing trend is the use of integrated tasks, in which test takers are required to use multiple skills harmoniously to complete test tasks successfully. Normal communication involves the routine integration of different language skills (e.g., speaking and listening to maintain a conversation), and the integration of skills has been prominent in ESL/EFL instruction in recent years. The extensive use of tasks that integrate language skills in the writing and speaking sections is a key feature of the TOEFL iBT test. One of the two TOEFL iBT writing tasks requires test takers to read a passage, listen to an academic lecture on the same topic, and integrate the written and spoken information. Four of the six speaking tasks engage multiple modalities, requiring candidates to respond verbally to written or spoken materials or both, and evaluate, summarize, and synthesize the information. Separate reading and listening sections that primarily use selected response items provide distinct measures of reading and listening abilities. This test design approach reflects the integrated nature of language use while yielding relatively distinct measures of reading, listening, speaking, and writing. The PTE Academic has also adopted this practice of using some integrated tasks which require

summarization of written or spoken texts. The IELTS speaking section, which is an oral interview, integrates listening and speaking skills. However, IELTS reading and writing have moved away from this practice in order not to confuse the measurement of abilities associated with different modalities, removing the thematic link between reading and writing tasks (University of Cambridge ESOL Examinations, 2012).

There is growing use of test materials and tasks that aim to reflect what learners encounter in real life more authentically. For example, the TOEFL 2000 spoken and written academic language corpus collected by Biber is a rich real-life corpus that has informed the design and development of the TOEFL iBT (Biber, Conrad, Peppen, Byrd, & Helt, 2002; Biber, 2003, 2006). Both the corpus and the rich array of associated linguistic and discourse characteristics have provided the foundation for the creation of TOEFL iBT content that represents key features of real-life language use. The development of the IELTS test has also drawn upon the Cambridge Academic English Corpus (Barker, 2010), which includes written and spoken academic language at undergraduate, graduate, and professional levels from a range of worldwide institutions. The Pearson International Corpus of Academic English (PICA) has also been developed based on existing written and spoken corpora that are relevant to academic contexts (e.g., the World Wide Web, Longman higher educational textbooks, and the British National Corpus) to provide materials for the content development of the PTE Academic (Pearson Education, 2010b).

Test Delivery Mode

Computer-based testing has become an important trend since the 1990s with the growing dominance of computers in our daily lives, education, and the workplace. The TOEFL CBT, launched in 1998, was the first EAP test that used a computer-based delivery mode. Since its inception in 1964, the TOEFL had remained a paper and pencil test for over three decades. The TOEFL iBT, introduced in 2005, takes advantage of its delivery platform, and uses innovative item types such as schematic tables in reading and integrated tasks in speaking and writing. IELTS has followed a similar path: It started as a paper-based test (under a different name, English Language Testing Service [ELTS]) in 1980 and launched a CBT for its reading, listening, and writing sections in 2005, with its paper-based test still remaining as the dominant delivery mode. The PTE Academic, as the newest addition to EAP tests, was launched as a CBT in 2010.

Cognizant of the inequities in access to computers and Internet that exist among potential TOEFL test takers across different regions of the world, especially in less economically prosperous regions, TOEFL has taken a cautious approach to introducing computer technologies. A large-scale study sponsored by TOEFL investigated the computer familiarity of TOEFL CBT takers and its impact on their TOEFL CBT scores (Eignor, Taylor, Kirsch, & Jamieson, 1998; Kirsch, Jamieson, Taylor, & Eignor, 1998; Taylor, Jamieson, Eignor, & Kirsch, 1998). Taylor et al. (1998) revealed that computer familiarity did not have a significant influence on test scores when an optional computer tutorial was provided for test takers to gain familiarity with the required computer literacy skills prior to starting the test.

IELTS has also conducted research regarding the impact of computer familiarity on test performance, and did not find any significant differences between paper-based and computer-based IELTS scores for reading, listening, or writing sections (Maycock & Green, 2005).

Scoring Methods and Technologies

With the advent of Internet-based testing, the transmission of test-taker response data has become instantaneous. Taking advantage of this delivery system, the TOEFL iBT test program uses an online scoring network (OSN) to score its speaking and writing sections. Raters get trained through a comprehensive online training tutorial and receive certification by passing a scoring test, after which they may score responses remotely. Scoring leaders receive face-to-face training at ETS on a regular basis. Raters score remotely using the OSN and are supported by scoring leaders by e-mail, phone, or instant messaging (Xi & Mollaun, 2011). The use of OSN also allows the scoring leaders to use a variety of real-time rater quality control measures, such as examining raters' scores on monitor responses (prescored responses) and randomly checking raters' assigned scores during operational scoring. Postscoring rater quality check analyses are also conducted to inform future rater training.

IELTS uses single human scoring for both its writing and speaking tests. Because IELTS speaking is administered in a face-to-face format, its scoring is conducted in person by trained examiners. This is different than TOEFL iBT speaking, which utilizes remote human scoring through the OSN. The format of the IELTS scoring allows only postscoring rater monitoring. A sample of taped interviews and IELTS writing responses from selected test centers worldwide are double scored by more experienced IELTS examiners to monitor raters on a regular basis, and to provide feedback for future rater training.

The use of automated technologies in scoring constructed response tasks has also been a major trend in EAP testing in recent years. In particular, TOEFL iBT uses e-rater as a second rater to score writing tasks in conjunction with human scoring for the purpose of improving the efficiency of scoring and the reliability of scores (prior to the introduction of e-rater, each writing response was double scored by human raters). PTE Academic, on the other hand, is a fully automated test, using natural language processing (NLP) and speech technologies to score writing and speaking tasks that require both short and extended responses.

Score Reporting and Interpretation

Although large-scale EAP admissions testing is moving toward the use of integrated tasks which engage multiple modalities of language (e.g., a task that engages both listening and speaking skills), current score-reporting practices conform to the traditional partition of four modalities: reading, listening, speaking, and writing. Essentially, all three tests report scores on each modality in addition to a total score. In the case of the TOEFL iBT, this score-reporting practice has been motivated by theoretical expectations that the abilities associated with the four modalities are distinct and supported by empirical research that shows

the scores on the four modalities still emerge as separate factors, although they also load on an overall language ability factor (Sawaki, Stricker, & Oranje, 2009). IELTS reports a band level score for each of the four modalities and an overall band level score (bands 1–9). The PTE Academic test also reports scores for enabling skills including, for example, grammar, oral fluency, pronunciation, spelling, vocabulary, and written discourse (Pearson Education, 2010c).

Using performance descriptors is another characteristic of the score reporting of current EAP admissions tests. The TOEFL iBT score reports for test takers, for example, include performance feedback on each modality, which provides descriptions of language competencies for typical students at three to four levels for each modality. The levels and associated performance descriptors were derived using scale anchoring research for reading and listening (Gomez, Noah, Schedl, Wright, & Yolcut, 2007), and through summarizing the typical characteristics of the response samples at different score levels for writing and speaking. The IELTS test provides band level scores (0–9) with half-point bands and a brief performance descriptor for each of the nine whole-score bands. The IELTS writing and speaking sections are scored using a nine-band score scale, and raw reading and listening scores are converted to the nine band levels. The band level boundaries for reading and listening differ slightly across forms to adjust for minor differences in form difficulty. The band levels of the four sections are averaged to derive the overall band level. The scoring rubrics for IELTS writing and speaking provide the score users with detailed band level descriptors, and inform the brief descriptors for overall band levels. It is not clear how the performance descriptors related to IELTS reading and listening for each overall band level are derived. The PTE Academic score report includes the total score, communicative skills scores, and enabling skills scores that are on a 10–90-point scale, but does not provide detailed performance descriptors.

Another major trend in score interpretation is linking the test scores to the Common European Framework of Reference for Languages (CEFR) (Council of Europe, 2001). The CEFR is a set of language proficiency standards originally developed for benchmarking the language proficiency of second or foreign language learners in Europe, but it has become increasingly influential all over the world. The CEFR defines six levels of competency in a second or foreign language: A1–A2 (Basic User), B1–B2 (Independent User), and C1–C2 (Proficient User). All three test providers have published information on how their test score levels correspond roughly to CEFR levels, as well as methodologies and results of their CEFR linking studies (Tannenbaum & Wylie, 2008; Pearson Education, 2010a; Lim, Geranpayeh, Khalifa, & Buckendahl, 2012). The intention is to provide a common set of benchmarks for test users to select the appropriate cut scores on each test.

Current Research

Although the process is often informally referred to as “validating a test,” we should heed Cronbach’s 40-year-old admonition that “One validates, not a test, but an *interpretation of data arising from a specified procedure*,” and that “the evidence

that justifies one application may have little relevance to the next" (1971, p. 447). This central message has been echoed more recently by Kane, who wrote that "Validation involves the evaluation of the proposed interpretations and uses of measurements" (2006, p. 59). This chapter focuses on the validation of the fundamental claim made by EAP tests used for admissions that the test scores are relevant and useful for making admissions decisions.

One of the clearest links between theory and practice is the argument-based approach to validation as described by Kane (2006). In this approach two kinds of arguments are employed: an interpretive argument and a validity argument. The interpretive argument "specifies the proposed interpretations and uses of test results by laying out the network of inferences and assumptions leading from the observed performances to the conclusions and decisions based on the performances" (Kane, 2006, p. 23). The interpretive argument posits six inferential steps: domain description, evaluation, generalization, explanation, extrapolation, and utilization. Each of these steps requires backing in the validity argument.

The validity argument provides evidence that "the interpretive argument is coherent, that its inferences are reasonable, and that its assumptions are plausible" (Kane, 2006, p. 23). Following Kane's approach and Chapelle's (2008) extension of Kane's work, we use validity inferences to organize exemplary research studies related to the three tests.

Domain Description

The domain description is based on the warrant (or generally held belief) that the observations on the language test represent relevant knowledge, skills, and abilities for use in the target domain of academic discourse in an English-medium university. Support for this warrant should show the link between the critical language tasks and skills in the target use domain and the observations of performance (tasks) on the test. In the late 1970s and 1980s linguists emphasized the importance of communicative competence, and not merely knowledge of grammar rules, for success in the classroom (e.g., Munby, 1978; Canale & Swain, 1980), and this insight heavily influenced the development of the first IELTS test. As reported by Milanovic and Saville (1996), the development of the original IELTS as a four-skills test was influenced by the work of Munby as well as by EAP teachers, language testers, applied linguists, and score users.

The communicative competence movement, in particular the work of Canale and Swain (1980), also influenced the development of the TOEFL in the late 1970s and 1980s with the addition of productive speaking and writing skills in the form of the TSE and TWE. In 2005, the TOEFL iBT was introduced as a four-skills test that makes extensive use of integrated tasks. The design of the new test was heavily influenced by needs analyses that identified the academic language tasks and skills deemed important for academic success in all four skills areas in tertiary classrooms (Rosenfeld et al., 2001), and the work that was specifically targeted at identifying the types of writing tasks that were assigned in academic degree programs (Bridgeman & Carlson, 1984; Hale et al., 1996).

Evaluation

The evaluation inference requires a link between the targeted abilities and the actual observed scores on the test. As noted by Chapelle (2008), three assumptions about scoring, task administration conditions, and statistical properties need to be supported: (1) Rubrics for scoring responses are linked to the constructs of interest; (2) task administration conditions elicit evidence of targeted language abilities; and (3) the statistical characteristics of items, measures, and test forms support the intended decisions.

The kind of work needed to validate rubric development and rater training is illustrated by Bridges and Shaw (2004), who describe a five-phase revision project for the IELTS writing test. This revision had three main objectives: "1. the development of revised rating scales, including description of assessment criteria and band descriptors; 2. the development of materials for training trainers and examiners; 3. the development of new certification/re-certification sets for examiners" (p. 8). Based on the research, definitions were provided for five scoring criteria: task achievement, task response, coherence and cohesion, lexical resources, and grammatical range and accuracy, with descriptions for each criterion provided for each of the nine band levels.

TOEFL iBT writing and speaking scoring rubrics were developed from an extensive research base that examined the dimensions that raters attended to when scoring responses to prototype TOEFL iBT writing and speaking tasks (Cumming, Kantor, & Powers, 2001, 2002; Brown, Iwashita, & McNamara, 2005). In addition, the task characteristics and scoring rubrics of writing and speaking tasks were modified based on the characteristics of the responses collected during the prototype studies and on raters' actual experience working with the preliminary scoring rubric (Pearlman, 2008).

The PTE speaking and writing tasks are scored exclusively by machine. In order to accomplish this, rubrics had to first be developed for human scoring so that the human scores could be used to train the machine. The reliability of these human scores was demonstrated, and the comparability of the human and machine scores was established (de Jong & Zheng, 2011). However, very limited information has been provided on the automated features used and how they are combined to generate the automated scores for individual tasks in the PTE Academic test. It is therefore difficult to make fair evaluations of the extent to which automated scoring models capture targeted language abilities in that test.

Evidence for the evaluation inference should also demonstrate the psychometric quality of the scores produced by the test, including evidence that the tasks are at an appropriate difficulty level for the population and have the ability to meaningfully discriminate among different levels of examinee proficiency. Such data are critical at the initial development and implementation phases, and typically have been provided by major publishers (e.g., Clapham, 1996; Chapelle, Enright, & Jamieson, 2008; Pearson Education, 2011). Because not only populations taking an assessment but also test preparation strategies can change over time, the psychometric characteristics of test items must be continuously monitored, as initial positive results do not guarantee the maintenance of quality over time.

Generalization

Evidence is needed to support the warrant that the scores on the particular tasks administered are good estimates of scores that would be received with comparable tasks, test forms, and rating conditions. There must be a sufficient number of tasks that are reliably scored so that parallel forms can be created and their comparability demonstrated.

Reliability is a deceptively complex concept, and it is easy to make inappropriate comparisons across tests that report “reliability” estimates, especially for constructed response tasks. Reliability estimates reported for constructed response tasks in the three tests include inter-rater reliability (University of Cambridge ESOL Examinations, 2006), Cronbach’s alpha (Pearson Education, 2011), test-retest reliability (Zhang, 2008), and reliability based on the generalizability theory (G theory) that takes into account multiple sources of error such as errors associated with rater judgments and task variability (Taylor & Jones, 2001; Shaw, 2004; Lee & Kantor, 2005; Educational Testing Service, 2011). When comparing reliability estimates, we should distinguish different types discussed above, and in the case of reliability estimates based on G theory, we should look closely at the sources of measurement error that have been modeled. For example, since the PTE Academic test is exclusively machine scored, the reliability of constructed response tasks concerns task variability only and is typically reported as Cronbach’s alpha.

In general, all three tests report very high overall score reliability in the range of .94–.97 (Educational Testing Service, 2011; Pearson Education, 2011; University of Cambridge ESOL Examinations, 2011).

Explanation

Evidence is needed to show that scores may be attributed to the target construct of academic language proficiency. This evidence may come in the form of test-taking processes and strategies or the internal factor structure of the test. Factor analyses of the TOEFL iBT indicate the presence of a strong general proficiency factor, with group factors for the four skills (Sawaki et al., 2009). Investigations of the processes and strategies involved in responding to TOEFL iBT reading and speaking test tasks have revealed that they are meaningful and consistent with the test designers’ expectations (Cohen & Upton, 2006; Swain, Huang, Barkaoui, Brooks, & Lapkin, 2009). Through think-aloud and questionnaire responses, Bridges (2010) provides evidence that the cognitive processes used by examinees in responding to IELTS writing prompts reflect the kinds of processes that are important for academic writing. Using screen capture and stimulated recall techniques, Chan (2011) demonstrates that the written summarization and essay tasks in the PTE Academic test engage different cognitive processes, as expected in real-world academic writing tasks.

Extrapolation

Evidence is needed to support the warrant that the knowledge, skills, and abilities measured by the test are related to language performance in the university context.

Data might include self-assessments, instructor judgments, or other indicators of language performance in an academic setting. Sawaki and Nissan (2009) provided evidence that TOEFL iBT listening scores were related to performance on listening tests created by subject matter experts using video-based academic lectures covering introductory topics in history, psychology, and physics. Weigle (2011) reported moderate relationships between TOEFL iBT writing scores and measures of writing proficiency in an academic context including instructor ratings of students' general writing proficiency and ratings of students' writing samples from a nontest environment. Bridgeman, Powers, Stone, and Mollaun (2012) found strong relationships among the scores assigned by TOEFL iBT speaking section raters on the one hand and undergraduate students' comprehension and ratings of TOEFL iBT test takers' speech samples on the other. A number of research studies have also been conducted on the IELTS test to support the extrapolation inference. Weir, Hawkey, Green, Unaldi, and Devi (2009) examined the academic reading activities and problems of students in their first year of study at a British university in relation to the construct measured by IELTS reading, and reported encouraging results that the reading problems experienced by the students differed significantly across IELTS band levels, with fewer problems reported by students scoring at higher band levels. Breeze and Miller (2008) examined students' IELTS listening scores and final grades in the courses taught in English and found small positive correlations between them. Ducasse and Brown (2009) investigated the validity of IELTS speaking, comparing interview interaction and university classroom interaction, and found that both types of interactions require students to produce information and opinions in response to questions, although classroom interaction involves a wider range of interactional and interaction management functions, which may not be evident in IELTS interviews.

Utilization

The ultimate evidence needed for the entire validity argument is that the scores are actually relevant and useful for making the correct admissions decisions. Evidence supporting this link includes predictive validity research that investigates the extent to which test scores predict academic success, and standard-setting research that helps users to understand score meaning and set admissions standards.

Academic success has typically been defined in terms of grades of international students assigned by faculty, although grades can be impacted by a host of factors beyond English language proficiency, such as subject-area knowledge and expertise and motivation. Evidence of the ability of IELTS to predict academic success comes from a number of small-scale studies (e.g., Kerstjens & Nery, 2000; Feast, 2002; Lloyd-Jones, Neame, & Medaney, 2007). A 2012 study of a few thousand undergraduate and graduate international students from 10 universities in the United States indicated that at both undergraduate and graduate levels, students with higher TOEFL iBT scores tended to be more successful in their academic studies (reflected in higher GPAs) than students with lower scores. At the graduate level, TOEFL iBT scores tended to predict academic performance over and beyond GRE scores (Cho & Bridgeman, 2012).

The TOEFL program has provided score users with descriptive information to help them to interpret test scores (Educational Testing Service, 2004), a standard-setting manual that provides guidance on how to set cut scores for admissions purposes (Educational Testing Service, 2005), and empirical research on setting standards on the TOEFL iBT speaking section for the initial screening of international teaching assistants (Xi, 2007). A number of case studies have been conducted to establish the appropriate IELTS cut scores for individual programs at different universities (Golder, Reeder, & Fleming, 2009; Singh & Sawyer, 2011).

The evidence cited here gives but a few examples that illustrate the six-step validity argument for the use of EAP tests in university admissions, and many more relevant studies exist. But even if we cited all of the existing studies, additional evidence would be warranted as tests and the academic environment continue to evolve. As Cronbach (1989, p. 151) observed, validation is “a lengthy, even endless process.”

Critical Research and Development Issues and Future Directions

In this section we discuss current trends in EAP testing for university admissions and exemplary, wide-ranging research that pertains to the inferences supporting test score interpretations and uses. As the domain of academic language use evolves, the need arises to refine the constructs of academic English proficiency. Since the early 2000s, automated scoring technologies have seen increased applications in large-scale EAP tests for university admissions. This fast growth rate calls for close scrutiny of each application of automated scoring to ensure appropriate and responsible use. Integration of language skills, while gaining momentum in practice, requires us to develop theoretical models and rethink the practice of test design and score reporting. Linking test scores to CEFR levels has been motivated by the need for helping score users understand and use scores from different tests, but has raised controversy and issues.

Needs for Refining the Constructs of Academic English Proficiency

English language tests used for admissions purposes for postsecondary institutions are expected to reflect the communication demands in English-medium instructional environments at the university level. One of the impetuses for refining the construct of academic English proficiency is the fact of continual changes in the academic language use domain. Two notable developments in the domain may prompt us to refine the constructs of academic English proficiency: increasing diversification of the academic language use domain, and the changing nature of communication at colleges and universities.

English as a Lingua Franca English-medium academic environments for higher education have become increasingly diverse. This diversification manifests itself both in a rapid increase in international student populations and faculty and in a

significant growth in the number of programs which primarily use English for content instruction in countries where English is not a dominant language, as occurs in some European countries (Coleman, 2006; Jenkins, 2011). This suggests that students are being increasingly exposed to both standard and nonstandard varieties of English in the course of their interactions in classrooms and on campus. The development of two large corpora of English as a lingua franca (ELF), namely the corpus of English as a Lingua Franca in Academic Settings (ELFA) (Mauranen, Hynninen, & Ranta, 2010) and the Vienna-Oxford International Corpus of English (VOICE) (Vienna-Oxford International Corpus of English, 2011), are reflections of this trend.

These standard and nonstandard English varieties come with variations in the phonological and prosodic properties of spoken discourse, in the syntactic, lexical, and discourse characteristics of both spoken and written discourse, and in culture and pragmatics. The extent to which these variations should be represented in the constructs of English as a second or foreign language remains controversial. Debates are continuing about whether and which educated speakers of standard varieties of English (e.g., British English, American English) should set the norms for English teaching and testing (Quirk, 1985, 1990; Kachru, 1996; Davies, Hamp-Lyons, & Kemp, 2003). Although English language teachers have started to embrace the notion of ELF (Cook, 1999; Seidlhofer, 2004), language testers have adopted a more cautious approach to defining the role of English varieties in constructs. Taylor (2006) argues that the purpose and intended uses of a test drive the decision to include English varieties in tests. Elder and Davies (2006) contend that if language varieties are part of the target language use domain, including them in language tests will likely enhance score meaning and interpretation and bring about positive impact on teaching (Elder & Davies, 2006). Xi and Mollaun (2011) make a similar argument that design decisions regarding linguistic standards and norms to be used in tests need to be based on the intended use of the test and the context in which the learners will be expected to use English for communication.

The research on ELF may have different implications for test content and scoring criteria for EAP university admissions tests. In terms of test content, for the assessment of listening, the trend is to include standard varieties of English. As for the inclusion of non-native accents, although an argument can be made that these are a prominent part of the academic language use domain, the multiplicity of non-standard English varieties presents challenges in conceptualizing and operationalizing constructs that include them. The sampling of non-native accents and its implications for test validity and fairness need to be carefully considered (e.g., What non-native accents to include? Would non-native speakers of English be held to higher standards than their peers who are native speakers of English?). As for the assessment of speaking, some characteristics of ELF have been incorporated into the scoring rubrics of EAP admissions tests, where the emphasis is on the impact of accents on overall intelligibility and comprehensibility rather than on degree of "nativeness." The writing rubrics still adopt standard English norms by educated speakers who speak standard varieties of English. A key aspect of real-life communicative competence that remains outside the scope of EAP admissions testing is culture and pragmatics associated with different English

varieties. However, this conceptualization may change as our understanding of the target language use domain evolves.

Technology-Mediated Communication The selection of test delivery mode reveals the developers' conceptualization of the test constructs. The growing use of computers and multimedia technologies in communication will impact the way we define the constructs for EAP admissions tests. Do we define the constructs based on the belief that language ability should be assessed in such a way that technology is considered a non-essential component of the construct (e.g., testing writing using a handwritten essay), or even as a potential source of construct irrelevance? Or do we define certain computer literacy skills (e.g., reading on the computer screen, keyboarding skills) as an integral part of the constructs, to reflect computer-mediated reading and writing literacy required for the actual target language use domain? Or do we even go one step further and define the constructs as communication skills that are fully integrated with computer literacy and digital information literary skills, such as using digital technologies to find needed information and evaluate, organize, and synthesize it to fulfill a task? How far do we go and where do we draw the line in delineating the constructs?

Currently TOEFL and IELTS are taking a very careful approach to specifying the role of computer technologies in the construct definition, given the large variation in access to computers among the target test takers. As discussed earlier, both programs have introduced computer- or Internet-based versions and have conducted research to understand the computer literacy skills among the test takers and their impact on test performance.

In the near future, with the increasingly prevalent use of computers around the globe, arguing for or against a construct definition encompassing technology-mediated English communicative abilities may become irrelevant. However, irrespective of our approach to construct definition, research that investigates how computer literacy skills interact with language skills to impact the overall communication needs to continue.

Growing Use of Technology in Simulating Real-World Academic Language Tasks

The use of computers in delivering EAP university admissions tests has afforded new opportunities for the development of innovative tasks, such as schematic tables that require test takers to organize written information into a chart, and the use of integrated tasks that involve the use of written, spoken, and visual materials as stimulus materials. However, the potential of computer technologies, including tablets, has yet to be fully tapped in simulating real-world academic language use scenarios that capture more faithfully the domain of interest.

Opportunities and Challenges Offered by Automated Scoring Technologies

Automated scoring technologies offer many benefits, including improving the efficiency and reliability of scoring. However, limitations of the current

state-of-the-art technology still put constraints on the kinds of test tasks that can be included, thus compromising the construct coverage and representation of tests that rely solely on automated scoring technologies. A promising area of inquiry, though, is to further explore and expand the use of automated scoring technologies in monitoring or complementing human scoring, which is known to be susceptible to error.

Integration of Language Modalities

The integration of multiple language modalities in language tasks is motivated by needs analyses of the academic language use domain at the university level and reflects the nature of actual communication in academic environments. However, few theoretical models have been developed to parallel this empirically motivated practice. Particularly lacking are models that posit how language is processed, organized, and synthesized across modalities in written or speech production. Empirical studies on the cognitive processes involved in communication that engages multiple modalities will help validate these theoretical models.

The current trend toward the use of integrated language tasks in EAP admissions tests provides impetus for rethinking the practice of reporting scores for each modality. Additionally, the use of integrated language tasks in high stakes EAP admissions testing is having a significant impact on the way language skills are learned and taught (Wall & Horák, 2006, 2008, 2011) and would further blur the divisions among four modalities. The reporting of scores on integrated skills, such as a combined reading and writing skills score based on tasks that seamlessly integrate these two modalities, may be warranted in the future.

Linking Scores to the CEFR Levels and Score Interpretations

Virtually all of the test providers of EAP admissions tests have mapped their scores to the CEFR levels in response to the growing use of the CEFR as a benchmark for language standards. The intention is to facilitate the interpretation of scores on different admissions tests. However, due to differences in the approaches used by various testing agencies to link scores to the CEFR, misalignment issues have surfaced. This type of linking information has created more confusion than clarity about the relationships among the scores on different tests, a situation which has prevented test users from using the admissions test scores appropriately (de Jong, 2009). Further, given that the CEFR is not geared toward the specific domain of academic language use in higher education contexts, standards need to be developed that take into account the subdomains of academic language use and the unique linguistic characteristics of language used for communication in academic environments.

Conclusion

In this chapter we have presented an overview of the current landscape of EAP admissions testing for higher education, focusing on current trends and critical

issues to resolve. The field of EAP admissions testing has attracted the most significant research and development efforts in language testing. Therefore, it is critical that research efforts be maintained and increased to continue to set the benchmark for the development and validation of language tests around the world. Although this chapter focuses on admissions testing, the issues and future directions discussed may also be relevant to ESL and EFL testing in other domains.

Government and Military Assessment

Rachel L. Brooks

Language Center, USA)*

Introduction

Governments worldwide are extensive users of foreign languages, as they deal with foreign nations and immigrants. The stakes are very high in government contexts, as governments negotiate with other countries, ensure fair court proceedings, and collect intelligence to protect their national security and the lives of citizens. Language testing in government and military contexts is driven by practical, and sometimes urgent, needs to ensure that personnel using foreign languages are capable of performing pertinent tasks. The focus on operational needs often leads to language tests that are specifically designed to evaluate language-related job performance skills rather than general language proficiency. Nevertheless, testing general proficiency is also important, as having personnel with broad, general language skills gives governments the flexibility to meet needs as they arise. This chapter focuses on language assessment practices and issues that are specific to government contexts, often exemplified through the US federal government.

History

For as long as there has been language learning, there has been language testing in all settings, including government. Prior to the mid-20th century, language assessment was mainly localized, focusing on achievement or professional examinations, and with little cross-organizational collaboration or wide-reaching standardized scales. With World War II, the need for standardized testing became apparent, and the government began focusing on general proficiency testing as well.

Before the 1940s, the focus of government and military language training in the USA had been on reading proficiency. World War II and subsequent international conflicts brought to light the need for a shift to aural and oral language training. Radio transmissions had become clearer and more far-reaching, allowing for increased audio interceptions. The deployment of soldiers to foreign lands increased, necessitating speaking skills to communicate with locals. American soldiers were not linguistically prepared to meet the operational demands of their posts, and the only tests available were classroom tests that varied from class to class. The shift of practical language uses led to a shift in teaching curriculum and testing practices. Kaulfers (1944) outlined a methodology for evaluating aural and oral language abilities, including rubrics and rating criteria, and in 1949 the Army released the first Army Language Tests, standardized tests of proficiency in reading, listening, writing, and grammar in 25 languages (Pulliam & Ich, 1968).

The standardization of language testing supported both the placement of soldiers in language courses and the selection of post-training assignments. Pre-World War II, language course placement in the US military was determined by a test battery, including IQ tests, general language aptitude tests, and tests of how well a person could speak a “first” language (Myron, 1944).

These selection criteria were not effective in determining which language a military language learner should pursue, and the US government developed an interest in a formalized test of language aptitude, rather than relying on assumptions about which students would be best at language learning. In the early 1950s, the Department of Defense produced the Defense Language Aptitude Test (DLAT). The Modern Language Aptitude Test (MLAT), first produced in 1959, was also widely used by government agencies in both the USA and Canada. The DLAT was revised in 1976, and came to be known as the Defense Language Aptitude Battery (DLAB).

Along with aptitude testing came the need to assess the abilities of those who knew a foreign language. The Army Language Tests released in 1949 were found to be inadequate for measuring proficiency, and in 1954 the Army Language School (now the Defense Language Institute) was directed to construct new tests in accordance with best practices (Pulliam & Ich, 1968); these tests, the Army Language Proficiency Tests, were the precursors to the current Defense Language Proficiency Tests. Meanwhile, in 1952, the US Civil Service Commission was tasked with inventorying the language abilities of government employees, requiring standardized assessment criteria and procedures and a way to assess language proficiency regardless of how the language ability was attained. No such criteria were found in academia, leaving the US government to develop its own (Herzog, 2003). The US Foreign Service Institute (FSI) came up with its first rating scale, with score levels 1–6. An independent testing office at FSI, established in 1958, shaped the criteria into a format for reliable oral testing, the “FSI test.” In 1968, other US government agencies joined with FSI to expand the criteria to cover speaking, listening, reading, and writing, known as the Interagency Language Roundtable (ILR) Skill Level Descriptions. In the years following, government agencies at the federal level worked to expand and update their language skills tests. The FSI test was adapted for general proficiency use by a number of agencies, and became known as the Oral Proficiency Interview (OPI).

Around the same time, international recognition for the need for information sharing on language learning and testing was growing, and in 1966, the Bureau for International Language Coordination (BILC) was established through funding from the British Ministry of Defence. BILC served as an advisory body for language training matters for the North Atlantic Treaty Organization (NATO). In 1976, BILC recognized a similar need as the USA for standard testing criteria and adapted the ILR Skill Level Descriptions, also referred to as the ILR scale, to create a standardization agreement for language testing, STANAG (Standard Agreement) 6001 (Green & Wall, 2005).

In the subsequent years, both the ILR Skill Level Descriptions and the STANAG 6001 underwent revisions. The ILR scale adopted “plus” levels, which indicated language users with ability that substantially exceeded the base level, yet did not fully meet the next higher level. In 1985, the US Office of Personnel Management approved these criteria as the official criteria for evaluating the language proficiency of government personnel (Interagency Language Roundtable, 1985). In the early 21st century, the ILR began to address the need to measure language in operational language tasks such as translation, interpretation, transcription, and audio monitoring. The Translation and Interpretation Committee of the ILR joined with the Testing Committee to develop a set of performance skill level descriptions, including Translation (2006), Interpretation (2007), and Audio Translation (2011).

Both the ILR and STANAG scales are still used, with the STANAG 6001 undergoing regular revisions. The use of the STANAG 6001 scale has been pivotal in several international military initiatives. In 1994, the Partnership for Peace Initiative called for Central/Eastern Europe Caucasus and Central Asia representatives to fill NATO positions. Each of these officials had to meet STANAG requirements prior to selection. The mid-1990s gave rise to the Peacekeeping English Project, funded by the British Ministry of Defence and Foreign Commonwealth Office, which provided assistance to 20 countries in English language training and testing according to the STANAG 6001 criteria (Green & Wall, 2005).

The ILR and the STANAG scales have been important influences in the development of testing criteria for nongovernment contexts. As the first nationally recognized scale of language proficiency, the ILR scale was popular across government and academia. However, levels 3–5 were difficult to attain in a purely academic setting; therefore, in the early 1980s, the Educational Testing Service and the American Council on the Teaching of Foreign Languages obtained a federal grant from the US Department of Education and developed the ACTFL/ETS Proficiency Guidelines. To accommodate the lower proficiency needs of academia, the three highest levels (3–5) were condensed into one level (Superior). By 1999, the lower three levels included sublevels. In 2012, ACTFL revised their Guidelines to include a level above Superior termed Distinguished, which is roughly equivalent to the ILR levels 4 and 5.

The Common European Framework of Reference (CEFR) has been developed for use across Europe, and is also used, in revised form, on other continents and in other countries. The CEFR provides a common standard for evaluation of language proficiency and determining objectives for various courses of studies and expectations for outcomes. It has been used in largely academic, but also some government contexts. A few studies have been conducted to determine alignment

between the CEFR and ACTFL/ILR scales (Mosher, Slagter, & Surface, 2007); however, no definitive studies have shown correlation between the two in operational testing.

The Government Context

As practiced in government contexts, language testing's essential focus is on meeting operational needs. Research tends to focus on solving immediate practical problems. Time and resource limitations often prevent people who work in government language testing from publishing or presenting at conferences to the extent that would be expected from those working in academia. Thus, although there is considerable work being done in language assessment by government and military programs, the work is often not very visible to those outside the organization in which it is conducted.

Government and military language-testing needs reflect constantly changing world events. For example, during the Cold War the types of tests developed by NATO governments were driven by the focus on Eastern and Central European languages and on skills in listening to recorded transmissions. In more recent years the focus has turned toward fighting terrorism; governments now deal regularly with languages that have virtually no history of instruction outside (or sometimes within) the countries in which they are spoken, such as Arabic dialects, Pashto, and Cebuano.

Governments are also coming to understand that foreign language needs are not limited to highly trained professionals with good command of foreign languages, such as professional translators, communications monitors, and diplomats. Troops on the ground in foreign countries combining military and security missions with winning the hearts and minds of local populations interact at all levels with local populations and thus must speak and understand the local language at a basic level. Language testing is expanding beyond assessing high level comprehension of a standard language into assessing functional, rudimentary proficiency of what is spoken on the streets.

Since the major driving force behind government and military language testing is operational need, performance testing is extremely important; what one learned in a language-training program is less important than how one can apply it. Tests of specific skills, such as translation, summarization, interpretation, and transcription all arise from operational tasks. However, assessing essential functional proficiency remains important, so that when an urgent need arises, people have skill sets flexible enough to fill that need quickly. For example, a language analyst may be working on translating documents in a certain language related to a particular topic. If suddenly there is a need to send interpreters in that language to a disaster-stricken area, knowing whether the analyst is a good translator for a particular content area may not be as important as knowing whether that analyst has sufficient listening and speaking skills in general subject areas. Government and military organizations highly value personnel who maintain high levels of general proficiency in several skills (reading, listening, speaking, writing), and can carry out specific language-related tasks.

This need for both general proficiency and specific performance skills leads to difficulties for language testing. It is not uncommon for personnel to earn high scores on performance tests, but then to perform relatively poorly on proficiency tests. In some occupations, the reason for poor performance on proficiency tests is that language-capable personnel typically work in only a limited context, which restricts vocabulary and cultural knowledge. Another reason may be that in some occupations, notably translation and interpretation, the linguists must convey information without inserting opinion or analysis, whereas understanding opinion and reading or listening between the lines are crucial elements of higher proficiency levels. In such situations, many examinees and test score users, not fully understanding the differences between job performance and overall proficiency, expect scores on the two types of tests to be similar; when scores do not align, the validity of the tests may be questioned.

Accurate interpretation of test scores is a major challenge for language-testing organizations in government. Users of tests have varied backgrounds and have conflicting desires for score usage. The challenge is in two areas: understanding what exactly is being tested, and understanding the relationship between a score and reality.

Organizations often need to measure multiple skills, or both performance and general proficiency, but budgets and time for multiple tests are limited. In such cases, language testers may find stakeholders trying to glean information about performance from the results of proficiency tests, or becoming alarmed when a cadre of professionals who had been thought to be competent suddenly look less qualified because proficiency results are low. In other cases, organizations may try to use a speaking test to measure listening comprehension, because the speaking test is easier to administer than the listening comprehension test. An additional difficulty is that, although governments typically use a common set of proficiency descriptions as a criterion for proficiency tests, interpretations of the descriptions may vary, and the very pervasiveness of the proficiency descriptions leads to inappropriate application of the skill level descriptions to performance contexts.

Issues with understanding the relationship between a score and reality are subtle but may carry great consequences. Language testing for government and military is typically high stakes: Examinees' careers and pay depend on test outcomes and the safety of citizens can depend on the ability of language professionals to transfer information accurately. However, no test is completely accurate. With any test, a decision must be made whether to lean toward leniency or strictness, that is, whether it is more important to limit false negatives (examinees who have the requisite skills, but whose test scores indicate they do not) or false positives (examinees who do not have the requisite skills, but whose test scores indicate they do). In the government and military context, many examinees are tested in languages in which very few people in the country have any knowledge. Therefore, a false negative may mean the loss of a resource that is difficult or impossible to replace. On the other hand, a false positive may put a person in the position of handling a task without the proper qualifications. Often different score users for a test will have different priorities for the leniency or strictness of a test, making it difficult to create a test with an appropriate balance between false positives and false negatives.

An additional challenge for testing in government and military is maintaining coherent testing programs in the face of the variety of needs for different languages and levels of ability. Organizations may want a multipurpose test to assess examinees at very different proficiency levels, making it difficult to create tests with high overall precision. Organizations that need to assess general proficiency will want a given level in proficiency in Russian to mean the same thing as that level means for Cebuano, even though the languages and volumes of examinees are very different. For languages with many examinees, testing programs likely have resident language experts serving as testers or developers, providing ample opportunities to gather information on the reliability of tests. For languages with few examinees, organizations may have no one qualified to develop tests or to serve as a tester, and will have little opportunity to gather information on reliability.

Testing in the government and military context, then, is characterized by a high stakes nature, a great number and diversity of languages, variety in the uses to which tests are put, and, most importantly, a need to meet operational demands.

Perspectives from Different Organizations

The organizations that are probably most noted for the use of foreign language training and testing are the diplomatic services. Personnel in these agencies have regular contact with foreigners from numerous international backgrounds, requiring high level language skills. Specifically, diplomats need to converse with foreign officials, read foreign documents, and listen to broadcasts in other languages. Diplomatic personnel such as translators and interpreters routinely perform specialized language tasks such as translation of international treaties and agreements and interpretation of negotiations and official addresses. Translators and interpreters must be able to understand nuance, tone, implied meanings, and cultural references. Moreover, employees of diplomatic agencies serve as the face of their country in foreign lands, therefore miscommunication could potentially lead to serious ramifications for international relations and policy. Consequently, diplomatic personnel typically endeavor to communicate as effectively and appropriately as educated native speakers of the foreign language. Skills such as negotiation, persuasion, tact, and other influencing skills must be mastered.

Within the military, high level officers, like diplomats, may need to negotiate and communicate agreements with foreign military officers. Primarily, however, defense organizations focus on giving military personnel the communicative skills they need to survive in foreign lands, typically speaking and listening in routine or survival communications, such as gathering information from residents about local activities and performing security operations. Other personnel may monitor recorded or written communications from hostile groups. Although military personnel often do not need near-native proficiency, the stakes are high: Inaccurate transfer of information could lead to loss of life or property.

In clandestine service, agents working under cover need to develop structural competence, vocabulary, and pronunciation that are parallel to those of native

speakers, but also acquire native speakers' cultural and pragmatic skills, so as to be indistinguishable from them. Language errors have the potential to lead to loss of life or intelligence. Other agents gather intelligence through audio intercepts, so listening skills are paramount. Listening comprehension tasks are complicated by the inability to ask for clarification and by poor recording quality. Additionally, a large number of language tasks require decoding vague, accented, slang, and veiled language. Language testers work to interpret how this type of task fits into the general rating scales, and how to reliably assess listening in such contexts.

Investigative and law enforcement agencies generally serve both criminal and intelligence missions. Operational requirements demand that language personnel have both monitoring and translation abilities, with added legal requirements that govern the collection of and reporting on evidence and intelligence. Monitors overhear, and then write analytical summaries of information relevant to investigations, which are often distinct from the main idea or supporting details of the audio. National privacy laws restrict material that can be monitored, so audio is truncated, causing additional listening challenges. Documents that are collected for investigations need to be translated so that the information is accessible to agents working on the related cases. Translation errors can lead to the dismissal of evidence admitted in court proceedings, potentially affecting the overall safety and security of the country's citizens. As in military organizations, most interpretation assignments are informal and involve interviewing speakers of other languages. Investigative agencies also employ undercover agents who are high level speakers of foreign languages. Like clandestine agents, it is imperative that they are indistinguishable from native speakers for their safety and the safety of others. In all of these cases, single skills testing does not sufficiently measure language for the task, therefore performance testing of combined skills is increasing.

Whereas translators and interpreters who work for investigative agencies have allegiance toward their agency, translators and interpreters who work for judicial organizations must be impartial. Inaccuracies in court interpretations can result in unwarranted imprisonment or unprosecuted crimes. High levels of proficiency in speaking and listening do not necessarily result in high quality interpretation. Therefore, most court systems test for interpretation skills directly rather than inferring them from the results of speaking proficiency tests.

In the USA, as in many parts of the world, the Department of Education oversees school curricula, initiatives, and assessments in all subject matters, including language. Educational institutions use language testing and their corresponding frameworks to measure the progress of student language learning. Education personnel referring to rating scales are generally interested in the lowest levels offered, as the majority of students will achieve results at these levels. Combined skills such as interpretation and translation are not taught except in specialized schools, therefore educational agencies refer largely to the scales for the four primary skills. Often outcomes on these tests are used to measure student achievement and teacher performance.

Governments may send citizens to foreign countries, or to areas of the home country where minority languages are spoken, as government-funded

humanitarian volunteers. In some cases, for example the US Peace Corps, humanitarian volunteers serve for one or two years in foreign countries teaching language or providing aid services. Most language learning that is done is in-country and addresses survival needs rather than professional contexts, therefore participants typically only achieve low levels of language proficiency. As in educational departments, service personnel may be tested via proficiency tests to measure how much language learning was achieved. In other cases, such as the US National Language Service Corps, volunteers are reserves: They are tested for general language proficiency so that, when a need arises, the organization knows which volunteers are eligible to be sent.

Increasingly, almost all aspects of government work are affected by foreign languages, and all government agencies need some types of language users. Border officers need to conduct basic interviews, but they also need to be able to detect if a person is being dishonest. Financial agencies investigate and audit tax records and payments, requiring language personnel with reading skills to review records kept in foreign languages and writing skills to issue official letters in the language that the recipient can understand. Census workers conduct surveys in multiple languages to ensure accurate data collection and provide personnel capable of answering questions and conducting interviews with residents who have low levels of literacy to ensure accurate population statistics. Language testing is used to help ensure that the government's work is done appropriately.

Rating Scales, Tests, and Scoring

Whether it be the ILR, CEFR, or STANAG, most government organizations refer to a common set of rating scales with skill level descriptions to ensure comparability of test results across agencies. The skill level descriptions provide a common reference enabling organizations to set expectations about general ability. The descriptions do not provide comprehensive lists of abilities or linguistic functions, and as such are subject to interpretation. The scales must be general enough to meet the diverse needs of their users, while being specific enough to control for reliable interpretation by the different organizations that refer to them. The challenge of meeting the needs of all possible government players generally results in a lengthy development and approval process. Once a scale is published, significant resources are invested to develop and validate assessments based on the scale, further complicating the impact of subsequent scale revisions.

While broadly used scales tend not to evolve to a great degree, the manner in which they are applied by different participating agencies must evolve according to the operational needs of the agency. This focus influences the way in which agencies interpret scales, and how they spend test development resources. Although the scales refer mostly to proficiency and performance, training to a proficiency level results in needs for diagnostic and achievement exams that reference the levels. Selecting personnel for training is typically aided by aptitude tests that are independent of the rating scales (since they are not measuring any aspect of a specific language). Examples of each type of test are discussed below, beginning with those most closely aligned to rating scales.

Proficiency Tests

Two examples of US government-developed proficiency tests are the Defense Language Proficiency Test (DLPT) and the Oral Proficiency Interview (OPI). The DLPT is used to evaluate the reading and listening ability of military and civilian personnel in over 50 languages. Though it is largely used as a general proficiency assessment, it is also used as a screening test for other performance exams or as graduation requirement from training programs, although it is not aligned with any training curriculum. Most DLPTs focus on ILR levels 2–3 on the ILR scale, but there are also tests in some languages focusing on levels 3+ and 4, or on levels 0+ to 1+. The OPI, also known as the Speaking Proficiency Test (SPT), is a face-to-face or telephonic test of speaking proficiency in which testers engage in conversation-like activities with examinees. Testers set specific tasks, such as narrating a past event or supporting an opinion, but the subject matter of the tasks is typically determined through the test administration by information gathered from the examinee or selected from a range of relevant topics. The integration of various linguistic factors is evaluated and a holistic rating assigned.

The framework of the ILR Skill Level Descriptions has important ramifications for developing and scoring language proficiency tests. First, the ILR Skill Level Descriptions are generally interpreted as noncompensatory, that is, strength in one function cannot compensate for weakness in another function at a given level. For example, someone who can orally support opinions on societal-level topics using precise vocabulary (a level 3 skill) cannot be considered to have an overall level of 3 in speaking if there are persistent errors that interfere with comprehension, such as failure to distinguish singular and plural. Second, overall control of functions rather than total absence of errors or perfection of understanding is important. For example, a reader need not understand every word to understand the most important points in the text.

For receptive skills tests such as the DLPT, the scoring has focused on capturing what it means to generally control a function or level: How can one tell whether an examinee used a targeted skill to answer? How many items at a level must be answered correctly to demonstrate control of that level? Many receptive skills tests span several levels, and scoring is sometimes based on total items across the test instead of at each level independently. In such cases the total expected score for a level is linked to expected performance of typical examinees at that level, and measurement is less directly linked to specific tasks at the level of interest.

Performance Tests

Performance tests in government settings are linked to operational language tasks. In the USA, the Interagency Language Roundtable has recently developed new skill level descriptions for translation, for interpretation, and for audio translation. One example of a test that is aligned to these criteria is the Verbatim Translation Exam (VTE), a document-to-document translation assessment originally developed and validated by the Federal Bureau of Investigation (FBI), but now used by a number of international governments. Successful examinees must convey all of the information from the source language while maintaining the style of the

source language in the target language. Audio translation exams require examinees to listen to conversations in various languages and write reports of the pertinent information conveyed in English. Success is measured by the transmission of both the main ideas of the conversations and the relevant details.

Like proficiency tests, many performance tests, such as translation tests, are rated through holistic means. Often translation tests are evaluated by chunking the response passages into discrete units of meaning, and then deducting points from an overall possible total for missed meaning units or grammatical errors. This subtractive method does not account for cases where meaning units are present, but the combination of meaning units, addition of material not in the source text, or omission of items not considered meaning units (articles, prepositions, punctuation) can significantly alter the overall meaning of the passage. As a result, many government agencies have opted to score translation tests holistically, requiring that all meaning from the source be retained, including information, style, and cultural or inferred meanings. The ratings delivered are given in reference to a set of translation performance criteria, such as the ILR Skill Level Descriptions for Translation Performance.

Diagnostic Tests

Diagnostic tests are typically an outgrowth of proficiency testing: They are linked to the proficiency skill level descriptions and may be independent of any one curriculum. These tests are often used to provide information to examinees about their areas of weakness and what they need to do to reach the next level of proficiency. These tests are expensive and time-consuming to develop, and are usually available only in the languages with the largest populations of language users in the government. Some tests are associated with training programs and are conducted face-to-face as part of the in-course assessment, with instructors then providing tailored instruction to students based on the feedback from the diagnostic tests. Other diagnostic tests are designed for self-study and are delivered online: These are intended to be used by language-enabled personnel seeking to maintain or improve their proficiency, and they may be linked to self-study programs, offering specific study modules based on the diagnostic test results.

Formal diagnostic assessments linked to the ILR Skill Level Descriptions focus on providing information about an examinee's overall level, and also about particular areas of weakness relevant to achieving the next higher level. For example, an examinee might be given passages with questions targeting overall comprehension, understanding of time sequences, and understanding of basic grammatical relations; the information is compiled to produce a profile of strengths and weaknesses that can be used to tailor future study. Diagnostic assessments tend to focus on functions, with grammar and vocabulary being assessed as supports to functions rather than as goals of assessment. Diagnostic evaluators take detailed notes in order to provide extensive qualitative feedback to the examinee, avoiding mentioning a rating or score. Diagnostic evaluations are in use both for single skills (speaking, reading, writing, listening) and combined skills (translation).

Achievement Tests

Achievement tests are used by government organizations much as they are in academia: to assess whether students or trainees have learned what has been taught. As such, they tend to be developed within the organization doing the training, and may be highly tailored to specific purposes. Since government language-training programs are often linked to proficiency level outcomes, the rating scales in use by the government influence classroom achievement tests. In many cases, as in academia, these tests are designed and developed by people with no training in language testing, and the stakes of these tests tend to be medium to low, as they are typically only one method of assessing student progress.

Aptitude Tests

A final type of language test used within the government and military is aptitude tests. Aptitude tests are designed to predict success in training programs, so that government and military organizations can determine the best use of their personnel resources. Language training programs are very expensive, both in terms of money and in the time personnel spend in the programs: In some cases, a military recruit's term of duty may be up only a few months after training is completed. Predicting which recruits are likely to succeed is thus very important.

The Defense Language Aptitude Battery (DLAB) is used primarily by US military recruiters as part of an extensive battery of tests designed to place recruits in appropriate occupational areas. Scores on the DLAB are used to determine eligibility for language training programs and, in some cases, to determine which language examinees will study. Languages are divided into four difficulty categories, and, for personnel in careers with strong language requirements, only those with the highest DLAB scores are eligible for placement in programs in the most difficult languages. The test focuses on language-related cognitive skills, such as distinguishing speech sounds, making generalizations about grammatical relations, and following grammatical rules. Research is in progress on an expanded aptitude battery that includes noncognitive measures, such as short-term memory.

Current Research

Research into language testing within the government is largely focused on improving specific products and procedures. Language testers in the government have as a primary duty to produce tests and ensure continued quality results; research is generally considered a luxury, unless specific problems with tests are identified for which research could help provide a solution.

It had been assumed for many years that establishing proficiency in a foreign language would be sufficient to assign translation tasks to native speaker linguists. Research by Lunde and Brau (2005, 2006) investigated the correlation initially between reading translation abilities, and later between writing and translation abilities. The research found no significant correlation between strong translation

ability and strong ability in either reading or writing, leading to the conclusion that a separate skill, the ability to transfer language from one language to another, was needed beyond knowledge of the two languages in order to successfully translate.

Government language testers deal extensively with human raters evaluating a large number of exams, so there is a logical interest in rater reliability and the effects of various rater characteristics, such as native speaker status, rater language proficiency, and rater first language. Rater characteristic research has benefited from studies done within the government context, as it often deals with language proficiencies higher than those typically achieved through academic contexts and with more formalized, large-scale assessment. Research on raters has shown that rater variables such as native speaker status and language proficiency do impact how language is evaluated.

Standard setting has not been widely applied to government language tests. Beginning in 2009, the Department of Defense began planning for standard-setting studies to set cut scores for the DLPT. Several standard-setting studies have been conducted, and results are currently being analyzed.

Exploring the relationship between proficiency and difficulty is an ongoing area of research. The ILR Skill Level Descriptions have been described as a “functional scale” to distinguish them from scales that might describe learners’ progress. A hallmark of the concept of proficiency levels is that there is a wide range of material that a given language user at a particular level might be expected to handle. Operationally, what this means for language testing is that, within the set of material that would be considered to represent a given level, there is a wide range of difficulty. It is common for there to be some test items at one level more difficult than test items at higher levels—that is, although there is a correlation between proficiency level and difficulty, there is considerable overlap in difficulty between levels. The result of this for testing is that judging an examinee’s proficiency level based on right–wrong data may lead to problems in rating. An examinee at ILR level 2, for example, might miss many level 2 items, but potentially answer several ILR level 3 items correctly. This characteristic also makes standard-setting studies difficult to interpret, as typically standard-setting panels look at proficiency rather than difficulty in making judgments, and when proficiency and difficulty do not align well, the validity of the judgments may be called into question. Some small-scale studies have been done to examine the correlation between difficulty and proficiency. In addition, a larger-scale research effort is under way to try to isolate factors that affect difficulty of understanding audio material, beyond the factors referenced in the ILR Skill Level Descriptions. An initial study on the effect of the density of spoken texts on comprehension is in the planning stages.

Challenges

Language testers working in government organizations are constantly challenged to provide test instruments and assessment practices that meet operational demands as well as standards in the field. Best practices are constantly balanced with agency priorities and limitations and resources. Most agencies with full-scale

language evaluation programs administer thousands of tests annually, in locations all over the world, and in over 100 languages. In some cases, test items have responses in multiple languages, thereby requiring multilingual raters to deliver scores.

Fluctuating operational needs such as changes in language-related positions, responsibilities, and personnel often call for realignment of test batteries and passing scores or, in many cases, the development of an entirely new test. Test development is often limited by an immediate need for the test. Test developers must rely on modifying existing test instruments from within their agency or partner agencies. Production time frames are often months or even days instead of years for development and validation. Often deadlines must be met without additional funds or personnel. Developers rely on in-house technical personnel paired with translators from the field to produce the needed instrument.

The number and classification of languages is also an issue. Government agencies typically need individuals that have proficiency in a wide variety of languages. Most agencies regularly communicate in well over a hundred languages representing nearly every language family. Acquiring, training, and evaluating personnel for so many languages is challenging. Further, many languages have multiple variants that may need to be tested separately. Decisions as to whether to do so are often guided by considerations of mutual intelligibility, established recognition of the languages as separate, and operational needs; all of these considerations may change with time. For example, Serbo-Croatian was once tested as a single language, but the trend now is to test Serbian, Croatian, and Bosnian separately. These decisions are necessary but costly to the government.

Since most government agencies use a single scale across multiple languages, there are challenges in how to interpret language proficiency equivalently when languages function differently. Of particular interest are the issues of diglossia and the acceptability of other “foreign” language features in a language evaluation. For example, many Indian subcontinent languages such as Hindi, Punjabi, and Gujarati incorporate a lot of English, and it could be incorrect or inappropriate to use the Hindi/Punjabi/Gujarati word in certain contexts even when one exists. Moreover, creoles and patois completely convert to another language when certain proficiency levels are reached; for example Haitian Creole becomes French for certain functions and contexts. When high level language functions require shifting to another, separately evaluated language, government agencies are challenged to decide whether the upper level functions can be supported by the test language and, therefore, whether or not an examinee can reach the highest level of the scale in that language. For some Arabic dialects, professional, sophisticated, or contextualized language tasks would never be conducted in the dialect, but rather in Modern Standard Arabic (MSA). Since MSA is typically tested separately from dialect (to identify examinees that have MSA only and no dialect [often learners], or dialect only and no MSA [often heritage speakers or native speakers that were not formally educated in Arabic]), perhaps the highest (i.e., level 5) score cannot be reached in a dialect-only test.

Government language evaluators are challenged also to educate the test score users within the organization, often the managers, operational staff that need

linguists, and the examinees themselves. Typically, test score users are not accustomed to the nature of language or the interpretation of language test scores, leading to confusion, misunderstanding, and inappropriate score use. The indeterminate nature of language, with endless room for interpretation, can lead users to the conclusion that the language test scores were subjective, and therefore not accurate. Examinees often misinterpret their ratings' corresponding description to mean the entirety of what a person can do, not the minimum threshold of that level. Likewise, untrained users can overinterpret what a score represents, and assign an inappropriate operational task such as giving a translation task to an individual with a high speaking score.

Joint Governmental Efforts

The primary international organization for government language testing has been the Bureau for International Language Coordination (BILC). Established in 1966 through the British Ministry of Defence, it oversees the use of the STANAG 6001 and promotes interoperability between language-testing practices of NATO nations. BILC focuses on language training and testing occurring within the military arms of international governments, though these efforts sometimes have washback into other branches of government. BILC's founding member nations were France, Germany, Italy, the UK, and the USA, but it now includes 26 country members, mostly coming from Europe and North America. BILC meets on an annual basis to discuss pertinent policy and procedure issues, as well as further develop test instruments, research, and give member reports (NATO, 2004).

Most BILC member nations have nonmilitary government agencies that do not use the STANAG 6001 as reference for their language assessment. Beyond the use of the ILR by the US government, Canada uses the Canadian Language Benchmarks to measure language proficiency for immigration policy decisions (Centre for Canadian Language Benchmarks, *n.d.*). For French/English government position qualifications, applicants take the Test of Oral Proficiency in the Second Official Language, which has its own rating scale (Public Service Commission, 2011). Immigration agencies in Australia, Canada, New Zealand, and the UK have looked to broadly available commercial language exams, such as the International English Language Testing System (IELTS). As in Canada's exams, IELTS has a custom rating scale, and is used for government, professional, and academic purposes (IELTS, *n.d.*).

Government and military language assessment efforts in parts of the world outside North America and Europe have been less transparent. Although there are several government authorized language tests in countries outside the Western world, it is not clear whether or not they are being administered in government contexts. National government position announcements list foreign language requirements, but do not detail how language is to be assessed. For example, the Chinese Proficiency Test (Hanyu Shuiping Kaoshi, or HSK) is recognized by the Chinese government as the only official measure of Chinese for non-native speakers. Similar tests are administered in Japan (Japanese Language Proficiency Test, or JLPT) and Korea (Korean Language Proficiency Test, or KLPT), with all of

these tests delivering results according to internally developed rating scales. It is often the case that when no formalized evaluations are available, government institutions depend on private testing companies, universities, or informal evaluations to determine language proficiencies, even in high stakes situations. Nations that have small immigrant populations or that are emerging are unlikely to have official language-testing programs.

Future Directions

As discussed above, the focus for government language testing has historically been on producing a useful product, often without any input from people trained in language testing. There have not been set US government standards for quality of language tests or requirements for language testing procedures. In 2000, with the initiation of the newest generation of DLPTs, efforts were made to bring in language-testing professionals, and the professionalization effort made a significant step forward in 2009, when government language testers formed a subcommittee under the American Society for Tests and Materials (ASTM) to write a standard practice for language proficiency testing that specifically dealt with ILR-based tests. This standard practice was produced through collaboration between government personnel from many different agencies and private sector language-testing professionals.

The focus on language testing to meet current operational needs has shifted in recent years with the development of the strategic language lists. One such list is compiled annually by various US government agencies to record languages in which the government needs capabilities. Some of these languages are ones the government has little history of using, and as such have not been the focus of large-scale testing. The list drives testing requirements, leading to testing in much larger numbers of languages. The government has thus turned to the private sector to contract out test development and speaking proficiency testing, resulting in efforts such as the ASTM standard practice to codify and standardize expectations for procedures and quality control for language testing for government purposes.

The ILR Testing Subcommittee has long been a venue for collaboration and information sharing among government agencies. Recently the subcommittee has been involved in efforts to clarify and annotate the ILR Skill Level Descriptions for reading and listening, to which end there have been several “summits” involving government and private sector language-testing professionals coming together to discuss the ILR Skill Level Descriptions and articulate a common interpretation of them.

Since the establishment of the Common European Framework of Reference for Languages (CEFR) in 2001, its influence has spread throughout the language assessment world, including government organizations. Various organizations and individuals have made both official and unofficial efforts to link government language-rating scales with the CEFR. The first of these efforts came from government organizations affiliated with international efforts, such as aviation standards and immigration. Although links have been made, most government language

assessments continue to report scores on their original scales rather than according to the CEFR levels.

The top priority of government and military assessment is ensuring that government language personnel are qualified to perform the mission of their agencies. Overcoming the challenges of producing appropriate language evaluations for an ever-increasing range of languages using limited resources under considerable time constraints for multiple contexts, all while maintaining testing standards, is the norm for government testing agencies. Government and military assessment helped establish the foundations of language testing, and today the continuing need to meet dynamic operational needs results in innovative testing practices and enhanced collaboration, benefiting stakeholders both within and outside government contexts.

Language Assessment for Court Translators and Interpreters

Piers Armstrong

California State University, Los Angeles, USA

Introduction

The present treatment of legal translation takes the view that language assessment per se is inextricable from external social circumstances and stimuli, and so describes the broader pragmatic landscape in which legal-interpreting assessment is embedded, including court language as a target discourse for assessors, the expert competencies of legal interpreters, the research on these competencies, contrasting contexts of national needs for legal translators and interpreters, various qualification systems for legal interpreters and/or translators, and finally various test instruments. The key medium of the courts is oral, and thus it involves interpreting rather than (written) translation, which is more central to civil contracts and the study of law. This introduction concentrates on interpreting, as most key points pertain to both modes, but they do so more intensely in the real-time arena of interpreting. A second reason for the greater focus on interpreting here is that policy interventions advancing legal language assessment are largely driven by concerns for individual human and civil rights, and sensitivity to these rights is usually displayed in oral court-centered criminal law contexts rather than in civil law matters, which are more document-centered.

Most language assessment literature describes educational contexts that are normalized—students are selected on the basis of criteria of proximate competence and are institutionalized in a cohort where assessment reflects the syllabus material directly. To the extent that tests present real-world language, this is usually middle of the road linguistic fare, with common idioms and typical social contexts; highly localized terms, eccentric idioms, and grammatically questionable usages would seem needlessly problematic and inappropriate. In contrast, the stylistics and the pragmatics of court language use are eclectic, highly contextualized and wide-ranging in register. Lay native as well as non-native speakers of

the national language used in a court have limited competence in the specialized court language, or “legalese,” and usually become involved in legal matters through chance events. The “legalese” discourse used by court insiders is both technical and eccentric. Finally, legal interactions are unusual both because strategic manipulation of language may prevail over conventional communication (so that the discourse is deliberately obtuse), and because these interactions are adversarial. The court event itself, on whose outcome so much depends, is a sort of “high stakes test” in which most of the ethical standards and common sense of the high stakes test literature do not apply.

Finally, court interpreting is atypical in relation to other professional interpreting modes. Medical, business, and community interpreting conform to “common-sense” lay expectations—they are collaborative, allowing for paraphrases, semantic modifications, or even digressions that the interpreter intuitively senses to be conducive to overall communication. While there is significant national-cultural variation in legal interpreting norms (see below), according to the logic dictated by Western legal paradigms, objectivity is the central ethical tenet. Like the court reporter (who types court utterances into the record), the interpreter must disengage all personal opinion; additionally, the interpreter interlingually “parrots” the speaker, reproducing paralinguistic elements (such as subjective inflections and sentence intonations, grunts, ejaculations, facial gestures, pauses, hesitations, and hedges) because omission of them could change the overall contour of the message and thus be a form of editing. It is not the role of the interpreter to subjectively intervene so as to compensate for perceived misunderstandings of his/her listeners; the interpreter is not there to judge reactions. The classic metaphor of justice as blind—if we think of debilitation as much as of impartiality—is particularly illuminating of what is expected of the court interpreter. Nevertheless, this putative objectivity is often out of sync with the dynamic, political reality of court hearings; rather, legal interpreting can be a cocktail of the contradictions inherent in the court and of those inherent in translation and/or interpreting (further described below).

Courtroom Language and Interpreter Competencies

Court language is characterized by several heterogeneous idiolects and technical jargons. The first is “legalese.” This includes various overlapping categories:

- 1 a repertoire of metalegal terms (*judge; justice; magistrate; justice of the peace; lawyer; attorney; US attorney; witness; power of attorney; warrant; artificial person; affidavit; subpoena; arrest; indict; conveyance; deed; eminent domain; appeal; perjury; infraction; prima facie proof; misdemeanor; felony; offense; render . . .*);
- 2 terms deriving from common parlance but admitted into legalese in uncommon acceptations (*serve; consideration; information; complaint; diversion; direct examination; extinction; discovery; motion; decree; counsel; continue; commission; attachment; garnish; alien; degree; notice . . .*);
- 3 archaic grammar words—mostly prepositions and conjunctions (*aforementioned; forthwith; whence; whencesoever; whereof; therein; thereinbefore; therewithal; pursuant to . . .*);

- 4 locutions with idiomatic legal contextual meanings (*points and authorities; by the authority vested in me; so help you God; in chambers; Submitted; in pro per; motion to stay; letters rogatory; accessory before the fact; under my hand and seal; breaking and entering . . .*).

Legalese is also rooted in rather arbitrary particularisms: an opaque term or phrase, which was never widely used in ordinary language, may become a fixed feature in legalese (e.g., *peremptory challenge*). Finally, legalese, at the moment of creation (in legal opinions, etc.), is not infrequently subject to a sort of stylistic torture in its attempts to attain the polarized goals of precision (avoiding over-generalization) and all-inclusiveness (avoiding loopholes). For illustration of such competing virtues and stylistic management strategies, see Vijay Bhatia's summary (Bhatia, 2010) and application to legal translation (Bhatia, 1997).

The second category is forensic, comprising the jargon of any technical field needed for material evidence. These include fields that are somewhat particular to the courts (fingerprints, blood residues, firearms, intoxication, etc.) and less typical fields, which become relevant in particular cases (drugs, accounting, medical injury, or pain and suffering are common examples, but any specialized field, from stamp collecting to zoology to boxing, may become relevant to evidence in a particular case).

A third category covers popular parlance and subculture registers—idioms, informal speech, slang, and so on—which can feature in witness testimony. Californian Spanish–English interpreters, for example, are expected to know street slang for drugs (*cold turkey; free base; roach; pot; hog; angel dust; dime-bag; bindle; glass; ice; cap; kit*, etc.) in both languages: informal speech for Central American countries; and the distinct, deliberately oblique and rapidly changing idioms used within Spanish-speaking gangs.

Finally, legal interpreters (and even more so legal translators) must also be able to transpose between alien national frameworks, which presupposes some depth of legal understanding. Translators and interpreters are typically agile autodidacts in law and in comparative law. Their taxonomical *bricolage* generates solutions that effectively serve in concrete situations but that, if extrapolated, reveal inadequacies. A parallel process obtains in the officially translated versions of blank forms used by the court, which are usually generated ad hoc by nonexperts and are often problematic. Because of the court imprimatur, the inappropriate terms generated can gain coinage, become de facto standard terms, and make their way into bilingual dictionaries (for example, see Tomasi, 2002, for an illustration of the variegated Spanish renderings of “probation,” a characteristic and key term in US criminal law, in a whole series of bilingual legal dictionaries).

Court interpreters routinely use three main modes, listed here in order of importance: consecutive interpreting, simultaneous interpreting, and “sight translation.” Consecutive interpreting means listening to limited chunks of discourse and then rendering them into the other language during a pause in the original that allows for this rendering. The discourse is normally the dialogue of interrogation between lawyer and witness, which is usually limited to manageable utterances for the short-term memory of the interpreter (about 60 words). The requisite short-term memory faculty is distinct from interlingual knowledge and is highly

developed in good interpreters. Knowledge of popular speech, including marginal idiolects, is prominent in consecutive interpretation of the testimony of lay witnesses. In the case of expert witnesses (forensic experts of different sorts), technical lexicons are prominent.

Simultaneous interpreting is used in court largely for the ancillary function of apprising the defendant of what is being said at moments when the defendant either is merely accompanying proceedings passively (not being actively involved as a witness) or is being addressed but not questioned by the judge. Legalese is common in the latter case and in dialogues between judge and lawyers. The interpreter usually sits close to the defendant in these cases and quietly renders (“whispers”). This delivery is unmonitored and not transcribed. The intelligibility of this discourse to the defendant is limited not only by the foreign nature of the language but also by its legalese character. Normally, after the hearing, the defendant’s lawyer will reiterate the main points with the help of an interpreter. In this more informal situation, the lawyer will summarize and the interpreter may also tend to paraphrase the lawyer and to stray from the objective and toward the collaborative pole of interpreting styles.

“Sight translation” here means oral translation into court language of a written document in another language. Two main situations for this are: (1) when a foreign language document is presented as evidence in court; (2) when a defendant or a witness must fill out or respond to the contents of a court form. Quantitatively speaking, the first situation is relatively peripheral in court hearings, but it may concern vital evidence. The second situation is common but usually not challenging, in that the form’s content is familiar to the interpreter.

Theoretical Research on Translation and Interpreting Competencies and Strategies

Translation theory is a relatively young but vigorous field. The commonsense objective of translation is to establish equivalence of meaning between source and target and to overcome the inevitable asymmetry between source and target codes with respect to lexical items. However, the notion of “equivalence” is psychologically complex and distinct scholarly conceptualizations of it lead to serious philosophical differences of approach (Halverson, 1997). This leads to judgments of appropriate strategy that play out at the levels of individual words, of the overall meaning of phrases (which deviate, if stylistically indirect, from the base denotation of the words used), of the nature of representation (whether the “real” meaning is in the words themselves or in preverbal conceptualizations, of which both the source and the target language words are alternative transpositions), and of the situational dynamics of the respective occasions of transmission and apprehension.

One frequent practical dilemma consequent upon these considerations is the appropriate contextual “feel” of the translation—whether the translator should strive to preserve the semantic and contextual load of the original, with the disadvantage that the consequent product is “strange” for the target language reader but with the advantage that the latter assimilates more of the alien cultural frame

of the original (“linguistic fidelity” to the original; “foreignization” for the target language reader), or whether he or she should rather liberally transpose terms and context, so that the translation is a parallel alternative, in other words concrete meanings change but the overall reading experience remains analogous, in terms of relative strangeness or familiarity, to the reading experience of the original language reader (“domestication” to the target language, for “communicational equivalence”). The issue was first formulated as a dichotomy by Friedrich Schleiermacher, a seminal 19th-century scholar in biblical hermeneutics, and his articulation remains paramount for at least two reasons: (1) it illustrates how translation exists in a tension between competing poles and is thus inherently and even radically imperfect; (2) it extrapolates from the linguistic product to reception, and thus from text- and author-centeredness to a multiplicity of contributing agents. This points to translation as linguistic and social compromise and as pragmatic solution (see Armstrong, 2012).

From the 1960s on, scholars have opened translation to interdisciplinary considerations that range from cognition (psycholinguistics) to pragmatics (communication studies), power relations (social psychology, sociology, political science), and textual and cultural allusion (literary theory and cultural studies; here, the way in which a text or an utterance is embedded in a network of related references and practices). A sophisticated assessment of the quality of a translation is predicated on some prior mapping of the inter-relations of these planes. One such synthesis, based on a substantive review of prior theorizations emerging in Germany (*Übersetzungswissenschaft*) and elsewhere in the 1970s, 1980s, and 1990s, is undertaken by Juliane House in her “functional–pragmatic model of translation evaluation.” Of equal interest to any given theory are its treatments of prior theories. House (2001, pp. 244–7) convincingly dismisses the scientific validity of a whole series of prior and contemporaneous models or theories for the evaluation of translations: “mentalist” or traditional holistic intuition; functionalist approaches that attend more to the utility of the translation in its user context than to the fidelity of its transposition from the original; and linguistically oriented approaches (such as Hatim & Mason, 1997) that integrate pragmatics but do not provide a systematic frame for the evaluation of translation quality. Examining the relative scientificity of the construct of translation theory, Hebenstreit (2009) cites Albrecht’s finding that, in translation studies, definitions—a prerequisite of scientific method—are often mixed with explanations and are confused with models (Albrecht, 2005, pp. 23–7, cited in Hebenstreit, 2009, p. 11). Interestingly, Hebenstreit notes that “a significant part of [the formal] definitions are definitions of types or modes of translation like *translation* as opposed to *interpreting*” (p. 22). Generally translation theory is more concerned with semantic ontology (i.e., often, precision or depth of meaning) than with the mechanical constraints of cognitive processing and delivery, so central to interpreting. Alessandra Riccardi (2002), writing in an important anthology on translation theory that she also edited, noted a pattern of marginalization or subsumption of interpreting in translation theory. Ironically, in turn, her description of interpreting unintentionally marginalizes legal interpreting by subsuming it as a variant of collaborative interpreting (“liaison interpreting”) in which “clarification, explanations and interruptions are often necessary steps in fulfilling the objective of effective communication” (Riccardi, 2002, p. 75).

Interpreting and written translation have been more equitably integrated in recent summaries of psycholinguistic research, such as Shreve and Angelone's "Translation and Cognition: Recent Developments" (Shreve & Angelone, 2010). Shreve and Angelone note the influence of computational tools (corpus linguistics) and argue for the integration of process research (focusing on how mental expertise develops) with neurophysiology. In the same volume, scrutinizing interpreting from this viewpoint and summarizing many previous studies, Moser-Mercer (2010) and Diamond and Shreve (2010) describe the plasticity of the bilingual brain and the mechanics of short- and long-term memory development exemplified in professional interpreting, while Halverson (2010) argues for interdisciplinary approaches to the study of multilingual cognitive processing by interpreters. Halverson cites multiple studies from the 1990s by a leading bilingual cognition expert, Annette de Groot (see also de Groot, 2011). Writing with Ingrid Christoffels, de Groot also produced what remains the most useful summary of the literature on interpreter cognition and performance measurement (Christoffels & de Groot, 2005). They note the difficulties of reliable in situ performance studies and measures, and a consequent "lack of statistical power . . . [and] lack of ecological validity of the experimental setting and the stimulus materials" (Christoffels & de Groot, 2005, p. 455). In relation to the representational issues of particular interest to Halverson, they outline the continuum between meaning-based strategies (compare preverbal conceptualizations, above, or "deverbalization") and verbal transcoding strategies used by interpreters. While the former is ostensibly more appropriate (as it attends better to pragmatic intent, maps whole phrase units, filters against false cognates, etc.), the two in fact inter-relate cognitively both at the abstract level of modes of representation and at the concrete level of deployment of mental circuitry. Additionally they note that, in professional praxis, fatigue (which typically sets in after 30 minutes) can have a notable effect on the relative deployment of cognitive tools, increasing transcoding. They caution that theoretical accounts "seem to assume, albeit implicitly, that all interpreting is meaning-based interpreting . . . [whereas] . . . it seems plausible that both transcoding and meaning-based interpreting occur, but complete deverbalization seems unlikely" (Christoffels & de Groot, 2005, p. 465). This calls into question the reliability of schemata depicting the cognitive recoding used in interpreting (and translation), which tend to de-emphasize transcoding because it is not recommended. Finally, they note that language combination (i.e., the relative degree of difference between the source and the target languages) is an important variable affecting recoding strategies; this means a relatively greater degree of case-by-case language stickiness (i.e., in disciplinary terms, a linguistics-centered specificity) than is normally represented in psycholinguistic cognitivist research.

In sum, the theoretical research surrounding translation and interpreting is constrained by the relative recency and limited development of the relevant cognitive science, is necessarily interdisciplinary and complex, has not yet developed a consolidated empirical foundation, and has seen a succession of speculative models that are mutually contradictory. The research on subfields such as legal translation and interpreting, and, within that, on language assessment tests, is usually context-driven and even less susceptible to any systematic scientific generalization.

Research Specific to Court Interpreting and/or Interpreting Assessment

As noted above, just as interpreting is particular and different within translation (i.e., in relation to written translation), legal interpreting is such a particular niche and mode that it breaks with the general conceptual mould of interpreting. The charge of legal interpreting is neutral and precise rendition and reproduction of hedges, contradictions, and gaps. The ideals of objectivity and invisibility derive from the aversion of legal paradigms toward the recognition and acceptance of subjective mediation on the part of instruments or resources of the court such as interpreters (as opposed to the appropriately subjective advocacy of lawyers). Thus, in addition to the huge challenge that interpreting presents to cognitive mechanics, legal interpreting is fraught with philosophical contradictions. Various vested interests militate (usually unconsciously) against the exposure and recognition of these limitations and contradictions.

In many countries, particularly in former colonies or highly stratified societies, the role of the interpreter has traditionally overlapped with clerical and even defense lawyer functions. In Malaysia, for example, Ibrahim (2007) describes a paralegal advocacy role as normative for interpreters. Research on court interpreting suggests that, even in countries where legal interpreter neutrality and discretion are norms, much more collaborative interpreting practices occur than is recognized (Hale, 2002).

Awareness of the dearth of empirical research focused on assessment instruments for qualification (notably, admission and then formative and summative assessment within educational programs, and professional licensing) triggered a research forum in the American Translators Association, an organization more oriented to practicing translators and interpreters than to academics. This led to a notable series of academic anthologies published by John Benjamins, including Shreve and Angelone (2010, mentioned above), and Angelelli and Jacobson's *Testing and Assessment in Translation and Interpreting Studies: A Call for Dialogue Between Research and Practice* (2009a). This volume undertakes to address construct definition and rubric development, to describe empirical research implementing quasi-experimental and nonexperimental designs, and to present case studies describing admissions tests and professional certification. The range of topics—translation and interpreting, spoken languages and sign language, community and literary domains, moves toward discourse analysis and moves toward lexico-semantic discrete item analysis, localization software, and so on—is suggestive of the heterogeneous, fragmentary, and incipient nature of the field. Angelelli and Jacobson's (2009b) introduction provides an overview of the research and notes that "little has been published on the high-stakes certification programs and standards that exist in different countries: assessments seem to be conducted in a vacuum" (p. 2). In a similar vein, Angelelli's (2009) article titled "Using a Rubric to Assess Translation Ability: Defining the Construct" observes:

There is no one definition of translation competence . . . Neither is there a rubric that can capture different levels of competency in translation. Instead, there is a

continuing debate about how to define translation competence and exactly how its constituent elements are to be conceptualized, broken down, interconnected and measured. (p. 13)

The endurance, in practice, of generalistic conceptions of aptitude, despite the trend toward taxonomies of specialized skill criteria, brings us to perhaps the commonest big question in language assessment methodology for both translation and interpretation: the choice between overall holistic assessments (usually made on the basis of a general impression about performance vis-à-vis a set of recognized flaws or virtues) and discrete item analysis. The two are certainly not inherently incompatible, but it is usually more convenient to use just one. In both legal interpreting and translation tests, the trend has evolved from holistic to discrete item grading. The latter typically takes the form of a set of isolated words or syntagms, each of which constitutes a scoring unit; the solution for each unit is corrected against a preestablished glossary of acceptable answers (or “scoring dictionary”); new solutions by test takers which seem adequate can be referred to a committee for confirmation and inclusion (or not). The target text or script contains a set of specific and discrete segments (items) chosen because they will likely trigger errors revealing limitations in specific competencies. This frame usually involves a taxonomy of flaws (rather than virtues), such as omissions, additions, wrong verb tenses, wrong prepositions, misunderstanding of the source text, inappropriate calques, and so on. These elements are often weighted differentially, according to the perceived importance of the error, whether in terms of semantic precision or as an impediment to communication. While holistic assessment was the *de facto* norm (particularly in written exams in which multiple paragraphs were translated), scoring units are increasingly common in both written and oral tests. Proponents consider them more objective, more amenable to refinement of the correction reference instrument, and more economical. Holistic assessment, on the other hand, may better accommodate progressive agendas concerned with global discourse features. Either should be compatible with norm- or criterion-referenced tests, but holistic assessment may gravitate to norm-referencing (as in the informal testing of a set of job candidates assigned a global task and judged intuitively) and discrete item scoring units to criterion-referencing (the scoring unit construct usually works with a set of heterogeneous criteria—such as different skills, or, here, different modes of error). Intermediary modalities are always possible. Angelelli (2009) proposes a rubric for translation ability assessment that, like many rubrics used in formative assessment in education, uses a series of distinct but general criteria (source text meaning, style and cohesion, situational appropriateness, grammar and mechanics, translation skill) each of which is to be assessed holistically, on a scale of 1 to 5.

Eyckmans, Anckaert, and Segers (2009) propose a combination of the virtues of both holistic and discrete item analysis. They report on an experiment that compared the performance of raters by using three methods of assessment applied to Dutch–French translation students in Belgium—and also by using experienced translation teachers as raters. The three methods are: (1) holistic (intuitive–impressionistic); (2) “analytic” (“scoring units,” as described above; in this instance, the error categories were *meaning; misinterpretation; calque; register; style; grammar;*

omissions; additions; spelling; punctuation); and (3) the authors' own proposal, "Calibration of Dichotomous Items (CDI)." The CDI method also analyses discrete items, but with a notable statistical refinement in the development of the set of target items. The raters do not identify the set of target items by intuition, nor do they necessarily need to integrate all of the standard error categories; rather, the test takers' performances are all corrected without a preexisting rubric, but still analytically, in the sense that the category of each error is noted in the margin. The pool of all the concrete instances of error is then analyzed with a view to selecting those segments and attendant errors that, statistically speaking, best correlate to overall performance (presuming also, of course, that the error is considered relevant to the target competence). These items are thus selected on the basis of their statistical discernment value, but they are "norm-referenced" because they derive from actual test-taker performances and from comparisons between those performances, rather than from measurement against a preconceived set of error categories (as in "criterion-referencing"). This situational, "crowd-sourcing" approach may better accommodate the contention of many language teachers that the inherent subjectivity and unpredictability of language tends to escape preconceived schemata as to what constitutes correctness. The "dichotomous" feature means that answers are corrected with a binary logic of right or wrong rather than on a sliding scale of degrees of error, an approach intended to reduce rater subjectivity. The findings of these authors as to inter-rater reliability confirmed their expectation that holistic assessment was less reliable than traditional analytic assessment, which in turn was less reliable than CDI. The appendices of this study (pp. 89–93) provide details from all three rating methods, compared.

In summary, the bulk of research on court interpreting is qualitative research on discourse. There is little that is specifically concerned with the reliability and validity of legal interpreter tests, and few research partnerships triangulate between psychometric expertise, industry expertise, and user-need and social adequacy assessments. The statistical validations currently available are suggestive points of departure for the sort of partnership between disinterested academically based researchers, industry insiders, government agencies, and public interest groups that is needed for the psychometric and social validation of high stakes legal interpreter and translator exams.

National Contexts and Description of Modes of Professional Qualification

The assessment of court interpreters and legal translators cannot be divorced from professional qualification, which is usually managed by noneducational entities and which must in turn be understood in specific national contexts and from the perspective of language needs. The USA, Britain, Canada, Australia, France and Germany, for example, are all immigrant societies with one dominant language, one court language, and constitutional or equivalent guarantees of right of access to legal language services for limited proficiency speakers in the dominant language. South Africa, by contrast, is a multilingual society with 11 official languages, where neither the official court language (English) nor the de facto one

(Afrikaans) is a native language for many citizens. Interpreters are full-time state employees and are normally polyglots, with competence in indigenous languages for which formal assessment instruments are limited. Moeketsi and Wallmach (2005) report that, "in a normal day, the South African court interpreter might be required to interpret in five African languages plus English and Afrikaans" (p. 78). The conventional Western-style courts are also complemented by traditional courts in tribal lands. Given the complexity of language pairs and the variance among any single interpreter's competences in different languages, as well as the range of pragmatic situations in different jurisdictions, the strategy recommended by these authors and partly undertaken by the state is not to implement rigorous exams in specific language pairs, but rather to develop university degrees in court interpreting, in order to appropriately professionalize the many individuals with existing language skills and to use distance education models to enhance distribution of the educational model (Moeketsi & Wallmach, 2005).

Hong Kong presents another situation: the official court language was English and has become English or "Chinese" (Cantonese or Mandarin). Ninety percent of the population speaks Cantonese, and this is the dominant language of witness testimony. Interpreting needs beyond Mandarin, Cantonese, and English are limited. The legal system and codes represent a continuous adaptation from the British common law of the colonial period. Statutes are written in both languages; more remarkably, they can be invoked in court in either language at any time. As Ng (2009) describes, the inevitable asymmetries of key terms create a significant margin of manipulable ambiguity for lawyers. The key challenge here, then, is to refine legal translations. This occurs in a two-way process, which involves ironing out the wrinkles of ambiguity in the English precedents as much as eliminating any inappropriate leeway that emerges in the Chinese (Ng, 2009, pp. 47–8).

Finally, at the international level, the European Union is the largest and most dynamic arena for projects developing court interpreting and translation. Hertog and van Gucht (2008) provide a book-length summary of an analytic survey of legal interpreter and translator service provision and certification procedures, which is based on questionnaires with government and professional organs in all European Union (EU) states. The study culminated in the AGIS project titled "Aequilibrium or Instruments for Lifting Language Barriers in Intercultural Legal Proceedings" (see also the eponymous publication, Keijzer-Lambooy & Gasille, 2005), which was organized through the Directorate-General for Justice, Freedom and Security, at the Commission of the European Communities (COM, or European Commission), the administrative branch of the EU. An analytic snapshot of findings for each country is provided and one full-length profile (for Austria) is included as a sample. The study ranks countries for quality in terms of service, provision of service, or administration, and it does so according to several criteria such as training levels, accreditation entities, the availability of a register of qualified interpreters, and disciplinary procedures. The overall findings note the serious inadequacy of information, contradictions in responses, and a low level of understanding, by governments, of the need for quality interpreting standards. Where certification is managed by professional stakeholder entities rather than by governmental agencies, it is usually more tightly managed, and its handlers are better technical respondents.

Description of Modes of Assessment of Professional Qualification

Court interpreters and legal translators may become qualified through education/examination/education; through examination/education/examination; or on an ad hoc basis (scrutiny of résumé by a government office, by a court administrative office, or by a judge in the real-time context of a case). Even in the more organized contexts, it is essential to consider the nature and role of the sponsoring organ, which may be the legal administration system, a different government organ, a nongovernmental but central professional organization, or a professional organization that does not constitute a central authority and competes with other such organizations. Finally, in almost all countries there is a margin of tolerance of professionally undocumented interpreters (as when a bilingual person is used because s/he is available, without scrutiny of qualifications).

Malaysia is an illustrative example on various issues. The Malaysia National Institute of Translation was set up by the Ministries of Finance and Education in 1993 with an intention of centralization and systematization, but it has not yet succeeded in supplanting an ad hoc system that Bell (2007) describes as a “typically chaotic market” (p. 107). Bell also notes that the Institute’s authority is contested by other professional organizations. Court interpreters in Malaysia are civil servants with permanent employment. The criteria of selection are “a school certificate and a credit pass in the language concerned” (Ibrahim, 2007, p. 212); there is also a short course on court procedures following recruitment. Candidates will normally be linguistically qualified only in a subset of the country’s languages—a subset consisting of the languages of academic literacy in the school system (Malay, English, Mandarin, and Tamil)—so that arrangements for speakers of non-Malay indigenous languages, or immigrants, are ad hoc. In sum, the disconnection between different sectors, the disparity of traditional practices and missions, and the lack of a substantial central authority militate against the normalization of procedures and assessment that one might assume to pertain, given the relative stability of employment.

The logistic and epistemological complexity illustrated in the Malaysian case obtains in varying degrees elsewhere. In a good number of countries, rather than being operated directly for or by the judicial administration, court interpreter and/or legal translator certification is one specialization within interpreting and translation, being covered with other specializations under the authority of a government or central professional organization (the intended direction in Malaysia). In Australia, a central quasi-governmental organization, the National Accreditation Authority for Translators and Interpreters Ltd (NAATI), allows for accreditation by a NAATI exam or international equivalent, by completion of a recognized university course in translation and/or interpreting or international equivalent, or by evidence of advanced standing in translating or interpreting. NAATI exams are organized by level (paraprofessional, professional, advanced) and mode (oral interpreting or written translation) rather than by professional specialization (legal, medical, etc.). There are currently no interpreter tests at the advanced level. All tests include ethics components and “social and cultural

awareness” questions. The thrust of the Australian system, then, is to professionalize interpreting and translation holistically rather than to attend to any industry constituency or language subfield.

In Sweden, the Swedish Legal, Financial, and Administrative Services Agency conducts a general interpreting exam; a pass warrants official “authorization” as an interpreter (i.e., a license). Authorized interpreters can take an additional test for specialist qualification in legal or medical interpreting. Maintenance of authorization requires ongoing professional activity (Idh, 2007).

The situation in the UK is distinguished by a history of several decades of serious engagement with the issue of the need for interpreter services in police work; this has resulted in a substantial administrative infrastructure articulating relations between legal interpreters and other agential groups in the justice system (Hussein, 2011), and in a specific exam, the Metropolitan Police Test, administered by the Chartered Institute of Linguists (IoL or CIOL) for the Metropolitan Police Service. More recently there has been some centralization of qualification in other government areas, but less so for private and corporate demand, including civil law. Public service interpreters (PSIs) work with a range of government services and organs, including the courts. Various interpreter exams organized by professional organizations are accredited by a governmental organ, the Office of Qualifications and Examinations Regulation. Eminent among these exams are the Metropolitan Police Test and the Diploma in Public Service Interpreting (DPSI), which comprises a series of exams often taken over several years. A DPSI pass is calibrated to Level 6 of the Qualifications and Credit Framework of the National Occupational Standards for Interpreters and Translators (produced by CILT, the National Centre for Languages). This correlates to the C1 level (effective operational proficiency) in the Common European Framework and approximates to post-baccalaureate level (a completed BA). The central conduit to get work has been the UK National Register for Public Service Interpreters (NRPSI), also operated by the IoL. This requires a security check (verification of no criminal record). The Register enforces ethical standards and has grievance and disciplinary procedures. NRPSI qualification is at interim or full status. Each requires a combination of work experience, character references, and formal certification; progression from interim to full status within a set period is obligatory for maintenance of qualification (Corsellis, Cambridge, Glegg, & Robson, 2007). The DPSI exams are organized by IoL’s Educational Trust (IoLET), a professional services organization that is technically a charity. Candidates to DPSI exams choose from four public service specializations: English Law, Scottish Law, Health, and Local Government. A salient feature of the UK system of legal interpreter certification is that it is a publicly monitored and triangulated partnership, between government organs with general authority in certification, a dominant association of language service professionals, and the law services of the state. In July 2011, however, the Ministry of Justice, motivated by budgetary pressures, announced it would create a new register for legal interpreters and a single supplier contract system, a move contested by the CIOL.

In the USA court interpreter certification is controlled by agencies appointed by and for the legal administration system, largely in response to legislative mandates for the provision of services, in the context of government obligations

toward civil rights—notably the 1978 Court Interpreters Act, which established the right to an interpreter of any linguistically needful individual involved in Federal proceedings (in practice, the defendant), and the obligation of the Administrative Office of the United States Courts (AO) to “prescribe, determine, and certify the qualifications” of interpreters. Rights vary at the state level. The Californian constitution was amended (through Article 1, § 14, enacted in 1974 and complemented by subsequent legislation charging the court system with establishing qualification mechanisms) to include the right to an interpreter for criminal defendants. The US system lacks the public partnership aspect of the UK. Arrangements for legal interpreter exams vary with administrations, jurisdictions, and by language.

The Spanish–English exam for qualification for Federal courts (the FCICE) was developed over a long period by several dedicated teams, first commissioned directly by the AO’s Federal Court Interpreter Certification Examination program (also called FCICE) and eventually managed by the National Center for State Courts (NCSC), an independent para-governmental national nonprofit organization with research and administrative missions. The NCSC also partners with for-profit companies, notably Second Language Testing, founded by Charles Stansfield, which was mentioned above regarding the validation of the predictive validity of the FCICE written exam (Stansfield & Hewitt, 2005). In addition to the Spanish exams, the NCSC has, to date (2011), developed assessment procedures for Haitian Creole and Navajo; approved candidates in these three languages become “Certified Federal Interpreters.” For other languages, each local federal court proceeds on a case-by-case basis and can assess and classify a prospective interpreter as “professionally qualified” or, failing that, where needed, as a “language skilled/ad hoc” interpreter. Qualification as “professionally qualified” is warranted by passing, in the relevant language pair, the rigorous State Department conference or seminar interpreter test or the United Nations interpreter test, or by membership in the Association internationale des interprètes de conférence (AIIC) or in the American Association of Language Specialists (TAALS, also dedicated to conference interpreting). For membership, these organizations require some combination of conference work experience and sponsorship from an existing member rather than exams. Given these variations and the three tiers for particular languages, the US federal system for certifying and providing interpreters evidently leaves huge gaps and makes for contradictory standards.

Description of Tests

In the UK, the interpreting skills tested for the DPSI are the standard ones (see above), with the added specification of “whispered simultaneous,” which simulates court and other hearings (as opposed to the use of audio transmission equipment, as in conference interpreting). The exams are contextualized to the targeted public service functions. Interpreter candidates must also do written translation tests. The candidates are assessed holistically, on a scale from 1 to 12, on a series of criteria by rubrics specific to each test: for consecutive and whispered simultaneous, the criteria are accuracy (overall communication), delivery, and language

use (linguistic particulars); for sight, the criteria are completeness, accuracy and fluency/pronunciation; for the translation into English, the criteria are accuracy/appropriacy, cohesion and coherence, and effectiveness. The exam structure, rubrics, and contextual domains for each of the four specializations are available at the IoL website (www.iol.org.uk/).

In the US, the standard certification for translation—including legal, since there is no specific legal translation exam directly associated to court administrations—is through an exam conducted by the American Translators Association (ATA). ATA certification is valid for legal translation and effectively valid for civil law interpreting, but not for criminal law in states with a court interpreting certification system (the great majority). Each ATA exam tests one language pair in a specific direction. Typically candidates translate into their native language. Most ATA-certified members are qualified in only one language pair and direction (typically, into their native language), though some are qualified in more than one pair or direction. Each exam contains three texts of about 250 words each, all of moderate difficulty. The first is nontechnical and obligatory. The second and third texts form a pair; each is semitechnical, from the fields of law, business, medicine, or science; candidates choose one of these two texts. Candidates write out full translations. Books are allowed, digital resources are not. For correction, two raters give independent assessments; in the event of excessive difference, a third rater adjudicates. Raters refer to an established set of error categories (these are described in Doyle, 2003; Doyle's interest is in the use of this set in formative assessment in translation degree programs). Errors are penalized (subjectively) at four incremental levels of gravity (briefly described in Stejskal, 2003, p. 16, with an overview of the development of the exam). Appendix 2 shows a list of error categories, with the ATA's guideline flowchart for determining the point penalties for errors.

At the federal level and for most states, the legal interpreter exam consists of a bilingual written multiple choice screening test, followed by a more challenging oral examination.

The NCSC Consortium oral exam has been used by almost all member states (until 2010, California used its own oral exam). The NCSC Consortium oral exams exist in full and in provisional abbreviated forms, depending on language. The full format has four parts, with scripts and texts drawn or developed from specific realia: sight translation from the target language into English (based on witness correspondence to judge or court, or court documents), sight translation from English into the target language (based on police and other investigative legal reports), consecutive (based on court transcripts of witness examination), and simultaneous interpreting (based on extended statements by judges or lawyers). A medium degree of difficulty is targeted within the range of main court discourses. In the consecutive interpreting module, the distribution of utterances in terms of their length follows a bell curve with a crest at the 30–40 word cluster level (in terms of short memory, a level of difficulty which is quite demanding without considerable training). The speed of the simultaneous is 110–30 words per minute (i.e., a slow to moderate speed). Performances for all sections are graded through the deduction of points for set error categories (grammar; language interference; general vocabulary, legal terms and phrases; idioms and sayings; register; numbers and names; markers, intensifiers, emphasis and

precision; embeddings and position; slang and colloquialism). These categories are distributed and weighted consistently across languages (see Appendix 1).

There is greater variation among Consortium member states regarding use or not of the NCSC Consortium written exam. This is a monolingual 135 multiple choice exam in two sections, one on general English, the other on legal terminology, court procedures, and legal interpreting ethics. Section I (general English) includes sentence completion (9 items); synonyms in context (target term embedded in a sentence; 8 items); synonyms (21 items); antonyms (12 items); idioms (25 items). Section II (criminal law court contexts) contains sentence completion (36 items); court-related matters (10 items); sequence of court events (4 items); professional conduct (2 questions); and ethics scenarios (8 items). A minimum score of 80% (108 of 135 correct answers to four-choice items) is required to pass. The time is 135 minutes. Accommodations (including extra time) are available for persons diagnosed with a disability. A description of the NCSC Consortium written exam, including administrative procedures, overall test design, and sample questions, is available online (www.ncsc.org). Certain states use or have used bilingual exams and modes (or just modes) other than multiple choice. Until 2010 California used a bilingual multiple choice test. Washington (the state) has a two-part written exam; the NCSC test is used as a screening test for a second phase, in which candidates have 60 minutes to handwrite translations of ten passages of short paragraph length (50–75 words), which are graded for language skills, vocabulary choices, and readability (on the basis of the entire text rather than of scoring units).

The FCICE (Federal Court Interpreter Certification Examination, www.ncsonline.org/fcice), also administered through the NCSC, is in fact a Spanish exam (see above). The exam consists of two stages: a written screening test and the main oral exam. The FCICE Examinee Handbook (NCSC 2011), available online, provides examples of each section of the written and oral exams (including audio for the consecutive and simultaneous portions), together with an account of the development of the construct, an outline of the concepts of reliability, validity, and field-testing, details on correction methods (20% of written multiple choice tests are hand-scored, as a procedural verification), and the criteria and process for appeals and requests for re-scoring.

The FCICE written test consists of an English section and a Spanish section, each of which contains a bilingual subsection; each section has 100 items. Certain items are included as research for future test development and are not scored. The total time is 195 minutes. The passing score is 75%. The subsections, for each language, are: reading comprehension; usage (grammar and idioms); error detection; synonyms; and best translation of words and phrases. Though the content of reading passages and sentences can include non-specialist legal texts, the target domains are general lexico-grammatical language proficiency and general literacy in legalese rather than substantial paralegal knowledge. The content of the written test could be compared to the level of the GRE (Graduate Record Examination) Verbal examination of the ETS (Educational Testing Service) in the USA, with the caveat that, as in the NCSC Consortium state level exam, semi-technical legal discourse is used in some parts of the FCICE (see Appendix 1).

The FCICE oral exam takes about 45 minutes and includes five parts, with scripts and texts drawn or developed from specific court realia. The candidate

supplies the language that an interpreter would in real situations (with some variance of time constraints), in the following modes: (1) sight translation from English to Spanish (based on police and other legal reports, with a length of about 230 words); (2) sight translation from Spanish to English (formal legal documents); (3) simultaneous interpreting, for a Spanish-speaking defendant, of a simulated opening or closing argument to a jury, of approximately 840 words, delivered at an average of 120 words per minute (a speed considered slow to medium); (4) consecutive (simulating a lawyer's examination of a witness who replies in Spanish, with a length around 900 words and content derived from real court transcripts); (5) simultaneous interpreting, for a Spanish-speaking defendant, of a lawyer's examination of a witness (about 600 words, delivered at varying speeds up to 160 words per minute—a speed considered very fast, but not unusual in court—and with a content of semi-technical forensic evidence). The exam is assessed through a scoring dictionary for 220 scoring units distributed through the totality of these scripts. To pass, candidates must render 80% of the scoring units correctly. The test is intended to be non-regional specific (an answer acceptable in any regional Spanish known to the examiners is accepted). The scoring units are distributed according to the following three general error categories and nine subcategories: grammar and usage (grammar/verbs; false cognates/interference/literalism); general lexical range (general vocabulary; legal terms and phrases; idioms/sayings); conservation (register and slang/colloquialisms; numbers/names; modifiers/intensifiers/emphases/interjections; embeddings/positions).

Appendix 1: Legal Interpreter Written Exam: Bilingual, Contextualized Questions

FCICE (US Federal Spanish–English) written exam sample questions. Items from the fourth subsection of the English section. Candidates must read the whole paragraph, then answer questions regarding specific terms (underlined). The target term is followed by the question number in parentheses [(5) = question 5]. This sample is provided in the *FCICE Examinee Handbook* (NCSC, 2011). The correct answer and the rationale for it are provided. Note that the test designers have avoided the more challenging vocabulary items (e.g., “chattels”), and are targeting general “lexico-grammaticalese” rather than “legalese.”

WHEREAS: (5)

(A) Pursuant to an agreement of even date herewith (6) between the aforementioned (7) parties (the “Principal Agreement”) the Assignor agreed to

- procure the sale and the Assignee agreed to purchase or procure the purchase of inter alia the commercial real estate and chattels, details of which are set out (8) in the schedule hereto, together with the goodwill associated therewith, (together, the "Property"); and
- (B) The Assignor has agreed to enter into this Assignment to assign to the Assignee all its right, title and interest in and to the Property registered in its name.
- 5.
- A. por lo tanto
 - B. en vista de
 - C. considerando
 - D. conviniendo

The correct answer to question 5 is option C because the word "considerando" is the best rendering of "whereas."

- 6.
- A. de fecha pareja con aquí
 - B. de la misma fecha que el presente Convenio
 - C. con la fecha antedicha en este Convenio
 - D. con la fecha igual que éste

The correct answer to question 6 is option B because the phrase "de la misma fecha que el presente Convenio" is the best rendering of "of even date herewith" in this context.

Appendix 2: Error Analysis and Penalization Flowchart for a Translation Test

ATA Error Categories (from Doyle, 2003, p. 22)

Incomplete Passage; Illegible; Misunderstanding of Original Text; Mistranslation into Target Language; Addition or Omission; Terminology, Word Choice; Register; Too Freely Translated; Too Literal, Word-for-Word; False Cognate; Indecision, Giving More Than One Option; Inconsistency, Same Term Translated Differently; Ambiguity; Grammar; Syntax; Punctuation; Spelling; Accents and Other Diacritical Marks; Case (Upper/Lower); Word Form; Usage; Style.

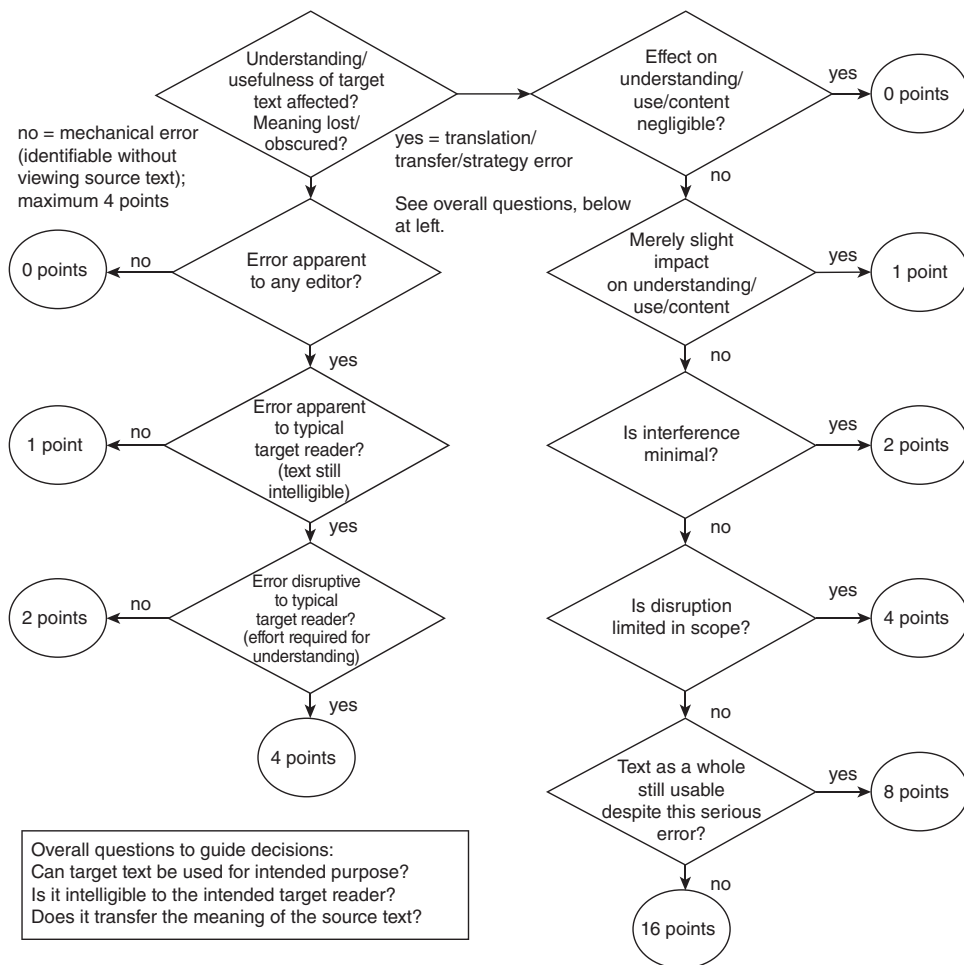

Figure 21.1 Flowchart for graders to assess errors in increments based on degree of impedance to communication of the original (ATA, 2009, available from http://www.atanet.org/certification/aboutexams_flowchart.pdf)

Language Testing for Immigration to Europe

Piet Van Avermaet

Ghent University, Belgium

Reinhilde Pulinx

Ghent University, Belgium

Introduction

In this chapter, based on longitudinal survey data, language-testing trends in the context of immigration in Europe are presented. Since the end of the 19th century, Europe has undergone major changes, not least with regard to processes of migration. The three main migration waves (in most Western European countries) between the end of World War II and the beginning of the 1990s can be characterized by a certain homogeneity: country of origin, socioeconomic background, and sociocultural background. Post-1991 migration is much more diverse and more “fluid”—what began as a temporary state of migration has gradually become permanent. Socioeconomic and sociopolitical developments, such as the fall of the Iron Curtain, the extension of the EU, globalization processes, and enduring poverty mainly in African countries, have also increased migration into Western European countries. At the same time, Europe is going through a process of economic and political unification. Exchange students, refugees, highly educated and less well educated labor forces are entering Western European countries. Reunification of “older” migrant families and marriages of third and second generation migrants with partners from the home country can still be observed. Post-1991 migration has not only become more diverse, it has also become more transitory: Exchange students stay on a temporary basis; numerous migrants are in transit; many political refugees or asylum seekers who enter Europe in one of the member states may stay there for some time before moving on to another country. At the same time, cheaper travel facilitates economic migration or mobility in a globalized world. In this context, diversity is quickly becoming the norm, but is also growing more complex. Traditional processes of acculturation no longer occur. Major cities are multicultural and multilingual by definition. An immigrant is no longer an immigrant, but a member of a complex metropolis, where differences

in norms and values are continuously being negotiated. These new “types” of migration, along with previous migrations from the 1950s to the 1970s, put much pressure on many European nation-states when it comes to concepts such as social cohesion, integration, access, citizenship, identity, culture, and language (Van Avermaet, 2012).

Integration and Citizenship Intertwined?

Given the topic of this chapter (testing) and the current political climate in Europe, concepts like integration, participation, identity, and citizenship are discussed as political terms. The change in the conceptualization of citizenship—moral citizenship prevailing over formal citizenship in policy discourse and social debate—can be situated in the transition of Europe into a superdiverse society. European societies are characterized by a dynamic interplay of variables among an increased number of new, small and scattered, multiple-origin, transnationally connected, socioeconomically differentiated, and legally stratified groups of immigrants who have arrived since the early 2000s (Vertovec, 2007). The phenomenon of more complex forms of migration due to geopolitical changes and the development of new forms of mobility is taking place simultaneously with the development and distribution of the Internet and other mobile communication technologies. These new technologies facilitate regular (and intense) communication between migrants and countries of origin and other social networks, and consequently change the structure and the significance of the diaspora (Blommaert, personal communication, August 24, 2011; see also Fortunati, Pertierra, & Vincent, 2011).

Questions about the meaning of national identity, maintaining social cohesion, and preserving national cultural and linguistic heritage are of growing concern for policy makers and society as a whole (Van Avermaet, 2009). This has led to a reconceptualization of citizenship based on the interplay between the two layers of citizenship. On the one hand, moral citizenship (Pulinx & Van Avermaet, *in press*) is seen as conditional for obtaining formal citizenship, and has been crystallized as knowledge of the language and moral values of the nation-state. More and more European countries have passed legislation making language proficiency and knowledge of the host society conditions for obtaining nationality, residency, or even entrance to the territory (Van Avermaet, 2012). Yet moral citizenship continues to play a role after the acquisition of formal citizenship. After becoming formal citizens with political and economic rights and duties, migrants have to continue to demonstrate their proficiency in the national language and their adherence to the norms, values, and beliefs of the host society. Full moral citizenship can only be achieved through a long process of integration in the host society. According to Schinkel (2008), an immigrant can never become or will never be perceived as a “full” citizen. The following comment often made to migrants of the second or even third generation is a clear example: “For a migrant your Dutch isn’t bad at all.”

In the current social and political discourse, the concepts of integration and citizenship have become interchangeable. This is not a neutral or simply semantic evolution susceptible to fashions or trends in public debate, but has significant

consequences. Immigrants coming to Western European countries are not simply required to integrate into the host societies: They have to do this by going through a compulsory and formalized trajectory aimed at adopting the language, values, norms, and beliefs of the new society—in other words by becoming moral citizens. This implies that immigrants are not citizens before migration, or at least not citizens of the “right kind” living by moral standards reconcilable with those of the host society. In the Netherlands and in Flanders (Belgium), new immigrants have to take an integration course, called “inburgering,” meaning literally “becoming a citizen,” as if they were not a citizen (or civilized) before arrival. Historically, citizenship in its formal meaning was a general concept referring to the predominantly political and economic rights and duties given by the state to all of its nationals. Moral citizenship used in the context of integration is exclusively applied to new immigrants and nationals with an immigrant background. But migrants of the first generation are not alone in having to unremittingly show how good their linguistic and societal knowledge is (knowledge which is continually questioned). The requirement of achieving and continuously demonstrating moral citizenship is passed on to the second and third (and fourth . . .) generation of people with an immigrant background. Citizens of a nonimmigrant background are exempted from this kind of moral scrutiny. Schinkel called this the virtualization of citizenship: “The situation arises, at least for a part of the population, in which people are citizens in the formal sense, but their integration and consequently their citizenship is considered to be defective. Thus, their citizenship is still questioned” (2008, p. 55, authors’ own translation). Moral—more than formal—citizenship is depicted as the endpoint of integration, but this endpoint will always remain out of reach for (new) immigrants.

In recent years, policy makers in Western European countries have attempted to define and describe the particularities of national identity. This has led to social and political debate, for instance in the Netherlands and in France, resulting mostly in a list of rights and duties largely resembling the Universal Declaration of Human Rights, and underlining mainly the separation between church and state, equality between men and women, and freedom of speech. Of course, the specificity of the Universal Declaration of Human Rights is precisely its universal relevance as opposed to national (or cultural and ethnic) particularity. The norms, values, and beliefs that immigrants, as part of “their” integration process, are supposed to acquire and meet, are not made explicit. The question is therefore whether they can be made explicit and presented as common values for the nation, given the fact that diversity is a unique and distinguishing feature of each society. The problem is, however, that our fundamental thinking about diversity does not take diversity as the starting point.

Language as “Lever” for Integration?

As already stated, both policy makers and wider society consider knowledge of the national language and of the workings of society as essential and definable elements of moral citizenship. Under the same assumption, proficiency in the national language and knowledge of society can thus be used as objective

measures for moral citizenship. The national language is viewed as part of a national identity in which language proficiency is an indicator of loyalty, patriotism, belonging, inclusion, and membership (Shohamy, 2006). Language ideologies are not constructed abruptly or accidentally, but are always situated in specific social, historic, and political contexts, such as the socioeconomic and sociopolitical developments in Europe combined with a rapid transformation into a multicultural and multilingual society. Furthermore, language ideologies are not only socially and politically situated, but are related to instances of identity construction, power relations, and assertion of power in societies (Blackledge & Pavlenko, 2002; Blommaert & Verschueren, 1998).

The language ideologies that currently dominate the integration and citizenship discourse consist largely of the following elements: (a) the use of a singular language by all members of society is a prerequisite for achieving social cohesion, (b) that goal of social cohesion can only be guaranteed by acquiring the standard variety of the national language, (c) language proficiency is a condition for social participation and must therefore be acquired beforehand, (d) language proficiency is seen as a marker for knowledge of the culture and social norms and values, and (e) unwillingness or refusal to learn and use the dominant language is regarded as a sign of disloyalty and defective integration and a threat to social cohesion. These ideologies are propagated and continuously repeated by policy makers, and remain unaffected by academic or empirical refutation. They become common sense, *doxas*, being an experience by which “the natural and social world appear as self-evident” (Bourdieu, 1972, p. 164). It encompasses what falls within the limits of the thinkable and sayable (“the universe of possible discourse”), that which “goes without saying because it comes without saying” (pp. 167, 169).

In many of the European countries that have language requirements as a main part of their immigration policies, language tests play a central role in the integration machinery and work as gatekeepers of the national order. They are powerful tools that are perceived as objective and beyond discussion, in spite of the fact that language tests are social constructs and reflect the norms and values of those who are in the position of power, developing the language tests.

On the basis of different surveys over time, there has been a proliferation of integration tests and courses across Europe through policy emulation. While an Association of Language Testers in Europe (ALTE)¹ survey in 2002 showed that 4 out of 14 countries (29%) had language conditions for citizenship, the 2007 ALTE survey showed that five years later this number had grown to 11 out of the 18 countries (61%) involved in the survey. The 2008 and 2010 surveys, conducted by the Délégation générale à la langue française et aux langues de France (DGLFLF) and the Centre for Diversity and Learning (SDL) of Ghent University, on behalf of the Language Policy Unit of the Council of Europe (www.coe.int/lang), revealed a further increase of countries setting stricter language conditions for integration in the host country (Extramiana & Van Avermaet, 2010). A comparable percentage (75%) of countries in 2008 and in 2010 had linguistic requirements as part of integration regulations. In 2008, 19% of the countries involved (4 out of 21) had language requirements prior to entry into the host country. This increased to 26% (6 out of 23) in 2010. In 2008, 57% (12 out of 21) of the countries involved indicated they had language requirements for permanent residency; this increased to almost

70% (16 out of 23) in 2010. In 2008, 76% (16 out of 21) of the countries had language conditions for citizenship. Of the 23 countries in 2010 that said they had language requirements of one kind or another, almost all countries (96% or 22 out of 23) indicated language conditions for citizenship. Almost half of the countries have made changes in their integration policy between 2008 and 2010. The increase in the number of countries with language and knowledge of society (KOS) conditions prior to entry in the host country is salient (from four countries in 2008 to six in 2010, with a further two introducing conditions in the near future, and some others seriously considering doing so and in the process of carrying out a feasibility study). In a few cases the required level of language proficiency, expressed in terms of the CEFR² levels (Council of Europe, 2001), has been upgraded. Another salient finding from the 2009 survey data is that some countries have language requirements but do not offer language courses, so candidates have to fund language lessons privately. The 2009 data also reveal that, as in 2007, although the specific language needs of migrants are acknowledged, many countries did not offer courses tailored to the functional language needs of migrants.

While the process of setting up stricter immigration conditions with a strong emphasis on language is fairly common across Europe, the developed policies and discourses at nation-state level do differ and hidden agendas feature in immigration policies across Europe. In some cases, these policies are used as a mechanism for exclusion or to control migration flows (Extra & Spotti, 2009; Van Avermaet, 2009). In others, they function as a mechanism for controlled immigration or to distinguish between the ingroup and the outgroup (McNamara, 2005). The discourse and the policies themselves are often an expression of the dominant majority group. A policy may be chosen as a firm defense against "Islamic terrorism," for instance, and be embedded in a discourse that takes advantage of the "fear" brought on by the possibility of a terrorist attack. To some extent, these immigrant policies have to be seen as a token of the revival of the nation-state, with its traditional paradigm of one language, one identity, and one uniform set of shared societal norms and cultural values. This is supposed to instill in people a feeling of national security, confidence, and order. This revival of the nation-state stands in stark contrast to the processes of globalization and the enlargement of the EU on the one hand and the increasing importance attached to regions, localities, cities, and neighborhoods on the other, referred to as processes of glocalization (de Bot, Kroon, Nelde, & Van der Velde, 2001).

Ethical and Validity Issues Regarding the Language Tests at Stake

It is clear from the previous section that, for many of the surveyed countries, passing a language test is a *condition* for entering the country, obtaining a residence permit, or acquiring citizenship. This raises some questions and concerns regarding the ethics of language testing (Shohamy, 2001; Van Avermaet, 2003), as well as regarding more technical and quality aspects of test development (Van Avermaet, Kuijper, & Saville, 2004), such as reliability and validity, and issues of impact (Hamp-Lyons, 1997; Shohamy, 2001, 2006).

First of all, as for all language tests, in contexts of migration it is essential to develop the right test (i.e., one that is valid, reliable, and ethical). This means that the test has to be fit for the specific purpose for which it is intended and that it has to meet professional standards which take into account not only technical and practical concerns but also ethical concerns. There is anecdotal evidence (although not officially recorded information) of testing institutes in Europe being contacted by policy makers and asked whether they had an existing language test “on the shelf” that could be put into use immediately as part of an integration or citizenship policy.

The test developer has to ensure that the testing system is appropriate for the high stakes decisions that will be made based on it, and that the test is suitable for the intended test-taker groups in terms of content, level, mode of delivery, and so on (Saville, 2011; Van Avermaet & Rocca, in press). In order for this to be achieved, Saville (2011) distinguishes nine questions which those involved in the development of assessment tools for migrants have to answer: Who is going to be tested? What features of the language will be covered and what is the justification for this? What proficiency level (e.g., CEFR level) is realistic for different groups? When and where will the testing take place—the venues and physical conditions? How will the administration be conducted and how will the integrity of the test be assured? How will the results be issued and verified? How will the results be used and what decisions will rest on the outcomes? How will data be collected in order to validate the test (e.g., to estimate its reliability)? How will the test’s impact on individuals, and on society more generally, be evaluated?

Most of the tests developed and designed for integration policies are standardized tests (Van Avermaet, 2012). Standardized tests have a strong reputation of objectivity and neutrality. It is necessary, however, to recognize that tests are sociocultural constructs and that the introduction is not an isolated event; rather it is anchored in political motivations and intentions (Shohamy, personal communication, July 7, 2011). Like many tests, tests for immigration purposes also tend to reflect the beliefs, norms, and values of the dominant majority group. By implementing these tests, the dominant majority group provides (or at least tries to provide) an answer to the following questions: When is a person a good citizen? When is a person integrated? Integrated in what? On which language construct is a test built? How much language does a migrant need to know? What is the link between social cohesion and knowledge of the national language? What is the role of the immigrants’ first language?

Attempts to answer these questions are rather one-sided; it is also doubtful whether the constructs at stake are well defined, and whether the answers are crystal clear and leave no space for multiple interpretations. From a construct validity perspective, however, we need to be able to answer the above questions. One could claim that most of the language and cultural tests developed for integration or citizenship purposes are not valid.

But even when these tests comply with the standards of test fairness, the question still remains as to whether it is ethically just to develop and administer tests to control migration flows, to exclude people, to determine whether they are in or out. In view of the moves by governments toward ever stricter language requirements for migrants, the language-testing profession has to take a broader

sociopolitical and sociolinguistic perspective. This implies, among other things, carefully and critically defining concepts like integration, citizenship, and social cohesion. More than elsewhere, the test developer has to reflect on the possible misuse or negative consequences of their tests. Test developers also have to interact with different stakeholders in society, including immigrants themselves, and should be concerned about whether taking a language test for integration or citizenship enhances processes of integration and social participation.

Shohamy (2001) distinguishes five perspectives for the language-testing profession to act ethically.

1. Ethical perspective: professional morality as a (virtual) contract between test developer, test taker, and society. Implication: societal consequences for the test developer in case of misuse is limited.
2. Awareness-raising perspective: The responsibility of the test developer is to make the users aware of all aspects of a test (and its use).
3. All consequences perspective: The test developer has to take the responsibility for all consequences of test use.
4. Perspective of sanctioning: In case of incorrect use of a test the test developer should be sanctioned.
5. Perspective of shared responsibility and open communication: Shared responsibility of all people (including nontechnicians, policy makers, etc.) involved in making, using . . . a test through open communication.

While perspectives 1–4 do not change the balance of power between different stakeholders, perspective 5 does, through communicative action, and is not dominated by the institutions to which the actors belong. The language-testing profession should attempt to take perspective 5 as a point of departure for the development of language tests for integration and citizenship.

Social Impact of Integration Tests

Investigating impact is integral to validation, and reviewing whether a test fits its intended purpose is an essential component in establishing the usefulness of an assessment system. This is consistent with Messick's views of validity (1989, 1996), especially "consequential aspects of validity." Impact also includes the effects and consequences a test has on the immediate learning context and on contexts beyond the classroom, for instance on an individual's career or on the life chances of migrants, and on educational systems and society more generally. Impact research must be an integral part of a framework for developing and validating examination systems for use in migration contexts.

Among other things, impact has to do with the question of why there are so many countries that have such strict integration policies in which language always plays a central role. The official discourse is that this facilitates the process of integration, strengthens social cohesion and social participation, increases migrants' access to the labor market and further education, and is seen as a lever to becoming a "virtual" citizen of the nation. Independent of the critical reflections

one can make with regard to these policies, the question is whether they have any impact. Do pre-entry language tests serve an integration objective? Do language tests (and integration requirements in general) enhance access to the labor market, to further education? And do “language for integration tests” contribute to the process of social participation and cohesion?

Given the relative lack of social impact studies regarding integration policies, it is difficult to give a comprehensive answer to these questions. Most of the studies that claim to look at the impact of the policies in place only look at the effectiveness and the quality of the programs (monitoring), the number of migrants attending language courses and taking language tests, the dropout rates, and the numbers of candidates that passed or failed the tests. Although these findings are very important, they do not tell us anything about the impact on integration processes or on social participation itself. It is, however, of crucial importance to have answers to these questions, since many countries use these arguments as reasons for establishing such policies in the first place.

An interesting study on the social impact of integration policies was recently conducted by the Integration and Naturalisation Tests: The New Way to European Citizenship (INTEC) Project (Strik, Böcker, Luiten, & van Oers, 2010). This was a comparative study in nine member states of the EU on the national policies concerning integration and naturalization tests and their effects on integration. The countries involved were Austria, Belgium, Denmark, France, Germany, Hungary, Latvia, the Netherlands, and the UK. The methodology used included both an analysis of policy documents and regulations, and some 329 interviews with immigrants, language schools/education centers, public officials, and NGOs.

The main outcome of this study was very clear:

This research, however, did not find any reason to promote the connection of the integration requirements with the granting of a certain legal status (admission, permanent residence or citizenship). This connection is not necessary to motivate migrants, and it inevitably leads to the exclusion of certain groups from a secure legal status. (Strik et al., 2010)

The report went on to suggest that this exclusion would not only hamper the integration of such groups rather than promote it, but also negatively impact family life and conflict with the right to family reunion. It recommended that the policy should be reconsidered. The report also concluded that language and integration policy had a limited effect on the actual integration of migration and that such policies should also take into account other factors, such as a receptive society, equal opportunities in the labor market, and efforts to fight discrimination.

Van Avermaet (2012), in a small-scale social impact study in Flanders, also found little evidence for the impact of integration policies in integration processes and social participation. Forty stakeholders from three categories were interviewed. Among them were language teachers involved in integration programs in Flanders, immigrants, and members of the “majority group,” including employers, people working at employment agencies, and people in the street.

Many of the teachers interviewed conveyed that a test is not so crucial in the whole integration process and emphasized the importance of alternative assessment procedures. They argued that a test is no more than a snapshot. They also said other aspects, like participation in and commitment to the course and motivation are at least as important as a formal assessment.

As for the immigrants that were interviewed, the picture was more diverse. A distinction could be made between immigrants who were in the process of taking an integration program, those who had finished a program recently, and immigrants who took a course more than a year before the interview was conducted. The first category of immigrants perceived the course (including the integration certificate) as very useful and necessary. They were all hopeful that it would increase their chances of finding a job. Those who finished an integration program at least a year before the interview were divided in their appraisal. Immigrants who found a job were mainly positive. Those who had not found a job, however, were rather negative about the value of such an "integration certificate." Those in the second category, who finished the program recently, said that the language they had acquired did not really help them in finding a job or on the shop floor.

As for the Belgian (Flemish) citizens that were interviewed, none of them said that they were familiar with or had any notion of the official integration policy in Flanders. After being informed briefly by the interviewers, half of the informants said they would prefer a centrally developed language test instead of the actual assessment policy. The other half of the informants said they were not in favor of such a central test, that a test at the end of the course was necessary, but that teachers were competent enough to develop and administer such a test.

None of the employers that were interviewed were familiar with the Flemish integration policy. From most interviews with the employers it also became clear that ultimately economic factors instead of language proficiency determined immigrants' chances of getting a job. Also, for employment agencies, a certificate of an integration course or proof of another Dutch language course had only limited value. In a couple of interviews with personnel at employment agencies, reference was made to language knowledge and job interviews with immigrants as a mechanism to exclude, to keep them from the shop floor: "Sometimes immigrant employees are sent back because they cannot communicate on the shop floor. I have the impression that this is often a false argument for covert discrimination against immigrant employees." These data clearly show that the impact of—in this case the Flemish—integration policy is very limited. With teachers as the obvious exception, hardly any of the other stakeholders had a clear notion of the policy. The integration certificate immigrants receive after an integration program has hardly any (market) value.

A Change in Paradigm

The Dutch sociologist Schinkel (2008) calls the actual discourse and policies with regard to integration and language tests a form of "social hypochondria." Hypochondria can be defined as a preoccupation with the fear of having a serious

disease based on a misinterpretation of bodily symptoms. Social hypochondria, then, can be defined as a preoccupation on the part of social agents with fears that a given social body (e.g., school, neighborhood, workplace, country, nation, etc.) has a serious disease or disorder, based on the social agents' misinterpretation of the symptoms occurring in that social body.

Most important here are the preoccupations and complaints about perceived threats to "social cohesion" and "social integration." Schinkel (2008) argues that the social body now feels constantly threatened by those who are considered not to belong, to be non-native. If empirical reality indicates that the feelings of threat to the health of a given social body on account of its ethnic composition, integration, and social cohesion are not accurate, then these feelings should be considered a form of social hypochondria.

Most European integration policies that aim at regulating access to different sociostructural domains prior to or after arrival in the host country are of a conditional nature. A policy of making immigrants first learn the language of the host country as an initial step to integration calls for critical reflection, however. Immigrants are seen as having a language deficiency. This deficiency is seen as an obstacle to integration and as a cause of violence and social conflicts. This argument is selective in the sense that it may only apply to a certain category of immigrants. Those "migrants" belonging to the "globalized" elite (and to a large extent unacquainted with the language of the nation-state) communicate with the indigenous multilingual elite in French, German, English, or Spanish. The "globalized" elite can be seen as partners of the local elite, while the "real immigrant" is not seen as a partner but as a competitor of the local man in the street. The selectiveness of the argument of "language deficiency" is astounding and it undermines the theory behind it, in which knowledge of the national language is seen as an absolute condition for societal participation (Blommaert & Van Avermaet, 2008). Those who belong to the "globalized" elite are to a large extent being relieved of every obligation to learn the language and to engage in social integration, even when they live in a ghetto of the wealthy and hardly have any contact with indigenous inhabitants.

Research into patterns of language choice among Italian immigrants in Flanders (Van Avermaet, 2008) has shown that the public nature of a societal domain is an important feature of language shift to the dominant majority language, rather than conditions of formality. The choice in favor of using Dutch with other Italians begins in those domains where Italians come into contact with indigenous people. When a domain evolves from an intralinguistic to an interlinguistic market (Bourdieu, 1991; Jaspaert & Kroon, 1991; Van Avermaet, 2008) where one meets members of the majority, a process of unification of markets can be observed. Different price-determining laws apply on a unified linguistic market, compared to an intralinguistic market. A policy which first aims at integration in certain societal domains will lead to the use of Dutch in those domains. That the use of Dutch by immigrants can be realized through an opposite policy, which sees the choice of Dutch as a condition for integration, and for that reason obliges the immigrant to learn Dutch, is not supported by research. A facilitating policy that first aims at the integration of immigrants in certain societal domains (e.g., work) leads to the acquisition of the host country language. People acquire the language when there

is a need. In making language a condition for integration, one refuses immigrants the opportunity to be active in domains where the intra- and interlinguistic markets (e.g., school, work, housing market) come into contact with each other. In a conditional policy one runs the risk that immigrants cannot be active in societal domains where language acquisition tends to be a natural process through contact. One actually excludes people from domains that make the realization of what one aims for possible. By maintaining a policy of having language as a condition for social participation and obliging immigrants to take language courses, one runs the risk of actually reinforcing the structural discrimination of minority groups that one wants to counteract.

An increasing consensus can be observed on the importance of providing tailor-made language courses and language assessment tools for immigrants (Van Avermaet & Gysen, 2006; Halewijn, Houben, & De Niel, 2008; Little, 2008). Each person has specific linguistic needs. The challenge is to meet these needs. Meeting the language needs of immigrants, however, is hard to achieve in a conditional policy. If language is a condition to enter the country, for instance, or to get access to the labor market, it is self-evident that every person has to take the same language course or test. If the conditions were different for every person, this would be unfair and unjust. If, however, integration policies were of a more facilitating nature, the language courses provided and language tests offered could better meet the needs of immigrants. A facilitating policy would provide more opportunities to respond to what immigrants actually linguistically need in order to function in certain domains of society, and it would also be more challenging to offer broader assessment tools, which focus on what immigrants can do rather than on what they cannot do. Such assessment tools are not intended to be an indication of just one CEFR level. Such tools aim at profiling the plurilingual competencies of a person.

Conclusion

This chapter argues that, along with globalization, processes of urbanization and localization can be observed. In these rapidly growing metropolitan areas, people of different social, cultural, ethnic, and linguistic backgrounds live together. The old 19th-century Herderian ideal of linguistically and culturally uniform nation-states is being more and more eroded and is already in some urban areas completely superseded. This diversity is acknowledged in most policy documents and in political discourse as a distinguishing feature of each society, and of urban areas in particular. The problem, however, is that our fundamental thinking about diversity does not take diversity as the starting point. Language tests as a condition for immigration, integration, and citizenship are clear examples of ideological monocultural and monolingual thinking. Having a policy where the knowledge of one language—the one that some, for ideological reasons, present as the legitimate norm—is imposed as a condition for functioning in urban social environments is not only anachronistic. It is also counterproductive, in contemporary superdiverse urban societies, to consider citizenship as an achievement, an achievement which is the sole responsibility of certain groups in society—an

impossible achievement, because some are dispensed from it and others will always be perceived as not yet belonging to the category of “true citizens” of the metropolis. Citizenship and the use of plurilingual repertoires in the city is a dynamic and contextualized process, which shapes itself in daily practice through negotiation in social networks. Citizenship as social practice is often perceived as passive. It is, however, neither neutral nor passive. The use of a repertoire as the legitimate norm in one context does not by definition hold in another context. Citizenship as social practice implies and presupposes the acceptance of the rights and duties that stem from the universal concepts around which a society organizes itself; above all, citizenship can only be realized if every form of discrimination and exclusion that disables social participation of some comes to an end. Citizenship as practice is only possible if one starts to accept the idea of a diverse, multicultural, and multilingual society, and consequently the concept of multicultural citizenship. Within a context where “superdiversity” is becoming the norm, it is important to reflect on the boundaries of the current recipes—integration policies including obligatory language tests—that are being used to promote and strengthen social and civic activity.

Assessment in Asylum-Related Language Analysis

Diana Eades

University of New England, Australia

Introduction

At the end of 2010 there were more than 10.5 million recognized refugees under United Nations High Commission for Refugees (UNHCR) responsibility worldwide, and 837,500 asylum seekers whose cases were still pending (UNHCR, 2011). More than three quarters of the world's refugees are living in a country neighboring their own, with about four fifths of them living in African or Asian countries, as are nearly half of the world's asylum seekers. For an asylum seeker to be recognized as a refugee, they have to meet the criteria of the 1951 United Nations Refugee Convention, which has been signed by the majority of the world's states. This declares that a refugee is a person who

owing to a well-founded fear of being persecuted for reasons of race, religion, nationality, membership of a particular social group, or political opinion, is outside the country of his nationality, and is unable to or, owing to such fear, is unwilling to avail himself of the protection of that country.

Thus, the primary decision to be made by immigration authorities in any country where a person asks to be recognized as a refugee is whether this asylum seeker has a "well-founded fear of being persecuted" in the country of their nationality, for reasons of race, religion, and so on. When asylum seekers arrive without nationality papers or other identity documents, another important part of the determination of refugee status involves verifying that the asylum seeker's claimed country of their nationality is valid. Does the person really come from where they claim to, or is this a false claim made in order to be granted refugee status?

Since the late 1990s, governments in first world industrialized countries have increasingly been using analysis of asylum seekers' speech in instances of doubt

about the genuineness of origin claims. This is referred to as “language analysis in the determination of origin,” or LADO. LADO rests on a fundamental assumption about the relationship between language and origin, namely that the way that a person speaks contains clues about their origin. Thus the assessment involved in LADO is whether—during an audiorecorded immigration interview—the asylum seeker speaks a language variety consistent with their claims of origin.

In 2004, a group of 19 linguists from six countries released a document titled “Guidelines for the Use of Language Analysis in Relation to Questions of National Origin in Refugee Cases” (LNOG [Language and National Origin Group], 2004). Widely cited, and endorsed by more than 10 professional organizations, the aim of the Guidelines, as they are usually called, was to bring relevant linguistic issues to the awareness of governments, legal professionals, and refugee advocates. It was also hoped that the Guidelines would provide some specific guidance to linguists asked to do LADO reports, who may not have considered relevant sociolinguistic issues carefully. (For further discussion of the Guidelines see Eades, 2010.)

Early LADO practice was framed in terms of the relationship between language and nationality, or language and country of origin. However, there now appears to be widespread agreement with Guideline #2: that language analysis “can not be used reliably to *determine* national origin, nationality or citizenship. This is because national origin, nationality and citizenship are all political or bureaucratic characteristics, which have no necessary connection to language” (LNOG, 2004, p. 262, emphasis in original). It is also widely recognized, however, that the analysis of an asylum seeker’s language may provide assistance for immigration authorities in questions about origin, namely in relation to where the person has been socialized. Socialization is a sociolinguistic concept, which, as explained in the Guidelines, refers to a person’s learning

implicitly and/or explicitly, how to be a member of a local society, or of local societies. . . . The way that people speak has a strong connection with how and where they were socialized: that is, the languages and dialects spoken in the communities in which people grow up and live have a great influence on how they speak. (LNOG 2004, p. 262)

Thus, the linguistic assumption which motivates LADO work is that which Patrick (2010, p. 76) refers to as the “Axiom of the Speech Community”: “Speakers who share language socialization are alike enough in their linguistic production and evaluative norms to be identified as members of the same speech community.”

While LADO involves assessment of an interviewee’s speech, there are three important differences between language assessment in LADO and in other contexts. First, most language assessment (whether in educational contexts or in other institutional contexts, such as citizenship applications) involves assessment of proficiency in a language. LADO, on the other hand, evaluates or assesses an asylum seeker’s claims about their origins, whether national, regional, or ethnic. In McNamara’s (2000) terms, LADO involves tests of authenticity of identity, rather than tests of proficiency. Second, as Fraser (personal communication August 15, 2011) argues, it is important to recognize that LADO is not testing what an individual can do, but is testing a forensic hypothesis. Further, while typical language

testing involves proficiency rating scales and often relies on standardized tests, forensic hypothesis testing involves probabilities and likelihoods that a particular hypothesis is true. Finally, there is an important contrast between LADO and other types of forensic hypothesis testing, as pointed out by Broeders (2010, p. 53). He explains that the goal of much other forensic assessment is individualization: linking evidence to a particular individual. Thus, in forensic phonetic hypothesis testing, an example hypothesis is that the suspect is the speaker in a particular recorded threatening telephone call. But, as Broeders points out, LADO is essentially “a classification process: the purpose of the exercise is to determine whether the speaker belongs to a group of speakers, more specifically—usually—the group of speakers in which he was socialized and learnt to speak his first language.”

Despite these differences in the nature of language testing involved, McNamara, van den Hazelkamp, and Verrips (2010, p. 61) make the point that

both [typical] language testing and [LADO] are constrained by the same principles. Both procedures involve:

- observing and interpreting *evidence* from a language user’s performance
- in order to reach *conclusions* about what they know (or don’t),
- and to make *decisions* based on these conclusions.

The next section of this chapter will outline the ways in which LADO is conducted and the role it plays in the gatekeeping process which assesses the claims of asylum seekers. The final section will examine some underlying assumptions about language and multilingualism, highlighting some problems with the use of LADO in the assessment of the origin claims of asylum seekers. Throughout the chapter, the term “language(s)” is used to encompass “language variety (varieties),” which includes dialect(s), as the distinction between language and dialect is well-known to be frequently unclear. Also, this chapter follows the gender-inclusive practice of using third person plural pronouns (*they*, *them*, *their*) as generic singular. While every effort has been made to provide up-to-date information at the time of writing (August 2011), readers should recognize that LADO is an evolving practice.

LADO Methods

Data Collection for LADO Assessment

Cambier-Langeveld (2010a, p. 69) reports that LADO is carried out by “approximately eight units . . . located in five countries (Sweden, Switzerland, the Netherlands, Germany and Belgium).” She explains that three of the units which carry out LADO analysis are private companies (De Taalstudio, Sprakab, and Verified), while the others are government agencies. These eight agencies or companies perform analysis for at least 10 countries in addition to the five already mentioned; these include Norway and the United Kingdom.

The basic principle in LADO is shared among the government agencies and companies involved, namely (as we have seen), that the way that a person speaks

often contains clues about their origin, and that this may help in the assessment of the genuineness of the asylum seeker's claims about where they have come from. But there are some notable differences in LADO methods, as we will see in this section.

LADO begins with the immigration authority collecting an audiorecording, typically containing an interview with the asylum seeker. The way the asylum seeker talks on the audiorecording is then analyzed. Table 24.1 summarizes some of the differences in approach to LADO data collection, based on the sources cited

Table 24.1 Examples of approaches to LADO

<i>Country where asylum is sought: relevant government agency</i>	<i>LADO interview carried out by</i>	<i>Interviewer is also analyst?</i>	<i>Analysis carried out by</i>	<i>Other details</i>
Belgium: Centre de Documentation des Instances d'Asile [Documentation Centre for Asylum Cases] (CEDOCA)	Interpreter in presence of immigration officer	No	Non-expert native speaker	At least 45 min
Germany: Bundesamt für Migration und Flüchtlinge [Federal Office for Migration and Refugees] (BAMF)	Interpreter in presence of immigration officer	No	Linguist	Interview may be carried out in lingua franca such as English, French; at least 20–30 min of applicant's speech
Netherlands: Bureau Land en Taal [Country and Language Bureau] (BLT)	Non-expert native speaker employed by BLT	Yes	Non-expert native speaker	
Norway: Utlendingsdirektoratet [Directorate of Immigration] (UDI)	Interpreter in presence of immigration officer	No	Non-expert native speaker	Applicant asked to talk in monologue(s); total 15–20 min
Switzerland: LINGUA in Office Fédéral des Migrations [Federal Office of Migration]	(Mainly) linguist contracted by LINGUA	Yes	Linguist	Phone interview; average 60 min
UK: UK Border Agency (UKBA)	Non-expert native speaker employed by private company contracted by UKBA	Yes	Non-expert native speaker	Phone interview; average 18 min

in this section. In some countries (e.g., Switzerland and the Netherlands), the LADO interview and analysis are carried out within a section of government, currently LINGUA in Switzerland, and Bureau Land en Taal (BLT) in the Netherlands. In some other countries—including the UK—this work is contracted to one of the three private companies referred to above: Sprakab and Verified are based in Sweden, while De Taalstudio is in the Netherlands. Those situations where the interviewer is also the analyst—as, for example, in Switzerland, the Netherlands, and the UK—are referred to as “direct analysis” (Baltisberger & Hubbuch, 2010, p. 11). A different data collection approach is found in countries where the LADO interview is carried out not by the analyst but by an interpreter in the presence of an immigration officer. In these situations the audiorecording is then sent either to one of the private companies or government agencies for analysis, or to a contracted analyst, as is current practice in Belgium (Vanheule, 2010, p. 180).

The policy about the language of the interview varies, as does the role of the person conducting the interview. The usual method of the Swiss government is for an audiorecorded telephone interview with the asylum seeker to be conducted by a contracted linguist with expertise in the language(s) relevant to the interviewee’s claimed origin (see Singler, 2004; Baltisberger & Hubbuch, 2010). Most of the experts who do this work are academically trained linguists who are contracted by the Swiss government on a case-by-case basis. Many have university positions, and conduct the LADO interview and analysis from their home country. Even if an expert is in Switzerland, all LINGUA LADO interviews are conducted by phone, because of concerns about personal safety of the interviewers (Baltisberger & Hubbuch, 2010, p. 11).

Another approach is the use of an international lingua franca, such as English or French, as the language of interview, when immigration authorities assume that this is a common second language in the country in question, and that the origin of the asylum seeker can be detected from the way they speak this lingua franca. BAMF (2008, p. 3) indicates that this approach is used in Germany with African asylum seekers who “claim not to be able to speak any local languages” (see also Simo Bobda, Wolf, & Lothar, 1999, and critique in Eades & Arends, 2004). The third policy concerning the language of the interview involves the asylum seeker being interviewed in their “native language” through an interpreter.

The length of the LADO interview varies. In Switzerland, LINGUA interviews average about 60 minutes (Hubbuch & Favaro-Buschor, 2011), and in Belgium they are at least 45 minutes (Vanheule, 2010, p. 180). In the UK, these interviews appear to be much shorter: In the 60 cases examined by Patrick (2011, 2012), the interviews average 18 minutes, with some as short as 12 minutes.

The topics covered in the interview also vary, but generally exclude the interviewee’s personal story of persecution and escape. Asylum seekers are told that this interview is to enable the authorities to verify their claims about origin, and that it is not a test of the veracity of their story (which they have already told immigration authorities at least once). It appears to be common for interviewees to be asked questions about geography, way of life, and general information about their home country, or where they claim to have spent most of their life (see Baltisberger & Favaro, 2007, p. 87). But it is not always clear to what extent the content of answers to such questions simply provides a framework of topics to

provide speech data for analysis of linguistic features, or to what extent this is also assessed within the LADO report. In Switzerland, the LINGUA expert's assessment of the asylum seeker's knowledge about daily life in their place of origin is integral to the LADO process (Singler, 2004; Baltisberger & Hubbuch, 2010).

While data for LADO analysis is most usually collected in an interview, the Norwegian government has only recently begun to use elicited monologues (Gustavsen, 2011), and it appears that some governments sometimes use a translation test, in which an interviewer asks the asylum seeker to translate words from a word list into their home language. Corcoran (2004) and Maryns (2006) discuss examples of immigration department interviewers—in the Netherlands and Belgium respectively—using such a rudimentary kind of translation test in assessing the genuineness of asylum seekers' claims to have come from Sierra Leone. Thus, asylum seekers were asked to give the Krio equivalent of isolated English lexical items, and to count from one to twenty in Krio. (Maryns, 2006, p. 254 discusses problems in using such an approach to LADO, and reports that this kind of translation test was being used "by several asylum agencies in Europe".)

When an asylum seeker chooses to appeal against an immigration department's denial of their refugee status claim, this appeal often involves a reanalysis of the original recorded LADO interview, typically carried out by a linguist contracted either privately by the asylum seeker's lawyer, or by an independent company (the major one being De Taalstudio; see Verrips, 2010). However, not all countries have an appeal procedure which enables asylum seekers to challenge an immigration ruling.

Data Analysis

The language analysis found in LADO reports appears to mainly center on the isolation of linguistic features found in the recorded speech sample, which are either congruent or not congruent with typical language use in the country, region, or ethnic group of origin claimed by the asylum seeker. Verrips's (2010) explanation of the working methods of De Taalstudio appears to be the only publication which discloses the requirements of experts' reports, and other information is not readily accessible to researchers. Much of the LADO work done by experts contracted by De Taalstudio involves producing contra-reports, that is reports used in appeals by asylum seekers on unfavorable immigration decisions which have been informed by an initial LADO report. De Taalstudio's reports describe the language use of the asylum seeker under the following headings: (a) sociolinguistic situation in the region, (b) phonology, (c) lexical properties, (d) morphology, (e) syntax, and (f) proficiency in language(s)/dialect(s) used. Further, expert linguists contracted by De Taalstudio are required to "present evidence supporting their conclusion and evidence that does not support it" (Verrips, 2011, p. 139). This appears not to be the case in LADO reports produced by the Dutch government's BLT. Verrips (2011, p. 139) found that "evidence which does not support BLT's conclusion may be systematically omitted" in these reports.

Concerns have been raised about the way in which LADO practitioners come to their conclusion about the language–origin connection. It is currently an

impressionistic assessment of the linguistic features found in the recorded speech sample, assessed in the light of the analyst's knowledge about the language(s) involved. As we will see below, it is common for LADO reports to conclude with a high degree of certainty that the person speaks or does not speak a variety of a particular language found in a specified country. Broeders (2010, p. 58) suggests that LADO move to an approach which would involve assessing the probability of the findings of the analysis under two hypotheses:

H1: the claimant is a native speaker of X, versus

H2: the claimant is a native speaker of Y but pretends to be a native speaker of X.

In order to be able to express such a probability ratio, the analysis would need to be based on the quantification of comparable descriptions of linguistic features of the language varieties X and Y. At the same time the analysis would need to take into account the complex range of variables impacting on the situation in which the sample of the asylum seeker's speech was recorded. One of the key factors is the possibility of speech accommodation in cases where the interview is conducted by a speaker of a different dialect of the same language. Also relevant to any probability ratio are societal attitudes to varieties such as the Sierra Leone creole language Krio. Such attitudes can lead to situations where people may be reluctant to admit that they can speak the language, even though this would support their claim to have come from Sierra Leone (Corcoran, 2004). It will arguably be some considerable time before a probability ratio approach will be possible, especially given the fact that linguistic descriptions of languages of the regions from where asylum seekers originate are often not extensive or comparable.

Analysts

Currently there is considerable debate about the qualifications that are necessary for the person performing the LADO analysis and judgment. On the one hand, many linguists have argued that only linguists with expertise in the specific language(s) concerned in a case have the expertise required (Eades, Fraser, Siegel, McNamara, & Baker, 2003; LNOG, 2004). Thus Guideline #3 states "Judgements about the relationship between language and regional identity should be made only by qualified linguists with recognized and up-to-date expertise, both in linguistics and in the language in question, including how this language differs from neighboring language varieties" (LNOG, 2004). The German and Swiss governments may be the only government agencies whose analysts are "mostly academically trained linguists" (Baltisberger & Hubbuch, 2010, p. 9; see also BAMF, 2008). Of the three private companies, only De Taalstudio also uses analysts who are trained linguists, specialized in the language(s) in question in a particular case. Many of these linguists contracted by De Taalstudio have "very high academic qualifications, like a PhD based on study of the language concerned, and a long track record of peer-reviewed publications" (Verrips, 2010, p. 281).

On the other hand, the policy of a number of government agencies, as well as of the two Swedish companies, is that the LADO assessment is carried out by analysts generally referred to as "native speakers," who write their LADO reports

under the supervision of a linguist (this includes the governments of Belgium and the Netherlands and the companies Sprakab and Verified—see Vanheule, 2010, p. 180; Cambier-Langeveld, 2010a; UKBA, *n.d.*, Section 4.1; and Verified, 2008, respectively). This supervising linguist typically has no claimed expertise—as either speaker or researcher—in the language(s) involved.

Who are these native speaker analysts? While the concept of the native speaker is problematized by sociolinguists and applied linguists, a major proponent of this approach in asylum seeker assessments (Cambier-Langeveld, 2010b, p. 22) defines the native speaker in LADO practice as

a speaker who has first-hand, extensive and continuous experience with the language area and with other speakers of the language and the relevant varieties, starting from an early age. This definition puts particular focus on the native speaker's lifelong experience with a language in spontaneous settings.

Following Patrick (2010), these analysts are referred to as non-expert native speakers (NENS), distinguishing them from analysts with linguistic training and expertise (linguists). While a linguistically trained analyst may also be a native speaker of the language in question, in practice this is rare, because of the limited opportunities for higher degrees in linguistics for people from the regions in the world where asylum seekers originate.

The use of NENS as LADO analysts is preferred by some agencies and companies because of the belief that they can better detect speakers “who may be hiding knowledge of a language, presenting a second language as their first language, or adding speech features that do not belong in their natural speech variety” (Cambier-Langeveld, 2010a, p. 73). But there is debate over the role of NENS analysts. For example, Eades argues that

unless [the supervising] linguists have expertise in the languages in question, they can have no basis for assessing the soundness of the judgments of the native speakers. Thus the supervision by a linguist without expertise in the language(s) in question would not be sufficient to ensure that the native speaker judgment is linguistically valid. (Eades, 2009, p. 33; see also Fraser, 2009, 2011; Patrick, 2011, 2012; Verrips, 2011)

While there is very little research directly relevant to LADO, Fraser (2009) reviewed a wide range of research from the fields of speaker identification, speech technology, and perceptual dialectology. This research sheds some light on “the accuracy with which people can use accent features to identify a speaker's regional or social/ethnic origin” (p. 119). Fraser's careful meta-analysis found support for “the assumption that people are generally better at recognising their own accent than identifying other accents.” But importantly, this research “makes very clear that . . . they are far from generally reliable, especially if they are intentionally or unintentionally misled by the context” (p. 128). One of the most important findings from Fraser's meta-analysis is that, while there is wide variation in the extent to which individuals are able to accurately place the origins of speakers of their own language variety on the basis of accent alone, there is no consistent correlation between accuracy and confidence. So, although many people believe they can

tell where someone comes from on the basis of how they speak, a person's degree of confidence in identifying an accent is not a reliable indicator of the accuracy of their assessment. And, in fact, it is often other contextual factors which help in the identification of origin.

The issue of the confidence of NENS analysts in their assessment in accent-origin identification is highlighted in Foulkes and Wilson's (2011) report of an experimental study. The experiment compared the abilities of four groups of subjects in identifying speakers of Ghanaian English (GhE) from a series of short audiorecordings. The four groups of subjects were:

1. LADO professionals (people who practice as NENS analysts, but not in cases involving GhE);
2. native speakers of GhE (who are not LADO analysts);
3. academic phoneticians (with no expertise in GhE); and
4. phonetics students (also with no expertise in GhE).

None of the subjects had studied GhE and only those in group (2) were speakers of it, but all were provided with reference materials which outlined phonetic patterns of GhE. Perhaps unsurprisingly, the GhE native speakers performed best at correctly identifying which of the speakers in the experiment were speakers of GhE. But, while they scored 86% correct, they never chose the response "unsure," and in fact their most frequent responses to questions asking them to rate their confidence in their assessment was "highly unlikely" or "highly probable." On the other hand, the academics said they were unsure in 26% of answers, giving reasons why they could not make a decision with adequate confidence.

This study cannot be directly extrapolated to the LADO context, for several reasons—of which the most important is that LADO assessments are never made by linguists without expertise in the particular language or languages involved. However, one of the findings of the study is of particular interest for LADO. When the "unsure" responses were discarded, the level of correct responses for academic phoneticians showed no statistical difference from that of the native speakers. As Foulkes and Wilson (2011, p. 3) point out, "reaching no firm decision (*unsure* in this experiment) may be the appropriate outcome in cases where materials do not present a consistent or clear picture, and thus no confident conclusion can be reached." Consistent with the studies analyzed in Fraser (2009), this study highlights the poor correlation between accuracy and confidence when linguistically untrained native speakers make the language–origin assessment (see also Fraser, 2011).

The possibility of misplaced confidence in identifying a speaker's origin is of particular importance in LADO assessments by NENS analysts for at least two reasons. First, such assessments are often made very quickly. For example, UKBA (*n.d.*, #8, emphasis in original) states that, in most cases, approximately 15 minutes after the LADO interview is completed, Sprakab will "telephone and email the preliminary language analysis results," choosing one of the following outcomes:

1. Applicant speaks language X found *with certainty not* in the country/area from which they claim to come.

2. Applicant speaks language X found *with certainty* in country/area.
3. Applicant speaks language X but uncertain as to where it is found.

Thus, not only is the NENS assessment made very quickly, but also the reporting format encourages that this assessment be expressed with extreme confidence, namely “certainty.” It is not known how often, if ever, the final report, sent to UKBA “within 72 hours” (UKBA, *n.d.*, Section 10) of the interview, reverses this initial assessment. However, Patrick (2011) found that 82% of 57 (final) LADO reports for UKBA in which the assessment was made by a NENS were expressed with unqualified certainty.

The second issue of concern in relation to the possibility of misplaced confidence has recently come to light with Zwaan’s (2010, pp. 221–2) discussion of the process of appeals against Dutch asylum decisions. Of specific concern are cases in which conclusions by NENS analysts working for the Dutch government (BLT) have not supported the applicants’ claims about their origins. In such appeals it has been common for the asylum seeker to provide a LADO report from a contra-expert, whose analysis of the initial LADO recording does not support the initial LADO report. Zwaan explains that, in the Netherlands,

The judge will assume that the [BLT] report is reliable unless the contra-expert’s report provides concrete evidence to doubt the validity and reliability of the language analysis. Such doubt will not arise easily. In general, *only when the contra-expert comes to a conclusion, with the highest possible degree of certainty, on the given origin of the asylum seeker by the asylum seeker, the judge will conclude that there is reason to doubt the reliability of the [BLT] report.* (emphasis added)

Thus, there may be a direct relation between the level of confidence expressed in the contra-expert’s assessment and the outcome of the appeal. The main factor may be a difference in how certainty is valued in the two professional cultures involved: science and the law. As scholars, linguists are trained and professionally socialized to be cautious in how they evaluate evidence in order to come to conclusions. In contrast, from a legal perspective, a judge may give preference to reports expressing the highest degree of certainty, as seen in Zwaan’s description above of the appeals situation. In the Dutch system, the great majority of contra-experts are linguists (Verrips, 2010), who would be most likely to express their findings with some degree of caution. On the other hand, the BLT reports are written by NENS without linguistic training and professional socialization. As previously mentioned, Foulkes and Wilson’s (2011) experimental study showed a confidence–accuracy difference between NENS and trained linguists, with NENS more frequently expressing greater confidence in opinions. If this difference operates in the real world of LADO practice, this sets up a possible contrast between the confidence and certainty of NENS assessments and the more cautious nature of linguists’ assessments. This potential contrast between NENS and linguists in their reports may unduly impact the evaluation of competing LADO reports in a case if there is a judicial preference for a high degree of certainty.

Concerns about the use of NENS analysts are sometimes countered with assurances (e.g., Cambier-Langeveld, 2010a, p. 85) that a central element in the use of

NENS analysts in making LADO assessments is the “testing of the native speaker’s capabilities.” Further, NENS analysts do not work alone. As already mentioned, an essential element of this approach involves supervision by a qualified linguist, as well as “specific linguistic and sociolinguistic training, so that the native speaker is aware of relevant linguistic issues.” Thus, Cambier-Langeveld (2010a, p. 89) argues that

both linguistic expertise and native speaker competence should be involved in LADO, in such a way that the analysis benefits from (a) the analytical capabilities and theoretical knowledge of the linguist and (b) the experience that the attentive native speaker has with the language (varieties) involved.

While this combination of experience, intuition, and training may sound convincing, many linguists are concerned about two issues. First, the assessment about the language–origin connection is made by analysts without linguistic training, who may at times rely to some extent on folk views about how people “should” speak a certain language, in the absence of an understanding of such issues as language variation, contact, and change. Second, as mentioned above, the linguist involved in such a partnership typically is not an expert in the language(s) in question. Thus, while this person may be called a “supervising linguist,” they are arguably unable to provide the necessary specific linguistic expertise. Fraser (2011, p. 124) points out that this practice appears to violate the code of practice of the International Association for Forensic Phonetics and Acoustics (IAFPA) which includes the statement that “Members’ reports should not include or exclude any material which has been suggested by others (in particular by those instructing them) unless that Member has formed an independent view” (IAFPA, 2010). Questions have also been raised about the training provided to these NENS analysts. Fraser (2011, p. 125) points out that “no information is provided about the nature of the tests, how they relate to actual LADO analyses, or what levels of performance are required.”

Verrips (2011, p. 134) raises a further issue which shows the complex nature of leaving the basic LADO assessment to NENS analysts without linguistic training. She investigated a large number of reports produced by NENS analysts in BLT in the Netherlands. In 45% (=600) of these reports “the analyst is *not* a native speaker of (at least one of) the languages that are analyzed in the report, let alone of the *dialect* that the asylum seeker claims to speak.” Instead it appears that the NENS analysts are often described in terms of nationality, not language varieties spoken. Given the large number of languages spoken in some of the specific countries involved (e.g., Nigeria, Sierra Leone, Sudan), this points to a disturbing lack of clarity about just what expertise is attributable to the NENS.

While most attention in discussions of LADO has focused on the use of NENS and trained linguists in making the language–origin assessment, in some countries the approach is more informal. For example, Spain has no established LADO procedure, but nevertheless does sometimes use “language analysis techniques . . . on an informal basis” (Morgades, 2010, p. 170). Typically this involves the judgment of the person who has interpreted a regular interview between the

asylum seeker and immigration official. In such instances, the immigration official considers that the interpreter's knowledge of the interviewee's language usage suffices for the interpreter to assess the genuineness of the origin claim. Jacquemet (2000) also reported on a similar use of Kosovar interpreters by the UNHCR in Albania. Such ad hoc interpreter assessments of the language and origin question often do not involve systematic analysis or even a written report.

Assumptions About Language and Multilingualism Underlying LADO Assessments

The connection between a person's speech and their origin—whether national, regional, or ethnic—is easiest to establish or verify

1. where the person is a monolingual speaker of a language variety
2. which is significantly different from neighboring language varieties, and
3. where this person has not spent time living with speakers of language varieties other than their own.

Such a situation might apply for example for many speakers of Australian English who have resided in Australia for their whole life. But it arguably does not typify the situation of most asylum seekers.

Multilingualism is more prevalent in societies around the world than monolingualism. Yet there is a widespread assumption in many industrialized societies that societal monolingualism is the norm, and the best way for social groups, even countries, to work. This monoglot ideology (e.g., Blommaert, 2010, p. 165)—also referred to as the myth of monolingualism or the monolingual language ideology—appears to underpin much of the way in which LADO assessments work. The basic premise of much LADO work is that asylum seekers have one clearly identifiable “native language” or “mother tongue” and that it is realistic to expect them to use just this one language in their interview. Thus, any use of even one word from another language can be taken as evidence that the interviewee is being dishonest about their origins (for specific examples see Eades, 2005, p. 511; 2009, p. 34). This ignores the language situation of asylum seekers whose primary socialization has been in bilingual or multilingual speech practices, as well as those whose escape and travel to the country in which they are seeking asylum has involved later (e.g., secondary, tertiary, etc.) socialization and language learning in further speech communities.

Further, even where bilingualism is recognized, there is often no recognition that many people have different kinds of fluency in the two or more languages they speak. Blommaert (2010, p. 162) highlights an example of an asylum seeker whose multilingual repertoire has been “constructed through informal learning processes” in several countries. As is common with asylum seekers and other new migrants, this person's repertoire is “highly ‘truncated’”—“highly specific ‘bits’ of language and literacy varieties combine in a repertoire that reflects [their] fragmented and highly diverse life-trajectories and environments” (p. 8). Ignorance

of this phenomenon of truncated multilingualism is evident in the use of problematic translation tests (referred to above), which presuppose that the asylum seeker will have the same proficiency in both or all of the languages they speak (see Maryns, 2006, p. 254).

Another significant consideration is that people who speak more than one language may typically use their different languages within a single conversation. The widespread and complex use of code switching in bilingual (and multilingual) conversations is not recognized in the common view within LADO that asylum seekers should use only one language in their interview. Verrips (2011, p. 138) found that in “159 Somali cases that were submitted to De Taalstudio for contra-expertise since January 2008, the BLT Somali analyst states that the ‘applicant tries very hard to mix some Southern features in his speech, but he does this inconsistently and it doesn’t sound natural.’” None of these 159 reports acknowledged that code switching is a common linguistic practice, nor did they provide the grounds on which the NENS analyst determined that this was “unnatural” use of Southern Somali features in the speech of applicants.

Further, the recent scholarly problematization of the notion of discrete named languages (e.g., Jacquemet, 2005) is highly relevant to the LADO process. In his discussion of linguistic diversity in the age of globalization, Jacquemet (2005) shows the importance of the concept of deterritorialization, which accounts “for the cultural dynamics of people and practices that no longer inhabit one locale.” Asylum seekers are a prime example of deterritorialized people, with lives often characterized by movement, and language use characterized by complex multilingual practices.

Yet, the practice of LADO is based on matching the way in which an asylum speaker talks in an audiorecorded interview with a reification which aligns static constructs of discrete bounded languages with borders. And, as we saw above, practitioners are often looking for evidence that speakers “may be hiding knowledge of a language, presenting a second language as their first language, or adding speech features that do not belong in their natural speech variety” (Cambier-Langeveld, 2010a, p. 73). Such an approach appears to assume that the decision about what a speaker’s first—and second—language is, is straightforward, and a simple matter of honest reporting. While this may be so for some people, for many asylum seekers it may well be an oversimplified misrepresentation, relying unrealistically on “taken-for-granted common-sensical knowledge of what is a ‘language’” (Jacquemet, 2005, p. 273).

But this does not mean that there is no place for linguistic assessment of the connection between the speech of asylum seekers and their origins. Recent work by Blommaert (e.g. 2010, p. 181) suggests a move away from the “structural notions of language,” to a focus on the sociolinguistic repertoires or resources of asylum seekers. These resources are “concrete accents, language varieties, registers, genres, modalities such as writing—ways of using language in particular communicative settings and spheres of life, including the ideas people have about such ways of using, their language ideologies” (p. 102). He shows that the speech of asylum seekers is indicative not just of origins, but of “biographical trajectories that develop in actual histories and topographies” (Blommaert, 2010, p. 171).

Conclusion

For many asylum seekers it is unrealistic to expect an analysis of their speech to provide a fair way of isolating their place of origin from the rest of their personal history. It is to be hoped that future research and practice on the assessment of the speech of asylum seekers will transform the goal of LADO from a narrow focus on the connection between language and origin, to an examination of the connection between language and biography.

Language Testing for Immigration and Citizenship in the Netherlands

Massimiliano Spotti
Tilburg University, Netherlands

Introduction

Anyone even slightly familiar with the Dutch situation can hardly fail to notice the degree to which the Dutch political discourse has channeled the attention of its indigenous inhabitants around concepts of nation, national language, and national loyalty since the beginning of the 21st century. Considering the most recent developments that have taken place in Dutch political discourse, one can hardly miss either how the concept of nation is being presented to the people as a homogeneous entity, with one language serving the role of (official) national language and one of its varieties—the standard one—generally being presented as neutral vis-à-vis all the others. As a result of such a policy, the (official) national language becomes a powerful tool of group belonging and its mastery comes to be considered pivotal to maintaining national order (Bauman & Briggs, 2003). Consequently, a fundamental difference between the people who fall within the nation, language, and territory equation and those falling outside it is that the former are legally recognized members of an “imagined community” of people (Anderson, 1991). These people—whether they know each other or not—all share a common identity, namely that of being fellow nationals through a wide range of semiotic resources, such as a national flag, a national anthem, a liberation day, a national football team. When engaged in questions of migration and citizenship, indigenous inhabitants base themselves on ideologies of language and belonging. These ideologies are generally shared attitudes and beliefs that work as the binding cement of the nation. They pave the way for a connection between citizenship and mastery of the majority language as a prerequisite for positive social participation and crucial for maintaining national order. Ideologies are propagated through discourses, which in turn are authored and authorized by “real” macro-historical actors, such as governments, ministries, and political parties, their electoral

Language Testing for Immigration and Citizenship in the Netherlands

Introduction

Anyone even slightly familiar with the Dutch situation can hardly fail to notice the degree to which the Dutch political discourse has channeled the attention of its indigenous inhabitants around concepts of nation, national language, and national loyalty since the beginning of the 21st century. Considering the most recent developments that have taken place in Dutch political discourse, one can hardly miss either how the concept of nation is being presented to the people as a homogeneous entity, with one language serving the role of (official) national language and one of its varieties—the standard one—generally being presented as neutral vis-à-vis all the others. As a result of such a policy, the (official) national language becomes a powerful tool of group belonging and its mastery comes to be considered pivotal to maintaining national order (Bauman & Briggs, 2003). Consequently, a fundamental difference between the people who fall within the nation, language, and territory equation and those falling outside it is that the former are legally recognized members of an “imagined community” of people (Anderson, 1991). These people—whether they know each other or not—all share a common identity, namely that of being fellow nationals through a wide range of semiotic resources, such as a national flag, a national anthem, a liberation day, a national football team. When engaged in questions of migration and citizenship, indigenous inhabitants base themselves on ideologies of language and belonging. These ideologies are generally shared attitudes and beliefs that work as the binding cement of the nation. They pave the way for a connection between citizenship and mastery of the majority language as a prerequisite for positive social participation and crucial for maintaining national order. Ideologies are propagated through discourses, which in turn are authored and authorized by “real” macro-historical actors, such as governments, ministries, and political parties, their electoral

programs and their representatives. It is because of their historical rootedness that ideologies are not very likely to cause cognitive dissonance, being sold as they often are as “commonsensical” thinking or, to borrow a term from Bourdieu (1991), as *doxas*. The ideology inherent in testing would-be immigrants’ proficiency in the national language is one that presents the acquisition of *the* national language and the acquisition of *the* mainstream cultural norms and values for immigrants (newly arrived ones as well as legally recognized long term residents) as commonsensical, testing being an objective way of providing tangible proof of the immigrant’s progress on a continuum that goes from “being a foreigner” to “being an integrated citizen.” As a result of this, test results carry a heavy indexical load. This is so not only in terms of categories of inclusion and exclusion (i.e., who takes the test versus who does not), but also in terms of the values attached to such categories and their contribution, or lack thereof, to mainstream society (McNamara & Shohamy, 2008; Spotti, 2011a).

Another important element to be taken up here is what exactly the testing industry understands by language and culture. Often, if not always, this comes down to a modernist conceptualization whereby language and culture are looked upon as a whole gamut of skills that someone has at their disposal precisely because he or she was born, raised, and schooled in a specific nation. Naturally, immigrants who enter a nation, and in the case of the Netherlands also those immigrants who already are legally recognized long term residents, need to be put in a position where they can acquire these skills. “Correct” mastery of these skills carries positive consequences. Thus, for instance, immigrants who have managed to master cultural norms and values and are willing and able to put them into practice—an example might be an imam who shakes hands with a female minister of integration—are looked upon as being a “good” citizen, adhering as they are to the cultural practices of the receiving society. Similarly, immigrants who have learned to speak the majority language well are often praised by native inhabitants for being good language users through (informal) compliments like: “Well, you speak good Dutch for a foreigner.” The people in question, in fact, have managed to learn the official national language, most likely in one of its regional varieties, with a certain degree of appropriateness and thus are worthy of praise because it shows a form of civic integration into the mainstream, which in turn constitutes a contribution to the maintenance of national order. The testing industry takes this modernist understanding of language and culture a step further by adding a subtle yet remarkable twist. In seeing language and culture as stable denotational entities, the testing industry embraces an understanding of language and culture as skills that can be marketed, that can be bought and sold, and most important of all that can be measured. The upshot of it is that in the case of poor results, if someone fails the test and hence lacks—or at least fails to demonstrate—the ability to positively integrate into mainstream society, economic and residential sanctions become justifiable measures.

It is against this background that the present chapter sets out to illustrate the ideologies inherent in the testing for (a) admission and (b) integration of immigrants in the Netherlands. Rather than exploring these through the direct experience of the immigrant (Block, 2006), it takes the perspective of the nation-state’s testing machinery and focuses on a period that can roughly be indicated as

between March 2006 and January 2007 given that this period is key to a series of shifts within the political discourse surrounding civic integration of immigrants and the language-testing industry.

The texts referred to in this chapter are small samples taken from a large collection of official publications including policy documents, government reports, declarations issued by ancillary agencies—both governmental and private—asked to advise the government, as well as press conference declarations, released parliamentary interventions, and public interviews. It is on the basis of these documents that the chapter offers an insight into the testing regime for integration and its discourse, the implications for immigrants coming to and residing in the Netherlands and how this regime mirrors the polarization that has taken place in Dutch society.

Conceptualization

The current Dutch political discourse on immigrant minorities abounds with terms used to describe the identities of immigrant minority group members. As the first of many we encounter the term *allochtoon*. The concept, officially introduced in 1989 by the Scientific Council for Government Policies (WRR, 1989), was originally used to refer to a person born abroad or having at least one parent born abroad. The intention of the WRR in introducing the term *allochtoon* was to abandon a group-oriented approach to immigrant minority groups and to focus on individuals. Over the years, however, this term has acquired all kinds of negative connotations, becoming associated primarily with the absence of and need for linguistic integration and the lack of positive social participation in mainstream society. More recently, a further hierarchization has been added to the Dutch minority jargon with the introduction of the terms *westerse allochtonen* (Western immigrant minorities) and *niet-westerse allochtonen* (non-Western immigrant minorities). The former refers to EU citizens as well as those immigrants coming from English-speaking countries mostly, although it includes also Indonesians and Japanese. In the political discourse, members of this category are scarcely mentioned as constituting a threat to social cohesion, although Poles, Bulgarians, and Romanians are often singled out as posing a potential threat to the native manual labor workforce. The latter term, by contrast, includes mostly members of the Turkish, Moroccan, and Somali communities as well as new arrivals from other countries (Van den Tillart et al., 2000), who are presented as people in need of societal and linguistic integration. All of the above are identity ascription terms currently used in political and public discourse by native Dutch people to contrast with self-reference terms such as *autochtonen* (indigenous group members) and *Nederlanders* (Dutch people).

The array of terms used to refer to minorities pales into insignificance when compared with the armor of terms developed by the Dutch testing industry, particularly in recent years. First, there is the term *toelatingstest* (admission test), which is a test that takes place in the immigrant's own country of origin and which serves the purpose of making him or her eligible for admission to the Netherlands. Second, we have the term *inburgering* (civic integration) (De Heer, 2004). This term,

which first appeared in the *Wet Inburgering Nieuwkomers* (Law on the Integration of Newcomers) (WIN, 1998), deals with the need for societal and linguistic integration of *nieuwkomers* (newcomers), that is newly arrived immigrants on Dutch soil who are not qualified as refugees or asylum seekers. This need for integration also applies to *oudkomers* (oldcomers), generally low-educated immigrants who are long term residents in the Netherlands and who, in the vast majority of cases, already hold a residence permit.

In the following section, the reader is presented with a brief history of the laws and regulations for integration in the Netherlands. First, however, as frequent reference will be made to the measuring of language proficiency in Dutch following the terms spelled out by the Common European Framework of Reference (CEFR), it is necessary to briefly discuss the structure of the CEFR (Council of Europe, 2001), its original purpose, as well as the use that the Dutch government has made of this instrument within the framework of testing for integration (refer to Extra, Spotti, & Van Avermaet, 2009, for a comprehensive discussion of the use of the CEFR across Europe).

The Common European Framework of Reference

In many nation-states across Europe, one of the key features of the integration policy is the official national language. For the Netherlands, knowledge of the Dutch language is key to admission and integration and is a prerequisite for the applicant to be awarded a permanent residence permit or be granted naturalization. In order to flesh out and to implement this policy of linguistic homogenization, the CEFR was used to mark the level of language knowledge and proficiency to be attained by prospective immigrants. The CEFR, which has come to be a structural pillar of the (Dutch) regime of language testing for integration, defines levels of language knowledge and proficiency that allow us to measure the progress made by immigrants in the course of their integration track. The main objective of the CEFR is to offer a frame of reference, a metalanguage, as it were. It serves to promote and facilitate cooperation among educational institutions in different countries. It aims to provide a transnational basis for the mutual recognition of language qualifications. A further aim is to assist learners, teachers, course designers, examining bodies, and educational administrators to coordinate their efforts. And a final aim is to create transparency in helping partners in language teaching and learning to describe the levels of proficiency required by existing standards and examinations in order to facilitate comparisons between different qualification systems. It is important to emphasize that the CEFR was never intended to serve as a prescriptive model or a fixed set or book of language aims. Rather, it has a quantitative and a qualitative dimension. The former dimension covers learning development in domains (school, home, work), functions (ask, command, inquire), notions (south, table, father), situations (meeting, telephone), locations (school, market), topics (study, holidays, work), and roles (listener in audience, participant in a discussion). The qualitative dimension expresses the degree of effectiveness (precision) and efficiency (leading to communication) of language learning. A set of six levels and sublevels (A1, A2,

B1, B2, C1, C2) has been distinguished for use as common standards that should help course providers to relate their products such as coursebooks, teaching courses, and assessment instruments to a common reference system.

As mentioned before, the cornerstone of integration policies in most European countries is the official national language. For the Netherlands, knowledge is the main condition for those who want to apply for admission, be granted residence, and be awarded citizenship. To realize this monolingual policy, test makers in the Netherlands use the CEFR as a marker of the level immigrants ought to attain. This is problematic when the CEFR is used for admission, integration, and citizenship tests where a large part of the target group either has low literacy skills or is functionally illiterate. When we look at the CEFR from the L2 user's perspective, however, there is a severe lack of evidence that shows that all L2 learners of a given language at a given level (other than the lowest level A1) are able to perform all tasks associated with lower level descriptors. For the Netherlands, knowledge of both the Dutch language and Dutch society are the most important preconditions for those who aspire to being admitted to the Netherlands in the first place and for those who wish to qualify for a residence permit and later on for citizenship. In fleshing out this monolingual approach to language policy, the agencies involved in the making of the admission, integration, and citizenship tests—although, as we will see, the latter was incorporated in the integration test after June 2006—have used the CEFR as a reference point. The use of the CEFR thus turns out to be quite problematic for two reasons. First, the CEFR is used for the admission and integration examination even when a vast majority of the people being asked to take these tests have low literacy levels or are illiterate (Kurvers & Stockmann, 2009). Second, the level descriptors of the CEFR are mainly aimed at measuring the language knowledge of highly educated people. Lower- and semi-skilled people who have no background in higher education or do not study at a higher level do not fall within the categories described in the CEFR, as a result of which, backed up by the national authorities, recourse is being taken to introduce new CEFR levels (e.g., A1–) for use in the admission test. The role played by the CEFR in the Dutch testing machinery becomes even more problematic when one looks at the consequences involved in not coming up to the minimum level required. If they fail to attain the level required, people are refused citizenship, residence, or even admission. Summarizing, it is important to emphasize that the proficiency levels employed as a measure for testing immigrants were never intended to be used for that purpose.

The Moralization of Citizenship Through the Use of Language Testing

The legislative pillars of the Dutch testing regime for newly arrived migrants have been built on since 1998. Before 1998, there was but one government document (RRIN, 1996) that pointed to the obligation of newcomers to learn Dutch. The law that was approved in 1998 prescribed that newcomers—from the moment of their arrival in the Netherlands—were obliged to attend courses of Dutch as a second language and understanding Dutch society with a particular focus on work

situations. They were also advised to take part in the final examinations of these courses, so that they could show the certificate as proof that they had actually taken these courses. Although these courses were in place, there was no specification of the level of language proficiency to be achieved, as the law proposed only one level newcomers should strive to attain—more specifically level 3, which is comparable to level B1 of the CEFR. This situation changed dramatically in 2003 with the General Government Accord (Hoofdlijnenakkoord, 2003) and even more in 2004 with the introduction of the government resolution on the Revision of Civic Integration Regulations (Verdonk, 2004a). In comparison with the law approved in 1998, there are a series of fundamental changes that show the Dutch government's new approach toward integration of newly arrived migrants. These changes are:

- the use of an admission test that has to be taken (and passed) before newcomers are allowed to enter the Netherlands;
- both newcomers and oldcomers are obliged by law to undergo civic integration in Dutch society;
- the obligation to undergo civic integration lies with the migrants themselves, both financially and in terms of content. This also implies that they are free to select the package that will help them fulfill their civic integration obligations;
- the obligation to undergo civic integration is fulfilled only when all the components of the examination on this issue have been passed.

In the revised version of the Civic Integration Regulations of 2004, newcomers to the Netherlands emerge as constituting the main cause for concern. What is new in the 2004 document is the attention paid to the integration of oldcomers who had not sufficiently mastered the Dutch language and who were receiving unemployment benefits (see Pluymen, 2004, for a critique of the link made in these regulations between permanent residence status and social benefits). Oldcomers who had already been given a permanent residence permit or a Dutch passport were also invited—though not compelled—to participate in the integration track. To this group, consisting of some 85,000 “allochtonous” citizens (as they are referred to in the document), the following applied: They were to register for compulsory intake at the immigration office of the municipality of residence; they were to undergo a civic integration track to be financed by themselves; they were given a free choice from among existing civic integration programs and providers that were approved by the government, newcomers being given three and a half years to become integrated, oldcomers being granted five years. These changes eventually led to the introduction of the admission test, which is to be taken abroad, and to a revision of the civic integration exam, which has to be taken once one has arrived in the Netherlands. To establish the norms to be adhered to for these two exams, a committee was appointed in 2004 to advise the government on this issue. The committee, commonly known as the Commissie Franssen (the Franssen Committee), named after its chairman, gave its first advisory opinion in 2004. On the basis of criteria such as functionality, feasibility, selection of previous educational tracks, and motivation, the committee came to the conclusion that

proficiency in written Dutch language skills should not be examined while proficiency for oral skills should be fixed below the lowest level of the CEFR. This level was subsequently classified as A1– (see Adviescommissie Inburgeringsnormen, 2004). The committee also advised the government not to test knowledge of Dutch society because of a low level of knowledge of the Dutch language and to instead run a compulsory course providing an “introduction to life in the Netherlands.” This final recommendation was not taken on by the government, and the admission test includes a component on knowledge of Dutch society (IND, 2005).

The Law on Integration Abroad (*Wet Inburgering Buitenland*) was introduced in March 2006 (WIB, 2006). Immigrants who want to enter the Netherlands of their own free will are to undergo an exam on spoken Dutch and an exam on knowledge of Dutch society before they are allowed into the country. With January 1, 2007 as the projected date of enforcement, then Minister of Integration Rita Verdonk proposed the last few changes to the Law on Civic Integration in June 2006 (*Wet Inburgering Nederland*). These changes, however, met with severe opposition from a majority in parliament, who rejected any unequal treatment of “native” and “naturalized” Dutch nationals. Verdonk’s appeal to parliament for “political courage” did not succeed, not even with her own party members in parliament, and led to a halving of the original target group numbers. Apart from these changes being rejected, many other amendments to the proposed law were passed, making it even more detailed and complex, and thus even more difficult to carry out in practice. In order to cope with the difficulties encountered, Verdonk in accordance with the wishes of a majority in parliament, decided to only partially introduce the new law in 2007, limiting it to newcomers without Dutch citizenship. In June 2006, the Dutch cabinet fell after its refusal to approve a general pardon for those asylum seekers without legal residence status who had entered the Netherlands before April 2001, in spite of the fact that a narrow majority in parliament was in favor of it. The center-left government that succeeded the cabinet in November 2006 approved this pardon as one of its first measures. On November 13, 2007, Ella Vogelaar—then minister of integration, housing, and communities—released a press statement that can be taken as tangible proof of a discourse shift to a more egalitarian climate within Dutch political discourse. Her declaration reads as follows:

The cabinet wants to put a stop to the increasing polarization in the Netherlands. . . . Integration can only succeed if both non-native and native citizens accept Dutch society as their society. They need to support the liberties, rights, and duties connected to the Dutch civic state. . . . The cabinet appeals to all citizens to participate actively in society on the basis of mutual acceptance and equality. (Vogelaar, 2007, author’s own translation)

Although it would appear to announce a change in the tone of the integration debate, the measures adopted in 2003 and 2004 for civic integration remained in force, resulting in a harsh testing regime. Applicants who do not manage to pass the admission exam are not allowed to enter the Netherlands. Those who did not pass the civic integration exam in the Netherlands did not get a permanent residence permit (in the case of newcomers) or could not apply for citizenship (in the

case of oldcomers). After 2007, other complementary measures followed, particularly measures dealing with the actual implementation and the costs of the civic integration track, and there was a shift from the costs being partly subsidized through loans from the municipality to the costs being solely the responsibility of the immigrants. In the most recent government resolution, we read:

It can be expected from anyone coming to reside in the Netherlands that he or she abide by the rules that obtain here and that he or she actively participate in society by mastering the Dutch language, attending education, and taking part in the workforce. Qualifications are the key to successful participation and integration. (Gedoogakkoord, September 30, 2010, author's own translation)

The official agreement closed between the current Dutch minority government and the party pledging its support to this government to create a majority in parliament (provided the agreement is adhered to) stipulates the following measures:

Immigrants and asylum seekers are solely responsible for their own integration in our country. To those who lack the financial means to pay for these purposes, the cabinet offers the possibility of loaning money, which implies that the money loaned will have to be paid back. Ultimately, the resolution adopted by the cabinet implies that, barring exceptional circumstances, failure to pass the integration exam will result in withdrawal of the temporary residence permit. The cabinet further proposes to accept the bilateral agreement between the EU and Turkey, making the due changes to the regulation that inhabitants of Turkey fall within integration regulations. (Gedoogakkoord, September 30, 2010, author's own translation)

The coalition agreement entitled "Vrijheid en verantwoordelijkheid" ("Freedom and Responsibility") stresses once more that immigrants who want to reside in the Netherlands have to follow the rules spelled out for civic integration and participate actively in the fields of education and work. In relation to the civic integration exams, the agreement states that: "The examination requirements are made stricter . . . there is the projected use of a test which makes it possible to determine whether loyalty to the Netherlands is deeper than loyalty to any other country" (Regeerakkoord, 2010, p. 23, author's own translation).

Since April 2011, the changes made to the Law on Integration Abroad have been put into practice. Since this date, the norms for the oral exam abroad have been raised from A1- to A1 and immigrants have to take a test in literacy and reading comprehension, scoring at least level A1-. On June 17, 2011 the cabinet approved another series of amendments, including the following: civic integration applicants pay for their own costs with the possibility of taking out a loan for those with insufficient financial means, and the examination must be passed within three years. The language proficiency level to be attained remains at CEFR level A2 minimum for newcomers. Also, the level for knowledge of Dutch society remains unchanged even though the exam now consists of a central part and an ancillary part. In the meantime, the level proposed for naturalization is CEFR level B1 (the level equivalent to that required for the State Examination Dutch, Program 1). The Netherlands has been the first country to introduce an examination for

Dutch language to be taken in the applicants' country of origin and the first to grant someone entry into the country on the basis of a computerized test administered over the telephone. The admission test puts applicants under considerable financial strain, if only because in most places there is no Dutch embassy nearby where the test can be taken, and in addition working with a DVD and a computer requires a certain level of technical skill. But above all, the exam on knowledge of Dutch society—which really is a language test cloaked as a civic knowledge test—requires potential migrants to make the norms and values of mainstream Dutch society their own. Clearly, these tests do not improve and reduce the time required for applicants' integration, but instead underscore the huge possible gaps between applicants in terms of literacy, language skills, computer skills, and socioeconomic background. Effectively, this means that doors remain open only for those applicants who fall within the category of literate, financially self-supporting, technically skilled people who can prepare for the exam and who have a high employability rate once they have entered the Netherlands. The exam on civic integration in foreign countries thus imposes an implicit hierarchization on the immigrant population in terms of who is considered suitable for entering the Netherlands. Table 23.1 presents a schematic overview of the historical developments that have taken place in the civic integration regulations from 1998 to 2011.

What is worth pointing out is that as of April 1, 2011 a new assessment component has been included in the civic integration exam, which is the literacy and reading comprehension exam. In order to pass this part of the integration exam, the examinee has to be able to read in Dutch (in the Latin alphabet) at CEFR level A1. This exam consists of five different tasks: (a) reading words out loud, (b) reading sentences out loud, (c) reading parts of texts out loud, (d) completing incomplete sentences, and (e) answering questions related to a short text. The answers to the other two parts of the examination are to be spoken into a telephone receiver. These answers are subsequently analyzed by a speech recognition program that assigns a score to each answer. The whole civic integration exam costs €350. Applicants can take the test as many times as they wish within the time allotted for reaching a pass level in all of the components. Each time they take the test, however, they will have to pay €350. Only when applicants have passed all three parts of the integration exam will they be given permission to apply for a visa to enter the Netherlands and, with that, a temporary residence permit.

Challenges and Future Directions

Prior to the fall of the Berlin wall, migrant groups were fairly easy to circumscribe. Such groups often became recognizable sedentary “ethnic” communities in their own right in the host country. In the aftermath of the political events that took place in 1989 and 1990, a new pattern of migration emerged that has changed the face of European urban conglomerates, many of them now showing a widely diverse influx among their populations originating from Eastern Europe, Asia, Africa, and Latin America. The motives for and the forms of migration have also changed. Immigrants no longer enter merely as unskilled labor forces.

Table 23.1 Overview of civic integration regulations from 1998 to 2011

<i>Year</i>	<i>Resolution</i>	<i>Applying to</i>	<i>Requirements</i>	<i>Consequences</i>
1998	WIN (Law on Integration of Newcomers)	Newcomers	Attend a course for Dutch as a second language Compulsory participation—take exam as proof of participation, but there is no obligation to pass	None
2003/2004	Hoofdlijnenakkoord/ Contourennota (Main Contours Agreement)			
2006	WIB (Law on Integration Abroad)	Newcomers	Take test on TGN (spoken Dutch) Take test on KNS (knowledge of Dutch society) Obligation to pass	MVV (provisional permission to stay)
2007	WI (Law on Civic Integration)	Newcomers and a specific group of oldcomers	Main part of the test: test on spoken Dutch digital practice exam exam on knowledge of Dutch society Part of the test centered on real-life situations: Portfolio and/or assessments Newcomers to complete this part within 3.5 years, oldcomers within 5 years	Residence permit with the possibility of naturalization
2011	Changes made in the WIB	Newcomers	Higher pass norms for test on spoken Dutch Addition of GBL test (literacy and reading comprehension)	
Adopted resolution	Changes to the integration benchmarking Proposals for changes to the integration benchmarking and its examination	Newcomers and oldcomers	Pass within 3 years Sanctions have been made heavier	
Proposal	Changes to the naturalization benchmarking		Pass level raised from A2 to B1	

They include refugees, short-time migrants, transitory migrants, highly educated foreign employees, visiting foreign students, and workers commuting from one nation to another. The blending of “old” and “new” migration has brought about a new, what might be called postmodern, form of diversity, one for which the term “super-diversity” has been coined (Vertovec, 2006). This type of diversity is diversity of a more complex kind in that the ethnic origin of people, their motives for migration, their “careers” as migrants (sedentary vs. short term and transitory), and their sociocultural and sociolinguistic biographies cannot be presupposed (see Maryns and Blommaert, 2006; Blommaert, 2010; Spotti, 2011b).

This new migratory wave is confronting the popular conceptions of “immigrants” with new challenges: the challenge of grasping who an immigrant actually is as well as the challenge of grasping their administrative position. As a result of all this, critical questions need to be raised with regard to the rationale and future of nation-states in Westernized Europe, about the dynamics of their dense and fast-moving urban spaces, about the embedded but as yet still omnipresent supremacy of the perspective of the majority within the institutions that regulate the entrance of migrants, and about the capacity of the bureaucracies of nation-states to handle them. As a response, politicians—regardless of their political affiliations—are pushed to think about and enforce modernist measures that allow access to the nation-state territory, a process in which the national language and the knowledge of mainstream cultural norms and values play a critical role (see Extra, Spotti, & Van Avermaet, 2009; Mar-Molinero, Stevenson, & Hogan-Brun, 2009). The Netherlands is no exception in this regard. Both the granting of access and the civic integration of new and old immigrants are processes deeply entrenched in a rigid set of modernist measures regulated by ideologies of fitting within a certain canon of language as well as cultural behavior. In other words, from the very beginning of a person’s immigration track, the Dutch state machinery requires the would-be resident to comply with an ideology of linguistic homogenization sold as a prerequisite for active societal participation, starting from the principle that, if all noses point in the same direction (i.e., if we all speak Dutch and we are led by a common set of cultural norms and values), then maintenance of national order is guaranteed. There is very little point in rebelling against the modernist measures proposed by the nation-state machinery. This chapter aims to lay bare some of the paradoxes involved in granting citizenship to immigrants through language testing and testing cultural knowledge of the host country.

Testing “newcomers” and “oldcomers” on language and culture has become the localized reaction through which national realities respond to the supranational socioeconomic processes of globalization (see Blommaert, 2008, for evidence on how modernist ideologies play an important role in asylum-seeking procedures). In this process, CEFRL levels play a key role. While these levels were initially intended as a tool to assess/measure multilingualism—and here we need to ask ourselves what kind of multilingualism is being measured and for the benefit of whom—they have now been turned into a powerful modernist tool to measure linguistic homogenization. They focus more on what newcomers and oldcomers lack in mainstream society than on what they might be able to contribute and add in terms of linguistic resources. Furthermore, through the testing

enterprise, the official language as well as the cultural norms and values of the majority have narrowed the desirable linguistic and cultural package to a *civic doxa* of (national) homogenization (Bourdieu, 1991). Although both newly arrived immigrants and long term residents bring along and might have already developed perfectly valuable linguistic and cultural resources by themselves, these resources do not symbolically qualify as valid skills—whether linguistic, cultural, or both—because they do not fit in the Herderian equation of nation, language, and territory. Not only does this imply a disqualification of the immigrant's own resources, it also implies huge financial constraints, to be made even sharper from 2014 onwards, which are imposed on both physical access to the country of residence and actual participation in the tests, not to mention the sanctions implicit in failing them.

Developmental Considerations and Curricular Contexts in the Assessment of Young Language Learners

Alison L. Bailey

Frances A. Butler

Language Testing Consultant, USA

Introduction

Recently one of the authors had the privilege of watching the classroom interactions of a group of preschool students and their teacher. The teacher made sure all the children had a chance to participate in the discussion about the towers they were constructing with colorful, magnetic, geometric shapes. One girl, whose listening and speaking competencies were particularly well developed, stood out. What follows is a description of what was observed.

Sitting with her classmates, alert with arms folded and eyes fixed on her teacher, Emily [a pseudonym] showed her understanding of every direction the teacher gave to her small group of fellow students, and when there was something she didn't comprehend she asked the teacher for clarification. Emily also spontaneously offered comments on the activity saying that she liked it and explaining how her construction of a tower differed from that of her peers. Emily even solicitously asked her neighbor if he would like some of her geometric shapes to complete the task. Later, on the playground, in a less structured environment, Emily frequently ran over to her teacher with cries for help to negotiate her possession of the swing set from her peers or to establish her right to climb the slide and jungle gym. By the end of the 20-minute play session, Emily was by herself, unable to use language to persuade her peers to play with her, and her pleas for intervention from the teacher ineffective.

We begin the chapter with this description of the contrasting academic and social communicative demands placed on young children to illustrate the powerful effects of context on children's language performances. Any assessment made of Emily's in-class performance during the highly structured interaction in the context of a teacher-directed activity would have placed her well within the teacher's expectations for her age. The same assessment of her linguistic competence in the unstructured and informal context of the playground would have revealed Emily's inabilities to convey her wants and needs to her peers and effectively solicit the aid of the adults in her environment. Taken alone, either of these two assessments would fail to provide administrators, educators, and parents with an accurate profile of Emily's oral language abilities. Utilizing multiple measures of the same target skill can help ameliorate adverse impact on the accurate evaluation of student competence from the limitations of a single assessment tool. However, not simply multiple measures, but multiple contexts for displaying skills and knowledge must also be taken into account. As the descriptions of Emily's vacillating performances above illustrate, the need to assess students in different contexts is especially true of young learners, for whom an important developmental consideration is the ability to generalize acquired skills and knowledge to new and varied contexts. Assessing narrowly in just one or two contexts may not provide young learners with sufficient opportunity to demonstrate their language skills during assessment. Nor will assessment in just one or two contexts reveal that a learner's skills can be flexibly used across a wide range of contexts.

For the purposes of this chapter, we define *young language learners* (YLLs) as being 3 to 12 years old. Although YLLs are part of the larger language-learning population, their specific needs set them apart from adolescent or adult language learners (e.g., McKay, 2006; Bailey, 2008; Inbar-Lourie & Shohamy, 2009). Thus language assessment of this particular group of learners warrants separate consideration. Assessment of YLLs must reflect the developmental and curricular needs of young children—not just the increasing difficulty of what language content they are taught or are acquiring, but also *how* they are assessed to best capture their knowledge and skills (e.g., National Association for the Education of Young Children & National Association of Early Childhood Specialists in State Departments of Education [NAEYC & NAECS/SDE], 2003). This means that test developers, language researchers, and classroom teachers need to adjust what language constructs they measure and how they measure them as children develop.

In terms of content, the youngest children we describe in this chapter (ages 3–7) will still be acquiring the more sophisticated formal features of their language (e.g., passive verb forms in English). Their conversational skills are still being honed in terms of rules for turntaking and providing contingent responses. In contrast, the older children we describe (ages 8–12) will likely have mastered these aspects of language but may, for instance, still be challenged by non-literal uses such as metaphor and humor. With regard to how young children are assessed, many key underlying assumptions of assessment with respect to older children and adults, for example the homogeneity of test takers, cannot be made for young children. However, some children may well be familiar with test-taking scenarios (e.g., conversing with unfamiliar adults, responding to multiple choice questions, etc.) while others, particularly younger children, will not.

Moreover, curricular content and instruction across the early years of schooling also differ considerably, with resultant implications for the content and method by which children at different ages can best be assessed. Younger children will likely be encountering literate forms of language for the first time, for example. For this reason, listening and speaking skills will still dominate much of what they know about language and will be of particular interest to their teachers. Older children, in general, are using print to formulate new knowledge in a variety of subjects across the school curriculum, so that reading and writing acquire more salience for their teachers. Consequently the chapter is divided into sections addressing younger (3–7) and older children (8–12) separately, to best capture the different assessment considerations and concerns that are developmentally and educationally driven.

Organization of the Chapter

In the sections that follow, we first define the population of YLLs. Then we discuss the types and purposes of language assessments for use with young learners. Next we examine developmental and curricular considerations for assessment separately for younger and for older children. We conclude with recommendations for the improvement of language assessment for YLLs.

Defining the Young Language Learner

YLLs are a diverse group. They come from a wide range of backgrounds and bring to their language-learning experience, as McKay (2006) pointed out, “their own personalities, likes and dislikes and interests, their own individual cognitive styles and capabilities and their own strengths and weaknesses” (p. 5). YLLs vary according to sociocultural environmental differences and at the same time share similar features. Butler and Stevens (1997) provide an interactive model of elements in children’s sociocultural environments that shape young learners prior to and during the early school years and beyond. Such variables as language exposure, parental education, community attitudes, socioeconomic status, and ethnic heritage all play a role in the young learner’s educational experience, as the child is developing linguistic and social skills. Similarly, in a discussion of indigenous student diversity in Australia, Malcolm (2011) reminds us that within-group differences will have implications for language instruction and assessment.

YLLs may be monolingual or bilingual/multilingual, and they may be in the process of learning two or more languages. Monolingual children are typically exposed to one language from birth, the predominant input coming from the home environment. Bilingual or multilingual children speak more than one language with varying degrees of proficiency, which are mediated by situation and need. For example, depending on the circumstances, a child will associate a specific language with a particular person or people in a specific context. One language is usually dominant. In some instances, children may be exposed to two languages simultaneously from birth and handle each language as a distinct system.

A variety of terminology has arisen in the literature to refer to children who come to school speaking a language other than the majority language of the country in which they are living. In addition to developing their home language, these children are faced with acquiring the language of the school and broader community. The terminology that refers to these children includes:

- Second language learner (SLL). In the United States, SLLs are generally called *English language learners* (ELL) or *English learners* (EL). In England and Wales, SLLs are referred to as students with *English as an additional language* (EAL) and, in Australia, as students with *non-English speaking backgrounds* (NESB). In these contexts SLLs may be speakers of an *immigrant language*, a language that originally comes from outside the country, or speakers of an *indigenous language*, a language native to a specific country such as Navajo in the US and Māori in New Zealand.
- Dual language learner (DLL). DLL is a term that has recently emerged to acknowledge the potential development of children's first language alongside their second language (Howard, Sugarman, Christian, Lindholm-Leary, & Rogers, 2007).
- Heritage language learner (HLL) and Heritage language speaker (HLS). HLL acknowledges the linguistic and cultural backgrounds of students in today's schools (e.g., Polinsky, 2008). Currently there are no agreed upon definitions for HLL/HLS due to the range and complexity of the language and cultural background of students. Students may or may not speak—or be studying/learning—the language of their parents, grandparents, or great-grandparents, but the goal of maintaining the cultural heritage and capitalizing on it during language instruction is frequently recognized.

A final category of young learner includes those children who are studying a foreign language in school or are taking classes in a foreign language at a language institute outside of school. The distinguishing factor in both situations is that the foreign language learner will usually have very little direct exposure to native speakers of the language.

Within broad groups of YLLs, both monolingual and SLLs, there will be children who come to school with language delays and disabilities that impact their acquisition, first and second. In both cases the initial task is to identify those children. With regard to ELLs, Westby and Hwa-Froelich (2010) note that, "by differentiating ELLs who are typical L2 [second language] learners from those who have particular language-learning difficulties, educators are positioned to provide more appropriate and effective interventions to promote L2 development" (p. 210).

Defining Assessment for YLLs

The field of education is replete with assessment terms: external, large-scale, high stakes, formative, summative, classroom, and diagnostic are some of the most frequently referenced and generally refer to the purpose for which the assessment

is used. For example, *summative* is used to refer to the purpose of summing up a period of learning to gauge students' attainment of specific goals; *large-scale* refers to assessments that are administered to groups of students in schools, or across school districts, regions, or entire countries and are often used for the purpose of accountability; and the purpose of *diagnostic assessments* is to provide instructionally tractable information about a student's difficulties, misconceptions, or obstacles in learning.

Although a variety of assessment terminology exists, in a fundamental sense two characteristics define the level at which assessments operate: the *macro-level* and the *micro-level* (Black, Wilson, & Yao, 2011). Macro-level assessments cover a longer period of learning than micro-level assessments and, by their nature, provide information at a larger grain-size than micro-level ones. Because of the period of learning covered and the difference in the granularity of the data, assessments in these two categories are used for different educational decision-making purposes in the context of language learning.

Theoretical Considerations

In a National Research Council (NRC) (2001) report summarizing decades of cognitive research and psychometrics, the authors propose three key elements underlying any assessment: cognition, observation, and interpretation. Cognition refers to a theory or empirically grounded view of how students develop expertise in a domain, for example, language learning, and it is needed in order to determine what should be assessed. Observation concerns the tasks or situations to which students are asked to respond in order to demonstrate important knowledge and skills. These should be designed to provide evidence that is linked to a model of learning—a progression that traces the development of expertise—and to support the inferences drawn from the student responses. Interpretation refers to all the methods and tools for reasoning from the observations. For example, in large-scale assessment the interpretation is usually a statistical one. In the classroom context the interpretation is often made by the teacher using a qualitative model.

Consistent with this general approach to learning and assessment expressed in the NRC report is McKay's (2006) description of assessment of second language and foreign language learning, in which she called for language acquisition theories to underpin language assessment approaches. In particular, she stressed that both sociocultural and cognitive theories of development need to be taken into account in the assessment of YLLs, to make sure that the assessment not only measures growth in language skills and knowledge but also captures the development of new identities that can be formed by language learning. Sociocultural theories are also crucial for taking account of the heterogeneity in YLLs' backgrounds highlighted in the previous section.

Assessment Decisions

At the broadest level, educational decision making encompasses two sets of decisions that are applicable to the language assessment context. One set concerns

students' movement through the entrance, transitional, and exit points of the education system (Allal, 2010). The second set involves judgments made in order to keep learning moving during its ongoing course, in contrast to assessment that comes at the end of a period of learning (Black & Wiliam, 1998; Bailey & Heritage, 2008). In Broadfoot and Black's (2004) terms, the first set of decisions is used to prove that learning has taken place, while the latter set primarily serves to inform decisions to improve learning.

Macro-Level Language Assessment Decisions Decisions based on macro-level assessment include determinations about students' proficiency levels for the purposes of accountability, which students will be placed in specific language programs, their access to educational resources, and particular designations they will be given to signal the levels of language achievement at the end of a period of learning. Macro-level assessments that make use of norming samples are also used to diagnose divergent development—for example, to distinguish among language disorders, language delays, and differences in development due to the presence of second or dual language acquisition. The macro-level can also inform decisions about strengths and weaknesses in student language learning—for instance about which students need more assistance (but it may not suggest what kind of assistance)—and changes that need to be made to curricula and programs. Finally, macro-level data can also provide an opportunity for reflection on the part of teachers and students about their respective work.

Micro-Level Assessment Decisions Micro-level assessments provide much finer-grained data about shorter periods of learning and, for that reason, mainly serve to inform decisions that are more proximate to immediate teaching and learning. In addition to typical assessment formats, micro-level data sources include dialogue, explanations, and representation. Micro-level data enable teachers to work in the students' *zone of proximal development* (ZPD)—an expression used by Vygotsky (1978) to define the area where he hypothesized learning takes place. Working in the ZPD involves the consistent identification of the edge of a student's development, in order to support the continued forward movement of learning (Heritage & Heritage, 2011). For language learning, the "edge work" involves determining the scaffolding needed to consolidate emerging language structures to move to a new state of linguistic competence, from which the next developmental steps in language learning can occur. Micro-level data can also be used by teachers to reflect on their teaching practices and by students to closely monitor their own learning against clearly specified goals and criteria.

Assessment in the Early Childhood Years

Focusing on 3–7-year-old YLLs, we characterize key cognitive and social-cultural developments along with curricular characteristics that can impact the design, use, and limitations of language assessment.

Developmental Characteristics

Developmental considerations have a large impact on the content and the manner of language assessment. These considerations include the constraints placed on assessment practices by the still growing cognitive abilities of YLLs, such as limits to memory load and slower processing speeds. Young children also experience short-term motivation issues—their attention can wander more easily than that of older children and adults (Hasselgreen, 2005). McKay (2006) prompts us to ensure, because of the heightened vulnerability of this learner group, that assessment is a positive force in young children's lives. The youngest YLLs run a greater risk of testing fatigue and the anxiety and wariness associated with the unfamiliar. In sociocultural terms, children may not yet be aware of linguistic and cultural differences around them, and the pragmatic demands placed on them in a testing context (e.g., giving known answers, selecting the best answer) may differ from those at home.

Curricular Characteristics

With the youngest YLLs we consider in this chapter, curricular issues may not appear to play as important a role in the assessment of their language competencies as they do with older children. However, if we acknowledge that there are curricula associated with participating in an early childhood care and education (ECCE) setting and expectations for using language to relate to family and friends, then we must also entertain the need for assessments that determine language growth and mark the successful attainment of language milestones in these contexts as well.

The oldest children in the 3–7 age span will have begun compulsory schooling. The focus of the early school curricula is predominantly on oral language (McKay, 2006) and on the processes of learning to read and write. Teachers and schools are increasingly being held accountable for student outcomes in these domains. For ELLs in the US for example, early literacy skills are assessed from the very start of compulsory schooling (No Child Left Behind Act [NCLB], 2001).

Consequences of Developmental and Curricular Characteristics for Assessment

Ideally, young children should only be assessed if the content included is relevant to them and if the information yielded from the results is beneficial to student learning (Shepard, 1994). Because a young child's test performance can so easily be impacted by issues like fatigue, memory load, or lack of familiarity with testing and a tester, a variety of different probes will be necessary to maximize the validity of the inferences drawn. In addition, the range of language contexts at this stage in children's lives needs to be taken into account, so that assessments can ascertain how young children are developing language skills across a variety of settings. This, as illustrated to a small degree in the introductory scenario, not only prevents missing out on opportunities to capture language abilities that may initially be constrained to just one or two contexts, but also yields information about how

well children are generalizing their new skills and knowledge across different contexts.

Cognitive constraints dictate that the content and manner of assessment be age-appropriate. For example, assessments given in the paper and pencil formats found in later elementary classrooms cannot be taken by younger YLLs because they have not yet acquired literacy skills, nor likely the abilities to work independently within a group setting. Ideally assessments would be embedded in the course of familiar activities or routines and administered one on one by familiar adults. Children's short-term motivation, coupled with their lack of test-taking familiarity and awareness about the personal consequences of testing, also have implications for the content and design of assessments; assessments have to be exceptionally interesting if they are to succeed in measuring the language competencies of the youngest learners (Hasselgreen, 2005).

Oral language development predominates in ECCE curricula and consequently language assessment should place a strong emphasis on this domain, not only for ascertaining children's speaking and listening skills for their own sake, but because oral language skills in the areas of phonological processing and extended discourse among preliterate children are also important for later literacy development.

Current Assessment Practices

Classroom assessment is frequently seen as central to the language assessment of the youngest YLLs. This form of assessment largely includes micro-level data collection techniques such as teacher observation, record keeping, portfolios, as well as student self- and peer assessment. Self-assessment, whereby students gauge their own performances, has been particularly encouraged by the Common European Framework of Reference for Languages: Learning, Teaching, Assessment (CEFR) (Council of Europe, 2001) in the absence of available formal language assessments for this young age group, or when teachers lack training to reliably administer these assessments. Two additional characteristics of the YLL language assessment situation make self-assessment attractive: the heterogeneity of language abilities and backgrounds in the classroom; and a lack of alignment between formal assessments used across different language-learning situations. Adoption of the European Language Portfolio has been encouraged in order to document student progress largely through self-assessment; for example, a version for learners as young as 3–7 years is already in use in Spain (Hasselgreen, 2005).

Authentic assessment refers to real-world or to simulated real-world activities that children can engage in, and this type of assessment is particularly appropriate for YLLs for the developmental reasons outlined above. Process-based assessment measures (e.g., dynamic assessment in which a child is taught a new language strategy to apply to a language task, or is provided scaffolding during responses to reveal the degree of necessary assistance) can be used to show how readily and in what manner children are learning language. These forms of assessment are used in determining readiness or learnability in young children, as well as in diagnosing language-learning disabilities and distinguishing disabilities from delays and L2 learning (Westby & Hwa-Froelich, 2010). However, much diagnostic assessment is done with norm-referenced tests that compare

children's performances against a sample of same-age typically developing children. Assessment of SLLs is frequently conducted with criterion-referenced tests based on standards. For example, the US under NCLB saw the introduction of English Language Proficiency (ELP) assessments aligned to ELP standards by each state, and the National Languages and Literacy Institute of Australia developed the *ESL Bandscales* (McKay, Hudson, & Sapuppo, 1994).

Limitations to Assessment Practices

Clearly current assessment practices with young children face forbidding challenges. The potential for misuses and abuses in the assessment of young children in general are long acknowledged and well documented elsewhere (e.g., see Shepard, 1994; NAEYC & NAECS/SDE, 2003). Two misuses specific to language assessment are worth mentioning here. First, when socioeconomic or cultural mismatches (or both) exist between children's knowledge and test content or procedures, the validity of inferences drawn about their language competencies is called into question. For example, children raised in non-Eurocentric cultures may be unfamiliar with the picture-labeling task that is ubiquitously used by Anglo-American mothers and test developers to capture receptive vocabulary knowledge (Peña, Iglesia, & Lidz, 2001). What is really measured is a child's prior exposure to culturally embedded practices and routines for learning language. Second, use of monolingual tests of the two languages of DLLs is also inappropriate because such assessments are not normed for bilingual performances (Davidson, 1994). Such assessment practice will always underestimate the language competencies of the bilingual child—the bilingual child is not two monolinguals in one person. Rather, depending on the specifics of their linguistic environments, young bilinguals will have some linguistic skills in common across their languages, but many others unique to each.

Macro-level assessments, in particular, face severe limitations when administered to young children. Assessments that are decontextualized, focusing on children's language skills and knowledge without being embedded in the classroom content, will only measure a very narrow range of the language knowledge acquired by YLLs (Inbar-Lourie & Shohamy, 2009). Additionally, there may be curricular mismatches between the content that is taught to YLLs and the content assessed, particularly in cases where curriculum and instruction is under local agency control but the macro-level assessment used for accountability is not.

There is a lack of emphasis placed on the assessment of oral language skills, which play such a prominent role for children developmentally, in ECCE curricula, in ELP standards, and in the English language arts and other content area standards YLLs will encounter in school (e.g., in the US, the Common Core State Standards Initiative [CCSSI], 2010). Tests of written language can be administered effectively with groups of children, whereas oral language largely relies on one-to-one testing. However, it is absurd that oral language should be neglected in favor of assessing written language skills in young children, who have largely yet to acquire print skills—particularly if the reason is that written assessment is easier and cheaper to collect and score than generating and analyzing oral language samples. Privileging written assessment above oral could potentially lead

to negative language testing experiences for YLLs at the very start of their school careers. In addition, this could fail to provide teachers with relevant data on children's oral language instructional needs and progress. However, micro-level assessment, which can avoid many of these limitations, also has drawbacks. The field must find ways to apply the concept of validity in formative assessment contexts. McKay (2006) has suggested that teachers need to make success criteria explicit and to crosscheck them with others in order to argue for valid and reliable assessment for formative purposes.

Finally, a limitation that both macro- and micro-level assessment of language share is to equate younger children with lower levels of proficiency. YLLs are heterogeneous in their language abilities and assessment systems must be able to capture a full range of proficiencies here, as much as in older children and adult language learners—something that the CEFR for example does not manage well, with its restricted range on the attainment of YLLs (Hasselgreen, 2005).

Assessment in the Middle-Childhood Years

In the middle-childhood years language development is significantly influenced by the particulars of the instructional system children happen to be exposed to. In this section we examine the developmental and curricular characteristics specific to 8–12-year-olds in tandem with general language learning and language learning and use in the content areas.

Language Development and the School Curriculum

In middle childhood the size of children's vocabularies increases significantly. Vocabulary expansion involves increasing one's representation of word meanings and of their corresponding forms. The growing conceptual and real-world knowledge that occurs in middle childhood is accompanied by a semantic refinement of words (Verhoeven & Perfetti, 2011), with increased use of precise and accurate vocabulary needed for knowledge construction in the content areas. Combined with the need for an increased vocabulary is the requirement for children to increase their knowledge and use of syntactic structures, which support understanding in specific disciplines. For example, Halliday (1994) suggests that it is not possible to "do science" using ordinary language; rather science involves the use of appropriate vocabulary and structures. In addition to increased demands of spoken language, the reading and writing demands of the curriculum, as children move from the early primary years into later elementary and middle school, require that they engage in increasingly advanced literacy tasks. These tasks involve language "in ways which condense information through lexical choices and clause structures that are very different from the way language is used in ordinary contexts of everyday interaction" (Schleppegrell, 2004, p. 4).

Dutro (2003) nicely illustrates the difference between academic and "ordinary" language when she considers the language capability needed to read the sentence *If we had provided the soil with essential nutrients, the plant would have grown larger* (p. 4). To read this successfully, students need knowledge of conditional mood

if. . . *would have*, knowledge of the past perfect *had grown*, knowledge of the comparative form of the word *large larger*, as well as sufficient background knowledge and vocabulary about plants to understand the words *nutrients* and *soil*. They would also need to understand the more complex syntactic structure of the conditional clause at the beginning of the sentence.

In addition to being able to read more complex texts as the demands of their written work increase through middle childhood, students must become more sophisticated in their writing. In this period children's written expression develops from one that is more akin to spoken discourse (e.g., with chained clauses and generalized conjunctions) to a more mature structure, incorporating dependent clauses, varying sentence structure, and expanded vocabulary (e.g., Scott, 1988).

Related Developments

Apart from increases in children's linguistic knowledge, language-learning middle childhood is accompanied by the development of additional abilities related to their capacities. Children become increasingly self-aware and conscious of their capabilities in comparison with those of their peers. They also develop an orientation toward achievement, which, in turn, has an impact on their motivation and their success in school (Dweck, 1999). The development of self-awareness and motivational patterns is particularly salient in the context of SLLs, who—because of perceived or explicitly referenced limitations in language capacity with respect to that of their peers (e.g., from test results and teacher feedback), or when their home culture and language is not valued—may be more likely to develop a negative or inferior view of themselves and their learning capabilities. For this reason, a recent policy research brief from the National Council of Teachers of English [NCTE] (2008) in the US stresses the importance of teaching and testing SLLs with culturally relevant resources.

Erikson (1968) viewed middle childhood as a time when children learn to cooperate with peers and adults. Thus, in addition to children's increasing ability to reflect on themselves, this period of development is characterized by their ability to accommodate an ever widening set of interactional patterns with both peers and adults, and to modify what they say to take stock of their conversation partner's knowledge or perspective—components of Emily's social cognition that were yet to develop and impacted her language and pragmatic competencies, as we saw at the start of this chapter.

Language Assessment

Supporting children in middle childhood to meet the language demands of the curriculum means that teachers need to have instructionally tractable information about students' (1) vocabulary development in oral and written language, especially in the content areas; (2) syntactic and grammatical development in oral and written language; and (3) reading abilities, particularly as they relate to the language process underpinning successful comprehension. Because children do not learn in lockstep, teachers must access a range of assessment opportunities to meet the needs of individuals. In particular, macro-level assessments are unlikely to

provide the level of proximate detail necessary to consistently move an individual child's thinking, language, and literacy learning forward.

Furthermore, because middle childhood is a time when interactional patterns expand, teachers should also pay attention to this aspect of students' development. Children learn through their oral interactions with peers and adults, and the ability to take into account another's knowledge and perspective is important in the process of learning. Although this is rarely made available through existing assessment, teachers need information related to how students are interacting, in real time, with peers and adults, so they can harness emerging developmental capabilities in support of oral language learning.

One promising avenue that departs from the "one size fits all" approach is the innovative scheme of voluntary testing piloted in England and Wales, which recognizes achievement at different levels, in different skills, and in different contexts (Department for Children, Schools, and Families, 2007). Language learners, including YLLs, can take externally rated tests in listening, speaking, reading, or writing at an appropriate level when teachers deem them ready to do so. Assessments are embedded in a flexible framework, "a ladder" that allows learners to progress in ways that are consonant with their level and needs.

There are several advantages to this kind of language assessment approach. First, the assessments are directly related to students' level of competence and provide a measure of what students can do. Second, they can be used for summative purposes, to provide an indication of students' language status and to prove that learning has taken place. Third, many of the assessment tasks can be adapted by teachers to provide additional sources of information to support proximate teaching and learning. Guidance is offered to teachers on how they can make these task adaptations, with the additional benefit of teachers being able to adapt the content to the sociocultural context of their students. In this way the assessment system combines macro- and micro-level approaches to assessment and thus counters the negative and deficient orientations that children can develop from assessment experiences.

Collecting proximate data is dependent on teachers' knowledge of how language competence develops—an understanding of the progression of listening, speaking, reading, and writing skills (Bailey & Heritage, 2008). Sources for these data can be a range of oral language contexts and students' written work, and they can be seamlessly integrated into everyday teaching and learning activities. When the assessment opportunities are mapped to a progression, teachers have an interpretive framework for making decisions about where students are in their learning and what they need to do next to move learning forward (Heritage, 2008).

Recently, in foreign and second language education, the learning and instructional aspects of self-assessment have gained attention (Butler & Lee, 2010). Students in middle childhood have a greater capacity for self-assessment than younger learners, and, given the benefits of metacognitive activity to learning (see NRC, 2001), it seems sensible to incorporate this form of assessment into language learning. Teachers must develop their own skills to assist their students in self-assessment and provide opportunities for students to actually assess their abilities effectively for further learning.

Concluding Comments and Future Directions

To summarize, some of the concerns that have been expressed in this chapter arise from the predominance of information from macro-level data in the current language assessment environment. These concerns center on: (1) the decontextualized nature of the language assessed, in contrast with the contexts of academic learning or social interaction with teachers and peers; (2) the lack of direct application to the children's immediate learning needs; (3) the presentation of material to which students have not yet been exposed or that they did not have the opportunity to learn, which thus limits their use for identifying language levels; (4) the predominance of print materials that cannot provide direct information on children's oral language use in a range of academic and social contexts; and (5) related to the decontextualized nature of these assessments, a distinct possibility of mismatches between test content and the students' own background experiences, which raises important issues about fairness and how students are afforded the opportunity to show where their language competence really lies. As long as macro- and micro-level assessments remain aligned to language standards that do not reflect progressions of how language competency develops, the utility of the data generated from each type of assessment will remain a concern.

In what follows we offer recommendations for addressing these concerns in the future.

Improvements to Assessments

Getting the Content Right The language demands placed on YLLs, both monolingual and DLLs, include oral and written language in general, as well as the language associated with, and supportive of, the content areas. In some instances assessments will need to be created to capture the language skills described in existing standards. In other instances new standards will need to be created in order to operationalize the language and literacy constructs that have emerged in new standards for content knowledge and skills (e.g., CCSS, 2010). At yet another level, we must conduct further empirical research on all the ways in which language and literacy function in the lives of young children. Such research is a vital precursor to accurately operationalizing language constructs for assessment development.

Expanding Notions of YLL Assessment We also recommend expanding notions of what should be assessed with regard to the language learning of YLLs. This should include the assessment of the quality of the environment in which YLLs learn. That is, data generated by these assessments will be pertinent to classroom teachers and to those holding programs accountable for children's readiness for formal schooling and later for their continued growth. Assessment of teaching practices can also play a role here, particularly teacher self-assessment for refining teachers' own learning.

Integration of Macro- and Micro-Level Data It is noteworthy that the notion of "edge work" in micro-level assessment contrasts with the all too common view

of assessment for formative purposes as something undertaken to “fix” problems in student learning. Assessment for formative purposes is an approach that starts from where each student is in learning and moves that student forward to the next manageable level in the development of expertise. The integration of macro- and micro-level data in a comprehensive and coherent system of assessment is needed in order to maximize the potential of assessment data for supporting student learning. We see a greater role for process-oriented forms of assessment in this regard. For example, the scaffolding or assistance to perform at desired levels of proficiency that is typically seen in micro-level approaches is possible in large-scale assessment via partial credit models (Mattos, 2000). This can provide feedback both for instruction and for determining performance levels.

Improvements to Assessment Practices

Preparing to Assess In the US, the development of language is the aspect of learning that receives the least attention in pre-service and in-service courses of educators (Wong Fillmore & Snow, 2000). This is reported to be the case in the European teaching profession as well (Hasselgreen, 2005). Moreover, the assessment literacy of teachers is also frequently overlooked (Stiggins, 2002). Not surprisingly, therefore, teachers typically lack the knowledge they need to assess and promote language learning. Furthermore, administrators generally do not have knowledge of language development and assessment and are not able to support their teachers in this important arena.

Attention to YLLs in the Language Testing Profession High stakes decision making for identifying, placing, and exiting individual students from language support services frequently accompanies the assessment of young SLLs in school systems. This makes the inclusion of the YLL population in wider discussions of the technical quality (i.e., reliability and validity) of language assessment all the more critical. We also recommend greater investment in assessment resources by public and private initiatives that can lead to advancements in the technology for YLL assessment.

A Role for Standards and Progressions As mentioned above, in many cases the standards needed to create effective language assessments do not exist. We recommend the creation of learning progressions that are descriptions of the trajectories of skills and knowledge on the basis of empirical research to which level standards that are more general can be anchored. While progressions exist for aspects of first language acquisition during the school years (e.g., Scott, 1988), many terminate at the preschool milestone. What teachers need are clear models of general language learning and of language learning related to specific content areas across the school years. These progressions are needed in order to provide the interpretive framework both for determining students’ current language status and for deciding the proximate next steps that can move language learning forward (Bailey & Heritage, 2008). Specifically, we envisage pairs of related progressions, one for language and one for the language needed for content learning, so that language development may be clearly seen to be connected to the

content areas and used effectively in instruction and assessment. Of course, teachers do not simply need more standards, or even progressions; they also need knowledge about effective ways to elicit evidence of students' language learning and the skills to interpret the information and to translate it into instructional action.

For too long, the assessment and language-learning needs of YLLs have gone ignored at all levels of the educational system. Our hope is that this chapter has conveyed the seriousness of the current situation in relation to language assessments and their use. Moreover, by considering developmental, sociocultural, and curricular issues, we have highlighted why current assessment practices are failing to serve the needs of YLLs and of their teachers. We have also suggested avenues for further exploration in improving the educational experiences and prospects of future generations of YLLs.

Assessing Heritage Language Learners

Lorena Llosa

New York University, USA

Introduction

In the last few decades, research on heritage language learners' acquisition and instructional needs has grown as enrollment of these students in language classes has increased. Heritage language (HL) learners are children of families who speak "ethnolinguistically minority languages who were exposed to the language in the family since childhood and as adults wish to learn, relearn, or improve their current level of linguistic proficiency in their family language" (Montrul, 2010, p. 3). These learners enroll in language classes in high school and college but the language classes typically offered are designed for students learning the language as a foreign or second language and are not appropriate for addressing their unique needs. HL learners are believed to excel in "listening and speaking skills and cultural/sociolinguistic knowledge" in comparison to second language (L2) learners who are believed to "possess stronger reading and writing abilities of the prestigious variety as well as metalinguistic knowledge of the target language" (Fairclough, 2011, p. 274). Also, HL learners differ in their motivation for learning the language and their attitudes toward their heritage language (Kondo-Brown, 2005).

The presence of HL learners in foreign language classes has resulted in a number of challenges for instruction and assessment. Elder (1996, 1997, 2000a, 2000b) discusses these challenges in the context of Australia. The discussion centers on the fairness of assessing heritage or "background" and "non-background" speakers using the same foreign language outcomes-based assessments.

More recent work on the assessment of HL learners has been conducted in the context of higher education in the USA and has focused almost exclusively on placement testing. Recognition of HL learners' unique needs has resulted in the proliferation of heritage language classes separate from foreign language classes

in many US universities. Accurately assessing and describing HL learners' language proficiency is a critical first step to placing them in appropriate classes in order to provide them with effective, targeted instruction. Given that most recent published work related to the assessment of HL learners deals with placement, this chapter focuses primarily on this topic.

This chapter first reviews the various characterizations and characteristics of the HL population. The next section discusses approaches to placement testing of HL learners and reviews specific studies that have been conducted related to these different approaches. Finally, the chapter concludes by discussing challenges in the placement testing of HL learners and future directions for research.

Heritage Language Learners

A general consensus has not yet been garnered on the definition of the term heritage language, a term still contested and discussed in the literature. Bale (2010) provides an extensive list of terms that are synonymous with heritage, including "aboriginal, ancestral, autochthonous, (ex-) colonial, community, critical, diasporic, endoglossic, ethnic, foreign, geopolitical, home, immigrant, indigenous, language other than English, local, migrant, minority, mother tongue, refugee, regional, and strategic" (p. 43). The term heritage language is specific to the North American context and it is seldom used in global contexts (Rothman, 2009). Carreira (2004) explains that the difficulty in designating a constant description of HL learners relates to the heterogeneity of this population (p. 1). In the USA, some HL learners may have been born abroad, while others are first or second generation born in the USA. Likewise, some have gained proficiency in reading, writing, and speaking in the heritage language since childhood, while others have developed little to no proficiency despite profound ties to the HL community. Questions concerning who counts as a HL learner have culminated in a debate in which some scholars believe that HL learners are defined based on affiliation with a particular ethnolinguistic group while others center the definition on language proficiency (Bale, 2010). Affiliation-based definitions of HL learners focus on actual or perceived membership in an ethnolinguistic group. Carreira (2004) argues that HL learners may be members of a community (with linguistic roots other than English) or those learners who wish to connect to their family or ethnic background.

However, in the literature that specifically deals with HL acquisition and pedagogy issues, proficiency-based definitions prevail. Proficiency-based definitions are contingent on the ability of learners to speak or understand the language, no matter how limited that proficiency. Perhaps the most frequently cited proficiency-based definition is that of Valdés (2001). She defines a HL learner as one who "is raised in a home where a non-English language is spoken" and who "speaks or at least understands the language and who is to some degree bilingual in that language and in English" (p. 38). Specifically, it is the context of language learning that differentiates heritage and foreign language (FL) learners: HL learners begin their language acquisition at home whereas FL or L2 learners begin their language instruction in the classroom (UCLA Steering Committee, 2000).

Despite the various definitions of the term, there is agreement that when it comes to instruction, HL learners have different needs than FL or L2 learners. HL learners have been exposed to the language outside of the classroom and therefore tend to have more developed listening and speaking abilities and a better control of the phonology of the language than L2 learners. HL learners also possess a range of cultural knowledge that distinguishes them from L2 learners who are often unfamiliar with the target culture. On the other hand, L2 learners who have only been exposed to the target language in formal instructional settings have stronger metalinguistic knowledge of the language and are often stronger readers and writers than HL learners.

Even though HL learners differ from L2 learners overall, they also comprise a very heterogeneous population. One example of the diversity of the HL population is provided by Ranjan (2008) in the context of Hindi education. He explains that there are at least four types of HL learners in Hindi HL courses. One group is those who have learned Hindi formally before in India or the USA. The second group is those who have had exposure to Hindi through parents and/or grandparents but who never studied it formally. The third group is those who have not had exposure to Hindi but who have a background in a cognate Indo-Aryan language such as Gujarati, Punjabi, Marathi, and Bengali—languages that share the grammatical features of Hindi and some common vocabulary. The fourth group of HL learners is those who do not have any background in Hindi or any Indo-Aryan languages. Their background is in what are considered noncognate languages like Dravidian. These students share some common cultural background with the other groups and their exposure to Hindi is likely limited to watching Hindi movies. And, in addition to the diverse characteristics of these groups, within each group identified student may vary in their levels of proficiency, ranging from very low to very high levels of proficiency.

This diversity in HL learners presents a challenge for language educators such as those in universities who have traditionally dealt with FL learners who begin their language learning from zero. To begin to address the needs of the HL population, many university programs offer a separate HL track with multiple levels. In order to place students in the appropriate tracks and levels, programs need to assess students' language abilities.

Approaches to Placement Testing of HL Learners

The placement of HL learners has been an issue of concern even decades before the term HL learner was used to describe this population. In 1984, Parisi and Teschner wrote an article entitled "Can a Single Instrument Adequately Serve Native Speakers and Non-Native Speakers Alike?" Their paper explored this question in the context of Spanish language education at the university level (Parisi & Teschner, 1984). Several approaches are used to place HL learners into HL courses at universities. Most common are the use of self-placements, informal interviews, and demographic questionnaires. Some institutions use standardized foreign language exams while others use their own locally developed placement tests. Each of these approaches is reviewed next.

Self-Placement and Demographic Questionnaires

In a survey of Spanish HL programs at universities in the southwest of the USA, 47% reported that placement in Spanish HL courses was based on student self-identification or self-placement (Beaudrie, 2011). Similarly, Valdés, Fishman, Chávez, and Pérez (2006) found that in California students self-selected into HL courses at 74% of the universities that participated in a statewide survey about Spanish HL programs. Despite being a very common approach to placement, there have been no documented attempts to investigate whether self-selection and self-placement result in proper placements.

Another placement approach that does not involve the use of a formal assessment is the use of demographic questionnaires. Kagan (2005) advocates for the use of “linguistic biographies” for placing Russian HL learners. These linguistic biographies include information about students’ age at immigration, family relationships, attitudes toward assimilation and language preservation, and future aspirations. Kagan claims that these variables can lead to the effective placement of Russian HL learners into three groups: Group 1 consists of students who have not been away from the Russian-speaking community for long (for example, students who graduated from high school in Russia) and perform as educated native speakers; Group 2 consists of students who attended a Russian-speaking school for about five years and have a fairly complete knowledge of the grammatical system but do not have the vocabulary and sociolinguistic knowledge of educated native speakers; Group 3 are either students who attended elementary school in a Russian-speaking country or students who were born in the USA to Russian-speaking parents. Kagan claims that this classification is supported by preliminary empirical data: Russian HL learners’ knowledge of grammar and vocabulary, as measured by a translation task from English into Russian, correlates with their years of schooling (Kagan and Dillon, 2001).

Standardized Foreign Language Exams

Some universities use standardized foreign language exams to place HL students into college-level HL programs. In Spanish HL programs, the Spanish Computerized Adaptive Placement Exam (S-CAPE) and the American Council on the Teaching of Foreign Languages (ACTFL) Oral Proficiency Interview (OPI) are often used (Fairclough, 2006). In Korean programs, the Scholastic Aptitude Test (SAT) II Korean is often used for placement purposes (Sohn & Shin, 2007). The use of these types of assessments for placing HL learners has been criticized because these assessments were designed for FL learners and assess the sequence of acquisition that typically occurs in the classroom (Valdés, 1989). Sohn and Shin (2007) explain that the problem with using the SAT II Korean is that it is often too easy for some HL learners and thus the results are not useful for placement. Because the SAT II Korean only measures receptive skills, most HL learners score above the passing score for the one-year foreign language requirement at some institutions, even though many of them cannot write in Korean. Sohn and Shin (2007) explain that “placement tests designed for foreign language students often do not test the language skills that heritage students have trouble mastering” (p. 415).

Even when productive skills are assessed, many issues arise when using these standardized foreign language tests with HL learners. In the ACTFL OPI scale, for example, the criterion for high level of proficiency is the “educated native speaker.” Valdés (1989) argues that by focusing on the “educated native speaker” these exams privilege the standard variety of the heritage language and do not recognize the many varieties of a language like Spanish.

Kagan and Friedman (2003), however, argue that the problems of using the ACTFL OPI with Spanish HL learners may not apply to other HL groups such as Russian. They argue that, unlike the situation with Spanish where there are multiple nonstandard varieties, there is minimal dialectal variation among Russian HL learners. Kagan and Friedman conducted a study to examine the extent to which the OPI can provide an accurate description of Russian HL speakers’ oral proficiency before they begin formal language instruction and whether the “educated native speaker” standard of the ACTFL guidelines can be applied to HL speakers of Russian (p. 537). Participants were 11 Russian HL learners enrolled in a beginning Russian course for HL speakers at a university in the western USA. The 20- to 30-minute interviews administered were a combination of an OPI and a Simulated Oral Proficiency Interview (SOPI). The interviews were administered to a group of students in a computer lab. A test administrator posed the questions and students recorded their answers. The test administrator was able to modify the level of the questions based on her observation of students as they responded. The interviews were rated according to the ACTFL OPI Tester Training Manual.

The authors claim that the ACTFL OPI can be used with Russian HL speakers because they were able to apply the scale to assess their performance. This conclusion is unconvincing however, given that no independent measure was used to confirm that the ACTFL ratings indeed captured the full range of students’ HL proficiency. The authors also claim that the educated speaker norm can and should be used as a reference for Russian HL learners because Russian has few dialectal variations, and Russian heritage language differentiates itself from “standard” Russian mainly due to the use of code switching, English borrowings, and calques. Ultimately, Kagan and Friedman (2003) conclude that while the OPI should not serve as the sole measure of heritage student proficiency, the OPI can be a part of an accurate placement procedure for HL learners in conjunction with linguistic biographies and a written test.

Locally Designed Placement Exams

In a survey of Spanish HL programs, Beaudrie (2011) found a great deal of inconsistency among university programs in the definition of course levels and HL students and this might explain why some programs have opted to develop their own placement exam to address the needs of their particular students and programs. Only a few programs, however, have documented their test development efforts in the literature.

Domingo (2008) offers a description of the placement test used in the Filipino program at UCLA. This program does not offer separate HL and FL tracks but 80% of the students enrolled are of Filipino heritage. In this case study, Domingo describes the placement exam used and reflects on its limitations: the test is not

aligned to the goals of the program or the course syllabi and it ignores HL students' abilities, listening in particular. Domingo, who developed the existing placement test, laments the lack of resources that have prevented her from systematically developing the test, piloting it, and evaluating its psychometric properties. This is an interesting case study in that it illuminates the challenges for placing and instructing HL learners in the context of less commonly taught languages where resources and assessment expertise can be very limited.

Kondo-Brown (2004) discusses the placement procedures for the Japanese language program at the University of Hawai'i at Manoa which serves a diverse group of students including HL learners. These procedures include a Japanese placement battery that consists of three multiple choice tests (listening comprehension, grammar, and kana/kanji recognition) and an essay writing test that is not graded and is used for confirmation purposes. Kondo-Brown conducted a study to examine how well student background variables predicted performance on these placement tests. She found that the strongest predictor of performance for all of the tests except the kana/kanji recognition test was the parental language variable (whether students had two Japanese parents, one Japanese parent, or no Japanese parent). When examining score distributions, she found that all of the placement tests were effective in separating students without a Japanese parent into different proficiency levels. On the other hand, she found that the multiple choice tests were not effective for placing students with at least one Japanese parent. For advanced HL learners with at least one Japanese parent a ceiling effect was created when using these tests. She did find, however, that the essay writing task could effectively separate even these students into different proficiency levels and thus concludes that for advanced HL learners whose parents speak the language assessing their productive language skills is critical for placement.

Sohn and Shin's (2007) study of the Korean placement exam at UCLA arrived at a very similar conclusion. The Korean placement test consists of a multiple choice (listening, reading, and grammar) and a composition section. Similar to Kondo-Brown (2004), they found that the multiple choice section was very easy and scores were unable to discriminate between the more proficient and less proficient students. Instead, the mean score of the composition section was lower and it had a large standard deviation suggesting greater variability. Also, the correlation between the multiple choice tests scores was high, but the correlation between the multiple choice tests and the composition test was relatively low. These findings indicate that among Korean HL learners there was a severe discrepancy between their writing and other skills. Therefore, the researchers rejected using the total score as a criterion for placement decisions. Instead, they adopted a noncompensatory approach by creating cut scores for each section of the test and basing their placements primarily on the composition section.

Based on their experience with the Korean placement test, Sohn and Shin (2007) present four recommended strategies for placement: First, performance standards (what students are supposed to know and should be able to do at each placement level) must be defined and transparent. Second, placement tests for HL learners should assess written literacy skills and place greater emphasis on cognitive academic language ability (rather than conversational fluency alone). Third, "false positive errors" should be reduced and a noncompensatory approach should be

adopted to ensure that HL students are not placed in advanced classes for which they are unprepared. Fourth, a diagnostic oral interview test should be administered to those students who display a significant difference in scores between the multiple choice section and the composition section, particularly to identify “fake beginners” who actually belong in higher-level language courses.

Beaudrie and Ducar (2012) describe the development of a “simple yet effective placement exam with limited resources” (p. 77). The computerized placement test for the Spanish HL program at the University of Arizona begins with a background information survey used to identify learners with HL versus L2 backgrounds. Those who are identified as HL learners take a multiple choice test that focuses on specific errors in HL writing at various levels of instruction. Perhaps the reason why they can rely on a relatively simple placement test (compared to other tests described in this review) is that the placement process is not limited to the placement exam. Instructors in the L2 track are trained to identify HL learners and encourage them to switch to the HL track if appropriate. Also, all HL instructors administer a three-page background survey, a written diagnostic test, and an oral interview during office hours to ensure that students are in the right class and to gather important information for instructional planning.

Potowski, Parada, and Morgan-Short (2012) offer an example of an online computerized adaptive placement exam administered to L2 and HL learners of Spanish at the University of Illinois at Chicago (UIC). Unlike other placement tests described in this review that distinguish L2 and HL learners using a demographic survey, the placement test at UIC distinguishes the two populations on the basis of linguistic criteria. Their placement battery consists of five tests overall. Depending on their performance, students are automatically directed to different tests until placement is determined. One of the tests is specifically designed to distinguish L2 from HL learners. The first iteration of this test consisted of four parts. Part 1 assessed students’ familiarity with colloquial lexical items and phrases, some dialect neutral and others Mexican to reflect their local student population. Part 2 assessed spelling and accent placement, Part 3 assessed grammar (gerund/infinitive, prepositions, and colloquial morphosyntax), and Part 4 assessed test takers’ metalinguistic knowledge by asking them to match verb forms with verb tense labels. It was predicted that L2 learners would outperform HL learners on Parts 2, 3, and 4 that focused on more formal components of language, and that HL learners would outperform L2 learners on Part 1, given that even low proficiency HL learners would be familiar with the colloquial vocabulary and advanced L2 learners would not. After piloting this test, Potowski et al. (2012) found that Part 1 was the only part that successfully and clearly distinguished L2 from HL learners. When revising the test, they only included the colloquial vocabulary section and expanded the number of items.

Unlike other articles included in this review that describe the development of a new placement test, MacGregor-Mendoza (2012) documents the evaluation of a placement test that has been used in the Spanish HL program at New Mexico University for over 15 years. Based on a careful examination of its effectiveness, MacGregor-Mendoza concludes that the placement test has not been working as intended. She explains that “the problems concerning the lack of usefulness of the Spanish Placement Test stem from the mismatch between the linguistic

expectations underlying the content of the instrument, the linguistic practices of our local SHL learner population, and the lack of alignment between the Spanish Placement Test and SHL programmatic goals" (p. 15). Informed by the results of the evaluation, MacGregor-Mendoza (2012) offers specific recommendations for the successful development and implementation of a HL placement test.

Perhaps the most documented HL placement test is the one used in the Spanish for Heritage Learners program at the University of Houston (Fairclough, 2006, 2011, 2012; Fairclough, Belpoliti, & Bermejo, 2010). Fairclough et al. (2010) describe the process and decisions made in the development of an online placement test specifically designed for Spanish HL learners. The rationale for the test development is further discussed in Fairclough (2012) which provides a working model and recommendations for developing HL placement exams. The University of Houston offers two Spanish language tracks: a second language track and a HL track. The HL track includes four different levels. Enrollment in the HL track had been increasing and there was a need to develop a practical and useful placement test to place students into the different course levels offered by their program.

To create the blueprint the test development team reviewed a variety of materials to inform task development, including prior research on US Spanish and the acquisition of Spanish as a HL language, HL textbooks, and HL learners' performance on the old paper and pencil placement test (this work is reported in detail in Fairclough, 2006). They designed tasks so that they would target typical features of HL learners' language. For example, a dictation task was included because research has found that spelling is challenging for HL learners, particularly those at the lower level of proficiency who have not received formal instruction in Spanish. Similarly, a task focused on verbs was included because research has shown that HL learners tend to simplify the Spanish verbal system. The words included in the dictation were selected based on their analysis of common errors that HL learners had revealed in the old paper and pencil exam and in class compositions.

The final exam includes the following sections: a demographic questionnaire; a receptive section which consists of a lexical recognition task; a productive section which consists of a partial translation task, a dictation task, a grammar task, and a task focused on verbs; and the creative section which includes an oral task and a reading-writing task. Fairclough et al. (2010) explain how this online, "branched" assessment is used for placement purposes: Students who are identified as HL learners based on the questionnaire take the lexical recognition task. If they do not score high enough they are placed in the lower level class, an intensive Spanish class that combines HL and L2 learners. Those who score high enough on the lexical recognition task take the productive section of the test (partial translation, dictation, grammar, and verbs). Based on their performance on these tasks students are placed in the intermediate course in the HL track or they continue to the oral component of the test. Those who score low on the oral component are placed in an intermediate speaking course. Those who pass, take the reading-writing section. Students who do well on the reading-writing section receive 12 hours of credit and are eligible to enroll in advanced and literature courses. Those who do not do well on the reading-writing task enroll in an advanced writing class.

The receptive and productive sections of the exam were piloted with 99 students across the four levels of the Spanish HL track. They found that the lexical recognition task was effective in differentiating between level 1 and the other levels but not among levels 2, 3, and 4. (A validation study of the lexical recognition task is discussed in more detail in Fairclough, 2011, reviewed below.) They also found that the productive section could successfully differentiate between levels 1 and 2 and the higher levels but it did not detect differences between levels 3 and 4. These findings provide evidence that the test is working as intended since the purpose of the lexical recognition task is to identify students who need to be placed in the lower level (not to differentiate among students at the higher levels). Similarly, the fact that the productive section does not detect differences between the higher levels is not a problem because those who score high on the productive section then go on to the creative section. The researchers are currently piloting the creative section.

Fairclough (2011) reports in detail on the validation of the lexical recognition task, the receptive section of the placement exam used in the Spanish for Heritage Learners program at the University of Houston described above. The study included 330 participants, of which 183 were HL learners and 147 were L2 learners. Each group included students enrolled in first, second, third, and fourth year Spanish courses at the university. Students completed a background questionnaire, the lexical recognition test, and two measures of general language proficiency. For the measure of general language proficiency, half of the participants took a cloze test and the other half took the productive section (partial translation, dictation, grammar, and verbs) of the full test described above. The Yes/No lexical recognition task consists of 120 Spanish words selected from a corpus of the 5,000 most frequent words in Spanish (Davies, 2006) and 80 pseudowords. Students were instructed to select “yes” if they knew the meaning of the word, and “no” if they did not know its meaning.

Fairclough (2011) reports that L2 learners recognized about 55 of the 120 words and wrongly selected 12 of the 80 pseudowords, whereas HL learners recognized 104 words and wrongly selected 18 pseudowords. Fairclough posits that this significant difference is due to the fact that L2 learners only knew a word if they learned it in class, while HL learners were exposed to more Spanish input and had “a much better ‘feel’ for what could be a Spanish word” (p. 289). The difference between the levels in the L2 group of students was statistically significant across all the levels, while there was only a statistically significant difference between the beginner level and other levels for HL students. Thus, the author concludes that a wider range of words is necessary to avoid the ceiling effect with HL learners. Fairclough acknowledges that the Yes/No test only measures receptive knowledge of decontextualized lexical items, but also argues that the moderately high correlation between scores on the Yes/No test and the other two tests (cloze test and the productive section) suggests a relation between passive vocabulary knowledge and general language proficiency. The author concludes that the placement of students in HL or L2 tracks, and in appropriate course levels, are challenges that can be partially met with the use of the Yes/No lexical recognition test, a tool that is easier and faster to administer than other test formats.

Discussion and Future Directions

This chapter introduced the HL population and common approaches to assessing these students in order to place them into appropriate language courses. Despite the prevalence of placement tests and procedures in language programs, the available research on these procedures for HL learners is limited as is evident in this review. Recent published work has begun to describe new tests being developed in individual institutions but validation research on these assessments and other placement approaches is still scarce. One of the reasons for the limited amount of research in HL assessment is that, until recently, there had been very little understanding of the linguistic profiles of this diverse population. There is now a growing body of research that specifically investigates the development of the linguistic and grammatical knowledge of HL learners with the potential to inform assessment development. This work has compared HL learners to native speakers and to L2 learners in terms of phonetics and phonology, morphosyntax, and syntax, in order to better understand both HL, L1, and L2 acquisition (for a review of this work see Montrul, 2010). However, as Montrul (2010) points out “while linguistic and acquisition-oriented research has offered a more nuanced perspective on the language and development of heritage language systems, far more needs to be done to make more direct contributions to the heritage language classroom” (p. 19). This work has not yet contributed to informing assessment development either. One notable exception is Montrul and Perpiñán’s (2011) study comparing the tense, aspect, and mood morphology knowledge of HL and L2 learners of Spanish. This study focusing on HL and L2 acquisition has direct implications for assessment.

Montrul and Perpiñán found that HL learners are more accurate than L2 learners with early acquired aspects of language (e.g., grammatical aspect). Interestingly, they also found that HL learners are not more native-like than L2 learners with structures acquired during later language development (e.g., mood). On the other hand, they found that L2 learners are more accurate than HL learners on tasks that rely on metalinguistic knowledge and written tasks. Similarly, Bowles (2011) also found that Spanish HL learners perform better on tasks that tap into implicit knowledge of the language whereas L2 learners perform better on tasks that tap into explicit knowledge.

Montrul and Perpiñán (2011) conclude that there are distinct implications of these differences between HL and L2 learners for assessment. They recommend that a variety of tasks be used to suit the needs of both L2 and HL learners. This is particularly important because oral production tasks may underestimate the grammatical knowledge of L2 learners and certain types of written tasks may underestimate the grammatical knowledge of HL learners. Importantly, Montrul and Perpiñán (2011) also claim that the aim of HL instruction must be considered when designing assessments. They state, “if the aim of HL instruction is to help HL learners develop fluid and spontaneous use of their HL, then their knowledge should be assessed with tasks that minimize the need to rely on metalinguistic knowledge” (p. 124). Instead, if “the aim of HL instruction is also to help heritage speakers become fully competent in the four skills of the heritage language, then

teachers should incorporate a variety of written tasks that help learners to develop their metalinguistic knowledge" (p. 124).

Although studies like Montrul and Perpiñán (2011) that compare HL and L2 learners contribute to increasing understanding of the HL population, it is essential to keep in mind that the findings of studies such as this one cannot be generalized to all HL learners. Kondo-Brown (2005) cautions researchers that the dichotomous comparison of HL versus FL or L2 learner may not be adequate: "when HL is used as a variable, we need to keep in mind the heterogeneous nature of the HL population and clearly and carefully specify which subgroup of the HL population is under investigation." (p. 575). For example, in the Montrul and Perpiñán (2011) study, HL learner refers to a very specific type of HL learner: students born and schooled in the USA with at least one parent who was a first generation immigrant, native Spanish speaker. Their study may have arrived at different conclusions had they compared L2 learners to other types of HL learners. Kondo-Brown's (2004, 2005) study with Japanese HL learners highlights the importance of keeping in mind the heterogeneity of the HL population and the possibility that some types of HL learners may be similar to FL learners and could potentially benefit from the same courses and assessments as those in the FL track.

Future work on the development of placement tests for HL learners should draw on empirical work on the language development of this population, but it should also be informed by local experiences. Given US demographics, it is not surprising that much of the work on HL acquisition and instruction has been conducted in the context of Spanish HL education. The field would benefit greatly if more HL programs addressing different languages would document and discuss the development and effectiveness of their placement approaches. Also, rigorous validation studies on new assessments would contribute to our understanding of HL assessment.

A notable gap in the research literature is the lack of studies that examine the effectiveness of self-placements. Even though much of this review was devoted to a few locally developed placement tests, it is important to keep in mind that the majority of language programs rely on other approaches, such as self-placements. Therefore research that investigates the extent to which self-placements result in accurate placements would make an important contribution. Also, given the expense, effort, and resources required to develop a placement test, many programs continue to use standardized foreign language tests for placing HL students despite the well-documented problems of using a test developed for FL learners with this population. As Kondo-Brown (2010) recommends, more research needs to be done to determine whether the ACTFL OPI (and other standardized foreign language tests) can be used effectively to assess and place different types and levels of HL learners.

Finally, more research is needed on other types of assessments used with HL learners for purposes other than placement. One example of this work is the article by Elder (2005) that addresses the role of language assessments in evaluating the effectiveness of HL programs. There is also a dearth of research on the assessment of HL learners in classrooms. One notable exception is Carreira (2012) who advocates for the use of formative assessment in HL classes. She explains that given the diversity of the HL population and the limited numbers and types of HL

courses offered by institutions, even specialized HL classes enroll students with a wide range of abilities regardless of the sophistication of the placement test or procedure used. As a result, HL instructors are faced with the following question: “is it fair and realistic to expect the same of all students in the class? Doesn’t this placement outcome virtually doom the less proficient learners to low grades and guarantee high grades to the more proficient learners?” (Carreira, 2012, p. 102). Given the prevalence of the challenge to fairly assess a diverse group of L2 and HL students in the same classroom, it is surprising that, with the exception of Elder (1996, 1997, 2000a, 2000b), this issue has not been addressed in the HL literature. Carreira (2012) proposes that one way to fairly and effectively deal with student diversity in the classroom is to implement formative assessment since this type of assessment can help students take charge of their own learning and instructors adjust their instruction to meet individual students’ needs. Empirical work that examines the uses of summative and formative assessments in classroom contexts would make an important contribution to the research base on the assessment of HL learners.

Assessing Teachers' Language Proficiency

Cathie Elder

University of Melbourne, Australia

Sun Hee Ok Kim

Independent Researcher, New Zealand

Introduction

While teachers' language ability is undoubtedly an important component of teacher professional competence, recognition of its importance is a relatively recent phenomenon, perhaps due to the growing number of non-native-speaker (NNS) teaching professionals employed in contexts where the medium of instruction is not their mother tongue. Concerns about teacher language proficiency are particularly prevalent in non-English-speaking countries, where, as a result of globalization, communicative ability in English is assumed to be at the core of success in the global economy and communication (Graddol, 2006), and where English is introduced, often from the early years of primary school, not only as an object of study in its own right but also as the medium for teaching other subject areas. Implementation of these English-centered policies has raised questions about the quality and proficiency of locally trained teachers or educational professionals from non-English-speaking backgrounds (Butler, 2004). Parallel concerns have been raised in English-speaking countries with regard to foreign language teachers, whose reluctance to use the target language (TL) in the classroom is believed by some to be at least partly due to lack of proficiency (Duff & Polio, 1990; Littlewood & Yu, 2011). Limited language proficiency has also been noted as a problem for locally educated bilingual teachers who are required to teach different content areas of the mainstream curriculum in their mother tongue, which may previously have been used in fairly restricted domains (Guerrero, 1999). In addition, the linguistic and communication skills of international teaching assistants (ITAs), employed to teach their field of study to English-speaking undergraduate students in American universities, have long been subjected to scrutiny (Halleck & Moder, 1995).

As a result of these concerns, teacher language ability is now mentioned explicitly in many professional standards frameworks used to assure teacher quality. Many educational authorities employing NNS teachers (whether of language or other subjects) also require a minimum score on a given language proficiency test as part of their teacher certification procedures.

The question of what type and level of language proficiency teachers need to teach learners in different contexts, however, remains controversial, with some seeing teacher proficiency as synonymous with native-like competence and others describing teacher language use as a specific purpose domain in which natives and non-natives alike may require training. In this chapter we consider the nature of the teacher proficiency construct as operationalized across a range of language proficiency tests and in a number of diverse contexts of use.

Defining the Construct of Teacher Language Proficiency

Defining the construct of teacher language proficiency is a complex undertaking given the range of disciplines across which teaching may occur, the different tasks that teachers are expected to perform, the various contexts in which teaching takes place, and the diverse cultures associated with teaching and learning. Elder (2001) proposes that teacher language proficiency be viewed broadly as encompassing “everything that ‘normal’ language users might be expected to be able to do in the context of both formal and informal communication as well as a range of specialist skills” (p. 152). These specialist skills include a command of subject-specific terminology and, more importantly, the discourse competence required for effective classroom delivery of the lesson content, which itself may vary according to cultural expectations regarding the role of the teacher vis-à-vis the students and according to the age, ability, and motivation of the students. The teacher’s primary task, after all, is to “transform the content knowledge he/she possesses into forms that are pedagogically powerful yet adaptive to the variations in ability and background presented by the students” (Shulman, 1987, p. 15). The demands that this “teacherly” behavior makes on language proficiency may differ considerably from those required for interaction between peers who share the same frame of reference. Teachers need to communicate their knowledge and engage their students using a range of linguistic and discursal devices such as questioning techniques, rhetorical signaling devices, and simplification strategies (Elder, 2001; Kim & Elder, 2005), which will differ from context to context. The discourse competence required to deliver a formal university lecture on a specialist area of physics, for example, will be very different from that required to teach in a primary school science classroom. Setting up the conditions for effective learning will, in some teaching situations, require teachers to draw on a repertoire of different genres and weave them together in ways that contextualize the meaning of the learning task (Kamberelis, 2001). Teachers will also need classroom management techniques, including instructions and other forms of “crowd control,” which draw on language forms and discourse strategies that may not be routinely used in everyday communication.

While there may be some degree of commonality across all areas of teaching, the language demands of the teacher role will inevitably differ according to the subject taught. In the case of language teaching, where language is not only the medium but also the object of instruction, teachers will need both metalinguistic knowledge (arguably equivalent to content knowledge in subject areas like mathematics or physics) and the communicative strategies needed to render this awareness or knowledge comprehensible to and usable by the student (Cullen, 1994). A further requirement of effective language teaching in the communicative paradigm is that the teachers provide adequate exposure to rich models of the TL for their students as well as ample opportunities for TL use (Ellis, 1984).

In sum, regardless of the teaching content or context, it is hard to argue against the proposition that the language proficiency of teachers entails more than just general or academic language proficiency, and this is supported by ample research showing that teachers' classroom discourse is distinct in structure from that occurring in other language use domains (e.g., Sinclair & Coulthard, 1992). Thus, native and non-native teachers alike, regardless of their general or academic proficiency level, will require training in appropriate communicative behaviors for the classroom, just as health professionals require training in how to elicit information from and offer advice to their patients.

The above considerations regarding the construct of teacher language proficiency raise important questions for assessment, including the following:

- Can a general or academic proficiency test really measure what is required for the language teacher to function effectively in the professional domain?
- If general or academic proficiency is insufficient, how can the particular communication skills of teaching be validly measured? Is it possible to assess these classroom communication skills outside the classroom context?

These questions will be touched on in our overview of different models for testing the language proficiency of teachers below, and addressed more fully in the "Challenges" section later in this chapter.

Teacher Language Proficiency Tests

Currently language proficiency tests of different types are used to measure teacher language proficiency in various contexts. Such tests include those designed to assess general or academic proficiency and those that are more specific in the sense that they elicit language use of particular relevance to the professional teaching context. We deal first with the more general or academic proficiency models and then move on to more profession-specific measures.

General Proficiency Tests Used for Teacher Certification

Where language proficiency is specified as a requirement for teacher certification it is more commonly tested via a test of general or academic language proficiency than via a classroom-specific measure. This is true both for teachers of foreign languages and for those teaching academic subjects in a language (often English)

that is not their mother tongue, although the required thresholds may differ from context to context. Examples of general proficiency tests widely used in these different contexts are considered below.

Assessments for Foreign Language Teachers The American Council on the Teaching of Foreign Languages Oral Proficiency Interview (ACTFL OPI), a widely used oral proficiency assessment tool linked to the well-known ACTFL guidelines, is designed for the purpose of measuring general proficiency across a broad range of languages. The ACTFL OPI is now incorporated in the framework of *ACTFL Program Standards for the Preparation of Foreign Language Teachers* (American Council on the Teaching of Foreign Languages, 2002) as well as being an integral part of the NCATE (National Council for Accreditation of Teacher Education, 2008) requirements for foreign language teacher certification in the United States.

ACTFL OPI claims to assess functional speaking ability through a structured conversation (face-to-face or via telephone) between an ACTFL-certified interviewer and the candidate on topics based on the “interests and experiences” of the test candidate. The OPI has, however, drawn multiple criticisms on validity grounds. Concerns raised include the use of an idealized native-speaker criterion in the wording of the level descriptors (Bachman & Savignon, 1992; Chalhoub-Deville, 1997) and reliability problems stemming from the lack of clear criteria for measuring the components of communicative competence (Salaberry, 2006). While these criticisms are leveled at the use of the OPI for any general purpose, there are particular problems associated with using this instrument to measure language proficiency for the classroom, not least the use of the interview-like elicitation procedure where the candidate (the would-be teacher) assumes little responsibility for maintaining the flow of interaction (van Lier, 1989).

As for the standards required for teacher certification, the practice of setting different cut points for teachers of different languages is worth noting. That is, teachers of languages such as French, German, Hebrew, Italian, Portuguese, Russian, and Spanish (Group I–III languages) must attain a minimum of Advanced-Low to be certified as having adequate proficiency for teaching, while those who teach Arabic, Chinese, Japanese, and Korean—that is, languages more distant from English on the FSI scale (Group IV languages)—are required to perform only at the Intermediate-High level. This requirement appears to be based on the assumption that teachers of these languages in the United States have English as their first language and therefore cannot realistically be required to achieve at an advanced level given the time available for foreign language instruction within the American system. The criterion for teacher proficiency appears therefore to be based on expediency, rather than on a principled decision about the optimal standard required for effective performance in the classroom. This somewhat permissive stance with regard to the language proficiency requirements for foreign language teachers stands in stark contrast to the situation for non-English-speaking-background teachers applying to teach in English-medium education contexts, as discussed further below.

Standardized Tests of Academic English Proficiency for Non-Native Teachers in English-Medium Education Contexts Many such teachers in English-speaking countries are now required as a precondition of employment to sit high stakes English tests

like the Test of English as a Foreign Language (TOEFL) or the International English Language Testing System (IELTS) when applying to teach in English-medium schools. While these tests have undergone rigorous validation procedures for their prime purpose of selection for university entry, their relevance to the teaching context is uncertain. The tendency to set cut scores on these tests high is to no avail if the tests are under-representing the test construct or indeed measuring construct-irrelevant language abilities, and may result in inaccurate decision making regarding who is communicatively competent for the classroom. The few available studies comparing examinees' performance on such general measures and on those specifically designed to assess language proficiency for the classroom have to date produced mixed findings. Elder (1993a) showed that the academic module of the IELTS was a relatively weak predictor of non-native trainee students' performance on a teacher education course, although not necessarily inferior to local proficiency measures designed to measure skills relevant to teaching. Halleck and Moder (1995), on the other hand, found general proficiency on the (old) TOEFL test to be a poor indicator of performance on a specific teaching test for ITAs. Xi (2008), by contrast, focusing on the performance-based speaking component of the TOEFL Internet-based test (iBT), reported moderately strong correlations with local measures used for the screening of ITAs at four US universities (although the size of the correlations varied depending on the extent to which the local test elicited what the author describes as the "nonlanguage" abilities relevant to teaching). The iBT speaking test was also found to be a reasonably accurate predictor of which students would be assigned to teaching duties at each institution. Xi concludes that the iBT speaking test is useful for screening purposes, while cautioning that further studies need to be conducted to ensure that the skills it tests are similar to those elicited by the other more teaching-specific oral proficiency measures. A discourse analytic study by Theodoropoulos and Hoekje (2005), for example, suggests otherwise, finding that neither the TOEFL iBT nor the Speaking Proficiency English Assessment Kit (SPEAK) test (Educational Testing Service, 1982) was successful in eliciting prosodic cues, such as intonation and stress, to mark the boundaries between different segments of speech, even though using such cues has proven to be critical for clear communication in classroom contexts.

In general then, it appears that while there is some overlap between what is measured by general or academic and teacher-specific tests, there are also some important differences that may need to be taken into account. While some general proficiency measures containing a performance-based speaking component may suffice for screening purposes, they do not guarantee classroom readiness and may have limited utility as diagnostic tools to support the teaching and learning of communication skills relevant to the teaching domain.

Tests Specifically Targeting Teacher Language Proficiency

While language for specific purposes (LSP) tests specifically designed to capture what is particular about teacher language proficiency are not widely used by accreditation or qualification authorities worldwide, there are several such tests that have been the subject of published research, are currently adopted in

particular contexts, or both. Some have been developed to measure the proficiency of non-native teachers of any subject taught through the medium of the relevant language, while others are specifically developed for teachers of languages (including English as a foreign language [EFL]). Examples of each are offered below.

English for Specific Purposes Tests for Non-Native Teachers in English-Medium Teaching Contexts The Professional English Assessment for Teachers (PEAT) is a test designed to assess the English language competence of overseas-trained teachers (OTTs) intending to teach in government schools in the Australian state of New South Wales (NSW). It was developed with a view to ensuring high standards of English for the purpose of maintaining the quality of English-medium education, with a requirement of Band A or A+, which implies “vocationally proficient” or “native-like” ability (Murray & Cross, 2009, p. 3) in each skill area in order to be qualified for provisional or conditional accreditation.

The test consists of four components, representing reading, listening, writing, and speaking respectively, each with three tasks that either simulate different school situations (in the case of listening, writing, and speaking) or use authentic materials (in the case of reading). For example, listening tasks include two-way and three-way interactions involving colleagues, parents, students, or all three, and a monologue such as a deputy principal’s announcement at a regular staff meeting. Reading texts are drawn from NSW policy documents, authentic workplace-related texts, and authentic samples of student writing (UNSW Institute of Languages, *n.d.*). The fact that these materials are referenced to a particular teaching context of course raises questions about the validity of using the PEAT in other states of Australia and indeed in New Zealand, as appears to be done.

In spite of practice test materials and training opportunities for those wishing to prepare for the test, there have been negative reactions to it from some candidates, including those from Outer Circle countries, who have grown up speaking and using English and contest a requirement that is not imposed on Australian-born teachers. A study of test-taker attitudes (Murray, Cross, & Riazzi, 2012) revealed that such reactions were more prevalent among those with experience as teaching assistants in Australian schools, due, the researchers surmise, “to an increased sense of self-confidence at being able to function in the role, leading to greater resentment of the PEAT as obstacle.” Such reactions might also be evidence of skepticism about the capacity of a language test, however context-sensitive, to capture what is important for workplace effectiveness—an issue that recurs with other teacher proficiency models (see below).

The Taped Evaluation of Assistants’ Classroom Handling (TEACH), originally developed at Iowa State University, is one of the better known tests used in universities in the USA for the purpose of screening prospective ITAs. It is worthy of consideration here because of the key role ITAs play in teaching in their field of study to English-speaking undergraduate students in universities. This role assumes the capacity to deliver high-level lesson content using English in a manner appropriate to the subject and to the needs of their undergraduate students.

The TEACH is used in conjunction with the OPI (reviewed above) both for the purpose of screening and to identify communication problems that prospective ITAs might have (Douglas, 2000). The testing procedure involves a simulation of

a university classroom where the candidate performs a microteaching activity on one of the topics chosen from a list suggested by the department in which he or she is expected to teach. During the test the candidate is required to explain the assigned topic to the audience, intended to represent an undergraduate class, and then to answer this audience's questions on the lesson content. The audience consists of two or three raters with little background knowledge in the ITA's area, at least one undergraduate student, and a few others such as the test proctor and technicians (Douglas, 2000; Papajohn, 1999).

Performance is scored against four categories: (a) overall comprehensibility of spoken English; (b) cultural awareness of appropriate teacher–student relationship in a US university classroom setting; (c) communication skills (explaining a topic clearly, use of supporting evidence or examples, addressing a class, use of the blackboard, showing interest in the students as learners); and (d) ability to understand and answer students' questions (Douglas, 2000, pp. 165–7). The aggregate score is reported together with the OPI result and given the same weighting. Thus the requirement for certification includes both general linguistic skill and classroom communicative competence in equal measure.

While the TEACH test, as a direct performance-based measure, aims to be both situationally and interactionally authentic, the different topics assigned to test candidates for their mini-lessons have been identified by Papajohn (1999) as a potential threat to test validity. Although the test is conducted within the context of the examinee's field of specialization, the features of individual topics within particular areas of specialization vary in their degree of conceptual abstractness, complexity, or both. This, according to Papajohn (1999), influences the effectiveness of the teaching performance and also the degree of comprehension of the nonspecialist audience, with a resultant impact on the ratings assigned to candidates. Fairness issues of this kind are germane to performance-based assessment given the difficulty of ensuring equivalence across tasks simulating real-world interaction.

Two further issues of fairness have been noted in relation to classroom-specific tests like TEACH. Both stem from the attempt to combine general proficiency and occupation-specific communication skills in the overall test construct. The first is the unfairness of including teaching skills in the requirements for ITAs when these are not required of native speakers of English (Gorsuch, 2003). The second is depriving native-speaker TAs, who may also be inexperienced teachers, of access to the teaching-embedded linguistic training opportunities available to ITAs who are unsuccessful on the test (Hoekje & Williams, 1992).

An even more direct, context-embedded approach to measuring the language proficiency of international students is the Classroom Language Assessment Schedule (CLAS), an observation tool developed for use in training programs for OTTs of mathematics and science recruited to fill teacher supply shortages in Australian secondary school classrooms (Elder, 1993b, 2001). The observation tool was developed to aid teacher supervisors in identifying the language strengths and weakness of these OTTs in the context of the school-based teaching practicum component of their training, so that appropriate English as a second language (ESL) support could be offered as required. The schedule takes the form of statements indicating desirable teacher language behaviors such as "projects and pitches voice appropriately," "explains diagrams/models/use of equipment

clearly," and "clearly signals acceptance/rejection of student response." The statements are listed under various categories: General Proficiency, subdivided into Intelligibility, Fluency and Flexibility, Accuracy and Comprehension; Subject-Specific Language; and Classroom Interaction. The supervisor uses the checklist to signal areas of need as she or he observes the trainee's lesson and rates performance on each category, concluding with a final determination on Overall Communicative Effectiveness. Elder (1993b), as part of the process of validating the observation schedule, compares the ratings assigned by the math and science teacher supervisors for whom it was designed and those awarded by ESL experts. She finds that while the background of the rater makes little difference to overall determinations of communicative effectiveness, the importance each type of rater attaches to the various rating subcategories differs, with the subject-specialists focusing more on how the subject content is delivered and the ESL teachers more oriented to language features per se. Her findings raise the vexed question for LSP assessment of who is best equipped to judge performance on occupation-specific measures and what weightings should be assigned to general proficiency versus classroom-specific language skills.

LSP Tests of Language Teacher Proficiency The Language Proficiency Test for Teachers (LPTT) is a suite of tests developed for teachers of different foreign languages (Italian, Japanese, and Indonesian) in Australia (Elder, 1994; Hill, 1997; see also Hill, 1995) for the common purpose of setting a benchmark for teacher education by making explicit the occupational language requirements of foreign language (FL) teachers; and, potentially, ensuring that those applying for employment are sufficiently proficient in the TL to perform their teaching duties effectively. The design of the tests is based on an inventory of the functions performed by the teacher in the TL as revealed in a job analysis and a review of relevant second language acquisition (SLA) literature (Elder, 1994). While specifications differ according to the particularities of each language, the basic blueprint for test design followed the model developed for Italian teachers, the speaking component of which is considered below.

The LPTT: Italian (speaking) requires the candidate to perform various classroom-like tasks assuming the role of a primary school teacher (Elder, 2001). Tasks assume different types of audience (whole class or individual student) and cover the different overall purposes of classroom communication ("medium-oriented"/"message-oriented"/"activity-oriented"/"framework-oriented") proposed by Ellis (1984) as well as the range of functions (narrating, describing, explaining, exemplifying, etc.) characteristic of teacher discourse. Task formats are various and include "reading aloud," "story retelling," "giving instructions," "assigning and modeling a role play," "presentation," and "explaining learner errors" as if to a classroom audience. Assessments are made both against linguistic criteria and on task fulfillment, which measures the appropriateness of features of communicative behavior (e.g., style of delivery) for the classroom. In addition, a metalanguage category is included for the task of "explaining learner errors" (Elder, 2001).

Although the test has been lauded "as a model of LSP test development practice" (Douglas, 2000, p. 155), there are limits to its authenticity, as discussed in

Elder (2001). The fact that the test interlocutor or audience is an adult native- or near-native-speaker examiner, for example, places constraints on the test's plausibility as a measure of classroom competence, and produces a "clash of frames" between the traditional function of a language test, namely as a vehicle for the test taker to display their level of linguistic sophistication, and the parallel requirement that the "teacher-like" tasks are carried out in such a way as to render the language clear and comprehensible to a classroom audience. The linguistic simplification involved in, for example, giving simple instructions to a young learner may actually mask the candidate's level of sophistication (see Elder, 2001, for an illustration of how this plays out on a particular task).

Again, this raises questions about the relative weighting that should be accorded to classroom competence versus general linguistic proficiency on teacher-specific language tests more generally—an issue that remains unresolved in this case. In fact, the LPTT suite of tests has never been implemented for its intended purpose of languages other than English (LOTE) teacher certification in Australia. Current policy in most Australian states favors the more generic prerequisite of an undergraduate major in the TL or its "equivalent" as determined by the relevant language department using whatever testing measure it deems to be appropriate. This policy is expediency-driven and, given inevitable variation in curriculum content and methods of assessment across university language departments, is no guarantee of adequate language standards for teaching.

The inadequacy of formal schooling in a language as preparation for teaching it was one of the motivations for the development of the *Teste de Proficiência Oral em Língua Inglesa* (TEPOLI). The TEPOLI is used, primarily for research purposes, to assess the oral proficiency of EFL teachers enrolled in teacher education courses in Brazil (Consolo, 2006) as part of a broader policy of upgrading these trainees' oral English skills to a level appropriate for teaching in Brazilian classrooms. The test includes two tasks, one involving a picture description and follow-up interaction between two candidates "simulating teacher talk," and the other comprising a role play drawing on input generated from a transcript of student production in an EFL class. The latter task is designed to assess command of metalanguage and requires the candidate to explain and talk about the English language—an ability that research on metalinguistic knowledge in other contexts has shown to be disturbingly absent among many advanced FL learners in university contexts (e.g., Elder, Erlam, & Philp, 2007).

The inadequacy of a language major or any general educational level as a measure of communicative readiness for teaching is nowhere more clear than in Hong Kong, where the minimum requirement for teachers of English was until fairly recently "Grade C" in English in the Hong Kong Certificate of Education, an examination taken at the age of 16. Concern about the standards of English in schools triggered the government's decision to implement a new policy for "upgrading" teacher language standards. The Language Proficiency Assessment for Teachers of English (LPATE) was introduced in this context, along with a parallel version for Putonghua (i.e., LPATP), as part of the post-1997 educational reform that envisaged the universal attainment of biliteracy (in English and Chinese) and trilingualism (in English, Putonghua, and Cantonese) through school education.

The LPATE, implemented until 2006 as a formal proficiency test for all new and serving languages teachers and subsequently for new teachers only (Coniam &

Falvey, 2013), consists of five components encompassing the four skills (reading, writing, listening, and speaking) plus classroom language use. Reading, writing, and listening skills are assessed by paper and pencil tests; the speaking test, like the LPTT, includes tasks in various formats that require different modes of delivery for different functions. Interestingly (as with the CLAS reviewed earlier), the classroom language assessment (CLA) is made in the candidate's actual classroom, perhaps in recognition of the difficulty of measuring classroom competence in the test situation.

The introduction of the LPATE was marked by controversy, in particular due to the failure to involve primary school teachers in the initial consultation process (Coniam & Falvey, 2007), and also due to what was perceived as an unrealistically high minimal language proficiency requirement, resulting in fear, anxiety, and resentment among teachers (Glenwright, 2005). In spite of recent revisions to the test, including the removal of reference to the native speaker in the scale descriptors (Lin, 2007), the pass rates remain consistently low for speaking and writing.

Some test-design issues have also been raised, such as the questionable relevance of including interaction or conversation with peers as part of the test, given that most of the teachers' peers are likely to be speakers of Cantonese or Mandarin who do not necessarily communicate with one another in English, and the undue weighting accorded to writing, given that teachers of English in Hong Kong make limited use of writing skills in performing their professional duties (Coniam & Falvey, 2001). In sum, as noted in other cases, both the design and the implementation of the LPATE has posed significant validity and fairness challenges and the question of whether this test has met its own objective of raising standards of teacher language proficiency in Hong Kong remains uncertain (Coniam and Falvey, 2013).

LSP Tests for Teachers of Bilingual Education Two tests for teachers in bilingual education contexts are worthy of brief mention in that they also acknowledge the specificity of the classroom context in their design. One, the Arizona Classroom Teacher Spanish Proficiency Exam (ACTSPE), was designed in the mid-1980s for the assessment of the Spanish language proficiency of prospective teachers in bilingual education, who often have little formal training in their native language (Guerrero, 1999). The test was developed to ensure that bilingual teachers have adequate proficiency for the demands of their professional role, which includes not only the delivery of subject content through the medium of two languages but also the development of bilingual competence in their students. As a criterion-referenced, performance-based test, the ACTSPE consists of several tasks, some of which are simulations of the TL use domain, including those that are classroom-centered, such as oral reading of an excerpt of a literary work, and others that are oriented to aspects of the teacher's professional role extending beyond the classroom context, such as the translation of a letter to parents (Grant, 1997).

Similar tests have been introduced in a number of other US states since the introduction of the ACTSPE. The controversy surrounding bilingual education, however, culminating in the replacement of the Bilingual Education Act (1968) by the No Child Left Behind Act, may have implications for the future development of such tests (Menken, 2011).

A further test that acknowledges the specific language demands of teaching is the National Māori Language Proficiency Examinations (NMLPE): Teaching Sector Māori (TSM), introduced as part of language revitalization efforts to improve standards of Māori teacher proficiency (Skerrett, 2011) and meet the continuous demand for trained teachers able to teach Māori-medium or immersion classes in New Zealand (May & Hill, 2005)

To be qualified to teach using Māori as the medium of instruction, a candidate must obtain level 4, the second highest level, on a preliminary Level Finder Examination (LFE), an indirect measure of general language proficiency, after which she or he is eligible to take the TSM, a four-skill test including classroom-specific tasks not dissimilar to those on the LPTT. The teacher proficiency construct is thus seen as requiring a base level of linguistic skill that is necessary but not sufficient for effective classroom performance. As with some other occupation-specific measures reviewed above, performance on the TSM is assessed on both general linguistic and classroom-specific criteria: syntax, vocabulary, register, and strategic knowledge for writing tasks, and naturalness, intelligibility, accuracy, "language for teaching," and "language appropriateness" for speaking tasks (Māori Language Commission, 2010, pp. 41–2).

It is noteworthy that, as with the TEACH, an actual audience, in this case of other test candidates as well as raters, is present for the more teacher-like tasks, presumably in an attempt to bridge the credibility gap between the artificial environment of a test and the classroom situation.

Challenges

The above, admittedly selective, review has revealed in passing some of the complexities associated with assessing the language proficiency of teachers. These challenges will be summarized below under the two questions raised at the outset of this chapter.

- Can a general or academic language proficiency test really measure what is required for the language teacher to function effectively in the professional domain?

It would seem that the ability to use language in a range of everyday and academic contexts is important for teachers but that the classroom represents a specific domain of competence that draws on very particular kinds of communicative abilities. Attempts to pin these down are complex, as noted earlier, given not only the breadth of tasks the teaching professional needs to perform but also the variety of contexts in which teaching takes place. It is tempting, in the face of this complexity and diversity, to simply resort to general or native-like proficiency as the ultimate criterion. Invoking the native speaker has, however, long been discredited as a solution to construct definition, for a range of reasons. First, the "native speaker" is a symbolic criterion that resists empirical definition (Davies, 2003). Second, many teachers are not native speakers of the language they are teaching (or teaching through) and are neither native-like nor likely to become so, making

it unrealistic and unhelpful to impose such a criterion to assess performance even if it were able to be operationalized effectively. Third, the contexts in which learners of languages are likely to use the language or languages they are taught may well be dominated by non-native users (Brown & Lumley, 1998). Fourth, the linguistic performance of those who claim to be “native speakers” is highly variable, and it cannot be assumed that even highly educated native speakers are communicatively competent for the classroom (Bachman & Savignon, 1986; Davies, 2003). Indeed, in the case of language teachers, it seems that non-native speakers, by virtue of their experience as language learners, are more likely to have the explicit knowledge about language—that is, the content knowledge that can be considered part and parcel of the language teacher’s repertoire—than are native speakers (Andrews, 2003). As bilinguals they may also be better placed to understand the task of learning a new language and hence to tailor their communication to the learners’ needs (Cook, 1999). Thus we can conclude that invoking an idealized notion of native-speaker competence as a benchmark for the assessment of teacher language proficiency is unhelpful, and also that the validity of using well-known, high currency tests like IELTS or TOEFL or the ACTFL OPI, designed to measure more general or academic proficiency, is questionable for such a purpose. Although these tests may be reasonable predictors of performance on other more teacher-specific assessments, as noted above, they are likely to under-represent the teacher proficiency construct. Furthermore, if used on their own, rather than in conjunction with more teacher-specific measures, they are likely to have negative wash-back on the kinds of language teaching and learning undertaken in preparation for performance in a classroom context. This is all the more true of policies that avoid proficiency testing altogether and simply stipulate a university degree or major study as the prerequisite for teaching, without due attention to what is taught and learned in such courses.

- If general or academic language proficiency is insufficient, how can the particular communication skills of teaching be validly measured? Is it possible to assess these classroom communication skills outside the classroom context?

The specific-purpose measures reviewed above all face authenticity and fairness challenges. Although space constraints have precluded our reviewing the various tasks used to simulate teacher performance in any detail, what emerges from the above review is the difficulty of adequately capturing the construct of classroom communication in a language test, for various reasons. As noted in relation to the LPTT, the complex array of language functions and discourse strategies involved in interacting appropriately with learners who may have limited command of the TL may be difficult to elicit in the test situation in front of an adult examiner or examiners. There are also issues of generalizability across tasks (with the TEACH), across contexts (as noted for the PEAT), across languages (as described by Hill, 1995, with respect to the Italian, Indonesian, and Japanese tests in the LPTT battery), and across lessons (in the case of the CLAS, which needs to be administered repeatedly to ensure an adequate sample of teacher performance). Still unresolved in teacher-specific assessment is the question of who should judge performance and according to which criteria. The claim that the validity of a

specific-purpose test demands that assessment criteria should reflect the perspective of key stakeholders in the professional context poses considerable challenges for language assessment, since these stakeholders may have a view of communication quite different from that of the language assessors traditionally charged with assessing communicative performance (Elder, 1993b; Elder et al., 2012). Finally there are important issues of fairness associated with specific-purpose testing for any occupational purpose. If communicative competence for the classroom is bound up inextricably with teaching skill, is it fair to assess candidates with minimal teaching experience on skills that they may develop later in the context of their professional training?

The answer to these questions may differ according to the context of teaching and the precise purpose for which teacher language proficiency is being assessed. A general proficiency screening tool may be useful in deciding who clearly lacks the linguistic skill for teaching, perhaps in combination with a more context-specific, performance-based measure to be applied for borderline cases. A "weak" approach to performance testing (McNamara, 1996), where test tasks are merely a pretext for eliciting a relevant language sample to be assessed by language experts according to traditional linguistic criteria, may suffice when a test is used for admission to a training program, on the grounds that, provided that the student has an appropriate linguistic foundation, the subsequent training can offer instruction on how to teach. A "strong," performance-based approach, focusing on communicative effectiveness for professional purposes with all that this entails, will be more relevant in the training program itself, since the task of the teacher educator is to acculturate the trainee to the expectations and practices of the workplace. Likewise, in assessing readiness for the workforce, provided that adequate training opportunities are offered in advance of assessment, it seems appropriate to use a specific measure tailored to the language demands of teaching, or indeed to assess communicative performance in the classroom itself with both teacher experts and language experts as judges. In such situations there are also strong arguments for assessing both native and non-native users of the language in question, on the grounds that all need to meet the same standards of communication.

Future Directions

In this chapter we have considered how teachers' TL proficiency is viewed and measured in different educational settings by briefly reviewing a number of tests that are used (or intended for use) to assess the language proficiency of teachers. Included in the review are locally developed LSP tests for the measurement of occupation-specific communication skills for the teaching of both languages and other academic subjects, and international tests designed to assess more general or academic language proficiency. The review has highlighted the interplay between different views of teacher language proficiency and various intersecting constraints at the test level and in the broader social contexts in which these tests are administered.

We have proposed above that different assessment solutions may be required for different situations, one being the context of training, which is a relatively

neglected area as far as teacher language proficiency assessment is concerned. Greater priority needs to be given to exploring the diagnostic function of teacher-specific language tests and how they can be used to encourage appropriate learning in the interests of improved professional practice.

A further pressing area for research concerns the design of profession-specific tasks on tests of the kind reviewed above and the extent to which these relate to the real-world domain of teaching. Since the validity claims of LSP assessment rest on the authenticity of test tasks and assessment criteria, such tests need stronger empirical evidence to ascertain that their teacher-like tasks do indeed elicit features of language characteristic of the TL use situation, which may differ markedly from one teaching context to another.

Last but not least is the question of how much proficiency is enough for effective teaching performance. There is still a remarkable lack of clarity on this issue, with generally no explicit justification or empirical evidence for existing minimum thresholds or relative weightings given to general versus profession-specific abilities. In some cases, as we have noted, these standards are determined less by principle than by local constraints such as the limited availability of highly proficient teachers, which in turn has potential consequences for the quality of schooling. Standard-setting exercises in which expert teacher professionals make judgments about these matters on the basis of actual samples of contextually relevant performance are clearly needed, coupled with further research on the vexing question of the role of teacher language proficiency, compared to other nonlinguistic factors, in effective teaching performance.

Assessing the Oral English Abilities of International Teaching Assistants in the USA

Timothy Farnsworth

CUNY Hunter College, USA

Introduction

In US universities, international graduate students are often called upon to fill the role of teaching assistant in undergraduate lecture courses. Since the early 1970s, the numbers of international students have steadily increased, and in many research universities they form a majority of graduate students, particularly in engineering and the physical sciences. Concern about the English language skills of these students as international teaching assistants (ITAs) has led to the implementation of ITA-specific language coursework and assessment in many institutions. It has even led several states to mandate the assessment and monitoring of their English communicative ability. At the heart of the “ITA problem” is the conflict between the need of undergraduates to receive a high quality education, and the needs for universities to put non-native-English-speaking graduate students in the classroom and for those graduate students to receive funding. This chapter discusses the main issues in ITA assessment in US universities, describes common assessment approaches to the problem, and provides a detailed look at one ITA assessment program. The chapter concludes with a set of best practice recommendations.

The Communicative Needs of the International Teaching Assistant

International graduate students are in almost all cases prescreened for their English language ability before gaining admission to the university, usually by taking the Test of English as a Foreign Language (TOEFL) in their home country. However, it is clear that the level and type of language ability needed to succeed

as a student in a US university are quite different than those required of a teaching assistant (Hoekje & Williams, 1994). Not only do ITAs need to be able to give clear lectures but, critically, they need to be adept at responding to student questions and dialogue, guide students in laboratory experiments, and successfully negotiate meaning in one-on-one office hour situations. The issue has been studied since the 1980s, with Bailey (1985) among the first to examine it.

A number of researchers have looked specifically at the discourse demands placed on ITAs. Hoekje and Williams (1994) argued convincingly for an overall theoretical framework of communicative competence, specifically including discourse or rhetorical aspects of spoken language and attention to the specific communication settings ITAs find themselves in. The textbook often used in ITA training courses, *Communicate: Strategies for International Teaching Assistants* (Smith, Meyers, & Burkhalter, 1992), also takes essentially this approach. Madden and Meyers (1994), in their edited volume on ITA language demands, focus specifically on discourse demands. Several chapters in this volume emphasize the critical role that student questions and ITAs' response to them play in settings including office hours, laboratory sessions, and classroom teaching. Others have looked at the structure of ITA discourse and found that perceptions of incoherence often arise from non-native-like patterns of lexical coherence markers and discourse structuring (Tyler, 1992). Hoekje and Linnell (1994) placed ITA discourse demands in the context of authentic assessment, comparing teaching assistant (TA) discourse against three different ITA assessments. The authors concluded that only the mock teaching performance assessment required candidates to engage in the type of discourse required of TAs.

Gorsuch (2003) examined the cultural demands of the ITA experience. Results suggested that rather than looking at cultural differences between ITAs' home countries and their new ones, a more useful frame would be to consider their status as new teachers adapting to the cultural norms of their institutions. Halleck and Moder (1995) examined the value of teacher compensatory strategy use in the ITA classroom, and found that for less linguistically proficient ITAs, such strategy use had a limited effect.

Other researchers have looked at pronunciation skills and ITA effectiveness (Pickering, 2001), emphasizing the role that intonation and specifically suprasegmental parts of speech influence not only comprehensibility but also perceived stance or tone of ITA discourse. Hinofotis and Bailey (1981), in one of the earliest studies in this area, found pronunciation to be among the areas most critical to ITA success. Grammatical and lexical competence has not been as widely studied, perhaps because ITA candidates generally come to graduate school with a high degree of linguistic competence (being preselected for this competence by the TOEFL) but initially struggle with the social and dynamic interactive aspects of language use as well as accurate pronunciation.

Common Problems in ITA Assessment Systems

ITA assessment is a unique problem from a few perspectives. There are multiple stakeholders concerned with TA assignments, and some of these stakeholders have conflicting goals and needs. Some question whether ITA assessment is fair

at all, since native-speaker graduate students are not assessed. Finally, there is the question of just what factors really do make a good TA, and even whether the need for a high level of language ability is really the most relevant issue with non-native TAs.

At the heart of the issue of ITA assessment are multiple, entirely legitimate, competing interests. Undergraduates have a stake in the quality of their education, and being able to understand and communicate with their TAs is clearly a critical aspect of that. A speaker's accent or specific word choice may not matter as much in social situations as it does in academic ones in which the hearer is tasked with comprehending complex new materials, and communication breakdowns between teacher and student that may be trivial in other contexts can have a seriously detrimental impact on classroom learning. However, international graduate students and their departments have a real need to put ITAs in the classroom. In some disciplines, there may in fact only be a small minority of native speakers available as TAs, in any case. Additionally, TA experience is seen by many as a critical component of graduate training. Newly minted PhDs on the academic job market certainly have a need for demonstrated teaching skills and experience. By potentially denying qualified international graduate students TA opportunities, ITA certification programs run the risk of handicapping these students in their eventual career goals, especially if their goals include academia. Thus, ITA certification is a high stakes endeavor for the entire university, with some stakeholders (undergraduates) benefiting from high, strict standards and other stakeholders (departments, ITA candidates) benefiting from more lax standards.

Some observers believe that ITA certification in itself is fundamentally an unfair or unethical enterprise. They note that international graduate students have already been screened for their language ability before being granted admission, most often by taking the TOEFL Internet-based test (iBT) in their home countries. Once they arrive on a US campus, it might be seen as unfair to subject them to rules and strictures that do not apply to native graduate students. In graduate programs in which TA-ships are coveted, the best and otherwise most qualified candidates may often be international students, and preventing such students from teaching may not in fact be in the best interest of undergraduate education despite what undergraduates themselves may express. For example, during the development of the ITA exam described below, the Test of Oral Proficiency (TOP), undergraduates in focus groups were shown video of ITA candidates. They could not meaningfully agree on what constituted an acceptable teaching performance, which TAs were acceptably proficient in English, or the degree to which candidates' language and communication skills contributed to such a performance.

Finally, it may be the case that the oral English language ability of ITAs may not be the main factor that determines perceived ITA quality. Chiang (2009), for example, studied communication breakdowns in ITA office hour interactions and concluded that the source of these was not primarily linguistic but intercultural. Others have argued that undergraduates may be exaggerating communication problems of the ITA as a way of blaming others when they fail to understand difficult material, and that in any case, learning to communicate with individuals from other cultures and language backgrounds is a necessary and appropriate part of the college experience. Plakans (1997) noted that negative perceptions of ITAs were associated with more traditionally aged, less well travelled, less urban

students. It may be that for some undergraduates, negative perception of ITA language ability is a proxy for a fear or dislike of individuals from other cultures.

Common Approaches to ITA Assessment

To address ITA language proficiency, universities have adopted a number of approaches, which generally can be categorized as one of the following four. First, many universities lack a specific set of policies or assessments, and the decision to allow an international graduate student to take a TA position is made on an ad hoc basis. Another approach is to utilize a standardized measure of oral language ability, such as the TOEFL iBT Speaking subscore, and design an ITA policy around this. Many universities use locally administered performance assessments, varying in nature from authentic mock teaching assessments to semi-direct oral assessments unrelated to teaching contexts. Finally, many institutions have designed assessment systems that reflect a combination approach utilizing some combination of ad hoc decision making, standardized measures, and performance assessments. The major factors driving the choice of assessment system include number and makeup of potential ITAs, demand for ITAs, size of university, resources available, local assessment and English as a second language (ESL) expertise, and decisions on some questions of ethics and fairness that do not have easy answers.

Some universities have avoided setting specific ITA policies, for a number of reasons. There may be too few potential ITAs to justify creation of a policy and program. The university may employ few graduate students in general as teachers, which may be the case at a smaller teaching college or a university with few doctoral programs. There may be a lack of local expertise in language education and language assessment. Finally, the culture or organization of the university may well be such that ITA decisions are left to individual departments to make. Departments may then craft specific ITA policies of their own, but it is probably more common that such decisions are made on a case-by-case basis. There are a number of potential disadvantages to an ad hoc ITA assessment system. The most obvious danger is that undergraduate education will be compromised by ITAs unable to communicate effectively in English. Perhaps equally important to consider, however, is the damage to the career of an otherwise qualified graduate student if an inappropriate decision is made to keep him or her out of the classroom. This fundamental issue of fairness will be discussed in more depth in the following section. There may be very good reasons besides lack of resources to avoid reliance on a formal assessment of any kind and instead allow ITAs to work on a case-by-case basis.

Other universities have opted to rely on large-scale, standardized assessments to make ITA decisions. Until the 2004–5 introduction of the TOEFL iBT, which includes a speaking section and oral language subscore, the most commonly used assessment was likely the Test of Spoken English (TSE) and its institutional twin, the Speaking Proficiency English Assessment Kit (SPEAK). While the TSE has been retired due to the inclusion of speaking in the TOEFL iBT, the SPEAK test is still very much in use, and will be discussed later in this chapter. These measures

are all considered “semi-direct,” meaning that although the candidate does give an impromptu response, the input (the questions) are fixed, and there is no actual dialogue between tester and test taker. The TOEFL iBT Speaking subtest consists of six tasks, all of which require the test taker to respond orally, the responses being recorded via the computer, to a series of prompts designed to simulate common undergraduate communication situations. These situations include conversations between students and their professors and brief academic lectures. The situations do not include any ITA-specific speaking contexts, nor do they require the test taker to demonstrate any ability to clarify, restate, or perform other functions characteristic of teacher discourse. The construct validity of the TOEFL iBT Speaking subscore for use in ITA programs has been investigated (Axe & Farnsworth, 2007; Farnsworth, 2007; Xi, 2007). Xi (2007) found that TOEFL iBT Speaking subscores correlated with locally administered performance exams, but when the local assessment was designed in part as a measure of teaching skill, correlations were much lower. Wylie and Tannenbaum (2006) investigated the setting of cut scores for universities to use the TOEFL Academic Speaking Test (TAST), which eventually became the speaking subsection of TOEFL iBT. These researchers found that a TAST score of 26 most closely corresponded to a TSE score of 50, a commonly accepted cut score for ITA certification on TSE and SPEAK. It is not immediately clear, however, to what degree this study is applicable to using TOEFL iBT Speaking for ITA certification.

There are a number of clear advantages to using the TOEFL to make ITA decisions. The foremost advantage is a practical one: Since nearly all international graduate students enter graduate school with TOEFL scores on file, the cost and time involved in using these scores are minimal. In addition, no local expertise in administering, preparing, and interpreting a high stakes oral assessment is necessary. Finally, the TOEFL is among the most rigorously researched and validated language assessments, and therefore test users can at a minimum be reasonably satisfied that the scores are sufficiently reliable, that test administration has been carefully attended to, that records are secure, and so forth. The extent to which the TOEFL iBT Speaking measures the skills needed by ITAs has been investigated by Farnsworth (2007), who concluded that the TOEFL iBT Speaking and a locally administered performance test, the TOP (described below), did seem to measure the same abilities to a large degree. The extent of match between the discourse demands placed on the ITA and the specific discourse demands of the TOEFL iBT Speaking, however, have not been researched.

Many universities have developed or adapted their own assessments for ITA certification. These can generally be divided into two categories: teaching simulations and direct or semi-direct oral assessments. In general, teaching simulations reflect an attempt at authentic assessment, and may be more resource intensive and require more local expertise than an interview or semi-direct style of assessment. They may also require candidates to demonstrate teaching skills, subject matter expertise, or both, either explicitly through the scoring or implicitly via the effects of the test method. This is an issue that must be considered carefully from an ethical perspective.

Teaching simulation assessments generally require the ITA candidate to present a mock lecture on a topic in the candidate’s field, and may involve other activities

such as simulated office hours, presenting a syllabus, and so forth. The test administrators and raters are usually the ESL or applied linguistics faculty of the institution but may involve one or more faculty members or students from the candidate's department as well. One of the earliest teaching simulation assessments for ITAs is likely the Taped Evaluation of Assistants' Classroom Handling (TEACH test) (Douglas, 2000), developed by Douglas for use at Iowa State University in 1985 and used as a model in many other institutions. The test takes about 10 minutes to conduct and requires the candidate to give a short lecture on an assigned, field-specific topic, selected by the examiners from a list and given to the examinee 24 hours before the test. Following the lecture, the candidate is asked several questions about the material by the examiners. The test is scored using a rubric that includes categories for comprehensibility, question handling (listening), clarity of presentation (organization), teaching skill, and cultural awareness. It is thus an example of what Douglas (2000) calls a "strong" English for specific purposes (ESP) test, since the criteria for evaluation go beyond what is traditionally considered to be language knowledge and into the realm of teaching skills, cultural awareness, and possibly subject matter knowledge. Many universities have adopted similar assessments. One such is the TOP, which adopts a similar task but a different approach to rating, and is discussed in detail in the following section.

The other common assessment type for addressing the ITA problem has been the semi-direct speaking test. The most common of these by far for ITA assessment has been the SPEAK test, developed by the Educational Testing Service (ETS) as the institutional version of the TSE. Both tests are now retired (not supported) by ETS. The SPEAK test has gained wide acceptance for ITA testing and, perhaps surprisingly, in the assessment of health-care professionals. Cascallar, MacCallum, Sarwark, and Smith (1995) administered the SPEAK to 119 ITA candidates at three different institutions and found an acceptable degree of reliability, rater consistency across institutions, and predictive validity for ITA decision making. In the test, candidates respond to 12 questions from a booklet that contains accompanying visuals such as maps, graphs, and picture stories. The expected responses to each question vary from about 45 seconds to 90 seconds, and are recorded and scored later. The majority of the questions are on general topics, asking candidates' opinions on issues or asking them to narrate a picture story or give directions from a map. Only one question on the various forms could be construed as "academic": Candidates are asked to describe a simple line or bar graph and interpret the meaning given some basic information. The questions are scored by raters, trained locally using ETS-provided materials, and test scores are reported as a single holistic score from 20 to 60.

A perusal of ITA assessment policies and procedures at a number of US universities makes clear that the SPEAK test is still very much in use for ITA decision making despite some clear drawbacks such as a lack of clear connection to academic contexts, lack of interactivity, and potential negative "washback" effects on ITA instruction (Janet Goodwin, personal communication, 2005). Instead of instructing graduate students on classroom presentation and specific language skills, pressure may exist within ITA education programs to "teach to the SPEAK test," with less than ideal consequences for ITA education. Other problems with

the SPEAK test are related to the small number of forms and decades-long usage in high stakes situations, resulting in very little test security: With only six SPEAK forms and many candidates depending upon a passing score for employment, students have resorted to memorizing questions on multiple test forms, purchasing copied forms, and so forth. To counteract this problem, some universities have constructed their own versions of the SPEAK test, possibly with less than adequate validation work to ensure the score comparability and fairness of the new versions.

Of course, there are a variety of institutions using other methods to assess ITAs' oral proficiency. The assessments may include interviews, tests of listening, or even traditional written tests in addition to or in place of the methods discussed above. However, the vast majority of ITA programs in the USA have chosen to use the TOEFL iBT Speaking, a teaching simulation, a semi-direct test of speaking (often the SPEAK test), or some combination of these three approaches to make ITA certification decisions. Combination approaches may be designed to identify and exempt highly proficient ITA candidates from an in-house performance exam. A program may adopt other exemption measures, such as exemption based on long-standing residence in an English-speaking country, or possession of an undergraduate degree from a US university.

Case Study of an ITA Assessment Program

To illustrate these issues and problems in ITA certification in the real world, an example of a large and apparently successful ITA program will now be discussed. The University of California, Los Angeles (UCLA), has a large number of international graduate students and a large number of courses requiring graduate TAs, and thus a pressing need for ITAs. In the 1980s, the university mandated that potential ITAs be assessed for their oral language proficiency and offer coursework designed to support their oral communicative ability. For many years the SPEAK test, discussed above, was used to make ITA decisions. Candidates were required to achieve a score of 45 on SPEAK to work as TAs. However, dissatisfaction with SPEAK led to development of a new exam to replace it, the Test of Oral Proficiency.

The TOP was developed in 2003–4 by Farnsworth and a team of faculty advisers and others, and has been in continuous use at UCLA since that time (Schmidgall, 2011). Farnsworth first gathered information on SPEAK alternatives in use at other universities, and made the decision to create a new test rather than adopt an existing test wholesale. At UCLA this was more feasible than at some other institutions due to the local expertise in language assessment and ITA instruction, the resources of the university, and the large scale of the problem—hundreds of candidates yearly. The two most influential models for the TOP were the TEACH test discussed previously and the “ITA Test” found in Smith, Meyers, and Burkhalter (1992). The test development process included consultations with local experts in teaching English to speakers of other languages (TESOL) and applied linguistics, undergraduates, and faculty members in various departments. Standard-setting sessions were designed to include

faculty in diverse departments, members of university administration, and TESOL and applied linguistics experts. Raters of the previous SPEAK test were also key contributors to the standard setting, which involved watching and rating the videos of pilot test exams with the various stakeholders. Farnsworth (2004) investigated the degree to which teaching skills and language skills were in fact separable constructs from the standpoint of rating. TOP pilot test videos were scored using a rating system for teaching skills and another for language skills. It was found that these skills were separable, or at the least ratable, to a sufficient degree on the TOP as proposed.

The format of the test is similar to the teaching simulation tests described previously. Testing takes place inside classrooms with the candidates standing in a “teacher” role in front of a whiteboard. Two raters rate each candidate and sit at the back of the room. They are also in charge of giving instructions to the candidate, checking the time, and so forth. Two undergraduate students serve as a mock “class” and audience for the presentation. The primary purpose of this is to allow the raters to concentrate on rating the performance without having to simultaneously act as “students.”

Test takers complete two tasks after a brief introduction. The introduction is designed to orient the test taker to the undergraduates as his or her audience and to put the test taker at ease. It takes up to 3 minutes and is not scored. Undergraduates typically ask a few simple personal questions, and the raters explain the situation and tasks and answer any procedural questions.

The second task requires the examinee to explain some classroom-related procedural material to the “class:” a syllabus, guidelines for a course paper, lab rules, and so forth. The material is provided 5 minutes in advance of the exam and consists of about half a page of text. The materials were adapted from actual syllabi and course materials in various disciplines. Humanities and social sciences students receive different material than students in the physical or “hard” sciences. This task takes approximately 5 minutes to complete. The undergraduates are required to ask questions, feigning incomprehension if necessary so that the speech sample involves the examinee in some degree of negotiation of meaning. Undergraduates in this and the third task are provided with question scripts, but are also allowed to improvise when needed.

The third task is the traditional lecture-and-discussion section presentation, where the candidate presents a basic topic in his or her field and is asked follow-up questions from the undergraduates. This task takes approximately 10 minutes to complete. Candidates are allowed to present a topic of their choice with the following limitations:

- It must be appropriate for a lower division course in their field.
- It must be language-rich: no complex visual aids, art, technology, and so forth are allowed.
- Candidates in mathematics are given specific guidance because of a strong tendency of these candidates to rely on board work for their explanations.
- Candidates in foreign languages are instructed to present an academic aspect of the language study such as linguistics, literature, or history and culture of the language.

During the first two years of TOP use, some unusual topics were presented, involving nonacademic talks and presentations using very little language, that necessitated the above list.

During the task, the undergraduates are instructed to ask clarification questions, interrupt, and so forth, so that the task requires the candidate to do more than simply lecture. When the topic chosen is far outside the knowledge base of the undergraduates, the undergraduates are instructed to ask questions from a simple script, such as, "Sorry, I didn't understand [X] point . . . Could you just explain that again?"

Raters score the exam using an analytic scoring rubric. Pronunciation and lexicogrammatical competence scoring categories are included. Rhetorical organization refers to discourse-level aspects of the speech sample, and raters are instructed to look for use of spoken cohesive devices in particular. The measures in the question-handling category demonstrated listening ability and appropriate response to questions, and thus reflects both listening skills and functional skills such as asking for clarification and rephrasing. Teaching skills, topical knowledge, and cultural knowledge are not considered construct-relevant, though the rhetorical organization category may unavoidably overlap with these skills (Farnsworth, 2004). Thus, the TOP is an example of a "weak" LSP test according to Douglas's (2000) formulation. The test is conceived as an authentic language performance test that uses relatively realistic tasks to engage test takers in relevant language use, instead of as an "authentic task" that is assessed to some degree on language knowledge, pedagogical skills, and content knowledge.

Exams are scored by the two raters and scores are added up for the two tasks and averaged across raters to arrive at a final score. The pronunciation category is given greater weight in the scaling, which reflects the great importance placed on this aspect of ITA communication both among the test development team (Janet Goodwin, Donna Brinton, personal communication, 2004) and in the research literature (Hinofotis & Bailey, 1981; Anderson-Hsieh & Koehler, 1988; Pickering, 2004). Pass, fail, and marginal passing scores are disseminated via e-mail to candidates. When raters disagree substantially, a third rater views the video of the exam and averages their score with the closest of the two original raters.

Training of raters and undergraduates is ongoing but most training happens before the start of the academic year. Raters are mainly drawn from the graduate program in applied linguistics and TESOL at the university. Rater training materials utilize a series of videotaped anchor exams, with extensive notes on each justifying the scoring decision. Training happens in a small group setting, with new raters trained alongside experienced ones. Undergraduates' training is similar; they watch sample videos of good questioning practice and generate questions, some of which become a part of the questioner scripts.

Students who fail the exam are encouraged to seek ESL coursework and training at the university, and are counseled by the test coordinator on their areas of relative strength and weakness. This counseling has become a valuable part of the assessment process, and raters are directed to write detailed, sophisticated notes on the scoring sheets justifying their scores. Candidates generally find this type of highly specific feedback, based on the notes and their video, to be

invaluable. Candidates who receive a “marginal passing” score are allowed to work as TAs only if they take an approved ESL ITA preparation course prior to or concurrently with their first quarter of teaching assignment. Candidates who pass the exam are approved to work as TAs and not required to take further coursework.

Approximately 300 tests are administered every year (250 unique candidates; some take it multiple times) using this instrument (Schmidgall, 2011). TOP is administered quarterly and before the start of the academic year, with the largest number of candidates just before the academic year begins, for four total administrations per year. Inter-rater reliability is high for a test of this type; Schmidgall (2011) provides dependability estimates (ϕ) of around .90 through the first six years of TOP use. In 2009, Columbia University adopted the TOP as an ITA screening measure in combination with a locally developed measure.

In general, the TOP and its associated policies appear to be very effective in screening ITA candidates and directing them to appropriate ESL coursework when needed (Farnsworth, 2004, 2007; Janet Goodwin, personal communication, 2008; Schmidgall, 2011). It has a degree of credibility among UCLA international graduate students that the previous SPEAK exam did not have; it appears to be reliable and fair; and the ESL instructors who teach the ITA courses approve as well. However, the exam is relatively resource intensive, requiring a coordinator, video equipment, classrooms, and a pool of trained and expert raters as well as willing undergraduate assistants. An institution with a smaller number of ITAs, fewer resources (most especially access to trained raters), or both, may find this type of assessment system to be too much of a burden. One possibility for reducing this resource burden would be to exempt candidates with high TOEFL iBT Speaking scores, or those who can show an extended residence in an English-speaking country, or both.

Recommendations and Conclusion

The specific approach to ITA assessment taken within any program will depend on the overall scale of the problem, resources, and available expertise, and institutional variables such as the degree to which instructional policies are centralized. With regard to ITA policies and an assessment program, the following may serve as helpful guidelines or suggestions.

If resources are available, consider using a mock teaching assessment similar to those described here. These tests require both funding and local expertise, but their authenticity brings many advantages. The first is of course that the assessment is likely to be more valid if the tasks are realistic and the language required is similar to that required of actual TAs. The second major advantage relates to the washback effect on ITA ESL preparation; in any high stakes testing situation, pressure to use class time for test preparation is enormous. When the test format and necessary language are aligned with the real on-the-job communicative needs of the ITA, the ITA prep class is likely to be much more effective. The alternatives to a mock teaching assessment, such as the SPEAK test, may not be accurate enough to distinguish between candidates at the margins of acceptable

competence, in part due to the lack of authentic language and testing situation. Using a standardized test such as the TOEFL iBT Speaking may have the same problems but offer even less flexibility.

Offer ITA-specific language coursework to support candidates who do not pass. General ESL courses, even those offered for graduate students, are unlikely to be as useful as those that focus on classroom language, cultural aspects of the US classroom, pronunciation, and discourse demands of spoken academic communication. Also, offer specific and clear feedback to students when they do not pass the assessment so that they go into the ESL coursework with a clear idea of their purpose for being there and thus are more motivated to study oral communication.

Do not assess ITAs on the basis of their sociocultural competence, teaching skill, or subject matter knowledge. This view is not universally held, as seen by the inclusion of sociocultural competence categories in the scoring of some common ITA assessments, such as Smith, Meyers, and Burkhalter's (1992) and Douglas's (2000) description of the TEACH test. It is clear that a successful TA establishes rapport with students, uses effective teaching techniques, and is a master of the subject matter. Furthermore, LSP research (Douglas, 2001) has called into question the primacy of purely linguistic scoring criteria for this type of assessment. However, native-speaker TAs are not usually chosen on the basis of these attributes, and are not usually required to demonstrate competence in them prior to teaching; nor are these skills usually taught within a typical graduate department. Thus it seems fundamentally unfair, and a potential legal liability, to ask international students to demonstrate these additional competencies, regardless of the perceived need for culturally competent TAs or the assumption that native-speaker TAs already have these skills. An additional argument against including nonlinguistic scoring criteria is that the assessors of such an exam may be unqualified to rate nonlinguistic aspects of a teaching performance: What qualifies as an appropriate illustrative example in a physics lecture (i.e., teaching skill) and whether the physics theory is in fact correct (i.e., subject matter knowledge) are not things that ESL experts are necessarily qualified to judge.

Consider a relatively generous policy to exempt candidates from an ITA testing requirement. Students with very high scores on a standardized and well-validated test of speaking, such as the TOEFL iBT Speaking or the International English Language Testing System (IELTS), are likely to pass a mock teaching assessment as long as the scores required for exemption are relatively high (Farnsworth, 2007; Xi, 2007). Similarly, long-time residents, citizens, and undergraduate degree holders from an English-speaking country are very likely to pass such an assessment. The savings from not testing these students could be utilized to strengthen ITA ESL courses.

ITA assessment is a high stakes situation for all stakeholders, not least the undergraduates whose education in some measure depends on the communicative abilities of the ITA. Meeting their needs, while being fair to ITA candidates and sensitive to departmental needs for teachers, is an important challenge. Institutions employing ITAs need to devote sufficient resources to ensure not only that ITA candidates are assessed in a valid and fair manner, but that support for their ESL learning is high quality and specific to their unique needs.

Assessing the English Language Proficiency of International Aviation Staff

Ruixia Yan

Misericordia University, USA

Introduction

In international aviation, sufficient English language proficiency on the part of the flight crew is crucial because English is used as the international language for communication between pilots and air traffic controllers (ATCs) irrespective of whatever their first languages may be. Pilots and ATCs understand that controller–pilot communication is as important as technical proficiency for safety (Alderson, 2009, 2010, 2011; Yan, 2009; Cutting, 2012). Research shows that human errors associated with English language communication problems between pilots and ATCs account for 70–80% of all airline accidents and incidents (Plant & Stanton, 2012; also see International Civil Aviation Organization, ICAO, 2011). Therefore, international operations present safety problems if pilots and ATCs whose native language is not English lack sufficient command of English. To date, however, there is a lack of research on the English language factor in the context of international aviation. This chapter investigates the importance of English language proficiency of pilots and ATCs for international aviation safety and critically discusses current English language testing used in international aviation. Because of the high stakes involved, it is essential to ensure the highest possible reliability and validity in English language proficiency testing for international pilots and ATCs. This study, therefore, also explores how to improve reliability and validity and the implications for English language testing and training in international aviation are also addressed.

Previous Views

The goal of the air traffic system is to achieve the safe, efficient conduct of aircraft flights and to maintain a safe, orderly and expeditious flow of air traffic (ICAO,

The Companion to Language Assessment, First Edition. Edited by Antony John Kunnan.

DOI: 10.1002/9781118411360.wbcla050

2008, 2009; see also ICAO, *n.d.*). Researchers have studied the safety issue from various aspects, such as information transfer between pilots and ATCs (ICAO, 2008, 2009; Alderson, 2009, 2010, 2011), pilots' knowledge, skills, and abilities (von Thaden, Wiegmann, & Shappell, 2006; Bristow & Irving, 2007), reliability and stability of equipment such as aircraft, communication systems, etc. (de Voogt & van Doorn, 2006; Cristancho, 2007), stress of pilots and ATCs in emergency situations (Li & Harris, 2006; Gates, Duffy, Moore, Howell, & McDonald, 2007), etc. The previous studies on aviation safety have emphasized the equipment factor but have neglected the factor of language communication between pilots and ATCs. According to the Boeing statistical summary of the worldwide aircraft accidents 1996 through 2005, equipment failures account for only 17% of the accidents, however, human errors related to pilots and ATCs' miscommunications, stress, fatigue, etc. caused more than 55% of the accidents (Boeing, 2005). Isaac, Shorrock, and Kirwan (2002) also indicate that the majority of accidents in hazardous activities are caused by human error, and human error will inevitably occur (Kontogiannis, 2011). Boeing (2011) summarizes the worldwide fatal accidents 2001 through 2011 and shows that system or component failure or malfunction only caused 4 out of the total of 87 fatal accidents. Therefore, equipment is not the weakest link in the aviation system, although an aircraft is built of thousands of parts, components, and systems. Language communication between pilots and ATCs is essentially a major factor for aviation safety (Alderson, 2009, 2011; Yan, 2009).

Current Views

With the growth in the volume of international air travel and the cosmopolitan nature of the staff involved, recent research has begun to examine the factor of the language communication between pilots and ATCs in aviation, especially in international aviation (Alderson, 2009, 2010, 2011; Yan, 2009; Cutting, 2012). Barshi and Healy (2011) show that there is no way that a nonhuman interpreter could handle the requirements of communication in an emergency between pilots and ATCs. Therefore, information transmission between pilots and ATCs must have the human interface and pilots and ATCs have to have a common language to communicate with each other. Alderson (2010, 2011) indicates that language is essentially the final safety net in aviation operations (also in Shawcross, 2007). Without successful language communication between pilots in the air and ATCs on the ground, aviation would be an impossible industry because events in aviation, routine or emergent, rely heavily on verbal communications between pilots and ATCs (ICAO, 2008, 2009; Arminen, Auvinen, & Palukka, 2010). That is, language communication between pilots and ATCs is an essential and critical component. According to Day (2004), the most vulnerable link in the airspace system is information transfer between pilots and ATCs, and safe flights depend on successful pilots and ATCs' language communications. Matthews (2004) indicates that between 1976 and 2000 more than 1,100 passengers and aviation crew died in accidents in which the language factor had played a contributory role. Based on a review of 28,000 aircraft incident and accident reports, over 70% of the problems

were in information transfer, and this issue continues to be the largest category of problems ever reported (Shawcross, 2007). Also, the first six months of 2004 were among the safest ever for airlines, however, statistics still indicated that insufficient language proficiency in comprehension or expression of pilots or ATCs continues to feature in incident and accident reports of aviation (Shawcross, 2007). Clearly, the language factor is crucial, unambiguous and efficient communication between pilots and ATCs is vital for the safe and expeditious operation of aircraft (Cutting, 2012), and risks caused by language and linguistics in international aviation must be explored more deeply (Tiewtrakul, 2010).

Current Research

As mentioned, English has been used as the default language for communication between pilots and ATCs in international aviation, and pilots and ATCs' sufficient command of English language is a safety imperative. However, there is a lack of research on the language factor for international aviation safety. Although English language testing procedures have been developed to ascertain the licensed pilots and ATCs have sufficient proficiency in English for safe and efficient communications, the assessment procedures are often invalid or, even worse, nonexistent (ICAO, 2008). This section, therefore, discusses the language factor for international aviation safety, current English language testing in international aviation, and how to enhance reliability and validity of language testing.

English Language Proficiency for International Aviation Safety

On an international flight, a pilot or ATC will be confronted with other flight crew speaking English with different accents and degrees of proficiency. That is, for pilots and ATCs whose native language is not English, crosscultural and multilingual exchanges are often required while transmitting information to each other. For example, while a Chinese pilot is flying from Beijing to Paris, he or she may cross 10 national boundaries and speak to more than two dozen air traffic controllers, each with a different first language background, speaking different regional varieties of English at varying levels of proficiency (Shawcross, 2007; Alderson, 2010, 2011; Cutting, 2012). According to international aviation regulations, although pilots may use the language of the country they are flying over, pilots and ATCs must be able to communicate in the default language of international aviation—English. For international pilots and ATCs who lack sufficient proficiency in English, international operations present serious problems (ICAO, 2008, 2009). For instance, more than 1,500 passengers and flight crew lost their lives in accidents in which inadequate English language proficiency of pilots or ATCs had been a contributing factor between 1970 and 1995 (Shawcross, 2007). The ICAO Accident/Incident Data Reporting System also shows that the “language barrier” on the part of pilots and ATCs is an important reason (ICAO, 2008). Language barriers exist in all language exchanges and can seriously compromise the communication process between pilots and ATCs in aviation. Different people may get different meaning from the same words, phrases, or sentences because

everybody filters language expressions through different perspectives, cultural and linguistic backgrounds, and life experiences. For example, the Tenerife disaster, on March 27, 1977, is one of the worst accidents in aviation history, killing 583 and injuring 61. The major cause was a miscommunication between the Dutch speaking pilot and the Spanish speaking ATC regarding the meaning of "We are now at takeoff." The pilot meant "We are now taking off," but the controller understood it as "We are waiting for permission to take off." In November 1996, a Kazakhstan Airline plane collided midair with a Saudi Arabian Boeing 747 over Charkhi Dadri, New Delhi, India, killing 351 people. This accident was caused by language miscommunication between the ATC, who was an Indian, and the pilots, who were Saudi and Russian. Day (2004) pointed out that although the fatal airline accident rate has continuously decreased, pilots and ATCs' miscommunication on account of poor English language skills is still frequent. Therefore, the language factor is critical for international aviation safety, and the importance of English language proficiency cannot and should not be underestimated (Alderson, 2009, 2010, 2011).

Formulaic Language Is Not Sufficient for Language Communication Between Pilots and ATCs

The ICAO language standards indicate that the language proficiency requirements in aviation include the use of both phraseologies and plain language (ICAO, 2009). The phraseology is formulaic language, which is standard, idiomatic, serial, and memorized speech or language in predictable form (Alderson, 2009, 2011). Examples of phraseology are "request start up," "cleared for take-off," "hold at C1," etc. According to the ICAO (2009), the purpose of formulaic language is to provide maximum clarity and brevity in communications while ensuring the messages are unambiguous. That is, standard phraseologies can help to decrease the problem of human factors associated with pilots and ATCs language communications and help to ensure safe operations. However, standardization is not a complete solution to miscommunications between pilots and ATCs since formulaic expressions can only be used to address routine events or situations which are foreseeable. In cases of nonroutine, unexpected, or emergency operational situations, standard phraseology is not sufficient for effective and unambiguous communication. That is, standard phraseology fails to address the full range of problems that can arise (ICAO, 2008, 2009). Accident investigation reports illustrated that the inability to communicate in common English can lead to serious operational errors and even deaths, especially in cases of nonroutine and emergency situations (ICAO, 2009). Also, studies indicate that pilots and ATCs tend to switch from standardized phraseology to a more conversational style in emergency situations (Campbell-Laird, 2004). In emergencies, pilots and ATCs must depend on what is called "plain" language to manage situations. Researchers also found that bilinguals or multilinguals tend to use their primary or dominant language, or their most familiar dialect, to handle unexpected situations or urgent needs (Yan, 2009).

Therefore, formulaic language, or a list of standardized phrases pertinent to aviation contexts, cannot deal with the full range of situations requiring

radiotelephony exchange between pilots and ATCs. That is, formulaic language is not sufficient for pilots and ATCs' language communication. Actually, aviation English is not entirely distinct from general English. Mitsutomi and O'Brien (2001) proposed an aviation English model consisting of the following three components:

- air traffic control phraseology,
- English for specific purposes (ESP), and
- English for general purposes (EGP).

In this model, air traffic control phraseology works most of the time. When the phraseology fails to work on unexpected occasions, EGP is used, which, in aviation contexts, includes mostly aviation-specific tasks and vocabulary (ESP).

Pilot and ATC Awareness of the Importance of the Language Factor for International Aviation Safety

Because of the high risks involved, pilots and ATCs' awareness of the importance of language communication in aviation safety is crucial. To date, however, research in this respect is very scant. Yan (2009) used a survey to elicit information about what pilots and ATCs actually think about the factors related to aviation safety based on their experience and perspectives. The questionnaire was composed of 30 items, with 23 Likert-scale items, and a multiple choice cloze test. The survey was completed by 98 pilots and ATCs in China. It was found that the participants did not have sufficient awareness of the importance of language communication in aviation safety. Therefore, they can benefit from training to improve their awareness of the significance of becoming proficient in English.

A multiple choice cloze test was included in the survey to get a brief measure of the participants' general English language proficiency. Research indicates that cloze testing is an integrative method (as contrasted with discrete-point assessment) focusing on language use to assess test takers' knowledge of phonology, morphology, syntax, semantics, and pragmatics (Yan, 2009; see also Chapter 13, *Assessing Integrated Skills*). That is, cloze testing is valuable to measure the examinee's comprehension of the material and to assess general English language proficiency for both native English speakers and non-native English speakers (Oller & Jonz, 1994). Aviation English is a language for specific purposes (Douglas, 2004), and tests for the aviation industry should include tasks that are similar to and representative of those of the examinees' target language use situation (Douglas, 2004). However, aviation English is essentially general English with additional elements inherent to aviation (aviation terms, new meanings of familiar words, grammar structures peculiar to the aviation industry, etc.). That is, general English is not opposed to aviation English or vice versa. Actually, aviation English rests on the knowledge of general English. Therefore, the participants' general English language proficiency assessed by the cloze test in the survey should be able to reflect their aviation English level. The cloze text used in the survey is less difficult than advanced college material, and the results revealed that the English skills of the participants were weak.

In conclusion, English language proficiency is vital for international aviation safety. Yan (2009) demonstrates that the surveyed pilots and ATCs did not have sufficient awareness of the importance of language communication in aviation safety and their general English language proficiency was not sufficient. Therefore, it is critical to improve pilots and ATCs' awareness of the importance of their English language proficiency and to ensure that international pilots and ATCs possess proficient English through reliable and valid aviation English testing and training programs.

Current English Language Testing in International Aviation

Aviation English testing is quite different from other types of language testing because of the life and death consequences. Professional and personal stakes involved in aviation require a high level of professional standards and personal commitment throughout the testing and training process (ICAO, 2008, 2009; Alderson, 2010, 2011). Since English language proficiency of pilots and ATCs is a safety imperative, and there are no short cuts regarding language learning and safety (ICAO, 2008, 2009; Arminen, Auvinen, & Palukka, 2010), the ICAO introduced new language proficiency requirements (LPRs) which established six levels of skill in six areas of English language usage: pronunciation, structure, vocabulary, fluency, comprehension, and interactions (ICAO, 2008, 2009; also see Macmillan Education, 2010). Air traffic personnel whose English language proficiency is at

- ICAO Level 6 (Expert) will be issued a valid English language proficiency endorsement for all time, that is, they will not be required to demonstrate English language proficiency in the future;
- ICAO Level 5 (Extended) must resit the test in six years;
- ICAO Level 4 (Operational) need to be retested every three years;
- ICAO Level 3 or below will need specific aviation English language training to reach the minimum ICAO operational level.

The new ICAO language proficiency requirements strengthen the requirement for English proficiency of pilots, ATCs, and other aviation personnel in international aviation, establish the minimum skill level (ICAO Level 4) requirements for language proficiency for flight crews and ATCs, and standardize the use of ICAO formulaic phraseologies. Very importantly, the new requirements not only affirm the important role of ICAO standardized phraseology, but also emphasize the necessity of pilots and ATCs' demonstration of a minimum level of proficiency in plain language when phraseology is not applicable (Alderson, 2011). The new requirements indicate that the effective use of plain language is vital in aircraft operations, especially in unusual and emergency situations.

One example following the new ICAO requirements is New Zealand's English language proficiency tests. Only after the candidates have passed all of the Private Pilot License (PPL) theory examinations to ensure they have enough aviation knowledge can they take the English language proficiency tests. Depending on a candidate's level of English competence, the candidate may sit one of two tests.

One is Level 6 Proficiency Demonstration (L6PD), which is a 7- to 10-minute test of recorded human voice prompts carried over the telephone to imitate the real pilot-ATC communication environment. This test is for native English speakers or candidates whose English level is relatively high. The second test, Formal Language Evaluation, is for those for whom English is not their native or dominant language. This test determines whether the candidate meets the ICAO minimum operational Level 4 standard or higher, and is a 20- to 25-minute two-phase test including a live interview conducted over the telephone and a similar test to the L6PD. As of 2009, around 1,500 candidates have sat the L6PD and about 220 have sat the FLE (ICAO, 2009).

Because of the high stakes involved, the consequences of inadequate language tests being used in licensing pilots, ATCs, and other aviation personnel are potentially very serious. The ICAO (2008) has expressed concern that no license is required for language testers in the aviation industry. Also, the ICAO (2009) indicates that aviation English testing is still an unregulated industry. Alderson (2009, 2011) expressed shock and dismay that although some tests in the aviation industry did exist, there were no independent data available on the quality of current aviation English examinations. In Alderson (2010), a survey concerning the current aviation English tests was reported. Commissioned by the European Organization for the Safety of Air Navigation (Eurocontrol), the Lancaster Language Testing Research Group did a validation study of the development of a test called ELPAC (English Language Proficiency for Aeronautical Communication). As part of the study, a survey was conducted using a questionnaire based on the Guidelines for Good Practice of the European Association for Language Testing and Assessment (EALTA). The questionnaire was sent to numerous organizations whose tests were used for licensure of pilots and ATCs. Only 22 responses were received and they varied considerably in quantity and quality. Results from the survey reveal a considerable variation in the quality of the tests, a lack of available evidence or system to qualify the tests, and insufficient awareness of appropriate procedures for test development, maintenance, and validation. Researchers of the study concluded that they do not have sufficient confidence in the meaningfulness, reliability, and validity of several of the aviation language tests currently available for licensure. Therefore, they recommend that the quality of language tests used in aviation be monitored to ensure they follow the accepted professional standards for language tests and assessment procedures.

Since the ICAO Level 4 language proficiency requirements became applicable in November 2003, steps have been taken to help in implementing the new language proficiency requirements effectively and timeously. For instance, in cooperation with the ICAO, the International Civil Aviation English Association (ICAEA) developed a set of Guidelines for Aviation English Training Programs. Although the guidelines will be of invaluable assistance in the process of selecting aviation personnel and fine-tuning training programs and end user objectives and there has been a significant change to the environment in which aviation English is now carried out (ICAO, 2009), there is a lack of any system of accreditation, validation, or specific teacher qualifications. According to the ICAO (2009), the final goal of aviation English training is to ultimately enhance safety by enabling the effective implementation of the ICAO language proficiency requirements.

However, the current reality concerning English language teaching or training in international aviation is that, although there are various internationally recognized bodies qualified to provide accreditation for schools teaching English as a foreign language, there is currently no formal system of accreditation or qualification for schools or teachers developing and delivering aviation English training. That is, English training is still an unregulated industry, which is quite similar to aviation English testing.

Inadequate English language testing and training, poor quality, and insufficient research on the language factor in international aviation may lead to language testing or training that is unreliable, invalid, ineffective, or inappropriate, which will, accordingly, increase the possibility of miscommunications between pilots and ATCs leading to fatalities (Alderson, 2009, 2010, 2011). Therefore, it is crucial to improve the reliability and validity of English language testing and training in international aviation.

Improving Reliability and Validity in Assessing English Language Proficiency

Based on the preceding discussions in this chapter, it is evident that English language proficiency of international pilots and ATCs is directly connected to international aviation safety. Therefore, a critical issue in the industry is that English language testing should be as reliable and valid as possible to ensure that pilots and ATCs have sufficient English language proficiency to communicate and to successfully manage unexpected events and emergency situations.

Reliability and validity are two important traits of any assessment or testing. Generally, reliability is about the consistency of findings, and validity asks the question whether a measurement measures what is intended to be measured. Douglas (2004) indicated that in language-testing situations, reliability means whether a particular assessment of language ability is consistent, both across individuals taking the same test, and within an individual being assessed at various times. Validity is commonly viewed as the most important quality of a test (Yan, 2009). The conception of validity is connected to different questions from various perspectives (Borsboom, Mellenbergh, & van Heerden, 2004). The current study follows Borsboom et al. (2004; also Oller, 2012) and argues that a measure is valid when changes in the measure reflect changes in whatever is being measured. That is, validity in measurement refers to the truthfulness of findings. The other traits of tests and measurements that are commonly referred to, including reliability, authenticity, etc., are features of validity and of truth (Oller, 2012; see also Chapter 26, *Assessing Test Takers With Communication Disorders*).

According to the empirical study completed by Yan (2009), both reliability and validity of testing can be enhanced by improving communication between the teacher and examiner, the curriculum and test, and the test takers. Applied in the aviation contexts, if the testing or training goals, format, content, administration approaches, rating scales, etc. are communicated better to pilots and ATCs before any language testing or training occurs, it should follow that the reliability and validity of testing and training will be improved.

Also, as discussed above, validity is essentially truth in whatever is being measured, and validity necessarily implies reliability. Therefore, the validity (and of course reliability) of aviation English testing and training should be enhanced by improving the agreement between the testing and training content and approaches with what is really involved in aviation situations. That is, valid language testing and training in aviation should be as authentic as possible and reflect the real work domain. Accordingly, the characteristics of authentic language use of pilots and ATCs in real working situations should be incorporated into aviation language testing and training. Shawcross (2007) summarizes the unique features of pilots and ATCs' language use as the following:

- Aviation communication is essentially oral. Most of the communications between pilots and ATCs are not visual.
- The language used in aviation includes very specific lexicon such as weather, mechanics, aerodynamics, geography, navigation, etc. Pilots and ATCs often use common words such as "clear," "hold," etc. in a way different from everyday usage. Also, aviation language often has operationally relevant language functions such as orders, requests, offers to act, feasibility, etc.
- Language communication in aviation is a blend of formulaic standard phraseology and natural speech to handle nonroutine or unexpected events.
- Communication is often conducted in a stressful environment, especially in cases of emergencies.
- The language skills required by the ICAO areas include pronunciation, structure, vocabulary, fluency, oral comprehension, and interactions. Reading and writing are not emphasized in aviation.
- Pilots and ATCs' language competency generally are assessed in more real-life effective communication situations, such as in an operational environment, rather than in purely linguistic terms.
- In international aviation, the ultimate level of language proficiency (ICAO Expert Level 6) is a language understandable and intelligible to the international community, not native speaker-like English.

According to the ICAO, all different accents and varieties of English should be governed by the same proficiency requirements in the aviation industry. The ICAO language proficiency requirements clarify what level of English language proficiency of pilots and ATCs is appropriate for international aviation. That is, the purpose of the ICAO language proficiency requirements is to ensure, as far as possible, that the language proficiency of pilots and ATCs is sufficient to reduce miscommunication as much as possible and to allow pilots and ATCs to handle routine and in particular nonroutine situations. In short, English language should be problem-alleviating or problem-avoiding rather than an obstacle.

- Finally, in any language test in accordance with the ICAO Rating Scale, the various levels of proficiency are defined by the lowest score in all six skills.

In accordance with these features, valid English language testing and training in international aviation should have the following characteristics. First, the format and contents of language testing and training in aviation should reflect the real

language use of pilots and ATCs. For example, the format of valid English language testing and training in aviation should emphasize the verbal rather than the written aspect of language with visual cues being not accessible to the pilots or ATCs, because air-ground radiotelephony communication is generally oral without visual cues. Also, the contents of valid aviation English testing and training should include both formulaic phraseologies standardized by the new ICAO requirements and plain language, since the pilots and ATCs' radiotelephony communication includes standard phraseology at the core and operational exchanges in plain English when phraseology is inadequate.

Second, aviation English testing and training should view language as dynamic, holistic, and integrative. In reality, language communication between pilots and ATCs in naturalistic aviation situations is meaning-based, and therefore holistic and integrative (see also Chapter 13, *Assessing Integrated Skills*). Accordingly, valid English language testing or training procedures should reflect this fact and stress operational efficiency rather than linguistic correctness. Actually, operational efficiency is the ultimate criterion by which English proficiency is assessed according to the new language proficiency requirements (ICAO, 2008, 2009).

Third, the delivery of language testing and training should be as authentic as the real-life situations in aviation. For instance, pilots and ATCs communicate via radiotelephony, therefore, aviation English testing and training should be carried out over the telephone to simulate the radiotelephony environment as closely as possible. The delivery of valid language testing and training should manage the noise issue systematically and very deliberately because the acoustic quality of radiotelephony in real working situations of aviation is often poor (Alderson, 2009, 2011). In addition, the delivery of language testing and training should reflect the fact that in real international aircraft operations, pilots and ATCs have to deal with different accents, dialects, and varieties of English. Also, language communication in aviation is very time sensitive, especially in unpredictable circumstances or emergencies in which speed and clarity of communication between pilots and ATCs are of the essence for aviation safety. Therefore, the issue of time constraints should be reflected in language testing and training in aviation. However, it is not always so in reality. For example, the Tests of English Language Proficiency for Aviation (TELPA), which have been used in Korea, are designed to be "almost 100% aviation-specific with authentic and work-related situations and materials in aviation" (General Tests of English Language Proficiency, G-TELP, 2005, p. 1). For every test item, test takers are provided with 30 seconds to think before they answer in TELPA. However, it may not be possible to have 30 seconds to think before pilots or ATCs make any decisions to deal with emergencies in real aircraft operations. Therefore, neglecting the element of appropriate time constraints in TELPA is violating the authentic aviation environment, which makes the validity of such testing questionable.

In conclusion, validity and truth are essentially the same attribute, and validity implies reliability. For the English language testing and training used in international aviation, the reliability and validity of testing and training can be improved if the format, contents, delivery, etc., of testing and training are compatible with real-life aviation demands and situations and are better communicated to pilots and ATCs.

Challenges

The major challenge of this chapter is that there is a lack of data and research on English language testing in international aviation, which makes it difficult to judge the sufficiency of the implementation of the new ICAO language policy to ensure the quality of the English language testing procedures. Without sufficient access to the testing and training contents, format, structure, administration and delivery methods, rating scales, etc., the reliability and validity of the language testing and training is unclear. For the same reason, there is a lack of clarity as to whether the testing processes currently used or proposed meet the ICAO language standards.

Future Directions

Developing the English language proficiency of pilots and ATCs helps to improve international aviation safety and enhance personal and professional fulfillment. However, preceding discussions indicate that there is a lack of analysis of the language communication between pilots and ATCs and research on language testing in international aviation is scant. Therefore, future research needs to be directed toward corpus analyses of the language used in international aviation to investigate the specific underlying problems associated with pilots and ATCs' English language communication, such as comprehension, standard phraseology, intonation, word use, grammar (see also Chapter 6, *Assessing Grammar*), and the use or misuse of pauses, etc.

Also, special attention should be focused on assuring the quality of the English language testing and training currently used and proposed in international aviation. That is, future research should be directed toward evaluating whether the language testing or training is as authentic as possible, is able to provide reliable and valid measures of the language proficiency of pilots and ATCs, and is practical in terms of administration, time, money, personnel, etc. For the same purpose, future research should be directed toward developing a formal system of accreditation or qualification for schools, teachers, and others to develop and deliver reliable and valid English language testing and training in international aviation.

Assessing Health Professionals

Lynda Taylor

University of Bedfordshire, England

John Pill

University of Melbourne, Australia

Introduction

Language assessment for occupational purposes typically evaluates whether someone has the relevant linguistic and communication skills in another language to be able to take up a professional or vocational role within a specific domain of work. Assessment tools are often performance oriented, designed not only to reflect a range of linguistic and communicative demands but also to simulate elements of real-world, work-related tasks typical of a given professional domain (Basturkmen & Elder, 2004).

One occupational domain which has experienced a huge rise in the global movement of personnel, and where language for specific purposes (LSP) testing has consequently also grown, is the health professions (e.g., medicine and nursing). Language proficiency measures are used to evaluate an individual's readiness to practice safely and function effectively in a health-care context. Incidents where the language skills or communicative competence of health professionals trained in another country are perceived to have contributed to negative health-care outcomes attract considerable public and media attention, as well as provoking political debate. However, the issues involved in assessing the language and communication skills of health-care workers are complex, touching upon testing policy and practice, as well as concerns of a moral and ethical nature.

This chapter focuses mainly on the English language assessment of health professionals seeking to practice in predominantly English language contexts. This is because so much migration of health professionals has been to English-speaking, "developed-world" contexts (i.e., the UK, North America, Australasia), resulting in well-established language assessment policy and practice. The chapter also focuses largely on language tests for *doctors*, giving limited attention to tests for

other health professional groups. English language assessment for doctors is widespread and long-standing.

The term “international medical graduate” and its abbreviation “IMG” are used to describe doctors trained in one country and seeking registration in another. This is the most commonly used term, replacing “overseas-trained doctor” and “foreign medical graduate,” although the population it describes varies from context to context, as IMGs are not a homogeneous group. Similar terms exist in other professions, e.g., “internationally educated nurse.” Once these health professionals have obtained registration in a jurisdiction, their status is no different from any other practitioner; nevertheless, the term may continue to be applied, often to indicate problematic cases where a deficit (e.g., in language, professional knowledge, or cultural competence) is perceived.

The next section describes varying approaches to the language assessment of health professionals across different jurisdictions. Later sections examine relevant research and highlight challenges and issues confronting those who work in this area. The concluding section considers possible directions for future research.

Approaches to Language Assessment of Health Professionals

In this section, various patterns of assessment currently implemented in different countries for particular health professional groups are presented for illustrative purposes. The present form of the testing procedure is described, followed by some discussion of its history and of prior versions to contextualize developments over time.

General-Purpose Language Test With Tests of Professional Competence: Doctors in the UK

The General Medical Council (GMC) is a regulatory body within the UK’s national framework for setting and maintaining standards for medical practice. It is responsible for registering doctors to practice medicine in the UK. Different regulations apply based on an applicant’s nationality and country of training. Doctors trained outside the European Economic Area (EEA) and Switzerland must provide, among other things, evidence of satisfactory English language capability, then evidence of their current level of medical knowledge and skill, typically by passing the GMC’s own Professional and Linguistic Assessments Board (PLAB) (see http://www.gmc-uk.org/doctors/before_you_apply/imgs.asp). The PLAB (see below) is designed to confirm that IMGs applying for professional registration have achieved the minimum standard required to practice safely. Doctors from within the EEA are treated differently. Their medical qualifications and language skills may not be tested in this way according to current law. Instead, language assessment may be carried out as part of an individual’s registration for training or application for employment; this tends to be more ad hoc, with little consistency of standards or test instruments among the bodies involved. (The regulations applicable in this area are complex and under review.)

The GMC uses the International English Language Testing System (IELTS), a general-purpose language test, as its measure of English language capability. To meet the GMC's language proficiency requirements, candidates must obtain an overall band score of 7 on the academic version of IELTS (representing a "good user" on a 9-band scale), with a minimum score of 7 in each of the four areas tested (speaking, reading, writing, and listening) at one sitting. If the test certificate is more than two years old, additional evidence is needed documenting how the applicant has maintained their English language skills. IMGs who meet the necessary requirements are eligible to take the PLAB, which is in two parts and delivered in English. Part 1 is a computer-based test with items testing medical knowledge and skills. Part 2 is an objective structured clinical examination (OSCE) involving short clinical scenarios designed to test clinical skills, including the ability to communicate effectively with patients, relatives, and other health workers.

Currently, therefore, the GMC uses a general-purpose language test as a measure of language capability, partly as an initial screening mechanism; this is followed by a separate professional competence test, which includes assessment of specific work-related communication skills. GMC assessment of IMGs has evolved over time and a brief overview of past policy indicates factors affecting approaches to assessing health professionals.

The GMC was among the earliest health profession bodies to develop a test designed to evaluate both the professional and the language abilities of doctors trained in another country (Douglas, 2000, pp. 3–4). The Temporary Registration Assessment Board (TRAB) was introduced in 1975 for IMGs seeking temporary registration to practice medicine in the UK (Rea-Dickins, 1987). For its time, the TRAB was a sophisticated test, not only in terms of format and content but also in how the test was developed and constructed. Linguists worked collaboratively with medical experts to analyze the language used by doctors, nurses, and patients in British hospitals. This "needs analysis" informed decisions about the nature of the professional knowledge and language ability to be assessed; test tasks included a recorded listening task, a written essay, and an oral interview.

The TRAB was subsequently revised and renamed the PLAB, becoming a two-stage test of English language proficiency and medical knowledge/communication skills still administered by the GMC. In the early 1990s, however, the GMC considered separating the English language proficiency measure from the medically orientated communication component of the PLAB. IELTS, a four-skills language proficiency test originally developed for university entry, was well established by the mid-1990s. Initially, the GMC endorsed IELTS as an *option* allowing PLAB candidates exemption from the comprehension of spoken English and the written English sections of its own Use of English component. In 1997–8, IELTS became mandatory for all candidates as part of the new PLAB Part 1 and Part 2 system (described above), with a gatekeeping function to confirm the adequacy of candidates' general English proficiency before their assessment on specific clinical communication skills. Candidates who achieved a satisfactory result in IELTS were eligible to take the Objective Structured Clinical and Oral Examination, as Part 2 was named at that time (Douglas, 2000, pp. 280–1).

One reason for the GMC's adoption of IELTS as a mandatory "filter" test was its availability. The GMC was concerned at the number of IMGs incurring

significant personal cost and upset because they travelled to the UK, took but failed the language proficiency stage of PLAB, and had to return home, unable to proceed to the PLAB clinical stage. By 1995, IELTS was available at test centers worldwide throughout the year. Candidates could thus take the initial language proficiency test locally and, when successful, travel to the UK to complete the PLAB requirements. Occasional reviews by the GMC have amended the required minimum scores for the four components of IELTS while the overall band score has remained at seven. Not surprisingly, perhaps, the sufficiency of a general-purpose language test for use in a specialized context such as medicine has been questioned.

Specific-Purpose Language Test With Tests of Professional Competence: Health Professionals in Australia

As a contrast to the use of a general-purpose language test described above, a specific-purpose English language test used predominantly in Australia is now presented. A further specific-purpose language test is the Canadian English Language Benchmark Assessment for Nurses (CELBAN) (see Centre for Canadian Language Benchmarks, 2003; Epp & Lewis, 2009).

The late 1980s saw a significant contribution in the field of test development for assessing language in the workplace context and specifically in the assessment of health professionals. The present version of the Occupational English Test (OET) was designed as a performance test to evaluate the English language competence of medical and health professionals wishing to study or practice in Australia (McNamara, 1996). A consultancy report on the previous version recommended the creation of a new test to “assess the ability of candidates to communicate effectively in the workplace” (Alderson, Candlin, Clapham, Martin, & Weir, 1986, p. 3). The OET covers 12 health professions—medicine, nursing, dentistry, physiotherapy, veterinary science, pharmacy, occupational therapy, dietetics, radiography, speech pathology, podiatry, and optometry—with a format allowing the development of tests for further groups as required. The initial design of the test was informed by job analyses principally involving doctors and nurses. It seeks to simulate a number of job-related performance tasks and includes separate subtests for listening, reading, writing, and speaking skills. The task-based, authentic nature of these assessments means that the skills cannot be completely detached from each other; for example, the writing task—generally a letter of referral—is prompted by a set of patient notes which have to be read, and one of the listening tasks involves note-taking (a writing skill). All test takers complete the same components for the receptive skills, while for the productive skills test content is tailored to the specific requirements of each health profession; for example, writing tasks set for nurses are different from those for dentists. OET results are reported as grades (A to E); a grade B in each of the four subtests is the standard currently set as satisfactory by most regulatory authorities. McNamara (1996) offers an in-depth account of the original development and validation of the OET, while Douglas (2000, pp. 130–44) provides extensive analysis and discussion of aspects of the test.

The introduction in 2010 of an additional task for the reading component of the OET exemplifies how ongoing validation studies maintain and strengthen links between LSP tests and the real-world contexts they are designed to represent. The OET reading test previously consisted of multiple choice question (MCQ) items focusing principally on the detailed comprehension of two texts on health-related topics written in an academic style. Exploratory research into what health professionals read in their workplaces and how they interacted with those texts showed that, while intensive reading remained important, health professionals often used skimming and scanning techniques across several texts to find specific information quickly, skills that were under-represented in the existing test. In the additional task, test takers complete a gap-fill summary drawing on information on the same topic in three or four short texts extracted from different sources (e.g., research abstract, professional journal article, patient information sheet, tabulated data) within a limited time. The speeded nature of the task requires test takers to use the reading techniques the test is designed to measure. The construct of the expanded test therefore seeks to represent more fully the reading practices of the professional context.

To illustrate how such language assessment fits with other professional examinations for registration to practice, the example of IMGs seeking general registration with the Medical Board of Australia is outlined. Applicants must meet the English language requirement set by the Board and obtain certification by the Australian Medical Council (AMC), the national standards body for medical education and training. There are several ways to obtain the AMC certificate (see <http://www.amc.org.au/index.php/ass/apo>). Applicants following the standard pathway by examination take a computer-based MCQ examination of medical knowledge, then a clinical examination assessing their clinical and communication skills which involves a series of observed interactions with standardized patients (similar to the UK's PLAB Part 2 and the USMLE Step 2 Clinical Skills examination described below). The AMC examinations are delivered in English and assume a level of language proficiency in test takers but this is not assessed directly.

Integration of Language Assessment Into a Test of Professional Competence: Doctors in the USA

To apply for a licence to practice medicine independently in any one of the states of the USA it is necessary to pass three separate steps of the United States Medical Licensing Examination (USMLE). Step 1 and Step 2 (which has two components) must have been passed to obtain a residency position (graduate training) and Step 3 is usually completed following the first year of residency. Two points about the USMLE are noteworthy: first, language assessment is integrated into the test of professional competence; and, second, the same assessment is applied regardless of where initial training was undertaken or what language it was delivered in, i.e., doctors with qualifications from medical schools in the USA or Canada are not distinguished from doctors trained elsewhere (IMGs). In other words, a separate language proficiency test is not required. The format of the Step 2 Clinical

Skills (CS) examination (one component of Step 2) is similar to that of professional examinations in the UK and Australia (see above). Candidates engage in a series of clinical encounters with standardized patients. However, while physician examiners observe and grade candidate performance in the British and Australian clinical examinations, in the USMLE the standardized patients are themselves trained to grade performance following each encounter by considering three areas: data gathering, communication and interpersonal skills, and spoken English proficiency. Spoken English proficiency relates to “[m]ispronunciations, incorrect word choice, or other language deficiencies that may have caused a breakdown in communication” and is scored as a holistic judgment on a scale defined from 1 (“needs significant improvement”) to 9 (“very good”) (van Zanten, 2011, p. 81). Following each patient encounter, the doctors write up patient notes; these are assessed by physician examiners for their content but no further linguistic assessment is undertaken.

Candidates must demonstrate satisfactory scores across the encounters in each of the three areas, so insufficient spoken English proficiency would cause a candidate to fail the Step 2 (CS) examination. The other elements of the examination are Step 1 and Step 2 Clinical Knowledge (CK; the second component of Step 2), which are computer-based tests of professional knowledge and skills delivered in English without language proficiency being assessed directly. It might be argued that a single holistic score based on spoken English proficiency alone is insufficient evidence of the range of language skills required by a health professional. Conversely, the fact that this assessment is carried out by lay people—not physician examiners or language professionals—could indicate that the outcomes are valid and well suited to ascertaining readiness for interaction with patients in a supervised training context.

Between 1998 and 2004, only doctors qualified outside the USA or Canada were required to take the equivalent of the Step 2 (CS) examination, then called the Clinical Skills Assessment. As well as performing satisfactorily in this test, these doctors had to obtain an English language proficiency test score acceptable to the examining body, the Educational Commission for Foreign Medical Graduates, e.g., by taking the Test of English as a Foreign Language (TOEFL)—a general-purpose English language test developed (like IELTS) for university entrance—or the Commission’s own English test, first developed in the 1950s. Prior to 1998, there was no performance test using standardized patients in the assessment of clinical and communication skills; the Test of Spoken English, an optional element of the TOEFL format at that time, was used (Powers & Stansfield, 1983).

Theory and Research

This section links the current language assessment policy and practice presented in the previous section to theoretical insights and research findings from the past 50 years in the fields of applied linguistics and language testing, clinical communication skills and, specifically, language assessment of health professionals.

From the 1970s, developments in the field of occupational training and personnel selection helped shape the evolution of LSP testing, including the testing of

health professionals (O'Loughlin, 2008, pp. 69–70). O'Loughlin cites Jones (1979), who recommended that medical graduates, along with teachers and airline workers, should be tested through performance using language, not solely on knowledge about language. In addition, developments in sociolinguistics and discourse analysis (Hymes, 1972; van Dijk, 1977) along with the emerging concept of communicative competence (Canale & Swain, 1980) inspired new approaches involving more performance-orientated, task-based testing.

During the 1980s, the concept of language proficiency expanded to embrace notions of pragmatic and cultural understanding, discourse structure and management, and reader/listener awareness, and this was reflected in language teaching and testing. Throughout the 1990s and into the 2000s, innovative research focusing on features of spoken language improved understanding of the complex nature of spoken interaction, including the notion of “co-construction” by speakers in a conversation (Young & He, 1998; Brown, 2003). Such developments inform views on how oral tasks should be designed for assessment purposes, what evaluation criteria are most relevant, how rating scales should be constructed and examiners trained (e.g., McNamara, 1996; Lazaraton, 2002). In addition, Bachman and Palmer (1996) introduced the notion of the target language use domain.

Having a deeper and broader construct of language proficiency, however well theoretically and empirically grounded, does not mean that this is easy to operationalize in a language proficiency test. The dilemma of what should be tested and what is actually testable has often been raised (e.g., Candlin, 1986; Davies, 2001). Developments in language testing theory and practice have clear implications for the assessment of health professionals. Any specific-purpose assessment task designed to evaluate communication skills *in context* needs to be informed by a sound understanding of the criteria for successful communicative interaction (see Chalhoub-Deville, 2003). For example, the asymmetrical power relationship that exists between a doctor (typically the “knower”) and a patient plays out in the way those interactants initiate and respond within that context, choosing and using language accordingly to achieve their goals.

From the perspective of medical education in recent decades, recognition has increased among health professionals of the importance of effective communication, both in consultations with patients/clients and, more recently, in intra- and interprofessional interaction in the workplace. This area of competence is increasingly included in professional standards and codes of conduct published by regulatory bodies, while communication skills training has been introduced into the curriculum in many health professional education contexts (e.g., von Fragstein et al., 2008). Models and guides for clinical communication have been developed and critique is offered on whether these skills are better taught separately or integrated with other areas of medical training (e.g., Silverman, Kurtz, & Draper 2005; Skelton 2008). How language and communication skills interact with professional knowledge (and factors such as personality and cultural competence) in the realization of the routine tasks of health professionals remains to a large extent uninvestigated, though discourse analysis of health-care encounters has a growing literature (e.g., see Candlin & Candlin 2003; Sarangi 2010).

Empirical research into the validity and impact of language tests for assessing health professionals remains relatively limited, although a body of literature is

beginning to develop around the specific-purpose tests mentioned above. Published research on various aspects of test development and validation is available for the early PLAB (Rea-Dickins, 1987) and the OET (Alderson et al., 1986; McNamara, 1996). These studies emphasize the close collaboration between health professionals and language specialists with regard to the initial occupation-specific needs analysis, the subsequent design and piloting of a trial test, and final implementation of the operational version. The OET has stimulated research studies on several issues of interest in LSP testing: e.g., authenticity of task and interaction (Lumley & Brown, 1996), rater characteristics and bias (Lumley & McNamara, 1995), rater training (Knoch, 2011), and rating patterns (Iwashita & Grove, 2003).

An OET-related project investigated the “indigenous assessment” (Jacoby & McNamara, 1999) of health professionals in medicine, nursing, and physiotherapy, studying commentary from educators and supervisors on the performance of trainee health professionals (native and non-native English speakers) in face-to-face interaction with patients. The aim was to learn what aspects of performance in this context were valued in the three professions. Perhaps unsurprisingly, language as represented in proficiency tests was not a priority in comments in the data, although issues of intelligibility and grammatical accuracy were mentioned. Comments focused on the trainees’ professional knowledge and their use of communication strategies, for example, to engender patient-centeredness. The researchers argued (e.g., Elder et al., 2012) that language was fundamental to the trainees’ performance, as the work being done in the consultations was achieved principally through language and was perceived as being done more effectively when language choices were more appropriate (e.g., using lay rather than medical terms) and when particular linguistic strategies were used (e.g., signposting changes of topic).

Understanding more clearly how language contributes to the success of interaction in a health professional–patient consultation may allow the construct of the LSP test to be extended to represent more fully the expectations of the real-world context. In the OET’s case, further criteria for assessment of test-taker performance in the speaking subtest were developed based on the study’s findings. In addition to the analytic criteria currently used—intelligibility, fluency, appropriateness of language, and resources of grammar and expression—two further criteria were proposed: clinician engagement, concerning the use of language to demonstrate awareness of the patient and a positive professional manner, and management of interaction, covering linguistic strategies to manage the interaction and structure it coherently for the patient. A clearer understanding of the scope of assessment criteria used and their possible expansion based on research of this kind may help address the issue raised by Wette (2011) that the constructs of current language proficiency tests used for health professional registration are sometimes assumed by test users (perhaps for reasons of convenience) to be broader than warranted by test specifications.

As the scale of measuring the competence of health professionals trained in other jurisdictions has grown, some licensing bodies have adopted an existing general-purpose language proficiency measure rather than develop a domain-specific tool. As a result, a number of studies report benchmarking and standard-setting exercises with language proficiency tests selected for specific

occupational domains. For example, the National Council of State Boards of Nursing developed a nursing-specific standard on IELTS and TOEFL (computer-based and Internet-based) that US jurisdictions could consider for use in their licensure decisions for internationally educated nurses. Findings from standard-setting exercises were considered by the Council's examination committee in conjunction with other relevant information to produce legally defensible passing standards on the tests (O'Neill, Tannenbaum, & Tiffen, 2005; O'Neill, Buckendahl, Plake, & Taylor, 2007; Wendt, Woo, & Kenny, 2009). In each case, panels of experts scrutinized the contents of the components of each test and judged sample performances on the tests against expectations of performance from a minimally competent entry-level nurse for whom English is a second language. The panels included licensed and practicing nurses (native and non-native English speakers) from differing specialties and from across the USA, as well as nursing educators, clinical supervisors, and regulators. In a study of internationally educated health professionals preparing to take the OET or IELTS to meet English proficiency requirements for registration in New Zealand, Read and Wette (2009) found broad equivalence between the scores on the two tests as they related to the standards required by the regulatory authorities, although the data available were very limited.

Challenges and Issues

Following the review of theory and research above, this section considers various challenges and issues in assessing health professionals, organizing them according to three "problematic" aspects of LSP tests identified by Douglas (2001, p. 45): *authenticity*, *specificity*, and *inseparability*. A fourth aspect has been added relating to practical considerations and policy constraints which often affect assessment in the health-care domain. The discussion focuses on domain-specific testing, presupposing that, despite the challenges and issues raised, an LSP test is more likely to be an effective predictor of a test taker's ability to perform in a particular context than a general-purpose test of language proficiency. There is currently only limited evidence to support this assertion; the jury is still undecided on the endeavor of LSP testing. At the same time, however, any assertion that a general-purpose language test is a sufficient measure for such a sensitive context as health-care provision must be countered in a similar manner.

Authenticity

Simulating tasks and content from the workplace in a test provides a context in which test takers can feel "at home" with the routine and topics of their profession. When a test seeks to reflect the workplace, the preparation materials and courses that invariably develop alongside it are also likely to reflect that content; this may be found to create positive washback that goes beyond the test to help set appropriate expectations among test takers for their future roles as well. However, tensions arise because a test cannot fully replicate the workplace, and what constitutes an authentic response can be contested. For example, although regulatory bodies indicate that a range of writing skills should be assessed, doctors

may complain that they rarely write extended text by hand at work, instead using templates set up on a computer. The mismatch between linguistically oriented assessment criteria and the authentic performance criteria of the workplace has been discussed above in regard to the OET speaking test. Extending the scope of OET assessment criteria to reflect more fully the values of health professionals appears feasible, making the “weak” performance test “stronger” by McNamara’s definition (1996, p. 197); however, the capacity of OET assessors—that is, language professionals who are not health domain experts—to act as proxies and make judgments in the place of health professionals also needs to be demonstrated. “Indigenous assessment” may not distinguish “native speaker” from “non-native speaker”; a decision is nevertheless required regarding the level of language proficiency deemed sufficient for adequate patient safety and practical efficiency.

Specificity

The section on approaches to language assessment of health professionals revealed variation in the use of general- or specific-purpose testing tools for assessing the language proficiency of health professionals. The issue should perhaps be viewed as one of degree. Proponents of LSP tests argue the importance of sampling directly from workplace tasks and content to provide the opportunity for test takers to demonstrate they have the particular linguistic skills for a specific context—e.g., a suitable range of lay terms to describe health conditions and their management. The argument is that evidence of these context-specific skills would not be elicited in a general-purpose language test. However, particular groups of test takers may feel disadvantaged or disaffected if a reading text is on a topic that is not specific enough to their particular discipline; for example, doctors might complain about a text on dental hygiene, even though text and test items are designed to be accessible to test takers from various health professions and not biased in favour of dentists. The same concern may arise *within* professional groups: a test taker with experience in paediatric intensive care nursing may feel disadvantaged by a writing task concerning home nursing visits to an elderly patient. This argument can continue to the point where individual test materials would be provided for each test taker. The “weak” model of second language performance tests, in which the test is intended to elicit a sample of language from the test taker for assessment using linguistically oriented criteria, supposes that this lack of differentiation is not relevant to assessment or outcome. However, as noted above, when the scope of assessment criteria becomes “stronger” to reflect criteria used in the workplace more directly, characteristics of test task and content and how test takers deal with them are more likely to affect assessment of test takers’ performance.

A different perspective on specificity concerns how local or national characteristics are reflected in a test. For example, would it be appropriate to use a test designed for nurses in the Canadian context to assess nurses for training and employment in the UK? Health professionals moving to Australia are criticized for not understanding so-called “Aussie slang” and this might be suggested for assessment in the OET. However, doing so would disadvantage health professionals taking the test elsewhere, perhaps without ever having visited Australia. This

type of culturally specific knowledge is perhaps best acquired in situ; nevertheless, it remains a matter of degree. The same can potentially be argued for brand names of medications, or procedures for certifying sick leave. To summarize, a test's specificity will affect how well test performance can be generalized to predict future performance in other contexts.

Inseparability

The inseparability "problem" concerns how far language knowledge and use can be separated from other types of knowledge and their application, whether in theory or practice. Can language knowledge be distinguished from specific-purpose background knowledge, e.g., medical knowledge, or are they "inextricably entwined" (Douglas, 2001, p. 50)? If the latter, to what degree, and with what implications for assessment? If language knowledge can indeed be separated out from other domain-related knowledge, then assessing linguistic competence using a general, decontextualized measure of language proficiency makes sense, since the test scores can justifiably be used to predict performance, even in a highly specialized context. However, if this is not the case, there are significant test development implications in terms of content sampling, task design, assessment criteria, and score interpretation. Collaboration is required from the outset between language and content specialists along with input from test users such as accreditation bodies. The essential, relevant criteria—Jacoby and McNamara's (1999) "indigenous" criteria—must be identified, and assessors may consequently need to be language-aware *and* content-familiar (e.g., see Harding, Pill, & Ryan, 2011, for discussion of what assessors marking the OET listening test need to know). Douglas's (2001) view of the inseparability of language knowledge and specific-purpose background knowledge seems to have growing empirical support from recent research into the nature of language proficiency among native and non-native speakers (Hulstijn, 2011).

As described above, jurisdictions vary in their approach to assessing health professionals. Such variation in policy and practice can be explained on historical, sociopolitical, profession-related, and pragmatic grounds, or even through lack of access to or awareness of linguistic expertise. It also illustrates the dilemma involved in attempting to deal separately with language, communication, and professional skills. What is interesting about the different approaches presented in this article is the extent to which they each reflect a view that communication skills are fundamentally linked with professional skills. One reason for this may be a growing sense within the health professions of the necessity of good communication skills as health care evolves both socially and technologically. The concept of "patient-centered care," with its more holistic focus on the patient, is now common in Western health-care practice: patients are involved in discussion of their health as it relates to their life situation and goals, and management plans are negotiated not imposed. Similarly, the technologies and advances in knowledge of modern medicine often involve users of the health-care system in making choices, and to do so requires risks and uncertainties to be explained clearly. More generally, contemporary Western society has higher expectations of "consumer satisfaction" and is more litigious when errors are made, with health professionals

and their employers being held to account. Brown (2008) presents a summary of these issues in the UK context.

In addition, as health-care provision globalizes, with increasing numbers of health professionals working in a second or foreign language, the issue of the relationship between language knowledge, communication skills, and professional competence becomes more acute. Patients and the media often blame language deficiencies when “things go wrong” involving non-native-speaker health professionals. This may further legitimize the need for language testing in the eyes of the general public. But is the root cause to do with language? While language may be blamed (as the most obvious “difference” between “insiders” and “outsiders”), difficulties may be due to a mismatch of cultural or professional expectations or a combination of these issues. Raising the score demanded on a language test will not help if the problem is not language-related.

Practical Considerations and Policy Constraints

In addition to Douglas’s (2001) three “problems,” matters of practicality and issues of policy and fairness must be addressed. The decisions of health professional registration bodies to create, adopt, or recognize tests are often shaped not only by consideration of test content and quality but also by basic pragmatic considerations, including: availability of test centers; frequency of test administrations; cost to test takers and other test stakeholders; test security, integrity, and turnaround of results; and documentary support for test stakeholders. There can be a tension between selecting an established and widely available assessment tool that is recognized and benchmarked internationally, and creating a new test, tailored to a given context or health profession group and thus immediately relevant, but potentially costly to produce and maintain.

Furthermore, the political dimension must not be underestimated: workforce flows are managed by governments, and language tests and test providers inevitably become involved in legislation and public policy. Changes in the political, legal, or economic environment trigger policy changes, and political priorities may override language-testing sensibilities. Test users demand and expect a single, clear “answer,” something language testers rarely want to provide. For their part, registration bodies face the complex task of balancing the management of public policy and risk while seeking to facilitate fair access and professional development opportunities for individual health professionals.

Future Directions

The previous section raised several challenges and issues in health professional assessment which are likely to be the focus of attention for language test developers and users, shaping future developments. Space constraints allow just a few additional areas to be highlighted here.

First, the growing use of technology in health professional contexts—e.g., consultations and professional interaction by telephone or through video-conferencing, use of computer-based records systems—will affect approaches to LSP assessment

and the design of test tasks. Ongoing applied linguistics research and needs analysis must keep pace with how communication demands are changing within health-care systems in an interconnected and computer-literate world. More generally, too, current measures of language proficiency for health professionals must continue to be reviewed and evaluated regarding their fitness for purpose, as the broader context in which they function evolves.

Second, the increasing dependence of health-care systems in more economically developed countries on health-care professionals trained elsewhere risks depleting the health resources and systems of the countries providing this valued “commodity,” many of which have great need of health professionals’ skills among their own populations but are unable to compete in a global marketplace. A further moral and ethical challenge is “brain waste”—migrants who cannot maintain their professional status in the new country (perhaps because they are unable to obtain necessary language certification) and whose professional skills consequently become unavailable. The language-testing community needs to reflect on its role in this complex situation.

To conclude, a basic reframing of the scope of language assessment in this field is outlined. The inter-relationship of language proficiency, communicative competence, and clinical communication skills requires much further study, as already noted. Nevertheless, it is generally agreed that all health professionals, regardless of language or cultural background, can be trained to communicate more effectively. If language is considered a fundamental tool in the performance of the work of health professionals, such training should focus more explicitly on improving their understanding of how particular linguistic choices and strategies can facilitate efficient communication. Doing so would also affect language assessment in this field, expanding it beyond the current “deficit model,” in which a language test is viewed essentially as a hurdle requirement to establish that performance of non-native speakers meets a minimum standard; instead, it would include a more constructive role for assessment in the ongoing improvement of the language and communication skills of *all* practitioners for the particular contexts in which they work. These contexts could include those where more than one language is used as a matter of routine and where English, for example, is a lingua franca. Training and assessment must be developed in and for the workplace, to meet the actual needs of practitioners; they must also be developed in parallel, as complementary aspects of professional development and support. Furthermore, the role of language in accomplishing effective communication should be acknowledged in national professional standards and regulatory documents. Representing language as the essential tool for effective health-care communication in this way would help address current practical controversies about the validity of testing native speakers (e.g., moving from Australia to the UK) and legal restrictions on testing language proficiency (e.g., within Europe), as well as generate a new and progressive agenda for research on language assessment for health professionals.

Assessing Test Takers With Communication Disorders

John W. Oller, Jr.

University of Louisiana, Lafayette, USA

In general, the key to valid human testing and assessment—with or without the complications of “communication disorders”—is to discover the highest and best performance the person being assessed can deliver in required tasks. Failures are more likely to occur by chance, and for that reason they are less informative. A failure on a test item, or a breakdown in any communication context—say, a pilot fails to understand a directive from an air traffic controller (see Yan, 2009)—may be owed to illness, stress, lack of sleep, stormy weather, computer breakdown, physical pain, prior injury, alcohol or drugs, lack of skill, one or more disorders, an invalid test—and the list of such factors and their interactions is interminable. By contrast, in complex discourse processing, successful performances cannot occur by chance.

Among the advances of natural language-processing theory and research (Manning & Schütze, 1999; Mitkov, 2004; Jurafsky & Martin, 2009) is the practical confirmation of Chomsky’s mathematical arguments (1956, 1978, 1988) concerning the “poverty of the stimulus.” Summing up its two essential parts, first, language learners rarely encounter ungrammatical strings and, second, most of the grammatical strings they meet up with—like this one—have never been met before.

Consequences of the “Poverty of the Stimulus”

As soon as a string reaches a length of about seven words, the chance of its being found by a search of the entire World Wide Web is practically zero. Try searching, for instance, for the first seven words of the sentence just preceding this one; and imagine how unlikely it would be to find a string of any higher number of words—say, the length of any paragraph in this book. Jurafsky and Martin (2009,

p. 87) confirm the poverty-of-stimulus argument by saying that “the Web isn’t big enough.” To measure the probability of any particular string of about seven words, the Web is too small; and the poverty of the Web generalizes to the whole world and to all history. If the universe of discourse is not big enough to pay the debt incurred by the poverty of the stimulus, how do language learners acquire, and thus become able to understand and produce, well-formed strings of symbols in the natural languages they come to know? How can they differentiate grammatical strings (most of which are completely novel) from the vastly greater multitudes of ungrammatical strings (never before encountered either)?

It follows from the same line of reasoning that breakdowns in communication are easy to account for; but successes are not so easily explained. As a consequence, leaving aside linguists in the language-testing community, the necessary consequences of the poverty-of-stimulus argument are not generally known or taken into consideration by most measurement professionals. Yet from the poverty-of-stimulus argument it follows by logical necessity that successful discourse-processing performances, including agreements among informed interlocutors, are, in principle, necessarily more informative than failed performances (Uebersax, 1988, 1992; Oller, 2012). This necessary conclusion holds for correct answers to test items that result in higher item scores, part scores, whole test scores, summative, formative, normative, criterion-based, or whatever kinds of cognitive scores, judgment calls (e.g., on portfolios), or ratings may be generated.

Breakdowns and Disorders Are Uncountably Many but Agreement Is Unitary

Just as every grammatically well-formed sample of discourse (written, spoken, manually signed, or some combination of those modalities) can be converted into a multitude of ungrammatical (not well-formed) strings, it follows that breakdowns are possible at every conceivable level of linguistic organization. Breakdowns can occur at the level of phonetic features, sound segments, syllables, morphemes, words, phrases, sentences, and so forth. The more complex the discourse, the more ways there are for it to go wrong. In light of the poverty-of-stimulus argument, it is unsurprising that human communication disorders occur. On the other hand, the fact that communications normally succeed according to some is a “miracle” (Einstein, 1936, p. 60).

Typically, a normally developing child reaches a vocabulary of well over 50 words some time between the first birthday and the second (Bates, 1976; McLaughlin, 2006; Oller, Oller, & Badon, 2006; Owens, 2012). Explosive growth is already occurring as the *number of possible strings increases with the number of elements that can be combined and with the growing length of strings, e.g., from one word, to two, and so on*. This rule holds in language and genetics, and in all similar constructive processes by which meaningful strings of representations are connected to objects, persons, and events in the real world. An iterative series of combinatory explosions occur in which the number (N) of possible strings having a given length (l) is equal to the size of the vocabulary (v)—the inventory of elements to be combined—raised to the power of l : $N = v^l$.

Striking to the heart of the matter, from a natural language perspective, surface constraints on combinations cannot possibly account for meaningful discourse in natural languages (Chomsky, 1956, 1978, and 1988) nor in biological systems (Marks et al., 2012; Oller, 2012). We must look deeper, all the way to the pragmatic constraints on actual events in the real world. We must treat the entities, relations, and sequences of events in the real world as we treat other inventories of elements—sounds, syllables, words, and so on—in grammatical systems. No degree of phonological, morphological, and syntactic constraints—whether combined or in separation from one another—together with semantic selectional restrictions will get us all the way home, to fully meaningful human discourse. We cannot look merely to meanings in the abstract semantic sense; we must go all the way to the pragmatic facts of ordinary human experience. Because this conclusion is shocking to theorists who seek to discover the foundations of grammar by studying surface forms and to practitioners who seek to assess human language abilities without including discursive reference to actual persons and events in the world of experience, the indefeasible logical and linguistic basis for the conclusion must be spelled out.

As the number of randomly possible strings explodes with the increasing size of each inventory of combinable elements, from phonetic features to sounds, syllables, words, and so on, and as the length of the strings that are used in discourse increases, the ratio of intelligible strings to meaningless ones diminishes at an accelerating rate, until the chance of randomly discovering a valid interpretation for any sizable string reaches a vanishing point (Oller, 2012). Therefore, to discover the meaningful strings of discourse in any natural language, access to well-formed strings—including valid references to known persons, events, and sequences of events in the real world of experience—is required. The learner or discoverer of the grammatical underpinnings of any natural language must have access to ordinary true uses of that language. The first such true uses, which are typically understood by infants as they acquire a native language, are referring terms correctly mapped onto their real-world logical objects—persons, things, places, events, and so forth.

In what Manning and Schütze (1999) have called “statistical natural language processing,” “a central problem”—one that is increasingly being recognized as *the* central problem—is the determination of referential relations (pp. 111–12). The authors readily acknowledge that such determinations are pragmatic in nature, requiring “knowledge about the world” (p. 112). Jurafsky and Martin (2009) observe that the “first step in most IE [information extraction] tasks is to detect and classify all the proper names mentioned in a text” and then to figure out which terms “refer to the same real-world entity” (pp. 725–6). Subsequently, event sequences in which those named entities participate must also be resolved along with times and places in the world of experience. As my colleagues and I have argued in various contexts (Oller, Chen, Oller, & Pan, 2005), with respect to the vast and growing literature on child natural language acquisition, the child’s so-called “first words” require mapping familiar entities (persons, objects, events, and the like) onto relatively less familiar symbols in such a way as to solve for the conventional pragmatic uses of those symbols. The same procedures are needed in the discovery and resolution of the meanings of symbolic systems in general—e.g., in cryptanalysis of unknown languages as well as of genetic and biological codes (Marks et al., 2012).

Logical Consequences of the Combinatorial Explosions

In normal development from infancy to maturity, an inevitable series of “combinatorial explosions” (Gatherer, 2007) arises. There are exponentially growing multitudes of strings of elements, which are possible as the combinable inventories of elements increase in number. For instance, consider that roughly 12 phonetic features combine to form 30 to 50 phonemic elements that combine to form perhaps 2,000 to 4,000 pronounceable syllables that combine to form over 600,000 words (as listed in the *Oxford English Dictionary*; not counting proper names and other new entries that are being invented all the time). Those words can be used to form uncountably many phrases, sentences, and higher discursive strings. At the same time, as the greater numbers of higher strings are being formed, they must conform to increasingly stringent constraints.

How is such a vast multitude manageable? It is so because of what C. S. Peirce (1839–1914) referred to as the “unity of conception” (Peirce, 1866/1982, p. 520). In fact we discover a declining series of constraints of differing degrees:

pragmatic > semantic > syntactic > morphotactic > phonotactic constraints

Among the necessary consequences flowing from these observed relations is the following one: all else being equal, the difficulty of guessing the meaning of any given string, or of discovering or producing a meaningful string, becomes exponentially greater at each lower degree of the series. Turn this consequence around and it shows that, to acquire a language or to discover the underlying basis for meaningful discourse in that language, the most efficient method by a series of exponentially increasing margins is to rely on known pragmatic referential relations found in ordinary true reports or narratives.

It is in ordinary true reports of shared experience that the unity of conception (and the greatest attainable levels of agreement) can be achieved. This achievement is possible only to the extent that interlocutors use references to shared facts as a scaffolding, to maintain the thread of discourse. As the interactions, in any discursive context—including, of course, testing and assessment contexts—become more complex, the unity of conception becomes less and less likely to be attained by chance. Both theory and empirical research show that it cannot be attained at all unless the interpreter gains access to the pragmatic constraints on ordinary discourse. Thus, while the number of strings that are possible at any given level of a language is exploding to greater and greater multitudes, and as the length of allowable strings is increasing from word to phrase, sentence, paragraph, chapter, volume, series, and so on, the constraints restricting the range of valid constructions (or meaningful continuations) in a given string are simultaneously converging toward a theoretical limit of unity.

Just as fingerprints are unique indicators of the identity of particular persons, the constraints on statements that are true (and thus fully appropriate and interpretable with respect to some particular state of affairs; and we take this to be the most mundane sense of the word “true”) are uniquely appropriate to the states of affairs of which the statements in question are true. To borrow an example from

Davidson (1996), if Brutus killed Ceasar, then it is true to say that he did; otherwise it is not. As a result, valid representations of known facts contrast markedly with meaningful fictions, and even more so with errors, lies, and random arrangements resulting in the uncountably many strings of uninterpretable nonsense that would arise if their construction or the discovery of their meanings were left only to chance. Valid reports of known facts—say, name, address, date of birth, place of residence, and so on—define the narrative experience of every human being uniquely. As soon as a few valid facts about the actual history of any given person are known, the range of all possible persons who might be confused with that individual is soon narrowed down to just one individual—all the other possible candidates having been eliminated. The personal history of any individual is a far more certain identifier than a fingerprint. In fact a fingerprint without a valid connection to a particular individual means nothing. Yet to establish the meaning of a birth certificate, or of any other identifier—DNA or whatever—requires access to a true narrative linking the physical evidence to that person's history. Forgo the referential connection to a particular person and the fingerprint, DNA, or name will be as useless as a speck in the wind. The critical question to be addressed is: How is it possible to narrow any fact of history down to just one possible interpretation?

From a strictly logical (mathematical) perspective, the question is not how a particular individual needle (say, represented by unity—the number 1) *could be lost in a very large haystack* (represented by a large number of needles); rather the question is *how any particular individual needle could be found*. The problem is analogous to solving the equation

$$x = 1/\infty,$$

where the symbol ∞ is taken to be an uncountably large multitude of multitudes, a practical infinity. The ratio of one element—a unity—to a practical infinity cannot, it seems, be determined by chance. For this reason, correct solutions to complex discursive problems—valid interpretations, as manifested in nothing but agreement among interlocutors—are far less likely to occur than failure to achieve agreement. In all kinds of assessment, when item writers and test takers agree on the correct answer to any given discursive problem (e.g., the correct answer to a question, or a good performance on an interview, speech, or narrative as contrasted with one not so good, and so forth), that agreement (if all else is held equal) must be taken as more informative than any failure to agree. As a result, it follows from rigorous mathematical reasoning that correct answers to test questions—higher scores and higher ratings (if all else is held equal)—are more informative than incorrect answers or failed performances resulting in lower scores and/or lower ratings.

Adding Disorders to the Mix

With all of the foregoing in mind, consider next why and how communication disorders make successes in communication even less likely to happen and also

complicate assessment in general and language testing in particular. Take genetic disorders as paradigm test cases. About 6,000 genetic disorders and diseases have been classified (Kuhlenbaumer, Hullmann, & Appenzeller, 2011), and it is likely that many more remain to be discovered. If the biological language systems involved in those disorders are, as they must be, subject to the same sorts of combinatorial explosions as natural human language systems, the poverty-of-stimulus argument assures that there are many more ways for things to go wrong than to go right. Similarly, it follows that the constraints on valid representations, from DNA upward to RNAs, proteins, cells, tissues, organs, and whole individual organisms and groups of them, are more informative than the countless multitudes of meaningless combinations that are possible. It also follows, in a deep logical sense, that all such disorders, from genetics to human linguistic systems, are communication disorders by their very nature.

The standard reference works seeking to define communication disorders, along with the vast array of supposed, suspected, and commonly diagnosed “mental disorders,” are the various editions of the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders* (1994–2013; expected to appear soon in its fifth edition) and the ten volumes of the *International Classification of Mental and Behavioral Diseases: Diagnostic Criteria for Research* (especially see ICD-10). It is noteworthy that the diagnosis of complex discursive disorders depends critically on the role assigned to language assessment: witness the current controversy over the extent to which language and social abilities ought to figure in the diagnosis of autism (Ghaziuddin, 2010; Kaland, 2011).

Taking account of the fact that even the disorders listed in standard reference works are far too numerous to iterate in a few thousand words, the key point of this chapter is to argue that the uncountably many human communication disorders that can occur—including the relatively few that have already been classified—can be sensibly and exhaustively classified according to the systems of communication they disrupt.

Four Major Classes of Disorders

Disorders of communication are commonly distinguished in three ways: first and most commonly, by their symptomatology: How does the disorder affect the appearance, behavior, and/or abilities of the individual affected? Second, difficulties can be classified with respect to therapy: What can be done to prevent, lessen, halt, or possibly cure the problem? Third, difficulties are classed by their known or supposed etiology: What are the known or suspected causes of the condition or problem? Taking all these traditional methods into account, in the interest of parsimony and comprehensiveness, some of my colleagues and I have proposed classifying all communication disorders on the basis of the systems that are impacted (Oller, Oller, & Badon, 2010). By this method four major classes of disorders are defined, which cover in principle the full scope of all known and possible disorders: (1) those that affect the body itself; (2) those that impact the senses; (3) those that impede movements of the body (here involuntary movements such as in digestion are differentiated from voluntary and

intentional ones); and (4) those that impact the emotional, cognitive, linguistic, and social capabilities.

Of course, it is recognized that actually occurring disorders may involve multiple categories. In fact “comorbidity”—that is, the phenomenon of co-occurrence of disorders in the same individual—is the rule rather than the exception. It should also be noted that, logically, the most common disorders progressing upward, from category (1) through category (4), must become less severe in order for the affected individual to survive. Severe congenital disorders are often fatal, and the more severe the condition resulting in discernible communication difficulties the shorter the expected life span. For instance, individuals diagnosed with autism have a shorter life span (Mouridsen, Hansen, Rich, & Isager, 2008) than comparable individuals without autism. Also, it is reasonable to suppose that more severely affected individuals are the most impacted. If such a conclusion can be generalized, testable predictions about relative rates of prevalence can be derived from the measurable severities of the disorders defined with the help of the classification system discussed in the following sections.

Disorders of the Bodily Systems

At the earliest stages of development—for example at conception, when the chromosomes of the biological parents are uniting—the unfolding story of the first two cells depends on correct readings (sometimes many different readings of genes and, evidently, of the contexts in which they are embedded; see Marks et al., 2012). Successful interpretations are essential to the viability of the unfolding biochemistry, neurophysiology, structural integrity, feelings, moods, behavior, and eventually to the physical, emotional, cognitive, and social abilities of the developing individual.

It is difficult to overestimate the importance of accurate readings of the words, phrases, sentences, and so on of the genetic material and of its biochemical matrix that enable development to proceed. As these readings do so, all else being equal, genetic errors early in the sequence, unless they can be corrected, are certain to have a more devastating downstream impact than later errors, and thus they are also more likely to be fatal. It follows that normal development depends on a very long sequence of correct interpretations of increasingly many genetic and biochemical messages as development progresses. Of the approximately 6,000 known or suspected genetic diseases and disorders, about half are monogenic—believed to be caused by a single gene (Kuhlenbaumer et al., 2011). On the one hand, given the billions upon billions of biological interpretations that can go wrong, it is surprising that any individual human being ever comes to maturity as a healthy organism. On the other hand, it is less surprising that, over the long haul, cumulative injuries to genetic material guarantee mortality and that the potential for disorders and disease conditions must generally tend to increase over time, leading eventually to an unsustainable burden where vital systems will fail.

The bodily disorders that are most commonly treated by speech–language pathologists are clefts of the lip and palate. These also constitute the most common

survivable birth defects (Centers for Disease Control, 2011). Clefts, depending on severity, may also make the distinct articulation of some segments of speech difficult to impossible. Treatments involve surgery to repair the cleft, possibly followed by speech therapy to enable articulatory distinctions that may remain difficult to make owing to missing or damaged nerves controlling the articulators, facial expressions, and so on. It almost goes without saying that the potential impact of such disorders on language and social abilities, and therefore their relevance in language testing, depends greatly on the severity of the condition and on the nature of the language tests.

Sensory Disorders

There is an entire host of disorders of the senses. They range from barely detectable ones to complete loss of, or failure to develop, one or more of the senses—vision, hearing, smell, touch, and taste. Interestingly, research shows a hierarchy of control systems and cross-modality interactions between the senses and higher systems. Although in human beings all the senses—especially vision, hearing, and touch (and including balance, pain and pleasure, and so on)—are linked to both hemispheres of the brain, all sensory representations tend to fall largely under the control of the subordinate hemisphere—typically, the right one. The senses are also subordinate to movement, which is in turn subordinated to linguistic and cognitive control; and this is largely—almost exclusively, in normal human beings—the domain of the dominant hemisphere; for an elaboration on the research and theory showing these dominance relations, see my feature article offered on Glenn Fulcher’s “Language Testing” Web site (Oller, 2011).

From experimental investigations we know that sight is dominant over hearing. This is demonstrable in syllable perception. Perhaps the most important result in experimental psychology with respect to the hierarchical arrangement of the senses and cross-modal dominance relations appears in what is known as the “McGurk illusions.” When a video of a person saying /*ða*/ is played with an auditory recording of the same person saying /*ba*/, the auditory impression accords with the visual sequence rather than with the actual auditory recording. That is, listeners hear what they see in the moving visual image of the speaker saying /*ða*/, rather than the auditory signal /*ba*/—which is actually the one that is recorded. Only if the visual image is turned off (or ignored) will the listener actually hear the recorded auditory signal /*ba*/. This effect was demonstrated by Arnt Maasø (2012) in different series of syllables (retrieved on the same date from the same site).

The effect is robust and generalizes to higher levels. It follows not only that vision outranks hearing: motor feedback from kinesthetic understanding of how a given articulatory movement must sound outranks and overrides the auditory signal; and, at a still higher remove, cognitive/linguistic information about meaning can override visual and auditory sensations as well as kinesthetic (motor) feedback. For instance, if a listener knows that the sentence (and meaning) that a speaker is aiming to produce is “My dad taught me to drive,” even if the auditory and visual signals are actually recordings of a nonsense form that resembles the

intended one (say, [maɪbæbɔpɪmɪpʊbɪɑɪv]), the listener will typically hear “My dad taught me to drive.”

What this demonstrates with respect to disorders is that some sensory impairments in hearing, or in vision, or in both, can be compensated for through reliance on higher levels of linguistic and cognitive organization. While it is commonly known that “lip-reading” can be of service in profound deafness and loss of hearing, the McGurk effects show that all human beings rely on the coordination of visual, auditory, and kinesthetic feedback to a far greater extent than has been generally realized. The McGurk “illusions” show why and how it is possible for completely blind and deaf individuals such as Laura Bridgman (1829–89) or Helen Keller (1880–1968) to learn to understand written discourse. In fact Helen Keller, with the help of what is now called the “Tadoma method” (see Gallagher, 2002), was even able to learn to read speech with her fingers and to produce intelligible speech on her own. The video showing how Annie Sullivan helped Helen Keller do this can be retrieved from <http://www.youtube.com/watch?v=Gv1uLff35Uw> (last time visited on December 10, 2012).

Motor Disorders

Communication disorders involving movement can be roughly divided into those that affect only autonomic systems and those that affect volitional movements. Although autonomic systems can be further divided into sympathetic (those that turn up the juices, in “fight or flight” responses) and parasympathetic ones (those that tend to regulate and calm the former), clinicians working with communication disorders tend to rely on even less finely graded divisions. They talk about swallowing disorders, motor–speech disorders (meaning ones that affect swallowing and vocalizations), and fluency disorders. Those pertaining to swallowing and voluntary vocalizations, oddly enough, fall almost exactly at the boundary separating the autonomic and volitional systems of motor control. We can, for instance, control the initiation of a swallow, but its continuation to completion comes under the control of the autonomic (visceral) nervous systems.

Disorders of both types of muscular control (autonomic and voluntary) may involve a variety of problems, ranging from flaccidity due to want of muscle tone at one extreme (this is sometimes referred to in early childhood as “floppy child syndrome”) to cramping of muscles with rigid spastic paralysis at the opposite extreme (as is common in Parkinson’s and related disease conditions). Variations also occur; they are due to oscillation between the extremes. Fluency disorders, as they are called, are peculiar inasmuch as they also fall near the hypothetical borderline that separates motor from linguistic disorders.

Linguistic and Discursive Disorders

The descriptions “stuttering” and “fluency disorder” suggest a higher level in the hierarchy of human communication systems. This broad category can involve every level of motor difficulty, from the autonomic systems to the highest levels

of linguistic and discursive motor control—the systems governing rhythm, stress, intonation, and all of the accompanying “paralinguistic” systems, as well as the emotional complexities that generally come under the control of the subordinate hemisphere. The difficulty of sharply distinguishing success and failure or normal and abnormal in motor performances is well illustrated by the history of attempts to define stuttering events. Are they strictly motor difficulties, as some clinicians and theorists seem to suggest (Kalinowski & Saltuklaroglu, 2006; Stuart, Frazier, Kalinowski, & Vos, 2008)? Or are stuttering events typically governed by linguistic factors that involve the complexities of natural language grammars (Bloodstein, 1950, 2006)?

The peculiarities of stuttering disorders also demonstrate how difficult it can be to distinguish ordinary difficulties in language acquisition and use from persistent and recurrent disorders, whether chronic or not. The fact is that every normal speaker of a language sometimes hesitates or stammers in a manner that is virtually indistinguishable from the stuttering of an individual diagnosed with a chronic fluency disorder (Adams & Runyan, 1981; Guitar, 2006, p. 5). How are we to tell the difference? Likewise, how can the normal fits and starts, hills and valleys of ordinary language acquisition be distinguished from disorders and disabilities in general? These problems are not easily solved, not even by expert diagnosticians.

Consider the “standard definition” of stuttering proposed by Wingate (1964). She pointed to

disruption in the fluency of verbal expression . . . characterized by involuntary, audible, or silent repetitions or prolongations in the utterance of short speech elements, namely: sounds, syllables, and words of one syllable . . . marked in character and . . . not readily controllable . . . [s]ometimes accompanied by accessory activities

—and here she alludes vaguely to such “secondary symptoms” as foot-stomping, teeth grinding, grimacing, and the like, which reveal “an emotional state, ranging from . . . ‘excitement’ or ‘tension’ to . . . ‘fear,’ ‘embarrassment,’ ‘irritation,’ [the cause of which] is presently unknown and may be complex or compound” (p. 498). Wingate’s standard “definition”—though notably vague and circular—has been followed by a long series of arguments about where the emphasis should be placed.

Perkins (1990) insisted that the speaker’s perceptions of what is happening during stuttering events are more definitive than the impressions made on the listener. In favor of Perkins’s claim is the fact that *some stuttering events* are almost impossible for anyone but the speaker to detect, because they are marked only by avoidance—possibly by hesitations, silence, or a substitution at the surface. But it is also possible to emphasize, in addition to the producer and perceiver, the stuttering events themselves, in the larger world of common experience. The latter position logically connects the first two. In seeking the simplest, most comprehensive and consistent theory of stuttering—or of *any complex communication disorder*—is it not necessary to take all three of the logical positions of discourse into consideration? Is it not, in fact, logically necessary to examine linguistic discursive

skills in some depth, on a case-by-case basis? Presently, it seems that there is increasing emphasis on real cases rather than abstract descriptions (as in Oller et al., 2010; Gillam, Marquardt, & Martin, 2011; and references cited in these standard works).

Perhaps the most interesting, and certainly the fastest growing, diagnosis on the horizon falls under the large umbrella of the “autism spectrum” (Habakus & Holland, 2010; Oller & Oller, 2010; Olmsted & Blaxill, 2010). The degree of severity of the disruptions experienced in autism ranges from fatal at one extreme to subtle, even difficult to detect at the opposite end. Sadly, the more severe instances are the most common. Under the still prevailing rules of the fourth edition of the *Diagnostic and Statistical Manual of Mental Disorders* (DSM-IV) for diagnosing autism spectrum disorders, according to the Centers for Disease Control and Prevention from 2000–2, roughly 50% of those diagnosed with autism were “cognitively impaired” (Autism Developmental Disabilities Monitoring Network, 2007, p. 20). Other estimates suggest that the incidence of severely regressive autism is probably being underestimated (Hansen et al., 2008) and may account for over 80% of the cases diagnosed in the first decade of the 21st century (Pangborn, 2005, pp. 149–51). However, because of uncertainties associated with diagnostic procedures, definitive estimates cannot be produced.

Language Assessment as Foundational to the Diagnosis of Disorders

Some readers may suppose (as an anonymous reviewer of this chapter argued) that a diagnosis of communication disorder—provided, say, by a pediatrician, psychiatrist, psychologist, or neurologist, or by a licensed clinician (diagnostician) with a master’s or a higher academic degree—can be used as a basis for improving the interpretation of language assessment tasks and procedures whenever disordered persons are among the test takers. However, to suppose *that* involves the assumption that the diagnosis of communication disorders can be achieved *apart from* (or independently of) a valid language assessment. Professionals in many areas of study, especially outside of medicine, are apt to accept this idea, partly on the authority of the medical profession. They may ask or think: Aren’t there standardized toolkits for the identification, diagnosis, and treatment of communication disorders, written by the American Psychiatric Association and the World Health Organization? Therefore why should assessment specialists and practitioners *not* just accept the standard descriptions of disorders and apply them according to the interpretation of language testing and assessment procedures? Why can’t language assessment professionals just take the diagnostic categories, prevalence estimates, and so forth, at face value and go from there?

The reasonable answer is that the valid assessment of language acquisition, language use, and discursive abilities is crucial to the valid diagnosis of communication disorders in general. In cases where bodily deformities, sensory losses, or movement disorders (or a combination of these) produce discursive (linguistic) communication difficulties—either the sort that may result in mild to serious disabilities and in behavioral and emotional consequences downstream, or the sort

that may result in a prison sentence—discursive abilities continue to play *the* central role in the diagnostic process itself (Svensson, 2011). To think that neurologists, psychiatrists, pediatricians, and the like—who are not required to study language acquisition or grammatical theory—can identify, diagnose, and rationally treat such problems without reference to language testing is to stand reason on its head. Language assessment is crucial to the diagnosis of discursive communication disorders. No amount of study of communication disorders will enable the discovery of the milestones of normal development any more than studying random strings of ungrammatical material can lead to the discovery of the grammar of any natural language. Studying a random string of letters, spaces, and punctuation marks—say, **ia'a scteg I. iiii klnoen rdrstyz*—would be a hopeless basis for trying to discover the meaning of a true and well-formed (grammatical) statement like *It's raining like crazy outside*.

To validly identify, diagnose, and treat communication disorders, it is necessary to work in the other direction. It is essential to start from meaningful and successful communications and work toward the identification, diagnosis, and treatment of disorders.

Tests and Diagnostic Tools Currently in Use

Given the importance of human discourse-processing capacities to any complex human assessment, testing, or diagnostic procedure, language testers might expect for it to be commonplace to deploy sophisticated and up-to-date language assessment theory and methods in the diagnosis of communication disorders. However, commercially published diagnostic tests and procedures applied in the field of communication disorders focus predominantly on surface forms: phonetic, phonemic, and morphemic contrasts, with some coverage of phonotactic and morphosyntactic complexities. An exceptional test focusing on the generalized semantic values of single nouns and verbs is the Peabody Picture Vocabulary Test, now in its fourth edition (Dunn & Dunn, 2012). Rarely, however, do tests and assessment procedures attend to the syntactic, semantic, and pragmatic complexities of normal discursive processes. Although for several decades now research papers and books have been calling for, and exemplifying, richer, deeper, and more discursive procedures not only for language testing in general (Savignon, 1983; Valette, 1977), but also for the assessment and diagnosis of disorders (Omark & Erickson, 1983; Hamayan & Damico, 1991; Fourie, 2011), in most instances common diagnostic procedures continue to place emphasis on a narrow range of surface forms and words.

In audiology, for instance, diagnostic procedures are still aimed largely at distinguishing pure tones, single syllables, or carefully selected but isolated words (Dobie, 2011). In speech–language assessments, “language” tests typically focus on whether an individual produces certain distinctions among phonemes, morphemes, and in the surface forms of words (Eisenberg & Hitchcock, 2010). Various tests and procedures seek to elicit some of the famed 14 grammatical morphemes identified by Brown (1973). Also, some testers have tried to finesse the diagnosis of communication disorders in individuals who do not know English well (or at

all) by using what they call “processing-dependent measures” (PDMs). Three such “PDMs” have been deployed (Campbell, Dollaghan, Needleman, & Janosky, 1997). They are widely used and cited in the research literature. A Google search on March 16, 2012 shows 171 citations of the original PDMs, and the Web of Knowledge on the same date lists 91 citing articles. The vast majority of the entries accept the theory that the PDMs developed by Campbell and colleagues do not require prior knowledge of English and can therefore be applied without bias in assessing and diagnosing disorders in individuals with a native language other than English. Three tasks were proposed and have been widely used: (1) “nonword repetition,” which consists in repeating pronounceable nonsense of one, two, or more syllables conforming to English phonotactic requirements; (2) “competing language processing,” which consists in judging the truth value of a simple sentence in English and recalling the last word used in one, two, and so on up to five different sentences; and (3) “the revised token test,” which consists in carrying out simple commands that require the manipulation of objects (e.g., *put the green triangle on the red square*).

To single out just one of many reports endorsing PDMs for diagnosing disorders, Windsor, Kohnert, Lobitz, and Pham (2010) suggest that the nonword repetition task measures “LI [language impairment] and native language experience” (p. 298). None of the many articles consulted (the ones abstracted on the Web of Knowledge) refers, however, to the substantial history of language-testing research using elicited imitation, dictation, and retelling tasks of various kinds as measures of second language proficiency. With reference to the nonword repetition task in particular, Yan and Oller (2008) have argued that knowledge of the phonotactic system of the test language is a dominant factor. Even more obviously, English language knowledge and skills figure in performance on the competing language-processing tasks and on the revised token test. The critical role of English knowledge in the successful performance of such tasks is easily demonstrated by presenting the same tasks to monolingual English speakers in any language other than English. It should also be noted that elicited imitation and repetition procedures, judging the truth value of simple sentences, and demonstrating comprehension by carrying out commands are all well known language-testing procedures. Interestingly, elicited imitation procedures as applied in both testing and therapy by speech–language pathologists are known in the professional argot as “stimulability” tasks or tests. An individual is said to be “stimulable” if he or she is willing and able to repeat presented surface forms. Clearly, when the material to be repeated (or comprehended and judged for truth value, or carried out as a series of commands) contains a significant string of syllables or words in English, the task already involves a significant element of language testing.

More complex discursive procedures—such as engaging in conversation, summarizing a storyline or dialogue, creating a narrative, writing an essay on an assigned problem—and tasks or observational procedures assessing ordinary levels of discourse processing at any age are more difficult and expensive to apply, more time-consuming, and less commonly used than surface-oriented procedures. It is also common knowledge that insurance claim forms, medical coding, and the standardized manuals for defining disorders help to maintain the inertial

momentum by sustaining the emphasis on surface-oriented tests and diagnostic procedures.

Summing Up the Special Problems Posed by Disorders

In assessing discursive language abilities, measurement rarely focuses on sensory abilities, motor skills, or specialized knowledge domains. Rather attention is usually directed toward language proficiencies deployed in the routine handling of commonly known facts of experience. However, disabilities complicate things. For instance, suppose that an international pilot or air traffic controller—all of whom are required to use English as the language of international aviation—tends to stutter when under stress. If the English language testing to which that pilot is subjected does not include tasks that involve high stress contexts where the fluency disorder can be discovered, lives may be at risk when rapid communications under stress are required of that pilot.

The diagnosis and measurement of the severity of disorders must be based on prior knowledge of the milestones of normal development across multiple systems of representation. Therefore a reasonably complete notion of how language and related representational systems typically develop is required for the valid diagnosis of disorders. Useful information toward that end depends ultimately on valid representations. Agreement in the interpretation of complex discursive exchanges is more informative than disagreement. As the number of elements in any vocabulary of combinable units grows along with the length and complexity of strings, the likelihood of an accidentally coherent and interpretable (valid) representation of any complex fact of ordinary experience rapidly diminishes toward a vanishing point. Nevertheless, because of increasingly informative constraints, in ordinary discourse, relatively complete agreement is commonly achieved. It follows that correct responses to test items, agreement on interpretations, convergence of understanding and of representation—in general any of these—must be more informative than any number of failures, breakdowns, errors, or misunderstandings. The latter, after all, are often owed to confusions that can be sorted out with difficulty, if at all. Therefore, comparatively little information can be gleaned from failed or half-hearted efforts at communication. An error can occur for many reasons; but successful communication—understanding or producing complex representations—is a very different matter. Mathematically speaking, it is virtually impossible to stumble accidentally upon any coherent interpretation of a representation of any complex fact of ordinary experience. It follows therefore that we must look to the highest and best (that is, successful) representational efforts in assessing representational abilities, and/or in seeking to determine the level of severity of any representational disability.

Introduction to Volume II

This volume presents chapters on overall approaches, assessment and learning, assessment development, and the use of technology. Specifically, the volume opens with chapters on large-scale assessment, norm- and criterion-referenced assessment, task-based assessment, and computer-assisted assessment. These chapters are critical as the ways in which assessments are designed, developed, scored, and interpreted depend largely on the overall approach to assessment. Chapters on different types of assessments are presented next. These include performance, portfolio, dynamic, and self- and peer assessment, monitoring progress and tracking achievement and growth, providing diagnostic feedback, and training test developers in assessment literacy. Chapters on the details of the development process follow. These include defining constructs and assessment design, writing assessment specifications, writing or selecting items and tasks, texts and response formats, and using test-taking strategies. Field testing, standards and guidelines, statistics and software, standard setting, administration, and detecting cheating complete the development process. The volume concludes with forward-looking chapters on the use of technology in language assessment, specifically the use of new media and corpora, eye-tracking, acoustic analysis, and computer-automated scoring of writing.

Large-Scale Assessment

Janna Fox

Carleton University, Canada

Introduction

Kunnan (2008) defines large-scale language assessment as tests and testing practices that are designed and managed for “uniformity . . . across geographical regions, administration time, test raters and score interpretation” (p. 135). His definition is consistent with discussions of large-scale tests “as those that are administered to groups of examinees over multiple administrations . . . [and] require that the meaning of the test scores remains steady so that appropriate comparisons can be made and trends measured” (Wendler & Walker, 2006, p. 446). Although large-scale language assessment plays a critical role in contexts such as college admission, immigration, or licensing for occupations, Kunnan (2008) focuses on its role in general education and learning, noting that large-scale language assessment has “become increasingly important in the last 25 years in many parts of the world in school, college, and university contexts” (p. 135). He links the rise of large-scale language assessment to educational reform and accountability policies, but he also discusses its importance in considerations of test fairness—a key requirement for test quality and validity (see, for example, Messick, 1989; American Educational Research Association [AERA], American Psychological Association [APA], & National Council on Measurement in Education [NCME], 1999).

Previous Views or Conceptualization

Fairness has long been a goal of large-scale language assessment. Davidson, Turner, and Huhta (1997) highlight its historical origins in the Chinese civil service examination system introduced in imperial China during the Han Dynasty, which

ruled from 202 BCE to 221 CE. The Chinese examination system was designed to select government bureaucrats on the basis of merit (rather than connections, or privilege) and test administration procedures were systematically defined to achieve fairness through uniformity. Durant gives a vivid description of one such procedure:

In the Examination Hall were ten thousand cells, in which the contestants, cribbed and confined, lived with their own food and bedding for three separate days, while they wrote essays or theses on subjects announced to them after their imprisonment. (Durant, 1935, p. 801)

As Durant's account suggests, large-scale language assessment has been associated with: (1) controls for uniformity across test versions, sites, administrations, raters, and interpretations; (2) large numbers of test takers; (3) high stakes; and (4) bureaucratic or accountability agendas. Further, as Davidson et al. (1997) point out, large-scale language assessment places "value [on] centralized control, because it is thought that such control helps guarantee test quality . . . [which] is often checked using statistics" (p. 305). Implicit in the views of these authors is the role that educational measurement has played in achieving (or attempting to achieve) *uniformity* in testing and testing practices. In the following section two key features of the measurement tradition in large-scale language assessment are briefly discussed: specifically, the psychometric properties of tests, development, and validation; and scale development, norm- and criterion-referenced.

Current Views or Conceptualization

Test Development in Large-Scale Language Testing: From Specifications to Validation

The development of a large-scale language test begins with a clear *mandate*, based on the determination that a need can best be addressed by testing. Next, the specific purpose of the test is defined, for example, to assess the proficiency of a second language (L2) applicant to an English-medium university, or to certify the interactional competence of a technician seeking a license to practice a trade. Then the *construct* and content domain are identified (for example the academic language required for undergraduate study, or the communicative skills required of an electrical technician). Given that uniformity across multiple versions and test sites is a goal of large-scale language assessment, the purpose, construct, and content of a test must be defined in sufficient detail regarding the knowledge, skills, processes, and so on, "so that it is clear whether or not any particular item, content, or skill falls within the scope of the test framework" (Linn, 2006, p. 28).

The next critical step is the development of *test specifications* that "delineate the format of items, tasks or questions; the response format or conditions of responding; and the type of scoring procedures" (AERA, APA, & NCME, 1999, p. 38). Test specifications provide test developers with the blueprint or recipe for the development of multiple versions of a test, which are as parallel or similar as possible. In order to ensure maximum similarity, large-scale testing requires ongoing research

to collect evidence that the test is consistently measuring the same construct in the same way across test takers, test administrations, and raters. The higher the stakes of the test, the greater the need for such *validation* evidence.

As Davidson et al. (1997) suggest, much of this evidence has been provided through statistical analysis of test data, scores and performances. Routinely, large-scale testing organizations—for example the Educational Testing Service (ETS), www.ets.org/, developer of such proficiency tests as the Test of English as a Foreign Language, Internet-based test (TOEFL iBT); or the University of Cambridge English for Speakers of Other Languages (ESOL) Examinations, www.cambridgeesol.org, developer of the International English Language Testing System (IELTS)—publish studies that investigate the quality of item/task function using statistical approaches informed by either classical test theory or item response theory (IRT). They also investigate test fairness through statistical analysis of items, to determine if items function differently for some groups of test takers on the basis of age, gender, language background, and so on, through differential item functioning (DIF); and they use generalizability theory to investigate the sources of measurement error.

Scale Development in Large-Scale Language Assessment: Controlling for Uniform Interpretation

Statistical analysis also plays a role in developing scales, which define what test performances mean. “The primary goal in scaling is to create scores that aid interpretation” (Linn, 2006, p. 35). Scaled scores are derived from raw scores, which have been converted in order for their meaningfulness to increase. Norm-referenced scale scores (e.g., percentile, rank, or grade-referenced) provide a meaningful comparison of how the performance of an individual test taker compares to a group norm or to a reference population. TOEFL iBT scores, for example, range from 0 to 30 for each section of the test (i.e., listening, reading, writing, speaking) and from 0 to 120 for the total test score. ETS statistically anchors the interpretation of these scores in several ways. For example, it relates scores on each of the sections of the test and on the total test score to earlier TOEFL versions, to the Computer Based Test (CBT), and to the Paper Based Test (PBT) by score point and range. It also publishes standard-setting research with universities that have established required cut scores on the TOEFL iBT (see www.ets.org/TOEFL), and it provides support for institutions that wish to carry out their own standard-setting sessions. Further, it relates scores on TOEFL iBT to other well-established tests of proficiency such as IELTS (see www.ielts.org/).

Criterion-referenced scales consist of categories or descriptors that define levels of performance. In recent years there has been increased interest in criterion-referenced scales that relate test scores to descriptions of what learners can do across increasing levels of proficiency. Early work in the 1980s gave rise to the American Council on the Teaching of Foreign Languages (ACTFL) guidelines, which Swender (cited in Fulcher, 2007) referred to as “the de facto framework for describing language performance in the USA in both education and the workplace” (p. 159). More recently, the Common European Framework of Reference for Languages (CEFR) links a six-level scale (A1, A2, B1, B2, C1, C2) to descriptors

that define standards to be attained at progressive stages of language learning and identifies outcomes that allow for international comparisons. When the CEFR was first launched in Europe in 2001, it was designed as a generic description or taxonomy of language ability, for application to all languages. In recent years, however, reference level descriptions (RLDs) have been developed for national and regional languages (see www.coe.int/). A number of other criterion-referenced scales, which, like CEFR, provide a taxonomy of language-learning stages, have been developed outside the European context. See, for example, Fulcher (2007) for a discussion of the Canadian Language Benchmarks (CLB) or www.language.ca/.

Current Research

Conflicting Views of Large-Scale Assessment

Fulcher and Davidson (2008) question whether large-scale language testing, “important as this is, can be directly applied to the classroom” (p. 23). They first critique notions of validity as these apply to large-scale testing, questioning their relevance in relation to the day-to-day interactions in the classroom. They argue that large-scale language testing is concerned with the provision of aggregate information and takes a psychometric view, which limits context to “the environment where the test takes place” (p. 25). Indeed, they argue, from a measurement perspective context can contribute to construct-irrelevant variance (Messick, 1989), if it is not controlled or neutralized—for example, if a score is enhanced due to a contextual factor (say, because a passage to be listened to is played twice rather than once by a sympathetic proctor), or if it is undermined (say, because of a noisy roadway, which is just outside the room where a tape-recorded listening comprehension test is being administered). According to Fulcher and Davidson (2008), such contextual factors are not part of the construct—not part of what is being measured—and therefore they introduce error in the measurement. From a classroom perspective, however, they argue that the “context is part of the construct” (p. 25); the learning environment is shaped by contextual factors—interactional, experiential, and uniquely individual.

Further, they contrast a teacher’s local and situated assessment of student performance with the attempts of large-scale testing to control for marking consistency; to favor marking by machines or by machine-like raters, “so that the humans do not become part of the score meaning” (p. 27). In classroom assessment “the teacher is familiar with each and every learner” and assesses “the current abilities of the learner in order to decide what to do next, so that further learning can take place” (p. 27):

[In] the classroom learning environment it is feedback to the learner, from any source, that helps him or her to identify what needs to be learnt next [in order for him or her] to become an independent user of language in a new context. This means that the feedback must contain diagnostic information, and this is not usually found in formal tests. (Fulcher & Davidson, 2008, pp. 28–9)

Thus Fulcher and Davidson (2008) conclude that large-scale language assessment can be of little relevance to the dynamic interactions that characterize learning

and developmental changes at the classroom level. Their perspective may have been informed by the present educational climate, in which large-scale language assessment, motivated as it is by educational reform agendas, is frequently used to hold schools accountable for learning. Indeed, the link between large-scale language assessment of school-age learners and educational accountability agendas is an international phenomenon, which is particularly evident in tests of literacy (Leung & Lewkowicz, 2007). Perhaps the most prominent example of this phenomenon is found in the United States as a result of the No Child Left Behind (NCLB) policy (Chalhoub-Deville & Deville, 2011), “which entails a punitive system of sanctions for schools and educators based on student performance (defined in large part by test scores)” (p. 307). A number of powerful large-scale tests, aligned to exacting external curricular standards, have been funded through the NCLB’s Enhanced Assessment Grant program: for example the Comprehensive English Language Learner Assessment (CELLA), the English Language Development Assessment (ELDA), the Mountain West Assessment (MWA), or the Assessing for Comprehension and Communication in English State-to-State for English Language Learners (ACCESS for ELLs). Concerns about the impact of NCLB testing on ELLs in the United States are similar to those raised in McKay’s (2000) discussion of school accountability agendas in Australia, the development of literacy benchmarks and their assessment, or in Fox and Cheng’s (2007) consideration of the impact of the Ontario Secondary School Literacy Test (OSSLT) on ELLs in Canada.

Kunnan (2008) also acknowledges that large-scale language assessment has generally served external bureaucratic or accountability purposes that impact language learners and their teachers. He argues, however, that large-scale language assessment also has the potential to address local pedagogic and learning agendas of teachers and students at the school or classroom level. Assessment can provide timely, constructive, and useful “diagnostic information to all stakeholders (teachers, students, parents, school administrators, etc.)” (p. 135), and, as a diagnostic or learning tool, it can be used to inform stakeholders at classroom and curricular levels.

Three recent initiatives corroborate Kunnan’s view that large-scale language assessment can support teaching and learning: (1) the development of formative assessment approaches in large-scale NCLB testing of school-age ELLs, (2) large-scale approaches to diagnostic assessment at university level, and (3) portfolio-based assessment initiatives of adult immigrants.

Although the NCLB testing of school-age ELLs has tended to focus on learning outcomes or on the summative assessment of achievement, there is increasing work being done on large-scale formative assessment such as the Formative Language Assessment Records for ELLs (FLARE) project, a spin-off of the body of work surrounding the ACCESS for ELLs test.

The Diagnostic English Language Needs Assessment (DELNA) (Read, 2009) is one of a number of *large-scale diagnostic assessments* that have emerged in the past few years. Developed at the University of Auckland, the assessment is administered to all entering first-year undergraduate students in order to provide a free check of their academic language at the beginning of their university program. If the check reveals weaknesses, additional diagnostic assessment takes place, along

with academic counseling and recommended course or tutorial support. The DELNA is leased by many universities around the world.

Although portfolios have been used in large-scale assessment with varying degrees of success (see Fox, 2008, for a review), newer portfolio initiatives, like the Council of Europe's European Language Portfolio, may encourage self-assessment and showcase plurilingual and pluricultural capability. Another example is the Portfolio-Based Language Assessment (PBLA) initiative, introduced by Citizenship and Immigration Canada (CIC) to support learning and teaching in Language Instruction for Newcomers to Canada (LINC) courses. This large-scale assessment initiative is designed to support self-assessment and to encourage the systematic interpretation of language development in relation to criterion-referenced proficiency benchmarks codified in the CLB.

Such initiatives in large-scale assessment are not without challenges. Some of the key challenges evident in the literature on large-scale assessment are discussed in the next section.

Challenges and Future Directions

As Kunnan (2008) suggests, the potential of large-scale assessment is this: systematic or stable forms of assessment may not only increase our knowledge of overall achievement, but also lead to timely and useful interventions that support teaching and learning directly. Some argue that a critical question for large-scale assessment is the degree of precision with which teachers and learners can use the information provided by large-scale testing to improve learning (see Fox, 2009; Read, 2009).

A second issue highlighted in the literature relates to the potential misinterpretation of the results of large-scale language assessment. Within educational contexts there is a growing recognition of the critical need to increase the assessment of literacy and, along with this, an acknowledgment that there are few assessment courses for prospective teachers, in spite of the critical role that assessment plays in teaching and learning.

Finally, the use of large-scale language assessment to implement policy is of increasing concern, particularly in such controversial contexts as immigration and citizenship testing. McNamara and Ryan (2011) argue that uniformity in testing and testing practices and the preoccupation of language testers with fairness as a feature of test quality (achieved largely through psychometric means) ignore larger issues of justice. They note that, "the more technically perfect a test, the harder it is for opponents of the test to get a foothold on its shiny surface" (p. 174).

Spolsky (1995) reminds us that concerns over the social impact of large-scale tests and testing practices have been raised since their first widespread appearance in Europe in the 15th century. His is a reminder worth noting. In future, large-scale language assessment will increasingly be evaluated not only for the technical quality of tests and testing practices, but also in relation to the socio-political contexts in which it is used and the overt (and covert) agendas it serves (Shohamy, 2001).

Norm-Referenced Approach to Language Assessment

Jungok Bae

Kyungpook National University, Republic of Korea

Introduction

Comparing one thing with another is one of the most basic of human intellectual activities. A variety of techniques have been developed to make this fundamental activity more meaningful, valid, and accountable. The norm-referenced (NR) approach to assessment provides a standard for comparisons. It remains to date the paradigm for many externally mandated high stakes tests (Fulcher, 2010).

This approach stands in contrast to the alternative paradigm, the criterion-referenced (CR) approach (see Chapter 34, *Criterion-Referenced Approach to Language Assessment*), which emerged historically in response to perceived problems in what some called the “pervasive” NR testing of the day (Brown & Hudson, 2002, p. 6). In the CR approach, attention is given to whether a specified criterion is achieved and to what degree, independent of any reference to the achievement of others (Glaser, 1963). This approach was founded in the educational field by Glaser (1963) and Popham and Husek (1969) in the 1960s; however, in the field of language assessment the active use and discussion of CR have been relatively recent (Hudson & Lynch, 1984; Brown, 1989, 2005; Kunnan, 1992; Brown & Hudson, 2002; Davidson & Lynch, 2002). NR assessment, however, has been practiced for more than a hundred and seventy years (e.g., Quetelet, 1835, where he introduced the concept of the “average man”).

While language assessment has retained its uniqueness as a discipline (Davidson, 2004), much of it operates using logic and principles established within the disciplines of educational and psychological testing, fields which were prominent in developing the NR assessment approach. Because of its prominence in these fields, it is important to understand the NR approach as a basis for language assessment.

The first section of this chapter addresses the purpose of NR assessment and score interpretation. The second section addresses test development in the NR framework. This includes NR test content and variations. It also covers item analysis, which cannot be excluded from the NR approach. The final part of the chapter addresses norms, from which the term “norm-referenced” is, of course, derived.

In this chapter, the NR approach will be addressed based on classical theory. There are other tools that can be useful for developing NR tests, including item response theory (Chapter 75, Item Response Theory in Language Testing), Rasch analysis (Chapter 77, Multifaceted Rasch Analysis for Test Evaluation), generalizability theory (Chapter 72, The Use of Generalizability Theory in Language Assessment), factor analysis, and structural equation modeling (Chapter 73, Exploratory Factor Analysis and Structural Equation Modeling). Such a discussion is outside the scope of this chapter.

NR Assessment Purposes and Score Interpretations

The purpose of NR assessment is to make a decision about test takers’ performance in comparison with those who have taken the same test. Performance results are reported and interpreted with reference to the performance of all other test takers on the same test. Suppose that an elementary school student in a language arts class earned a raw score of 74. How would parents know what a raw score of 74 meant? Traditionally, two approaches have been used to interpret scores. If the parents were informed that a perfect score was 100, they could interpret their child’s score, understanding that the child had achieved 74% of the total possible points. The parents might conclude that this 74% achievement was not very satisfactory compared to total mastery of the subject at 100%. They would have the ready figure of 100% as a criterion for success, against which they would find their child wanting. This is a CR interpretation of a score.

It is natural, however, that the parents would also wonder about how the other students did on the test. The NR assessment is better prepared to address this question because it provides comparative information. Such an assessment may inform the parents that *only three* other students scored higher than their child’s 74, while *thirty* other students scored lower than 74. So in fact, their child had actually done quite well compared to the performance of the majority of the other students in the class. This example shows another aspect of the child that might have been overlooked if the CR assessment were used exclusively. Beyond looking simply at how a student ranks within his or her class, this example points to the kind of additional clarity that can be brought to a situation by understanding a student’s score in relationship to groups that can be defined around him or her, whether age group, gender, language group, local, national, global, or however you define them. An NR interpretation makes any of this possible, and gives parents, administrators, and researchers the opportunity to see this child and any of these groups in an objective and fungible manner. Further examples of the application of NR and methods of score interpretation will be given as the chapter develops.

NR Test Development

Language tests in the NR framework are designed to be useful for achieving a primary purpose, which is to determine test takers' relative level of performance. This is really "to detect sufficient differences among test takers" so that sensitive comparisons can be made with those who have taken the same test (Popham, 2001, p. 27). Given this purpose, NR tests have been developed with the following characteristics.

General Test Content

In NR assessment, the test content is described only in general terms. NR test results are often used in the process of admitting candidates into a program, placing students in appropriate classes, and determining what level of language proficiency candidates have in cases where only a rough estimate of language proficiency is needed. The test instruments used for such purposes are called proficiency tests. Examples include the Test of English as a Foreign Language (TOEFL), the International English Language Testing System (IELTS), the Modern Language Aptitude Test (MLAT), and a variety of English as a second language or as a foreign language (ESL/EFL) placement tests. Test takers come from a variety of educational programs, regions, and countries. The test content in these proficiency tests is independent of the content covered in specific educational programs and contexts. A description of the content domain for such tests, that is to say, a definition of the abilities to be tested, would have to be more general (language skills, writing skills, reading ability, listening ability) than specific (the ability to write a narrative essay, listen to and comprehend advertisements, or understand grammatical parallelisms).

Consider TOEFL and IELTS, which are proficiency tests. These tests aim to help university officials determine whether candidates have a sufficient command of English to pursue graduate studies in an English-speaking country. The potential candidates are from across regions and educational programs. Their prospective academic disciplines vary. To include all of this variety, the specification of the content domain should be broad and general. The public only need to know that TOEFL assesses academic English proficiency in reading, listening, speaking, and writing. Contrary to the emphasis given to the importance of having clear, delimited descriptions of test content in CR test design (Brown & Hudson, 2002; Davidson & Lynch, 2002), NR test designers like those of the TOEFL and IELTS are not concerned with specific descriptions of the abilities being tested, such as "Task 1 measures the ability to write a lab report."

Companies that produce standardized proficiency tests typically provide a manual in which the test content is introduced. In them, detailed descriptions of the test content are neither necessary nor expected. Information such as test format, subparts, sample items, and number of items with general descriptions suffice.

Variation as the Primary Emphasis

A good NR language test should be designed to result in a good dispersion of scores. Consider placement tests, for example. Their purpose is to assign

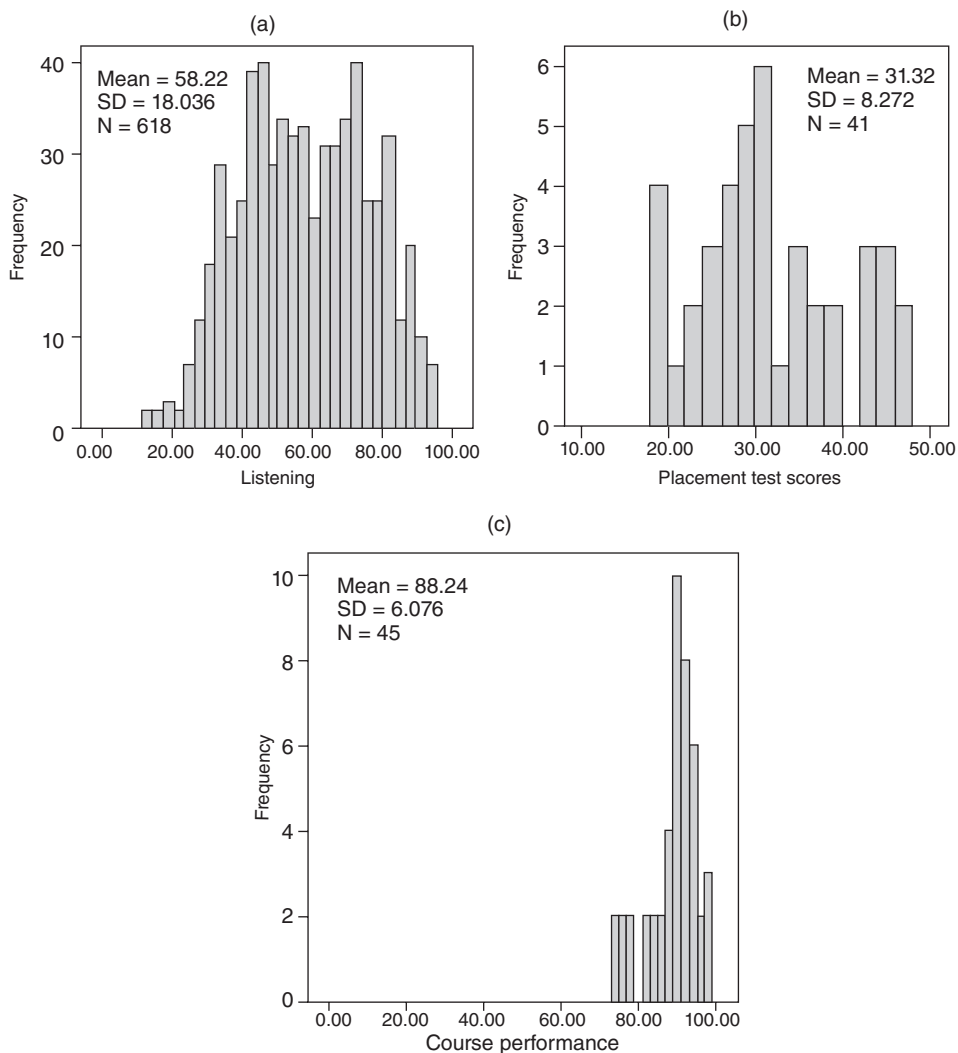

Figure 33.1 NR score distributions

newcomers to a level of language class that is most appropriate for their current proficiency. To establish the students' levels compared with the range of available class levels, the test items should have the power to discriminate between the candidates' proficiency levels. The scores that result from a well-functioning placement test will range from low to high, assuming that candidates with a matching range of abilities participated in the testing. (See Figure 33.1(b), where the scores range from 19 to 48.)

Another type of NR proficiency test is one used for admitting candidates to a program that accepts only a limited number of students. The Center for English Education for Gifted Youth (CEEGY) (<http://ceegy.com/index.asp>), operating at Kyungpook National University, admits only 30 students every other year into a program where they are privileged to receive, free of charge, a very special kind of education for two years. Since parents are interested in gifted education and

the center is fully funded by the city board of education, several hundred youths apply each time admission is opened. The center administers proficiency tests, including tests of listening, reading, and creative writing skills, to identify the most proficient students. The test items must be designed to spread out performance results so that the program can accurately discover the differences among the hundreds of test takers and select those 30 who perform the best.

The placement and selection tests mentioned above are NR tests; the tests' content domain is general and the students' scores must be compared with those of all test takers. Let us look at the score distributions from these tests.

In Figure 33.1, histogram (a) shows scores from the listening test introduced above. Histogram (b) shows scores from the placement test, mentioned above. These tests did generate a wide dispersion of scores along the ability continua, generating an approximately normal distribution (see properties of normal distribution in the section below on "Norms").

Compare these histograms with histogram (c), which shows scores from a CR assessment. The scores were generated from an evaluation of students enrolled in a university undergraduate course called "methodology for English language teaching." At the end of the course, most students achieved close to the mastery level; thus, the score distribution became negatively skewed with a smaller dispersion.

Item Analysis

In well-functioning NR assessments, item analysis is performed to generate a greater spread within test scores. In this process, a large number of items are administered to test takers, who can be real test takers or those similar to the target group. Based on the test takers' responses on the items, the items are analyzed for their effectiveness. Analyzing items involves three aspects, and if you know these three aspects, you know the essentials of item analysis. They are item difficulty, item discriminating power, and distracter analysis. Together they determine item effectiveness in the NR perspective.

The item analysis principles presented below also appear in essence in a variety of statistics books. The procedure for conducting item analysis, as outlined in Gronlund and Linn (1990, pp. 247–8), is given below.

- Rank all students from highest to lowest based on their total score.
- Select the upper 25% and the lower 25% of the total number of students. (Others recommend 27%.) When there is a smaller number of students (e.g., 20), use all of them and divide the entire group into upper and lower groups (10 each).
- Put aside the middle group. It is assumed that the responses of the students in the middle group follow essentially the same pattern.
- Prepare a table for item analysis of each test item (see Table 33.1).
- For each item, tabulate the number of students in the upper and lower groups who selected each of the alternatives.
- Compute the p - and d -values based on the answer choices made.
- Evaluate the effectiveness of the distracters for each item.

Table 33.1 Example showing tabulation for item analysis

Item # 26

	Alternatives					Omits	Indices	
	1	2	3	④	5		Item difficulty (P)	Item discriminating power (D)
Upper 9 students		/		###			$\frac{5}{18} = 0.28$	$\frac{5}{9} - \frac{0}{9} = \frac{5}{9} = 0.56$
Lower 9 students		### /	/					
<i>Comment</i>								

Note. The correct answer is alternative 4, marked by the circle around it. This form is an application of the example sheet provided in Gronlund and Linn (1990, p. 248).

Item Difficulty Item difficulty refers to the proportion of test takers who answered each item correctly. The formula is given below.

$$p = \frac{\# \text{ right}}{\# \text{ total}}$$

The # *right* stands for the number of test takers (selected for use in the item analysis) who answered the item correctly, and # *total* represents the total number of test takers (selected for use in the item analysis) on the test. Therefore, if eight out of ten students got an item right (8/10), the *p*-value would be .8, meaning that 80% of the entire group got the item right. The *p*-values range from 0 to 1, so that 0 means that no one answered the item correctly and 1 means that everyone did. A *p*-value of .5 indicates an item of medium difficulty. Thus, the greater a *p*-value is, the easier an item is. In a way, the *p*-value represents the *ease* of an item rather than its difficulty. For this reason, the *p*-value is also called an item *facility* index. When selecting items, an item with a *p*-value of around .5 is considered potentially a good item. In the absence of "good" items, $p = .3-.7$ can still work well.

Item Discriminating Power Item discriminating power is the extent to which an item discriminates between students with high and low ability. The formula below is the one that appears in Brown (2005):

$$d = p_{\text{upper}} - p_{\text{lower}}$$

where p_{upper} is the item difficulty index of the upper group, and p_{lower} is that of the lower group. It is possible for *d*-values to range from -1 to 1. Let us imagine three extreme cases for *d*.

First of all, let us look at $d = 1$. If $d = 1$, then everyone in the upper group answered the item correctly ($p_{\text{upper}} = 1$), and no one in the lower group got the item right ($p_{\text{lower}} = 0$); therefore, the item's ability to differentiate between students who can and cannot answer correctly is the greatest possible. The higher the d -value of an item, the greater its discriminating power.

Next, let us consider $d = 0$. Suppose that the same number of students from both the upper and lower groups got an item right. This would make the values for both p_{upper} and p_{lower} the same, and so the d -value would be zero. The discriminating power of this item therefore is nil. Items like this are completely ineffective from the NR perspective.

Finally, let us consider $d < 0$ (d is negative). Suppose more test takers from the lower group got the item right than those of the higher group. Then p_{upper} would be smaller than the p_{lower} , resulting in a negative d -value. Unfortunately, this item is discriminating in the opposite direction. This phenomenon does happen in real life, and why it does would be an object of investigation.

In selecting test items, those with a high d -value are preferred. To follow Ebel's recommendation (1979, p. 267, quoted in Popham, 1990, p. 277), generally items with a d -value above .4 are considered very good items. Items with a d -value below .4 and above .2 are considered potentially good, but are in serious need of improvement. Items with $d = .4$ can be either very good or potentially good. Items with a d -value below .2 are poor items, to be removed or saved only with revision.

So when considering p - and d -values together, the best items would have medium p - and high d -values. It may be that items satisfactory in *both* respects will not be available in sufficient numbers. Some items may satisfy the d - but not p -values, or vice versa. Organizations administering large-scale testing may have the financial and human resources to develop a large number of items, pretest them on a large number of test takers, and run item analyses during their test development process. For small-scale testing, teachers and researchers often do not have an item pool with a sufficiently large number of items. In these cases, items may be pretested on a small group, item analysis can be done by hand calculation, and defective items may then be revised. The process of item analysis for small-scale testing is illustrated below. It should be made clear here that the purpose of all this analysis is test revision, to select items that are working well as NR items, and to remove ones that are not, or perhaps to save them with revision.

Illustrations This section illustrates the item analysis procedure outlined above, using the results of a practice test. The test was developed by the members of a department of English education faculty, including the author of this chapter. The purpose of the test was to help students prepare for a new, highly competitive, English-teacher certification exam.

Briefly, the practice test had 40 items and was administered to 36 undergraduate students. The students' answer sheets were scored and sorted from the highest to the lowest. The nine answer sheets belonging to the upper group (25% of the 36 who took the test) were pulled out, and likewise for the lower group of nine students. A table for item analysis was drawn up (see Table 33.1). The numbers of

students who selected each of the alternatives were tabulated in both groups. This was done by noting which alternatives each student chose. The tabulation is presented in Table 33.1. The p - and d -values were hand-calculated based on how many students selected the key (i.e., correct answer).

All items were then organized in one table (Table 33.2), and this table was presented to the item developers to improve the items.

Items with problematic p - and d -values are subject to revision. In Table 33.2, a few items are very good: items 12 and 23 have d -values higher than .4 with a medium p . Items in the fairly good range are items 4 and 30. Other items are either only marginally good or poor. Some items are completely ineffective, having a negative d -value (e.g., item 36). Items 8 and 9 are too easy with very high p -values, thus having no discriminating power ($d = 0$). We see an item that no one got right (item 32, $p = 0$), which therefore failed to discriminate between those who studied and those did not ($d = 0$). Such items should be rejected, if we had any conscience, but are often used anyway, in the absence of quality test items.

Distracter Analysis What can test designers do to revise defective items? This leads to the third topic in item analysis: distracter analysis. A good distracter appeals to people who do not know the answer. When students who do not know the right answer select a distracter, that distracter has done its job by attracting them. Ideally, if all of the distracters function as intended, they should all be appealing to students who are not able to answer correctly. A distracter chosen by no students just occupies space in the test book.

In Table 33.2, we can see item 26 had pretty good discriminating power ($d = 0.56$), and this item was relatively difficult ($p = .28$). It is a satisfactory item based on the d - but not on the p -value. Looking at distracter behaviors for this item (Table 33.1),

distracter 1 has no worth because no one chose it. It may be possible to revise this distracter so that it looks less obviously like a wrong choice, so that it may then attract some people. Distracters 2 and 5 were functioning as intended because more students from the lower-scoring group did choose them. Distracter 3 was poor because it attracted more students from the higher-scoring group and very few lower-scoring students. This alternative should be improved to make the distracter somewhat more attractive to the lower-scoring group.

Challenges: Ensuring Items' Content Quality

Something to be aware of when looking at item statistics is what happens to the content-related validity of the items. Attention to item statistics can turn our attention away from their content quality. Several items may be relevant to and representative of the content domain, and so have good content-related validity. If, however, after pilot testing, those items turn out to yield unsatisfactory p - and d -values, they may be viewed as defective from the NR perspective. These items are likely to be trashed, or may be saved through revision. The revised items, however, may now be only marginally related to or poorly representative of the content domain. Thus, while it is legitimate for NR test developers to try to generate a greater spread within test scores, they should be aware that they may be increasing the items' discriminating power at the expense of their content quality.

Therefore, the challenge is to maintain content validity while ensuring the discriminating power of test items. I suggest the following strategy:

- Design a sufficient number of items beyond the number of items minimally required for a test, giving priority to content quality.
- Conduct an item analysis (or at least roughly review test takers' answers to the items to get a sense of the p and d , although, obviously, actual calculations are preferable).
- Select items based on the p - and d -values.
- Revise items that fall below threshold values, being careful to maintain a strong awareness of *content validity*, rather than considering only the statistical worth of the item.

In the process of item analysis, some items will be rejected. Others can be revised or would not "pass the test." If, however, you designed a sufficient number of items at the beginning, "giving priority to content," you should not find yourself in a panic at the last minute trying to revise some relatively poor items that did not perform well in item analysis.

Norms

This final section addresses norms. Norms are comparative data, which are used to represent test takers' scores in comparative and defensible terms. These norms are referenced as the basis for determining an individual's relative standing on a

test, which is why the approach is called *norm-referenced*. When making comparative evaluations, a particular group of test takers is referenced. For a small-scale assessment, the group to which the test takers themselves belong (for instance, all classmates) is referenced. However, for a large-scale test, the reference group becomes, for instance, all of the high school students in a country. Before test developers make a test public, they administer it to a large number of test takers that can represent those for whom the test is intended. This group is traditionally called a “norm group,” which is a type of reference group. The statistical results of test scores from the norm group are compiled and called norms or normative data. A standardized test comes with a manual or other documentation which includes these norms. The test is then said to be “normed” with respect to the representative group of test takers (Gronlund & Linn, 1990; Bachman, 2004).

Many large-scale standardized tests are normalized with respect to different subgroups. For instance, private schools and public schools may demonstrate different performances, and test developers can stratify (i.e., differentiate) the norms based on the school type. Norms can be stratified by subgroups, such as school grades, age, gender, ethnicity, and national, local, or global levels, and performance can be evaluated with regard to these separate norms.

Types of Norms

In this section, we will focus on several types of norms: the normal curve, standard scores, and percentiles. As we do so, we will also look at the origin of norms and the ways in which norms are displayed and reported in the real world.

The Normal Curve A distribution of scores from a typical population that is ideal for comparing the scores of test takers is the normal curve, or normal distribution. Figure 33.2 shows this curve, commonly called “the bell curve.” The normal curve is a theoretically generated distribution with useful statistical properties.

Psychometricians have found that the normal curve has the following properties. First, the mean of the group is the median (the middle score); therefore, half of the raw scores fall below the mean, and the other half above the mean. The distribution of the raw scores is thus symmetrical. Second, the distribution is further partitioned into units of standard deviation (Standard deviation is a measure of how spread the scores are from the mean; it is “a sort of average” of the distances of the scores from the mean, to use Brown’s [2005, p. 103] phrasing.) Each area partitioned by the standard deviations contains a fixed percentage of scores. We can describe students’ relative standing in reference to units of standard deviation in this normal curve system. In Figure 33.2, vertical lines have been drawn from the curve to the baseline at one standard deviation, two, and three standard deviations above and below the mean. About 68 percent of the scores fall within plus or minus one standard deviation of the mean (approximately 34% below and another 34% above). Within two standard deviations of the mean, we can find about 95% of all the scores. Ninety-nine percent of the scores fall all within plus or minus three standard deviations of the mean. Thus, almost all scores under the normal distribution can be expressed by the ± 3 standard deviations from the mean.

Figure 33.2 Proportions of scores in the normal curve and corresponding scores
 This figure has combined and adapted two figures appearing in Gronlund and Linn (1990, pp. 350, 355) in a condensed form to be suitable for the content presented in this chapter. The proportions (%) are rounded numbers.

The theory behind this is that if we observe a certain variable (be it language ability, a psychological attribute, or any kind of observable human behavior) among a large enough number of people (called a population), the dispersion of the scores measuring that variable typically would show the same pattern of the normal curve above. A particular test taker’s score on that variable could then be compared to this normal curve, the pattern demonstrated by a typical population.

Let us look further at what it means that standard deviation units can express relative position. For this purpose, an example adapted from Gronlund and Linn (1990, p. 351) is useful (see Figure 33.2). Raw scores from two different tests have been printed beneath the scale showing standard deviations. Tests A and B have the following means (*M*) and standard deviations (*SD*):

	<i>M</i>	<i>SD</i>
Test A	56	4
Test B	72	6

We know that Test B is easier (because the mean is higher) and that Test B has a greater dispersion of scores. The mean of the raw scores has been placed at the point where the deviation from the mean is zero, which is the mid-point on the baseline. (Remember, *SD* is a measure of the dispersion of scores from the mean, so a raw score which happens to be a mean score will have zero distance from the mean, and therefore, the *SD* for the mean is zero.) Notice that +1*SD* is equivalent to 60 (i.e., 56 + 4) on Test A and 78 (i.e., 72 + 6) on Test B. Notice also that 2*SD* corresponds to 64 (56 + 2*4) on Test A and 84 (72 + 2*6) on Test B. In this manner, all of the raw scores on the two tests can be converted to

standard deviation units. Since the “standard deviation’s distance is the common unit of measurement” (Popham, 1990, p. 149), and since we use that on the baseline, it is useful for making comparisons of scores on tests. For instance, a raw score of 48 on Test A equals a score of 60 on Test B, because both scores are 2 *SD* units below the mean.

Standard Scores A standard score indicates where the test taker’s score falls in relation to the mean of the group, that is, above or below the mean, and to what degree. A standard score gives this information in equally sized standard deviation units. Thus, it has great mathematical usefulness. There are several types of standard scores, and readers will find more detailed information in many traditional books on statistics. In the sections below, the essence of several standard scores will be introduced.

z scores: A *z* score describes in standard deviation units how far a raw score is above or below the mean of a group. The formula for obtaining *z* scores is as follows:

$$z = \frac{X - M}{SD}$$

where *X* is a raw score, *M* is the mean of the raw scores, and *SD* refers to the standard deviation of the raw scores. For instance, using the example scores calculated earlier (Figure 33.2), the *z* score for the raw scores 60 and 64 on Test A (*M* = 56, *SD* = 4) are shown below:

$$z = \frac{60 - 56}{4} = 1 \quad z = \frac{64 - 56}{4} = 2$$

Notice that a *z* score of 1 means that the raw score from which the *z* was derived falls one standard deviation unit above the mean of the raw score distribution. If the raw score is smaller than the mean, the *z* score will be negative (–). For instance, a raw score of 44 on Test 1 (Figure 33.2) would lead to the following result: $44 - 56 / 4 = -3$. The *z* scores range from –3 to +3, and this range explains virtually all of the distribution’s raw scores. If we transform all of the raw scores into *z* scores, the mean of the *z* score distribution will be zero, and the standard deviation will be 1. (See Figure 33.2 for *z* scores expressed in the normal curve.)

T scores: Since *z* scores contain negative values and decimals and the mean is zero, they are somewhat difficult to interpret. To avoid this, *z* scores can be modified using a linear transformation. *T* scores are one example of this. *T* scores are obtained from *z* scores by the following formula:

$$T = 50 + 10z$$

Multiplying by 10 gets rid of the decimal element of the *z* scores (except in cases where *z* includes two or more decimal places; then it can additionally be rounded to make the value an integer), and adding 50 removes the minus sign. So, then, in the distribution of the *T* scores, the mean becomes 50, and the standard

Table 33.3 Percentages for stanines (KICE, 2012b, p. 16)

Stanines	1	2	3	4	5	6	7	8	9
%	4	7	12	17	20	17	12	7	4
Cumulative %	4	11	23	40	60	77	89	96	100

deviation becomes 10. (See Figure 33.2 for how T scores are expressed under the normal curve.)

Because T scores are easier to interpret, assessment programs often use *them* in reporting scores. For instance, the Spence Children's Anxiety Scale (SCAS) (Spence, 1998) measures a child's anxiety levels. Raw SCAS scores are rescaled to T scores with a mean of 50 and an SD of 10. According to SCAS information (Spence, 2012), scores *within* 1 SD (i.e., a T score of 10) above the mean (50) are considered within the normal range. Spence (2012) also recommends that a T score of 60 (or 65) be used as indicative of an elevated level of anxiety.

Stanines: Stanines (a term derived from *standard nines*) are single digits numbers (1–9) that divide the normal distribution into nine parts. To illustrate the use of stanines, let us look at the Korean College Scholastic Ability Test (KCSAT). The KCSAT measures the academic abilities of Korean high school students for college admissions. The Korean Ministry of Education, Science, and Technology annually commissions the Korea Institute for Curriculum and Evaluation (KICE) to develop and implement the KCSAT. According to KICE (2012a), in reporting scores for the subjects of English and Korean language, among others, raw scores are transformed to z scores first, and these are then converted by linear transformation (using a formula: $100 + 20z$) so that they have a mean of 100 with an SD of 20. (These transformed scores may be referred to as KCSAT standard scores.) These scores are also rounded off to an integer, and are divided into stanines as can be seen in Table 33.3.

Using the fixed proportions (Table 33.3), the highest 4% of the standard scores (which appears, perhaps surprisingly for Western readers, on the left in this chart) are given a stanine score of 1, and the next 7% a stanine of 2 (the cumulative percentage for stanines 1 and 2 becoming 11%), and so forth. The middle 20% of standard scores are assigned to a stanine of 5, and stanines continue to 9 on the right, where the lowest 4% of the scores are shown, and finally 100% of the cumulative scores are represented. (This numbering is in the reverse order from the way a stanine scale would usually be shown in traditional Western statistics books: see the stanine scale in Figure 33.2. Obviously, KCSAT assessment professionals took into account that number 1, rather than 9, is a more familiar symbol to stakeholders to represent the best rank, as in “#1 Teacher”).

The stanine scale is a rather “gross” scale consisting of only nine values to represent all of the standard scores; however, stanines are useful for providing a rough approximation of test takers' performance relative to others who have taken the same test (Popham, 1990, p. 157).

Table 33.4 shows a sample report form for the KCSAT, which provides, for each subject field, a test taker's standard score, stanine score, and percentile rank (the last of which, percentile rank, is detailed in the next section).

Table 33.4 Example: KCSAT report card (excerpt)

<i>Registration Number</i>	<i>Name</i>		<i>Resident ID</i>
12345678	Hong Gil-Dong		940905-1234567
<i>Tests</i>	<i>Korean Language</i>	<i>Mathematics</i>	<i>English</i>
Standard score	131	137	141
Percentile rank	93	95	97
Stanine	2	2	1

Note. This report card is an abbreviated version of a report form as illustrated in KICE (2012b, p. 16). Only three subjects are illustrated in this excerpt.

Percentiles A percentile, or percentile rank, is one of the most commonly used norms. This statistic states the percentage of the other scores in the norm group falling at or below the individual test taker's score. It expresses a test taker's relative standing in terms of the percentage of other test takers' scores falling at or below his or hers. If Jane "scored at the 72nd percentile," it indicates that 72 percent of the students in the norm group achieved a score at or below Jane's score. A percentile only gives information about an individual's score relative to the scores of others. Percentile scores do not represent equal units, but they are nevertheless easily comprehensible by nonprofessionals.

A useful example of a table of norms using percentiles is given in Table 33.5. This table of norms comes from the Modern Language Aptitude Test—Elementary: Spanish (MLAT-ES) test manual (Stansfield & Reed, 2005) published by the Second Language Testing Foundation. The test is an adaptation of the MLAT—Elementary, which was an outgrowth of the earlier MLAT, developed by John Carroll and Stanley Sapon.

The test manual (referenced above) introduces the MLAT-ES norms as follows. The MLAT-ES was administered to 1,186 students in the 2004/5 school year. Ten public and private elementary schools in Spain (441 students), Mexico (252 students), Costa Rica (266 students), and Colombia (224 students) participated in creating the norms. The norms do not represent a stratified sample of these Spanish-speaking countries. However, they do provide an average score and a range of scores at each grade level. They serve as a useful initial reference for score interpretation, at least until a larger sample can be tested or local norms developed.

How to read norms tables: Table 33.5 illustrates percentile norms for raw total scores on the MLAT-ES by grade. The test manual provides directions on how to read the norms tables as follows. To read the percentile rank, users can locate the raw score in the appropriate column for the grade of the test taker, and read the percentile equivalent in the right-hand or left-hand columns. Each percentile rank in the table coincides with a raw score or a raw score group. For example, in Table 33.5, a test taker in Grade 4 whose raw score is 72 has a percentile rank of 60. This percentile rank indicates that his score surpasses that of 60 percent of the group and that the test taker is surpassed by about 40 percent of the group.

Table 33.5 Norms for students in grades 3, 4, 5, 6, and 7 on the MLAT-ES, total score (Stansfield & Reed, 2005, reproduced with permission)

<i>Raw total scores corresponding to designated percentiles</i>						
<i>Percentile</i>	<i>Grade 3</i>	<i>Grade 4</i>	<i>Grade 5</i>	<i>Grade 6</i>	<i>Grade 7</i>	<i>Percentile</i>
99	102–123	117–123	117–123	118–123	120–123	99
97	97–101	114–116	114–116		119	97

48	43–47	60–63	73–74	88–89	96	48
45	41–42	58–59	70–72	86–87	95	45
42	40	55–57	67–69	84–85	93–94	42
39	39	53–54	65–66	81–83	88–92	39
36	37–38	50–52	62–64	79–80	86–87	36
33	34–36	48–49	59–61	76–78	85	33
30	31–33	46–47	55–58	73–75	83–84	30
27	29–30	43–45	52–54	70–72	81–82	27
24	28	40–42	51	67–69	80	24
21	27	38–39	47–50	64–66	77–79	21
18	26	35–37	46	59–63	75–76	18
15	23–25	32–34	42–45	56–58	72–74	15
12	20–22	30–31	39–41	51–55	64–71	12
9	16–19	23–29	37–38	45–50	57–63	9
6	13–15	20–22	33–36	40–44	52–56	6
3	11–12	17–19	26–32	35–39	44–51	3
1	0–10	0–16	0–25	0–34	0–43	1
N	207	206	289	306	178	N
Mean	51.2	65.9	75.6	86.5	94.0	Mean
SD	25.3	28.0	25.9	23.0	19.4	SD
Reliability	0.97	0.97	0.97	0.96	0.95	Reliability
SE_M	4.72	4.70	4.67	4.47	4.24	SE_M

It is worth looking at how percentile scores correspond to standard deviation units in the normal curve. Thanks to the fixed percentages in the normal curve (Figure 33.2), we can transform *SDs* to percentile ranks. For instance, to stack up scores from the left of the figure, 0 *SD* (a distance of 0 from the mean) equals a percentile rank of 50, because 50% of scores fall below that point. Likewise, +2*SD* equals the 98th percentile rank, because about 98% of scores are below that point.

A few points should be made in summing up the discussion on norms. First, the various norms discussed above represent statistical techniques through which assessment professionals can help to make sense of raw scores from the NR perspective. The standard score norms and percentile norms converted from raw scores usefully indicate a test taker's relative standing in the norm group or various strata of norm groups within which the student may be nested. The converted scores have the advantage over raw scores of providing a standard of reference across multiple versions of the test and across different occasions of testing.

Second, caution should be exercised as follows (Gronlund & Linn, 1990; Popham, 1990) about the meaning of the word *norm*. Norms and normative tables merely embody the summary of the performance data of a large number of individuals, members of many different groups of individuals from different times of testing. They should not be misunderstood as ideal goals or standards.

Challenges: Achieving Quality Norms

Test developers and score users should be familiar with what constitutes good normative data. The following list, compiled from Gronlund and Linn (1990) and Popham (1990), outlines criteria that should be considered in determining the adequacy of normative data:

- *Sample size*: The sample in the norm group should be large enough to assure that the data provide a reliable basis as a score reference.
- *Subgroup norms*: Normative data should be differentiated by subgroups so that separate norms for subgroups can be used for reference.
- *Representative group*: The norm group should represent the kinds of test takers for whom scores will be interpreted. There is a temptation for supervisors of normative data collection to go after the largest, most convenient sample, which may not satisfy requirements needed for a good normative sample.
- *Recentness*: Normative data should be reasonably up-to-date, gathered in the last few years.
- *Test manual*: The test manual should include information about how the norms were established, such as data collection and scoring procedures. Such information provides consumers of the test with a standard for using the test and for interpreting scores, as well as confidence in the test itself.
- *Alternate forms*: Equivalent forms that are alternate forms of the test should be provided. Information about the degree to which these forms are comparable should also be supplied.

It is a challenge to provide really comprehensive, high-quality normative data that meet these criteria since this involves extremely costly procedures and people

trained in NR techniques. Nonetheless, high stakes NR tests are expected to have normative data that are of good quality, and the high cost of providing norms is justified. However, for tests that are less likely to be in demand, test developers face the challenge of having to consider cost effectiveness and at the same time providing good normative data. Ideally, prospective test users should carefully evaluate the norms when they consider adopting a test, but not all users have the knowledge necessary to adequately evaluate test norms. Small-scale test developers may not have the means to provide well-researched and differentiated norms, and consequently score users may have limitations in interpreting the scores.

Future Directions

NR language assessment has grown out of a common human tendency to evaluate things by comparing them with each other; not only things, but our performance and that of others in the world around us. Throughout the decades, norms and normative data have been developed within this way of thinking and have made comparative interpretations of language performance more uniform, more justifiable, and more meaningful.

While the CR approach to language assessment has its merits (Chapter 34, Criterion-Referenced Approach to Language Assessment), the NR approach provides unique information that the other approach does not. At times, the NR approach is simply more useful than the CR approach (and vice versa). For instance, by placing more students into the proper levels of classes using the NR approach, it may keep us from placing blame on people for not learning things that were beyond their reach. However, we should also beware of the potential harm of misusing the NR approach. In other words, the elaborate preparation necessary for NR assessment is neither appropriate nor necessary in all contexts. It is best suited for proficiency tests including tests for selection and identification. When limited resources and benefits must be distributed fairly, accurate selection must be made from among a large number of candidates. Then it is justifiable to use the NR approach. Comparison itself may not be a welcome idea philosophically, and yet comparative information is an essential tool in making necessary decisions about the allocation of limited resources.

Popham (2000) lists inappropriate uses of standardized NR achievement tests; among other cases, the misuse includes evaluating schools, evaluating teachers, and making instructional decisions about which objectives should be taught. How can we use the NR approach properly, while, at the same time keep from overusing and misusing the approach? The answer, to apply Popham (2000, p. 31), is to improve the “assessment literacy” of all participants with regard to both NR and CR. This includes not only language testers and educators, but also policy makers, media representatives, parents, and all citizens.

Let us understand the role and purpose of the NR approach alongside a fair appraisal of the role and function of CR assessment. The CR approach focuses on clearly defining content and referencing scores to the content. Because of this focus, the approach is particularly relevant to the kind of performance assessment practiced in language classrooms (Davidson & Lynch, 2002). It is best suited for

capturing the degree of mastery of required content that a student has acquired after instruction and individual study. Although there is room for NR evaluation in such a context, there are times to focus on the desired level of achievement in the subject matter content set by the educational system.

Neither approach should be criticized as if there were something wrong with the approach itself (see Howe, 1992), but rather each one should be understood and appreciated according to the purposes and contexts for which it is best suited. Perhaps, as a reviewer of this chapter commented, both approaches are best distinguished rather by score interpretations and use. Both approaches, however, are really the same in the way that items are developed: The CR approach to test design focuses on content validity; NR test developers are now taking on the challenge of heightening the content validity of test items while paying attention to increasing the discriminating power of their tests. Therefore, in terms of test development, the NR/CR difference is not as great as once thought, since good assessment involves “clear thinking” by well-intentioned people trying to apply “certain fundamental practices” (Davidson & Lynch, 2002, p. 7).

Finally, the two approaches should also be understood as having complementary roles, and whenever appropriate, it would be ideal to incorporate both perspectives (e.g., Brown, 1989; Bae & Lee, 2012). By properly understanding both approaches we will be able to not only focus our efforts where they can do the most good but also utilize the merits of each approach.

Criterion-Referenced Approach to Language Assessment

Thom Hudson

University of Hawai'i, USA

Introduction

Cumming (2009) has noted the need to align curricula, pedagogical approaches, and tests through criterion-referenced measurement (CRM) and standards-based assessment. The growing influence of outcomes-based and competency-based assessment has raised an awareness of the need for language assessment to reflect the specific learning objectives of a program or the particular abilities needed for language proficiency certification. The need to assess targeted features of a domain is the focus of CRM.

The aim of this chapter is to provide a background for CRM within language assessment and to illustrate example CRM projects. The chapter discusses the types of interpretations that are made with CRM assessment and examines how CRM testing differs from norm-referenced measurement (NRM) testing (see Chapter 33, Norm-Referenced Approach to Language Assessment). It then presents three different projects, each of which applies to contexts that are different in scale. However, each provides insight into the CRM approach. Finally, the chapter discusses specific challenges in the CRM development process.

Background

Language researchers, teachers, and administrators administer tests for two basic reasons. First, the testers want to be able to order examinees such that they know which examinees score higher and which examinees score lower. They may wish to create two groups of research subjects such as advanced and low, or they may wish to select the top 20 candidates for admission into a program. These are relative types of decisions, in which examinees are evaluated relative to others who

have taken the same or a similar test. Second, the testers may wish to determine which examinees have mastered a particular domain of knowledge or skill. The testers might want to determine whether a particular examinee has learned a syllabus objective or can demonstrate control of a curricular standard. These are absolute types of decisions, which compare the examinee to a designated skill or set of skills. The first type of test inference is norm-referenced in nature and the second type is criterion-referenced in nature. It should be noted that while we may talk of CRM tests and NRM tests, we are actually concerned with CRM and NRM interpretations of test scores. Further, it is not the case that either CRM or NRM is inherently better than the other. Relative value depends upon the use to which the assessment is directed.

CRM assessment is the primary form of assessment carried out by teachers in classroom settings. That is, most language teachers are less interested in how their students rank in relation to other students than in what their students can do with the language feature that has been taught. The lack of descriptive clarity resulting from NRM tests does not provide teachers with clear objectives at which to aim specific instruction. Within educational testing, the idea of CRM can be traced to Glaser and Klaus (1962) and Glaser (1963). Glaser (1963, p. 520) indicates that

Criterion-referenced measures indicate the content of the behavioral repertory, and the correspondence between what an individual does and the underlying continuum of achievement. Measures which assess student achievement in terms of a certain criterion standard thus provide information as to the degree of competence attained by a particular student which is independent of reference to the performance of others.

Thus, CRM measures are tied to a specific and well-defined assessment domain with items appropriately sampled. The domain may represent a body of skills or knowledge identified in a particular language curriculum, in state-mandated standards, or in a particular occupational task. The CRM test assesses the content and skill standards for the domain of interest. Test scores are linked to what examinees can do, not viewed in relation to what other examinees can do. It should be kept in mind that the term *criterion* refers to the knowledge and skills that the test is designed to measure. It does not refer to the cut score that is used to determine mastery or nonmastery of the skill. The cut score represents some performance standard that is established operationally, and may take many arbitrary values across a single test depending upon its purpose (see Chapter 57, Standard Setting in Language Testing). For example, a criterion task might be identified for an office worker. This task might be "Write a memo in response to a boss's request, providing health information to office colleagues based on input from telephone health service" (Brown, Hudson, Norris, & Bonk, 2002, p. 25). Performance standards can be established such that examinees can be rated as *Inadequate*, *Able*, or *Adept* on the basis of performance descriptors. The criterion is writing an office memo. The *criterion* represents the underlying skill or knowledge base to which the test is being generalized, not necessarily the level of performance.

A discussion of CRM must address terminology that is used across various disciplines and eras that employ assessment. Throughout the literature there are

a number of terms that often partially overlap in their assessment dimension. We find such terms as *criteria*, *standards*, *outcomes*, *objectives*, *targets*, *benchmarks*, or *competencies*. From a measurement perspective, all of these in some way assume that a domain of tasks that should be performed has been defined. Here, they will be referred to as criteria. The domain “consists of a set of skills or dispositions that examinees display when called on to do so in a testing situation” (Popham, 1978, p. 94). As will be seen, a continual tension exists in CRM relating to the notion of a “well-defined” domain. When the domain is essentially an instructional curriculum, the definition is easier to realize than when the domain is something as large as “language proficiency” or “writing ability.” There is often a tension between whether the criteria are narrowly drawn, such as “the ability to make letter–sound correspondence in oral reading,” or broader and less constrained, such as “can use library resources to write a research paper.” The goal is to identify criteria that are specific, measurable, and reasonable.

In the early history of CRM in the 1960s and 1970s, it became identified with very narrow specifications of skills and objectives. Such an association led some educators to reach conclusions that it was not useful for assessing higher order skills or complex learning. However, this association was largely due to the fact that the early work in CRM was situated in a historical period when education in general, as well as language education, was steeped in behavioral psychology, audiolingualism, structural linguistics, and learning systems. In fact, the first article in the issue of *American Psychologist* that contained the article by Glaser quoted above was by psychologist B. F. Skinner and was entitled “Operant Behavior” (Skinner, 1963). The identification of CRM with the atomization of skills into discrete units and narrow instances of learned information, then, is an interpretation reflecting the particular paradigm of those times, not inherent characterizations of CRM.

Views of CRM have changed from the focus on narrow skills to broader constructs representing cognitive language processing and sociolinguistic ability. As Linn (1994) has noted, the notion of CRM provides a framework for conceptualizing the types of performance, task-based, or authentic assessment that have gained in use over the past decades. The conception that the criterion measure should have fidelity with the inferred target construct emphasizes the need for the assessment tasks to reflect the real-world criterion as much as possible. Criterion-referenced performance assessment allows measurement of students’ abilities to respond to real-life language tasks. Because such assessments focus on descriptions of real-world tasks, when done well, they allow test setting to approximate real-life contexts. Note the caveat in the previous sentence, “when done well.” The current discussion does not diminish the difficulty of designing and delivering the complex forms of assessment under discussion. Much more about this difficulty will be discussed in the sections of this chapter that address specific testing projects.

As CRM has been adopted for the measurement of more complex constructs, more contextual dimensions need to be provided in order to make consistent generalizations. That is, when language was viewed as primarily a grammatical entity made up of rules, the criteria specification could be more spare in terms of defining contextual constraints. A criterion objective could be as straightforward

as “Student will be able to use the simple past to express a completed state or action.” However, in tests that measure more complex and authentic language tasks it is frequently necessary to specify the context and conditions in more detail. For example, if a task analysis indicated that a learner would need to be able to order a computer, the criterion description would have to address whether the task is to take place face to face, over a telephone, or via the Internet. It would need to include sociolinguistic restrictions regarding age differences and perhaps gender. There are a number of qualifications regarding modality, social status, and language complexity that will need attention if appropriate generalizations are to be made.

Although tests associated with NRM and CRM interpretations may use the same item or test formats, they are developed through somewhat different processes. They have different purposes, may produce different content, generally have different test structures, and undergo different test development procedures.

Test purpose: As noted above, CRM interpretations are absolute rather than relative. An examinee’s score is interpreted without recourse to how other examinees performed. The test is to assess the amount of material known by each examinee, and to provide a clear description of what the test performance indicates in terms of the domain. With an NRM score, however, the score is interpreted in terms of other examinee scores. The goal is to spread examinees out along a score continuum. This fundamental difference in purpose between the two families of measurement has impacts for the test content and test development procedures.

Test content and structure: CRM is to measure a specific domain while NRM typically broadly measures general language abilities or proficiencies. For CRM, a particular job or task may be analyzed for specific tasks necessary to carry out the activity. The content of the test is tightly constrained by the results of the needs analysis upon which the CRM test is based or by the curriculum it is designed to measure. CRM tests typically consist of a series of short, well-defined subtests with homogeneous item content in each subtest, while NRM tests have a few relatively long subtests with heterogeneous item content. These structures facilitate scores for the types of decisions and descriptions that are to be made by each type of test.

Test development: The test development process provides the clearest differences between how tests are developed to address the two different test uses. NRM test development is primarily psychometrically driven. A primacy is placed on statistical considerations such as item discrimination and test score distribution. As noted above, NRM tests are designed to provide a means for providing instruments that allow relative comparisons among examinees. This means that a driving force in item development and selection is to develop items that spread the examinees out and provide maximum discrimination. The impact of this is that items that do not provide discrimination, regardless of how well they reflect the domain of interest, are excluded from the test. Further, items that correlate with one another well will be retained for the test and items that do not correlate well will be excluded. Thus, each item is internally consistent in its ranking of examinee ability. This can have a cumulative effect on the nature of the construct or domain that is being tested.

CRM tests are generally constructed with a descriptive foundation in keeping with the goal of describing an examinee's performance in relation to the defined domain. The process of test development commonly begins with a general description or summary statement of the domain to be assessed. (See Davidson & Lynch, 2002, for a detailed explication of the process.) Some mechanism is then presented for delineating item characteristics and constraints. There are a number of possible formats for this. Some formats involve creating a template with a sample item, attributes of the item format, and descriptions of the examinee responses (Davidson & Lynch, 2002). Alternatively, the item specifications may describe components that are systematically varied in item production, components such as language complexity, cognitive demand, and communicative complexity (Norris, Brown, Hudson, & Yoshioka, 1998; Brown et al., 2002). Regardless of the particular form, the item specifications provide a clear frame for what the items or tasks will look like and what the examinee will be expected to do. The statistical analysis of items also reflects the purpose of the CRM approach. Items are analyzed to determine whether they discriminate between those examinees who would be expected to have mastery of the domain and those examinees who would be expected not to have mastery. For example, a group of examinees who have not received instruction in a particular domain would be compared with examinees who have received instruction. Items that consistently distinguish between the two groups would be retained as candidate items for the test.

A large number of language assessment schemes have been developed with claims to CRM purposes. They reflect a range of views on assumptions about the focus of CRM. Skehan (1989) has posited four possible senses of CRM, and these distinctions are useful in considering the different CRM examples discussed below.

1. The simplest and least demanding sense of CRM is any measurement that is not norm-referenced. Scores on tests that are interpreted in terms of percentiles, such as the Test of English as a Foreign Language (TOEFL), would not be considered CRM. This is perhaps the least satisfactory meaning of the term in that it does not relate the measurement to a specified domain.
2. The most common sense of the term is in instances when some external standard is defined such that an examinee's performance can be interpreted as master or nonmaster. A focus of this sense of CRM is on the decision to be made and the cut score that is established. Such a test should be based on a clear real-world activity, perhaps identified through a needs analysis.
3. A principled sense is that of Popham's (1978, p. 93) definition, "A criterion-referenced test is used to ascertain an individual's status with respect to a well-defined behavioral domain." Status on the criterion is assessed by sampling the well-defined domain and setting a cut score.
4. The final, and most difficult to achieve, sense of CRM that Skehan describes relates to proficiency levels that are the basis for the criterion referencing. The levels of proficiency are viewed as cumulatively relating to development. Each stage of development would thus have a real-world proficiency dimension and a relationship to other stages of development.

The chapter thus far has described CRM and contrasted it with NRM approaches. However, in the end, the principal distinction is with test use. That is, how do test users employ the test results? There are instances when examinees are administered a test that is purported to be a language CRM test, but the scores are then used to place examinees in language courses whose syllabus in no way reflects the content of the test. In such cases, the score interpretation is not being made in a CRM manner. Likewise, if someone uses TOEFL scores to reflect knowledge of specific nursing English, the test is not being used in an NRM manner.

Example CRM Programs

The testing programs discussed below reflect different levels of Skehan's senses of CRM. They reflect differing assessment concerns in the development and interpretation of foreign language rubrics and benchmark frameworks for assessing proficiency levels in foreign language learning. The first is a project across several states in the USA as they address accountability in standards-based education. The second is a framework for language assessment and instruction across many countries in Europe. The third is a small project examining task-based assessment.

ACCESS for ELLs®

Within many publicly funded schools in the USA and worldwide, standards-based education has been promoted for education in general as well as in foreign and second language education. An example CRM approach is the Assessing Comprehension and Communication in English State-to-State for English Language Learners (ACCESS for ELLs) test. This test is aligned to the English Language Proficiency Standards (ELPS) for English language learners (ELLs) in kindergarten through grade 12 (K-12) developed by the WIDA Consortium. (The original states were Wisconsin, Delaware, and Arkansas, hence WIDA. With the addition of many more states joining the consortium, the acronym now stands for World-class Instructional Design and Assessment.) The WIDA Consortium in 2011 included 26 US states and the District of Columbia. The Consortium promotes the development of assessment and educational materials for ELLs.

Much of the impetus for the establishment of WIDA and the ELPS was the passage of the No Child Left Behind Act of 2001, which clearly stated that states were to create English language proficiency standards for ELLs that were tied to academic content standards. It also mandated that ELLs in K-12 were to be assessed annually on their language proficiency. Some large states such as California and New York had standards of their own, but several smaller states formed the WIDA Consortium to work together on the development of ELL standards.

In developing the standards, WIDA adopted a view that envisioned academic English language proficiency as a three-dimensional construct involving language complexity, cognitive engagement, and context. The theoretical underpinnings come from second language research that posits a continuum of expected performance by ELLs as they develop in school (Cummins, 1981; Lindholm-Leary, 2001;

Bailey & Butler, 2002). The Teachers of English to Speakers of Other Languages (TESOL) organization had developed and published the *ESL Standards for Pre-K-12 Students* (TESOL, 1997) as a response to standards-based educational reforms that were taking place throughout US public education in the 1980s and 1990s, and to advocate for language minority students (Gomez, 2000). These standards provided English as a second language (ESL) standards in parallel with the academic content area standards that were being developed in math, language arts, and so forth. These standards became a template for states and districts in developing their local criteria for ELLs. As it began developing its standards, the WIDA Consortium initially adopted these standards as a starting point. Over a lengthy period of time in 2003, WIDA developed descriptors and sample progress indicators for each level identified for pre-K-12. They sorted all indicators into the skill areas of listening, speaking, reading, and writing. National and local experts from state and district departments of education, teachers, and university faculty reviewed the standards. The existing standards were reviewed and refined. These were then augmented taking existing state standards into account. Through additional internal and external evaluation, the ELPS were refined and put in place in 2004 (Gottlieb, 2004).

The ELPS provide the basis for two frameworks (Gottlieb, 2004). There is a framework for large-scale state assessment and a framework for classroom assessment. The two frameworks have the following common elements: “1) English language proficiency standards, 2) language domains, 3) grade level clusters, and 4) language proficiency levels” (Gottlieb, 2004, p. 1). The standards also have performance definitions that describe the levels of proficiency. Both frameworks share the same ELPS. The ELPS reflect the language needed for classroom and schooling functions, as well as language for learning in school content areas. Thus, the ELPS recognize that ELLs are learning the language and learning school content concurrently. Each standard applies to the domains of listening, speaking, reading, and writing. The five standards are shown in Table 34.1.

The frameworks incorporate both language proficiency levels and grade level clusters. This allows the model to adjust both to age-appropriate topic expectations and to differing language proficiency within grade span intervals. There are five levels of language proficiency, which are labeled, from lowest to highest, (1) Entering, (2) Beginning, (3) Developing, (4) Expanding, and (5) Bridging. There is

Table 34.1 WIDA standards (adapted from Gottlieb, Cranley, & Camilleri, 2007)

<i>ELP standard</i>	<i>ELLs communicate</i>
1	For social and instructional purposes within the school setting
2	Information, ideas, and concepts necessary for academic success in the content area of language arts
3	Information, ideas, and concepts necessary for academic success in the content area of mathematics
4	Information, ideas, and concepts necessary for academic success in the content area of science
5	Information, ideas, and concepts necessary for academic success in the content area of social studies

Table 34.2 Example PIs (adapted from WIDA, 2008)

<i>Standard</i>	<i>Domain</i>	<i>Level</i>	<i>PI</i>
Math	Reading	4	Ordering of procedures involved in problem solving; sequential language is called for (p. 56)
Language arts	Writing	3	Paragraph construction to convey such information as procedural journal entries (p. 62)
Science	Speaking	2	Descriptions of scientific developments produced from illustrations (p. 72)

also a sixth exit level, (6) Reaching, which designates attainment of English language proficiency sufficient for success in English-only regular classes. Key to the CRM nature of the ELPS are performance indicators (PIs) for each language proficiency level. The PIs describe expectations of examinee performance for the five standards, grade clusters, language domain (listening, speaking, reading, writing), and proficiency level. There are over 800 PIs across the frameworks, standards, domains, grade clusters, and levels of proficiency (Gottlieb, 2004).

Performance definitions of the levels include descriptors for linguistic complexity, vocabulary usage, and language control. Examples of three of the levels are shown in Appendix A.

The ACCESS for ELLs is the test operationalization of the WIDA ELPS framework. The ELPS are the basis for test and item specifications. Items written from the PIs reflect the form of the academic language requirements in the standards. The item specification encompasses a theme and indicates item characteristics of proficiency level, structure of the item prompt, and response expectations (Bauman, Boals, Cranley, Gottlieb, & Kenyon, 2007). Each test item on the test is designed to assess student ability on one of the PIs. Three example PIs are shown in Table 34.2.

The majority of items are initiated by teachers from the states that use the test. These teachers are trained in the basis of the framework and in item and test specifications (Bauman et al., 2007). Items are reviewed and edited for match to the PI and content and bias.

The Common European Framework of Reference (CEFR)

Another large-scale language assessment project with a CRM perspective is the Common European Framework of Reference (CEFR) for languages, undertaken by the Council of Europe (Council of Europe, 2001). As with the WIDA Consortium, its framework broadly aims to provide a frame for development of language syllabi and curricula, planning and development of teaching materials, and a basis for language assessment. Central to the framework are its “can-do” statements. These are statements that specify what a language user is able to do.

The CEFR was developed to meet a perceived need for a common European system for calibrating language proficiency across languages. As the project began, in the early 1990s, there were already a sizable number of existing language proficiency scales with different pedigrees (North, 2002). Some scales descended from

governmental assessments and some were directly related to instructional curricula and syllabi. However, most of these scales had not been validated or empirically derived. Forty-one of these proficiency scales were deconstructed such that each descriptor was broken down into can-do sentences, such as “Can use a variety of strategies to achieve comprehension, including listening for main points; checking comprehension by using contextual clues” (North, 2000, p. 365). This produced some 1,679 descriptors, which were evaluated by teachers at secondary, vocational, and university levels for relevance, usability, and effectiveness (North, 2000). Thus, the descriptors derived from the varied language scales became the universe of criteria.

The descriptors were rated according to aspects of communicative language proficiency (linguistic, pragmatic, sociocultural, independence), strategy use (reception, interaction, production), and communicative activity (interactive listening, interaction, production) as well as for provisional level (breakthrough, way-stage, threshold, etc.). Through the process, the goal was to remove repetition and reach a workable number of descriptors, while producing positively worded statements for independent calibration. The descriptors were to be criterion statements with a yes/no answer in a CRM manner (North, 2000). Teachers rated examinees from many first languages on each of the descriptors. The descriptors were then analyzed with the Rasch model to determine how each scaled and fit with the model. The analysis produced a scale with descriptors from least difficult to most. Scale-level descriptors were produced through this process. The scale framework involves three bands, each with two levels of difficulty (A1 to C2). See Appendix B for the global scale. Examples of the descriptors for level C1 and A2 can be seen in Table 34.3.

Table 34.3 Example descriptors for the CEFR (adapted from Council of Europe, 2001)

C1:

Can summarize long demanding texts.

Can select an appropriate formulation from a broad range of language to express himself or herself clearly, without having to restrict what he or she wants to say.

Can vary intonation and place sentence stress correctly in order to express finer shades of meaning.

Can express himself or herself fluently and spontaneously, almost effortlessly. Only a conceptually difficult subject can hinder a natural, smooth flow of language.

Can follow films employing a considerable degree of slang and idiomatic usage.

A2:

Can copy out short texts in printed or clearly handwritten format.

Can produce brief everyday expressions in order to satisfy simple needs of a concrete type: personal details, daily routines, wants and needs, requests for information.

Can generally pronounce clearly enough to be understood despite a noticeable foreign accent, but conversational partners will need to ask for repetition from time to time.

Can construct phrases on familiar topics with sufficient ease to handle short exchanges, despite very noticeable hesitation and false starts.

Can handle very short social exchanges, using everyday polite forms of greeting and address. Can make and respond to invitations, suggestions, apologies, and so forth.

The scale contains can-do statements that address positive aspects of the learner's language ability. That is, it does not contain statements including descriptions of what the examinee is not able to do. These can-do statements define criteria against which performance can be referenced.

The scales are being implemented and referenced in many locations throughout Europe and elsewhere. One potential threat to the validity of the framework is that in the scaling process, items that did not scale statistically were eliminated. This resulted in the elimination of items relating directly to sociocultural competence and work-related descriptors (North, 2002). This might affect construct representation.

Assessment of Language Performance (ALP)

The previous CRM examples have been rather large-scale projects. The Assessment of Language Performance (ALP) (Brown et al., 2002), on the other hand, was a small-scale test development project designed to use a CRM approach in task-based language assessment. The ALP was designed to provide a model for the use and development of CRM task-based assessment for test developers in contexts with specific needs. Its goal was to provide examples of an array of possible task contexts in such general topic areas as health and recreation, travel, food and dining, work, and the university. Thus, the tasks that were developed in the project were not based on a specific analysis of content and needs, as should be done with an operational test. Rather, a number of tasks in each of the general areas were generated to demonstrate how task-based assessment can be developed.

The project focused on how real-world tasks can function to reveal an examinee's language ability in use. It attempted to employ CRM for the more authentic type of tasks noted by Linn (1994) above. Task-based language teaching has received increasing recognition in second language acquisition and second language pedagogy literature over the past two decades (Crookes & Gass, 1993; Norris et. al, 1998; Ellis, 2003). Task-based tests for the ALP are considered assessments that require examinees to engage in behavior that simulates, with as much fidelity as possible, goal-oriented target language use outside the language test situation. Performances on these tasks are then evaluated according to predetermined real-world criterion elements (i.e., task processes and outcomes) and criterion levels (i.e., authentic standards related to task success) (Brown et al., 2002).

A number of test and item specifications, modeled after Popham (1978), specifying real-world task simulations and scales to assess examinee performance on each one, were developed to represent exemplars of the approach. In the construction of the tasks, task difficulty was controlled through manipulations of factors defined as *language code complexity*, *cognitive complexity*, and *communicative stress factors* (Skehan, 1998). Tasks were identified and designed in relation to these variables to determine whether a task should be predicted to be more or less demanding for the examinees. For example, the item specification in Table 34.4 provides indications for item writers regarding how a task item can be manipulated to make the task more or less difficult on the basis of these three factors.

In this example, the examinee must assist a friend, who has broken his hand, by taking a telephone message and completing a postal change of address form. Such a task requires multiple modalities, both listening and writing.

Table 34.4 Sample task (Norris et al., 1998)

Task:	Filling out a change of address form	
Prompt:	Your roommate has broken the third metacarpal bone in his writing hand. You have volunteered to help him when he needs to have written work completed. He has just called and left a message on your answering machine. Listen to the message. Then fill out the change of address form that he left with you	
Code:	low	Minimally requires comprehension of the information left on the answering machine (vocabulary, forms, pragmatic/strategic aspects); ability to parse salient information for the change of address form and note same information; transfer of same information to change of address form (thus understanding of the categories on the change of address form from the post office).
	high	Hard if not impossible to manipulate the complexity of the change of address form; increase the code difficulty by increasing the range of information left on the machine (rendering understanding of code saliency more difficult); authentically, this is a pretty immutably low-level task.
Cognitive complexity:	low	Simple comprehension and transfer of salient information; ability to process the appropriate biographical data for the corresponding categories on the change of address form.
	high	More difficult if more information is provided and if the required information is “buried” in superfluous detail (e.g., “okay, my old address is 2386 Miso Street—by the way, were you at that party the night we blew up the living room . . . ,” etc.
Communicative demand:	low	No interaction; no inherent time pressure.
	high	Examinee has zero control over the information required or the information provided; three modalities (listening, reading, writing); stakes are somewhat high (you don’t want to screw up this task or your roommate’s mail will disappear into oblivion).

The task factors could be varied to change the relative difficulty of each task. For example, if an item writer wanted to make the task somewhat more difficult, the cognitive complexity could be increased by adding additional material not relevant to the completion of the task. Across the entire set of tasks in each version of the ALP, tasks were created that spanned all difficulties that would be appropriate for the target test population.

Appendix C presents a rating scale designed specifically for the task. Each task on the ALP had a separate task-dependent rating scale. Categories on these scales refer specifically to requirements for successfully completing the task. In developing the task-dependent scales, a criteria identification team was formed of people familiar with the types of tasks on the test. These were a highly experienced ESL/

EFL (English as a foreign language) teacher, an advanced second language user of English with much experience in accomplishing the types of tasks on the test, and a member of the university community with experience working with international students. The criteria team met and (a) became familiar with the specific tasks; (b) produced draft criteria of what insufficient, minimally sufficient, and efficient task performances would look like; (c) worked with the drafts rating actual performances; and (d) revised scoring rubrics for each item. As can be seen from the rating scale, both task success and quality of performance are included in the rubric.

The ALP represents an approach where the tasks are essentially items reflecting criteria that would be identified through needs or job analyses. The difficulty is in identifying task types that can represent categories of target outcomes. A further difficulty that is dealt with in the test development process is identifying the particular target performance standards that the overall test is designed to measure.

Challenges

The projects above have shown examples of assessment attempts to provide tests designed to specify what examinees can do in relation to the criteria developed for each project. The scales aim to provide clear descriptions of what examinees can do at any level of the description. However, there are challenges in the development of CRM assessments.

One challenge in CRM test development with complex domains relates to the grain with which the domain is specified, and, consequently, how many standards are defined. In the process of defining the domain, a large number of standards may be identified, leading to excessive numbers of narrow criteria. Such overspecification can result from specifying not only the dominant skills and knowledge necessary to describe the domain but also any enabling skills necessary to reach the dominant skills. The result is often a dauntingly large pool of item specifications that are impossible to sample on any particular test. It is important that objectives be written at a reasonable level of specificity, or grain size, so that they do not contribute to the proliferation of specifications, while at the same time being specific enough that items can be generated. (See Chapter 42, *Diagnostic Feedback in the Classroom*.)

A correlative challenge is that institutionally produced standard statements may be so vague that they are virtually useless in the operationalization process. That is, content standards may not be written in a way that facilitates the generation of items. For example, a standard such as “Students demonstrate the language skills necessary to engage in scientific inquiry” does not constrain the specific criteria for each item specification very well. Such standards are only a beginning in the CRM process. Test and item writers must collaborate with teachers, administrators, and other stakeholders in clarifying what specific types of examinee performances will lead to inferences about the examinee’s language and ability to engage in scientific inquiry. This is an ongoing and iterative process that often involves much more effort than is necessitated in NRM test development.

Finally, the process of having refined a set of test and item specifications can at times have a hindering effect on curricular change. That is, once the framework

for assessment is refined, there can be a reluctance to make changes in the educational approach that will necessitate a reworking and rethinking of the assessment system. It is important to recognize that test development is a process that evolves and is not a finish line. It is part of the entire curricular process, not the end result.

Future Directions

As standards-based and performance-based systems of education continue to expand, the role of CRM will increase. As that happens, care needs to be taken to carry out additional education about the process on at least two fronts. First, continued focus should be placed on the criterion aspect of the assessment, not simply on the accountability aspect. Test developers and users should keep in mind that they need to continually clarify the domain that is being assessed. This means focusing on a range of item types, not just multiple choice items. Complex domains need complex measures. They need performance assessments in addition to the multiple choice types of items. Otherwise, teachers will focus on teaching that does not elicit more complex performances.

Second, continued education needs to be carried out regarding the appropriate types of statistical analysis and interpretation for CRM. Many of the larger projects still report traditional NRM statistical analyses in their periodic reports. They continue to report traditional forms of reliability that do not capture the types of decisions that are the basis for CRM assessment. It is understandable that this happens since the traditional indexes have been the most commonly reported and understood. However, measures that focus on discriminating groups, such as master/nonmaster, rather than discriminating individuals, should become more of the focus.

Appendix A: WIDA ELP Performance Definitions (Adapted from Gottlieb et al., 2007)

<i>Sample level</i>	<i>Linguistic complexity</i>	<i>Vocabulary usage</i>	<i>Language control</i>
5. Bridging	Specialized or technical language of the content areas	A variety of sentence lengths of varying linguistic complexity in extended oral or written discourse, including stories, essays or reports	Oral or written language approaching comparability to that of English-proficient peers when presented with grade level material

4.

(Continued)

<i>Sample level</i>	<i>Linguistic complexity</i>	<i>Vocabulary usage</i>	<i>Language control</i>
3. Developing	General and some specific language of the content areas	Expanded sentences in oral interaction or written paragraphs	Oral or written language with phonological, syntactic or semantic errors that may impede the communication, but retain much of its meaning, when presented with oral or written, narrative or expository descriptions with sensory, graphic or interactive support
2. 1. Entering	Pictorial or graphic representation of the language of the content areas	Words, phrases or chunks of language when presented with one-step commands, directions, WH-, choice or yes/no questions, or statements with sensory, graphic or interactive support	Oral language with phonological, syntactic, or semantic errors that often impede meaning when presented with basic oral commands, direct questions, or simple statements with sensory, graphic or interactive support

Appendix B: Common European Framework of Reference Global Scale (Adapted from Council of Europe, 2001)

Proficient user	C2	Can understand with ease virtually everything heard or read. Can summarise information from different spoken and written sources, reconstructing arguments and accounts in a coherent presentation. Can express him/herself spontaneously, very fluently and precisely, differentiating finer shades of meaning even in more complex situations.
	C1	Can understand a wide range of demanding, longer texts, and recognise implicit meaning. Can express him/herself fluently and spontaneously without much obvious searching for expressions. Can use language flexibly and effectively for social, academic and professional purposes. Can produce clear, well-structured, detailed text on complex subjects, showing controlled use of organisational patterns, connectors and cohesive devices.
Independent user	B2	Can understand the main ideas of complex text on both concrete and abstract topics, including technical discussions in his/her field of specialisation. Can interact with a degree of fluency and spontaneity that makes regular interaction with native speakers quite possible without strain for either party. Can produce clear, detailed text on a wide range of subjects and explain a viewpoint on a topical issue giving the advantages and disadvantages of various options.

Basic user	B1	Can understand the main points of clear standard input on familiar matters regularly encountered in work, school, leisure, etc. Can deal with most situations likely to arise whilst travelling in an area where the language is spoken. Can produce simple connected text on topics which are familiar or of personal interest. Can describe experiences and events, dreams, hopes and ambitions and briefly give reasons and explanations for opinions and plans.
	A2	Can understand sentences and frequently used expressions related to areas of most immediate relevance (e.g. very basic personal and family information, shopping, local geography, employment). Can communicate in simple and routine tasks requiring a simple and direct exchange of information on familiar and routine matters. Can describe in simple terms aspects of his/her background, immediate environment and matters in areas of immediate need.
	A1	Can understand and use familiar everyday expressions and very basic phrases aimed at the satisfaction of needs of a concrete type. Can introduce him/herself and others and can ask and answer questions about personal details such as where he/she lives, people he/she knows and things he/she has. Can interact in a simple way provided the other person talks slowly and clearly and is prepared to help.

Appendix C: Example Task-Dependent Rating Scale (Norris et al., 1998)

Item/Rating	Descriptors				
Item 1	Inadequate		Able	Adept	
	Examinee incorrectly fills out change of address form such that any essential elements (listed in the <i>able</i> descriptor) are not processable by the post office (this might include illegibility, incorrect placement of information, absence of information, etc.)	Examinee performance contains some elements from the <i>inadequate</i> descriptor and some elements from the <i>able</i> descriptor	Examinee fills out change of address form according to information given by John, minimally including with correct spelling and correct locations (see form for details) —name —new address —old address —starting date —signature and printed name (either John Harris or examinee’s own name)	Examinee performance contains some elements from the <i>able</i> descriptor and some elements from the <i>adept</i> descriptor	Examinee correctly fills out change of address form with ALL applicable information given by John on the answering machine message (see form for details)
Rating	1	2	3	4	5

Task-Based Language Assessment

Koen Van Gorp

Bart Deygers

Katholieke Universiteit Leuven, Belgium

Introduction

Task-based language assessment (TBLA) is an approach to language assessment that focuses on what learners are able *to do* with language as opposed to what they *know* about language. Central to TBLA is the notion of tasks. The performances on tasks provide a teacher or a test user with authentic and contextually relevant information about the (second) language development or language performance of a student. In spite of the pedagogic benefits associated with a task-based approach, it remains a domain in language testing and language teaching that faces many challenges. In particular, questions of reliability, content validity, and authenticity remain to be researched more thoroughly (Wigglesworth, 2008; Norris, 2009; Bachman & Palmer, 2010). This chapter will present some challenges TBLA faces when used formatively (based on the assessment framework of a Dutch language method for primary education) as well as summatively (i.e., for reasons of certification as shown by the Certificate of Dutch as a Foreign Language).

Task-Based Language Assessment and Task-Based Language Teaching

TBLA is a crucial element within task-based language teaching (TBLT) (Van den Branden, 2006b; Norris, 2009). In TBLT tasks are essential pedagogic constructs that “drive” classroom activity (Samuda & Bygate, 2008). In the language-teaching literature, a task is defined in various ways (for a recent overview, see Van den Branden, 2006a; Samuda & Bygate, 2008). Van den Branden (2006a) defines a task as “an activity in which a person engages in order to attain an objective, and which necessitates the use of language” (p. 4). According to Van den Branden, students

learn a language when provided with opportunities to use authentic language meaningfully (i.e., meeting the language use needs of learners and society) and engagingly (i.e., in active and interactive language-learning processes). In their definition of a “language use task,” Bachman and Palmer (2010) include the notion that a task is always situated in a particular setting. In our view this provides a useful addition to the definition of a task because it adds a socially situated dimension to the definition (McNamara & Roever, 2006; Firth & Wagner, 2007). Expanding Van den Branden’s definition of a task leads us to the following definition: A task is a functional activity in a particular setting in which an individual uses language to attain an objective.

In line with the communicative and functional language that tasks elicit, language testers have become interested in task-based assessment following a general move away from purely discrete-point, indirect testing. TBLA is not a new phenomenon, but builds on earlier concerns with communicative language testing (e.g., Morrow, 1979) and language performance assessment (e.g., McNamara, 1996). As such, TBLA subscribes to a framework of language that can be described as “can do/performance”-oriented rather than “ability”-oriented (Bachman, 2011). The basic tenet of TBLA links up with Cureton’s advice: “If we want to find out how well a person can perform a task, we can put him to work at that task, and observe how well he does it and the quality and quantity of the product he turns out” (Cureton, 1950, p. 622).

A summative assessment task from *TotemTaal*, a Dutch language syllabus for primary schools (see below), can serve as an example of the performance-oriented approach. In this test students in the final grade of primary school are asked to write a brochure about the rain forest. Throughout the preceding unit, “Jungle fever,” the students have been exploring life in the rain forest. At the end of the unit they are asked to write three short informative texts: one describing an animal, one describing a plant, and a last one describing the importance of the rain forest. The students write their texts based on a number of preset questions and on rich visual input. Furthermore, the students are given work sheets that induce them to structure their performance, to work out a catchy title, and to make their texts visually attractive. The teachers give feedback using a rating scale that deals with form and content but also aligns the performance with the expected writing skills as formulated in the syllabus.

The example above illustrates how TBLA allows for a dynamic interaction between cognitive, contextual, and linguistic variables that govern real-life language performance (Skehan, 1998). Furthermore, it stimulates the natural integrated use of language skills (Colpin & Gysen, 2006) and allows for the use of compensatory strategies in situations of real language use (Norris, Brown, Hudson, & Bonk, 2002).

Since TBLA relies heavily on meaningful, real-world language performance, authenticity is a vital task component. Ideally, task-based assessment should directly reflect the tasks and interactions that learners are expected to perform (i.e., interactional authenticity) in real-life situations (i.e., situational authenticity) within a particular domain. However, when writing authentic tasks, identifying the target language use (TLU) may prove problematic. As Bachman (2002) points out, not all tests have a clearly defined TLU. Determining authentic content for a

test based on preset goals may be unproblematic (see *TotemTaal* below), whereas identifying the TLU for “broader” contexts might prove problematic. In those contexts, Bachman stresses the importance of a needs analysis (see “Summative Use of Task-Based Performance Tests” below), while pointing out that authenticity in testing is not without its limits. Indeed, not all real-life tasks can or should be operationalized.

TBLA is “an approach that attempts to assess as directly as possible whether test takers are able to perform specific language tasks in particular communicative settings” (Colpin & Gysen, 2006, p. 152). As such, TBLA’s construct of interest is task performance itself (Long & Norris, 2000). By emphasizing and assessing task performance, TBLA performs three main functions (Norris, 2009): (1) offering formative or diagnostic feedback to learners and teachers (i.e., assessment *for* learning); (2) enabling summative decisions that are indicative of targeted language-learning outcomes (i.e., assessment *of* learning); and (3) raising the awareness of learners, teachers, and other stakeholders about what language learning is all about by emphasizing valued and authentic language performance and target-task learning throughout the program (i.e., washback). In performing these three functions, TBLA practices provide a crucial link between language objectives and the educational program. The following paragraphs discuss a formative and a summative approach to TBLA. The formative use will be illustrated by a task-based assessment framework for language teaching in primary education, whereas curriculum-independent task-based certification tests will serve to exemplify the summative use of TBLA.

Formative Assessment in a Task-Based Language Syllabus for Primary Education

Most of the discussion about TBLA concerns its summative use. However, as Ellis (2003) points out, teachers will benefit most from a formative TBLA approach. Formative assessment allows teachers to be responsive to learner needs by indicating what students have learned or still need to learn, by providing information about curriculum planning and teaching (e.g., the suitability of classroom activities), and by offering relevant and meaningful learner feedback (Rea-Dickins & Gardner, 2000; Rea-Dickins, 2001). Especially in classroom practice, the distinction between formative and summative assessment is not as straightforward as sometimes portrayed. Formative assessment is not always “tidy, complete and self-consistent, but fragmentary and often contradictory” (Harlen & James, 1997, p. 374). Rea-Dickins and Gardner (2000) refute the idea that cumulative data collection in classroom assessment automatically leads to a reliable and valid representation of learner performance. They also point out that classroom assessment that is generally considered to be low stakes can have serious implications for individuals or groups of learners, and is in that sense high stakes. As a result, issues of reliability and validity should be treated with the same rigor for formative and summative assessment alike.

Notwithstanding its occasional “messiness,” formative assessment has the potential to advance students’ language learning (Rea-Dickins, 2001). When used

well, it produces coherent evidence about language learners' abilities to perform specific target tasks. To this end, TBLA has to provide "frameworks for tracking and interpreting important aspects of learner development over time" (Norris, 2009, p. 587). Therefore, teachers should be able to do more than acknowledge whether students have performed a specific task successfully. Teachers should be aware of the task specifications, of expected task performance, and of task performance strategies so they can help learners improve their performance. For those reasons, TBLA needs to rely on an assessment framework that generates rich information about in-class learning and teaching processes. Consequently, for teaching purposes and purposes of formative assessment, tasks should be conceptualized as a set of characteristics, rather than holistic entities (Bachman, 2002). These characteristics will be inherent to the task itself, but will also relate to learner characteristics. Task performance yields information about the interaction between learners and tasks, and it is precisely this information teachers need to assess students' progress as well as their ability to perform certain tasks.

Task Specification Framework

One example of how TBLA can provide a close understanding of language learners' development is the assessment framework in *TotemTaal*, a task-based Dutch language syllabus for Flemish primary education in Belgium (Berben et al., 2008b). *TotemTaal* was developed from 2005 to 2008 by a team of task-based syllabus designers at the Centrum voor Taal en Onderwijs of the University of Leuven in order to provide teachers with a task-based pedagogy in class. It is a Dutch-language curriculum encompassing listening, speaking, reading, writing, spelling, and language awareness tasks for both first and second language (L1 and L2) learners from grade two of primary education onwards.

As stated above, a good starting point for determining the language goals of any task-based syllabus (and consequently TBLA) is a needs analysis (Long, 2005). For *TotemTaal*, however, the attainment goals were predetermined by the Flemish Department of Education and the curricula by the Flemish educational networks. Based on these legally fixed and unalterable goals, pedagogic tasks were sequenced to ensure varying complexity and content over the different grades of primary school (for a detailed description, see Colpin & Van Gorp, 2007).

To enable task sequencing, monitor task complexity, and track learning opportunities, a task specification framework was developed. This framework defines task characteristics by means of six parameters. Each task challenges students to practice one or more of the four *language skills* while processing or producing a *text type* for a certain *public*, about a specific topic, representing or revealing a *world*, with a certain *function or purpose*. Dealing with the information in the text demands a certain *level of processing*. In addition, the text can be linguistically easy or difficult depending on vocabulary, syntax, structure, code, conventions, and so on. Table 35.1 illustrates these parameters for a reading task.

The task specification framework constitutes the backbone of *TotemTaal's* task-based approach and of its assessment framework. It guarantees content relevance and representativeness for both pedagogic and assessment tasks. The collection of tasks "Lost in the forest" for grade 5 illustrates *TotemTaal's* assessment framework.

Table 35.1 Task specification framework for the reading task “Which way out?” (5th grade) in *TotemTaal* (Berben et al., 2008a). Adapted with permission from the authors

Goals							
Parameters▶	Skill	Level of processing	Text-type	Public	World	Function	Attainment goal
Settings▶	Reading	Evaluating	Informative texts	(Un) known peers	Orientation (scientific description)	Inform	3.4

In the unit “Crispy fairy tales,” 10–11-year-olds first read part of a poem by Roald Dahl (from his book *Rhyme Stew*) about Hansel and Gretel, who are abandoned by their parents. The students have to find out where and when Hansel and Gretel were abandoned and got lost by reading and interpreting Dahl’s rhymes (e.g., “They walk, all four, for hours and hours / They see no robins, pick no flowers. / The wood is dark and cold and bare” [Dahl, 2003, p. 354]). After reading the poem the students look for a way to help Hansel and Gretel find their way out of the forest. In the task “Which way out?” the students are presented with several informative 100 word texts from children’s magazines about different means of orientation, such as the compass in the example below (see Table 35.1 for the specifications of this reading task).

A compass

The needle of a compass always points north. If you know this, you can work out the other wind directions. If you turn until the arrow points to the front of you, then the east lies to your right, the west to your left and the south is behind you. Always keep your compass away from steel and engines, because iron and electricity influence the direction of the compass needle. (Berben et al., 2008c, p. 36)

In pairs, the students determine the best way for Hansel and Gretel to get out of the forest, while taking into account the poem’s context: an unknown forest at night. The students reach a decision and formulate arguments as to why their suggested procedure would be successful for Hansel and Gretel (e.g., why wind directions help Hansel and Gretel find their way home). Before discussing their solutions with the whole class, students individually reflect on the task “Which way out?” They decide whether the reading task went well and, using a work sheet, they go through a list of strategies that can help them to reflect on their task performance. After the class discussion the teacher discusses the students’ reflections on their reading accomplishments.

Assessment Framework

The assessment framework of *TotemTaal* consists of four components, of which the first three are present in the lesson “Lost in the forest.” The implementation of these components in the classroom will be illustrated by the case of Caroline and her teacher. Table 35.2 provides an overview of the four components.

Table 35.2 Assessment framework in *TotemTaal* (Berben et al., 2008b). Adapted with permission from the authors

<i>Function</i>	Incidental formative assessment	Planned formative assessment		Summative assessment
<i>Format</i>	1. Observation and assistance	2. Observation and analysis	3. Reflection	4. Tests
<i>Who</i>	Teacher	Teacher	Student and teacher	Student
<i>Focus</i>	Looking at students' task performance (process)	Looking at students' task performance (process) and outcome (product)	Looking at own task performance and outcome	Looking at students' outcomes of task-based tests (product)
<i>Pedagogic tools</i>	<i>Guidelines</i> for teacher assistance of four language skills	<i>Frameworks and guidelines</i> for the observation and analysis of four language skills	<i>Teacher guidelines</i> for reflective talks <i>Portfolio</i> guidelines for students	<i>Task-based tests</i> for listening, reading, writing, spelling, and language awareness
<i>Written form</i>	No; "mental notes"	Systematized notes	Work sheets; portfolio	Test score

These four opportunities for gathering information about the students' developing language skills have partly overlapping intended purposes:

1. observation of task performance in order to provide teacher assistance if necessary,
2. observation and detailed analysis of task performance and task outcome of "targeted" individual students,
3. learner reflection and portfolio for self-assessment of task performance and language proficiency level, and
4. task-based tests for summative use.

The first component, observation and teacher assistance, could be viewed as strictly instructional: reading a poem. However, the reading task allows for in-task performance and process assessment. Every pedagogic task offers an opportunity to observe task performance and to assist students in successful task performance. Every task also allows the teacher to take "mental notes" about the students' strengths and weaknesses in a particular task performance. The guidelines in the teacher manual help the teacher to assess task performance and pinpoint the main task components, (i.e., the reading goal and the information-processing demands) and possible pitfalls concerning poem comprehension. The following teacher's note on 11-year-old Caroline deals with her comprehension of the reading goal: "Caroline had difficulty in deducing from the poem that Hansel and Gretel were abandoned in the forest at night. Was this because of the poetic structure of the

text? Check next reading assignment whether she's able to connect several pieces of literal information in the text."

The second observation component is a planned formative assessment (Ellis, 2003). During the task "Which way out?" the teacher focuses primarily on whether students understand the reading goal and on their manner of information processing. The teacher writes down any difficulties a student encounters during task performance as well as the coping strategies he or she may have used. These notes provide an intentional and systematic process and product evaluation of the student's task performance and supplement the teacher's mental notes. If possible and necessary, the teacher informs the student about his or her observations in order to gain further insight into the student's reading. When a teacher steps in to assist a particular student, the teacher's actions get an instructional focus. Specific guidelines for observation and analysis support the teacher in shaping his or her analysis (see Table 35.3).

The guidelines in Table 35.3 are a specification and concretization of a more general skill-specific analytic framework or analysis diagram that informs the teacher on how to analyze reading performances in general. Table 35.4 presents this analytic framework for reading tasks.

The framework for reading tasks in Table 35.4 provides the teacher with information about which aspects are essential to the performance of reading tasks in general and with a systematic way of tracking this information for individual students. The aspects that were identified as relevant, based on recent meta-analyses of effective reading programs (e.g., National Reading Panel, 2000; Slavin, Lake, Chambers,

Table 35.3 Reading task "Which way out?": guidelines for analysis (Berben et al., 2008a). Abbreviated with permission from the authors

See Analysis Diagram for Reading Tasks [Table 35.4]:

- Reading goal: Does the student read the texts? Is the student looking for possible ways to help Hansel and Gretel orient themselves?
 - Type of information: Does the student understand that he or she is looking for an appropriate way for Hansel and Gretel to orient themselves? Does the student take into account the circumstances in which Hansel and Gretel are lost?
 - *Guidelines for teacher-student talk:*
 - Reading goal: Does the student know that he or she has to read the information about the forest first and next has to look for a way out for Hansel and Gretel?
 - Reading strategies: Is the student reading all the texts with the same eye for detail or not? Is the student interpreting the titles of the different texts?
 - Relationships in the text: Does the student understand the relevant information in the texts? Ask questions: *How can you orient yourself using your watch and the sun?*
 - Visual aspects: Can the student carry out the instructions in the texts on the basis of the drawings?
 - Attitudes: Is the student motivated to find out how Hansel and Gretel can find their way out of the forest?
-

Table 35.4 Analysis diagram for reading tasks (Berben et al., 2008b). Abbreviated with permission from the authors

<i>Name of the student:</i>		<i>1st period of observation and analysis</i>		<i>2nd period of observation and analysis</i>		<i>...</i>	
		<i>S</i>	<i>H</i>	<i>S</i>	<i>H</i>	<i>S</i>	<i>H</i>
Reading goal: Is the student's reading goal-oriented?							
Can the student perform the reading task with the text? If so, has he or she understood the reading task and has he or she read in such a way as to reach the reading goal?							
Information processing: Is the student able to find the information he or she is looking for?							
Describe	Can the student find literal or explicitly mentioned information in the text?						
Structure	Can the student connect several pieces of literal information from the text?						
Structure	Can the student find implicit information in the text?						
Evaluate	Can the student compare information from the text with information from a second source or evaluate the information based on his or her own personal frame of reference?						
If not, hold a conversation with the student where you try to find out what went wrong							
Identifying the reading goal	Can the student identify the reading goal?						
Topic	Is the student familiar with the topic?						
Strategies	Does the student go about the reading task in an adequate manner?						
Other:							
Overall: How does the student perform with respect to							
Self-reliance	Does the student attempt to resolve the task on his or her own? Makes he or she use of the tools (strategies) at his or her disposal?						
Attitudes	Willingness to read, reading pleasure, willingness to reflect on own reading behavior						
Reflective ability	Does the student gradually develop the ability to think about his or her own reading skills? Does he or she apply these insights in subsequent reading tasks?						

S = self. H = with help or support from teacher or other student(s). Use + for positive performance, - for negative, ± for things in between.

Cheung, & Davis, 2009), are reading goal, level of information processing, topic, reading strategies, self-reliance, attitudes, and reflection. Other aspects are technical reading skills (e.g., fluency and accuracy), conventions of the text type, relations in the text (e.g., function words expressing grammatical relations), vocabulary, and visual aspects (e.g., illustrations and layout). These aspects, specifically the focus on reading goal, on levels of processing, and on reading strategies, connect all components in *TotemTaal's* assessment framework. In the teacher manual, the guidelines for teacher assistance, observation, and analysis and those for student reflection specify how these aspects of the reading process can be realized in a specific pedagogic task and what realistic expectations are for students of a certain grade.

In our example, the teacher takes the opportunity the formative assessment task provides to focus on Caroline and to observe her reading behavior in more detail. Observation and intervening (e.g., scaffolding) with Caroline's task execution provide the teacher with new evidence about Caroline's ability to connect several pieces of information from the text. This information will help the teacher when completing Caroline's analysis diagram (see Table 35.4).

Whereas the observation and analysis of task performances in the first two components is carried out by the teacher, the third component of the assessment framework encompasses learner reflection and portfolio. Learner reflection allows students to assess their own language experiences and their own language skills. It allows students to gradually build up their ability to self-monitor, to reflect metacognitively, and to regulate their own learning processes. Before discussing solutions with the whole class, students individually reflect on the success of performing the reading task "Which way out?" using a work sheet with a list of strategies (e.g., identifying the reading goal, making use of the illustrations, reading all texts or not, looking at the titles of the texts, underlining relevant information in the texts, and so forth). The strategies on the work sheet relate to the analytic framework for reading tasks. This component becomes instructionally relevant when teacher and student discuss the student's analysis and decide on alternative strategies for tackling future tasks. Through the use of a consistent framework, both teacher and learners are provided with both a frame of reference and a common language to talk about the effectiveness of their reading skills and learning processes. In the case of Caroline, the teacher takes the time to reflect with Caroline on her reading strategies. The teacher focuses on two of the strategies on the work sheet: "I used the illustrations in the text: yes/no" and "I underlined important information in the text: yes/no." Teacher and student discuss whether using these strategies would have helped Caroline in her task performance. Caroline agrees to pay more attention to these strategies and try them in the next reading task.

The fourth and final component in the assessment framework is task-based tests that are performed without teacher or peer support. These tests are directly linked to the attainment goals and provide the teacher with a complementary view of student task performance. These more formal task-based language tests also allow for diagnostic information, since the test items are directly linked to the different information-processing levels in the above-mentioned analytic framework. The test result can then underscore or refine the teacher's analysis of the student's information-processing abilities based on formative assessment, which is likely to improve the reliability of the overall teacher assessment. In this reading test, the

teacher in our example can again determine whether Caroline succeeds in independently combining pieces of information from a text. The teacher can check this directly since the rating scale links particular test items to specific information-processing demands (see also Table 35.4).

In summary, the assessment framework in *TotemTaal* provides teachers with a rich and balanced assessment repertoire that combines “classical” tests with “alternative assessment” (Fox, 2008). The assessment framework in *TotemTaal* is thus not diametrically opposed to that of traditional tests, but embeds curriculum-based tests in a broader assessment and teaching approach. It emphasizes the need for multiple assessment procedures or multiple sources of assessment evidence (Shohamy, 1996) and the collection of multiple performances over time to provide evidence of growth and learning. Multiple sources or procedures enable teachers to make a variety of inferences about the capacities for language use that students have, or about what they can or cannot yet do.

Information about students’ task performances is continuously gathered by teachers, both informally and formally. It is also provided by the students’ self-assessment. The assessment framework in *TotemTaal* encourages teachers to look at students’ performances for both product-evaluation and process-evaluation purposes, allowing for a smooth transition from instruction to assessment. This kind of assessment is an indispensable part of a responsible task-based pedagogy. Most crucially, the formative assessment components are an inextricable part of good teaching (Rea-Dickins, 2001).

Summative Use of Task-Based Performance Tests: The Certificate of Dutch as a Foreign Language

Task-based language testing is widely used summatively. Summative tests determine a student’s language skills by using target tasks as an indicator of ability to function in a particular TLU domain. The Canadian Language Benchmarks and the Occupational English Test are well-known examples of task-based language tests, a typology to which the Certificate of Dutch as a Foreign Language (CNaVT) also belongs. Each year, some 3,500 candidates in 40 countries sit one of the six profile-based tests that belong to the CNaVT suite. These tests are either societal (tourism and citizenship), professional (services and administration), or academic (student and tutor) in domain. The current suite of task-based tests is the result of a significant paradigm shift in the test development process of the CNaVT. Having administered competence-based tests of Dutch as a foreign language from the 1970s until the 1990s, the CNaVT moved toward performance-based testing in 1999, which entailed a fundamental reconceptualization of the test construct. For one thing, language level ceased to be the major focal point of the test. Instead, task performance and task outcome (Skehan, 1996) became essential.

Why Assess?

Turning a test inside out brings up a number of fundamental questions, starting with the most basic one of all: Why assess? In the test development process, the

fundamental consideration which precedes all other concerns about test construct and test specifications focuses on the very motive for assessing language at all (Van den Branden, 2006a; Bachman & Palmer, 2010). Since Dutch is quite a small language with limited international resonance, most students of Dutch take it up with a specific goal in mind and require certification to attain that goal, which may be societal, professional, or academic in nature. For other students, a Dutch language test has no other goal than to serve as a motivational yardstick that indicates the extent to which they are able to function in a specific domain.

When reshaping the CNaVT, a needs analysis was conducted in order to identify the test takers' reasons for taking a Dutch L2 test (Van Avermaet & Gysen, 2006). The needs analysis allowed for six profiles to be identified within the three domains. To date, each profile is monitored and updated on a regular basis so as to ensure the representativeness and authenticity of its task types as well as the abilities that are required to perform those tasks (Van Avermaet & Gysen, 2006).

To a large extent, the goals of test takers and those of the CNaVT as a test provider run parallel. Test takers wish to be tested reliably, validly, and authentically so as to be adequately informed about their level of linguistic competence within a given domain. Apart from these shared goals of test takers and test developers, it is of great importance to the CNaVT to generate positive washback. By using functional task-based tests, the CNaVT wishes to inspire teachers to consider using functional tasks in their teaching practice. Both the certification and the washback motive are entwined with the central philosophy that one learns a language not only to use it, but also by using it.

Are Task-Based Language Tests Testing Language for Specific Purposes?

The six profiles that are now in use adhere to the central concept of task-based performance testing, which implies employing real-world tasks as assessment material. Since task context will also shape the performance, the context of the task goes beyond what Douglas (2001, p. 172) calls "situational window dressing," and is a vital part of each task. The context in which a task is situated will not only influence the expected register but also, and more fundamentally, co-determine the rating criteria.

Since the CNaVT tasks are authentic and contextualized they are comparable to language for specific purposes (LSP) tests, from which they differ on one crucial point: content knowledge. CNaVT task constructs purposefully eliminate all subject-specific knowledge, which is a defining element of LSP tasks (Douglas, 2000), but also a possible impediment for test fairness if test takers have dissimilar backgrounds (Bachman & Palmer, 2010). In a sense one could define CNaVT tasks as generic LSP tasks: Each task calls upon a contextualized ability which is necessary within but not necessarily exclusive to a specific domain. Presentation tasks, for example, occur in tests of academic Dutch and business Dutch, but the contexts differ. In a recent test of business Dutch, candidates were presented with three possible locations for a large-scale conference. They were asked to pick one venue, based on a number of parameters such as capacity and cost, and argue the case for their choice as the best option for the conference. The criteria used focused on

the adequacy of the presentation in a business context. In the same year, the test of academic Dutch featured a presentation task in which candidates were asked to present a relatively general study concerning Internet use among youngsters. Here too, the rating criteria considered the context in which the task took place. Even though the tasks are similar at the core, the differing content and setting effectively alter the nature of the task. Accuracy, for example, is more important in the academic test, whereas persuasion is a more prominent criterion in the business context.

Striving toward “authentic” tests that reflect the context the test taker will be in (Wu & Stansfield, 2001) goes beyond the tasks and extends to the rating scales. In the example above, the two presentation tasks were rated using dissimilar rating scales because of the different TLU settings. In order to attain this level of authenticity, the CNaVT calls upon the expertise of stakeholders and domain specialists. Including subject specialists in task selection and task development is an important step in developing contextualized task-based tests.

Determining Rating Criteria

Consulting subject specialists employed in the target domain to specify their “indigenous” criteria (Jacoby & McNamara, 1999) constitutes an extra step worth taking in developing authentic, domain-related performance tests (Jacoby & McNamara, 1999; Douglas, 2001). Using domain experts does not imply that testing professionals should take a step back when determining the criteria to be used in the rating scales. Rather, it entails broadening the horizon by using indigenous criteria that “may be used . . . to supplement linguistically oriented criteria” (Douglas, 2001, p. 183). Since the importance and presence of formal linguistic elements and content-related criteria are decided in coordination with subject specialists or domain experts, a given criterion might be considered less important for one task than for the next, depending on the goal. In other words: Consulting domain experts for task selection as well as tapping into their “rich inventory of tacitly known criteria” (Jacoby & McNamara, 1999, p. 224) for establishing rating criteria can increase a test’s content validity and its predictive validity.

In an effort to further refine its rating criteria for the academic profiles, the CNaVT conducted a study in 2010 and 2011. The study consulted professionals working within an academic context in which they come into regular contact with students. Ten subject specialists took part in two focus group sessions and a larger group filled out an online questionnaire ($n = 231$). The respondents of the focus groups were first asked to voice the intuitive criteria they employ when determining the quality of a performance. Later they had the opportunity to refine their intuitive criteria based on test performances. After the first run, which was based on tasks, not on performances, most criteria dealt with content-related matters rather than formal aspects of language. The second session of the focus group, based on task performances, showed a slightly different picture. The relative importance of content diminished whereas the salience of formal aspects of language (e.g., linguistic correctness) increased. In the questionnaire, the respondents wrote down which criteria they employed when deciding on the quality of a performance. Next, they were asked to arrange in order of importance the criteria

that were established in the focus groups. The combined data from the focus groups and the questionnaire allowed for a unique perspective on authentic rating criteria. From the data, the CNaVT was able to conclude that content and structure were generally considered most important. Prototypical linguistic criteria such as spelling and vocabulary were always present, but considered less important than content, structure, and grammatical features. In future, similar data may help “determine the relative importance of different aspects of language ability for a given purpose of assessment in a particular context” (Sawaki, 2007, p. 356), which can in turn influence the weighting of criteria. In line with the logic of considering authentic criteria, the weight that is given to a criterion will differ from task to task and from profile to profile. In the focus groups and the questionnaire results, the criterion vocabulary, for example, was considered quite important for integrated writing tasks, but not important at all for an integrated speaking task in the context of a meeting with student services.

The above shows that the CNaVT has adopted not a holistic, but an analytic rating process in which subscores determine the final outcome. Using analytic rating has been shown to be reliable when using trained novice raters (Barkaoui & Knouzi, 2011), as is often the case for the CNaVT. Additionally, analytic rating scales allow for fine-grained distinctions between criteria. In spite of the different criteria that are used for rating, the test results only distinguish between pass and fail, which is in line with Long and Crookes’s (1992) statement that TBLA should be organized “by way of task-based criterion referenced tests, whose focus is whether or not students can perform some task to criterion, as established by experts in the field, not their ability to complete discrete-point grammar items” (p. 45).

Washback

As discussed above, the primary purpose of the CNaVT is to provide test takers with authentic and reliable task-based tests that employ valid rating criteria. The second function the CNaVT aims to perform has less to do with testing than with the influence of a test on teaching. The CNaVT’s washback philosophy is inspired by the belief that people learn a language in order to use it but also by using it within a meaningful context. Since “well-designed assessment tasks have the potential to provide positive wash-back into the classroom” (Wigglesworth, 2008, p. 114), the CNaVT aims to have an impact on classroom practice by introducing task-based approaches (e.g., by using engaging, real-world tasks as representative practice material) in the slipstream of the formalized tests.

Challenges and Future Directions

Since the early 1990s, TBLT has gained considerable momentum in the field of language education. In its wake, TBLA has developed as a medium summative orientation as well as, although to a lesser extent than, formative feedback. Apart from these two assessment functions, TBLA has proven itself to be a means for raising awareness with all stakeholders about language-learning processes and the ability to perform a variety of valued communication tasks. Although the

benefits of direct and authentic task-based tests are evident, there remain a number of challenges and unanswered research questions. The use of authentic and contextualized tasks in high stakes tests raises questions about generalization that are still waiting to be addressed (Bachman, 2002). Generalization is one of the major issues that links up with the validity of construct interpretations as well as with how task features act as sources of variability in task performances. With respect to formative assessment, it is still unclear whether TBLA can produce a less messy classroom practice than is often observed in research. Developing a coherent assessment framework in a task-based curriculum as *TotemTaal* does is important because it builds up an argument for a reliable and valid TBLA and provides a much-needed interface between theory and practice. However, it is in the implementation of the assessment framework by the teacher in the classroom that the real strengths and weaknesses of TBLA in informing instruction and learning processes are revealed. To ensure the efficiency and effectiveness of TBLA practices, “validity evaluations” (Norris, 2008) have to be set up within educational programs. This research is of great value to prove the utility and worth of TBLA both for teachers in classroom settings and for test institutes developing high stakes certification tests.

Computer-Assisted Language Testing

Ruslan Suvorov

Iowa State University

Volker Hegelheimer

Iowa State University

Introduction

Computer-assisted language testing (CALT) employs computer applications for eliciting and evaluating test takers' performance in a second language. CALT encompasses computer-adaptive testing (CAT), the use of multimedia in language test tasks, and automatic response analysis (Chapelle & Douglas, 2006). Chapelle (2010) distinguishes three main motives for using technology in language testing: efficiency, equivalence, and innovation. Efficiency is achieved through computer-adaptive testing and analysis-based assessment that utilizes automated writing evaluation (AWE) or automated speech evaluation (ASE) systems. Equivalence refers to research on making computerized tests equivalent to paper and pencil tests that are considered to be "the gold standard" in language testing. Innovation—where technology can create a true transformation of language testing—is revealed in the reconceptualization of the L2 ability construct in CALT as "the ability to select and deploy appropriate language through the technologies that are appropriate for a situation" (Chapelle & Douglas, 2006, p. 107). In addition, innovation is exemplified in the adaptive approach to test design and automatic intelligent feedback provided with the help of AWE and ASE technologies integrated in computerized tests.

Computer-based testing, once viewed as a convenient delivery vehicle for traditional paper and pencil tests (Garrett, 1991), has undergone important changes since the late 1980s. While a significant aspect of CALT continues to revolve around the delivery of paper-based tests, this area has witnessed major developments since the 1990s including computer-adaptive testing, new item types, integrated skills assessment, and automated evaluation.

In most of the recent books that deal with the assessment of various aspects of the English language (e.g., the *Cambridge Language Assessment Series*, edited by

Alderson and Bachman, on assessing vocabulary, reading, language for specific purposes [LSP], writing, listening, and grammar), the argument in favor of using computer technology to deliver assessments includes “efficacy” as a major component. That is, what is viewed as one potential advantage to using technology in assessment revolves around more expeditious test delivery, test evaluation, and score reporting. Incidentally, only *Assessing Speaking* (Luoma, 2004) does not include a section on computer technology. However, interest in the assessment of speaking has risen sharply since the early 2000s, an interest fueled in part by call center work, where speaking is viewed as a key to higher customer satisfaction ratings.

We begin this chapter by describing a framework for computer-assisted language testing that draws on scholars who have explored various aspects of CALT. We then provide a review of major computer-based tests and test delivery platforms, followed by a brief synopsis of recent research in the field. In our closing section, we outline challenges and new possibilities in CALT.

Description of Computer-Assisted Language Testing

Computer-assisted language testing comprises different aspects of language testing and technology use. In this section, we present a framework for the description of computer-assisted language tests as instruments developed within CALT (see Table 36.1) on the basis of various attributes that have been previously described in the literature, we define a computer-assisted language test as any test delivered via a computer or a mobile device. The framework consists of nine attributes and their corresponding categories. While the first five categories and the interactive category for the last attribute are unique to CALT, the remaining four attributes are also germane to traditional paper-based tests.

Table 36.1 Framework for the description of computer-assisted language tests

#	Attribute	Categories
1	Directionality	Linear, adaptive, and semi-adaptive testing
2	Delivery format	Computer-based and Web-based testing
3	Media density	Single medium and multimedia
4	Target skill	Single language skill and integrated skills
5	Scoring mechanism	Human-based, exact answer matching, and analysis-based scoring
6	Stakes	Low stakes, medium stakes, and high stakes
7	Purpose	Curriculum-related (achievement, admission, diagnosis, placement, progress) and non-curriculum-related (proficiency and screening)
8	Response type	Selected response and constructed response
9	Task type	Selective (e.g., multiple choice), productive (e.g., short answer, cloze task, written and oral narratives), and interactive (e.g., matching, drag and drop)

Directionality

Computer-assisted language testing can be linear, adaptive, or semi-adaptive. Linear tests administer the same number of test items in the same order to all test takers. In some linear tests, test takers can go back to previous questions and review their responses, whereas in other linear tests they are not allowed to do that. In computer-adaptive testing, each task is selected by the computer based on the test taker's performance on the previous task. Successful task completion results in a more complex question, while incorrect task completion results in an easier next task. By adapting the complexity of tasks to the test taker's performance, a computer-adaptive test requires ostensibly fewer items and less time to assess the language proficiency level of its users.

Unlike linear tests that often use classical test theory and its extensions, computer-adaptive tests (CATs) are based on item response theory (IRT). This test theory is based on two major assumptions: (a) unidimensionality (i.e., all test items must measure the same construct) and (b) local independence (i.e., test takers' responses to each test item must be independent from each other) (Henning, Hudson, & Turner, 1985). Depending on the type of IRT model, items for CATs can be created using one, two, or three parameters, namely, item difficulty, item discrimination, and item guessing (Jamieson, 2005).

Due to limitations of computer-adaptive testing—including high cost, increased exposure of test items, issues with algorithms for item selection, and difficulties with satisfying strict IRT assumptions—semi-adaptive tests have been proposed and used as an alternative. Compared to adaptive tests that are adaptive at the item level (i.e., by selecting the next item based on the test taker's performance on the current item), semi-adaptive tests are adaptive at the level of a group of items called testlets (Winke & Fei, 2008) or at the level of the whole test where test takers are given a version of the test that corresponds to their proficiency level as determined by a pretest (Ockey, 2009). It should be noted, however, that the term "semi-adaptive" is not universally accepted and, while some researchers distinguish semi-adaptive tests from purely adaptive tests (e.g., Winke, 2006; Ockey, 2009; Winke & Fei, 2008), others seem to consider such tests to be a specific type of adaptive test (e.g., Alderson, 2005; Jamieson, 2005).

Delivery Format

Language tests administered with the help of computers can be divided into computer-based tests (CBTs) and Web-based tests (WBTs). Computer-based testing involves the use of various offline delivery formats such as CDs, DVDs, and standalone software applications that can be installed on an individual computer. Web-based tests, on the other hand, refer to the evaluation of test takers' performance in an online format. Roever (2001) differentiates between low-tech and high-tech WBTs depending on their technological sophistication. (See Carr, 2006, for a more detailed discussion of Web-based language testing.) Some researchers (e.g., Ockey, 2009) predict that due to rapid technological advances WBT will gain more popularity and witness further development in the near future.

Media Density

One of the advantages of computer-assisted language testing regularly mentioned in the literature is the availability of different media formats and the possibility of their integration. On the basis of this attribute, tests delivered via computers can use a single medium (e.g., an audio-only listening test or a text-based reading test) or multimedia (e.g., a listening test with a video or a reading test with text and images). The use of multimedia, which may incorporate audio, images, videos, animation, and graphics, has gained much attention among researchers because it is believed to have the potential for enhancing the authenticity of language tasks. However, Douglas and Hegelheimer (2007) warn that this issue is not as straightforward as it might first seem because the implementation of multimedia in computer-assisted language tests results in a more complex construct to measure, which, in turn, poses a threat to test validity.

Target Skill

Computerized language tests can be designed to assess a single language skill (i.e., reading, writing, speaking, or listening) or a set of integrated skills (for instance, speaking and listening). Integrated skills assessment reflects the complexity of language use contexts (Chapelle, Grabe, & Berns, 2000) and is believed to enhance the authenticity of language tests through interactivity provided by integrated tasks (Ockey, 2009) that are typically performance-based (Plakans, 2009a). Integrated skills assessment, for instance, has been included in the new TOEFL iBT in order “to better align the test design to the variety of language use tasks that examinees are expected to encounter in everyday academic life” (Sawaki, Stricker, & Oranje, 2009). According to Plakans (2009a), tasks for assessing integrated skills are difficult to develop and are more prevalent in the English for specific purposes (ESP) and English for academic purposes (EAP) tests.

Scoring Mechanism

With regards to the scoring mechanism, test takers’ performance on computer-delivered language tests can be evaluated by human raters and by computers. Computerized scoring of the input can be done by matching exact answers or analyzing test takers’ responses. Exact answer matching entails matching test takers’ responses with the correct preset responses (for instance, responses to multiple choice and matching questions). This type of scoring is typically used for the evaluation of receptive skills (i.e., reading and listening) and, sometimes, productive skills (e.g., writing) in the form of one word or even short phrase answers provided that the test has a prepiloted list of acceptable answers, including the ones with common spelling errors (Alderson, 2005). The use of analysis-based scoring, on the other hand, enables performance-based testing, where test takers construct extended responses to complete writing and speaking tasks. Analysis-based scoring utilizes various natural language processing methods integrated in many automated writing evaluation systems such as e-rater[®] used in Criterion (e.g., Attali & Burstein, 2006; Burstein & Chodorow, 2010) and speech

evaluation systems such as *Ordinate* in the *Versant English Test* (e.g., Downey, Farhady, Present-Thomas, Suzuki, & Van Moere, 2008). The results of such automated assessment can be provided as a holistic score, diagnostic feedback, or both (Burststein & Chodorow, 2010).

Stakes

As any type of testing, computer-assisted language testing can have low, medium, and high stakes for test takers. Low stakes testing has little, if any, consequences for test takers, and is employed for practicing, self-studying, and track-keeping purposes. Computerized tests with medium stakes (such as testing of students' progress in a second language classroom) can have some impact on test takers' lives. High stakes tests, which do have life-changing consequences and implications, are typically used for admissions to educational programs, professional certification and promotion, and granting citizenship (Roever, 2001).

Purpose

Test purpose is associated with the type of tests and decisions that can be made on the basis of the test performance. Carr (2011) classifies test purposes into two broad categories: curriculum-related and other, or non-curriculum-related (p. 6). Curriculum-related tests can be used for the purposes of admission to a program, placement into a specific level of the program, diagnosis of test takers' strengths and weaknesses, assessment of their progress in the program, and their achievement of the program's objectives. The non-curriculum-related tests are used for language proficiency assessment and screening for non-academic purposes (e.g., to make decisions regarding employment, immigration, etc.).

Response Type

There are two main types of responses that can be provided by test takers during a computer-delivered language test: selected and constructed responses (e.g., Parshall, Davey, & Pashley, 2000). Selected response assessment involves tasks that require a test taker to choose a correct answer from a list of options (e.g., a multiple choice question). In the case of constructed responses, test takers must develop their own answers and produce short or extended linguistic output. These two categories, however, should be viewed continuously rather than dichotomously since some language tasks can require a response that would possess the features of both (for instance, arranging given words and phrases into a sentence).

Task Type

There are numerous types of tasks that can be created for computerized language tests. Task types can be divided into three broad categories: selective (e.g., multiple choice questions, yes/no questions), productive (e.g., written and oral narratives, short answer tasks, and cloze tasks), and interactive (e.g., matching, drag and

drop). Although some of these tasks are also possible in a paper and pencil test, others can be created and delivered only through computers. Alderson (2005), for instance, describes 18 experimental items that were created as part of the DIALANG project, which is a low stakes computer-based diagnostic test available in 14 European languages. According to Alderson (2005), these innovative items provide new opportunities for enhanced diagnosis and alternative types of feedback in CALT. Some examples of these items include multimedia-enriched items (e.g., pictorial multiple choice with sound, interactive image with sound, and video clips in listening), interactive items that require test takers to manipulate the test content (e.g., reorganization, highlighting/underlining, insertion, deletion, thematic grouping, transformation), and items that provide alternative ways to assess productive skills (e.g., indirect speaking with audio clips as alternatives, benchmarking in direct writing, and multiple benchmarks in speaking).

There is an obvious interaction among all the attributes from Table 36.1. Test purpose, for instance, may be interrelated with target skills: Diagnostic tests that are “more likely to be discrete-point than integrative” (Alderson, 2005, p. 11) tend to focus on a specific language skill (e.g., reading), whereas in proficiency tests the assessment of integrated skills is more preferable. Likewise, stakes may affect the selection of a scoring mechanism and delivery format: Considering the existing limitations of automated evaluation systems and potential risks associated with Web-based testing, high stakes test developers will likely opt for the CBT format and combine analysis-based scoring with human-based scoring, while some low stakes tests may welcome WBT and rely exclusively on automated assessment.

Computer-Based Tests and Delivery Platforms

Rapid technological advances and the ensuing quick expansion of computer-assisted language testing have resulted in a variety of commercial computer-delivered language tests and platforms for creating customized assessment. Hence, the discussion in this section will be divided into two streams: existing computerized language tests and instruments for constructing original L2 tests.

Existing Computerized L2 Tests

Since the emergence of the first computer-based and computer-adaptive language tests in the 1980s, numerous CALT projects have been initiated by academic institutions and test development companies. Chalhoub-Deville (2010) reviews a representative sample of computer-delivered language tests discussed in the research literature over the past several decades. This section, however, will briefly describe only the most recent and innovative developments in CALT that have gone beyond a simple adaptation of paper and pencil tests for computer delivery. Specifically, we will provide a short overview of major language tests that include the assessment of productive skills, mention their purpose and structure, and focus on some of their technology-enabled features such as automated scoring algorithms, the adaptive approach, and innovative test items.

Test of English as a Foreign Language Internet-Based Test (TOEFL iBT®) Being a high stakes test, TOEFL® (published by the Educational Testing Service, <http://www.ets.org/toefl/ibt/about/>) is probably one of the most recognized and known language tests in the world. First introduced in 2005, TOEFL iBT witnessed several major changes compared to the older, computer-based version of TOEFL (i.e., TOEFL CBT). In particular, the adaptive approach that was used in the structure and listening sections of TOEFL CBT was discontinued in the new TOEFL, whereas a new type of tasks—called integrated tasks—was introduced. Since the use of integrated tasks violated the assumptions of a three-parameter IRT model used in the adaptive part of TOEFL CBT, ETS made a decision to abandon the adaptive approach. This decision was also prompted by the need to have human raters assess test takers' speaking and writing responses (Jamieson, Eignor, Grabe, & Kunnan, 2008).

The purpose of TOEFL iBT is to measure the ability of non-native speakers of English to perform university-level academic tasks using their English language skills. Although TOEFL iBT scores are used primarily by English-medium universities around the world for making admission decisions, they are also accepted by immigration departments and various licensing agencies. The whole test lasts for about 4.5 hours and consists of four main sections: reading, listening, speaking, and writing. Integrated tasks include reading a text, listening to a lecture or a conversation, and providing a written or an oral response on the basis of what has been read and heard. The writing section of TOEFL iBT is evaluated by human raters and an automated scoring system called e-rater. The speaking section of a practice exam for the TOEFL is evaluated by the SpeechRaterSM engine; however, this automated scoring system is not used in the actual test (Higgins, Zechner, Xi, & Williamson, 2011).

BULATS Online Tests Business Language Testing Service (BULATS) online tests (published by Cambridge ESOL, <http://www.bulats.org/Bulats/The-Tests.html>) comprise the BULATS Online Reading and Listening Test, BULATS Online Speaking Test, and BULATS Online Writing Test. Designed to test the English language proficiency of business employees, job applicants, and candidates for business English language courses, these three high stakes tests can be used separately or in any combination depending on the client's assessment needs.

The BULATS Online Reading and Listening Test utilizes the adaptive approach to item selection, presenting new tasks on the basis of test takers' responses to the previous items. The test consists mainly of multiple choice questions and, depending on the level of test takers' language proficiency, lasts for about an hour. Individual scores for reading and listening as well as an overall score are calculated and displayed immediately after the completion of this test (Cope, 2009).

BULATS Online Speaking includes practical tasks that require test takers to answer interview questions, read aloud sentences, give two 1-minute presentations, and express their opinions on a topic. Responses are recorded on a computer and later evaluated by human raters.

Finally, the 45-minute BULATS Online Writing test assesses Business English writing skills via two tasks that must be completed on a computer in response to

given prompts: a 50–60-word e-mail and a 180–200-word report. Responses are subsequently rated by trained examiners.

BEST Plus™ Computer-Adaptive Version Basic English Skills Test (BEST) Plus (published by the Center for Applied Linguistics, <http://www.cal.org/aea/best-plus/ca.html>) is designed to assess the listening and speaking skills of adult learners of English in the US context. The computer-adaptive version of this test is CD-ROM based and takes 3 to 20 minutes to complete, depending on test takers' oral skills. There are seven types of tasks on various general topics such as health, transportation, and housing. The item types comprise photo description, entry item, yes/no question, choice question, personal expansion, general expansion, and elaboration. Upon reading a task to the candidate from the computer screen, a trained test administrator instantly evaluates the candidate's response and enters the score in the computer. The answers are scored on the basis of listening comprehension, language complexity, and communication (Van Moere, 2009). The next item selected by the BEST Plus system is based on the test taker's response to the previous question. Test scores are generated by the computer and become available immediately after the test.

COMPASS® ESL Placement Test The main purpose of the COMPASS ESL Placement Test (published by ACT, <http://www.act.org/compass/tests/esl.html>) is to assess the standard American English language skills of ESL students and place them into appropriate ESL courses at post-secondary educational institutions in the USA. The four major components of this computer-adaptive test— ESL Listening, ESL Reading, ESL Grammar/Usage, and ESL Essay (ESL e-Write)—can be administered either separately or in any combination.

The first three parts of the COMPASS ESL Placement Test are composed mostly of multiple choice questions (with some modified cloze items in the ESL Grammar/Usage test) that derive from listening and reading passages on various academic topics. The adaptive format of the test adjusts the difficulty level of the selected items to the individual test taker's performance. Based on the separate scores for the ESL Listening, ESL Reading, and ESL Grammar/Usage tests, students are assigned one of the four levels.

The 30-minute ESL Essay test is delivered and assessed online using automated scoring technology. The overall score for this test is assigned on a six-point scale and incorporates analytic scores for development, focus, organization, language use, and mechanics.

Versant™ English Test The Versant English Test (published by Pearson, <http://www.versanttest.com/products/english.jsp>), formerly known as PhonePass and Spoken English Tests (SET-10), is an automated test designed to measure the English speaking skills of non-native English speakers. This high stakes test is used in education and business for admission, recruitment, and promotion purposes.

The Versant English Test is composed of six sections: reading, repeats, short answer questions, sentence builds, story retelling, and open questions. It lasts for approximately 15 minutes and can be delivered over a telephone or a computer,

with tasks being presented orally in native-sounding voices. The assessment of test takers' responses is done by an automated speech evaluation system called Ordinate that assigns scores within several minutes after test completion. In addition to an overall score, test takers also receive individual subscores for sentence mastery, vocabulary, fluency, and pronunciation.

*Pearson Test of English (PTE) Academic*TM Developed by the same publisher as the Versant English Test, PTE Academic (Pearson, <http://www.pearsonpte.com/pteacademic>) is designed to measure the English language proficiency of international students in the academic context. First introduced in 2009, this high stakes computer-based test lasts for three hours and consists of four parts: introduction, speaking and writing, reading, and listening. According to the publisher, PTE Academic uses 20 innovative item types including items that provide integrated skills assessment. The test employs automated scoring tools to assess test takers' productive skills: The Intelligent Essay AssessorTM (IEA) is used to evaluate writing skills, whereas Pearson's Ordinate technology is integrated in the assessment of speaking. Score reports, consisting of an overall score, scores for communicative skills (i.e., listening, speaking, reading, and writing), and scores for enabling skills (i.e., grammar, spelling, pronunciation, oral fluency, vocabulary, and written discourse), are available online within five days of test completion. Each score ranges from 10 to 90 points. To date, PTE Academic appears to be the only high stakes computerized language test that uses automated assessment of both productive skills.

L2 Test Development Instruments

The advent of emerging technologies and the Web 2.0 era has generated a number of tools that can be utilized by language educators and practitioners for the development and delivery of low and medium stakes L2 assessment. These instruments include both standalone virtual learning environments that, among other educational purposes, can be used for creating and administering computer-based language tests, and specialized applications to construct individual test items that can later be embedded in different delivery platforms. In this section, we will adumbrate the principal features of the major free (Moodle and Google Docs) and commercial (Respondus and Questionmark Perception) options for creating computer-based language tests.

Moodle 2.2 Moodle (<http://moodle.org/>) is designed for teaching and learning purposes in a variety of educational settings. The latest version of this open-source course management system (CMS), released on December 5, 2011, provides some advanced opportunities for testing and assessment. The new Moodle 2.2 question bank allows for the creation of both selected response items (e.g., true/false, multiple choice, and matching questions) and constructed response items (e.g., cloze, short answer, and essay questions). Latest features in the question bank include new feedback options and delivery modes for presenting questions to test takers: adaptive mode, interactive mode, deferred feedback, immediate feedback, and manual grading. Besides the built-in quiz module that enables the integration of

questions from the question bank and provides various reports statistics, language instructors can utilize third party quiz modules for Moodle such as TaskChain (formerly QuizPort) that come with more advanced assessment features. TaskChain, for example, can be used to create semiadaptive tests that consist of an optional entry Web page followed by a set of quizzes with multimedia content and an optional exit Web page (see http://docs.moodle.org/20/en/QuizPort_module for more information about TaskChain).

Google Docs This Web-based office suite (<https://docs.google.com>) is a good free solution for Google users who want to easily create and publish online quizzes and tests using a Google form. This free application supports several types of questions including multiple choice, checkboxes, text (short answer questions), paragraph text (extended answer questions), and choose from a list questions. To make assessment more visually appealing to test takers, Google provides dozens of customizable themes that can be applied to tests and quizzes. Tests can be delivered via emails or embedded in other Web pages. Once students have completed the assessment, Google Docs will immediately generate reports with students' responses and summarize the results in a graphic form. More advanced features include the implementation of formulas to automatically calculate the number of correct points and final grades received by test takers.

Respondus[®] This commercial assessment tool (<http://www.respondus.com>) is designed for the development of tests that can be integrated in various learning management systems such as Moodle, Blackboard, ANGEL, and Desire2Learn. Respondus supports 15 question types including multiple choice, true/false, matching, short answer, and paragraph-writing tasks. Moreover, this application allows for the use of images, sound, video, and embedded Web content, thus offering language instructors a great degree of flexibility and helping enhance the authenticity of tests. The results of delivered assessments can be saved as custom reports and downloaded in an Excel format. Other options in Respondus include easy archiving and restoration as well as key word search to locate specific questions within a test.

Questionmark[™] *Perception*[™] *Questionmark Perception* (<http://www.questionmark.com/us/perception>) is an assessment management system conceived as a tool for educators and evaluation experts to create and deliver different types of tests, quizzes, and exams. Similar to Respondus, this system supports publishing of tests in other learning management systems using SCORM packages. *Questionmark Perception* can be used to create a great variety of question types. Some innovative items that might be of interest to language testing professionals include *Captivate Simulation* that utilizes simulation questions created in Adobe *Captivate*, and *Spoken Response* that allows test takers to record their responses in an audio format. In addition to multimedia and Flash support, *Questionmark Perception* provides options for importing questions from ASCII, QML, and QTI XML files. Assessments created with the help of this system can be delivered through

standard Web interface and applications for mobile devices. To prevent cheating, questions in high stakes tests can be administered in a secure mode through a *Questionmark* secure server.

This review of existing commercial products as well as tools used for the development of customized computer-based language tests reveals a variety of available language assessment options. While these assessment options demonstrate a strong potential of technology, they also expose challenges in computer-assisted language testing, including the difficulty of providing automated feedback on speaking tests and conducting fully automated evaluation of essays. Many of these challenges are the focal point of present research in CALT. Current efforts also revolve around conducting construct validation research, creating new types of tasks, integrating multimedia in increasingly more authentic language tasks, and advancing integrated skills assessment.

Research Studies and Major Developments in CALT

Construct Validity and Comparability Studies

A great deal of research in the field of CALT has been dedicated to investigating construct validity of computer-based tests. Construct validity evidence refers to “the judgmental and empirical justifications supporting the inferences made from test scores” (Chapelle, 1998, p. 50). According to Dooley (2008), construct validation in CALT is of utmost importance because it helps ensure that the test is measuring test takers’ specific language skill(s) rather than their computer skills. Such validation can be done by comparing traditional (i.e., paper-based) and computer-based language tests. Although comparability studies are often commissioned by test development companies, more independent research comparing paper-based and computer-based language tests is also available (e.g., Sawaki, 2001; Coniam, 2006).

One such independent comparability study was conducted by Sawaki (2001), who reviewed the assessment literature to examine the equivalence between conventional and computerized L2 reading tests. This yielded mixed empirical findings vis-à-vis the comparability of paper-based and computer-based L2 reading tests, highlighting the dearth of research on the effect of the mode of presentation on L2 reading and limitations of the methodological approaches used in the existing studies. The results of Coniam’s (2006) study, however, appeared to be more conclusive. He found high correlation between test takers’ performance on computer-based and paper-based L2 listening tests, even though their scores on the CBT appeared higher than on the conventional test.

Development of Computerized Language Tests

Another line of research in CALT focuses on reporting the development of CATs or other CBTs. Despite the large number of existing commercial assessments, individual researchers and institutions pursue the development of “homemade”

language tests to match their specific needs. Papadima-Sophocleous (2008), for instance, reports on the development of a computer-based online test, NEPTON, that attempts to combine the advantages of CBTs and CATs. The items for this test were selected on the basis of both content and statistical properties (e.g., item difficulty), and target different language competence levels, language skills, and activity types. Unlike a typical computer-adaptive language test, NEPTON allows test takers to browse the questions, change the responses, and complete the questions in any order.

Two other customized computer-based language tests are discussed in the studies by Alderson and Huhta (2005) and Roever (2006). Alderson and Huhta (2005) describe the development of a Web-based language assessment system called DIALANG. This large-scale project involved 25 higher education institutions in the European Union. Based on the Common European Framework of Reference (CEFR), DIALANG provides diagnostic assessment of reading, writing, listening, vocabulary, and grammar in 14 different European languages. Due to the computer-adaptive nature of the test, test takers are given the version of the test based on their responses to the vocabulary test and self-evaluation statements that they have completed at the beginning of the assessment. Another feature of DIALANG is its detailed feedback coupled with suggestions for test takers on how to move to the next CEFR level (Alderson & Huhta, 2005).

The test reported in Roever's (2006) study is a Web-based test of ESL pragmalinguistics. Consisting of 36 multiple choice and short answer items, this low stakes assessment was designed to measure the ESL learners' knowledge of speech acts, implicature, and routines. Although, according to Roever (2006), the test was sufficiently reliable and proved that it was possible to evaluate L2 knowledge of pragmalinguistics, it did not assess users' knowledge of sociopragmatics and relied on the written format for the evaluation of the speech act responses.

Use of Multimedia in CALT

The use of multimedia in computer-delivered language tests has been the focus of debate since the early 1990s. Some experts suggest that the inclusion of multimedia in language tests "can assist us in simulating a great many aspects of communicative language use situations" (Douglas, 2010, p. 118), thus making such tests more authentic. However, research in this area, namely on the use of visuals for listening assessment, has yielded some contentious results. On one hand, the use of multimedia has been found facilitative for test takers' performance on L2 listening tests (e.g., Ginther, 2002). Findings of other studies, however, suggest that test takers can get distracted by video and images (Wagner, 2007; Suvorov, 2009). According to Fulcher (2003), the integration of multimedia in speaking tests is even more problematic due to challenges with the timing of test takers' recordings on one hand, and the dearth of research on the effect of visuals on test takers' performance on the other hand. Thus, the question of whether it is worth investing the time and money to create and implement multimedia in language tests remains open.

Integrated Skills Assessment

Another trend of CALT research focuses on integrated skills assessment. Unlike the testing of unitary skills such as speaking, listening, reading, and writing, this type of assessment is believed to be more authentic due to the interactive nature of tasks that resemble what test takers may encounter in real-world situations (Jamieson, 2005; Ockey, 2009). Several major language tests have recently implemented tasks that assess the integrated skills of speaking and listening (Versant English Test); reading–listening–writing and listening/reading–speaking (TOEFL iBT); and reading–writing, listening–writing, listening–speaking, and reading–speaking (PTE Academic). Although Ockey (2009) maintains that “the future of integrated skills tests appears bright” (p. 845), the use of integrated tasks in CBTs poses certain challenges, namely the vagueness of language ability constructs being measured by such tests. This demands more research on multidimensional constructs and on inferences that can be made about test takers’ language proficiency based on their scores for integrated items (Plakans, 2009b).

Research on Automated Assessment

Significant research efforts are being employed in the area of automated assessment of productive skills. Although automated evaluation has been in use for an extended period of time, its application in language assessment is relatively new (Chapelle & Chung, 2010). Research on automated writing evaluation has resulted in products such as Intelligent Essay Assessor (Pearson), e-rater (ETS), and IntelliMetric® (Vantage Learning) that are capable of analyzing lexical measures, syntax, and discourse structure of essays. The Intelligent Academic Discourse Evaluator (IADE) is another example of a Web-based AWE program that utilizes NLP techniques to provide feedback at the level of rhetorical functions in research writing (Cotos, 2011). IADE has become the prototype of a complex AWE system currently under development at Iowa State University.

Although AWE systems are used extensively in many educational institutions, these systems are not universally accepted. According to Cotos (2011), supporters suggest that AWE systems are generally in close agreement with human raters and are thus more time- and cost-effective. They may also foster learner autonomy, promote the process writing approach that involves writing multiple drafts, and lead to individualized assessment. Critics, however, claim that the use of such systems encourages students to focus on surface features such as grammar and vocabulary rather than meaning. In addition, automated assessment of essays diminishes the role of instructors and impels students to adjust their writing to the evaluation criteria of these systems (Cotos, 2011).

Unlike automated writing assessment, ASE involves an additional layer of complexity in that the test takers’ oral output must first be recognized before it can be evaluated (Xi, 2010a). Despite ongoing research and recent advancements in automated speech recognition (ASR), these technologies are not robust at recognizing non-native accented speech because most ASR-based systems have been designed for a narrow range of native speech patterns. This limitation has been addressed in CALT in two ways. First, some automated speech

evaluation systems (e.g., the one used in the Versant speaking tests developed by Pearson) constrain the context of the utterance so that users' spoken output becomes highly predictable. Other ASE systems (e.g., SpeechRater developed by ETS) compensate for this limitation with free speech recognition by expanding the speaking construct to include pronunciation, vocabulary, and grammar, in addition to fluency (Xi, Higgins, Zechner, & Williamson, 2008). According to Xi (2010a), currently neither of these approaches "has successfully tackled the problem of under- or misrepresentation of the construct of speaking proficiency in either the test tasks used or the automated scoring methodologies, or both" (p. 294).

As shown in this section, research in CALT has led to several major developments, including multimedia language tasks, integrated skills assessment, and automated evaluation of productive skills. Although many of these developments have made a significant impact on language assessment, some of them showed only the potential promise of technology for advancing the field of computer-assisted language testing.

Challenges and New Possibilities in CALT

The views regarding the current status and the future of CALT vary slightly among researchers, with some being more concerned about the severity of existing problems than others. Ockey (2009), for instance, believes that due to numerous limitations and problems "CBT has failed to realize its anticipated potential" (p. 836), while Chalhoub-Deville (2010) contends that "L2 CBTs, as currently conceived, fall short in providing any radical transformation of assessment practices" (p. 522). In the meantime, other researchers (e.g., Chapelle, 2010; Douglas, 2010) appear to be somewhat more positive about the transformative role of CALT and stress that despite existing unresolved issues technology remains "an inescapable aspect of modern language testing" and its use in language assessment "really isn't an issue we can reasonably reject—technology is being used and will continue to be used" (Douglas, 2010, p. 139).

Still, everyone seems to acknowledge the existence of challenges in CALT, maintaining that more work is necessary to solve the persisting problems. In particular, a noticeable amount of discussion in the literature has been dedicated to the issues plaguing computer-adaptive testing, which, according to some researchers, led to the decline of its popularity, especially in large scale assessment (e.g., Douglas & Hegelheimer, 2007; Ockey, 2009). Of primary concern for CATs is the security of test items (Wainer & Eignor, 2000). Unlike a linear CBT that presents the same set of tasks to a group of test takers, a computer-adaptive language test provides different questions to test takers. To limit the exposure of items, CATs require a significantly larger item pool, which makes the construction of such tests more costly and time-consuming. Ockey (2009) suggests that one way to avoid problems associated with test takers' memorization of test items is to create computer programs that would generate questions automatically.

Furthermore, there is no agreement on which algorithm to use for selecting items in CATs (Ockey, 2009). Some test developers suggest starting a CAT with

easy items, whereas others recommend beginning with items of average difficulty. Additionally, no consensus has been reached on how the algorithm should proceed with the selection of items once a test taker has responded to the first question, nor are there agreed-upon rules on when exactly an adaptive test should stop (Thissen & Mislevy, 2000). Nonetheless, research is being carried out to address this issue and new methods of item selections in computer-adaptive testing such as the Weighted Penalty Model (see Shin, Chien, Way, & Swanson, 2009) have recently been proposed.

Another major problem with computer-adaptive tests concerns their reductionist approach to the measured L2 constructs. Canale (1986) was one of the first to argue that the unidimensionality assumption deriving from the IRT models used in CATs poses a threat to the L2 ability construct, making it unidimensional as well. This concern has further been reiterated by other experts in language assessment (e.g., Chalhoub-Deville, 2010; Douglas, 2010). Their main argument suggests that the L2 ability construct should be multidimensional and consist of multiple constituents that represent not only the cognitive aspects of language use, but also knowledge of language discourse and the norms of social interaction, the ability to use language in context, the ability to use metacognitive strategies, and, in the case of CALT, the ability to use technology. Hence, Chalhoub-Deville (2010) asserts that, because of the multidimensional nature of the L2 ability construct, measurement models employed in CBTs must be multidimensional as well—a requirement that many adaptive language tests do not meet. Finally, the unidimensionality assumption of IRT also precludes the use of integrated language tasks in computer-adaptive assessment (Jamieson, 2005). As a result of some of these problems, ETS, for instance, decided to abandon the computer-adaptive mode that was employed in TOEFL CBT and instead return to the linear approach in the newer TOEFL iBT.

The limitations of the adaptive approach prompted some researchers to move toward semiadaptive assessment (e.g., Winke, 2006). The advantages of this type of assessment include a smaller number of items (compared to linear tests) and the absence of necessity to satisfy IRT assumptions. Thus, Ockey (2009) argues that semiadaptive tests can be the best compromise between adaptive and linear approaches and predicts that they will become more widespread in medium-scale assessments.

Automated scoring is another contentious area of CALT. One of the main issues with automated scoring of constructed responses, both for writing and for speaking assessment, is related to the fact that computers look only at a limited range of features in test takers' output. Even though research studies report relatively high correlation indices between the scores assigned by AWE systems and human raters (e.g., Attali & Burstein, 2006), Douglas (2010) points out that it is not clear whether the underlying basis for these scores is the same. Specifically, he asks, "are humans and computers giving the same score to an essay but for different reasons, and if so, how does it affect our interpretations of the scores?" (Douglas, 2010, p. 119). He thus concludes that although "techniques of computer-assisted natural language processing become more and more sophisticated, . . . we are still some years, perhaps decades, away from being able to rely wholly on such systems in language assessment" (Douglas, 2010, p. 119). Since machines do not

understand ideas and concepts and are not able to evaluate the meaningful writing, critics contend that AWE “dehumanizes the writing situation, discounts the complexity of written communication” (Ziegler, 2006, p. 139) and “strikes a death blow to the understanding of writing and composing as a meaning-making activity” (Ericsson, 2006, p. 37).

Automatic scoring of speaking skills is even more problematic than that of writing. In particular, speaking assessment involves an extra step which writing assessment does not have: recognition of the input (i.e., speech). Unlike writing assessment, the assessment of speaking also requires the evaluation of segmental features (e.g., individual sounds and phonemes) and suprasegmental features (e.g., tone, stress, and prosody). Since automated evaluation systems cannot perform at the level of human raters and cannot evaluate coherence, content, and logic the way humans do, they are used almost exclusively in conjunction with human raters. As Xi (2010b) concludes, “We are not ready yet to use automated scoring alone for speaking and writing in high-stakes decisions.”

Other challenges faced by CALT are related to task types and design, namely the use of multimedia and integrated tasks. Although the use of multimedia input is believed to result in a greater level of authenticity in test tasks by providing more realistic content and contextualization cues, it remains unclear how the inclusion of multimedia affects the L2 construct being measured by CBTs (Jamieson, 2005). Some researchers even question the extent to which multimedia enhances the authenticity of tests (e.g., Douglas & Hegelheimer, 2007) since comparative studies on the role of multimedia in language assessment have yielded mixed results (see Ginther, 2002; Wagner, 2007; Suvorov, 2009). With regards to integrated tasks, their implementation in CBTs is generally viewed favorably because such tasks seem to better reflect what test takers would be required to do in real-life situations. The use of integrated tasks is therefore believed to increase authenticity of language tests (Fulcher & Davidson, 2007). However, Douglas (2010) warns that the interpretation of integrated tasks can be problematic because, if the test taker’s performance is inadequate, it is virtually impossible to find out whether such performance is caused by one of the target skills or their combination. This concern appears to be more relevant in high stakes testing than in low stakes testing.

Despite all the above-mentioned issues and concerns, most experts in computer-assisted language testing agree that technological advances and innovative measurement models will move this field forward and “the world of CALT will continue to develop” (Winke & Fei, 2008, p. 362). For true innovations and transformation of technology-enhanced language assessment to occur, CALT must be reconceptualized through “fundamental changes in the representation of the L2 construct, overall test design, task development, and even the context and purpose of tests” (Chalhoub-Deville, 2010, p. 522). New possibilities for CALT include, but are not limited to, integrating CBTs in distance and online language education; creating computer-based tests for narrower, more specific purposes; exploring the potential of technology (for instance, eye-tracking systems that enable screen navigation through eye movements) for designing language tests that will be able to better accommodate test takers with disabilities; developing innovative, more

authentic test items; and conducting interdisciplinary research to advance the field of automated scoring. Progress in automatic speech recognition and emotion recognition systems that identify emotions from speech using facial expressions, voice tone, and gestures (see Schuller, Batliner, Steidl, & Seppi, 2009) will inevitably create new opportunities for computer-based assessment of speaking. Furthermore, with the anticipated advent of Web 3.0 (Semantic Web), where computers will be able to generate new information, computer-assisted language testing might gradually evolve to the point where test items will be automatically generated by computers. For instance, to make speaking tests more authentic and mimic real-life situations, computers will act both as raters and as interlocutors, creating new tasks based on students' responses and adapting these tasks to students' performance. In the meantime, regardless of the types of future transformations and innovations that will occur in CALT, we should never forget Douglas's (2000) warning that "language testing . . . driven by technology, rather than technology being employed in the services of language testing, is likely to lead us down a road best not traveled" (p. 275).

Performance Assessment in the Classroom

Guoxing Yu

University of Bristol, England

Defining Performance Assessment

What is performance assessment? This section reviews the rationales, conceptualizations, and characteristics of performance assessment as understood in the fields of educational and language assessments.

The increasing popularity of, or the renewed interest in, performance assessment in education since the early 1980s, especially in the USA, has been driven mainly by the belief that assessment tasks should involve activities that are valued in their own right, meaningful and intrinsically motivating, and have the capacity of leading to improved learning and instructions and to “greater and more appropriate accountability” (Linn & Baker, 1996, p. 85). It is one of the outcomes of “the reaction on the part of educators against pressures for accountability based on multiple-choice, norm-referenced testing” (Khattri, Reeve, & Kane, 1998, p. 2) in addition to their belief in using assessment as a lever of educational reform. The development of the constructivist model of learning in the cognitive sciences has also contributed to the momentum of using performance assessment in large-scale and high stakes educational assessments (Khattri et al., 1998). It is perhaps the shifting conceptions of validity in educational measurement that have enhanced such momentum (Moss, 1992).

Performance assessment has been vaguely labeled as any type of assessment that requires students to produce something more than choosing a correct response from several options. *The Standards for Educational and Psychological Testing* (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education [AERA, APA, & NCME], 1999, p. 137) stated that performance assessments “attempt to emulate the context or conditions in which the intended knowledge or skills are actually applied.” Khattri et al. (1998, p. 2) posited that “all performance assessment must require students

to *structure* the assessment task, *apply* information, and *construct* response, and in many cases, students must also be able to *explain* the processes by which they arrive at the answers" (emphasis in the original). Performance assessments typically include open-ended tasks, involve higher order and complex skills, extended periods of time for performance, group or collaborative planning and activity, student or teacher choice of tasks (or both), and judgmental scoring (Linn & Baker, 1996). The defining characteristic of a performance assessment is "the close similarity between the type of performance that is actually observed and the type of performance that is of interest" (Kane, Crooks, & Cohen, 1999, p. 7).

It is this "close similarity" or proximity between the performance and the construct of interest that is particularly appealing for language assessment communities—testers and teachers alike—in the era of communicative language teaching and learning, which has been the major driving force for the use of performance assessment in both high and low stakes contexts, particularly since the 1970s (for a brief account of the history of performance assessment and testing in second language contexts, see Shohamy, 1995; Milanovic & Saville, 1996; McNamara, 1997). Chomsky's (1965) seminal work, defining "performance" as actually produced by people, in contrast with their language "competence" (that is, with their underlying knowledge of a language), has influenced the conceptualization of communicative competence, which in turn has "helped to bring performance to the centre of attention in language testing" (Milanovic & Saville, 1996, p. 5). Unlike performance assessment in arts, sciences, or mathematics, language is both the construct of interest and the medium of assessment in language-focused performance assessment. The dual role of language in assessing performance presents language assessment professionals with significant challenges, especially in defining the construct, designing the tasks and evaluation criteria, and interpreting test scores for use.

There also seems to be, in the field of language assessment, a proliferation of the use of the term "performance assessment" in a variety of forms, such as "authentic assessment," "performance testing" (e.g., Hauptman, LeBlanc, & Wesche, 1985; Wesche, 1987; Milanovic & Saville, 1996; McNamara, 1997), "performance-based assessment," "task-based performance assessment" (e.g., Wigglesworth, 2008), "task-based language performance assessment" (e.g., Bachman, 2002b; Norris, 2002), and "outcomes-based performance assessment" (e.g., Brindley, 1998). These terms fundamentally point to the same characteristics of "performance assessment" as used in the general educational assessment literature, encompassing authenticity and close similarity or proximity between assessment tasks and the target language use domain(s). These terms are also used interchangeably in some publications by the same authors, even in the same publication (e.g., Shohamy, 1995; Chalhoub-Deville, 1996; McNamara, 1997). It should be noted that there are scholars who tried to distinguish these terms as well, such as Brown, Hudson, Norris, and Bonk (2002), who tried to define task-based assessment as a subset of performance-based language assessment. Wigglesworth (2008) also seemed to endorse this kind of distinction, as the title of her article, "Task and Performance Based Assessment," indicates. However, as Ross (2012, p. 223) rightly pointed out, "As performance assessment becomes increasingly synonymous with task-based assessment, specification of what an assessment task

actually entails is subject to interpretive variability." In fact, task-based assessment and performance (-based) assessment often share a lot of common ground, if they are not synonymous, because performance assessment inevitably uses "tasks" as prompts to generate extended responses from test takers.

Davies et al. (1999, p. 144), in the *Dictionary of Language Testing*, provided an overview of what "performance test" is in relation to validity (predictive, construct, face, and consequential), reliability, and test administration. They defined "performance test" as a test "in which the ability of candidates to perform particular tasks, usually associated with job or study requirements, is assessed. Performance tests (also known as authentic tests or direct tests) use 'real life' performance as a criterion." Chalhoub-Deville (1996, p. 55) defined performance tests as those requiring students to "produce complex responses integrating various skills and knowledge and to apply their target language skills to life-like situations." Similarly, Milanovic and Saville (1996, p. 3) defined performance test as "a testing procedure which requires the candidate to produce a sample of language, either in writing or speech (e.g. essays and oral interviews)."

In terms of evaluation criteria, McNamara (1996) distinguished two forms of performance assessment: a weak performance test where the focus of assessment is "on the quality of the language alone" and a strong performance test where the focus of assessment is "on how well the candidate succeeds in the task" (Davies et al., 1999, p. 144), that is, on the outcomes of the action. Therefore, in the strong form of performance assessment, the "performance on tasks" is the construct of interest and "constructs of language ability or specific areas of language knowledge are irrelevant" (Bachman & Palmer, 2010, p. 219). In practice, however, it is always a continuum; there is no pure weak or strong form of performance assessment. It is a combination of *language* and *performance* contributing, in varying degrees, to the construct(s) of measurement that makes language performance assessment different from performance assessment of other subjects or skills, because the extent to which a language task can be successfully performed is almost inevitably related not only to test takers' language ability or specific areas of language knowledge, but also to a host of nonlanguage factors. The varying role of language and performance in performance assessment has implications for the design of the tasks and evaluation criteria, which is the focus of the next section.

Designing Performance Assessment

How do you design performance assessment? Before addressing the issues in designing language performance assessment with reference to task design and evaluation criteria, it makes sense to put two disclaimers in place. First, as Milanovic and Saville (1996) indicated that performance assessment is often in the form of speaking and writing assessments, it is important to review the two different types of performance assessments separately, which is, however, beyond the scope of this chapter. Interested readers are advised to consult Chapter 9, Assessing Speaking; Chapter 12, Assessing Writing; and Chapter 13, Assessing Integrated Skills. Second, it is also important to point out that there is not enough

space in this section to discuss the methods of task design in detail. Interested readers should consult Chapter 35, Task-Based Language Assessment.

There are two general approaches to designing performance tasks, of which Messick (1994) suggested that, “where possible, a construct-driven rather than a task-driven approach to performance assessment should be adopted” (p. 22). In a series of publications, Bachman (2001, 2002a, 2002b; Bachman & Palmer, 2010) also discussed construct validity issues and challenges in designing performance assessment tasks. For example, Bachman (2002b) stressed the difficulty in task sampling and selection, and in defining not only the difficulty and complexity levels of performance assessment tasks but also their content relevance and representativeness. Huang’s (2009) meta-analysis of the magnitude of task-sampling variability in performance assessment of students’ subject learning (including mathematics; science; first language listening, reading, and writing; and foreign languages) found that “the percentage of variance components for tasks were roughly 12% and 26% for person–task interaction” (p. 905). Although subject-wise, foreign language performance assessment was least affected by the task-sampling variability, according to the meta-analysis, the findings of this study do warn us that a substantial proportion of the variance in students’ performance could simply be attributable to task-sampling variability. It was noted in the meta-analysis that task-sampling variability was even higher than rater-related variation.

Closely related to sampling variability, another technical issue that performance assessment designers have to address is the generalizability of the content, conditions, and methods of the sampled tasks and students’ responses to the performance tasks. The enormous complexity and potential variability caused by the richness of the performance assessment settings can “easily jeopardize the fairness and the generalizability of conclusions we may reach about individual candidates” (McNamara, 1997, p. 134). As Ross (2012, pp. 223–4) wrote, claims or inferences made from performances about candidates’ language proficiency are “crucially dependent” on the thoroughness of task sampling and representativeness in relation to the construct of measurement, and on “how much they entail content felicitous [*sic*] with language use outside the assessment context, and the degree to which performances on such assessment tasks predict proficiency in non-assessment contexts.” Two key sources of variability are associated with performance assessment tasks (including the content and conditions of the tasks) and the evaluation of students’ performance (including rating criteria and raters’ behaviors).

In the construct-driven approach to task design, the initial step is to establish whether the construct of interest is the language (i.e., language abilities) or the performance (i.e., task completion) or both; in other words, whether it is the *weaker* or *stronger* form of performance assessment. Theories of performance assessment and communicative competences offer useful theoretical guidance for the development of the construct, along with the well-rehearsed needs analysis, which can help to define the specific contexts and conditions of the tasks that test takers need to perform and the criteria against which their performances are to be judged. “At the heart of the construct validity of many performance assessments is a rating scale . . . , as this offers an operational definition of the construct being measured, and is often the only place in which the test construct is defined” (McNamara, 1997, p. 135).

The design of performance assessment tasks and rating scales has drawn upon findings from numerous second language acquisition (SLA) studies, for example on how different task characteristics (e.g., dialogic vs. monologic, individual vs. group, structured vs. unstructured, timed vs. untimed, planned vs. spontaneous, extended vs. short responses) interact with the characteristics of the performers (e.g., gender, social and linguistic status, personality and language proficiency, to name just a few), and how such interactions may exert differential impacts on the different quality indicators of performance (e.g., complexity, fluency, and accuracy) (see *Applied Linguistics*, 2009). Similarly, a large number of studies in the field of language assessment have followed such SLA research traditions to identify construct-relevant and -irrelevant factors of task performance.

Some studies have tried to provide practical advice on how to design performance assessment tasks. Norris, Brown, Hudson, and Yoshioka (1998) is one such study in language assessment; it presents a prototype framework for second language performance assessment with numerous examples of prototypical functional language tasks, ranging from planning a weekend to filling in job applications and arranging a bank overdraft (see Norris et al., 1998, chap. 6). Further examples and analyses of task generation process are also listed in an appendix to the book, using the task difficulty matrix developed from Skehan's (1998) model of code complexity, cognitive complexity, and communicative demand of tasks. This "difficulty by design" approach is a useful entry point to understanding task difficulty levels. However, Bachman (2002b) argued that the conceptualization of task difficulty features "confounds" task characteristics with test takers' language ability. It is true that not all performance tasks are equal in terms of their difficulty level: some are more difficult inherently than others. Nonetheless, it is fundamentally the interactions between task characteristics and test takers' language and other abilities that shape the difficulty of the tasks in use. Task difficulty is "not solely dependent on analytically derived characteristics of a task" (Ross, 2012, p. 224). Or, in Bachman's (2002b, p. 453) words, "difficulty is essentially an artifact of test performance, and not a characteristic of assessment tasks themselves." Along with the complexity and challenge in working out the difficulty level of any performance task a priori, the evaluation of the artifact of test performance a posteriori requires equally, if not more, demanding efforts from task designers. The challenges in achieving higher consistency in evaluating language performance assessment are probably more acute than those in other subject areas.

At least two factors external to the students' actual performance to be judged can confound the assessment of the quality of their performance: evaluation criteria and raters. Quellmalz (1991) proposed six characteristics, which are highly relevant to language performance assessments, for developing sound evaluation criteria: significance, fidelity, generalizability, developmental appropriateness, accessibility, and utility. In terms of *significance*, the evaluation criteria should represent a sample of knowledge and strategies from the real-world target domain, including linguistic, cognitive, metacognitive and dispositional components of the task; in other words, it is not just the language that should be acknowledged as capable of playing some significant part in test takers' performance. In terms of *fidelity*, the evaluation criteria should be maintained by creating real-world tasks, conditions, expectations, and quality levels. In terms of *generalizability*, the

evaluation criteria should be representative within and across domains (when appropriate) and should represent instructional practices. In addition, a common understanding of the criteria should be shared by various stakeholders, especially raters, test takers, and teachers. In terms of *developmental appropriateness*, the evaluation criteria should be consistent with theory-based stages in learners' language and literacy development and emphasize the accomplishments rather than weaknesses of test takers. However, as Fulcher (2012, p. 386) cautioned, this can be "entirely misleading," as "there remains a paucity of empirical evidence for any link between hierarchical scale descriptors and second language acquisition." In terms of *accessibility*, the evaluation criteria should be written in a style that is clear and accessible to all stakeholders, especially test takers, raters, and teachers. In terms of *utility*, the evaluation criteria should focus on performance features that can be addressed and achievable within reasonable time frames. Governing the evaluation criteria are the purposes of the use of language performance assessments, that is, the extent to which the assessment focus is on language or performance. As Fulcher (2012, p. 386) noted, "it has been exceptionally difficult to keep the two apart" (see also above on the weak and the strong forms of performance assessment).

From language assessment perspectives, Fulcher (2012) provided a critical account of the history of evaluation criteria for performance assessments, dating back to the 1910s. He critiqued five methodologies currently in use for the construction of evaluation criteria for performance assessments. These are intuitive and experiential; scaling descriptors; performance data-based; empirically derived, binary choice, boundary definition (EBB); and performance decision trees (PDTs). The *intuitive and experiential* method draws on primarily expert committees and their experience and expertise to develop the descriptors a priori. It is a kind of "armchair" approach. Similarly, the *scaling descriptors* (e.g., the Common European Framework of Reference for Languages [CEFR] descriptors) method draws on not only other extant rating scales but also experts' (e.g., language teachers' and testing professionals') perceptions of a particular level of the descriptors with reference to the language proficiency of an imagined typical group of language learners. In the *performance data-based* method, discourse analysis is employed to identify key features and levels of language proficiency from speech or writing samples, that is, from test takers' actual responses to particular performance tasks sampled (as representatively as possible) from the target language use domains. The *EBB* method does not involve an analysis of the actual performance samples per se; rather, it is through an evaluation by judges (often experts) of what makes one sample superior or inferior to another that the evaluation criteria are developed. The *PDT* method incorporates EBB and performance data-based approaches; it involves an analysis of discourse in context or use to understand whether certain discourse and pragmatic features for efficient and effective communication in language are present or not.

In practice, the evaluation criteria are often developed using a combination of the above methods. Evaluation criteria should be treated as an evolving document which is influenced reciprocally by the theories of language and language performance assessments and the empirical evidence accumulated from the actual use of the evaluation criteria.

The application of the evaluation criteria is ultimately dependent upon the interpretations of the criteria by raters. Central research questions in this area include how and why raters make different interpretations of the criteria (e.g., Cumming, Kantor, & Powers, 2002; Eckes, 2008), and to what extent rater training may improve the reliability of their marking (e.g., Lumley & McNamara, 1995; Weigle, 1998) and hence the overall quality of language performance assessments.

In addition to the challenges discussed above in relation to task design and evaluation criteria development and implementation, there are a number of other disadvantages or challenges which are inherent in performance assessment, as Nitko (1996, pp. 257–8) pointed out. For example, completing performance tasks for students and scoring performance task responses are time-consuming; performance on one task provides little information about performance on other tasks; completing performance tasks may be discouraging to less able students; and performance assessments may under-represent the learning of some cultural groups, which raises issues such as educational equity (Darling-Hammond, 1994; Gordon & Bonilla-Bowman, 1996) and equality (Baker & O’Neil, 1994). Furthermore, performance assessments may still be “corruptible” due to “teaching to the test” effects, although it is widely acknowledged that performance assessments are potentially better in this regard than assessments based purely on multiple choice questions. However, as Linn and Baker (1996, p. 85) argued, although the movement toward performance-based assessment was not primarily driven by psychometric considerations, the assessments “nonetheless need to be psychometrically sound, especially when they are used to make important decisions.” Reliability and validity are perennial issues with performance assessment. In Linn and Baker’s (1996, p. 100) words, “technical quality is an unassailable requirement of performance assessments.” In addition to psychometric soundness and coherence (including reliability and validity), the accessibility, accountability, capacity, and practicality of performance assessments remain key challenges and barriers faced by teachers, education authorities, and examination boards when implementing performance assessments, whether in large-scale, high stakes assessment contexts or in teacher-initiated, low stakes, classroom-based ones (Linn, Baker, & Dunbar, 1991; Baker, O’Neil, & Linn, 1993; Linn, 1994).

Future Directions

The section above reviews, in a broad-brush style, the key challenges and methods in designing language performance assessment tasks and evaluation criteria as the two major areas of focus. This section will explore further these two major areas, but in slightly more detail and looking more to the future, largely from research perspectives. The theoretical and logistic assumptions, requirements, and challenges in the use of language performance assessments have been well documented elsewhere (e.g., Norris et al., 1998; Bachman, 2002b). Here I will make a number of suggestions in some of the key areas that I believe can enhance the validity argument for the use of language performance assessments for different purposes. These suggestions are made not necessarily in order of importance,

because any aspect of performance assessment, however small or large—ranging from defining the construct of interest, conducting needs analysis, sampling for task design, developing and applying evaluation criteria, score reporting, interpretation, and use, to the impacts by design on various stakeholders (e.g., on learning and professional development of students and teachers) individually and as a whole—can potentially hold significant threats for the validity argument for language performance assessments.

Research evidence in language performance assessments has been pointing in different directions, and inconsistently, to the effects of the variability in task characteristics (including assessment methods), task–person interactions, evaluation criteria and methods (holistic vs. analytic, augmented vs. non-augmented), and rater training on the quality of the use of performance assessments to measure students' achievements. It is therefore essential for both task designers and users to have a better understanding of these effects. A meta-analysis similar to Huang's (2009) would be a timely research endeavor to gain an overall and comprehensive picture, if possible, of the use of language performance assessments in different contexts, and to pave the way for further research efforts on the detailed planning and implementation of language performance assessments. Below I suggest six integrations of different aspects of language performance assessments that I believe might help to improve the validity argument for the use of language performance assessments for different purposes.

(1) *Integrating performance assessment with teaching and learning and with teacher professional development* to achieve better reciprocal resonance between assessment, teaching, and learning (e.g., the Integrated Performance Assessment [Glisan, Uribe, & Adair-Hauck, 2007]). Student responses on performance assessments, that is, spoken and written corpora, can be used to inform teacher professional development (Bunch, Aguirre, & Tellez, 2009). Gordon and Bonilla-Bowman (1996) elaborated on the "curriculum-embedded, performance-based assessment" which "assumes a system in which teaching, assessing, record keeping, criticizing, evaluating, exhibiting, and reflecting all serve to enable and enhance learning," and which treats teaching, learning, and assessment as "continuously interacting components, utilizing instructional materials to provide opportunities for assessment and assessment procedures as instruments for instruction" (p. 36). Using portfolio assessment as an example of student performance assessment tools, however, they pointed out several challenges concerning students of diverse characteristics, such as diversity in their learning styles (e.g., some prefer small group work, while others may prefer a more traditional learning situation); diversity in their developed abilities; and culture and language diversity, which "can amplify the effect of differences in both developed ability and learning style" (p. 44). Summative reporting and outcome-based performance assessment (Brindley, 1998)—that is, yes/no decision making—are limited in terms of washback of performance assessments on teaching and learning, because yes/no decision making does not provide further information on how students performed in the tasks. Without focusing on the language sample produced, the assessment can be misleading, and unhelpful for teaching and learning. In this sense, it is desirable that language performance assessments remain in the *weak(er)* form to value the "language" part of the assessments, in the foreseeable future.

(2) *Integrating classroom-based or teacher-initiated performance assessments with large-scale, high stakes assessments.* In other words, the classroom-based or teacher-initiated performance assessments are part of the mandated large-scale, high stakes assessments. SLA and task-based language teaching (TBLT) research studies on the effects of task conditions (e.g., planning time, task complexity and difficulty) on performance (e.g., complexity, fluency and accuracy of responses), and of raters' behaviors when assessing the quality of test takers' performance, have led to our better understanding about task-based performance assessment, especially in large-scale language-testing contexts. However, it remains a significant challenge for both language testers and teachers to understand to what extent and how the findings and the principles of performance assessments in large-scale and high stakes language tests can be adapted in classroom settings, and vice versa. The School-Based Assessment (SBA), which was recently introduced into the Hong Kong educational assessment system, is a good example of integrating teacher-initiated performance assessments with high stakes mandated assessments (*TESOL Quarterly*, 2009; see also Chapter 101, *Assessing English in East Asia*).

(3) *Integrating language with content knowledge in language performance assessments.* Although language performance assessment tasks should primarily test students' language abilities, any overuse or overemphasis of language can easily lead to tasks being artificial, unnatural, or inauthentic. In the current world of learning and instruction, language is often taught and learned side by side with other subjects, for example in content and language integrated learning (CLIL). The use of assessment tasks integrating other subject or content knowledge but still requiring substantially language skills to complete the tasks therefore becomes a natural choice in the current world of learning, where language is not learned in isolation from other subjects. However, there are a series of issues and challenges that we must address, such as how to evaluate students' performance in response to such content-integrated or intensive language tasks; to what extent content knowledge should be valued or taken into account when modeling or extracting students' language abilities; in what contexts language becomes a peripheral or predominant assessment focus; and to what extent there should be differential flexibility and accommodations in place for learners of different learning styles, language and cultural backgrounds, and maturity in language, literacy, and other domain knowledge. These points apply particularly when the assessment involves a diverse group of learners, as in state-wide assessments for accountability purposes, and in international educational assessments for comparison purposes. There has been extensive research on the relationships between the English language proficiency of English language learners (ELLs) and their performance in content-integrated or intensive performance assessment tasks (Aguirre et al., 2006) within the political agenda or context of the 2001 "No Child Left Behind" Act in the USA. The findings from these studies can provide useful guidance in the design of language-focused performance assessments. For example, studies on the effects of providing assessment accommodations (Abedi, 2008), especially linguistic simplifications, for ELL learners on their content-integrated or intensive task performance can shed light on how language functions in performance-based assessments.

(4) *Integrating computer technology in task design and in delivery and analysis of empirical data.* Computer technology permeates every aspect of modern life; it can

be used for the development and delivery of performance assessment tasks, and indeed itself is already part of computer-mediated performance tasks. It would be unimaginable for empirical data collected from performance assessments not to be analyzed using statistics computer programs. Technological advances in statistical modeling offer tools to better understand performance assessments. For example, Rasch techniques are often used to detect bias in rating (e.g., Lynch & McNamara, 1998). Multilevel modeling techniques typically used in school effectiveness research (Yu & Thomas, 2008), but rarely used in language assessment research, can be applied to better understand the effects of factors at the student, school, district, state, or country level on the students' performances. Performance data, especially language samples, are now also routinely subjected to automated scoring systems in large testing organizations. Automated scoring systems potentially can make the wide use of performance assessments in high stakes tests possible. Tools developed in automatic natural language processing can also be used to analyze performance data.

(5) *Integrating the assessment of the process and the product of the performance.* Nitko (1996) emphasized the potential to assess "two aspects of a student's performance: The product the student produces and the process a student uses to complete the product" (p. 240). In language performance assessment tasks, it is often the product, that is, the responses, that test takers produce that are assessed; however, it is perhaps equally important to look at the processes of how test takers produced the responses, either individually or collaboratively, for summative and formative processes. For example, the students' performance at different stages of completing the tasks might contribute to the final grade for their performance; and teachers might provide formative feedback to students before they move on to the next stage of the tasks. During the process of performance assessment, it would also be desirable to involve students in task design and evaluation criteria development; for example, in deciding what is important information that they think should be included in a summary (Yu, 2007).

(6) *Integrating different language skills and modes of presentations to enhance the authenticity of assessment tasks.* Performance assessments have traditionally been linked with independent speaking (e.g., interviews, role plays) and writing tasks. The renewed interest in using integrated assessment tasks (e.g., reading-to-write, discourse synthesis, and summarization [*Language Assessment Quarterly*, 2013]) provides an excellent opportunity to expand the repertoire of performance assessments. For example, the assessment of speaking may involve reading a passage and listening to a lecture, as in the Test of English as a Foreign Language Internet-based test (TOEFL iBT), or the assessment of reading comprehension may involve oral or written summarization of the source texts presented on computer screen (Yu, 2008, 2010).

Concluding Remarks

In this introductory chapter I aim to provide readers with an overview of what performance assessment is, how to design performance assessment tasks and evaluation criteria, and some of the key areas for further development which I

believe will help to enhance the validity argument for the use of performance assessments for different purposes. Taking into account the key rationale and features of performance assessments, I have made a number of suggestions with regard to the integrations, interfaces, reconciliations, and sometimes even competing contrasts between summative and formative performance assessments; between standardized and classroom-based performance assessments; between the opportunities for students to learn and for teachers' professional development; between teacher and students' initiation of performance tasks and the requirements of accountability, fairness, and other quality indicators of performance assessments; between the process and the product of performance; between linguistic and nonlinguistic factors contributing to performance success; between construct-driven and task-driven task design; between individual work and group processes; and between evidence and consequences of performance assessments. In the foreseeable future, performance assessment in the field of language assessment will remain as a weak(er) form, given the focus on "language" as the key learning outcomes in many contexts.

Monitoring Progress in the Classroom

Rama Mathew

Delhi University, India

Matthew E. Poehner

Pennsylvania State University, USA

Introduction

Among the most widely researched topics in language assessment over the past 15 years has been how assessment practices relate to and support teaching and learning. This trend is in clear evidence at professional meetings such as those organized by the International Language Testing Association (ILTA) and the American Association of Applied Linguistics (AAAL), where colloquia organized around this topic have become a regular feature. Special issues of leading journals both in language assessment (see, for example, McNamara, 2001; Rea-Dickins, 2004) and in general education (see, for example, Stobart, 2006; Klenowski, 2009) further attest to the vigor with which researchers are attempting to conceptualize assessment that promotes learning. Debates in many countries over the deleterious effects of regular large-scale, standardized testing have no doubt contributed to interest in other means of understanding learner abilities and progress. In addition, the growing popularity of models of learning that emphasize the social origins of abilities, together with the dominance of communicatively oriented language curricula, has further fostered an environment that more readily recognizes assessment as a natural feature of teaching and learning activities rather than a standalone endeavor that requires learners to perform under unique testing conditions.

This chapter proceeds from the perspective that assessment can best support teaching and learning when these two activities are aligned. Put another way, we argue that assessment may function to monitor learner progress, and in so doing it provides the necessary basis from which instructional decisions may be made. We are thus clearly more concerned in this chapter with assessments undertaken for *formative* rather than *summative* purposes. This is not to undermine the value of the latter for language education. Rather, it reflects a commitment to understanding learner abilities while they are in the process of developing and while

feedback may be offered and classroom instruction attuned to support that development. It is in this regard that one may contrast summative assessment (henceforth, SA), or assessments of the products of learning at the completion of an instructional cycle or program, with formative assessment (henceforth, FA), where the express purpose is to know about the current state of learner development in order to determine the way forward (Assessment Reform Group, 2002). The emphasis on monitoring as well as guiding learner development is also brought out explicitly in recent research in the area of dynamic assessment (henceforth, DA) (see Chapter 41, *Dynamic Assessment in the Classroom*).

In what follows, we offer an overview of current conceptualizations of assessment that endeavor to help teachers to monitor and support learner development in an ongoing manner. We also discuss important innovations in how learner progress itself may be understood. We then turn to issues that must be overcome, at conceptual and systemic levels, for effective assessment practices to be implemented in the classroom.

Clarifying Terms

Before moving on, we wish to disambiguate certain terms that are sometimes used interchangeably but that in fact have particular meanings. To begin, it is important to understand what the terms *testing*, *assessment*, and *evaluation* mean in the context of monitoring progress in the classroom. Following Harris and McCann (1994), *assessment* refers to activities designed to provide information relevant to drawing inferences about learning processes, products as well as learner progress. The notion of classroom-based assessment thus includes a range of formal and informal activities undertaken by teachers and students. Testing, in contrast, is more specifically concerned with measuring an individual's ability or knowledge in a given area to determine what he or she knows or has learned. Finally, the term *evaluation* evokes a broader, often program-wide perspective that "involves looking at *all* the factors that influence the learning process, such as syllabus objectives, course design, materials, methodology, teacher performance and assessment" (Harris & McCann, 1994, p. 2).

For the purpose of this chapter, we follow a definition of FA adapted from Bell and Cowie (2001) that understands it as the *process* used by *teachers and students* to *recognize* and *respond* to *student learning* in normal, noncontrived classroom activities in order to *enhance that learning, during the learning* (see also Assessment Reform Group, 2002, emphasis added to mark important features). Thus, it is not the case that all assessments undertaken in classrooms are formative in nature. FA requires comparing actual (present) and reference (future) levels of performance and using the resultant information to bridge the gap between these levels. In this way, successfully orchestrating assessments that are both informative of learner abilities and that support their continued development is critical to monitoring progress.

Previous Views or Conceptualization

The idea of monitoring progress in the classroom has emerged from developments in two somewhat distinct but overlapping areas: the development of educational

evaluation models with particular reference to language evaluation, and the shift from curricula that are objectives-based to those that are communicatively oriented. Beretta (1992), citing scholars of that time (for example, Bloom, Scriven, Stake, Stufflebeam, Tyler), traces developments in the history of language evaluation beginning with major conceptual shifts during the early 1960s. While Bloom (1969) had proposed a formative role for evaluation which provided for giving feedback and correctives at each stage of the teaching–learning process, models of evaluation at the time were found to be sorely lacking in this respect. For example, Tyler’s (1949) “rational” model in which behavioral objectives were specified beforehand and tests were designed to test the achievement of these objectives, had enjoyed considerable popularity but was critiqued for failing to take account of *process*, that is, of what happened in the classroom. Researchers increasingly realized that no matter how well specified the objectives are at the beginning of an instructional program, restricting evaluation exclusively to learning outcomes does not account for unexpected outcomes and outcomes that are hard to define let alone capture through external tests. This gave rise to a host of new models that emphasized the need for descriptive data and value judgments that could improve programs. Scriven proposed a distinction between *formative* and *summative* assessments, with the former tracking process and progress while the latter seeks to determine outcomes of a program. Others offered practical recommendations for monitoring learner progress through the CIPP model (context, input, process, and product) and advocated a process of delineating, obtaining, and providing useful information for judging decision alternatives using systematic observation, interviews, diaries, and rating scales aside from product assessment.

During roughly the same period, the shift toward communicative language teaching ushered in a view of language teaching as involving the use of language for meaningful communication as a means of learner language development and not simply as an end goal. Communicative language teaching views the negotiating of meaning that occurs in ongoing interaction among teachers and learners to be the key element in second language development (see Brumfit and Johnson 1979). This perspective implies that different learners could be learning different things from the same interactions. This state of affairs rendered assessment far more complex than it had been previously. Specifically, it was recognized that rather than understanding assessment in terms of learning outcomes derived in a linear relation from particular teacher input, it is necessary to examine these processes as they occur in the classroom over time.

Against this backdrop, evaluation during the 1980s shifted from an activity focused on testing learners at the end of a program to integrating an evaluation system into curriculum design in order to investigate processes of learner development and how instruction could best meet learner needs. The need for understanding and interpreting data about language learning from the classroom was recognized (see Lewkowitz and Moon, 1985, for a comprehensive account of how learners can be involved in the evaluation process). At around the same time, Stenhouse (1975) emphasized the need for the teacher to be a researcher and a learner. Stenhouse conceived this as *research-based teaching*. He argued:

It is difficult to see how teaching can be improved or how curricular proposals can be evaluated without self-monitoring on the part of teachers. A research tradition

which is accessible to teachers and which feeds teaching must be created if education must be significantly improved. (1975, p. 165)

This confluence of shifts in educational evaluation and growing research into processes of second language acquisition, particularly in classroom settings, set the stage for the considerable research over the past 20 years on FA vis-à-vis the pivotal role of teachers.

Current Views

The move in recent years away from models of assessment that measure how well learners perform under testing conditions to models that emphasize how assessment may generate feedback to enhance learning has been described as a move from *assessment of learning* to *assessment for learning* (AfL). While distinctions such as these have been discussed extensively in the educational and language assessment research literatures, FA has struggled to establish itself in a way that does not define it in contrast to SA. For example, Rea-Dickins and Gardner (2000) have contested the assumption that the outcomes of FAs, in contrast to SAs, are of relatively low consequence to learners. These authors argue that classroom FAs are often the basis for very high stakes decisions, such as allocation of resources, identification of learners with particular needs, and placement of learners in courses of study. For their part, Black and Wiliam (1998) cite the invaluable benefits of FA to promoting educational goals. In their influential review, drawing on their own work and other research on FA in several countries, these authors assert that there is probably no other way of producing significant and substantial gains across a range of age groups and school subjects. In the last two decades, the realization of the importance of FA for purposes of monitoring progress has resulted in curriculum documents specifying a scheme for FA (see, for example, Curriculum Development Council 2001; Assessment Reform Group 2002).

Regardless of whether one recognizes FA as a high stakes undertaking, it has also been argued that FA cannot, and should not, be judged according to the same criteria as formal testing as these represent fundamentally different activities, each with their own goals and underlying assumptions about learners (e.g. Leung & Mohan, 2004). However, it is also to be noted that FA, unlike SA, does not have a robust conceptual framework to guide its practice. There have been, however, a number of proposals that intend to do precisely that. We discuss four that have influenced practices of monitoring learner progress in the language classroom.

Conceptual Frameworks of FA

Perhaps one of the most straightforward conceptualizations of how learner progress may be systematically monitored is Nitko's (1995) framework for *curriculum-based continuous assessment*. Of particular interest here is that his model advocates informal continuous assessment, which includes teachers' perceptions

of student learning through the use of techniques such as observation, talking and listening to students during lessons, and reviewing homework. This becomes the (ad hoc) basis for monitoring student progress for the purpose of (a) identifying a student's learning difficulties on a daily and timely basis and (b) providing immediate feedback to a student about his or her learning. Interestingly, since the curriculum becomes the basis for assessing student learning, all assessments, both teacher-based and external ones, can be aligned with the learning targets, making it a seamless fabric of teaching, learning, and assessment. However, a shortcoming of this framework is that it does not, at least explicitly, take account of the unintended outcome(s) of teaching, that is, those processes that go beyond the official curriculum.

The matter of unintended outcomes is taken up in the work of Bell and Cowie (2001). They propose two forms of FA, *planned* and *interactive*, that function together to provide a detailed and ongoing account of learner progress. Planned FA involves eliciting assessment information using specific assessment activities, mainly with the whole class, then interpreting and acting on the information obtained. Interactive FA, on the other hand, is more spontaneous and occurs during the course of regular classroom activities as teachers notice learner difficulties and engage with them, often individually or in small groups, to respond to problems that often cannot be predicted. Indeed, the authors employ descriptors such as *unanticipated* and *incidental* to capture this type of FA. Drawing on a two-year research project in New Zealand, Bell and Cowie (2001) noted that teachers switched between the two depending on their instructional goals and learner needs. In this way, assessment functions as an ongoing and integrated component of teaching and learning.

Rea-Dickins and Gardner (2000) and Rea-Dickins (2001) have similarly recognized the value of different forms of FA in creating a picture of learner progress over time and have offered further specification of the kinds of strategies teachers may employ at different "stages" of activity. Drawing on extensive research with teachers of English language learners (following from Clarke, 1998), they have proposed a nonlinear model of classroom assessment that identifies particular strategies employed by teachers when planning assessment, getting to know individual students through observation during the teaching, and working with students on specific tasks giving feedback and reviewing progress. Moreover, although Clarke's conceptualization of the processes and strategies involved in teachers' decision making is in stages, it is not necessary that the cycle be completed, rather it depends on the purpose of the assessment.

More recently, Black and Wiliam (2009), building on work done in the area, provide a unifying theoretical basis for the diverse processes that are said to be formative. They accord equal status to the three agents (teacher, learner, and peer) in the learning process, focusing on the relationship of teacher's agenda, the internal world of the learner, and the intersubjective. They identify key strategies that contribute to effective FA and suggest activities to enact these strategies, such as classroom questioning, comment-only marking, self- and peer assessment, and formative use of summative tests. The last activity according to them is a complex one but can move the learner forward and clarify criteria for success if used appropriately.

Finally, dynamic assessment (DA) has recently gained attention from researchers interested in classroom assessment. DA is unique in that it derives from a theoretically coherent account of human abilities and their development, namely the theoretical writings of Russian psychologist L. S. Vygotsky (1978). As such, DA proceeds from the perspective that education intended to guide learner development (rather than, say, impart factual knowledge) must necessarily integrate teaching and assessing as an activity that brings together products and processes of development through joint interaction among learners and teachers or assessors, also referred to as mediators. Full discussion of Vygotsky's work and its relation to assessment practice is beyond the scope of the present chapter (see Poehner, 2008), and interested readers are encouraged to consult available references. What must be appreciated is that a Vygotskian theoretical perspective maintains that to fully capture the range of an individual's capabilities it is necessary to examine both the products of past development (i.e., abilities that are fully formed) as well as abilities that are currently in the process of their formation and that are therefore most amenable to instructional intervention (Poehner, 2008). While the former may be determined through observation of learner independent performance, as occurs in most assessments, the latter may be interpreted according to their engagement in joint activity, and in particular their responsiveness to mediation intended to support them as difficulties arise and their independent performance breaks down. In this way, a mediator in DA assumes the more traditional role of assessor, as she or he is charged with observing learner performance of assessment tasks but is also responsible for interacting with learners to obtain a robust developmental diagnosis. Thus, DA is committed to understanding learner development through intervention, a position that demands the integration of assessing and teaching.

To understand how learner progress may be monitored, it is important to consider the complexity of tasks themselves and how they may be structured and sequenced in a program in order for learners to continue to experience the struggle that necessitates interaction and support. To be sure, the tasks that learners are able to undertake are obviously an important indicator of abilities. In the field of L2 testing, Bachman (2002) has challenged test developers to not simply theorize task or item difficulty in the abstract but to examine—through appropriate qualitative methods—the processes through which learners engage with particular tasks in order to understand the challenges that they pose. The grounded, empirical basis Bachman suggests for determining task difficulty resonates with the notion of *transcendence* in DA. Poehner (2007) characterizes transcendence as a framework for ongoing monitoring of learner performance that foregrounds the processes of learner engagement with tasks through mediator-learner dialogue. In this way, it is possible to track the challenges learners experience as they engage in tasks over time. This serves the double function of monitoring their progress vis-à-vis particular kinds of tasks while also enabling teachers to make adjustments to task demands, increasing the level of complexity so that learners continue to experience the challenge that necessitates interaction and opportunities for development. Transcendence is considered in greater detail later in this chapter.

Processes Involved in Monitoring Progress: Teacher and Learner Roles

Although there is no standard procedure that can be recommended for monitoring progress in the classroom, the processes involved in FA highlight the need for full participation of both teachers and learners in an attempt to make it more responsive to individual learners, to promote learning and equity in education. It can be seen to consist broadly of a two-part activity (Black and Wiliam, 1998), which begins with the perception by the learner or teacher of a gap between the present state of learner ability and the intended goal. This is achieved through self-assessment or self-monitoring, and through not only spontaneous but planned observation of individual students, pairs, or groups, asking questions, and maintaining records of how students progress from one activity or unit to another. This leads to the second part, in which action is taken by teacher and learner to bridge that gap and to set new goals; this essentially involves the learner(s) in negotiating and collaboration with peers and self- and peer assessment. As regards the tools for monitoring, virtually all “teaching” tasks such as oral, listening, and reading tasks, portfolios, group projects, and teacher-made tests along with checklists, reflective journals/diaries, interviews, online discussions can be used. It is beyond the scope of this chapter to provide a detailed discussion of “how” monitoring can be carried out in the classroom; there are a number of resources available for the purpose (see, for example, Brown, 1999).

The central role played by learners in FA has led some to identify effective FA practices with a broader, learner-centered classroom culture. From this perspective, learners and teachers must have a shared understanding of the goals of particular activities, must be involved in assessing work (their own as well as others’) and should not be regarded as passive recipients of knowledge but should be empowered to guide their own learning (for discussion, see Mathew, 1998). If learners are content to get by with minimal effort, avoid taking risks to solve a difficult problem, look for clues from teachers to get at the right answer, are eager to get into teachers’ high esteem through short cuts, or fail to recognize helpful feedback, then FA might give rise to negative results (Black and Wiliam, 1998). If, on the other hand, teachers are not willing to give up their position of power, a characteristic of a teacher-dominated classroom, and allow students to take charge of their learning, implementing FA is not easy. However, there is evidence to show that with adequate orientation to learner-centered pedagogies including FA practices, teachers can effectively participate in the assessment of their learners instead of relying on a one-off snapshot taken by an outsider (e.g., Hasselgren 2000; Davison 2004).

Current Research

Recent trends in research on language assessment, echoing the broader field of educational assessment, have provided a catalyst for both conceptual and practical investigations into the relation between assessment and teaching and learning. These include, on the one hand, concern over the potential washback effects of

formal testing on classroom activity and, on the other, proposals that have challenged and enriched FA, such as AfL and DA. Some of this research has been specific to content areas, particularly science and mathematics, and has addressed issues involving second language learning only indirectly. There has, at the same time, been considerable research conducted in the field of language assessment, and we highlight some of that work here.

Zangl (2000) carried out assessment in Austria in two primary school contexts—one where English and German are used equally throughout primary school and the other where English is used in short intervals of 20-minute lessons three times a week by the class teacher. The assessment was based on data collected from structured interviews to assess spontaneous speech in pupil–pupil and teacher–pupil interactions, along with oral tests to elicit speech samples focusing on morphology, syntax, and semantics or lexicon. The framework used in the analysis of language assessment is not only flexible to be adapted to other languages but also provides insights into the learner’s strengths and weaknesses in the language development process so that the teacher can fine-tune the language input. Based on the study, Zangl advocates, among other things, that assessment approaches capture the development path of each individual in the light of the performance level of the class as a whole.

Rea-Dickins (2001) used a framework (discussed above) grounded within the assessment practices of teachers to understand teachers’ assessment decision-making process. Drawing on a larger study of teacher assessment of young learners in an English as an additional language (EAL) context, interview and observation data of three teachers in three schools, the study revealed that the assessment strategies had three identities linked to teaching, learning, and bureaucratic needs. Further, it raised important questions about whether FA does indeed create opportunities for language learning and how one could judge it, thus conceptualizing the notion of quality of FA.

Edelenbos and Kubanek-German (2004) sought to understand the knowledge and abilities teachers must possess to conceptualize and carry out effective assessments of learner progress in the classroom. Through interviews and classroom observations of ten teachers over two years, they singled out five activities in which teachers displayed what they term teacher *diagnostic competence*, with three features: first, a teacher must have a keen interest in how children learn languages; second, he or she must develop hermeneutic approaches such as observing, seeing, and comparing; third, she or he needs to understand how students’ prior knowledge can affect language development. The working definition they propose of the concept of diagnostic competence is very useful and should have a lot of promise for further work in the area.

Leung and Mohan (2004), noting that much FA is dialogically realized through teacher–student talk, as in the models of both interactive FA and DA discussed earlier, propose an analytical framework to understand teacher decision making as it pertains to interweaving assessment with teacher–learner interactions. They suggest that in language-learning contexts not only is discourse a focus of assessment (*assessment of discourse*) but that assessment may be achieved through discourse (*assessment as discourse*). Based on an in-depth case study of two teachers, Leung and Mohan identify four, not necessarily linear, stages teachers pass through

while monitoring student learning. Their data suggest an emphasis on student processes as well as products, student–student interaction, teacher use of scaffolding and, most important, student decision-making discourse, all under locally adaptive conditions.

Crossouard's (2011) research in primary schools in socially deprived areas of Scotland, where social equity is a major concern, sought to address tensions between SA and FA so that assessment *for* learning, *as* learning, and *of* learning became symbiotic. The study employed a task design that afforded opportunities for teacher and student dialogue through open-ended collaborative phases of the task, thus providing space for peer and teacher assessments and for addressing classroom power relations. While the study confirmed the usefulness of the task design, it raised questions about the way criteria took shape in classroom dialogue and suggested further research into understanding the relationship between teaching, learning, and assessment vis-à-vis teacher roles and social equity.

There is a substantial body of knowledge that attests to the effectiveness of training students and teachers in different aspects of FA and creating an assessment culture in which teaching and learning and assessment are closely aligned: self-monitoring by students which leads to autonomy and language learning (e.g., Banfi, 2003; Little, 2005); self-assessment, even with young learners, which shows that most pupils are quite realistic about what they can and cannot do in English (e.g., Hasselgren, 2000); peer assessment, especially for enhancing students' higher cognitive thinking and raising teachers' and students' awareness about the strategies necessary for maximizing learning (e.g., Cheng & Warren, 2005); involvement of students in the design and development of tasks as well as criteria setting (e.g., Mathew, 1998).

Another area of research is automated scoring and feedback systems that afford efficient, instantaneous feedback and have the potential to transform and enhance learners' language-learning experiences (see Xi, 2010a). Computer-based technologies can help to assess skills or knowledge which are difficult or even impossible to assess using conventional media, such as the ability to work in a team, which includes adaptability, coordination, decision making, interpersonal and communication skills, and awareness of cognitive processes in order that students can develop their own learning skills (McFarlane, 2003). The special issue of *Language Testing* (Xi, 2010b) on this theme marks a significant step in this direction.

Finally, a recent study by Ableeva (2010) involving DA illustrates how the concept of transcendence, discussed earlier, can help to provide a robust and ongoing account of learner progress. Ableeva designed a DA program for the purpose of monitoring and guiding, through interaction, the development of learner listening comprehension in French as a second language. Working with undergraduate university students in the USA, Ableeva asked learners to listen to authentic aural texts of spoken French and to recall in English (the students' first language, L1) everything they understood. This baseline assessment was conducted at the start and end of the program. During the intervening weeks, the researcher engaged in one-to-one interactions with learners, to help extend their abilities. The concept of transcendence was formalized through a series of transfer tasks learners attempted at the end of the program that differed in increasing

degrees from earlier tasks. In particular, the aural texts employed in the program presented interviews with native speakers of French during which a range of topics (e.g., cuisine, politics, cinema) were discussed. Aural texts used for transfer tasks included television news broadcasts and radio commercials and thus differed quite significantly from the interview recordings in register as well as in complexity. What is perhaps most interesting is that none of the learners had progressed during the program to a point where they performed completely independently during the final sessions or in the transfer tasks. That is, all continued to require some mediation for successful comprehension. However, important differences persisted both in the amount of mediation each individual required and in the quality of their responsiveness. Following Ableeva, the value of transcendence is in examining the interplay between the level of difficulty posed by a task and the degree of support learners need.

Challenges

Although the importance and value of FA have been endorsed by curriculum bodies and assessment experts alike, there are a number of conceptual and implementation issues that need to be addressed. One issue involves establishing effective FA practices in contexts traditionally dominated by a high stakes testing culture unlike those contexts where there is more interest in actual developmental progress. For SA and FA to coexist and each meet their intended purpose, it is important that FA not be subordinated to or fashioned after practices that are successful in meeting summative goals. As Harlen and James (1997) observe, it is widely and erroneously assumed that any assessment conducted by teachers in classroom contexts necessarily represents FA. Indeed, Cheng, Rogers, and Hu (2004), following a three-year comparative survey of teacher assessment practices in Canada, Hong Kong, and China, observe that while teachers do see value in classroom assessment as an instructional tool, very often what they do in class is colored by the mandated external assessments as well as by their own beliefs about assessment. The authors report that teachers' work in the classroom valued discrete item formats targeting lower-order cognitive processes in a manner parallel to external, formal exams. One of the greatest challenges facing teachers as they plan ways to implement assessments that support learning may be their own and their students' unexamined beliefs about the merits of assessments that are informal and continuous. Performance- or grade-oriented students and parents, used to high stakes assessment that they (incorrectly) regard as scientific, fair, and objective, may not appreciate assessment of "soft" skills where the focus is on the process of learning. Moreover, teachers may not be fully comfortable with the emphasis placed on engaging *with* learners in FA as co-participants. While this is crucial to helping learners eventually gain greater autonomy and more effectively participate in self- and peer assessment, teachers may feel that their expertise and authority are undermined. Similar is the situation in India, where what happens by way of classroom assessment is a mirror image of what SAs demand, with the result that FA is reduced to a series of "mini-SAs" done several times over (e.g., Mathew 2004).

Another challenge to establishing effective practices for monitoring learner progress is that it is increasingly clear that assessment exists within a broader educational culture. Effecting change in assessment practice therefore must be seen as part of a larger undertaking to challenge conditions within an educational system and the assumptions about teaching, learning, and assessing that are at work. Unless schools and secondary boards officially acknowledge the need to carry out continuous assessments that feed back into teaching, neither students nor teachers are likely to attach importance to the activity, let alone engage in it. For example, curricula that are organized around small units, each narrowly focused on discrete features of language, do not easily lend themselves to meaningful tasks or projects that could be leveraged to provide learning opportunities across time while also enabling teachers to track learner development over the course of several days or weeks.

Davison (2004) offers an excellent illustration of contextual constraints that must be overcome for effective practices to be implemented. Writing in the context of English language instruction in Hong Kong, she reports that in spite of official recommendations teachers were faced with considerable obstacles as they adopted FA practices, notably large classes and the number of lessons mandated to be taught. Shepard (1995, p. 43) argues that "if teachers are being asked to make fundamental changes in what they teach and how they teach it, then they need sustained support to try out new practices, learn new theory, and make it their own." Furthermore such radical change takes time. Even in countries where there is professional support for teachers to remain up to date on emerging teaching and assessment practices (e.g., Europe, New Zealand), deep-rooted tensions often remain between recommendations from professionals regarding "best practices" and policy decisions that create the contexts in which teachers must operate.

The matter of best practices is also far from straightforward. Teachers are faced with a number of choices when implementing a systematic program for monitoring learning, and ultimately their decisions must reflect what they know of their learners and the goals they and their learners set. Decisions must be made regarding tasks appropriate to meeting curricular goals, criteria for scoring or rating student work, whether work is to be conducted (and scored) on an individual basis or by groups, and the forms of assistance or scaffolding that are permitted. In addition, the research recommendations to which teachers might turn while making these decisions are not always consistent.

Finally the need for orientation in pre-service and in-service teacher workshops to the characteristics of FA and how it could be translated into classroom processes cannot be overemphasized. In traditional setups, one-off teacher orientations typically focus on modern teaching methodologies and techniques, if within a communicative language-teaching CLT framework, to a total exclusion of how teachers can and should monitor students' learning; any activity focusing on building progressively on how teachers mediate learning in actual classroom contexts in follow-up workshops through iterative cycles is almost absent. Physical and infrastructural facilities are further constraints to implementing progressive practices since FA practices are, if at all, incorporated into old structures that have nurtured SA.

Future Directions

It is clear from this discussion that monitoring progress in the classroom is a complex process and needs to be understood both at macro (policy) and micro (classroom) levels. Since FA is embedded within the curriculum, all aspects of FA would need to focus on assessing and assisting the student in relation to the curriculum. At the macro level, when introducing FAs, we need to be aware of the *what* and *how* of introducing this innovation: the more exam-oriented the culture, the lower the level of acceptance of FA among all the stakeholders—education administrators, principals, teachers, students, and parents—is likely to be, even if on the surface some of the features may appear to have been absorbed. Further, reforms would have to address all three components—teaching, learning and assessment—simultaneously. That is, the likelihood of FA being successful and sustained over time is greater if a “vision” of a whole-curriculum reform is conceptualized, concretized, and supported, as has occurred in some contexts (e.g., Curriculum Development Council, 2001). In contrast, piecemeal approaches tend to get distorted or diluted and are frequently met with resistance; in some cases, such initiatives finish by being abandoned altogether (see Mathew, 2004).

The four “models” and the DA perspective presented here all focus on different and crucial, although overlapping, aspects of FA. It seems that any theory or model of FA, to be meaningful and comprehensive, would have to bring together, at a minimum, the following three domains: the teacher’s agenda, the learner’s level of development and capabilities, and the interaction between the two within the social world of the classroom and the school. While there is no one optimum model that will serve all FA purposes, a way forward might be to accept the plurality of different perspectives and work with them. Eventually researchers and, more importantly, teachers will have to be able to understand the underlying principles so that they can adapt and extend the models in real classroom contexts. Changes in classroom practice needed are central rather than marginal, and each teacher will have to make meaning of the model of FA in his or her own way and help in turn to enrich the model(s). For this she or he will need continuing support from both administrators or schools and researchers.

A key direction for the future lies in the development of teachers’ understanding and use of classroom assessment skills. Teachers have to learn to work within a collaborative, constructivist framework and adopt assessment strategies involving group or interview and portfolio approaches, questioning, and observation techniques while being aware of the social and cultural influences on assessment and developing competences to be able to interpret student learning. Teachers need time and space to develop a sense of ownership and to articulate and critique their own implicit constructs and interpretations. We need to provide opportunities in our initial and in-service teacher-training programmes for teachers to develop confidence and expertise in making and using judgments about and for learning.

Future research should include case studies looking closely at what strategies teachers adopt to monitor progress, students’ language-learning processes, and

the kind of fine-tuned support they need, especially low achievers. This would also throw light on the kind of training teachers and students need for carrying out self- and peer assessment.

There are very few research-based, empirical accounts by teachers themselves of how they monitor students' progress in their classrooms; it is still the assessment "expert" or outsider who is investigating classroom processes, elevating assessment to a level of scholarly discourse although teachers are involved in research as participants. Since monitoring progress is *research-based teaching* (Stenhouse, 1975, p. 141) and is the business of the teacher, teachers documenting the processes they (and students) go through, and drawing insights from that, should form an urgent research agenda if the enterprise of FA is to come of age.

Achievement and Growth in the Classroom

Michael J. Kieffer
New York University, USA

Achievement and Growth

Language educators often want to know the extent to which students have successfully learned the knowledge and skills covered in a particular course of study. In particular, questions about language and content achievement often focus on students' progress, learning, or development—that is, on their *growth* in achievement over time, rather than simply on their levels of skills and knowledge at a single point in time. For instance, while classroom teachers need to know where their students begin, the more essential question is often how much they have learned in a given unit, semester, or year. Similarly, researchers are often concerned with how growth trajectories for different populations compare and which instructional or learner variables predict growth in achievement over time.

Although modeling growth in achievement is relatively new to many applied linguists, it has been used recently to address several important research questions about language learners. For instance, researchers concerned with second language reading development have compared reading growth trajectories of English as a second language (ESL) learners with those of native English speakers in the US and Canada (e.g., Kieffer, 2008, 2011; Lesaux, Rupp, & Siegel, 2007; Mancilla-Martinez & Lesaux, 2010, 2011; Nakamoto, Lindsey, & Manis, 2007; Roberts, Mohammed, & Vaughn, 2010). Researchers have also used growth modeling to investigate ESL learners' growth in content achievement, specifically in the domain of mathematics (e.g., Roberts & Bryant, 2011; Wang & Goldschmidt, 1999). Finally, researchers have employed growth modeling to evaluate the effects of particular instructional or programmatic approaches (e.g., Marsh, Hau, & Kong, 2000; Uchikoshi, 2005).

This chapter addresses three central issues in assessing and describing growth in achievement for language learners. The first issue revolves around modeling

growth appropriately to distinguish students' rates of growth from their initial levels, while isolating true growth parameters from the measurement error involved in assessment at any given point in time. The second issue involves addressing threats to the validity of inferences about gains in achievement. The third issue, which is not unique to assessing growth but is nonetheless an essential one in any discussion of achievement testing, involves addressing the relationship between content knowledge and language proficiency in order to support valid inferences about the constructs of interest. While far from exhaustive, these three issues are central concerns that need to be at the forefront of language testers' minds when addressing questions about students' growth in language and content achievement. The sections that follow describe each of the three challenges and provide potential solutions, along with illustrative examples from research that has employed these solutions.

Modeling Growth in Achievement

Language researchers and educators are frequently interested in how much students have learned over time. To answer this question, they must be able to distinguish between students' initial levels of achievement and their growth in achievement over a course of study. This requires three elements: (1) repeated, longitudinal measurement; (2) use, in this measurement, of scores that represent the same construct over time; (3) analysis of these scores through appropriate statistical models. Each of these three elements is discussed below.

First, as may seem obvious, modeling growth in achievement requires assessing the same students at multiple time points or occasions of measurement. What is less obvious is that such measurement needs to be conducted on three or more occasions to provide the basis for modeling "true" rates of growth. "True" is used in the measurement sense of a "true score" that has been freed of measurement error—which in this case is occasion-specific measurement error—as opposed to an "observed score," which is the combination of a true score and some random measurement error. When achievement is only measured at two points in time, true growth is confounded with occasion-specific measurement error (Singer & Willett, 2003). In addition, if achievement in the outcome is hypothesized to be curvilinear, which is often the case, more than three measurement occasions are needed to model the curvature in students' growth trajectories.

Second, modeling growth requires that the observed scores tap the same construct over time. A simple approach, which is appropriate in some situations, is to administer the same measure on repeated occasions. However, there can be methodological or practical concerns that make this approach inappropriate. Foremost among them is the following one: as students grow older and progress through a course of study, they will likely perform increasingly well on many of the items on the measure—a situation that leads to ceiling effects. In this case, there is a need to include increasingly difficult items, which can provide more developmental information about students' abilities at higher levels of performance. When such items are added or leveled forms of an assessment are created, there is a need to vertically link the scores from the easier and more difficult

versions of the tests, so as to place them on the same developmental scale. Item response theory methods (e.g., Hambleton, Swaminathan, & Rogers, 1991), including the Rasch model (Bond & Fox, 2007), can be used to create such vertically linked scales. In addition to scaling of this kind, there is a need to collect validity evidence that the increasingly difficult forms tap the same underlying construct or constructs; such evidence can include invariance of the factor structure and consistency in convergent and divergent validity evidence. Because a thorough discussion of the issues involved in creating vertically linked scales is beyond the scope of the current chapter, readers are referred to Kenyon, MacGregor, Li, and Cook (2011) for a discussion of these issues in the context of language testing.

Third, longitudinal data should be analyzed using individual growth modeling techniques that separate out occasion-specific measurement error from an individual's true initial status and true rate of growth (e.g., Bollen & Curran, 2006; Singer & Willett, 2003). Although a thorough discussion of how to conduct growth modeling is beyond the scope of this chapter, a basic, conceptual introduction to growth modeling and a discussion of why it is important will be provided below. Readers interested in learning more should consult the excellent books by Singer and Willett (2003) and by Bollen and Curran (2006).

Consider a case in which one individual student's language achievement has been measured on three occasions (labeled Time 1 to Time 3), as shown in Figure 39.1. These occasions could be years apart, as in large-scale longitudinal studies, or weeks apart, as in a classroom-based investigation. On each occasion the student was assessed in his or her language achievement and the resulting scores were plotted as dots in Figure 39.1. If we were simply concerned with this student's level of achievement at a given time, we would be content with the values for the individual dots. However, if we wanted to know how much this student had gained in achievement, we would need to find a way to incorporate the information from the multiple points in time.

A simple approach that may come to mind is to subtract the student's level of achievement at Time 3 from his/her level of achievement at Time 1 (47–18), to

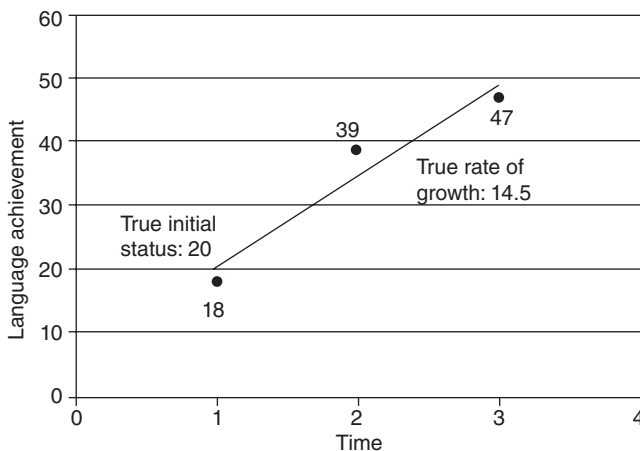

Figure 39.1 Plot of observed values and true growth trajectory for a hypothetical student

create what is called a “difference score” (29). Although this would give us a sense of how much the student gained, there is a problem with this approach. At each of the three testing occasions, there is some noise or random measurement error due to the lack of a perfect reliability of scores; when we subtract Time 1 achievement from Time 3 achievement, this noise is conflated with true growth in achievement.

A better approach is to hypothesize that the three scores observed at Times 1, 2, and 3 represent an unobserved, or latent, true growth trajectory. We can estimate this trajectory easily enough by fitting a linear trend line to the three points, as shown in Figure 39.1, which yields an estimate of this student’s intercept or true initial status (20) as well as of his/her true rate of growth (14.5) per unit of time (i.e., years or weeks). The vertical distance between each dot and the fitted line can be considered an occasion-specific measurement error, while the parameters (i.e., intercept and slope) for the growth trajectory can be considered free of occasion-specific measurement error.

In the logic of growth modeling, this process of hypothesizing an underlying true growth trajectory for each student and of estimating that trajectory’s intercept and slope by fitting it to data observed on three or more occasions is “repeated” for each student in the sample. This procedure yields parameter estimates for the intercept and slope for the population-average trajectory, which represents the true initial status and the true rate of growth for an average student. It also yields estimates for the variation in students’ intercepts, the variation in students’ slopes, and the covariance between intercepts and slopes, which together represent the distribution of trajectories that surround the population-average trajectory.

For a concrete example, consider a study I recently conducted with a colleague in which we investigated Spanish-speaking ESL children’s vocabulary and morphology development between grade 4 and grade 7 (Kieffer & Lesaux, 2012). We measured English vocabulary each year using the same instrument: the Peabody Picture Vocabulary Test (PPVT), third edition (Dunn & Dunn, 1997). Figure 39.2

Figure 39.2 Empirical growth plots for English vocabulary knowledge for a cohort of 90 Spanish-speaking ESL learners. Drawn from Kieffer & Lesaux (2012) in *Applied Psycholinguistics*. © Cambridge University Press

displays empirical growth plots (Singer & Willett, 2003) that capture the trajectories in English vocabulary for each of the 90 participants in our study; these trajectories are estimated using an Ordinary Least Squares (OLS) regression, which is represented by the thin lines in various shades of black and gray. The population-average trajectory is represented by the thick black line at the center of the plot. As shown, the students demonstrated on average substantial growth in their English vocabulary achievement, but they also demonstrated substantial variation in the levels and slopes of their growth trajectories. Through analysis performed by using individual growth modeling, we found that the population-average trajectory had a true initial (grade 4) status of approximately 100 raw score points and a true rate of growth of approximately 10.5 raw score points per year.

We also found a statistically significant and practically meaningful amount of variation in students' true initial statuses (standard deviation = 14.8) and true rates of growth (standard deviation = 3.3). In our study this variation between children was important, because we were interested in individual differences in students' vocabulary growth and in whether this growth could be predicted from the students' awareness of derivational morphology. Individual growth modeling allows researchers to estimate the covariance between initial status and rate of growth, which, apart from being important for modeling growth processes appropriately, is also useful for investigating whether students with an initially high achievement have a higher or a lower rate of growth than students with an initially low achievement—in other words whether the “rich get richer” or whether rather the low-performing students catch up with the more high-performing ones over time. In our study we found that the covariance between true initial levels and rates of growth in English vocabulary was not statistically significant, but in many studies of growth this covariance is significant, and it is important to consider it.

At this point it is worth noting that there are actually two approaches to growth modeling: (1) individual growth modeling that uses the multilevel model for change (Singer & Willett, 2003) or the hierarchical linear modeling (HLM) framework (Raudenbush & Bryk, 2002); and (2) latent growth curve modeling that uses the structural equation modeling (SEM) framework (Bollen & Curran, 2006). The two approaches are conceptually related and can yield identical results under certain conditions, but they are operationalized slightly differently and offer different advantages and disadvantages.

The multilevel model for change approaches longitudinal data as “nested” or hierarchical and non-independent. Occasions are viewed as nested within participants, in the same way in which students are nested within classrooms in other multilevel or HLM models (see Raudenbush & Bryk, 2002); the population-average growth parameters are viewed as fixed effects, while the variance estimates for variation in intercepts and slopes are viewed as random effects (that is, as sources of residual variance that have been separated from one another). In this approach, the growth model is specified as having two hierarchical levels: one that is within participants, and one that is between participants. The multilevel model for change has the advantages of being appropriate even when sample sizes are relatively small, being robust to missing data for individual occasions, and being appropriate when individual participants are assessed on different schedules. Readers are referred to Singer and Willett (2003) for a thorough discussion of the strengths

and limitations of the multilevel model for change as well as for valuable advice on how to use the model in practice.

In contrast, latent growth curve modeling in an SEM framework approaches the growth parameters of true initial status and true rate of growth as latent variables, each of which is associated with multiple observed indicators—that is, observed scores at each occasion. In this approach, variance in initial status is partialled away from variance in rates of growth, and population-average parameters are estimated via latent means. Latent growth modeling has the advantage of allowing parallel process growth-on-growth models (see Kieffer & Lesaux, 2012 for an applied example) as well as the possibility of incorporating other features of SEM, such as using latent composites for each measurement occasion. Readers are referred to Bollen and Curran (2006) for a thorough discussion of the strengths and limitations of latent growth curve modeling in the SEM framework.

Modeling growth in achievement has been used to address numerous questions relevant to applied linguistics and language learning. Several of these examples come from the area of second language reading development for immigrant children in the US and Canada. For instance, I have used growth modeling of data from a nationally representative sample to investigate the extent to which ESL learners in the US catch up with, or fall behind, their native English-speaking peers in reading achievement across the elementary and middle school years (Kieffer, 2008, 2011). Roberts et al. (2010) used growth modeling with this same dataset to investigate how reading trajectories differ according to the students' primary language group. Similarly, Mancilla-Martinez and Lesaux (2010) described growth trajectories in word reading and vocabulary for Spanish-speaking ESL learners in the US between early childhood and early adolescence, Mancilla-Martinez and Lesaux (2011) investigated how early home language use predicted growth in vocabulary for this same cohort, and Nakamoto et al. (2007) described how Spanish-speaking ESL learners grew in word reading and reading comprehension between first and sixth grade. In a study conducted with a large cohort of ESL and native English-speaking children in an urban Canadian district, Lesaux et al. (2007) used latent growth modeling data to describe students' nonlinear trajectories between kindergarten and fourth grade in word reading and to investigate the cognitive predictors of growth for each group. Growth modeling can also be used to investigate the effects of an intervention on students' language growth, as demonstrated by Uchikoshi (2005), who investigated the effects of an educational television show on ESL students' narrative development of English.

Growth modeling has also been used to describe content achievement trajectories for second language populations. For example, Roberts and Bryant (2011) used latent growth modeling with nationally representative data to compare the mathematical achievement growth trajectories between kindergarten and fifth grade for ESL students in the US from varying primary language groups and socioeconomic backgrounds. Similarly, Wang and Goldschmidt (1999) used multi-level growth modeling to investigate the roles of opportunities to learn and language proficiency in ESL middle school students' mathematics growth over three years.

Growth modeling has been used more rarely in studies conducted outside North America. One study that stands out is Marsh et al. (2000), which evaluated

the effects of late immersion and of language of instruction on language and content achievement growth in high school for Chinese-speaking students in Hong Kong. This study is unique not only in that it looks beyond the North American context and uses appropriate growth modeling techniques, but also because it combines language achievement and content achievement growth as outcomes of instruction. Overall there is a need for more research that applies growth modeling to various contexts, in order to address many of the fundamental questions of language learning.

Making Inferences about Gains in Achievement

Even when appropriate methods are used to model growth, there can be additional threats to the validity of inferences about gains in achievement. In particular, a threat to validity can occur if the gains on an achievement test are due to improvements in construct-irrelevant abilities (e.g., test-taking skills, familiarity with item formats) rather than to the construct itself, a problem known as score inflation (Koretz, 2009). Although score inflation is more commonly discussed among educational policy researchers, it has important implications for language testers interested in measuring change in achievement over time.

Koretz and Béguin (2010) define score inflation as “increases in scores that are larger than improvements in mastery of the domain would warrant” (p. 93). Research suggests that such increases can occur when educators focus too narrowly on specific content as it is tested and provide test preparation that focuses on aspects of the test that are unimportant to the content domain, including item formats or specific construct-irrelevant features of scoring rubrics (e.g., Stecher, 2002). Trained to perform better on specific items, but not necessarily equipped with deeper knowledge and skills in the domain, students produce higher observed test scores without necessarily demonstrating improvement in the underlying construct. Score inflation is typically demonstrated by improved scores on specific achievement tests, combined with the absence of improvements on other measures of the same construct. Research has shown that score inflation on achievement tests that are involved in accountability systems can be very large (e.g., Klein, Hamilton, McCaffrey, & Stecher, 2000; Koretz & Barron, 1998).

Consider, for example, a simple second language vocabulary assessment in which students provide a synonym for a target word. In such a case, the specific words chosen for the assessment can be considered a sample drawn from the larger population of vocabulary words that students need to know for the target language use situation about which the assessment is designed to provide information. To draw a valid inference about students’ second language vocabulary knowledge, performance on the targeted words should be representative of students’ knowledge of that larger population of vocabulary words. However, imagine that certain specific words appear repeatedly on this assessment and that students and teachers have access to a list of frequently tested words. If students focus their attention on memorizing synonyms for these specific words, they may show dramatic improvement in their vocabulary scores, but without having gained much additional knowledge of the broader domain of second language

vocabulary. If they take another vocabulary test with a different sample of words, it is unlikely that they would show the same gains. In measurement terms, they have improved their observed scores but have not shown commensurate improvement in the underlying construct of second language vocabulary knowledge.

In this way score inflation is related to the concept of washback—that is, the impact that tests have on teaching and learning (e.g., Shohamy, 1993). Like other forms of washback, score inflation involves the responses of teachers and students to the features of assessments. Unlike more positive or benign forms of washback, score inflation refers to situations in which the teachers' and the students' responses to assessments inappropriately focus on construct-irrelevant or highly specialized features of the assessment, such that teachers' and students' actions do not lead to generalizable improvements on the targeted constructs. Washback effects, including score inflation, can be particularly strong when tests come with high stakes for students or teachers.

Evidence of score inflation generally involves a comparison of students' gains on the achievement test of interest (typically, a high stakes test) with their gains on a second, "audit" test (typically, a low stakes test) of the same constructs (Klein et al., 2000; Koretz & Barron, 1998). When gains that are apparent on the first achievement test do not generalize to the second test, scores on the first test may be inflated. Recently Koretz and Béguin (2010) suggested a new approach, of using self-monitoring assessments, in which audit components are integrated into the operational tests. Although score inflation and its remedies have attracted somewhat less attention among language testers than among researchers in educational policy, they constitute an important problem for all language testers to keep in mind when attempting to make inferences about gains in achievement over time.

Assessing Growth in Content and Language Achievement

In considering achievement testing for language learners, it is often important to keep in mind content-area achievement (i.e., learning of skills and knowledge in content areas such as mathematics, science, and social studies) as well as language achievement (i.e., learning of language skills and knowledge). As advocates of content-based language instruction have suggested (e.g., Grabe & Stoller, 1997), language learning is often enhanced by integrating instructional goals for content learning. In particular, for immigrant children in K-12 settings, providing access to grade-level content is a key concern. This issue is relevant not only for assessing growth in achievement, but for assessing achievement in general.

As with any assessment, achievement tests should be developed to maximize the extent to which scores reflect abilities that are central to the targeted construct and minimize the influence of irrelevant abilities. In the case of second language learners taking assessments in content areas (e.g., mathematics, science, social studies), a major challenge is to ensure that assessments capture students' content achievement rather than irrelevant language abilities (e.g., Abedi, Hofstetter, & Lord, 2004; Kieffer, Lesaux, Francis, & Rivera, 2009; Martiniello, 2007; Robinson, 2010). This task can be more complicated than we might assume, because academic language abilities and content-area achievement are intricately related.

Consider, for instance, a teacher in a content-based ESL program in the United States teaching immigrant students from many language backgrounds. Suppose she wants to know how well her students have mastered both the social studies content she has taught and the English language skills she has targeted. A simple solution is to create two tests: one to measure social studies content and one to measure English language skills. This simple solution becomes more complicated when we consider various questions. Should the social studies test be presented in English? Even if it is practical to produce first language versions of the social studies test for all of the students' language backgrounds, are such tests appropriate if students have been learning the content in English? If the test is written in English, how can the teacher be sure that students' performance reflects their content knowledge rather than their English skills? Should the English language test include social studies contexts for using language skills they have learned?

Similar problems arise when discussing large-scale assessment. In the US and other countries there has been an increasing call for including language minority learners into large-scale achievement testing for accountability purposes. Educators in the US agree that incorporating ESL learners into accountability testing has succeeded in raising awareness of these learners' needs and of the achievement gaps between these learners and their native English-speaking peers. However, requiring students to take mathematics, science, and social studies achievement tests in a language in which they are not yet proficient raises serious concerns about the validity of inferences made on the basis of these test scores. Most central is the question of whether the achievement gaps found reflect true differences in the targeted content knowledge or whether they reflect differences in irrelevant language abilities.

There is reason to be concerned about the validity of inferences that are based on test scores if the scores reflect individual differences in abilities that are distinct from those that are the target of assessment (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 1999). Given that language plays an integral role in most, if not all, academic learning, any test of academic achievement is also, to some degree, a test of language ability. However, the extent to which a given content-area test measures irrelevant aspects of language proficiency can differ considerably according to the design of the test. Research conducted by Jamal Abedi and colleagues has demonstrated that there is indeed a substantial link between ESL students' English language proficiency and their performance on tests of mathematics, science, and social studies (for a review, see Abedi et al., 2004). Furthermore, although there may be substantial differences between ESL learners and their native English-speaking peers in content knowledge, research shows that the size of this knowledge gap often depends on the language demands of the assessment. Several correlational studies have found that assessments and individual test items that have greater linguistic complexity yield larger performance gaps between ESL learners and native English speakers, by comparison with items of less linguistic complexity (Abedi et al., 2004).

One solution that has been offered to address this problem is to simplify the language of the content-area tests. This approach involves changing the vocabulary and grammar of test items so as to eliminate irrelevant linguistic complexity

while striving to maintain the same content vocabulary and level of complexity in the content task. Such changes include eliminating rare vocabulary unrelated to the content, shortening or simplifying sentence structure, replacing passive voice with active voice, and replacing complex verb forms with present tense verbs. On the basis of correlational evidence, we would expect these changes to yield improved performance for ESL learners on these assessments. However, in a meta-analysis of 11 experimental and quasi-experimental studies that included 16 samples of K-12 students in the US, colleagues and I found that simplifying the English of science and mathematics tests did not significantly improve ESL learners' performance (Kieffer et al., 2009).

How can we explain this divergence in the findings? Why have correlational studies consistently found that test items with more linguistic complexity yielded larger performance gaps, but our meta-analysis of experimental and quasi-experimental studies found that simplifying the English does not yield improved content-area performance? In explaining our findings, we raised the hypothesis that observed performance gaps between English language learners and native English-speaking students may reflect real differences in their content knowledge and in related academic language proficiency, rather than differences in construct-irrelevant language skills. We argue that simplifying the English by carefully avoiding the simplification of content vocabulary and relevant grammar does not remove the construct-relevant academic language demands that may differentiate between ESL and native English-speaking students. While test makers concerned with assessing content-area achievement of English language learners have focused consistently on irrelevant language demands, they have overlooked the extent to which construct-relevant academic language demands are intricately related to the demonstration of content knowledge on achievement tests.

The importance of academic language proficiency has also gained increasing attention from developers of language assessments, particularly in applications for K-12 settings. For instance, Albers, Kenyon, and Boals (2009) compared a newly developed K-12 English language proficiency test to four earlier generation assessments currently used by states to identify and place ESL students. They found that, while the new assessment had moderate to large correlations with the older ones, it also tapped unique language skills that are more academic in nature. Albers and colleagues argue that the academic language focus of the new assessment renders it more useful for making decisions about whether ESL students are prepared for mainstream instruction and for informing instruction for ESL students who are not yet ready for the mainstream.

Given these findings, what recommendations should be made about assessing content knowledge and language proficiency in ways that can support valid inferences about these constructs? First, as with the development of all assessments, designers of content-area achievement tests should be explicit about the theoretical definitions and operationalizations of the constructs of interest. When language learners are included in content-area achievement testing, whether in classroom contexts or in large-scale accountability testing, this requires that test makers are clear about the essential academic language demands of the content areas they are targeting. Second, building on this operationalization, test makers should design content achievement test items that minimize the influence of

irrelevant language demands. Third, the language of content assessments should match the language in which students had opportunities to learn the content, as Abedi and colleagues (2004) have also suggested. Fourth, those involved in the ongoing validation process for achievement tests should attend to the relationship between content knowledge and language proficiency by collecting and analyzing data on this relationship so as to inform the development of content-area tests that capture relevant, essential language demands while minimizing irrelevant language demands.

Conclusion

Assessing language learners' growth in achievement is essential to many of the aims of language educational research and practice. Without an appropriate description of the extent to which students have grown in their language and content achievement, educators cannot examine many of their questions about the effectiveness of particular instructional approaches, the roles of individual differences in language development, or the efficacy of programs that seek to benefit language learners. As this chapter has shown, describing growth in achievement requires that language testers attend to several key issues that include modeling growth appropriately, paying heed to the possibility of score inflation, and addressing the relationship of language proficiency and content knowledge. Because the discussion of each of these issues has been far from exhaustive and because other related issues are also important, readers are encouraged to read more on these topics. Advancing the quality of educational research and practice in language learning will require more careful attention to the opportunities and complexities offered by describing growth in achievement.
