Introspective Methods

Miyuki Sasaki

Nagoya Gakuin University, Japan

Introduction

In this chapter, I follow Gass and Mackey (2000, p. 1) who define “an introspective method” as “a means of eliciting data about thought processes involved in carrying out a task or activity” on the basis of the two assumptions that “it is possible to observe internal processes in much the same way as one can observe external real-world events” and that “humans have access to their internal thought processes at some level and can verbalize those processes.” These assumptions draw on the classical Ericsson and Simon (1993) information-processing model whereby “a cognitive process can be seen as a sequence of internal states successively transformed by a series of information processes” (p. 11). Introspective methods provide internal processing data that cannot be obtained from simple observation or other quantitative measures such as test scores. Of all the introspective methods, this chapter focuses on three measures that have been frequently used in applied linguistics: think-aloud reports, retrospection without memory aids, and stimulated recalls. All three are known to maximize the merits and minimize the demerits of introspective methods when carefully used (Green, 1989). Because space is limited, I will not deal with other introspective methods such as discourse analysis, diary analysis, interview data, or questionnaire responses. Nor will I deal with methods eliciting “metacognitive” (Bowles, 2010, p. 13) verbalization of the participants’ explanations or with justifications for their thinking processes.

First, I briefly describe how and why introspection became a legitimate research method in the humanities (including the social sciences) in general, then in the field of second language acquisition (SLA), a field in which introspection has been used most often in applied linguistics, and later in the field of language assessment (LA). I will subsequently define and explain the three methods and report

on how they have been used in the field of SLA as well as in LA. I will discuss possible advantages and disadvantages of these three methods when applied to both SLA and LA research. Finally, I will present three representative studies and demonstrate how introspective data have been collected and analyzed in past LA research. By critically evaluating these three studies, I will also discuss both the positive and negative features that prospective researchers should bear in mind when planning to use these methods in their studies. I will conclude the chapter by mentioning several possible directions that future studies could take.

The History of Introspective Methods

Introspective Methods in the Humanities

Following the *Oxford English Dictionary* (2011), let us define the term “introspection” broadly as the “examination or observation of one’s own mental and emotional processes.” Lyons (1986) states that introspection as a means of probing a person’s thought processes can be found as early as in Augustine’s *De Trinitate*, written in the fifth century. During what Lyons calls “the golden age of introspection” (1986, p. 2) between the 17th and the early 20th centuries, introspection was the target of serious analysis both in philosophy (e.g., Descartes in 1637) and in psychology (e.g., James in 1890). However, with the advent of behaviorism at the beginning of the 20th century, these classical introspective methods were dismissed as unreliable because behaviorists believed that psychology should be based strictly on externally observable cases of human behaviors.

In the 1950s, mainly in reaction to the limited focus of behaviorism, researchers in various fields (e.g., psychology, linguistics) began to pay more attention to human cognitive mechanisms and to experiment with people’s thinking processes, and behaviorism in turn began to wane. This “cognitive revolution” recreated the need for introspective methods as tools for eliciting data. This time, however, users were much more systematic about data collection processes in order that the collected data be both valid and reliable from a then dominant positivist epistemology (i.e., valuing empirically based “objective truth,” see, for example, Denzin & Lincoln, 2000, for a definition). Among various introspective methods, those used for collecting verbal report data, which are dealt with in the present chapter, became especially popular from the 1980s onward and have now become “major sources of data on subjects’ cognitive processes in specific tasks” (Ericsson & Simon, 1993, p. xi) in the fields of psychology and education.

Motivated by such developments, researchers in applied linguistics also started to use verbal reports as data in the late 1980s mainly to investigate second language (L2) learners’ cognitive processes and strategies. As mentioned above, the most frequent users of verbal reports in applied linguistics up to now have been SLA researchers. More recently, however, LA researchers started to use verbal reports as often as SLA researchers. A brief description of how verbal reports have been used in these two fields follows.

Introspective Methods in SLA

Around the beginning of the 1980s, SLA researchers began to pay more attention to the *process* of second language development. This was a reaction against the then prevalent studies that mainly investigated the *product* of SLA through methods such as error analysis (e.g., classifications of learner errors, for example, Richards, 1974) or morpheme studies (studies of the acquisition order of particular grammatical morphemes by measuring how well learners could supply these morphemes where required, e.g., Dulay & Burt, 1973). Because “reconstructing unobservable phenomena from performance data will always entail situations where the ambiguity between product and process cannot be solved” (Færch & Kasper, 1987, p. 9), researchers sought methods that could more directly probe second language learners’ thinking processes. In the event, these researchers found that introspective methods, which began to gain legitimate status in the social sciences around the same time (see above), were useful for this purpose. Since then, methods in SLA research have become more methodologically rigorous and they have been used in many studies of learner strategies (e.g., Cohen, 2007), language processing (e.g., Nassaji, 2006), problem solving (e.g., Manchón, Roca de Larios, & Murphy, 2009), and classroom research (e.g., Mackay, 2006). Furthermore, some researchers (e.g., Swain, Lapkin, Knouzi, Suzuki, & Brooks, 2009) have recently begun to approach L2 learners’ introspection from a more sociocultural perspective, and they have claimed that learners’ introspection can be used not only as data to be investigated but also as tools for facilitating learning processes by mediating and sharpening the learners’ thinking processes.

Introspective Methods in Language Assessment

Compared to the field of SLA, the field of LA has been slower to adopt introspective methods probably because of its positivist inclination toward quantification. It was not until the notion of test validity was redefined as “an inductive summary of both the existing evidence for and the potential consequences of score interpretation and use” (Messick, 1989, p. 13) in the early 1990s that introspective methods began to be used in LA research. If we define validity in such a way, we need the “collection of evidence supporting the relationship between the test score and an interpretation and use” (Bachman, 1990, p. 23), which inevitably involves the test takers’ thinking processes. Once the above conceptualization of validity became widely accepted in the field, LA researchers began to use introspective data as the whole or part of their data sources, especially from the mid-1990s (see below).

Definitions and Characteristics of the Introspective Methods

The three methods I focus on in this chapter differ in terms of time variation and the existence of memory aids (i.e., prompts). I mainly focus on spoken, not written reports. Moreover, I do not distinguish between “talk aloud” and “think aloud,”

which are regarded as two different methods by some researchers (e.g., Green, 1989), because the difference is sometimes unclear either to the researchers or to the participants themselves (Ericsson & Simon, 1993). I believe that the difference is not crucial for LA analyses as long as instructions to the participants are carefully worded.

Think-Aloud Reporting

In think-aloud reporting, participants are asked to concurrently verbalize what they are thinking about. Ericsson and Simon (1993) explain how this type of verbalization can be closest to what is actually heeded especially when a participant's verbal report is not mediated by any particular instruction such as "Request for Explanations, Motions, etc." (p. 17). It is true that compared with retrospective methods (see below), this method is less likely to allow participants to produce accounts affected by knowledge stored in long-term memory and that therefore may not reflect what they were actually thinking at the time. In a think-aloud procedure, participants are thus asked to simply verbalize their thought processes.

In a think-aloud procedure, the researcher usually trains participants to be familiar with the "say everything that comes to your mind" process by using a task that is similar to the task participants are asked to think about aloud. This training also makes the data collection more reliable since participants are required to follow a standardized procedure. However, despite this training, some participants may not verbalize their concurrent thinking processes successfully, especially when the task to be completed is cognitively demanding or when the language they are required to speak is not their strong language (typically their L1). In such cases, researchers should encourage participants to keep talking. However, researchers should also be careful not to force participants to produce additional explanations or justifications beyond their pure thinking processes. In other words, encouragement should be neutral, such as "Keep talking" or "Tell me more" rather than "Explain more" or "Why did you say such and such?" (Green, 1989).

These problems are related to the potentially most serious disadvantage of the think-aloud method, namely that of reactivity. Although Ericsson and Simon (1993) maintain that the method does not influence participants' thinking process in any significant way (except by making the task completion time longer), a number of studies have reported either a negative impact (e.g., Goo, 2010) or a positive one (e.g., Sanz, Lin, Lado, Bowden, & Stafford, 2009). Furthermore, very few studies to date have examined the effects of think aloud on L2 learners with weak L2 proficiency simply because talking while conducting a task in the L2 imposes too heavy a burden on the learners' cognition, as mentioned above (e.g., Sasaki, 2000). Consequently, results of previous studies claiming little effect of think aloud on accuracy might have been biased toward L1 speakers or L2 speakers with high proficiency. Researchers thus need to carefully consider the merits and demerits of think-aloud methods when designing their studies.

Retrospective Methods Without Memory Aids

Retrospective methods ask participants to recall their thinking processes after the task is completed and to verbalize as much of the processes as possible. Retrospective methods are used in SLA and LA studies when applying think-aloud methods is too difficult for participants or when the task in question (e.g., making a speech) does not logistically allow researchers to use think-aloud methods. Retrospective methods are also advantageous over think-aloud methods in that, unlike the latter, the former do not usually require specific training of participants. In order to have participants produce retrospective accounts, it is only necessary for them to be instructed to do so. However, despite such merits, retrospective methods also suffer from the lack of the advantages of the think-aloud methods. Most seriously, content recalled through retrospective methods may not be as accurate as that elicited through think-aloud protocols, and the data collected through retrospective methods may include information not directly relevant to what was actually thought about during task completion (see, for example, Blackwell, Galassi, Galassi, & Watson, 1985, p. 400, for examples of “post hoc rationalization”).

In order to mitigate such demerits, researchers often use some types of aids to stimulate participants' recall. However, using such stimuli is sometimes operationally difficult or even impossible. For example, researchers may ask participants to recall what they are thinking about while listening to a recorded text in the L2 because collecting concurrent protocols from them is not possible during listening activities. In such a case, the time lag between participants' working on the task and their verbalization of it should be minimized so that they can recall their thinking processes while their memory is still fresh (e.g., Green, 1989; Gass & Mackey, 2000). The researchers might thus set up a pause after the participants listen to a coherent chunk of text and then immediately ask what they were thinking about while listening to the chunk. On such an occasion, providing some kind of memory aid (e.g., showing their videotaped performance) with the participants during each reporting session might be practically impossible or simply disturbing.

Retrospective Methods With Memory Aids (Stimulated Recalls)

Except in cases where providing memory aids is either impossible or disturbing (as described in the previous section), researchers who use retrospective methods are advised to use memory aids to stimulate the participants' recall processes. Using “some tangible (perhaps visual or aural) reminder of an event” (Gass & Mackey, 2000, p. 17) is expected to encourage the participants to produce reports that would be closer to what was actually thought about during task completion. Examples of “tangible reminders” are the videotaped performance of a participant's task completion or an audiotaped performance of an L2 teacher's teaching activities over one entire lesson. Such aids are especially helpful when short or frequent interventions for eliciting the participants' recall are not possible (e.g., as in classroom observations) because, as a member of the retrospective method family, this method also has the disadvantage of carrying a higher possibility of

Table 79.1 Advantages and disadvantages of the three methods

	<i>Advantages</i>	<i>Disadvantages</i>	<i>Ways of mitigating the disadvantages</i>
Think aloud	Considered to most faithfully reflect the participants' thinking processes	May influence the participants' thinking processes (reactivity problems); may not be conducted in the L2 if the L2 is too weak	Provide appropriate training and proper instructions before and during the participants' report
Retrospective without any memory aids	Can be applied when collecting concurrent reporting is not possible and when providing the participants with memory aids is impractical or impossible (e.g., the participants' recalling each time after listening to a short chunk of text); does not require special training	Resulting data may not faithfully reflect the content of the actual thinking processes	Minimize the lapse between the task and the reporting
Stimulated recall	Can be applied when collecting verbal reports is not possible and when providing the participants with memory aids is possible (e.g., the participants' recalling aided by watching the videotaped performance of the task); does not require special training; memory aids help participants produce more accurate reports of their past thinking processes compared to when such aids are not available	Resulting data may not faithfully reflect the content of the actual thinking processes	Minimize the lapse between the task and the reporting; use memory aids that help the participants most efficiently

false information being reported or extra explanations or justifications being retrieved from long-term memory than in concurrent think-aloud data gathering.

The advantages and disadvantages of these three methods along with some possible steps for mitigating these disadvantages are summarized in Table 79.1.

Studies Using Introspective Methods Published in *Language Testing*

In this section, I present how the three introspective methods reviewed above have been used in the LA field. Because investigating every paper published in the LA

field is beyond the scope of the present chapter, I take the journal of *Language Testing* as a representative example (due to its long history and prestige) and I present the general trend for the past 20 years by classifying all studies using the three methods published between 1991 and 2010. Of 347 articles (excluding editorials, introductions to special issues, and book reviews) published in *Language Testing* during these 20 years, 20 (5.8%) employed one (or two) of the three introspective methods discussed in this chapter (Table 79.2).

In Table 79.2, we can see that: (a) half of the 20 studies used the think-aloud method while eight out of the 20 studies used stimulated recall; (b) in 14 out of the 20 studies, participants could use their first language (L1) or their strongest language; (c) using these methods has become gradually more popular (8 studies in the first 10 years and 12 in the second 10 years); and (d) studies conducted in more recent years have begun to use introspection not as a way of gathering subordinate or supplementary data but as the main source of data to be analyzed. The last two tendencies are probably related to the new orientation to test validity focusing on the consequences of score interpretation and use (e.g., Messick, 1989) in the LA field as well as to the increasing popularity of introspection methods in the field of SLA, as I mentioned above.

Recently Conducted Representative Studies Using the Three Methods

The Three Studies and Evaluation Criteria

In the present section, I select the studies by Plakans (2009), Phakiti (2003), and Yi'an (1998) from the 20 studies presented in Table 79.2 as representative examples of LA studies using introspective methods because these three studies are among the latest to have used at least one of the three methods dealt with in the present chapter. I also make this choice because their research designs represent two important ways of using introspective methods in LA studies (i.e., whether the study mainly focuses on the analysis of the introspective data or whether the introspective data analysis is a complementary part of a quantitative study). By describing and evaluating the details of the methodologies used in these studies I hope to show how typical studies such as these have been conducted in the LA field in the past. In order to provide theoretical support for my evaluation, I draw on Green's (1989, p. 15) list of the following 13 "distinct phases in gathering and analyzing verbal reports regardless of the task or domain" because the list is one of the most comprehensive and practical guides available for properly conducting studies using introspective methods. Though I do not refer below to all of the 13 phases for each study, the full list is as follows:

1. Task identification
2. Task analysis
3. Selecting an appropriate procedure
4. Selecting subjects
5. Training subjects (for concurrent methods only)

Table 79.2 Studies published in *Language Testing* between 1991 and 2010 employing the three introspective methods

<i>Study</i>	<i>Year published</i>	<i>Participants</i>	<i>Targeted tasks</i>	<i>What was investigated</i>	<i>Method employed</i>	<i>Language of reports</i>	<i>Other data analyzed</i>
Anderson, Bachman, & Perkins, & Cohen	1991	28 Spanish-speaking English as a second language (ESL) students	ESL reading comprehension test (45 items)	Construct validation of the test	Think aloud	L1 and/or L2	Test content, test scores
Buck	1994	6 Japanese university students	EFL listening test (54 items)	Dimensionality of L2 listening processes	Retrospective	L1 and/or L2	Interviews, test scores
Cohen	1994	15 English-speaking 5th- and 6th-graders	Spanish math problems	Ratio of L1 and L2 use in solving the problems	Think aloud	L1 and/or L2	Interviews, classroom observation, Spanish proficiency and academic ability scores
Weigle	1994	4 graduate students in applied linguistics	Rating 4 ESL compositions	Effects of training on novice raters	Think aloud	English	Ratings
Storey	1997	25 Chinese-speaking English majors	Multiple choice English cloze test (13 items)	Construct validity of the test	Stimulated recalls	L2	None
Yi'an	1998	4 Chinese-speaking university students	ESL listening comprehension test (6 multiple choice items)	Method effect and L2 listening processes	Retrospective	L2	Observation of participants, their choices for each item
Weigle	1998	16 L1 English speakers	60 ESL compositions (6 rated while thinking aloud)	Effects of rater training	Think aloud	L1	Measures of rater severity and consistency

Sasaki	2000	60 Japanese university students	Two cloze tests	Effects of cultural schemata	Stimulated recall	L1 and/or L2	Test scores
Phakiti	2003	384 Thai university students (8 for stimulated recalls)	Reading comprehension test (85 multiple choice items)	Relationship between test takers' cognitive and metacognitive strategies	Stimulated recall	L1	Test scores, questionnaire responses
Yamashita	2003	12 Japanese university students	A cloze test (16 items)	Test-taking processes of skilled and less-skilled readers	Think aloud	L1 and/or L2	Test scores
Luoma & Tarnanen	2003	6 Finnish L2 students with various L1s	Self-rating test of writing	Development of the test	Stimulated recall	L2	Self-rating and teacher rating scores
Edelenbos & Kubanek-German	2004	49 lessons from 20 schools (1 teacher for stimulated recalls)	A list of teacher behavior patterns	Skills and abilities required of a language teacher	Stimulated recall	L1	Classroom observation
Davison	2004	12 ESL teachers in Australia and 12 in Hong Kong	6 argumentative texts	Comparison of teacher-based assessment in Australia and Hong Kong	Think aloud	English as L1 or as their strong language	Individual and group interviews
Uiterwijk & Vallen	2005	22 second-generation immigrant and 22 native Dutch primary school students	Final test of primary education in the Netherlands	Detection of possible linguistic DIF sources in a test	Think aloud	L1 or the strongest language	Test scores, literature reviews, expert judgments

(Continued)

Table 79.2 (Continued)

<i>Study</i>	<i>Year published</i>	<i>Participants</i>	<i>Targeted tasks</i>	<i>What was investigated</i>	<i>Method employed</i>	<i>Language of reports</i>	<i>Other data analyzed</i>
Rupp, Ferne, & Choi	2006	10 ESL university students with various L1s	Multiple choice L2 reading comprehension test	Investigation of validity of test	Think aloud	L2	Participants' rating of item difficulty
Cohen & Upton	2007	32 ESL students with various L1s	Reading test (13 items used for think aloud)	Validity of new type of L2 reading test items	Think aloud	L2	Test scores
Ockey	2007	6 ESL students with various L1s	Two computer-based listening comprehension tests with either still image or video	Investigation of test-taking processes for test with still image or video	Stimulated recall	L2	Time that test takers spent observing visuals, participants' reports
May	2009	4 trained raters	Rating processes for L2 English paired candidate speaking tests	12 videotaped paired speaking tests	Stimulated recall	L1	Test takers' performance, rater notes and discussion, test scores
Ducasse & Brown	2009	12 experienced raters	Rating processes for L2 Spanish paired candidate speaking tests	17 videotaped paired tests	Retrospective and stimulated recall	L1	None
Plakans	2009	6 ESL university students with various L1s	Test-taking processes of integrated reading-to-write tasks	Two reading-to-write tasks	Think aloud	L1 and/or L2	Interviews, written products

Note. Retrospective = retrospective method without memory aids; Stimulated recall = retrospective method with memory aids; DIF = differential item functioning.

6. Collecting verbal reports
7. Collecting supplementary data (optional)
8. Transcribing verbal reports
9. Developing an encoding scheme
10. Segmenting protocols
11. Encoding protocols
12. Calculating encoder reliability
13. Analyzing the data

Plakans (2009): Using Think Aloud

Plakans's study mainly focused on the analysis of the obtained introspective data. The purpose of the study is to check the validity of a newly developed integrated reading-to-write test by investigating the test takers' writing processes (Green's Phase 2). It was timely that the author selected as her research target the participants' thinking processes while taking the test (Green's Phase 1) because performance-based integrated types of tests were becoming increasingly popular as measures of L2 academic language skills (e.g., Chapelle, Enright, & Jamieson, 2008) when Plakans wrote her paper. Selection of the six participants (Green's Phase 4) is appropriate in that they came from the population who would take the test in question in terms of "their TOEFL scores, nationalities, degree status, and academic majors" (Plakans, 2009, p. 565).

The author's choice of the think-aloud method (Green's Phase 3) also seems suitable considering that the participants, who had relatively high TOEFL scores (520 to 630 in the computer-based version), were even "encouraged to use English (as L2)" when they thought aloud. Although three of the participants sometimes found this requirement "distracting" and "a problem" (Plakans, 2009, p. 567), the use of think aloud may still be justifiable because the participants seem to have produced sufficient amounts of analyzable data, judging from the reported findings. In the data collection stage, Plakans was also careful in that she had all participants trained (Green's Phase 5). Moreover, in the actual think-aloud sessions (Green's Phase 6), she created situations where writers "were not given time limits to complete the task . . . and those silent for longer than 20 seconds were reminded to continue talking, each being a method used to improve think-aloud data" (p. 567) following Russo, Johnson, and Stephens's (1989) recommendation.

Plakans does not mention how she conducted Phase 8 in Green's list (transcribing the verbal data) so we must assume that it was conducted adequately enough. Green (1989, p. 68) admits that the next phase of "developing an encoding scheme" is the most difficult and that "there is little consensus on the precise nature of the coding categories." Such categories can come from existing theory or literature (i.e., prior to examination of the data) or from the data itself (i.e., developed inductively), although it is common to use both sources. Plakans's procedure suggests a reasonable way to go about this process as she utilized the three categories (organizing, selecting, connecting) drawn from the discourse synthesis framework that had previously been developed and used in L1 academic skill studies. However, she also added five other coding categories including "language difficulties" that were specific to the data in her study. She was

successful in using these eight categories because intercoder reliability was reasonably high ($r = .83$, which appears to have been calculated by the common method of dividing the number of agreed upon protocol segments by the total number of segments coded by the two raters; Green's Phase 12). Plakans then analyzed the categorized verbal report data in terms of ratio of each category's use out of the total number of categories used by each participant (Green's Phase 13). Furthermore, when analyzing these data, she used information drawn from other data sources (the participants' L2 proficiency scores, interviews, and written products). Such triangulation of the analysis (Green's Phase 7) is desirable for LA studies focusing mainly on introspective data to avoid criticisms from strictly positivist perspectives.

Phakiti (2003): Using Stimulated Recall

This study is a good example of research using introspective data analysis to complement the quantitative data analysis. Unlike Plakans's study, the introspective data were added to the research design so that the author could "use the interview data to arrive at [a] useful explanation for some quantitative findings" (Phakiti, 2003, p. 38). In this sense, the qualitative analysis in the study was in a subsidiary position.

The main purpose of the study was to investigate the participants' use of cognitive strategies (used to solve the given task, e.g., translating, summarizing) and metacognitive strategies (spanning multiple tasks and subjects, e.g., planning, monitoring) while taking a reading comprehension test. Because a metacognitive strategy in the study was operationally defined as Bachman and Palmer's (1996) concept of *strategic competence* as "a mediator between the external situational context and the internal knowledge in communicative language use" (p. 27), Phakiti's study also attempted to check the validity of this concept using empirical data (Green's Phase 2). To achieve both purposes, the task of taking an L2 reading test was chosen (Green's Phase 1). The participants for the quantitative part of the study were 384 Thai students, and 4 successful and 4 unsuccessful students (as assessed by various measures) were chosen from these 384 students for the qualitative part of the study (Phase 4). The quantitative part of the study employed correlation analysis, exploratory factor analysis, and multivariate analysis of variance in the participants' scores on an EFL reading comprehension test (85 multiple choice items) and their responses to a questionnaire (with 27 items) exploring their use of cognitive and metacognitive strategies. This questionnaire was devised on the basis of previous studies of "reading, learning, and test taking strategies" (Phakiti, 2003, p. 35).

The qualitative part of the study used the stimulated retrospective method rather than the think-aloud method so that the eight participants (four successful and four unsuccessful) could take the test under exactly the same conditions as the other 276 participants who provided data for the major quantitative analysis in this study (Green's Phase 3). The time at which the retrospective interview session was conducted (Green's Phase 6) is not mentioned in the paper even though this can be crucially related to the validity and reliability of the obtained data (for more details, see Gass & Mackey, 2000). The eight participants for the

qualitative part of the study were individually asked to “report on strategies they used when attempting to complete” (Phakiti, 2003, p. 38) the targeted reading comprehension test while looking at the test to assist their memory. In addition, they were asked to take a similar but shorter reading comprehension test lasting 10 minutes, and they were again asked to report the strategies they used to solve the items on that test. Although these additional reports might provide more accurate recalls of the participants’ thinking processes, as the author himself concedes, they cannot be regarded as representing exactly the same strategies used for the test employed for the quantitative analysis.

Unlike in Plakans (2009), the fact that the data “were transcribed and translated into English” and that “the transcripts were double-checked for accuracy” is reported (Green’s Phase 8). However, unlike in Plakans, intercoder reliability is not reported (Green’s Phase 12) probably because the author was the only coder of the data. The data seems to have been coded according to the categories selected for the questionnaire used for the quantitative data, but the author seems to have added “emerging codes from data” (Phakiti, 2003, p. 39) although how he did so is not clearly explained. Nonetheless, Phakiti’s description of how he “developed the encoding scheme” (Green’s Phase 9) for the interview data was apparently theoretically driven (i.e., based on results reported in previous literature) and written up in the most detailed manner of the three studies presented in this section. Such description not only helps the reader understand the method underlying the data encoding but also makes the results of the analysis more convincing.

It is interesting to see how the results of the qualitative analyses complemented the quantitative results in this study, although the author warns that the qualitative results should be interpreted in a manner that is only “suggestive” (Phakiti, 2003, p. 38) because of the small sample size and the way the data were collected. For example, the quantitative analysis reveals a relatively high correlation between the use of cognitive and metacognitive strategies. However, the author found in the qualitative data that the participants’ strategies became either cognitive or metacognitive depending on their goals. Furthermore, the participants tended to use metacognitive strategies throughout the task completion process rather than sporadically. Such results seem to make the two-dimensional statistical results more easily interpretable by introducing a time-related dynamic dimension to these quantitative results (Green’s Phase 13).

Yi’an (1998): Using Retrospection Without Memory Aids

The purpose of this study was to examine EFL students’ test-taking processes while taking a multiple choice (MC) L2 listening comprehension test as well as the impact of the test methods on the processes (Green’s Phases 1 and 2). As in Plakans (2009), this study mainly focused on qualitative analyses of the participants’ introspection. This is one of only two studies among the 20 listed in Table 79.2 that used a retrospective method without memory aids (Green’s Phase 3). As explained above, during a listening activity, collecting concurrent think-aloud data is not possible and using memory aids can be difficult.

However, given the demerits of retrospective methods, the author seems to have devised several ways to make the data as reliable and valid as possible

(Green's Phase 6). Consequently, as "in a real test" (Yi'an, 1998, p. 29), the four Chinese participants listened to a 3.5-minute recorded interview twice (it appears that listening to the same text again was a conventional way of giving the kind of test Yi'an wanted to investigate). In the first listening, they listened to the whole 3.5-minute interview text while answering the six questions while in the second listening, they listened to the same interview section by section. The participants reported what they were thinking about every time each section ended, and it also seems that during such retrospection sessions, the participants were further interviewed with probing questions. It should also be noted that this data collection procedure was designed based on the results of the "written responses of 74 Singaporean Chinese" (Yi'an, 1998, p. 28) to the same listening test as well as the results of two pilot interviews. Such careful preparation before the main study is one of the virtues of this study. However, as in the two studies above, this study does not mention how the transcription was conducted (Green's Phase 8). Furthermore, as in Phakiti (2003), intercoder reliability is not reported (Green's Phase 12). It would have been advisable for Yi'an to ascertain the validity of the analysis by asking another expert researcher to check at least part of the obtained data.

Yi'an's (1998) procedure for "developing an encoding scheme" (Green's Phase 9) is different from that of the two studies above because the procedure employed in this study is mainly inductive and data-driven. This might be related to the fact that very few studies had been conducted on test-taking processes in L2 listening tests when this article was written. The author analyzed the collected data using three types of information: whether the participants offered direct reports of their thinking processes or explanations of their thoughts (based on Ericsson & Simon's, 1993), whether the answer for any given item was correct, and which letter from the four MC selections was chosen and how the choice changed over time. The patterns that emerged from these analyses provide meaningful information on both the validity of MC-type listening comprehension tests and what skills and knowledge may be required to solve such tests.

Additional Recommendations for Researchers

On the basis of my review of the three representative studies discussed above, I would like to add the following recommendations to Green's (1989) list for conducting proper studies using introspection processes.

1. Choose the think-aloud method if your targeted task allows its use, if you can allow the participants to use L1 when necessary, and if the task is not cognitively too demanding so that it does not distract the participants' thinking aloud too much.
2. If you choose retrospective methods, try to devise the procedure so that the participants' recall is as authentic and accurate as possible (e.g., try to make the lapse between the task and the retrospective session as short as possible).
3. Although it might be better to start with theoretically well-informed baseline categories when coding the data, do not hesitate to add more categories or to revise existing ones if the data require it.

4. Report how the transcription was conducted and how the data were segmented for the analysis.
5. Employ another coder and report intercoder reliability.
6. Describe how you analyzed the data in as much detail as possible.

Conclusion and Future Directions for Introspective Methods

Within the overall LA field, the now generally accepted consensus is that there is in the matter of test validation a continuing “argument” (Chapelle, Jamieson, & Hegelheimer, 2003, p. 411) over how well test scores are interpreted and used in each situation. Consequently, investigating participants’ test-taking processes through their own introspection has become increasingly important as part of this “argument” process. Among the methods eliciting test takers’ introspection, the methods described in the present chapter are the three most frequently used approaches obtaining the closest access possible to the participants’ internal thinking processes in the most accurate form. This focus on the learners’ emic thinking in situ has also been advocated in the recent sociocultural orientation of the SLA field (e.g., *The Modern Language Journal*, 2007). Considering this almost serendipitous synchronization of attention toward the learners’ internal processes, I present several possible directions that future introspective research might take in the field of LA.

First, the number of studies that use introspective data to supplement the quantitative data analysis, as in Phakiti’s (2003) study, will continue to grow. Such mixed method studies have been recommended ever since the above-mentioned consensus on test validation processes began forming as a result of seminal work by researchers such as Messick (1989). These studies will become even more desirable if the qualitative data analysis part is as carefully and rigorously conducted as the quantitative part so that the qualitative component complements the findings as an equal contributor rather than simply supplementing the quantitative component. For this purpose, how convincingly qualitative data such as participants’ test-taking processes can be analyzed for the benefit of readers in the LA field with dominantly positivist orientations remains a key issue to be investigated in the future.

Second, if we believe that test validation should consider the impact of test scores, we should consider how our LA research results can be used to help the test takers’ subsequent learning. In this sense, Plakans’s (2009) finding is valuable in that the integrated writing task in question made participants with higher L2 proficiency use academic writing strategies more often than those with lower L2 proficiency in both the thinking processes involved (e.g., discourse synthesis) and in the final written product (e.g., use of the source texts). Such results not only support the validity of the test when it is used to place students within appropriate ESL classes, but information obtained from such results also suggests what kind of skills (e.g., discourse synthesis) students with lower L2 proficiency will need to learn in their assigned classes. Studies such as Plakans’s are needed if LA researchers hope to bridge the gap between assessment and education.

Finally, we can look at the educational impact of verbal reporting itself. If it is true that “ideas are crystallized and sharpened and inconsistencies become more

obvious" (Swain, 2006, p. 100) while participants are taking a test and thinking aloud at the same time, we can view the impact either as negative in that this introspective method interferes with accurate descriptions of cognition, or positive in that the talking itself can facilitate the participants' learning. In fact, the three participants with higher L2 proficiency in Plakans (2009) "felt that talking while writing helped them. It moved their thinking along and assisted in their proofreading" (p. 567). Possible future studies could take either the former "method-effect" stance and investigate the reactivity effects of the use of introspective methods on the investigation of test-taking processes. Alternatively, they could take the approach employed by researchers from a sociocultural perspective such as those who believe in "dynamic assessment" (e.g., Poehner, 2008) and promote a combination of "assessment and instruction as a development-oriented activity" (Poehner, 2008, p. 1). Findings from studies based on the latter view can also contribute to knowledge accumulation in the LA field by adding a harvest of studies with nonpositivist perspectives that are quite different from those that have hitherto prevailed in the field.

Raters and Ratings

Alistair Van Moere

Knowledge Technologies, Pearson, USA

Introduction

The rater's primary role is to evaluate spoken or written performances with respect to a given set of criteria or *rating scale*. Although in language assessment rating requires judgment, it should not be confused with the kind of artistic or personal judgment that is applied, for example, in figure skating or wine tasting. In most language assessments the tasks are designed to elicit a certain language or certain performances, and the rating criteria adequately describe performances at different levels of ability. Raters use their judgment to match the candidate's performance to the descriptors in the rating criteria that best describe that performance. In this way the performance is translated into a numerical score. Figure 80.1 shows sample scale descriptors with four traits that relate to scores on a scale of zero to three.

From this perspective, the rater should not be seen as the almighty examiner or "decider" on how well candidates score. Rather, raters are participants in a process: they transform a performance into a score via the rating scale descriptors. Language performances can be very rich, and this makes rating a complex task. Performances may exhibit good grammar but poor word choice, strong fluency but low intelligibility, a good argument but poor paragraph structure. This makes it difficult to determine which descriptors best suit the performance and what score the performance deserves. Raters therefore draw on their experience with the task and the language. Their role is easier if the rating criteria are unambiguous and if the descriptors adequately describe the kind of performance that candidates typically produce on these tasks.

Research has uncovered how raters' decision making is susceptible to a host of interfering variables. These variables include the rater's first language (Kobayashi, 1992), their individual preferences for language features (Cumming, Kantor, &

Band	Development, structure, and coherence	Vocabulary range	Grammar, usage and mechanics	Content
3	The essay shows a good development and logical structure.	The essay shows a good command of a broad lexical repertoire and a good command of idiomatic expressions and colloquialisms.	The essay shows consistent grammatical control of complex language. Errors are rare and difficult to spot.	The essay adequately deals with the prompt.
2	The essay is less well structured, some elements or paragraphs seem poorly linked.	The essay shows a good range of vocabulary for matters connected to general topics. Evident lexical shortcomings lead to circumlocution or some imprecision.	The essay shows a relatively high degree of grammatical control; there are no mistakes which would lead to misunderstanding.	The essay deals with the prompt but doesn't address one minor aspect.
1	The essay lacks coherence, mainly consists of lists or loose elements.	The essay contains mainly basic vocabulary insufficient to deal with the topic at the required level.	The essay contains mainly simple structures and several basic mistakes.	The essay deals with the prompt but omits more than one or a major aspect.
0	There is no response, response is not English or irrelevant.	There is no response, response is not English or irrelevant.	There is no response, response is not English or irrelevant.	The essay does not properly deal with the prompt.

Figure 80.1 Sample analytic rating scale for assessing writing proficiency on four traits, adapted from PTE Academic (Pearson, 2012) © Pearson. Reprinted with permission

Powers, 2002), the amount of experience they have as raters (Lim, 2011), and the amount of training they have received (Knoch, 2011). The test designer is concerned with verifying whether these factors cause unwanted variation in the rating process and, if they do, with controlling or reducing these effects. This may be achieved, for example, by altering the test design (Van Moere, 2006) or by providing further rater training (Weigle, 1998).

Depending on the test context, raters may have several roles beyond the scoring of performances. For example, raters can provide feedback to the test designers about the wording of the rating scale, or about the characteristics of the test tasks and whether they elicit the intended language (Brown & Taylor, 2006). In speaking tests, raters may also act simultaneously as examiners and as interlocutors (see below, Brown, 2003). Thus, although some raters are mainly concerned with rating essays or audio files after the test event, other raters may have a more active role in test design and administration.

This chapter describes the rater's various roles and the process of accurately transforming a performance into a score. It also presents research on detecting variation in the rating process and on how to overcome this unwanted variation.

Practical Considerations

Rater Training

An assessment that involves rating performances requires considerable preparation. Ackermann and Kennedy (2010) provide a case study for recruiting, training,

and qualifying raters in the Pearson Test of English Academic (PTE Academic), which can be described in five main steps. First, raters were recruited on the basis of a set of required qualifications. For PTE Academic, raters had to possess “native or native-like” proficiency in English and have a bachelor’s or a higher degree; a recognized qualification in teaching English as a foreign language was “highly desirable.”

The second step involved developing training, or *standardization*, materials. A standardization guide contained 135 candidate responses from field testing. An example of every combination of item, trait, and score was represented in the guide, together with a written rationale for the assigned score. These are known as *benchmark* responses, and in this case they consisted of text or audio of candidate responses (a video is also possible). The standardization guide and the benchmarks were distributed to raters before the training, so that they could inspect sample responses that matched every cell in the rating criteria. The third step was rater standardization, or *norming*, sessions. The sessions included presentations informing the raters of the purpose of the test, candidates, items, and traits. Then supervisors trained raters in groups of ten, using the flashcard method. Raters were presented with a candidate response that they had not heard or seen before, and they held up their rating for that response on a card. In this way supervisors received independent scores from each rater and could immediately see any disagreement. In total, the standardization sessions lasted 12 hours for raters and 20 hours for supervisors. Note that rater training need not always be face to face; it can be conducted via online modules (e.g. Elder, Barkhuizen, Knoch, & von Randow, 2007).

Step 4 consisted of a qualification exam. Raters were required to achieve 80% adjacency agreement (see below) with a set of field test performances that had already been judged by the test designers. Approximately nine out of ten raters passed the exam and were hired to work as raters for PTE Academic. A fifth step occurred during and after the operational rating period. Raters and supervisors were surveyed and interviewed about the rating process. The survey gathered feedback about rating behavior, the technology used, the rubrics, and benchmark responses. For example, in their feedback raters noted that some terms in the rating scales were vague (e.g. “appropriate,” “native-like,” “relatively high”); the 12 hours of training were sufficient; the small group approach to training was comfortable and allowed raters to discuss the performances and descriptors.

Ackermann and Kennedy (2010) conclude by noting that, although various rater qualifications are desirable, the final recruitment decision can only be made once the rater training and qualification have been completed. This reflects the fact that some well-qualified and experienced teachers struggle to rate accurately and consistently, while some inexperienced teachers will have a natural talent for it.

Operational Rating

After training and during operational rating there can be many threats to the rating process. This section introduces some of the threats and shows how they might be mitigated (a) by monitoring and supporting raters; and (b) by devising a rating plan that allocates raters to performances or candidates.

There are various reasons why even trained raters might exhibit deviation from the expected standard. For example, if a rater is also the candidate's teacher, this allows for bias when the rater awards the score s/he thinks the candidate deserves rather than rating the performance that was given during the test (see O'Sullivan, 2000, on examiner behavior and interlocutor *acquaintanceship*). Further, there is good evidence that, as raters continue to rate, their judgment can *drift*: there is variation in their consistency over time (see below; Lunz & Stahl, 1990). Additionally, they could simply suffer from a momentary lapse of concentration that results in an inaccurate rating.

Another threat is the *halo effect*, which occurs when raters form an early impression about the candidate, and this impression affects their judgment throughout the test. For instance, if a candidate performs very well on the first task in a speaking test, the rater may form a positive impression and may rate the candidate highly in subsequent tasks too, even though the candidate performs poorly in them. Similarly, *transfer of judgment* occurs when the rater's impression of one of the candidate's attributes affects his/her judgment of another attribute. For example, a candidate is strong in fluency, and so the rater transfers the perception of strong proficiency onto other traits, such as grammar, even though the candidate's grammar may actually be poor.

For reasons such as these, it is advantageous to monitor and support raters during the operational rating. Raters can be monitored by periodically assigning to them *anchor papers*. Anchor papers have been given a score previously by the test designer or by a committee of experts. The ePen (NCS Pearson, 2011) online rater system typically allocates one anchor paper to each rater per 20 papers rated. Reports and graphs are automatically generated which give a snapshot of rater conformity and reveal whether any rater is drifting from the standard. Raters also receive support during rating. Supervisors provide guidance on scoring tricky or unusual performances. Supervisors also disseminate new information that arises as a result of the rating, such as how to score papers in which candidates answered in unanticipated ways, not encountered in the training.

Natural variation in rater behavior can also be mitigated through the *rating plan*, which is the procedure for allocating raters to performances or candidates. For example, in the Test of English as a Foreign Language, Internet-based test (TOEFL iBT), the recorded performances from candidates on six speaking tasks are allocated among three to six different raters, rather than to a single rater. Since each rater may only encounter one of the candidate's six performances, this successfully counters the halo effect in that it prevents raters from being influenced by the candidate's other five performances. A variation of this approach, for analytic rating scales, is for raters to rate each performance by one trait at a time. Thus, instead of listening to a spoken performance and assigning a score for grammar, a score for organization, and a score for delivery, the rater scores only grammar for several hundred performances, then organization for several hundred performances, and so on (see Ackermann and Kennedy, 2010). This keeps the traits separate in the rater's mind and prevents transfer of judgment.

Raters may also be paired by the rating plan according to their characteristics. Pairing a native speaker rater with a non-native speaker could "balance out" any bias associated with either rater's perspective when their ratings are combined

(Kobayashi, 1992, discussed below). In tests of English for special purposes, it is common to pair a language expert with a subject matter expert (SME). For example, in the English Language Proficiency for Aeronautical Communication (ELPAC) test (EUROCONTROL, 2007), an interview is conducted by one English language expert acting as a rater and one aviation expert acting as both interlocutor and rater. This approach allows each rater to focus on their strengths: the language expert evaluates linguistic competencies such as grammar or pronunciation, and the SME additionally evaluates the subject content or functional competence. Further, as the interlocutor is an SME, s/he can engage in domain-relevant language and interactions with the candidate.

A possible problem when two raters work together, however, is *rater collusion*. In some exams the scoring is felt to be more reliable if the raters discuss the candidate's performance and assign a score together. While this deliberation may have certain benefits, rater personalities or seniority might unduly affect the decision-making process. One rater might be overly persuasive, or raters may "trade off": as the first rater's opinion won over on the last candidate, so the second rater's opinion wins over on this candidate. For these reasons, the evaluation is often felt to be more objective if raters submit independent ratings.

One method that has emerged as an "industry standard" is adjudication. When a performance is rated by two raters and they do not agree exactly, the performance is diverted to a third rater—an adjudicator—who decides the final score. A similar technique is used by the Educational Testing Service (ETS) in the written section of the TOEFL, where one "rater" is the *e-rater* automated scoring engine and another rater is a trained human rater: if the two disagree, then a third (human) rater arbitrates (Enright & Quinlan, 2010). When test circumstances allow, adjudication is a good way to resolve disagreements in ratings.

Analysis of Ratings Data

The statistical analysis of ratings data is vital, as it informs stakeholders how consistent and reliable the ratings are. This section discusses the key concepts of *inter-rater* and *intra-rater* reliability (Fulcher, 2003). Inter-rater reliability refers to the extent to which two or more raters agree when they assign scores. When two raters independently judge that a performance deserves the same score on a rating scale, then a claim may be made for the accuracy of this rating. That is, their independent expert judgments confirm each other. Conversely, if two raters provide judgments that are far apart on the rating scale, that would imply that one or both of them have assigned a score that the performance did not deserve or that other raters would disagree with, and therefore the accuracy of the scoring is in doubt.

Intra-rater reliability is less frequently reported and refers to the consistency with which an individual rater assigns ratings. To estimate intra-rater reliability, performances that the rater has previously encountered are presented to the rater again, preferably at a later time or in a randomized order. For example, every time the rater finishes rating 100 essays, five of those essays are selected randomly and presented to the rater again. A rater's internal consistency is high if s/he has awarded the same score to the same performance when encountering it on

multiple occasions. High intra-rater reliability but low inter-rater reliability indicates that raters are disagreeing consistently; in this case it may be that each rater has different convictions about how to interpret the rating scale.

Classical test theory (CTT) provides numerous techniques for measuring and reporting rater reliability (for formulas, see Bachman, 2004). The Pearson product-moment correlation provides an estimate of the “go togetherness” of two sets of numbers; in this case, the extent to which two raters agree on a sample of performances. The coefficient is scaled from -1.0 (perfect disagreement) to 1.0 (perfect agreement) and is useful for investigating inter- and intra-rater agreement. Coefficients above 0.9 are generally considered to indicate an acceptably high degree of rater reliability for high stakes tests. In lower stakes tests, or in contexts where candidates are similar in terms of proficiency level, the test designer may tolerate coefficients of 0.7 or 0.8 .

Another simple yet effective method for explaining rater reliability to stakeholders (e.g. students and parents) is to report on the “percent agreements” in the ratings data: that is, the percentage of occasions on which two raters assigned the same score to a performance, the percentage of occasions on which they assigned scores with a difference of one point, with a difference of two points, and so on. Raters could then be required to agree exactly at least 80% of the time, and to agree exactly or within one point at least 95% of the time. The limitation to this approach is that raters might agree by chance; and they are more likely to agree by chance using a four-point rating scale than using a six-point rating scale. A technically better estimate of rater agreement is Cohen’s kappa coefficient. This statistic provides an estimate in which the proportion of agreement due to chance has been removed (Bachman, 2004).

Yet another statistic is appropriate for reporting *score reliability* (as opposed to rater reliability). The coefficient alpha, sometimes known as Cronbach’s alpha, is used to report on the reliability of the averaged or summed ratings from two or more raters—that is, on the degree to which measurement is repeatable. Alpha coefficients from ratings data tend to be lower than can be expected from correlation coefficients, but alpha coefficients above 0.9 are considered excellent, and above 0.7 they are acceptable for lower stakes.

All these statistics can be calculated from ratings data by using software such as Excel or SPSS. Reporting rater agreement and score reliability statistics such as the ones introduced here is essential for good testing practice, as they contribute to the *validity argument* for a test.

Current Theoretical Conceptualizations

Frameworks for the Rating Process

Views of the rating process in language assessment have developed along the same lines as views of test validity. A validity argument is conceptualized to take account of test score variability. That is, we would like to maximize *construct-relevant variance* (i.e., the ability that we intend to measure), and to minimize *construct-irrelevant variance* (i.e., unintended abilities, such as personality or creativity instead of language proficiency). Therefore much of the literature on the

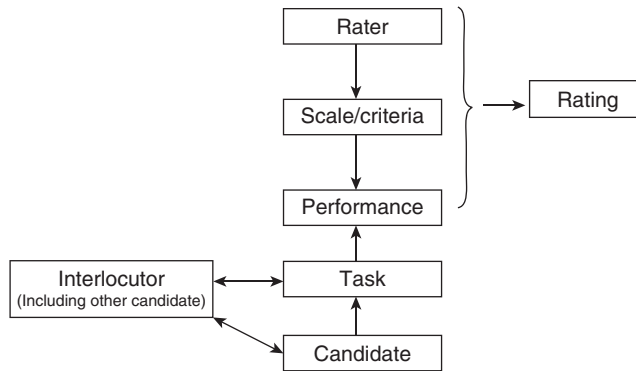

Figure 80.2 Interaction in performance assessment of speaking skills (McNamara, 1997, p. 453) © Oxford University Press. Reprinted with permission

rating process is focused on identifying sources of score variance or measurement error.

McNamara's model of oral assessment reveals some of these sources of variability (see Figure 80.2). In this model a performance-based assessment will ideally allow a candidate to clearly demonstrate his or her language competencies. But test variables and the manner in which the performance is elicited obscure the measurement of these competencies. Figure 80.2 shows that candidate performance is not simply dependent on the ability to be measured but is constructed through other test variables. The candidate's characteristics and language competencies interact with the task requirements, which results in a performance that may or may not be an accurate portrayal of their ability. Similarly, the rating process is not simply the rater's judgment of the candidate's performance; it is the rater's interpretation of the performance in relation to other variables such as task and rating scale.

Figure 80.2 applies to writing and speaking assessments. But, since it illustrates oral assessments, it gives prominence to an extra variable: the interlocutor. The interactive relationships between candidate, task, and interlocutor can all influence the candidate's performance in a speaking test.

This view of raters therefore sees them as cogs in the assessment process. Raters have a set of characteristics, such as native language, gender, level of fatigue, amount of training received, profession, preferences for and biases against certain tasks, topics, language features, performances, candidate types, and so on. These characteristics interact with a multitude of other variables in the assessment context, such as the candidate's native language, accent, gender, and performance, the time of day, the tasks and topics used, the interlocutor, the rating scales, and so on. This has led McNamara to state that the rating process is a result of a whole host of factors interacting with each other, "with a rating popping out at the end" (1997, p. 453). It is therefore essential to identify and reduce unwanted sources of variation that have a significant effect on ratings.

Drawn with this in mind, Figure 80.2 is something of a simplification of all the variables at work. Other researchers have suggested alternative models, of which

two are mentioned here. Bachman's (2002) model of oral test performance emphasizes the impact of *task characteristics*—such as task orientation, interactional relationships, goals, interlocutors, topics. Bachman notes that tasks cannot be said to be uniformly easy or difficult because candidates experience tasks differently, according to their individual strengths and weaknesses. Bachman's model illustrates how task characteristics interact with candidate and rater variables and therefore influence the eventual meaning of test scores.

On the other hand, in Fulcher's (2003) model of speaking test performance, task variables take a less prominent role in the larger system of variables at work. Fulcher notes that construct definition is central to rating scale design, and it is the scoring philosophy of the rating scale that has the greatest contribution to the score and its meaning. In this view of performance assessment, the consequences of varying task characteristics are secondary to the consequences of varying the rating criteria. Thus the construct of the test and the meaning of scores are operationalized in the rating scale.

These differences aside, the consensus in the literature is that raters interpret rating scales differently, that they place different amounts of importance on different aspects of candidate performance, and that their interpretations interact with task variables. The concern that there is unwanted variability, or measurement error, in the rating process has led to the use of certain statistical techniques that identify the sources of variability and measure their effects. Two approaches introduced here are generalizability theory and Rasch modeling. These techniques are part of the test developer's toolkit and have influenced how we think about measurement variability and validity.

Investigating Variability in Ratings

Generalizability theory, or G-theory, is a statistical framework that quantifies error associated with certain test facets (or variables). It is normally conducted using software such as GENOVA (Brennan, 1983). Using G-theory, researchers can estimate the impact of factors such as setting, time, items, and raters. For example, Van Moere (2006) conducted a study on sources of score variability in a 10-minute group discussion test at Kanda University in Japan. The test is used for placement decisions and progress monitoring. In this study candidates participated in a discussion test on two successive occasions, with two different raters on each occasion. A generalizability model was used to distinguish between the test facets and to estimate the strength of their effects. The model had three facets: candidate, test occasion, and rater. Most of the test score variance was attributable to candidate ability, which is construct-relevant, and so this was a good outcome. The rater facet contributed relatively little variance to test scores. This was also good, because it revealed that raters as a whole were not unduly influencing the candidates' test scores. However, there was a significant amount of variance associated with test occasions; candidates gave measurably different performances on different occasions of the test, and so they received different ratings (sometimes higher and sometimes lower). Thus raters as a whole did not contribute to unwanted measurement error, but test occasions did. Van Moere found that, in order to achieve a more reliable test, adding a third or a fourth

rater to observe each performance would increase reliability only a little. On the other hand, requiring that candidates take the test two, three, or four times would make a larger contribution to increasingly reliable test scores. Therefore it would be a more effective use of university resources if test administration involved students taking the 10-minute test twice with one rater rather than once with two raters.

Whereas generalizability theory can provide information about the *overall* effect of rater differences on test scores, the multifaceted Rasch model is able to distinguish *individual* differences among raters. That is, rather than reporting on the degree of variability associated with raters as a whole, Rasch analysis pinpoints which raters are adding to the variability and by how much, and which raters are conforming. The analysis is normally conducted using software such as FACETS (Linacre, 2009). Rasch is a probabilistic model that calculates candidate ability with reference to the conditions under which the candidate performed (see McNamara, 1996, for a comprehensive guide to Rasch modeling). For example, Bonk and Ockey (2003) also investigated the Kanda University discussion test, this time in a Rasch model with ratings data from 20 raters working in pairs who rated over 1,100 students. The researchers demonstrated how the Rasch model calibrates the elements of several facets of the examination (candidate performances, tasks, and raters) on a common log-linear scale and corrected for task difficulty or rater severity. Thus candidates who were rated by comparatively severe raters had their scores (or ability estimates) adjusted upwards; this compensated them for having been scored by a severe rater. Likewise, candidates who were allocated comparatively easy tasks had their ability estimates revised downwards; this corrected for the easiness of the task, which would otherwise have given them an unfair advantage over candidates who performed on harder tasks. Rather than averaging the ratings from the two raters, the authors recommend reporting Rasch *fair averages*, which have been adjusted for the facets in the model, such as rater severity or task difficulty. The authors claim that, due to rater differences, neglecting to control for facets such as rater severity in a Rasch model would be “irresponsible and may lead to spurious interpretation” (Bonk & Ockey, 2003, p. 104).

Theoretically, Rasch measurement negates the need for high rater agreement, since estimates of candidate ability are adjusted to compensate for the ratings of particularly severe or lenient raters. This being the case, rater training need not be required in order to ensure that raters agree with each other (inter-rater reliability). Rather, as long as raters act consistently when assigning ratings (intra-rater reliability), we could supposedly let the Rasch model take care of differences in leniency and severity between raters. However, Weigle (1998) notes that the implications of this go beyond controlling for unwanted measurement variability and actually impact the construct of the test. This means that raters would not necessarily need to agree on the definition of the ability being measured: if raters interpret the rating scale in internally consistent but idiosyncratic ways, then the construct being measured might in fact vary from rater to rater. Thus, even though Rasch modeling helps correct for rater severity, it is still incumbent on raters to have a common understanding of the intended grading criteria and to strive for the highest possible inter-rater agreement.

Current Research

This section reviews some literature on rater variables that are known to induce unwanted variance in the assessment process. In a narrative review of 70 studies involving essay tests, Barkaoui (2007) reports that 22 investigated rater variables. The most frequently studied rater variables in writing assessments are: raters' first language in relation to candidates' first language; raters' natural preferences for certain features of a performance, such as grammar or organization; raters' academic background; raters' training or experience. Several such papers are described here.

Concerning rater language background, Kobayashi (1992) investigated two groups of raters: 145 English native speakers and 124 Japanese native speakers. They each rated two compositions from Japanese university students for grammar, clarity of meaning, naturalness, and organization. A main finding was that the English native speakers were significantly more severe in terms of rating grammaticality than the Japanese native speakers. But, despite Kobayashi's findings, we cannot say conclusively that raters with different L1s always assign different scores to an essay. Other researchers have found that L1 has little or no language-related bias in the ratings (Johnson & Lim, 2009). Thus findings will vary from context to context and will depend on other variables, such as degree of rater training.

Similar studies have investigated the rating of oral performances. In speaking tests, rater and candidate language background can have a large effect, as this is closely connected with raters' perceptions of pronunciation, accent, and intelligibility. In a study by Carey, Mannell, and Dunn (2010), 99 examiners from the International English Language Testing System (IELTS) located at test centers in India, Hong Kong, Australia, New Zealand, and Korea rated the English pronunciation of candidates from China, Korea, and India. It was found that a significant proportion of raters assigned higher pronunciation scores when they were familiar with the L1 accent than when they had little or no familiarity with that accent. A similar finding was made by Winke, Gass, and Myford (2011) when trainee raters evaluated TOEFL iBT speaking performances using the TOEFL iBT rating scale. Thus it appears that even trained raters are susceptible to accent familiarity, and this may be considered a challenge in interview tests that are administered and scored by locally situated raters.

One limitation with studies that analyze ratings data alone is that they do not tell us *why* the raters behaved as they did, but only that different raters behaved differently. Thus qualitative research approaches are useful for providing insights into underlying causal information. *Think-aloud protocols* can be used to find out what the raters are thinking as they assign scores. Adopting this procedure, Vaughan (1991) identified several characteristic reading strategies that raters adopted as they evaluated compositions. Vaughan labeled these as the "first-impression-dominates style," the "two-category style" (with a focus, for example, on two categories such as organization and content), and the "grammar-oriented style" (with an almost exclusive focus on grammar). Cumming et al. (2002) also looked at the criteria that emerged from think-aloud data and identified three general categories: a self-monitoring focus (reading or rereading the essay,

comparing with other essays), a rhetorical focus (assessing topic development, task completion), and a language focus (considering errors, lexis, syntax). This demonstrates that raters have different personal preferences when it comes to the features of students' writing, and that they also adopt different styles in their approach to the rating process.

Various studies have been conducted on the effects of time on rater behavior. Again, the results have been mixed. Some researchers have found that raters can maintain their accuracy for long periods. For example, Lim (2011) noted that novice raters, who were at first inconsistent, improved rapidly and that the quality of their rating improved the more they rated. In Lim's study, raters were on the whole able to maintain their quality over long periods of time, up to three years. But not all researches had the same findings. Lumley and McNamara (1995) discovered large fluctuations in the behavior of some raters in rating sessions that were one month apart. Thus Lumley and McNamara maintain that it may be necessary to retrain raters more frequently than, for example, once a year.

It is also important to look at the effects of time not only in terms of test administrations spanning months or years, but also within a single session of rating. Lunz and Stahl (1990) showed the emergence of inconsistencies even over half-day grading periods. Therefore it is possible that a rater's judgment may vary even over several hours due to factors such as fatigue, evolving perceptions of how to interpret performances in relation to the rating scale, or the influence of candidates or other raters during the session.

One area of rater variability that specifically relates to speaking tests is the impact of rating and acting simultaneously as an interlocutor. In the Interagency Language Roundtable (ILR) oral proficiency interviews (OPIs) there are two raters; one rater just listens, while the other rater asks questions of the candidate and conducts role plays. Researchers have found that the examiner questioning style leads to lack of test consistency in assigning ratings. Reed and Halleck (1997) studied the ratings awarded to candidates being tested by two different trained examiners. They found that ratings awarded to the candidate when examiner 1 was the interviewer were systematically lower than when examiner 2 was the interviewer. Inspection of the recorded performances revealed that examiner 2 pitched the interview at a higher level. Examiner 1 selected lower-level role plays for the candidate and posed intermediate-level questions for many consecutive turns during the discussion, but examiner 2 selected higher-level role plays and also spiraled from intermediate- to superior-level questions during the discussion. This shows that interlocutors create lenient or harsh conditions, which in turn can impact ratings. The next section gives another example of this (Brown, 2003) and discusses how it can be overcome.

Challenges

Remediating Variability

One challenge that has received little research attention is how to reduce unwanted variability once it has been identified. For example, if some raters are accuracy influenced and others are fluency influenced, what is the best way to correct this?

This section briefly examines two contexts in which reducing variability has been attempted.

Rater training is often thought to reduce individual rater variability. Unfortunately, it is not always beneficial. Knoch (2011) tracked 19 raters over eight test administrations. After each administration, raters received detailed feedback of their rating behavior. The findings showed that raters did not improve, and neither speaking nor writing raters were able to incorporate the feedback successfully. Although raters felt that feedback was beneficial, this perception was not borne out in the actual ratings data. On the other hand, some remediation to counter the effects of variability appears to have been successful. For example, Weigle (1998) found that training improved intra-rater reliability. However, inter-rater reliability did not improve significantly. This demonstrates that it may be easier to improve internal consistency among raters rather than their leniency/severity. Thus the test designer should not assume that rater training is effective but should evaluate it empirically.

Another context in which there has been a concerted effort to reduce unwanted variability is the IELTS speaking test. Research on an earlier version of this test revealed several sources of measurement error. Brown (2000) selected video-recordings of four partial interviews and asked eight raters to rate each interview while providing a verbal recall protocol (32 protocols in total). Brown noticed that the raters disagreed regularly by two or three bands on the 9-point scale; for example, one rater would assign a 5 and another rater a 7. Further, although the rating criteria was a single holistic scale, the raters focused on different aspects of the performance, such as syntax, discourse, or candidate attitude. Thus raters arrived at different scores by relying on different aspects of the speech. Brown (2003) also showed that the examiner conducting the interviews created significantly different lenient or severe conditions. Two examiners were selected to interview the same candidate on two different occasions. One examiner gave more support by using techniques such as topic priming and topic extending, while the other examiner used rather closed questions and echo-and-tag questions, which failed to elicit extended responses from the candidate. Raters who watched the first interview perceived the candidate as "willing and responsive," while those who watched the second interview perceived the same candidate as "unforthcoming and uncooperative."

Drawing on research such as this, the IELTS speaking test was revised in 2001. The holistic criteria were divided into four analytic scales: fluency and coherence, lexical resource, grammatical range and accuracy, and pronunciation. A subsequent survey involving 269 examiners reported a largely positive response regarding the new scales, although examiners cited the pronunciation scale as difficult to interpret and apply confidently (Brown & Taylor, 2006). After a further revision, yet another survey showed increased rater satisfaction, but pointed to still other improvements that could be made (Yates, Zielinski, & Pryor, 2011). A second change to the test format was the introduction of an interlocutor script or "frame," which aimed to create a more structured test and to standardize examiner language and behavior. Investigations revealed that, in general, interlocutor frames reduced variation in the interview technique of examiners, but that examiners frequently found the specific wording awkward, over-lengthy, or unclear (Brown

& Taylor, 2006). This feedback could be used to develop the wording of future frames. This iterative process exemplifies the cycle of research, revision, and incorporation of rater feedback that is necessary to reduce variability and increase measurement consistency. However, this is a costly and time-consuming process, and many institutions will not have the resources or expertise to go these lengths.

Investigating Rating Scales

Investigating the rating scale is important because the scale descriptors operationalize the test construct (Fulcher, 2003). It is necessary to evaluate whether the analytic traits do indeed measure different dimensions of the candidates' ability and whether the score bands separate candidates according to proficiency. Moreover, the different traits will usually need to be interpreted or combined in order to facilitate decision making or inferences about candidate ability.

Valid rating scales ordinarily demonstrate appropriate dimensionality when the traits represent different but related aspects of the same ability (see Sawaki, 2007). For example, if the ratings data show that the traits of grammar and vocabulary are too divergent (e.g., they correlate below 0.5), then these traits may not be subdimensions of the same overarching construct. Conversely, if the traits are too convergent (e.g., they correlate above 0.9) this may indicate that the raters cannot distinguish between the traits. An inter-correlation matrix among the traits provides a snapshot of the degree to which they are related; however, more thorough methods involve structural equation modeling or factor analysis (Sawaki, 2007). Band separability needs to be evaluated to ensure that bands distinguish between different levels of proficiency. Does the difference between, for example, a score of 2 and a score of 3 represent a discernible increase in the ability being measured? Multifacet Rasch modeling provides techniques for establishing band and trait separation values (see McNamara, 1996).

The next challenge is to decide how the trait scores should be combined or reported. There is not necessarily a "right" way to do this; the test designer must select an approach that reflects the testing goals and must provide a justification within the validity argument. To help provide justification, it is best if the decision is made with full understanding of (a) the construct definition and (b) the psychometric properties of the rating scale and rating data.

If trait scores are combined to report a composite overall score, then two approaches are *nominal* or *effective* weighting (Bachman, 2004). Nominal weighting reflects the test designer's intent relative to the test construct. A straightforward method is to average or sum the trait scores. Although this is easy to explain, an averaging approach assumes that all traits provide equally important information. Moreover, averaging allows candidates to compensate for weakness in one skill with strength in another skill, and to earn an acceptable overall score despite critical weakness in one or more traits. For these reasons traits can be weighted differently, according to their importance. Weigle (1998) reported the use of differential weighting in an ESL writing placement exam, where the score on one trait (language) received double the weight of two other traits (content and rhetorical control).

Effective weighting, on the other hand, is a statistical approach that reflects the degree to which individual traits empirically contribute reliable information to a

composite. For example, Sawaki (2007) used G-theory and confirmatory factor analysis to show that, of the five traits investigated, one accounted for approximately 33% of the composite universe score variance, while the other four explained only 15–18% each. Bachman (2004) refers to these percentages as “self-weights,” as they take into account the reliability of each trait score and its relation to the other trait scores. Bachman recommends using a weight readjustment procedure to obtain the desired effective weights of the traits.

Trait scores need not always be weighted and combined, however. An alternative is to report each trait separately, and so to provide a profile of candidate ability. This also allows for *noncompensatory* decision making where, for example, the candidate must score at least 4 out of 6 in each trait in order to earn a “pass.” This approach is required by the International Civil Aviation Organization (ICAO) for the six dimensions of English language communication in aeronautical radiotelephony, and so it is applied in aviation English tests such as ELPAC (see above). In this context, failing one trait means failing the entire test, and so the reliability of scoring each individual trait must be very high.

Future Directions

Investigations into raters and ratings are likely to continue in several areas. Research into the rating process is expected to draw increasingly on mixed method approaches to explain sources of score variance. A combination of qualitative and quantitative analyses is required to explain how particular aspects of method affect performance, how those performance differences are then reflected in ratings, and how method variables influence the basis for judgment (Winke et al., 2011). Thus it is not enough to show that there is a difference between raters with different characteristics; rather paradigms to explain the processes affecting rater behavior are now being sought. To some extent this means that it is advantageous to “get into the rater’s head,” but it also means that we want to understand raters’ decision making in the context of all the other test variables.

Another area where research is necessary is in the rating scales themselves. Although language testers have learned to “make do” with existing varieties of rating scales, there is a glaring discrepancy between rich language performances and the reductionism represented in rating scale descriptors. Various attempts have been made at alternative formats, such as detailed descriptors, decision trees, checklists, or descriptors with specific emphases (for a review, see Fulcher, Davidson & Kemp, 2011). However, in the majority of rating contexts, clear and unambiguous rating criteria remain an elusive goal.

Finally, automated scoring is gaining acceptance, for both speaking and writing tests, and particularly in large-scale testing contexts. Currently, automated scoring models are optimized to human ratings; that is, automated models are predictions of how a human would assign a rating. But one question concerns whether human ratings should be seen as the “gold standard” against which the machine should be compared. If human ratings and rating scales are fallible, as we have seen, then under what circumstances can the machine provide alternative, reliable measures? Since humans and machines are good at different things, it is necessary to

investigate how human rating and machine scoring can complement each other, or under what task or assessment criteria one might be better than the other.

Spoken Discourse

Anne Lazaraton

University of Minnesota, USA

Introduction

When second or foreign language (L2) learners take a speaking proficiency test, their scores are really the only outcome in which they are interested, especially in high stakes assessment contexts—where a sufficient score is necessary for university admission, citizenship, or employment. So it has been with language testers: the emphasis on test scores (or ratings, as they are likely to be in speaking assessment) leads to the primary concern about score as well as rater reliability—the degree to which a rater is consistent over time, across language samples, and with other raters. More recently, however, attention has shifted to issues of test validity, which considers the processes by which test scores lead to inferences about their meaning. This has become increasingly the case for L2 speaking tests, where investigation of the process of speaking assessment has become almost as important as questions about outcome scores. Two primary questions underlie the emphasis on test process: first, how can the language that one or more interactants produce in a speaking test be characterized? Second, how can careful analyses of that language lead to better testing practice, in terms of improvements to test design as well as to rating processes? To answer these questions, the analysis of spoken discourse has become a key strand of research in the language assessment community.

Background

First, a definition of discourse is in order. *Discourse* (from Latin *discursus*, meaning “to run about”) refers to the use of language in texts, which are “stretches of language [that] become meaningful and unified for their users” (Cutting, 2008, p. 2).

The Companion to Language Assessment, First Edition. Edited by Antony John Kunnan.

Generally speaking, discourse is understood as a spate of language that is more than just a word or even a sentence. Familiar examples of discourse texts include conversations, prepared speeches, e-mail messages, written summaries, and the like. With respect to spoken language assessment, the repetition of a word or phrase would not be considered an example of a discourse text; a 30-second spoken response to a test question would.

Discourse analysis is a systematic method for understanding oral (and written) language that is produced in a social context. There are a number of approaches to discourse analysis, each of which views discourse in a certain way: as a cultural practice (e.g., ethnography as it is practiced in anthropology); as individual, intention-based meaning (e.g., speech act analysis, as in linguistics and philosophy); and as the local construction of social order (conversation analysis, which traces its disciplinary roots to sociology), to name a few. Of these approaches to analyzing discourse, conversation analysis (CA) is seen as a particularly attractive option for looking at discourse in context as it is understood in second language teaching, second language acquisition, and second language assessment. Briefly, the conversation analyst attempts to understand “talk-in-interaction” and its structure as encoded in the organizational systems of turntaking (the ways that turns of talk are constructed and allotted), sequence structure (how actions such as requesting, complimenting, etc. are performed), overall structure (how conversations are opened and closed), and repair (the means by which problems of hearing and understanding are addressed). (Wong & Waring, 2010, provide an accessible introduction to this approach).

A more recent development in applied linguistics is critical discourse analysis (CDA), “an ideological approach that examines the purpose of language in the social context and reveals how discourse reflects and determines power structures” (Cutting, 2008, p. 3). CDA assumes a complex relationship between language production and social practice: that social practice must be viewed through the lens of power relationships (gender, race, class, etc.) and historical context; that research is always “interested” rather than objective; and that social change should be the goal of educational research. Although a more complete treatment of CDA and other disciplinary approaches to understanding discourse is beyond the scope of this chapter (but see Ellis & Barkhuizen, 2005, for a book-length treatment of different approaches to analyzing language) it is possible to describe the most important features of spoken discourse and its analysis as it is practiced in the larger applied linguistics community.

In general, discourse analysts make several assumptions about the data they work from. First, spoken discourse should be authentic in its context, meaning that it is naturally occurring and spontaneously produced. So, although the language produced in a speaking test may not be “naturally occurring” and “spontaneously produced” in the way that conversation is, it *is* authentic in the speaking text context. Data obtained from interviews, observations, intuitions, or in experimental settings are generally not preferred (Wong & Waring, 2010). Second, social context—the discourse setting as well as the demographic characteristics of the speaker or speakers—is understood as an important variable in understanding spoken interaction. We expect that language will be produced differently in informal chat and prepared speeches, and that the recipients of that talk will influence

the way it is produced as well. A prepared speech for a class of high school students will exhibit different discourse characteristics than one for a professional meeting of fellow researchers because the audiences are so different.

Third, for spoken discourse to be analyzed, it must be recorded and faithfully represented in written form, using one or more systems of transcription notation to represent features of speech, such as pausing, word stress, intonation, and whatever other aspects of talk the analyst is interested in. Transcription is a tedious, time-consuming activity, especially if one employs the conversation analytic system as set out by Atkinson and Heritage (1984).

Last, as a primarily qualitative research methodology, discourse analysts attempt to produce detailed descriptions of language phenomena as they are represented in the transcripts. In any reports that are written about the phenomena, the analyst will include the data segments on which the analysis is based. It is also worth noting that, unlike quantitative research methodologies, which entail numerical or statistical arguments based on large quantities of data, discourse analysts strive for rich, textual descriptions of a small number of examples—sometimes only one example! However, with respect to language assessment research, there is a trend towards larger numbers of discourse transcriptions that are then coded, categorized, counted, and statistically analyzed; it remains to be seen whether or not small sample size studies will be marginalized as a result.

The customary way to think about discourse is by distinguishing spoken discourse from written discourse. We know that spoken discourse tends to be more loosely organized, with simpler sentence structures and features of what has come to be known the spoken grammar of English (SGE; see McCarthy & Carter, 2006). For example, spoken English grammar includes elliptical structures such “I gotta go” and “I wanna go”—forms that would be seen as inappropriate, or even ungrammatical, in writing. Forms like *um*, *uh*, *sorta*, *y’know*, *well*, and *like*, which are known as hesitation markers (*um*, *uh*) or discourse markers (the others), do not occur in more formal varieties of writing even if they are omnipresent in spoken language. Written discourse, on the other hand, is likely to be more polished, more complex in its textual features, and (relatively) error free.

However, in the examples mentioned previously—an e-mail message and a prepared speech—these tendencies may be reversed: the written e-mail message may contain features of SGE, while the prepared speech would mirror the conventions of writing. For this reason, other dichotomous labels such as formal versus informal, planned versus unplanned (Ochs, 1979), and involved versus detached (Chafe, 1982) allow for a more precise description of a discourse text. As the nature of written discourse in relation to language assessment is covered in Chapter 82, Written Discourse, we will now confine our discussion to test discourse that is spoken.

Speaking Test Discourse

So what does the spoken discourse produced in a speaking test look like? One way to answer this question is to examine how test-taker speech is conceptualized in the rating scales designed for evaluating it. At a more micro level, ratings of test discourse tend to focus on the traditional linguistic skills, including

pronunciation, grammar, and vocabulary, sometimes separately and other times combined under a heading like “linguistic skills.” At higher levels, ratings of “fluency” in short turns (e.g., the placement and length of intra- and interturn silences) and in longer stretches of spoken language may be captured by categories such as “cohesion” or “coherence”—to assess how well test takers are able to maintain a smooth flow of speech and connect utterances in natural ways (by using connector words like *and* and *so*, hesitation markers like *um*, etc.). So, for example, the International English Language Testing System (IELTS, *n.d.*) factors in fluency and coherence, lexical resource, grammatical range and accuracy, and pronunciation to come up with a holistic speaking score on a 0–9-point scale. The Internet-based Test of English as a Foreign Language (TOEFL iBT) (TOEFL, *n.d.*) rating descriptors target delivery (fluency, pronunciation, and intelligibility), language use (grammar and vocabulary), and topic development (coherence, and for some tasks, task completion); iBT scores are reported holistically on a 0–30 scale, with an analytic description of test-taker skill in the three rating areas. Neither of these tests includes a rating of interactive communication—the ways in which test takers initiate turns, respond to questions, and use other communication strategies (although others do).

An essential distinction needs to be made between monologic discourse, which involves only one speaker, and interactive discourse, which is produced by two or more speakers who “co-construct” test talk. Co-construction is a fundamental feature of interactive discourse which is defined as “the joint creation of a form, interpretation, stance, action, activity, identity, institution, skill, ideology, emotion, or other culturally meaningful reality” (Jacoby & Ochs, 1995, p. 171). In the earlier days of modern language testing, speaking proficiency was primarily accomplished by audiorecording a single speaker responding to test questions, which would then be scored by trained raters afterwards. What came to be known as semi-direct tests of oral proficiency (or SOPIs) have been the focus of much language assessment research, often in comparison to the test performances that take place in interactive assessment contexts. The current iBT includes a computer-mediated (test takers speak to a computer), semi-direct test of speaking as one of the four major test sections (along with listening, reading, and writing). The SOPI format may be preferred for a number of reasons: it provides standardized administration, it allows for the convenient assessment of professionals in remote locations, and it is a cost-effective and efficient way to test large numbers of L2 speakers, as no interviewers are needed for real-time testing. However, the SOPI format does not allow for a co-constructed test performance, as there is no interlocutor with whom to engage (see Qian, 2009, for a more thorough treatment of the SOPI format). For this reason, interactive communication is not rated on the iBT.

In contrast, a direct, face-to-face speaking test is comprised of a test taker and one or more interlocutors who jointly produce test talk in real time. An interlocutor is a person with whom one speaks; all interviewers are also interlocutors, but it is not necessary that an interlocutor also be an interviewer, as in the case of a paired speaking test, where another test taker is considered the interlocutor. Both the American Council for Teaching Foreign Languages (ACTFL) Oral Proficiency Interview (OPI) (ACTFL, *n.d.*) and the speaking section of various Cambridge English for speakers of other languages (ESOL) tests (ESOL, *n.d.*) are face-to-face

interactions, involving an interviewer and one or more test takers. As will be discussed below, interactive speaking tests produce a different—some would say richer—variety of discourse than a SOPI does, but they also confound the rating of test discourse, because another person, namely the interlocutor, is implicated in constructing test talk. Obviously, these face-to-face interactions *do* allow for an evaluation of interactive communication and may be preferred for this reason.

With this background in mind, we now take a historical overview of spoken test discourse in language assessment as well as a survey of current thinking in the area.

Previous Considerations

Prior to the 1980s, not much was written about speaking test discourse, as there was an assumed (but untested) relationship between oral interviews and natural conversation (see Lazaraton, 2002, p. 13, for a sample of claims regarding their equivalence). However, in 1989 Leo van Lier published a seminal article that questioned this long-standing assumption. Specifically, he urged research that would shed light on the sort of “interactional event” an oral interview is by analyzing the test talk that is produced using discourse analysis. Such studies would uncover “the turn-by-turn sequential interaction in the interview” and how oral test discourse is structured (Lazaraton, 2008, p. 198). In this way, there would result a better understanding of the similarities and differences between test and nontest discourse—in other words, between a so-called conversation and an interview. In van Lier’s words, this research would help us “understand the OPI, find out how to allow a truly conversational expression of oral proficiency to take place, and reassess our entire ideology and practice regarding the design of rating scales and procedures” (van Lier, 1989, p. 505).

Similarly, Shohamy (1991) called for empirical research on speaking test discourse and the nature of the testing process itself. In her view, speaking tests like the OPI and Cambridge ESOL exams did elicit different types of spoken discourse (long turns, discussion, etc.), but research on the linguistic and discourse features of test talk was nonexistent. She claimed that an understanding of actual test discourse and the test process was critical for creating, using, and evaluating the rating scales that existed for speaking tests, which at the time were based on expert hypotheses about language rather than empirical study.

As a result of these calls for a new line of inquiry, Lazaraton (1991) conducted a conversation analysis on 20 English as a second language (ESL) course placement interviews at a US university in order to understand the nature of the interactional event (in van Lier’s terms) itself. In these interviews, potential students needed to make a case for why they deserved a spot in one of two different oral skills classes; the interviewers collected background information on the students using a written interview agenda (sometimes called a protocol or an interlocutor frame), while at the same time making rough judgments about their oral skills and thus their need for ESL coursework. Her findings suggested that the course placement interviews had an identifiable structure that mirrored the interview agenda, but one that was more like a traditional interview than a spontaneous

conversation, as had been the assumption in the language assessment community. She concluded that “the encounters share features with conversation, but they are still characteristically instances of interviews, and interviews of a distinctive kind, for the participants” (1991, p. 226).

Another early foundational study on spoken test discourse was reported by Ross (1992), who investigated the types of accommodations (the ways in which interviewers attempted to make their speech comprehensible to the test takers) that OPI interviewers in Japan engaged in, and what he termed the “antecedent triggers” of the accommodations. He found that interviewer speech modifications were related to test-taker answers (and their structure) to previous interviewer questions, as well as proficiency level of the test taker. Ross astutely observed that test-taker ratings should take into account the amount of interviewer accommodation that occurs; support for this claim has emerged from much subsequent research on interviewer behavior and the so-called interlocutor effect. That is, it has been shown that interviewers and other test takers with which a speaker engages in a speaking test—due to factors like language competence, rapport, and gender—may influence both the nature of language produced (in its accuracy, interactivity, and complexity) as well as scores assigned to speaking test performance.

Current Research and Conceptualizations

Research on oral test discourse over the last 15–20 years has focused on three broad areas: interviewer discourse, test-taker discourse, and the group oral. Each of these is now taken up in turn.

Interviewer Discourse

In a series of empirical studies commissioned by the University of Cambridge Local Examinations Syndicate (UCLES; the organization is now Cambridge ESOL), Lazaraton (2002) detailed specific features of interviewer speech she hypothesized might affect both the delivery and outcome of several “main suite” speaking tests, including the Certificate of Advanced English (CAE), the Preliminary English Test (PET), and the Key English Test (KET). She found that supplying vocabulary, completing or correcting test-taker responses, evaluating performance, and rephrasing questions were just some of the interviewer behaviors detected. Here is a fragment showing the interviewer drawing a conclusion that the candidate takes up:

CASE—Candidate 41, Examiner 2

IN: %oh. I see. % .hhh (.) and will you stay in the same (.) job?
 with the same company? in the future? (.) do you think?
 CA: hhh uh no:. .hhh hhh!
 IN: → you want to change again.
 CA: → yes? [I .hhh I want to change (.) again.
 IN: [hhh!

(from Lazaraton, 2002, p. 132)

Behaviors like these were seen as evidence that interviewer talk in these tests paralleled other interactions between native speakers and L2 learners, and was “authentic” in that sense. On the other hand, Lazaraton’s findings raised a red flag for Cambridge ESOL, if these interviewer speech modifications led to inconsistent test delivery. Over the years findings such as these were used to create and refine the interlocutor frame (the interview agenda) for the tests, as well as to train, standardize, and monitor oral examiners to ensure as consistent test delivery as possible, while still exploiting the authenticity of the face-to-face speaking test format.

Brown’s (2003) innovative research, working along the same lines in scrutinizing interviewer behavior, examined the discourse of two interviewers (one who was the most difficult and the other the easiest, based on statistical analyses) who acted as interlocutors with one test taker in two IELTS speaking tests. Her fine-grained discourse analysis pointed to the complexity of the interviewer–candidate–test score relationship; the discourse of the two interviewers differed in three main areas: the means by which they structured topical talk, their questioning technique, and their feedback and rapport strategies, all of which were difficult to separate from test-taker performance. Brown examined her data further by employing another qualitative research method, verbal protocol analysis, from which she determined that a “helpful” interviewer led to higher ratings, not necessarily because of a better performance, but because of the impressions about communicative effectiveness in this particular assessment context. As was suggested a decade earlier by Ross, this interlocutor effect may be one of the most crucial factors to take into account when discussing the validity of a speaking test and the discourse produced in it.

Test-Taker Discourse

An early foundational study by Shohamy (1994) examined test-taker discourse elicited from both a Hebrew SOPI and a face-to-face interview (the OPI)—at the time little was known about the similarities and differences in test-taker performance in the two modalities. She compared numerous language features in the SOPI and OPI, the former representing the “reporting-monolog” genre, and the latter, a “conversational interview.” Shohamy considered numerous features in her comparative analysis of the face-to-face OPI and the computer-mediated setup in a SOPI. Her analysis of OPI discourse data highlighted the use of various discourse strategies (deliberation, turntaking, clarification requests, and self-correction), prosodic features (intonation change, laughter, humming), and speech functions such as asking questions, exchanging information, agreeing and disagreeing, and sharing personal information. On the other hand, her SOPI discourse data reflected a more limited range of features, including paraphrasing, silence, hesitations, reporting, describing, and narrating. Notable statistical differences were found in the frequency of self-correction and paraphrase, which occurred significantly more often on the SOPI. According to Shohamy, the ongoing process of test validation is greatly enhanced by considering test data (such as hers) from multiple perspectives. That is, different tasks elicit different kinds of spoken interactions, which generate different sorts of discourse; test validation involves understanding

and characterizing the nature of this discourse in order to make claims about what has actually been tested.

In a related study, O'Loughlin (2001) examined a range of discourse features produced by test takers in a direct and semi-direct format of the **access**: test in Australia, which he characterized as "reporting/narrative monologs." A wide range of these features were analyzed, including register, speech moves, content, and topic of the discourse, as well as many others. O'Loughlin found that on monologic tasks the discourse produced in each format was "strongly similar," whereas in role-play tasks, differences were detected; in fact, "the less controlled live role play . . . appeared to have elicited language which more closely approximated to conversation than the other live tasks" (2001, p. 165). These findings are not consistent with Shohamy's, where differences in test format were detected across a number of discourse features.

Another approach to analyzing and/or evaluating the discourse produced in speaking tests, interactional functional analysis, is reported by O'Sullivan, Weir, and Saville (2002), who developed "observation checklists" for one of the Cambridge ESOL examinations (First Certificate of English, FCE). Drafts of checklists were generated by the researchers and employed by groups of English language teachers, testing experts, and teaching English as a second language (TESL) graduate students, who noted the frequency with which described speech functions occurred in sample test discourse. These functions included informational (e.g., summarizing, paraphrasing, stating an opinion), interactional (e.g., disagreeing, engaging in repair), and managing interaction (e.g., initiating, deciding, terminating). Based on feedback from the groups of (potential) test users, the checklist developers included fewer speech functions to tally and revised some of the remaining functions. The authors suggest that these instruments could eventually be used to validate operational speaking tests.

Other aspects of test-taker spoken discourse have received attention in the language assessment literature, including the proficiency level of the test taker (see the next section), the familiarity between the interviewer and the test taker, and first language conversational style (see, for example, many of the studies reported in Young & He, 1998). It may be that these variables are equally important in accounting for the discourse differences that have been noted. It is curious, though, that research on individual candidate discourse seemed to ebb in the 2000s, when the focus shifted to a relatively new speaking test format, what is known as the pair (or group) oral.

The Pair (Group) Oral

In recent years, a variation on the more traditional interviewer–test taker format has become popular: the group or pair oral, where test takers interact with each other for at least a portion of a speaking assessment. The pair format is appealing for a number of reasons: it mirrors pair and group classroom activities, thus lending itself to language-learning opportunities (this relates to the concept of washback); the power differential inherent in the interviewer–test taker encounter is alleviated or even eliminated when test takers talk with each other; and it is thought that the pair format allows for both a broader range of language functions

and task types to be deployed by test takers (see Taylor & Wigglesworth, 2009, on these points). When we consider that a second test taker in oral interviews is increasingly common, we also need to broaden our understanding of the “interlocutor effect” to include a peer as well.

Rather contradictory findings on this topic suggest that while test-taker proficiency level, gender, familiarity, and the like do influence the *discourse* produced with a partner, it is unclear if these variables impact outcome *scores* on the test. The effect of proficiency level on pair task discourse was the focus of Davis’s (2009) research on 20 first-year students in a Chinese university who represented relatively higher and relatively lower proficiency levels. Test takers engaged in two tasks in the classroom assessment, once with a partner with the same proficiency level and once with one at a different proficiency level, and were rated on grammar and vocabulary, pronunciation, fluency, and discourse management. His quantitative results indicated no significant difference in performance by proficiency level, although less proficient students produced more words when paired with a more proficient student. Using Galaczi’s (2008) framework of speaking test interaction patterns (see below), Davis’s qualitative analysis of interaction patterns in the paired tests indicated that most pairs engaged in a collaborative style, as evidenced by displays of mutual topic development. Although Davis cautions against drawing firm conclusions from the study, he claims that “it may not be unreasonable to think that interlocutor proficiency does not necessarily influence scores” (2009, p. 389). (See also Ildikó, 2009, who reports on a quantitative study of paired-task speaking test performance by over 100 test takers in Hungary).

A recent study by Luk (2010) reports on peer interaction in a school-based oral assessment in Hong Kong, using the concept of “impression management” to look at the test discourse. Eleven groups composed of four female students each discussed various characters that appeared in fiction books recommended by the school. The discussions were transcribed and, along with data from participant interviews and a questionnaire, analyzed to determine how each group managed the task. Specifically, Luk was interested in an individual’s desire to forge a positive impression with the assessor, and whether evidence of this desire could be located in the task discourse. The students utilized three “frames of talk” (task management, content delivery, and response) and engaged in other discourse practices; however, rather than interacting in the cooperative way that characterizes natural conversation, her participants seemed to be most concerned with presenting “the best possible impression of themselves as interlocutors in front of the teacher-assessor” (Luk, 2010, p. 49). Luk rightly points out that our desire to witness true interaction in test takers may be thwarted by their desire to put on the best possible performance.

Another intriguing study on the pair format in testing speaking is reported by Galaczi (2008), who used conversation analysis to study 30 dyads performing a collaborative task from the FCE examination. Her intent was not only to understand how the pairs interacted, but to provide empirical support for developing and validating speaking test rating scales. Three interaction management styles—collaborative, “parallel” (where test takers engaged in “solo” behavior), and asymmetrical, where a dominant–passive dynamic occurs—were evident. These findings were then used to compare interaction patterns with ratings on an

interactive communication (IC) subscale for the test. In this way she was able to suggest interactional behaviors that characterized the high and low ends of the IC rating scale. Galaczi concludes that “the relationship between CA findings and IC score data can be used to help inform the performance descriptors used for IC in the FCE speaking test marking scheme” (2008, p. 112). Furthermore, “the challenge will be to combine the proposed empirically derived descriptors with a theoretical definition of the construct and expert judgment and produce an assessment scale that covers all five bands [scoring levels]” (p. 113).

Finally, Brooks (2009) delved into test-taker performance in the traditional (individual) interview format as compared to the paired format. Scores and the discourse of eight pairs of test takers from a high stakes exit examination at a Canadian university were analyzed quantitatively and qualitatively; her inspection of test-taker spoken discourse in both the individual and the paired format led to the finding that the paired format allowed for a greater range of interactional resources to be displayed. The individual format was characterized by numerous interviewer questions, to which test takers then responded. On the other hand, in the pairs the test takers prompted elaborations from and finished sentences for their partners. Brooks notes that “in the paired format, test-takers demonstrated their facility in negotiating meaning and communicating with another language learner, co-constructing better, richer performances through their interaction” (2009, p. 361), thus lending additional support for the utility of the pair format in oral language assessment.

It is rewarding to know that while studies of spoken test discourse are interesting in and of themselves, there is also a practical application for research findings, including the development of interlocutor frames to guide the interview, information to inform the training, monitoring, and standardization of examiners, and, more broadly, to supply empirical data for investigating the validity, reliability, and fairness of these speaking tests.

Challenges

Despite the many encouraging findings about spoken discourse in oral language assessment, the testing of speaking is still a formidable undertaking, for both the testing organization and the researcher. With respect to the former, an important concern in oral skills testing is that the raters are trained, standardized, and then monitored regularly; raters and testing organizations want to ensure that both test delivery and rater evaluation produce scores that are valid, reliable, and fair. On a more basic level, the administration of face-to-face speaking tests can be a logistical nightmare without careful planning for assigning interviewers to individual test takers in pairs or groups, for coordinating test recordings with the assessment process, and for making sure that the recordings are checked for usability and then sent on to raters for the examination.

For researchers, it is very difficult to assess speaking in isolation from other skills, especially listening. The TOEFL iBT has taken a more holistic approach to oral language assessment by including four integrated speaking tasks on the test, where test takers listen and speak, or listen, read, and speak (the other two tasks

are independent, requiring only that the test taker respond to prompt). One of the disagreements among language assessment researchers is whether it is best to assess speaking as a skill in and of itself (with the understanding that aural comprehension is always involved), or in an integrated format, as much post-secondary academic study requires students to simultaneously engage in multiple skills.

A second problem that characterizes speaking test discourse is that there is no automatic record of the language produced; it must be captured in some way for raters to evaluate and researchers to analyze. Digital technologies have made recording spoken discourse much easier, but its written representation is still a slow and challenging task (but see Price, 2011). Research on spoken discourse produces voluminous amounts of transcribed data that are not usually quantitatively analyzed; finding an appropriate publication outlet was problematic in the early years of discourse analytic research on test talk. It has become easier in recent years as scholarly journals such as *Language Testing* and *Language Assessment Quarterly* now publish papers based on qualitative research, albeit with length limitations being a persistent concern.

Even if qualitative research is published in these journals, it is still an open question whether or not these sorts of analyses are taken seriously, as they do not allow for generalizable findings based on large amounts of data. In fact, it is unclear how qualitative, discourse analytic research is to be judged in the first place—what sorts of criteria should be applied to these findings? As Lazaraton (2008, p. 206) notes, “which criteria should be privileged—methodological rigor? Sociopolitical impact? Substantive contribution? Report accessibility?” At the present time, neither the broader applied linguistics nor the language assessment community has coalesced around straightforward answers to these questions.

Future Directions

In some ways, it is most exciting to look ahead to future trends in the analysis and assessment of spoken discourse. The most significant changes that I foresee entail the use of digital technologies. Not only can computer-assisted transcription analysis tools (see Price, 2011) aid those whose scholarship focuses on spoken test discourse, recent findings from corpus linguistics provide empirical evidence for claims about the frequency with which language features are used, how certain expressions co-occur with others, etc. These computer-based corpora (which are large collections of authentic spoken and written discourse) are particularly fruitful sources of information about lexicon and vocabulary use, features that figure prominently in speaking test rating scales. Taylor and Barker (2008) review a great deal of literature on language corpora and language assessment, concluding that “the application of corpora and corpus linguistics to the evaluation of L1 and L2 language proficiency is established and has a promising future” (p. 252). According to Luoma (2004, p. 27), “the most important point to remember from [her] detailed description of spoken language is the special nature of spoken grammar and spoken vocabulary” and their role in oral language assessment, an increased understanding of which has emerged from such corpus studies.

Additional technological advance can be seen in automated test scoring, such as the Educational Testing Service's SpeechRater™ system (Educational Testing Service, 2010), which is currently used to score responses to iBT practice speaking tests. It contains a trained speech recognizer, a feature computation model, and a scoring model that statistically predicts a score based on the computation model features. Nevertheless, a note of caution is sounded by Cumming (2008, p. 12), who points out that we need to be cognizant of the fact that "such technical advances may reduce, rather than enhance, assessments by replacing sophisticated human judgments with routine mechanical procedures."

Another area that deserves attention is the systematic development of speaking test rating scales. Fulcher and Davidson (2011, p. 5) favor a

performance data-driven approach . . . [that] places primary value upon observations of language performance, and attempts to describe performance in sufficient detail to generate descriptors that bear a direct relationship with the original observations of language use. Meaning is derived from the link between performance and description.

There already exists a great deal of speaking test performance data, with some notable attempts at matching data to scales and vice versa; Fulcher and Davidson's performance decision tree (PDT) suggests one way to move forward in this area. Briefly, a PDT represents a scoring model for a particular speaking test task by listing the competencies and skills that are needed for a successful performance of the task. A PDT looks like a flowchart with a series of yes–no questions that lead to the assignment of a particular test score; it can also be used to create rating descriptors for the task. Fulcher and Davidson argue that PDT descriptions of "interactional competence in context" focus on "observable action and performance, while attempting to relate actual performance to communicative competence" (2011, p. 23).

Formative, classroom assessment of spoken discourse has received only a fraction of the attention paid to large-scale, international language tests such as IELTS and the iBT (and the same can be said about self-assessment; see Cumming, 2008, on this point). Underhill's (1987) *Handbook of Oral Testing Techniques* remains a comprehensive source for teachers who want to understand, create, and use oral test types, elicitation techniques, marking systems, and test evaluation (although the chapter on "Assessing Speaking" in Brown and Abeywickrama, 2010, does contain a plethora of ideas for designing speaking test tasks then evaluating responses to them). Luoma (2004) believes that peer evaluation is one technique that deserves more attention in classroom assessment. Classroom speaking performances often include a peer assessment component; the challenge for the teacher is to decide how rating criteria are defined for the students. Luoma recommends that task criteria may be more appropriate and useful than linguistic criteria, and, in any case, that students be involved in these decisions. Given the superiority of face-to-face speaking assessment and the interactivity it entails, we need a better understanding of "discourse skills" as evaluated in classroom assessment and operationalized in rating scales. Luoma finds current descriptors "rather vague," subsuming many different subskills, based on assessor impression, rather

than empirical descriptions of what L2 learners can say and do. This is equally true for large-scale international speaking tests.

We now return to the questions posed at the outset of this chapter: How can the language that one or more interlocutors produce in a speaking test be characterized? How can careful analyses of that language lead to improved testing practice? This entry has highlighted some of the early and recent research on the nature of speaking test discourse, whether it is produced by an interviewer, a test taker, or test takers. However, capturing, representing, and analyzing test talk remains a difficult challenge, one that requires the language assessment community to endorse, if not adopt a range of approaches for investigating these issues. The continued, careful analysis of spoken test discourse—that of the interviewer and the candidate(s)—promises to provide empirical support for decisions about the most valid, reliable, and practical ways to assess L2 speaking skills in a particular context.

Written Discourse

Lia Plakans

University of Iowa, USA

Introduction

Language assessments have included written performance for a long time; however, writing initially served as a means to measure grammar or translation ability. In the last 50 years, writing in language tests has expanded in purpose and is used to make many more interpretations about language ability. This shift has been influenced by the fields of rhetoric as well as second language acquisition and education. This chapter will focus on research methods that investigate writing in assessment from linguistic and discourse perspectives, based on a “textual approach,” meaning that analysis is centered on the written text. The linguistic perspective focuses on issues such as grammatical accuracy or lexical and syntactic complexity, which relate to sentence level comprehension, as well as fluency. Discourse perspectives include organization, coherence, cohesion, and content; elements of writing that can impact the full length of a text.

There are other approaches to analyzing written discourse, including critical discourse analysis from the field of communication or systemic functional approaches from linguistics. These two perspectives on language and writing are quite different from each other philosophically, but both approach texts in terms of their impact on the readers and writers with attention to context. On the other hand, the textual approach is somewhat less attentive to contextualization or audience, which may make it more common in assessment research, as tests are often simulations of contexts and audiences, but not actually “real-world” communication. Interpretations based on imagined contexts and audiences are fallible since test takers are aware that their audience is the test evaluator with the purpose of measuring their language ability. Although they are not dealt with in the present chapter, research incorporating critical discourse analysis and systemic functional

linguistics into writing assessment research will be important areas for the field to explore.

In this chapter, linguistic analysis of written text will be presented first, followed by illustrative research. Then, approaches to analyzing the discourse of written text will be addressed, also with example studies. Last, potential areas of further discovery in written discourse in second language assessment will be discussed, leading into the conclusion of the chapter.

Linguistic Features

In second language acquisition (SLA), language development is frequently evaluated by “CAF,” which stands for complexity, accuracy, and fluency (Ellis, 2009; Housen & Kuiken, 2009). These landmarks of language ability have been applied in writing research, as well as speaking, to determine language proficiency and quantify language development. Given the close relation between SLA and language assessment, the areas of complexity, accuracy, and fluency have emerged in research on language assessment to investigate language performances. These features have been used to compare types of tasks and test-taker characteristics such as first language (e.g. Bae & Bachman, 2010). They allow researchers to scrutinize and build holistic, analytic, and primary-trait scoring rubrics as well as empirically based scales (Cumming et al., 2005; Knoch, 2009; Gebriel & Plakans, 2013). Given the visibility of CAF in the field, these features have been criticized and refined (Wolfe-Quintero, Inagaki, & Kim, 1998; Ortega, 2003; Norris & Ortega, 2009). These critiques have improved work in this area, by requiring researchers to consider interpretations of measures used to identify these features and to raise awareness of the missing “communicative” element in the features as markers of language ability. To discuss CAF, three areas will be reviewed: grammar and syntax in writing, lexical issues, and fluency.

Grammar and Syntax in Writing

Grammar has been a feature in research in language assessment for a long time; however, finding consistent and effective measures of grammatical accuracy has been problematic. The following approaches to grammatical accuracy (see Table 82.1) are commonly found in language-testing research, most of which can be quantified either as a total count or as a ratio.

Polio (1997) reviewed a number of these approaches for effectiveness and found that error-free T-units had higher rater reliability than holistic scoring, but it overlooked severity of different kinds of errors and only provided a very broad metric of accuracy. Error count and classification also had high reliability, but raters had some difficulty distinguishing the three types of errors (morphological, syntactic, and lexical/idiomatic) consistently. A challenge with research using error frequencies or ratios is in comparing differences across errors, for example, in a sentence, more possibilities exist for making morphological errors than syntactic errors, thus

Table 82.1 Accuracy measures

Error-free T-units/ error-free clauses	Writing is divided into the smallest grammatical units that can stand alone (T-units) or into clauses. Then the T-units without grammatical errors are counted.
Error counts	A piece of writing is marked for grammatical errors. Each individual error is counted to reach a total for the text.
Error classification	Similar to error counts, but the type of error is counted. For example, Bardovi-Harlig & Bofman (1989) distinguished morphological, syntactic, lexical/idiomatic errors.
Error severity	Errors in a text are marked and rated for how strongly they impact the meaning.
Holistic rating of grammatical accuracy	Each piece of writing is rated using a holistic scale. For example, Hamp-Lyons & Henning (1991) scored grammatical accuracy as: 1 = many severe errors, often affecting comprehensibility 2 = some errors but comprehensible to a reader 3 = few errors, and comprehensibility seldom obscured for a reader.

Table 82.2 Syntactic complexity measures

	<i>Interpretation</i>
Words per T-unit	Length of structures
Length of clause (word counts)	
Length of sentence (word counts)	
T-units per sentence	Coordination
Coordinate clauses per T-unit	
Clauses per T-unit	Embedding (subordination)
Dependent or independent clauses per clause	

Note. Most of these syntactic complexity measures are calculated as mean averages across a text.

the count may be higher, not because of the writer's low morphological ability, but because of the higher probability for this type of error. To overcome this, another approach has been taken, the use of a holistic scale (Cumming et al., 2005; Gebril & Plakans, 2013) and, like error-free T-units, it provides an overview of accuracy in a written text. However, this approach requires careful development or adoption of a scale appropriate to the writing task as well as diligent rater training and acceptable reliability estimates.

Related to grammar, research on written discourse often investigates syntactic complexity. Ortega (2003, p. 492) defined this aspect of writing as "the range of forms that surface in language production and the sophistication of such forms." Studies have compared complexity across score levels (Cumming et al., 2005; Gebril & Plakans, 2009) as well as tasks and languages. This feature of writing can be challenging because complexity in sentences exist in a number of ways. For this reason, research should use multiple measures to explore complexity and consider the implications of each measure carefully (Norris & Ortega, 2009). Table 82.2 shows several common metrics for this feature of writing.

Ortega (2003) synthesized the findings of 25 studies on syntactic complexity in second language (L2) English writing, and, in doing so, she makes a key point, not to equate complexity with “better” as complexity and other linguistic features are dependent on each other. For example, increased complexity may lead to a decrease in accuracy. The link between complexity and proficiency has been suggested to be nonlinear, particularly for subordination, as more proficient writers are more likely to have complex phrases rather than clauses, something not captured by the traditional measures (Ortega, 2003). In addition, research of grammar in written discourse needs to consider other conceptualizations of grammar, such as close ties to meaning and the lexicogrammatical approach, which recognizes the inseparability of vocabulary, semantics, pragmatics, and grammar (Purpura, 2004).

Lexical Issues: Diversity and Sophistication

Research involving lexical issues in writing assessment crosses into the vast area of vocabulary, which has a wide range of measures. Two features that have been most common in language assessment written discourse research have been diversity, having a sizable vocabulary, and sophistication, use of non-high frequency words (Laufer & Nation, 1995). Several approaches have been used to measure these aspects of lexical complexity, shown in Table 82.3.

While the word length measure is useful, it provides a very simplistic view of lexical sophistication. More nuanced approaches to this feature use word lists organized by frequencies or type (such as academic word lists) and compare these with the written text. Type/token ratios have been related to as fluency measures due to the impact of text length on this measure; a shorter essay might score higher because of the small denominator (total word count). An alternative that is gaining attention is mean segmental TTR, which calculates the TTR for each segment, then finds the mean average across segments in a piece of writing. Averages are still vulnerable to length, however, and thus Malvern and Richards (2000) proposed a new way to calculate this feature, which uses probability based on a sample from a text (about 100 words) to model lexical diversity as if a text were longer. This approach is appearing in studies to investigate lexical complexity in L2 writing and in language testing (Jarvis, 2002; Plakans & Gebril, 2012).

Fluency: Development and Flow

The third feature of CAF is fluency, which captures the length of a written text, usually using word count for a whole text or average word count across T-units

Table 82.3 Lexical complexity measures

Average word length	A basic measure that finds the average length of all the words in a text, with a longer word average indicating more sophistication
Type/token ratio (TTR)	The number of different words divided by the total number of words in a text. This measure is interpreted to show lexical diversity

or clauses. While on the surface, length seems superficial in measuring writing quality, researchers look at fluency as an indicator of development and flow. As a measure of development, it provides an indirect view on how much a writer can elaborate on a topic. Certainly, other measures can capture development as well, such as the number of points in an essay (Lewkowicz, 1994); however, fluency is the most common, perhaps because it is easy and objective to collect word counts. Flow, similar to automaticity, is a process-related aspect of writing in which the writer can write without frequent pauses. Since writing assessment is generally timed, length indirectly indicates the writer's ability to write with fluidity. Of the discourse features discussed thus far, complexity, accuracy, and fluency, this last feature has been most consistently indicative of writing proficiency or writing test score (Cumming et al., 2005); in other words, writers with higher proficiency produce longer responses and those with less proficiency write less.

While the features in this section are presented separately, an interesting proposal was made by Jarvis, Grant, and Bikowski (2003) in regard to studying linguistic features individually, "the quality of a written text may depend less on the use of individual linguistic features than on how these features are used in tandem" (p. 399). Therefore investigating these features working together rather than as a list of separate features is a direction for further research in language testing. This potential for interrelations has been explored using correlations (e.g., Yau, 1991); however, approaches such as factor analysis or structural equation modeling may provide more rigorous models of the relationships across these features.

Examples of Linguistic Features in Language Assessment Research

This section will present the details of example studies that included linguistic features in their investigation. These studies illustrate processes used to conduct written discourse research as well as research questions explored using these features.

Linguistic features in language-testing research are frequently applied to investigate variation in writing at different score levels or by writers with different proficiency levels. These studies ask questions about how complexity, accuracy, and fluency differ in performances across ability levels or if scores can be interpreted to indicate an ability to use these language features successfully. Another common use is to compare performances on two types of writing tasks, asking questions about how tasks elicit different linguistic features. A study by Cumming et al. (2005) is a worthy example of research combining both of these areas. The researchers investigated 216 compositions written for three prototype tasks developed for the Internet-based Test of English as a Foreign Language (iBT TOEFL). The three tasks included an independent writing task, an integrated reading-writing task, and an integrated listening-writing task; the performances on these tasks were scored at three levels: 3, 4, and 5. The analysis included the linguistic features of text length (total word count), lexical sophistication (average word length and TTR), syntactic complexity (number of clauses per T-unit and words per T-unit), grammatical accuracy (holistic scale), and several features focused on rhetorical structure and source use.

To conduct the analysis, the first step was to try out the marking of the selected features in 10 practice compositions, followed by marking 24 more compositions to establish inter-rater reliability. Some of these features can be calculated automatically, such as word count, others require rating, which, in most cases, first entails segmenting the compositions into T-units. Once the procedures were determined feasible and rater reliability was acceptable, all compositions were marked for T-units and the features of interest. The researchers used a nonparametric multivariate analysis of variance (NPMANOVA) to compare length, sophistication, complexity, and accuracy across the three score levels, and across the three task types as well as to explore an interaction between score level and task type. The results showed significant differences for fluency across score levels and tasks as well as for interaction between these two variables. Lexical sophistication measures and syntactic complexity measures were significantly different across score and task type, but not in interaction. Grammatical accuracy was only significant across score levels. Their results discuss the nuances of these differences, which are not covered in this summary, but can be found in their article.

Published research on the investigation of linguistic features in second/foreign languages other than English are emerging and will answer interesting questions, such as what is complex or sophisticated in different languages. A recent study by Bae and Bachman (2010) addressed features of length, grammar, spelling, and content by investigating the influence of these traits across two languages, Korean and English, and between two tasks, letter writing and storytelling. To measure these features, text length in English was the total number of words, however, this metric does not translate directly into Korean. The authors point out that spacing in English indicates separation of one word, but in Korean it may indicate more than one word, which makes the interpretation of spaces nonparallel. They decided that, despite this complication, if they were consistent in counting spaces in the Korean texts, the measure would still indicate length in a meaningful way. This thinking represents the future discussions needed in written discourse research to establish metrics appropriate to non-English and non-Latin languages.

In the study, grammar was measured as error count, including a distinction between critical and minor errors to account for severity. The writing examined was composed by elementary school-aged children (8–10 years old), and included 317 Korean texts and 268 English texts. The authors used a four-point “common scale” to rate each of the four features. This study employed confirmatory factor analysis (CFA) to test hypothetical models of a construct of writing ability in English and Korean. The results indicated statistical significance for a construct of writing ability that has a single higher order trait factor with a peripheral influence of task type for writing in English and for writing in Korean. In other words, the four features studied, while distinct from each other, all contribute to an overarching model of writing ability. This study points to the dilemmas of using the common metrics for linguistic complexity, accuracy, and fluency, which have been developed mostly with English as a second language (ESL) and English as a foreign language (EFL) writing research.

Both of these studies show the use of linguistic features to provide evidence for the construct of writing and the interpretation of scores from writing tests, serving the purpose of validation.

Discourse Features

The influence of the field of rhetoric and composition on writing assessment has led to performances being judged for features that capture connections across sentences and through the whole written text, such as organization, content, coherence, or cohesion. These features commonly appear in rating rubrics used in L2 writing assessment, but have not been as common in research as the aforementioned CAF. This absence may be attributed to the subjectivity in defining these features, for example, coherence is closely related to reader interpretation and thus not objectively evident in a piece of text. In addition, but related to the reader-based functions of organization, these features differ across languages. Kaplan's (1966) contrastive rhetoric theory raised the issue of cultural differences in patterns of logical discourse, and while his original proposal has been problematized (Casanave, 2003), it articulates the dramatic variation in discourse traditions across languages.

Organization

Organization is the basic structure of a written text. Usually organization is included as a category of analytic writing scales used to score assessments, and such scales are commonly adopted for use in research. These rubrics will often include issues such as having a clear introduction and conclusion, inclusion of a thesis statement, or flow of ideas. The following is a sample descriptor from the ESL Composition Profile (Jacobs, Zinkgraf, Wormuth, Hartfiel, & Hughey, 1981), which has had great popularity in both writing research and teaching:

Good to average organization: somewhat choppy, loosely organized but main ideas stand out, limited support, logical but incomplete sequencing. (p. 30)

Such kinds of scales allow for measurement of organization quality, however, research also looks at type of organization patterns or genre. These studies answer questions regarding how different tasks affect organization or writers' ability to use certain genres. In the study mentioned previously, Plakans and Gebril (2012) developed a coding scheme to capture the different organizational patterns in a comparative summary from the TOEFL iBT. To create the scheme they used a taxonomy developed in a prior study of first language (L1) reading–writing tasks (Kantz, 1990) and piloted it with a sample of 20 compositions from the 480 used in their study. During the piloting, raters could add categories and note changes needed to Kantz's framework. Using this process, a coding scheme was created that was appropriate to the specific task in the study (see Table 82.4).

Coherence

A discourse feature that is closely aligned with organization is coherence, which is defined as the logical structure of a text (Grabe & Kaplan, 1996). Coherence is challenging to study as it is a highly reader-based construct, thus not easily identifiable in a written text. However, there are some approaches used to judge

Table 82.4 Coding for organization patterns (Plakans & Gebрил, 2012)

<i>Category</i>	<i>Description</i>
1. Balanced summarizing	States selected ideas from source texts taken somewhat equally from both sources
2. Summary—mostly reading text	Summarizing the gist of the source texts, mostly from the reading
3. Summary—mostly listening	Summarizing the gist of the source texts, mostly from the listening
4. Review and comment	Combines a summary of material from the source text with commentary or additions by the writer (beyond an introductory or concluding sentence)
5. Free response to the topic	Discusses the topic with little reference to information from the source texts

coherence in written discourse (Grabe & Kaplan, 1996). First of all, evidence of a clearly defined topic in a text is a sign of coherence, but, in assessment, the prompt usually dictates the topic. Coherence can be found in subordination of ideas, sentences, and clauses as this reveals relationships between ideas in a text. Last, coherence is found when the text leads the reader through a sequential progression of ideas, such as cause and effect. This last approach clearly overlaps with the concept of organizational pattern or genre. A study of classroom assessment of writing by Watson Todd, Thienpermool, and Keyuravong (2004) used an approach to analyze coherence called “topic-based analysis” which first marks key ideas in a text, then articulates the relationships across them creating a hierarchy. The written texts are then mapped to the hierarchical framework to capture measures of coherence such as topic shifts or breaks in coherent flow. Since such mapping is highly time intensive, studies of coherence often use scales. For example, Knoch (2007) conducted a study that investigated a coherence scale that operationalized topic structure analysis (TSA), which looks at the topic of each sentence as well as its contribution to the overall theme of the text. Her results indicated that the scale led to rater consistency and allowed for meaningful differentiations across proficiency scores.

Cohesion

Cohesion is closely linked to coherence, and has been defined as grammatical and lexical links across phrases and sentences (Grabe and Kaplan, 1996). A widely attributed system for classifying cohesion originated with Halliday and Hasan (1976) which provided five types of cohesive ties used in discourse: reference, substitution, ellipsis, conjunction, and lexical ties. Reid (1992) focused on four features in studying cohesion in L2 writing, which overlap with Halliday and Hasan, but are operationalized for analysis. She used percentages of the following features in texts: pronouns, conjunctions, subordinate conjunctions, openers, prepositions. Hinkel (2001) used a similar list with a few additions and finer distinctions within features: phrase-level connectors, sentence transitions, logical or

semantic conjunctions, demonstrative pronouns, enumerative nouns, and resultative nouns. While few studies look at cohesion in writing assessment, it is usually included in research questions investigating coherence and organization to distinguish proficiency or score levels or to compare task types.

Given that cohesion is often identified as nouns, connectors, or repeated structures, computer programs can be written to find and count these features in writing. Coh-Metrix (McNamara, Louwerse, & Graesser, 2002) is a program developed in the Department of Psychology at the University of Memphis based on cohesion markers related to flow in text processing models, and has been used to investigate questions in L2 reading and writing (Crossely & McNamara, 2009). The program searches text for over 100 features that mark coherence, cohesion, and some other features such as word count. Having this quantitative advantage may increase attention to cohesion and coherence in future research on writing assessment.

Content/Development

Development is a feature of written texts that describes the depth and quality of coverage on a topic. As mentioned previously, development is sometimes inferred by fluency (word count), but also requires content analysis. For example, researchers have investigated content as number of points made in an essay (Lewkowicz, 1994) and as argument structure (Watanabe, 2001; Cumming et al., 2005). Finding points in an essay requires raters to read and mark topic shifts, then total them. Argument structure entails a framework of argumentation and a rating scale using this framework that evaluates the qualities of a text. Cumming et al. (2005) compared different types of writing tasks and test score levels for the following argument structures: claims, data, warrants, propositions, oppositions, and responses to opposition, finding significant differences with most of these variables. As interest increases for writing assessment that includes input texts, such as reading passages or short lectures, research into development should include investigation of the use of these source texts in the writing. A few studies have looked at the style of source integration by categorizing T-units that include sources as paraphrases, summary, or quotations (Watanabe, 2001; Cumming et al., 2005; Gebril & Plakans, 2009). Research has also begun to look at the nuances of source text use. For example, Basham, Ray, and Whalley (1993) considered writers' orientation to texts in a reading-writing task. They compared this aspect of development across three cultural groups in the USA: Latino, Asian American, and Alaskan Native. As with the other nonlinguistic features of writing, development/content is a common descriptor in rating scales used to judge writing holistically or analytically; however, the research based in language testing has only lightly touched on this feature of written texts.

Example of Discourse Features in Language Assessment Research

A study by di Gennaro (2009) compared performances by two groups of writers often found in composition courses in US colleges and universities, international students, who have just come for tertiary studies, and Generation 1.5 students,

who were born outside the USA but completed their secondary education there. These two groups are often placed in the same ESL writing classes; however, their needs have been described as different. The purpose of the study was to verify these claims by analyzing writing for five features: grammatical, rhetorical, cohesive, sociolinguistic, and content control. Di Gennaro used rating scales and three raters to evaluate the quality of grammar, cohesion, pragmatics, and content control. With these ratings she conducted a Rasch analysis to compare the two groups, finding that Generation 1.5 writers had more rhetorical control and international students were better with sociolinguistic issues, such as register. Differences were not found between the two groups for grammar, cohesion, or content. These findings discount the hypothesis that the two groups are different in grammatical control or ability to develop ideas; however, in comparing the features with each other, grammar was found to be more difficult than rhetorical issues for the Generation 1.5 students, while the opposite was true for international students. This weighting aligns with beliefs about the divergent needs of these two groups of students.

Future Directions

Research on written discourse in language testing should continue to address questions regarding linguistic features, while concurrently exploring the more subjective discourse features in texts. Along with these suggested avenues for research, studies should consider aspects of text that capture the communicative nature of language. The interactivity of writing deserves attention as it belongs in the underlying construct being measured by writing assessment. Several approaches may lead us closer to this goal. One is the issue of voice in writing, which can be defined in a number of ways, but essentially is the author's positioning of him- or herself in writing. Research by Zhao and Llosa (2008) examined this challenging writing feature in a study of L1 writing. They developed a rating scale for voice, based on previous scholarship. The analytic scale included: assertiveness, self-identification, reiteration of central point, and authorial presence. Analyzing 42 essays, the researchers correlated the analytic scale components with a holistic score on the writing, finding all aspects of voice had positive correlations with writing score, but that "reiteration of central point" was the only aspect that significantly predicted score. Intertwined with the concept of interaction and writer's voice is audience. Hyland (2005), in his book *Metadiscourse*, defines the concept of dynamic interaction in texts as constructed by intentions of the author to guide the reader. This guidance is revealed by *metadiscourse*. While a very complex concept, one approach to thinking of metadiscourse is captured in textual expressions referring to "the text producer, the imagined receiver, and the evolving text itself" (Hyland, 2005, p. 14). Although, as Hyland points out, "The notion of audience, however, is notoriously elusive" (p. 12), audience has been largely absent from language-testing research, and deserves further consideration. New approaches to analyzing written discourse, such as investigating voice and metadiscourse, will deepen our understanding of writing assessment or assessment that include writing performance. However, as with linguistic features such

as complexity or discourse features like organizational patterns, the roles of readers and writers in written discourse can be culturally varied, which should thus be considered in writing across languages.

Conclusion

The features discussed in this chapter have been used to explore many research questions about writing in language assessment. Much of this research can be characterized as validation evidence as studies delve into issues related to score interpretation and task selection. Language proficiency levels or test scores have been compared using these written discourse features. These studies seek to characterize levels of written performance and to distinguish high and low performances. Related to this research are studies that look closely at rubrics used to assess writing and if such scales reflect these writing features. Other research questions focus on test tasks to see if variation appears in writing performances. A few studies have also compared different groups of writers, for example those with different first languages, to see if their second language writing differs, with implications for language transfer as well as testing bias. As mentioned in the section on future directions, research questions need to be asked regarding interaction in writing, which embrace its communicative nature. Last, the English language has held dominance in the second language written discourse research and many questions about written discourse in assessment of other languages deserve exploration.

Mixed Methods Research

Carolyn E. Turner

McGill University, Canada

Introduction and Definition

Since the early 1990s, mixed methods research (MMR) has evolved into the third research paradigm alongside quantitatively oriented inquiry (numeric data) and qualitatively oriented inquiry (narrative data). MMR is interested in both quantitative and qualitative analyses and primarily works from a pragmatic stance to use “what works” best in order to answer research questions. The research question, rather than a preconceived paradigm (e.g., post-positivist, positivist, constructivist), is central and drives the choice of design. The interest in and practice of MMR have emerged rapidly and spread across many domains in the social and behavioral sciences including that of language testing/assessment (LT). Within this context the movement has more recently been called “the third research community” (Teddlie & Tashakkori, 2009).

The evidence of the addition of MMR to the repertoire of inquiry is abundant: the birth of the interdisciplinary *Journal of Mixed Methods Research* in 2007 (original co-editors, Tashakkori & Creswell, 2007); the annual Mixed Methods Conference; the increasing quantity of books focusing specifically on MMR; the number of journal articles specifying their MMR framework; the addition of special interest groups to educational conferences (e.g., the American Educational Research Association [AERA]); and the increasing number of university graduate level courses devoted to MMR. Due to this evolution, the focus since the early 2000s has moved away from questions concerning MMR’s legitimacy as a developing approach to questions and debates on the issues that come with any new entity of inquiry: definitions, conceptualization, nomenclature, rationale, teaching, research design models, and the process of conducting research. To add to these issues Tashakkori (2009) stresses the fact that the research community is a diverse group of scholars across disciplines and countries “who share certain assumptions and eclectic

modes of practice,” but despite what brings them together, these different backgrounds and perspectives also bring disagreements and challenges on formalizing and structuring the new paradigm.

Most importantly, however, it is useful to articulate and understand the basic premise of what brings the third research community together. The common ground lies in the “rejection of the dichotomy between the qualitative/quantitative approaches” (Tashakkori & Teddlie, 2010a), generally referred to as the incompatibility thesis. MMR is viewed as research in which “the investigator collects and analyzes data, integrates the findings and draws inferences using both qualitative and quantitative approaches or methods in a single study or program of inquiry” (Tashakkori & Creswell, 2007, p. 4). There is acknowledgment that the values of the researcher play an important role in the interpretation of results (Tashakkori & Teddlie, 2003; Greene, 2007). MMR does not claim to be the superior approach by any means. Johnson and Onwuegbuzie (2004) in their seminal article, “Mixed Methods Research: A Research Paradigm Whose Time Has Come,” advise researchers to focus on the research questions and to use the “contingency theory” when deciding upon the research approach to use. The claim is that the three paradigms (quantitative, qualitative, mixed methods [MM]) “are all superior under different circumstances.”

Within the above context, this chapter will discuss MMR as it has developed in general and as it has manifested itself within the LT research community. The chapter will first situate MMR from a historical perspective and, second, discuss to what extent the field of LT has followed the same trajectory. Third, MMR conventions and considerations will be described, and fourth, there will be a discussion of the ongoing issues and challenges in the use of MMR designs across the social and behavioral sciences, and to what extent this is reflected in LT research and has implications for future direction.

Historical Perspectives in the Social Sciences

Before exemplifying how the third paradigm of MMR is manifested in the LT literature, it is important to situate MMR in its historical context alongside the two other paradigms of qualitative and quantitative research.

Creswell and Plano Clark (2011) describe the development and evolution of MMR across four overlapping periods: formative period (1950s to 1980s); paradigm debate period (1970s and 1980s); procedural and development period (late 1980s to early 2000s); and advocacy and expansion period (recent years). The formative period is the time of the early antecedents of MM (e.g., the mixing of methods within quantitative studies as well as within qualitative studies; the beginning of triangulation across the two established paradigms, particularly in evaluation studies and sociology, such as the use of surveys, observation, and interviews; and the concept of including diverse perspectives, particularly in psychology). The paradigm debate period is when arguments concerning the “incompatibility thesis” mentioned in the previous section came to a height. Certain scholars argued that quantitative and qualitative approaches to research could not be combined because of the differences in philosophical foundations

and stances (the nature of reality), inquiry logics, guidelines for practice, and sociopolitical commitments (the role of values) (Greene, 2007). These debates are still present among some scholars, but the advancing current discussion concerning MMR and its legitimacy and practice have taken the focus elsewhere, leading to the two final periods: the procedural and development period and the current advocacy and expansion period, which will be elaborated on below within the context of publications that have documented well the evolving third paradigm of MMR.

As Creswell and Plano Clark (2011) have summarized, it is evident from the literature that the combining of different research methodologies has taken place, been discussed, and been reflected upon since at least the early 1980s. It is mainly since the early 1990s, however, that MMR has emerged as a third paradigm, and has actually done so at a rapid pace. This is well demonstrated in various formats and venues as mentioned above, but the publication of sequential books by the same sets of authors in a short period of time has been a significant indicator of the dramatic development in this area (see, e.g., Creswell & Plano Clark, 2007, 2011; Tashakkori & Teddlie, 1998; Teddlie & Tashakkori, 2009). In conjunction with these developments, there has been a precipitously growing body of literature across disciplines in the social and behavioral sciences. A sampling of this literature by numerous researchers has been pulled together and represented in two major handbooks: *Handbook of Mixed Methods in Social and Behavioral Research* (Tashakkori & Teddlie, 2003) and *Sage Handbook of Mixed Methods in Social and Behavioral Research* (Tashakkori & Teddlie, 2010b). The differences between the content of these handbooks reveal the rapid evolution of MMR in only seven years.

The purpose of the first *Handbook* published in 2003 was to bring together authors writing on the topic and to help justify, and establish a more solid base with principles for, what was being called at that time, "the third methodological movement." The aim was to legitimize it as a viable alternative to quantitative and qualitative approaches. Six principles emerged from the discussion: (1) MMR was not just the fusion of quantitatively and qualitatively oriented inquiry, but instead a unique procedure which used MM in a way that had "complementary strengths and nonoverlapping weaknesses" (first discussed in Brewer & Hunter, 1989); (2) mixing may occur at any stage of a study; (3) research design determines data collection procedures in MM but is also independent of those procedures; (4) data collection procedures are independent of data analysis techniques (e.g., data collected in one way may be analyzed both qualitatively and quantitatively, and data may be transformed); (5) if the data do not represent the theoretical phenomena or the attributes under study, then the research design is irrelevant (i.e., data quality is paramount); and (6) data quality is a necessary, but not sufficient condition for inference quality (Tashakkori & Teddlie, 2003, p. 696). The content of the second *Handbook* published in 2010 is distinctively different. Although the same authors felt "diversity of ideas" was a major strength of MMR and that much progress had been made on nomenclature and methodology, they were concerned the field might be approaching a point of entropy (Tashakkori & Teddlie, 2010a, p. 272). In other words, because of the growing pains of MMR, the authors felt it was time to articulate and synthesize the

diverse ideas that were identified with this emerging third paradigm and at the same time recognize and address the critiques. These same sentiments were being echoed elsewhere (e.g., Mertens, 2010; Creswell & Plano Clark, 2011) and the consensus was unfolding that any definition of MMR would need to recognize diverse viewpoints, but at the same time include a list of common core characteristics (e.g., methodological eclecticism, paradigm pluralism, mixing being able to take place at any level/stage of the study, emphasis on continua rather than a set of dichotomies) (see Tashakkori & Teddlie, 2010a, p. 273, for an expansion of this list). This represents the common stance at the time of writing this chapter.

The Use of MMR in Relation to LT Research

In most ways the evolution in LT parallels the general trajectory of MMR in the social and behavioral sciences. With continuing issues in the field of LT, some researchers look to the third paradigm to address their questions. There is growing awareness that by combining information from different sources, results (whether convergent or divergent) can often provide valuable insight into and deeper understanding of complex phenomena under study. We see such ongoing issues in the areas of validity and instrument development, classroom-based assessment, large-scale assessments, construct definition, and rater effects, to name only a few. Therefore, true to its theoretical foundations, MMR is evolving in the LT community because of its philosophical orientation, most often associated with pragmatism.

There are differences, however, in the trajectory of MMR in LT as compared to some other areas in the social and behavioral sciences. One of the main differences is that there is no specific body of LT literature that concentrates on MMR development or its impact on LT research such as is found in other fields (e.g., in nursing, Twinn, 2003). Also, with the exception of Kim (2007), there have been no attempts to consolidate MMR studies in LT in any publication or conference presentation. In order to identify such studies, one learns by browsing LT studies over the years. One can note the gradual increasing evidence of research employing both qualitative and quantitative approaches, but specific articulation of employing an MMR design is still rare. Therefore when doing a database search, locating such studies is challenging in that the term *mixed methods* is relatively recent and in addition is little used to date in the LT literature. In order to limit the search, journals salient in LT can be perused (e.g., *Assessing Writing*, *Language Assessment Quarterly*, and *Language Testing*). To determine whether a study is using MM, however, one must often look very closely at the article content, because such methodology is rarely articulated in the title.

Table 83.1 provides a few examples of mixed method-oriented articles and places them in a list of categories in terms of how they were identified. Such an exercise may or may not be useful on a large scale, but since MMR has recently emerged as the third research paradigm, some awareness may initially be informative in order to locate such articles. Elsewhere, Kim (2007) begins to discuss MMR in LT with sample studies, and other fields related to LT have made similar

Table 83.1 Categories identifying MMR in LT studies

<i>Category description</i>	<i>LT study examples</i>
No mention of MMR, but the use of mixing methods becomes apparent in results section	Clapham, 1996; Brown, 2003
No mention of MMR, but the use of mixing methods is indicated by such phrases as “combining research types” or “employing both qualitative and quantitative data and/or data analyses”	Lynch, 1992; Phakiti, 2003; Uiterwijk & Vallen, 2005
No mention of MMR, but inferred in methods section through instrument description and interpreted in discussion	Ekkens & Winke, 2009; Kiddle & Kormos, 2011
Some specific mention of MMR components in methods section	Turner, 2009; Barkaoui, 2010; Plakans & Gebriel, 2012
Overt specific reference to and description of MMR designs	Kim, 2009; Neumann, 2010; Tan, 2011; Zhang, 2011; Baker, 2012

small-scale attempts (e.g., Hashemi, 2012, in the general area of applied linguistics; Jang & Quinn, 2006, in second language [L2] acquisition).

The categories in Table 83.1 emerged as journal articles focusing on LT were identified as using both qualitative and quantitative approaches. Most often, however, especially in studies up to approximately 2003, there is rarely specific mention or discussion of the term MMR in the method sections of studies, but instead the concept that research approaches were combined emerges in the results section where both qualitative and quantitative data are reported and interpreted (e.g., Clapham, 1996, in a study of the effects of background knowledge on reading comprehension in test performance; Brown, 2003, in a study on interviewer variation and the co-construction of speaking proficiency). At other times, an indirect reference to MMR may be made in the methods section, such as “combining research types” or “employing both qualitative and quantitative data and/or data analyses” (e.g., Lynch, 1992, where a reading in English program for science and technology was evaluated; Phakiti, 2003, where the relationship of cognitive and metacognitive strategy use on an English as a foreign language [EFL] reading achievement test was examined; Uiterwijk & Vallen, 2005, where linguistic sources of item bias for second generation immigrants in Dutch tests were studied). In some articles even more recently, one can only infer MMR use in the methods section and must sometimes read all the way through the discussion section to identify whether MM were used (e.g., Ekkens & Winke, 2009, where data included a standardized assessment and learning journals when evaluating workplace language programs; Kiddle & Kormos, 2011, where test scores and questionnaires were used when looking at the effects of mode of response across semidirect and face-to-face versions of a speaking test). On the other hand, in further recent articles, we see some specific mention of MMR components in study methods sections (e.g., Turner, 2009, in a study examining washback in exams at the secondary level and the teacher effect; Barkaoui, 2010, in a study on English as a second language [ESL] essay raters’ evaluation criteria in relation to

experience; Plakans & Gebril, 2012, in an investigation of source use in a reading–writing test task). So we do see evidence of MMR studies in LT research as in the general area of the social and behavioral sciences, but the challenge is to find them, because of the terminology used and sometimes a lack of transparency in the research design. Therefore, as discussed above, a search in databases using MMR and LT as key words will not yield the actual number of LT studies employing the third paradigm approach.

A possible contributing factor to this is that salient journals in the LT field (i.e., *Assessing Writing*, *Language Assessment Quarterly*, and *Language Testing*) in their manuscript submission guidelines do not use the vocabulary of “mixed methods” research. They typically welcome manuscripts using “diverse methodologies,” if the matter is referred to at all. At the time of writing, the three journals included the following guidelines to authors on their Web sites:

- *Assessing Writing* (2012): “The scope of the journal is wide, and embraces all work in the field at all age levels, in large-scale (international, national and state) as well as classroom, educational and non-educational institutional contexts, writing and programme evaluation, writing and critical literacy, and the role of technology in the assessment of writing.”
- *Language Assessment Quarterly* (2012): “LAQ encourages novel ways of thinking about emerging issues (conceptual, empirical, clinical, historical, or methodological) and the use of varying research methodologies (quantitative, qualitative, or ethnographic) and narrative styles (research articles, essay reviews, interviews, and practitioner perspectives).”
- *Language Testing* (2012): “Research articles, whether quantitative or qualitative in approach, should be based on new data collected and analysed in a rigorous and well-designed investigation.”

An exception to the above (i.e., articles containing an overt specific reference to and description of MMR) can be found in the literature from the recent generation of scholars who are writing theses at the MA and PhD levels and have chosen to carry out MM studies. Increasingly this population is specifically elaborating MMR rationale and designs. This practice carries over into conference presentations and publications (e.g., Kim, 2009, investigating native and non-native teachers’ judgments of oral English performance; Neumann, 2010, exploring teacher assessment of grammatical ability in L2 academic writing; Tan, 2011, identifying mathematics and science secondary teachers’ beliefs and practices regarding the teaching of language in content learning in Malaysian schools; Zhang, 2011, examining the effects of raters’ language background on oral performance on China’s College English Test-Spoken English Test [CET-SET]; Baker, 2012, examining individual differences in rater decision-making style). This is the fifth category in Table 83.1.

As an added note, consciousness-raising of the benefits of combining both approaches in certain contexts can be found in the form of “calls” or suggestions by those who influence LT research (e.g., Messick, 1989; Cumming, 2004; Bachman, 2007a, 2007b; to name only a few). They encourage diverse methodologies to enhance the relevance and significance of LT inquiry.

Conventions and Considerations in Practice

The above provides evidence that MMR-oriented studies are gradually permeating LT research. The more current studies that specifically describe their use of MMR have appeared as alternative and sometimes innovative methodological approaches. With this transparency comes the awareness of the conventions being established in the MMR paradigm. These conventions bring with them distinct nomenclature, research design families (classifications) with notation, ways to conduct quality research, the responsibility and role of teaching/training future scholars, and alternatives in writing/reporting MMR. There are increasingly useful resources that provide detailed explanations on these conventions. Two very informative texts for new and old researchers alike are Creswell and Plano Clark (2011), *Designing and Conducting Mixed Methods Research*, and Teddlie and Tashakkori (2009), *Foundations of Mixed Methods Research*.

Given the large scope of emerging conventions, the discussion here will be limited to the importance of identifying a research design family and the creation of an accompanying procedural visual diagram. These are two practices unique to MMR. Because of the nature of each study and the fact that qualitative and quantitative approaches are employed and invariably mixed at different points, a research design can be complex. Identifying the type of design based on the research questions and then providing a procedural visual (similar to a road map) can enhance the clarity of the methodology to the audience, and in addition, help guide the researcher, research team, or both. Because an MMR study normally contains at least two phases, research designs need to be fluid. For example, if the design contains sequential phases, the results from one phase may affect the subsequent phase, which in turn may affect the original design. In addition, each MM study is unique, with unique research questions and context. Therefore there is not a finite number of research designs, but instead “families” or typologies. There is variation in the MMR literature on the specific names for prototype designs, but the overlap is abundant and the concepts are the same.

For this chapter, the six major families of MMR designs as defined by Creswell and Plano Clark (2011) will be used. It is to be noted, however, that (1) all “families” contain designs where the qualitative and quantitative phases are either concurrent (parallel), sequential, or embedded one within the other; and (2) different authors may employ alternative terminology to describe the same type of design. The abbreviations “qual” (qualitative) and “quan” (quantitative) will be used below. The six major MMR designs are:

1. the *convergent parallel/concurrent* design. An example: The researcher collects both qual and quan types of data such as journal entries and test scores over a specific time period, analyzes them separately, and then compares or merges the results, or does both, and interprets them. Both sets of data are given equal importance. (See Ekkens & Winke, 2009, where alternative assessment practices were being explored as evidence of learning in workplace English courses. It was concluded, however, that “learning journals and standardized tests differentially documented this specific population’s learning gains” and that

the full picture of language development could only be understood by examining both types of data [p. 283].)

2. the *explanatory sequential* design. An example: The researcher collects test scores (quan) and records some of the test tasks (qual) at the same time. The quan data take precedence, but the qual discourse data are transcribed and analyzed and inform the quan test score data. These results are interpreted. (See Figure 83.1 and White & Turner, 2012.)
3. the *exploratory sequential* design. An example: The researcher's goal is to build an instrument, a questionnaire, which will in turn produce a list of speech tasks and ability levels that are specific and relevant to L2 nurses. The qual results inform the content of the questionnaire. (See Figure 83.2 and the text below for a brief description of the study; see Isaacs, Laurier, Turner, & Segalowitz, 2011, for the complete study; Turner, Laurier, & Isaacs, 2010, for diagrams.)
4. the *embedded* design. An example: The researcher conducts a quasi-experimental study with pre- and post-tests within a classroom where an intervention to enhance speaking skills through strategy use is taking place. During the intervention, a qual component is added. Students are observed (videorecorded)

Figure 83.1 Explanatory sequential MM design

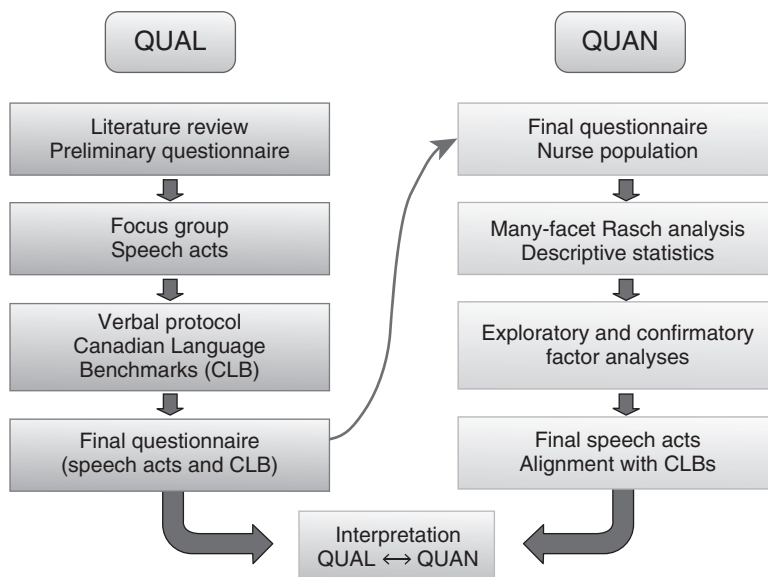

Figure 83.2 Exploratory sequential MM design: sample instrument development

and interviewed about their perceptions of the treatment. The qual data helps inform the results of the post-tests. (See Gunning, 2011, where the effects of strategy instruction and use on oral interaction tasks were studied among children in ESL classrooms. One phase of the study was quasi-experimental with an embedded component. Traditional assessment methods are at times challenging with children. Gunning describes how the use of MMR was appropriate in this setting.)

5. the *transformative* design. An example: The researcher will conduct any study modeled after designs (1)–(3), but within a theoretical framework that identifies and challenges social injustices. This context guides the methods decisions. (See Shohamy, Donitsa-Schmidt, & Ferman, 1996, where a critical discussion in the literature is continued on the use of tests embedded in educational systems for the purpose of enforcing control over the curriculum and prescribing the behavior of stakeholders. A study examining the use of two national tests over time is reported. Although not overtly stated, evidence of an MM design [a design similar to a convergent parallel/concurrent design, as in (1) above] is present in the instrument description section [i.e., questionnaires, interviews, and document analysis were employed] and in the results section where the data are triangulated and interpreted.)
6. the *multiphase* design: An example: The researcher will often use several phases, both concurrent and sequential, when doing a program evaluation over a longitudinal period. (See Lynch, 1996, for a thorough discussion with examples on mixed designs in language program evaluation studies.)

MMR conventions encourage researchers to include procedural diagrams (i.e., visuals) in their research reporting, as mentioned above. Figure 83.1 and Figure 83.2 are simplistic variations of what visuals can look like. Creswell and Plano Clark (2011) provide guidelines and notation for drawing such diagrams, but as one quickly finds, diagrams take many forms. For conference presentations and publications, however, they can be indispensable. MMR methodology is normally complex and a procedural diagram serves as a useful guide. Figure 83.2 represents a diagram used as a “road map” for a conference presentation (Turner et al., 2010). The study reported on the construction of an oral interaction scale for nurses serving linguistic minorities in their L2. An MMR design was used to identify and validate a set of speech activities relating to nurse interactions with patients and to identify the L2 ability needed to carry out those tasks. Several diverse procedures were used across the two sequential phases of this study, including direct input from nurses. The tools/procedures used in the first qualitative phase were a literature review, a preliminary questionnaire/working document, a focus group, and a verbal protocol. The product was a questionnaire for nurses. The second quantitative phase included descriptive statistics, Rasch analysis, exploratory and confirmatory factor analyses, and alignment of resulting speech tasks with the Canadian Language Benchmarks (CLB) scale bands (a previously validated rating instrument commonly used for workplace purposes). The product of the second phase was a list of speech tasks and ability levels that are specific and relevant to the nursing profession. They have since been employed in the development of a self-assessment instrument to facilitate L2 workplace

training for health-care professionals (Baker, Laurier, Turner, Lira Gonzales, & Ainsworth, 2012).

Evidence of such diagrams is sparse in the LT field for MMR studies. Hopefully this is a convention that will be increasingly pursued given the potential complexity of MM studies. Two very interesting recent studies would have benefited their readers by including such a diagram (Plough, Briggs, & Van Bonn, 2010, an MMR study examining the evaluation criteria to assess the speaking of graduate student instructors; Yu, 2010, a study looking at the effects of computer familiarity and presentation mode in summarizing extended texts).

Issues, Challenges, and Future Directions in MMR Research

Even though MMR has been in existence for quite some time, it is still considered a paradigm in its “adolescence” (Tashakkori & Teddlie, 2010b). The literature demonstrates it has made substantial and rapid progress in its development, but with this expansion and definition come new issues as well as the need to revisit old ones in a redefined paradigm. This chapter began by discussing the rapid growth of MMR and the evidence of this as represented in the literature and in particular in two handbooks dated 2003 and 2010. The second handbook concludes that some earlier issues have been resolved (e.g., the legitimacy of MMR), but that as with any growing endeavor several ongoing issues remain and new ones arise. The present issues and challenges are grouped into six categories: necessity of convergence in core ideas; conceptual stances in MMR; quality standards for MMR; the language of MMR; design issues in MMR; and the utilization of MMR for policy and practice (Tashakkori & Teddlie, 2010b, p. 809). These issues are intertwined and one aspect that permeates all of them is the area of pedagogy and mentorship. This is salient if MMR is to continue to grow, and if quality standards are to be defined and maintained in the future. Many of these challenges in conceptualizing and “doing” MMR have surfaced and become transparent in educational contexts as the first generation of instructors grappled with mentoring new researchers in this fairly new area of research. Some of the areas of concern for new researchers as well as mature researchers working within MMR are the following:

- the conceptualization of MM research questions (Do we separate qualitative and quantitative questions? Is there an overarching question? Do we have different questions for different phases?);
- sampling strategies across qualitative and quantitative data collection phases (How are purposive and probability sampling techniques utilized across the different approaches?);
- the qualities of a good MM study (How are established data collection strategies, such as observation, unobtrusive measures, focus groups, interviews, questionnaires, and test-like tasks, integrated into an MM design?);
- the practical issues when doing MMR research, such as time/length of study and sometimes the cost;

- the level of expertise needed to be able to do research with both qualitative and quantitative components (What are the alternative ways to integrate the different components?); and
- the manner in which an MM study should be written for publication (What are the considerations for length given its complexity?).

Many of these concerns are actually uncharted and are part of the evolving nature of this third research community. Debates and discussions can be found in the literature as these issues are addressed. For example, it has been suggested that MMR can sometimes be carried out by a team instead of just one individual. A team can be comprised of individuals with expertise in diverse data collection/analysis techniques (i.e., both qualitative and quantitative). This way researchers interested in the same questions can complement their work by combining their methodological expertise (Teddlie & Tashakkori, 2009). This may function well for seasoned researchers, but young scholars (e.g., PhD students), wanting to use and experiment with MMR in their dissertation studies, normally need to work individually. They therefore need to develop less complex designs in order to make their work feasible. It is such specific issues that are emerging in MMR and need to be discussed. Besides scholarly meetings, one ongoing current forum specific to the development of MMR is the *Journal of Mixed Methods Research*. In addition to articles from several disciplines, its editorials continue the conversation about the development of MMR. The future direction of MMR revolves around this conversation with the objective of defining itself within a community of scholars that is diverse, yet united in its rejection of the dichotomy between the qualitative and quantitative approaches to research. This community regards the potential of MMR as an approach to help broaden and deepen the understanding of the phenomena of interest. Given MMR's diversity, however, it appears consensus will come in the form of guidelines, lists of characteristics, and typologies of research design types rather than specific procedural instructions.

Only some of "the conversation" has been reflected in the LT literature. In other words even though studies combining qualitative and quantitative approaches are apparent, any debate or discussion of MMR issues seems less prevalent. There is one event, however, that attempted to focus attention on the evolution of the third paradigm in LT research. It was the theme of the Twenty-Ninth Annual Language Testing Research Colloquium, held in Barcelona, Spain: "Exploring Diverse Methodologies and Conceptualizations in Language Testing Research." Kim (2007) presented the first paper, entitled *Mixed Methods in Language Testing: Review, Illustrations, and Suggestions*. This paper helped highlight what appears to have been the main purpose for the evolution of MMR in the field of LT. It pointed out that it is the issues and questions of interest and the potential to examine them in more depth within an MMR design that have driven the increasing use of MM in the LT community. Examples from the literature on this purpose and rationale were provided: to understand complexity, to enhance the validity argument, and to reflect diverse views. Since that time, some LT studies continue to mix methods, but no particular emphasis is placed on MMR in LT venues and maybe there is no need to do this. What

is important, however, is the awareness of the potential of MMR as an alternative research approach.

This chapter has provided an introduction to the third research community in general and as it has been reflected in LT research. The chapter has only touched the surface of the complex intricacies that make up the content of MMR. To date, some LT studies are employing aspects of MMR as an alternative to more traditional LT research designs in order to obtain a more in-depth profile of the research problem at hand. It appears to be the issues under investigation that drive the use of MM; thus, as was discussed initially in this chapter, LT's rationale follows closely the philosophical orientation most often associated with MMR, that is, pragmatism.

Writing Research Reports

Kyle McIntosh

Purdue University, West Lafayette, USA

April Ginther

Purdue University, West Lafayette, USA

For those of us who hold academic and research positions, the importance of writing research reports cannot be overstated. If we do not spend a large portion of our time writing, then we will probably spend an even larger portion berating ourselves for lack of productivity, even as we try to find ways to write more efficiently and effectively. This preoccupation arises out of a practical concern with academic writing as the primary means by which we receive recognition and compete for grants, which in turn determines how we are evaluated for promotion and tenure, and later for promotion to full professorship. Of equal importance is the fact that the professional identities we create, outside of and beyond our local concerns and duties, are largely created and continually extended through our published work. Yet, despite the primary position of writing as a determining factor of academic success, explicit instruction in advanced composition or in writing for publication is seldom a component of instruction in master's and PhD programs. We offer this chapter as an initial step toward filling this gap.

Although writing research reports can be understood from many different perspectives, for the current purposes we only discuss three: professional development, genre, and argument. Understanding each perspective can contribute to the success of such endeavors. First, writing research reports represents a never-ending cycle of personal and professional development, which begins in graduate school and requires continual modification in order for one to make a successful transition from student to professional writer. This perspective requires close examination of the writing process as it is embedded in graduate programs and of the ways in which that process differs from writing for publication. Hopefully graduate student writing can be leveraged and strategies can be developed so as to make the transition to professional writing in academia less problematic than it would otherwise be. Second, a research report is the manifestation of a highly

structured, yet fairly malleable genre. Examination of the extensive literature describing the characteristics of this genre provides a useful entry point for subsequent practice. Third, a research report is the embodiment of an argument. From this perspective, the selection of a method, whether quantitative, qualitative, or mixed, will always be subsumed by a greater concern with the construction and quality of the argument itself. We examine each of these perspectives in turn. We also note that, with the possible exception of recent developments concerning validity arguments, writing research reports for testing and assessment shares much in common with writing research reports for the social sciences and for education in general.

Research Report Writing as Professional Development

Any entry on the topic of writing research reports must acknowledge the fact that the report itself represents only the final stage of a long and involved process. The research that produces the content of the report is primary. Identifying and then pursuing research questions, selecting methods, collecting and analyzing (and reanalyzing) data, and interpreting (and reinterpreting) results—all these operations comprise the bulk of the work. Such work is often carried out through a series of projects rather than in a single instance and remains, for the most part, invisible to those on the outside. Writing research reports, however, is what makes this work visible to a larger audience.

Graduate student training starts with the student becoming familiar with the extensive research literature associated with a wide array of disciplinary domains. The process of familiarization is the first means by which students are expected to develop an understanding of the practices involved in research writing. They are encouraged to read critically, uncovering problems and flaws, although, all things considered, critique is the easy part; practice is far more difficult. As Booth, Colomb, and Williams (2008) contend: “You can accurately judge the research of others only after you’ve done your own and can understand the messy reality behind what is so smoothly and confidently presented in your textbooks or by experts on TV” (p. 3).

Graduate students need to transition from a focus on the existing literature, in which critique predominates, to the actual production of original research, no matter how messy. In order to facilitate this transition, it is helpful to identify published research that may serve not only as the object of critique, but also as a model for practice. Furthermore, while explicit instruction in writing for publication is not commonly included in graduate training programs, implicit instruction based on the requirement for extensive reading of published research is the hallmark of graduate training in humanities, social sciences, and education (HSSE). Yet the value of reading may not be fully realized if critique is continually emphasized over practice. Students must find a study that presents a problem they find interesting enough to consider attempting a partial replication. Most importantly, they should find ways to actually collect and analyze data, so that they can develop a more realistic idea of the intricacies and difficulties involved. Even if the data set is very small and the final study is unlikely to be published, research

efforts are improved by conducting pilot studies. Furthermore, pilots are appropriate for presentations at local conferences and as posters at national ones.

Most graduate students are familiar with the process approach to writing, in which peer review and revision are required components. However, the papers written for graduate classes are often first drafts and are seldom revised or developed once a grade is assigned. The gap between even the best classroom paper and a paper ready to submit for publication can be substantial. The first encounter with serious revision often comes when students are writing proposals for their theses or dissertations. Thus it is easy to respond to required revisions as a kind of failure, especially if one has not been previously asked or expected to revise classroom writing. However, revision is part and parcel of the publication process; and, if students wait until the thesis or dissertation stage to undertake the additional work required when producing multiple drafts, it is probably too late. While in graduate school, one should seek serious critique, which extends beyond improving a paper and includes what might be required to get the paper published (before actually submitting it). This increases one's chances of being published and of being eventually offered a tenure track position. Search committees are attracted to a candidate with a track record, and having one or two publications, even as second or third author with a professor as first author, increases the likelihood of making it through the first cut.

The Least Publishable Unit

The idea of the *least publishable unit* (LPU) is familiar to those in science, engineering, technology, and mathematics (STEM), but much less so to those in HSSE. LPU is defined as the minimum amount of information required for a research report to be accepted for publication. Despite being roundly criticized for encouraging and producing the publication of trivial studies with limited impact, employing a research strategy that involves LPUs has its merits (see Owen, 2011). First of all, writing LPUs requires narrowing one's focus and learning how to *write short* in order to fit all of the required elements into a document no longer than the typical limit of 8,000 words. When one is planning to publish material from a dissertation, rather than envisioning a single publication, one should imagine *at least three*. By their very nature dissertations tend to be expansive, while published papers must be tightly focused, coherent, and constrained. Incorporating the idea of multiple subsequent publications at the start of the dissertation-planning process can assist in the transition from a major first work to a series of published papers ready to be included in a tenure review. When reading the research literature, it is fairly easy to identify studies derived from dissertations, as the author typically acknowledges the fact and thanks the dissertation committee for its support. Graduate students should pay special attention to these documents as models.

Publishing With a Professor

As with LPU, publishing with a professor or as part of a research group is the norm in STEM disciplines. At the opposite end of the continuum lies the single-authored monograph, the standard for evaluation in literature programs.

Authoring practices within testing and assessment lie somewhere in between. Opportunities may present themselves to publish with professors, especially those involved in large research projects or grants; they often welcome or invite student participation in exchange for authorship. In fact, graduate students may be able to fashion their own piece of a larger project, or a reasonable extension, and claim authorship for it. However, it is important to discuss expectations and make sure that they are clearly understood by all parties, from the beginning of the project or from the point where student participation begins. Many professors will include students as authors only if they contribute by writing portions of the final document; others will agree to authorship for supporting research efforts (e.g., coding, transcription, or running statistical analyses). In the best cases, publishing research reports becomes a supervised apprenticeship in which substantial amounts of work are distributed among the members of a research team.

Realistic Time Estimates

When one is estimating the time involved in getting any part of a research project completed, especially the writing and revision processes, it is important to be realistic and multiply all time estimates by three. A shortcoming of many grant and dissertation proposals is the unrealistic estimation of the time required to get the job done. Many graduate students underestimate the time needed because of the mistaken assumption that a short turnaround time gives the impression of efficiency; more often, such underestimates only indicate inexperience. Experienced grant reviewers know how long it takes to recruit subjects, transcribe data, run analyses, and write reports, and they always include time for unexpected problems and the intrusion of daily responsibilities.

Students interested in testing, assessment, and evaluation often have the advantage of being associated with a program that produces considerable amounts of data that can easily be leveraged for a variety of research purposes. A case in point is the English as a Second Language Placement Examination (ESLPE), which is administered quarterly at the University of California Los Angeles and has been used by many for dissertation and research projects (19 of which have appeared in *Language Testing*). Using a preexisting data set derived from an operational testing program can significantly reduce the time involved in data collection—as much as by a whole year—and should also ensure that the analyzed data are of acceptable quality.

Research Reports as a Genre

Of the structure, or genre, of research reports, Booth et al. (2008) emphasize functionality when they admit: “Whenever we’ve addressed a new research community, we’ve had to learn its ways to help us understand what its members think is important” (p. 4). The following section summarizes the considerable amount of research done on the characteristics of the research report, both within and across disciplines.

From its humble beginnings as a form of public correspondence between amateur scientists, which was first published in the *Philosophical Transactions of the*

Royal Society (Bazerman, 1988; Atkinson, 1999), the research report has grown into one of the most recognizable—and arguably rigid—written genres in the world today. Often visually represented as an hourglass, the typical research report starts off with a broad overview of the topic before narrowing its focus to a specific procedure, only to expand again near the end, as it looks toward directions for future research (Hill, Soppelsa, & West, 1982). According to Swales (1990), this basic structure can be further divided into introduction, methods, results, and discussion sections, more commonly known by the acronym IMRD. While this basic structure is only meant to serve as a prototype, there is sufficient evidence from genre analysis (Samraj, 2002; Parkinson, 2011) to suggest that a large number of published articles do in fact adhere to it.

In his CARS (“create a research space”) model, Swales presents the introduction as a series of rhetorical moves made to (1) map out a territory, (2) establish a niche, and (3) occupy that niche (1990, p. 141). Each of these three moves contains a series of optional, but by no means mutually exclusive, steps. For example, one might establish a niche by situating the research within a well-established tradition, while at the same time pointing to a gap in the previous research that the present study seeks to fill. Linguistically, the introduction is marked by the frequent use of active present tense verbs in reporting the findings of previous studies.

The methods section tends to be a more varied affair, across as well as within disciplines. While in HSSE writers are more likely to include a detailed step by step description of the procedures involved that would allow for replication (even though replication studies are rare in most fields), this is not always the case in STEM disciplines, where background knowledge about the methodology and its suitability for a given experiment may be safely assumed (Swales, 1990, pp. 169–70). Despite the attention to detail or lack thereof, the methods section is often distinguished by the use of specialized language and the predominance of simple past tense verbs and passive constructions.

In discussions of actual grammatical forms, the use of passive constructions deserves special mention. Style guides often encourage the use of active constructions. According to the 6th edition of the *Publication Manual* of the American Psychological Association (2010): “Verbs are vigorous, direct communicators. Use the active rather than the passive voice, and select tense or mood carefully” (p. 77). Perhaps this is intended to encourage any budding Hemingways among academic writers. Nevertheless, the use of passive constructions remains a hallmark of the research report. Booth et al. (2008) remark: “In English classes, students are told that they should use only active verbs, but they hear the opposite in engineering, the natural sciences, and some social sciences” (p. 263). They explain that the use of the passive allows writers not only to front the information given but also to focus readers’ attention on procedures rather than on agents. For this reason passives are frequently found in methods sections. Consider the following passage from Chapelle, Chung, Hegelheimer, Pendar, and Xu (2010), in which the functional differences between active and passive are apparent:

The cyclical activities of test development, piloting, and data analysis provided backing for the validity argument. During this process, the test development team revised the prototype items on the basis of the test results as well as test takers’ and

instructors' comments on the items. Scoring rubrics and answer keys were developed and revised on the basis of response analysis—a process that provides backing for evaluation inferences. (Chapelle et al., 2010, p. 459)

In the first two sentences the agency of the research team is highlighted, whereas in the last sentence the focus switches to rubrics and answer keys. The use of the passive “implies that the process can be repeated by anyone” (Booth et al., 2008, p. 263). In contrast, other performative verbs (e.g., argue, claim, prove, show, demonstrate) are often used in the active voice, to indicate the researcher's position. The use of active voice with performative verbs designed to mark a position also corresponds to an increased use of first person singular and plural pronouns. In his analysis of 240 research reports from eight different disciplines, Hyland (2001) finds first person pronouns and self-citation to be far more frequent than one might imagine, even in fields that pride themselves on objectivity. Consider this passage from a recent article published in *Language Testing*:

We are now in a position to outline the content and nature of a scoring method for complex service encounters which, being directly linked to performance and task, would form a critical part of the architecture of a complete service encounter test (Fulcher and Davidson, 2009). (Fulcher, Davidson, & Kemp, 2010, p. 20)

(If the double source seems confusing, please note that the former belongs in the original text, to which we refer here through the latter.) As Booth et al. (2008) explain: “Scientists typically use the first person and active verbs at the beginning of journal articles, where they describe how *they* discovered their problem, and at the end where they describe how *they* solved it” (p. 264). Thus the selection of passive and active verbs and the use of personal pronouns interact with rhetorical functions. Skilled writers can shift between these pairs as need be.

The results and discussion sections may appear separately or may be combined into a single one. When they are separate, the former is usually purely descriptive, while the latter provides possible answers for each research question on the basis of results, as well as directions for future research. There also tends to be notable linguistic differences: the results section employs mainly past tense verbs, while the discussion section more often uses the present tense. As Parkinson (2011) points out, the discussion section forms an argument based on the data presented in the results, and thus it depends heavily on causative verbs (e.g., *result (in)*, *cause*, *produce*, *determine*, *bring about*), conditional clauses (*if . . . then*), and inferential conjunctions or adverbs (e.g., *therefore*, *hence*, *consequently*).

Despite the aforementioned structural tendencies, substantial variations do exist between articles written in different disciplines. For example, Samraj (2002) finds that introductions in the field of wildlife behavior tend to follow the CARS model, while those in the closely related field of conservation biology concentrate more on problems outside of the literature (i.e., in the real world). She attributes this difference to the theoretical orientation and disciplinary identity of the former and to the applied orientation and interdisciplinary nature of the latter. Interestingly, some highly theoretical disciplines—like mathematics, physics, and even theoretical linguistics—rarely follow the IMRD structure (Swales, 2004).

Different journals may also require modifications to the IMRD structure. For example, *TESOL Quarterly* explicitly calls for a section on pedagogical implications, even when the research does not lend itself well to such pronouncements (for a critique of this practice, see Han, 2007; for a rebuttal, see Chapelle, 2007). *Language Testing* recommends that authors include test items or texts to allow for replication, despite the fact that replication studies are almost never published in that or any other applied linguistics journal, perhaps due to the emphasis on finding and filling gaps in the existing research.

Swales (2004) notes the emergence of the review article as a new subgenre of research report that does not require a methods or a results section, as it is comprised primarily of citations and discussion. Hu (2010) argues that the attention given to the IMRD structure has obscured the literature review as a separate but equally important component, with a set of rhetorical moves that roughly parallel those found in the CARS model. However, E. Benedicto (personal communication, April 9, 2010) counters that extended literature reviews are seldom developed beyond a cursory mention in theoretical linguistics research reports and are often omitted entirely.

Additional linguistic and rhetorical features help distinguish the research report as a genre. Martinez (2001) notes an abrupt shift from the relatively personalized introduction to the objectivity of the methods and results sections—a shift resulting in a tension based on the way experiences are represented by various verb types: mental (e.g., “believe”) material (e.g., “conduct”), and relational (e.g., “indicate”). The introduction focuses more on the mental, while the methods section is concerned with the material. The results and discussion sections are relational, although it should be noted that relational verbs were the most common type found in the 21 articles selected from the physical, biological, and social sciences. Hyland (1996) regards the frequency of hedges, or “the expression of tentativeness and possibility” in scientific research (p. 433), as a sign of the way writers negotiate with their peers in order to promote the strongest possible claims while retaining a degree of humility or protecting themselves against scathing critiques. For example:

Students’ perceptions of SBA [school-based assessment] are significantly correlated with their perceptions of external examinations, but their perceptions of the two are not significantly different. This *may suggest* that for these students SBA is simply another exam that they have to prepare for. (Cheng, Andrews, & Yu, 2011, p. 234; italics added)

Research reports in different disciplines use hedges for different purposes and to varying degrees, depending on the acceptability of the claims being made to those within the discourse community. One way in which the use of hedges may be evaluated is through the fact that they mark areas in which claims and warrants are vulnerable. Thus readers are inclined to take a closer look at the claims and warrants in the report and consider ways to strengthen them.

Dominance of English

Over the past several decades, English has emerged as the dominant language of international academic publication, approximately 75% of all published research

now being written in English (Curry & Lillis, 2004). Unsurprisingly, an overwhelming number of these reports come from those countries where English is spoken as the primary language (US, UK, Canada, Australia, and New Zealand). Not only do scholars who are raised, educated, and work in the English-speaking core hold a decided linguistic advantage, but they also have unfettered access to tremendous information resources, like public libraries and the Internet, through which they find multiple opportunities to familiarize themselves with the conversations and conventions of their fields. Conversely, many scholars who live and work on the “periphery” of the English-speaking world face a host of challenges when it comes to having their work recognized by the international academic community, including unfamiliarity with linguistic and discourse conventions, differences in publication cultures, and a lack of material resources; this is especially true in so-called “developing” countries.

In recent years a number of scholars in applied linguistics have highlighted this disparity, addressing the issue as it relates to authors (Flowerdew, 2000; Shi, 2002), editors (Gosden, 1992; Flowerdew, 2001), reviewers (Nylenna, Riis, & Karlsson, 1994; Burrough-Boenisch, 2003) and graduate students (Tardy, 2004; Li & Flowerdew, 2007). Several of these scholars have also proposed various ways to correct the imbalance and to bring about greater representation of L2 English-speaking scholars’ work in English language publications. Li and Flowerdew (2007) urge authors to seek out specialists in academic English at their own universities, for advice and assistance. Flowerdew (2000) suggests that peer-mentoring groups could be set up to help support one another through the writing and revision processes. Burrough-Boenisch (2003) reminds would-be authors that recommendations for revision are negotiable. Flowerdew and Li (2009) call for more L2 English-speaking scholars to serve as peer reviewers and editorial board members of international journals. Likewise, Belcher (2007) encourages editors to become more sensitive to the problems these scholars face and to assist them through the submission process. Nevertheless, she warns against publishing manuscripts that do not meet the professional standards of a particular journal. It should also be noted that all graduate students begin somewhere on the periphery of the research world, and most of the advice offered above is appropriate for all beginning academic writers. While having English as an L1 constitutes a distinct advantage, it certainly does not ensure success at publication.

Whether such steps can lead to greater inclusion of novice and L2 English-speaking writers remains uncertain. Belcher (2009), for one, sees an overall positive trend toward greater representation of international and female scholars in the field of applied linguistics, although the percentages remain relatively low. Flowerdew and Li (2009) remark on the increasing number of Chinese researchers being published in international science and engineering journals, but they lament that those in HSSE continue to be under-represented. While the dominance of English throughout the academic world may be perceived as a problem that needs to be solved (see Phillipson, 1992), such dominance is likely to remain the case in the foreseeable future. What all academic writers should keep in mind is that, “since few people read research reports for entertainment, you have to create a relationship that encourages them to see why it’s in their interest to read yours” (Booth et al., 2008, p. 18). This is especially true for reviewers, who are not paid for their work and have little time to find meaning in an overly convoluted text.

Learning the conventions associated with the research report as a genre, as well as the specific expectations of a given journal, can make the submission process easier and more productive for everyone involved.

Different Contexts

Despite the apparent hegemony of English, research reports continue to display tremendous variation as a result of the sociocultural contexts in which they are written and published. Canagarajah's (2006) case study of a Sri Lankan scholar writing in different languages and for different publications finds that, when writing in his native Tamil, the scholar made no attempt to establish a territory or a niche and did not announce a thesis or findings in the introduction. Canagarajah attributes this to the lack of a "publish or perish" atmosphere in Sri Lanka. This same "laid back" approach was maintained by this scholar in writing articles in English for local periodicals, but when he wrote for international journals he seemed to adhere more closely to Swales' CARS model, although he still did not bother to establish a niche or to review the existing literature. In such contexts a well-defined methods section is often missing, due to the difficulty of obtaining funding for experimental research. As a result, Canagarajah explains that many periphery scholars rely heavily on ethnographic or anecdotal data. Mauranen's (1993) comparison of economics reports written in English reveals that Finnish authors use less metatext to orient their readers and fewer references than their Anglo-American counterparts. However, Flottum, Dahl, and Kinn (2006) find as many differences in the use of metatext, first person pronouns, and bibliographic references between the three disciplines they studied (economics, linguistics, and medicine) as between the three languages (English, Norwegian, and French). To better account for all the variations that exist in research reports published in different sociocultural contexts, Swales (2004) proposes the OARO ("open a research option") model as an alternative to CARS—an alternative that "captures a kinder, gentler, more relaxed research world in which there is less competition for research space" (p. 244). In such contexts, writers may work harder to establish their credibility among members of a small community of peers, by demonstrating expansive background knowledge on a topic and by explaining the reasons for exploring it further rather than merely identifying a gap in the existing research and attempting to fill it. The resulting report may read more like an introduction and discussion, with little or no methods or results.

Writing Research Reports as Argument

One of the most thorough explications of argument structure as a foundation for research report writing is provided by Booth and colleagues in *The Craft of Research* (Booth et al., 2008). This volume, now in its third edition, is an excellent resource for research report writing in terms of the development and support of the underlying arguments—or the application of what has become known as an *argument-based approach*. The authors begin by pointing out: "Central in every chapter is our advice to side with your readers, to imagine how they will judge what you have

written" (p. xii). They later argue that, in terms of audience, the first and most important person who needs convincing is one's own self: "That's how a lot of research begins—not with a big question that attracts everyone in a field, but a mental itch about one small thing that only a single researcher wants to scratch" (Booth et al., 2008, p. 35).

The reasons that may encourage readers to change their minds are provided by arguments.¹ Arguments are defined as consisting of three primary elements: a substantive and contestable (falsifiable) *claim*, reliable and relevant *evidence* (data), and a *warrant* that links them together. Claim and evidence are linked by a *warrant*. This third element, the warrant, is the trickiest part, but its function and importance can be clarified by asking and answering the following question: "Given the evidence I have provided, are the claims I am making warranted?" This question should be familiar to readers as the widely accepted basis for evaluating the validity of a research study, test, or assessment: it is not possible to directly validate a study or a test, but we validate the inferences or claims we would like to make given the information provided. To a large extent, the validity of our claims resides in successfully anticipating and countering challenges to all three aspects of an argument: the viability of our claims, the reliability of our evidence, and especially the quality of the warrants that connect claims and evidence. Booth and colleagues explain:

When readers think that both a warrant and reason are true, and that the specific reason and claim are good examples of the warrant, they are logically obliged to at least consider the claim. If they don't, no rational argument is likely to change their minds. (Booth et al., 2008, p. 164)

The authors then go on to provide a series of examples in which warrants are made visible, so that they may be challenged and defended more effectively. They also point out that "readers of research reports tend to distrust a claim based only on an unqualified and unlimited warrant, because such arguments are usually more ideological than factual" (p. 170).

Mosteller, Nave, and Miech (2004), along with Kelly and Yin (2007), emphasize the importance of investigating rival thinking in their advocacy for the adoption of an argument-based approach designed to improve the quality of abstracts in educational research. Their discussions emphasize Popper's (1963) argument that theories should be proposed boldly, but tested ruthlessly. The anticipation of reasonable counterarguments is presented as part of the testing process. However, the application of the framework remains an exercise undertaken to support argument structure that is never explicitly presented.

Nevertheless, the provision of an explicitly presented argument framework is a practice that is gaining currency, especially in the testing literature. The development of validity arguments along these lines is most frequently associated with Kane (2001; 2006) and Mislevy (Mislevy, Sternberg, & Almond, 2003); the value of the provision of such frameworks is argued by Bachman (2005), discussed in Kunnan (2010), and fully explicated in Bachman and Palmer (2010); applications can be found in Chapelle, Enright, and Jamieson (2008) and in Chapelle et al. (2010).

Conclusion

The visibility of our work provides a means through which we establish our academic identities. It also leads to increased engagement and interaction within our communities of scholars and forms the basis of evaluation for tenure, promotion, and salary increases at our institutions. Yet, as we have tried to make clear in this entry, much of the actual work involved remains hidden from those graduate students who have not been given the opportunity to work directly with a professor or as part of a research team involved in collecting and analyzing data with the ultimate goal of publishing the results in the form of a research report. Reading published research reports is one way to gain familiarity with the conventions of the genre, but one must be careful not to allow critical reading to obscure more practice-oriented types of reading. By modeling one's research design on a published study, or even by attempting to replicate its results, graduate students can become more familiar with the conventions of the genre, as well as with the reasons why these conventions exist (e.g., to provide clarity, to show familiarity, to emphasize or obscure one's voice).

Of course, research reports, like any genre, are based largely on the expectations of a particular discourse community, and such expectations are subject to change. We see evidence of this in our own field, with the growing awareness of and interest in the work of scholars from outside of the English-speaking core. But, again, one does not need to be an L2 English speaker to feel like an outsider. Most novice writers experience isolation and uncertainty, but even experienced professionals may find themselves temporarily stymied when moving into a new subfield or submitting to an unfamiliar journal. Nevertheless, these skilled practitioners must be there to instruct novices—not only through the work that they have produced, but also by providing hands-on opportunities to experience the processes of research and research report writing. We anticipate this apprenticeship model for graduate students becoming the norm in our field.

Philosophy and Language Testing

Glenn Fulcher

University of Leicester, England

Introduction

Philosophy is concerned with “rational thinking about . . . the general nature of the world (metaphysics or theory of existence), the justification of belief (epistemology or theory of knowledge) and the conduct of life (ethics or theory of value)” (Honderich, 1995, p. 666). In education and language testing we are concerned with questions of ontology (what we believe to be true), epistemology (how we discover what is true), and the consequences of testing (the nature of ethical practice). This chapter will focus primarily on questions of ontology and epistemology, as ethics is dealt with separately in Chapter 95. Furthermore, while general agreement among language testers exists on key ethical principles to guide our practice, there are radical differences of views regarding ontological and epistemological questions.

As far as epistemology is concerned, the question usually boils down to: “Should the human sciences emulate the methods of the natural sciences or should they develop their own?” (Polkinghorne, 1983, p. 15). Realists—heirs to Hobbes, Mill, and Comte, who believe in the existence of what we observe and test independently of the observer or tester—give special place to the scientific method. Antirealists, on the other hand, usually hold that the constructs we claim to test are not independent of the language tester or the act of testing. The so-called “objects” of our observation exist only in relation to our interpretations of them as they are locally constructed. They would argue with Dilthey (1883/2008) that the richness of human experience and culture cannot be captured by methods developed for the natural sciences. Of particular importance in language testing is the “social turn,” which brings critical analysis to test use and impact. There is much room for disagreement here. Paradigm clashes are not unusual in the social sciences, but in language testing the fault lines are more pronounced because, for most of its

history, it has been firmly grounded in the scientific realism of early quantitative approaches: “One of the most important objects of measurement . . . is to obtain a general knowledge of the capacities of man by sinking shafts, as it were, at a few critical points” (Cattell & Galton, 1890, p. 380). In this chapter I set out the realist and antirealist positions, realizing that there are many gradations between the two. I argue that extreme positions on the cline are untenable. I make a case for realism in the pragmatist tradition, which is not to be associated with the naive realism that is the target of constructivism. I also recognize the role for critical research, especially where language testing is misused or abused. I conclude by proposing an optimistic view of the future within an Enlightenment-inspired framework.

I begin by describing the realist position, and then move on to antirealist stances. With Bachman (2006, pp. 196–7), I distinguish two kinds of antirealist stance, the *constructivist* and the *operationalist*, although I prefer to call the latter *instrumentalist* for reasons that will become clear, and because Kane (2006b, p. 442) explicitly distances his approach to validation from the operationalist position. I then discuss two key issues upon which language testers are in fundamental disagreement because of their philosophical positions. I then briefly indicate the research each position generates, and outline the challenges they face. Finally, I suggest a way forward based on classical pragmatism.

Conceptualizations

Realism

Realists hold to the Enlightenment view that the scientific method is the most productive in empirical research (whether quantitative or qualitative), as expressed by Popper (1959, p. 3):

A scientist, whether theorist or experimenter, puts forward statements, or systems of statements, and tests them step by step. In the field of the empirical sciences, more particularly, he constructs hypotheses, or systems of theories, and tests them against experience by observation and experiment.

The applicability of realism to social sciences has also been championed by educationalists such as Dewey, for whom

the scientific method is simply the method of experimental enquiry combined with free and full discussion—which means, in the case of social problems, the maximum use of the capacities of citizens for proposing courses of action, for testing them, and for evaluating the results. (Putnam, 1990, p. 190)

Theories and evidence that provide the basis for decision making need to be assessed using generally accepted criteria. In language testing, four have been suggested (Fulcher & Davidson, 2007, p. 20):

1. *Testability*: Theory generates predictions that can be tested, specifically to see whether scores support inferences from test taker responses to skills, abilities,

or knowledge, and to investigate if inferences are generalizable, and capable of extrapolation to the real world.

2. *Simplicity* (Ockham's Razor): The requirement that the theory does not use more abstract terms or constructs than are necessary to explain the evidence available.
3. *Coherence*: The need to construct theories that are in keeping with what is already known, as well as for the theory itself to be internally coherent.
4. *Comprehensiveness*: The requirement that our theories account for as much of the available data and facts as possible.

It is argued that these criteria are "paradigm free" and can be used in theory and model evaluation of any kind. However, the logic of the key criterion of testability assumes an evidential approach to validation, which in turn presupposes that the evidence exists. It seems reasonable that a researcher in any evidenced-based discipline must subscribe to this notion, encapsulated in this summary of Hume's position: "He holds that objects that have real existence must have duration and must be independent of what we individually think about them" (Meyers, 2006, p. 63). In order to test theories we must have experiences of enduring objects, events, or states that co-occur to a degree that would minimally allow us to make statements about the likelihood of, and possible reasons for, co-occurrence.

In language testing this leads to two claims. First, that individuals have a stable language competence and capacity for use that endures for some time even though it is subject to change (through learning or attrition), and that responses to test items or tasks can be translated into numbers that are indexical of that competence. This is not to deny that communication is a social act, but recognizes that, unless an individual has an enduring performable competence, they cannot engage in anything like the "co-construction" of discourse (Fulcher, 2003, pp. 19–20). Second, that score meaning can be generalized and extrapolated to relevant domains for a reasonable period of time, and with a known degree of probability: our theory makes predictions about the likelihood of future events.

Language testing has, for the most part, relied on realist assumptions throughout its history, partly because it has been largely dependent upon the normative practices in measurement that Quetelet imported into social science research from astronomy in the creation of his "social physics" (1842/1962, p. 9); and, as Hamp-Lyons (2000, p. 582) has argued, "The early history of language testing on the American side of the Atlantic is part of the larger story of intelligence testing, which was firmly grounded in positivism." This observation is largely correct, even if the geographical claim and the reference to positivism are not. First, there had always been an interest in measurement in the United Kingdom (Edgeworth, 1888, 1890), and in 1923 Ballard (1923, p. 29) could write

The British Press refers to mental tests as though they were new things invented by Americans. In point of fact they are neither new nor American. They have been the common property of the race since the dawn of history.

Ballard cites research by Cyril Burt, as well as the adaptation of the Binet tests. Second, the label “positivism” is now typically used pejoratively, and with less specificity than it deserves. Most researchers who hold a realist position do not hold positivist views or espouse the verifiability principle (Jordan, 2004, p. 32). Such a position is nominalist, and therefore profoundly antirealist. In arguing that only verifiable statements are meaningful, and that only words which refer to observables are capable of verification, all “theoretical” words are rendered unintelligible (Devitt & Sterelny, 1987, pp. 189–90). Without theoretical language, scientific research programs are unattainable; this is why positivism is referred to as “the linguistic turn” in philosophy.

Constructionism

Constructionism (or social constructionism) is a postmodern approach that does not ask about truth, but wishes to uncover the historical and cultural reasons that led to the currently dominant version of truth. This may take the form of deconstructing text where no form (particularly scientific) has any special status (Derrida), or uncovering the power structures that are claimed to marginalize people while legitimizing the power of the elite (Foucault). Constructivists hold that our tests and what they measure are contingent upon the social context in which they are designed and used.

All shades of constructionism are therefore *critical*, and the basic assumptions are laid out by Hacking (1999):

0. X is taken for granted. X appears to be inevitable.
1. X need not have existed. X could have been different.
2. X is bad.
3. We would be better off if X were changed, or if X did not exist.

To be a constructivist, it is necessary to subscribe to at least (0) and (1), and it is (1) that gives constructionism its edge: Our current beliefs and practices, including our theories and constructs, are contingent. If a constructivist also holds (2), she is usually committed to unmasking the evils of X in order to undermine the power or authority that is associated with it, or wishes to reform aspects of X. When a constructivist also holds (3) the attacks on X are usually strident, foregrounding injustices, marginalization, or subjugation of peoples. In applied linguistics the language becomes one of struggle and conflict, with charges of “cultural imperialism” and a determination by the powerful “centre” (Western cultures and Anglo-American norms) to keep the “periphery in a state of dependence” (Phillipson, 1988, p. 348). All groups who can be cast as minority or downtrodden are drawn into the argument, and labels such as “patriarchal,” “oppressive,” and “positivist” are attached to alternative views (Pennycook, 2001).

Social constructivist schools of thought bring the same critical approach to “knowledge,” which for them is also contingent. The concept becomes a battleground in education because constructivists claim that it is the powerful who decide what “knowledge” counts and is therefore learned and tested. Testing is

seen as the mechanism through which the elite exercise power and maintain their position (Foucault, 1975, pp. 184–94). Questions of inductive inference are irrelevant, because all “knowledges” are equal in value; facts do not help to build, support, or undermine theories, for “the facts emerge only in the context of some point of view” (Fish, 1995, p. 253). The ultimate statement of this extreme position was provided by Nietzsche (1888, ¶ 604):

“Interpretation,” the introduction of meaning not “explanation” (in most cases a new interpretation over an old interpretation that has become incomprehensible, that is now itself only a sign). There are no facts, everything is in flux, incomprehensible, elusive; what is relatively most enduring is—our opinions.

This carries a number of implications. First, no utterance (consisting of conventional signs—or words) can be evaluated in terms of whether it succeeds or fails to correspond to some external reality. Rather, use of language is a moment-by-moment attempt to deal with experience, whether of other people or of our environment. Attempts to decide if conventional signs “fit the facts” or describe “the way the world is” are futile (Rorty, 1989, p. 121); we are simply negotiating our way through existence. Reference from conventional signs to the real world as described by Frege (1892) is no longer of concern. Second, dualism is abolished. What is language? Nothing but “new forms of life constantly killing off old forms—not to accomplish a higher purpose, but blindly” (Rorty, 1989, p. 120). This nominalism (which constructivism shares with positivism!) makes it equally meaningless to ask questions about psychological states, as they are transitory and ephemeral. They simply cannot be known, explained, or predicted. What we are left with is the transient social construction of meaning on an interaction-by-interaction basis.

Instrumentalism

Although I have classed instrumentalism as antirealist, it may be more appropriate to call it *nonrealist*, because instrumentalists hold that, if a test assists in useful decision making, that is really all that matters. For instrumentalists the issue of whether the terms of theories refer to any real entity is simply irrelevant. They accept Hume’s fork, and hold that nondeductive (subjective) inference is always subject to question and error. One argument for instrumentalism is provided by Laudan (1981a) in his critique of realism, in which he uses historical evidence to undermine the premise that successful theories have terms that refer. For example, atomic theory failed to be empirically successful for hundreds of years, while the miasmatic theory of disease transmission was: it led to policies of moving people away from ports and introducing quarantine. Thus, theories are evaluated primarily on the grounds of the degree to which they enable us to predict phenomena and manipulate our environment in useful ways, as we can never be certain that our terms refer.

Each of the three positions described in the introduction have impacted upon language testing, leading to incommensurable stances that are explored in the next section.

Current Positions on Key Issues

I have selected two themes for discussion. My rationale is that these best illustrate fault lines that are directly related to philosophical beliefs.

Constructs/Theoretical Terms

Bachman (2006, pp. 182–3) writes: “When a researcher observes some phenomenon in the real world, he generally does this because he wants to describe, induce or explain something on the basis of this observation. That something is what can be called a ‘construct’.” These are nonobservable abstract nouns that are operationalized in such a way that we may make inferences about them from our observations (Fulcher & Davidson, 2007, p. 7). Realists minimally subscribe to the “reality” of these nonobservables.

This is very close to a correspondence theory of truth—the natural home of the realist. Models of communicative competence/language ability, from Oller’s use of Spearman’s “g” to modern componential approaches, rest on an assumption that the terms of the theory refer to real competences that are not merely useful fictions.

Some researchers explicitly work within this paradigm rather than just assume it to be the case:

We argue that the validity of any given teaching, learning, and assessment task—whether it is representative, authentic, and generalizable—is just a more complex version of the problem of determining whether a representation of a given state of affairs is true or not. We provide two logical arguments. Both of them show the construal (production and interpretation) of surface forms of discourse in order to represent faithfully (and truthfully) certain changing states of affairs in the real world is the necessary and sufficient basis for any validity to be found in any teaching, learning, and assessment tasks whatever. (Badon, Oller, Yan, & Oller, 2005, p. 2)

Badon et al. argue that the validity of a test of aviation English can be evaluated on the grounds of whether or not language used by pilots, air traffic controllers, and test takers represents a true state of affairs in the real world. The facts of real world events must be encoded into recognized conventional signs (linguistic realizations). Based on Oller’s theory of pragmatic mapping, the validity question becomes whether the construct to be measured exists, and whether variation in scores is causally linked to variations in the construct. It is therefore necessary to develop tasks which require test takers to refer to objects and events in the real world, and use language to control and change events.

The data-based approach to scale development, with its careful analysis of language use in context, but relating observable variables to constructs such as “discourse management” and “pragmatics,” would sit comfortably within this kind of interpretation (Fulcher, Davidson, & Kemp, 2011). For this reason we add the further observation that realist approaches do not abandon context. Rather,

The authenticity, representativeness, and consequent generalizability of teaching, learning, and assessment tasks depends on their incorporation of the sign systems,

social actions, and realia found in actual contexts of discourse. While codes, contexts, and interactions must be distinguished in theory, in practice they interact holistically. (Badon et al., 2005, p. 1)

For realists, *context is real*, not constructed, and so, while it is important to maintain a connection between the world and conventional signs, realists must also take seriously implicature and illocutionary intent.

Some would go further and argue that the term “construct” needs to be distinguished from “trait,” as the former implies that the theoretical term is a construction of the researcher: It may be part of a nomological net, but does not refer. That is, construct theorists are said to really be constructivists with a scientific air about them. For example, they may admit that a number of models could fit their data, and the theoretical terms could vary by model. In contrast, Blackburn (2005, p. 118) describes a “*real* realist, an industrial strength, meat-eating realist” as someone who holds that (a) there are no such things as constructs, only traits, which refer to properties that exist in the real world, are discovered not created, and exist independently of the researcher or theories, and (b) the terms define the properties in ways that are not contingent. This position is best represented by Borsboom and colleagues, who argue:

Realism, in the context of measurement, simply says that a measurement instrument for an attribute has the property that it is sensitive to differences in the attribute; that is, when the attribute differs over objects then the measurement procedure gives a different outcome. (Borsboom, Cramer, Kievit, Scholten, & Franic, 2009, p. 148)

Validity in this formulation is equivalent to the existence of what the test measures, and goes back to the strongest scientific claims for testing made in the 19th and early 20th centuries. The argument is that only “if this ontological claim holds, then the measurement procedure can be used to find out about the attributes to which it refers” (Borsboom, 2005, p. 152).

Constructivism is incommensurable with all shades of realism. Constructivists challenge the primary claim that there are facts or traits in the real world that exist independently of the mind of the researcher or test taker. The world itself is constructed. The trail of the human serpent is everywhere.

Do language testers deal with “facts” or things that exist? McNamara argues that they do not. He represents a trend in language-testing research that focuses upon the social nature of language testing, and the dependency of all concepts and communication on locally situated interaction:

Recent work has drawn attention to the potential of poststructuralist thought in understanding how apparently neutral language proficiency constructs are inevitably socially constructed and thus embody values and ideologies (McNamara, 2001, 2006). It is worth noting here that the deconstruction of such test constructs applies no less to constructs in other fields of applied linguistics, notably second language acquisition.

There is also a growing realization that many language test constructs are explicitly political in character and hence not amenable to influences which are not political. (McNamara, 2006, pp. 37–8)

The constructs have no “existence” in the external world, and their conventional names are signs constructed for social—primarily political—purposes. More specifically, tests play a critical role in the power struggles that constitute identity-forming social life, and may be deconstructed using Foucaultian insights (Shohamy, 2001, pp. 20–4, 54–8). The proper focus of attention is the social construction of tests, their social impact, and role in policy. Construct labels no longer refer, reducing them to the embodiment of the values and ideologies at play in the power struggles of the day.

As a direct consequence, the role of cognition is downplayed in critiques of validity theories, and the link between performance (observation) and competence (construct) abolished. Using the notion of performativity from feminist poststructuralism, McNamara also suggests:

We assume in language testing the existence of prior constructs such as language proficiency or language ability. It is the task of the language tester to allow them to be expressed, to be displayed, in the test performance. But what if the direction of the action is the reverse, so that the act of testing itself constructs the notion of language proficiency? (McNamara, 2001, p. 339)

Presumably, in the process of testing, we see just another transitory interaction, or what Davidson (1980) refers to as “a passing theory,” in which identity and meaning are temporarily constructed and deconstructed:

In linguistic communication nothing corresponds to a linguistic competence as often described . . . I conclude that there is no such thing as a language, not if a language is anything like what many philosophers and linguists have supposed. There is therefore no such thing to be learned, mastered, or born with. We must give up the idea of a clearly defined shared structure which language-users acquire and then apply to cases. (Davidson, 1980, p. 265)

The instrumentalist position makes no assumption about construct reality. Nor does it admit the necessity of constructs for language testing to be a successful enterprise. Validity is an issue of whether the testing processes lead to useful outcomes. This is the primary reason for the move from talk of “validity” (Messick, 1989) to talk of “validation” (Kane, 2006a). Although Kane uses the language of constructs and traits, he argues that “The use of trait language does not necessarily buy us much, and it can be misleading. It can suggest that we have found an explanation for an observed regularity, when we have merely labelled it” (Kane, 2006a, p. 30). Such an error is defined as “reification” (Kane, 2006a, p. 59). Kane (2009, pp. 54–7) has also argued that it is possible to avoid construct language completely, scoring only relevant observable variables displayed in tasks sampled from the universe of generalization. Chapelle, Enright, and Jamieson (2010) embrace this position, arguing that the construct of academic language proficiency has proved too difficult to define and articulate as a basis for test development and validation: “Kane’s organizing concept of an ‘interpretive argument,’ which does not rely on a construct, proved to be useful” (Chapelle et al., 2010, pp. 3–4). Bypassing construct labels and definitions, they move straight from observables

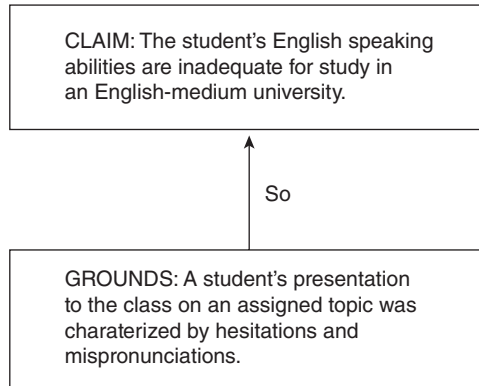

Figure 85.1 Interpretive argument. Adapted from Chapelle et al. (2010, p. 5)

to claims using the Toulmin model as the basis for an interpretive argument (see Figure 85.1).

The evidence leads to a score generated by scoring rules (the application of a scoring rubric), and an inference is made from the score to the claim. It is important to note that this is done without the need for a construct inference such as the student's "fluency."

The procedures for constructing and evaluating interpretative arguments are generic, but adapted to the specific claims of each assessment context (Kane, 2010, p. 79). Constructing and challenging arguments has an analogy in the courtroom where, "If the procedures have not been followed correctly or if the procedures themselves are clearly inadequate, the interpretive argument would be effectively overturned" (Kane, 2006a, p. 29). The role of the prosecution is to undermine the defence's argument with alternative explanations of the data. The argument of utility for an intended purpose is all that we are able to evaluate.

Neither the "real realists" nor the constructivists are keen on instrumentalism. For the former it does away with the all-important traits (Borsboom, 2006a, p. 431). For the latter it is too concerned with individual cognition (McNamara & Roever, 2006). But this does not matter to instrumentalists, because they accept both critiques: we need pluralism so that we have a range of approaches to solve different problems (Kane, 2006b). If it seems useful, instrumentalists go with it.

Society, Impact, and Consequences

It would appear that the realists have a problem with the impact of tests on society and individuals. Although consequences have been the focus of legal disputes for a long time (Fulcher & Bamford, 1996), the traditional position has been that there is a cause for concern only if "the adverse social consequences are empirically traceable to sources of test invalidity" (Messick, 1989, p. 88). The only exception was Cronbach (1988), who argued that any socially negative effect should be a concern for the test developer. On the other hand, the most strident

realists wish to abolish social impact and consequences from validity discussions completely:

Validity is not complex, faceted, or dependent on nomological networks and social consequences of testing. It is a very basic concept and was correctly formulated, for instance, by Kelley (1927, p. 14) when he stated that a test is valid if it measures what it purports to measure. (Borsboom, Mellenbergh, & van Heerden, 2004, p. 1061)

However, other realists do not agree. Badon et al. (2005, pp. 9–10) argue that, if a test can be shown to measure a trait that is critical to aviation communication, and if teaching this trait reduces miscommunication and hence aviation accidents, this would (a) constitute evidence of validity, and (b) have a positive social consequence.

Clearly, this is not likely to be enough for constructivists. McNamara and Roever (2006, pp. 2050–251), for example, describe Borsboom's version of realism as an attempt to "strip validity theory of its concern for values and consequences and to take the field back 80 years to the view that a test is valid if it measures what it purports to measure." They quote Shohamy with approval:

The ease with which tests have become so accepted and admired by all those who are affected by them is remarkable. How can tests persist in being so powerful, so influential, so domineering and play such enormous roles in our society? One answer to this question is that tests have become symbols of power for both individuals and society. Based on Bourdieu's . . . notion of symbolic power, [we] will examine the symbolic power and ideology of tests and the specific mechanisms that society invited to enhance such symbolic power. (Shohamy, 2001, p. 117)

When constructivists turn to instrumentalism, they find that "there is nothing in Kane's model of an interpretative argument, or in its adoption within language testing, even when it focuses on test use, that would invite such reflection" (McNamara & Roever, 2006, p. 39). For constructivists the focus is the test taker as a "political subject in a political context," and so research that ignores the social and ideological is suspect. Of particular concern is the topic of identity. This comes in two forms. The first is the use of tests for purposes of identifying/classifying, in contexts such as war, immigration, asylum, or citizenship, where there are possibilities of oppression or mistreatment. The second is related to the kind of identity the test taker must assume in order to pass this test, which includes using discourse that reflects the power relations of dominant institutions. In this sense all tests are claimed to be tests of identity (McNamara & Roever, 2006, pp. 196–9) and thus an exercise of power in their own right.

The instrumentalists take a middle position on social impact and consequences. They acknowledge that there are real policy and political issues, and questions of fairness for the individual. They are also happy to embed these within validity theory where Messick placed them. However, dealing with consequences is very much a technical matter: evaluating consequences that stakeholders feel are important using program evaluation as a model (Kane, 2006a, p. 56), rather than adopting a critical stance.

Current Research

Realism

Much of the research in designing assessments for specific purposes is generally realist. We have seen that this is the case with aviation English, arguably one of the highest stakes uses of tests. It seems unlikely that stakeholders would wish to use a test that the designers claimed did not measure constructs/traits of interest because they did not exist. Similarly, the growth of interest in diagnostic testing (Jang, 2009) and the assessment of language disorders (Oller, 2012) has a strongly realist flavor. Approaches that employ factor-analytic techniques, particularly structural equation modeling, make strong realist assumptions about traits (e.g., Song, 2008). Work into the design of scoring models also assumes that performance in domains of interest can be described in terms of relevant generalizable traits. For example, Fulcher et al. (2011) arrange observable variables from the analysis of service encounters into clusters under the trait headings of “discourse competence” and “pragmatic competence.” It is assumed that these “competencies” exist, and that they are manifested through their associated observable variables. Most current test development activity also takes place within a realist framework (Mislevy & Yin, 2012).

Constructivism

Constructivist research takes a number of forms. One trend is the description of language use, particularly investigating locally “co-constructed” interaction between participants in speaking tests (e.g., Brooks, 2009). Another area of interest is the description and assessment of second language pragmatics (Roever, 2011). There is always a strong fairness agenda in constructivist writing, with advocacy for those who are marginalized. This can be combined with test analysis techniques such as differential item functioning to discover if tests discriminate against subgroups (McNamara & Roever, 2006). Where constructivists excel is in carrying out case studies of the social use of tests, unmasking policy agendas behind test use, and investigating the construction of identities through competing discourses (Shohamy, 2001). Constructivist research in this vein helps maintain the conscience of the field by asking difficult questions about contingent constructed ideas.

As constructivists are inherently distrustful of tests and the motivations of their developers, there is little research into “constructivist test development.” The one exception is dynamic assessment (DA). Set within a sociocultural theoretical framework, DA uses assessment to scaffold language acquisition, and so is concerned with change (Fulcher, 2010, pp. 72–7). As each use of DA is considered a unique encounter, the preferred method of research is the individual case study, which cannot be generalized to any other case (Lantolf & Poehner, 2011).

Instrumentalism

Research within this tradition is concerned with establishing and following appropriate procedures, because reports of what was done count as validity evidence

(Chapelle, 2008, p. 320). While there will be variation of content according to purpose, procedures are generic. These are a useful addition to our validation tools. The second area of expansion is in the development and application of argument models to language-testing projects (Chapelle, Enright, & Jamieson, 2008; Bachman & Palmer, 2010) that expand and put into practice the work of Kane (2006a), which in turn depends upon Toulmin. The quality of argument is critical because claims are evaluated in terms of the warrants and backing brought to bear (Toulmin, 2003, pp. 15–16). Proper procedure and good argumentation are central to validation in the absence of ontological claims.

Challenges

Realism

Realism needs strong testable theories, which it is generally acknowledged do not exist in psychology or language testing even by real realists (Borsboom, 2006b, pp. 464–5). Closely related to this problem is the fact that “traits” in language testing are not separate from the individuals in whom we posit their existence; even if we can claim that traits like “discourse competence” or “fluency” really exist, separating out their effect on measures is simply not as easy as in the natural sciences. Perhaps the most intransigent problem in all social science research is that the researcher interacts with and changes the subjects of the research, both as a result of the research methods, and by naming traits (value labels in Messick’s terms). In short, there is a genuine problem not only with reference but also with defining and operationalizing traits (Fulcher, 2010, pp. 32–4), and this may be the most significant reason why social science theories have not lead to research programs that are as successful as those in the natural sciences.

Constructivism

The first problem is that constructivist research is ideologically driven. Those committed to a Foucaultian reading of the use of tests will see evidence of struggle and marginalization in any data they collect. In principle, there is no data that could falsify a priori beliefs. The second problem is concerned with what is constructed. Hacking (1999) argues that constructivism is useful as a tool to investigate “ideas” that are abstractions of observables and reified within a matrix of facts and relations. In language testing, such an “idea” would be “the native speaker” (Davies, 2003). Individual native speakers exist, and are not problematic. We manage to classify them accurately despite dialects and idiolects. But once we extract the idea of “the native speaker” it becomes a political, social, and problematic thing; and we know that it is used for political purposes, including in some cases weaving it into a matrix that relates it to territory and citizenship. However, critical social tools are not appropriate for the analysis of objects in the real world, theoretical terms, or “elevator words” like “knowledge” or “reality.” We do not construct people, trees, quarks, or (in the case of elevator words) everything. That would be to reduce the world to mere mental states (without individuals in which to reside).

Perhaps the most disturbing aspect of the strain of constructivism that has most influenced language testing is the deep pessimism about the world and its institutions. Everything is seen as evidence of conflict and there is no way out. Fulcher and Davidson (2008) constructed an imaginary dialogue between Mill and Foucault to tease out these problems. Mill was an optimist, so when he wrote about testing he saw it as helping to create personal development which would support the introduction of universal suffrage. For Mill we make progress through personal and social development. For Foucault there is no escape from despair, and tests will forever be instruments of oppression.

Despite the problems associated with constructivism it has served a useful purpose in drawing our attention to the very real misuse of tests. It is a legitimate enterprise to describe and critique the political contexts of test use (Fulcher, 2009), and to build explicit intended effects of tests into test development. However, the overarching ambitions of constructionism have also had a negative impact that needs to be critiqued—preferably before constructionism itself is taken for granted.

Instrumentalism

The only test of success in instrumentalism is the utility of a belief, practice, or test to improving life and furthering our projects. While engagement with data is important, it is accepted that all our theories are underdetermined, and hence no single explanation is “true.” This does not matter, however, as long as we have an assessment process that proves to be useful for making decisions with reasonable accuracy. Perhaps the major criticism to be directed at instrumentalism is its lack of ambition. It has given up on the larger questions of truth (just what is the nature and structure of language knowledge and ability for use in a specified domain?) in return for a purely epistemological solution to a practical problem.

This is not a new problem for instrumentalism, and neither is the standard response. Dewey (1912) argues that truth is wrapped up with the notion of “social credit,” or what works to improve the human condition:

I should say that as method for philosophy it indicated a more severe intellectual conscience; less free and easy use of the concept of Truth in general and more careful use of truths in particular to designate such conceptions and propositions as have emerged successfully from the test conditions that are practically appropriate. (Dewey, 1912, p. 80)

If this is accepted as a defence, then consequences become paramount. They are not optional to the development of the technical processes and argumentation, and cannot be relegated to an afterthought. However, recollecting Laudén’s argument for instrumentalism over realism, we must remember that, despite the practical success of miasmatic theories of disease, they were wrong. Without the noncontingent (true) explanation, we would not have been able to develop modern vaccines.

Future Directions

Bachman (2006, p. 200) correctly suggests that many studies do not succeed in clearly combining philosophical approaches. We should add that frequently they do not articulate their own philosophical assumptions, and some are internally incoherent. Even when they do articulate assumptions there can be less clarity than is sometimes required. This is the case, for example, in Fulcher and Davidson (2007), where there is some sliding between classical and modern pragmatism, which has led some readers to (mistakenly) assume that the text has a postmodern agenda. Researchers also need to be aware that while some combining is possible there are areas where assumptions are incommensurable. It is a disservice to the field to paper over the fault lines, for it is only in disagreement and healthy debate that progress is made (Mill, 1859/1998, p. 25).

The first important question for the future relates to the nature of our constructs/traits. Unless there is some general consensus, it appears that the field will follow three separate agendas. I will start by making explicit what is implicit in the preceding discussion—that the constructivist position is both confused and untenable in this respect. If everything is constructed and contingent, from processes to traits, our project is lost from the start.

The rest of the problem may be tackled by recourse to classical pragmatism. Pragmatism was defined by Peirce in Baldwin's dictionary (1902/1998, p. 300) as:

The opinion that metaphysics is to be largely cleared up by the application of the following maxim for attaining clearness of apprehension: "Consider what effects, that might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object".

This could easily be misinterpreted as an instrumentalist position, and was construed as such by later pragmatists such as William James. However, Peirce applied the maxim primarily to the notion of objects and constructs. The example he provided in the original 1878 formulation of the pragmatic maxim was the construct of "hardness," which manifested itself in the effect of the application of the construct, such as observing (and predicting) that a diamond will cut other materials, but not vice versa. This, he said, was to "insist upon the reality of the objects of general ideas in their generality" (1902/1998, p. 302). The construct of "hardness" is therefore "real" because of the practical consequences that flow from its definition and meaning.

In classical pragmatism, therefore, an abstraction is defined as a generalization of experience, labeled with an abstract noun. An example from the language-testing literature might be "fluency," a term given to a range of linguistic and processing features that we may experience and describe (Fulcher, 1996). Peirce (1903, p. 134) would ask under what circumstances such an abstraction can be real, and answers: "according to the pragmatic maxim this must depend on whether all the practical consequences of it are true." Next, he asks what kind of thing such an abstraction is:

What kind of being has it? What does its reality consist in? Why it consists in something being true of something else that has a more primary mode of substantiality. Here we have, I believe, the materials for a good definition of abstraction. (1903, p. 134)

In the case of fluency, the abstraction consists of a set of primary “substances” (in Peirce’s terms), which may include features such as speed of delivery, pausing (for content planning at syntactically appropriate slots), hesitating (causing syntactic disjunct), and so on. Peirce continues to a definition: “An abstraction is a substance whose being consists in the truth of some proposition concerning a more primary substance” (1903, p. 135). If the categories of “fluency” described in Fulcher (1996) can be observed, and if they vary in ways predicted (North, 2007, p. 657, found independently that the fluency descriptors were the only consistent set capable of acting as anchors in the construction of the CEFR), the abstraction is true, even though its name is conventional. Finally, Peirce (1903, p. 134) insists “*reality* can mean nothing except the *truth* of statements in which the real thing is asserted.” According to this treatment it is arguably the case that “fluency” is a trait that has the property of being real (although it is questionable how “real” it remains if reductionist strategies are employed for the sake of automated scoring or research, as in the case of Bernstein, Van Moere, & Cheng, 2010, p. 362), just as hardness and weight are real because of their practical consequences.

The pragmatist strategy therefore avoids the need for a strong correspondence theory of truth that is required by the “real realists” on the one hand, while incorporating the instrumentalist arguments supported by relevant empirical data on the other. It steers a course between extremes, incorporating the advantages of each, while mitigating the challenges.

Research agendas within such a framework could lead to substantive validation programs. This would have practical consequences; as Laudan (1981b, p. 145) says: “the aim of science is to secure theories with a high problem-solving effectiveness” and language testing is a problem-solving activity.

The second way forward is to re-engage with a progressive Enlightenment agenda that incorporates consideration of consequences, but without ideological baggage. All fields evolve, and for the most part advances are made through incremental theory building, empirical research, and conceptual development. Theory in natural sciences evolves as well, and each stage has allowed humans to manipulate their environment in predictable and successful ways in order to achieve more than had previously been possible. This is also true of language testing and the validation process. Karl Popper referred to this as verisimilitude, or the *approximation* of a theory to truth. Peirce (1877/1998, p. 155) held a similar view:

This great law is embodied in the conception of truth and reality. The opinion that is fated to be ultimately agreed to by all who investigate, is what we mean by the truth, and the object represented in this opinion is the real. That is the way I would explain reality.

Advancement requires a critical, collaborative profession, prepared to argue cases and abandon them when necessary. Peirce and Mill both knew that the cycle of

progress would be endless. Scientific inquiry does not lead to the discovery of “Truth” with a capital T, but makes genuine progress by not being wrong. A better language-testing future cannot be built on a static or ideological view of society, individuals, or trait definitions. It needs an optimistic agenda of expanding our knowledge, and learning how to build better tests in the service of meritocratic and just decision making.

Cognition and Language Assessment

James E. Purpura

Teachers College, Columbia University, USA

Introduction

Just like learning a second or foreign language (L2) or using it to communicate in naturalistic contexts, performance on L2 assessments is an enormously complex endeavor, involving multiple interacting elements that can impact not only the scores examinees receive (Bachman, 1990), but also the kinds of feedback they might be given. Some of these interacting elements include: the nature of the L2 being learned; the typological distance of the L2; the examinees' L2 knowledge, ability, and skills; their background attributes; their social (e.g., age) and psychological characteristics (e.g., anxiety); the task characteristics; and, of critical concern for the current chapter, the cognitive mechanisms that underlie L2 performance in assessment contexts. Given the contribution of these factors to score variability, it is essential that cognitive variables be considered in the design and development of L2 assessments, as well as in the interpretation and use of assessments as meaningful indicators of L2 learning or proficiency.

L2 testers' interest in the cognitive mechanisms underlying performance on L2 assessments stems from validity concerns related to the extent to which assessment tasks engage examinees, mentally, in ways that are congruent with the intended test construct (i.e., construct-relevant variance) (Messick, 1993). For example, if an assessment purports to measure an examinee's ability to make inferences about implied meanings on a reading passage, then we need to show that examinees do indeed need to make passage-related inferences to respond correctly, instead of relying on test-wiseness or background knowledge (i.e., construct-irrelevant variance). Similarly, if examinees must synthesize information from source materials on a writing task, we need to determine, perhaps through verbal protocols, that successful performers actually use synthesizing strategies, and that unsuccessful performers do not. In short, the link between the

assessment construct and the mental processes engaged in by examinees during performance is critical to the meaningful interpretation and use of assessment information.

The interest in the cognitive mechanisms of L2 performance on assessments stems also from validity concerns related to the internal structure of assessments (Messick, 1993) and to the extent to which score variation on these assessments depends upon both the components of the mind's cognitive architecture (e.g., attention, perception, short-term memory or STM, working memory or WM, and long-term memory or LTM) and the functions of these components (e.g., input processing, executive processing, fluid reasoning) in thinking, learning, and task performance (i.e., cognition). For example, an examinee asked to write an essay based on a graph might have high levels of L2 proficiency, but no experience of translating visual input on graphs (i.e., visual processing) into a coherent set of inferences (i.e., fluid reasoning) about some topic. As a result, she performs poorly. If the complex cognitive skills engaged in graph interpretation were not intentionally a part of the intended test construct, then score-based inferences from this assessment would be strongly influenced by the cognitive demands of graph interpretation, thereby casting doubt on the validity of the assessment.

L2 testers are further interested in the cognitive characteristics of test performance due to concerns related to the extent to which mental mechanisms account for differences in score meaningfulness across relevant subgroups or across different assessment conditions. In other words, what role do the components of cognition (e.g., attention, memory, experience) play in how examinee groups process assessment input, organize responses mentally, and generate successful responses? For example, a performance assessment given to different age groups (8- to 11-year-olds) might find variations in L2 performance to be more a reflection of developmental differences in attention span, WM, or test experience than a reflection of L2 knowledge. Or response analyses might show that high performers have acquired specialized representations of L2 knowledge, associated with specific problem-solving tasks (e.g., avoiding trial-and-error solution strategies), and this allows them to respond to problems more efficiently than low performers.

Finally, L2 testers are interested in how performance scores are affected by rater cognition, since score variation is not only a function of examinee performance but also a function of the rater's ability to compare mental representations of examinee responses with their own representations of some intended response, linked to a scoring rubric (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 1999). This highly complex cognitive skill has led several testers to investigate the processes that judges engage in while scoring performance and the effects that these processes have on consistent score assignment. In short, studies of rater cognition can potentially provide critical evidence for the interpretation and use of assessment information.

Given the important role that cognition plays in L2 assessment, the current chapter looks at the cognitive mechanisms governing performance on L2 assessments. I will describe several approaches to how cognition in L2 assessment has been conceptualized over the years. I will then present several strands of research

in L2 assessment related to the cognitive component. Finally, I will highlight challenges and describe new directions in addressing the cognitive component of L2 assessment.

Previous Approaches to Cognition and Language Assessment

The Factorial Approach to Cognition and Language Assessment

In an ambitious attempt at describing L2 communication, Lado (1961) described proficiency in relation to the linguistic resources of L2 knowledge (e.g., semantics, syntax, phonology) and the cognitive resources needed to use this knowledge in ordinary conversation. Drawing on structural linguistics as a theory of language, Lado depicted L2 proficiency as a discrete and finite set of elements (e.g., phonology, structure, lexicon), occurring within the four skills. These elements were thought to constitute a unique system for individual languages, even when languages were typologically similar (e.g., Sicilian, Italian). This skills-and-elements depiction of L2 proficiency assumed, from a cognitive perspective, that proficiency was achieved by internalizing simple, discrete components of the L2 before acquiring more complex units, acquisition being mediated by the distance between the native and target languages. These beliefs gave rise to a discrete-point approach to L2 assessment, where discrete linguistic elements are assessed within the different skills, scored for accuracy, and aggregated to produce an overall proficiency estimate.

Lado's assumptions about proficiency drew on behaviorist theories of learning. In his view, L2 success was attributed to imitation, repetition, practice, feedback, and feedback rewards designed to create linguistic habits, which served to free up attentional resources for communicating messages and attitudes— notions that still resonate for those interested in attention, memory, and automatization. He also believed that learning transpired in stages, basic forms or lexis being acquired before syntax and linguistically accurate communication. Finally, he credited successful performance to the beneficial or negative effects of L1–L2 transfer. In sum, Lado explained proficiency outcomes in terms of *external factors* from the environment, such as classical conditioning or L2 distance, rather than in terms of internal cognitive structures, thereby taking a *factorial approach* to characterizing cognition and L2 assessment.

Carroll (1961) also depicted L2 proficiency in terms of the individual linguistic elements engaged while performing the language skills, claiming that a focus on the individual components was particularly important when the assessment goal required fine-grained information. In addition, Carroll (1968) highlighted the importance of integrated L2 performance, where the discrete components worked together to contribute to proficiency. This led to an *integrative approach* to L2 assessment, where interacting elements of L2 knowledge in L2 use are assessed and scored with a rubric.

Carroll (1968) subscribed to a differential perspective of knowing and learning, characterized by assumptions of how examinees possess varying amounts of a trait,

such as speaking ability. Scores on performance tasks then reflected not only knowledge of individual components like phonology, lexis, morphology, and syntax, but also the integration of these components in language use—for instance in speaking. L2 proficiency was then characterized as a series of inter-related habits related to the individual linguistic components (“acquired stimulus–response mechanisms”) and explained with reference to constitutional variables (e.g., genetics), experiential variables (e.g., the learning environment), L1–L2 transfer, and motivation. From a cognitive perspective, Carroll attributed differences in L2 knowledge and integrated performance to (1) the speed of the response, (2) the diversity of the response, (3) the complexity of information processing, and (4) the examinees’ awareness and knowledge of the grammatical features of their L1. Interestingly, Carroll described the “complexity of information processing” of the language components in terms of abstract reasoning ability, or an ability to process linguistically complex information. However, these terms were never elaborated upon.

Both Carroll and Lado took a *factorial approach* to characterizing cognition and language assessment. They viewed cognition and assessment as separate, but inextricably related. They attributed proficiency to behaviorism and other factors affecting performance (e.g., L1–L2 distance), as well as to underlying cognitive mechanisms scantily understood at the time. Their views influenced how assessments were designed and developed (i.e., their division into discrete-point/integrative) and how assessment results were interpreted with respect to acquired habits, transfer, and other factors.

The “Learner Strategies” Approach to Cognition and Language Assessment

Drawing on advances in cognitive psychology in the 1970s and 1980s, several L2 testers (e.g., Cohen & Aphek, 1979) became interested in the internal mental processes that successful and unsuccessful examinees used to produce responses on different types of L2 assessments (e.g., reading) and on different task types (e.g., cloze). Information on these processes was obtained by asking learners to verbalize the “strategies” (i.e., the thoughts and behaviors) they reported using to respond to test questions, or by asking them direct questions about their strategies. The information uncovered from this research was used to ascertain if indeed the metacognitive, cognitive, affective, and test-management strategies invoked by examinees were relevant (or irrelevant) to the intended test construct. The reports were then used as documentation for test validity or as a basis for refining assessments.

The approach to uncovering examinee thoughts and behaviors during assessment produced long lists of strategies, which were subsequently categorized and used for characterizing strategy use. For example, Cohen (2011) compiled a list of strategies that examinees reported using while taking multiple choice (MC) tests of reading comprehension. The strategies fell into two clusters: (1) test-taking strategies related to language use (e.g., read the passage first and make a mental note of where different kinds of information are located); and (2) test-taking strategies relating to test-wiseness (e.g., use the process of elimination) (p. 230). In a more recent study of examinee strategy use, while taking the TOEFL (Test of

English as a Foreign Language) listening test, Douglas and Hegelheimer (2007) reported several strategy types for approaching the response task (e.g., making a hypothesis about a likely answer), and five strategy types depicting reasons for selecting a response option (e.g., the specific details in the option matched the details in the listening text).

This *learner strategies* approach to characterizing examinee responses from a bottom-up perspective has been useful in identifying isolated strategies or clusters of language use and test-wiseness strategies. However, the approach is purely descriptive, based on student self-reports, and largely atheoretical in that strategy use is not referenced to a theory of learning or of human cognition. Therefore it is difficult to discern how these strategies relate to processing or how they are collectively linked with success on tests. Nonetheless, this work provides a compelling glimpse into the behaviors that examinees reported using as they respond to test items and item types.

The Strategic Competence Approach to Cognition and Language Assessment

At approximately the same time, Canale and Swain (1980) discussed the theoretical bases of L2 teaching and testing in a study in which they described a comprehensive model of communicative competence, consisting of three main components: (1) grammatical competence, (2) sociolinguistic competence, and (3) strategic competence. They defined “strategic competence” in terms of “communication strategies”—that is, as “the verbal and non-verbal communication strategies that may be called into action to compensate for breakdowns in communication due to performance variables or to insufficient linguistic competence” (Canale & Swain, 1980, p. 30). They viewed “strategies” as actions or behaviors that individuals use to reconcile communication problems linguistically. For example, a learner unaware of the word *knowledgeable* might decide to coin a new word, *knowledgeful*, to maintain communication; or a learner might use a clarification strategy (“you mean *knowing about it*, right?) to *compensate* for lack of comprehension. More specifically, these strategies were readily observable in analyses of learner introspective data (Cohen, 1984).

Canale and Swain (1980) characterized compensation strategies as linguistic resources for handling problematic communication rather than as manifestations of underlying cognitive processes. They also claimed that the psychological factors associated with communication (e.g., memory, perceptual strategies) were *not* a component of a learner’s communicative competence *per se*, but were an attribute of interactive performance. Later, Canale (1983) extended their definition of strategic competence as compensatory strategies to include linguistic strategies used in all kinds of interaction; these were referred to as *interactional strategies*.

In identifying strategies used in problematic communication, Canale and Swain took a *strategic competence approach* to cognition and assessment. Furthermore, while it may not have been their intention, this approach highlighted cognition, alongside others areas of competence, as a critical component of L2 competence.

Finally, in the context of assessment, Canale and Swain maintained that performance tasks should be designed to capture the examinees’ L2 knowledge as

well as their strategic competence. To this purpose they recommended the use of performance tasks, since they require learners to integrate different knowledge components with little time to reflect upon and monitor their language input and output (Savignon, 1972).

Building on the work of Canale and Swain (1980), Bachman (1990) characterized communicative language use in terms of a learner's communicative language ability, which consisted of three broad components: language knowledge (i.e., organizational knowledge and pragmatic knowledge),¹ strategic competence, and psychophysiological mechanisms of expression. Bachman (1990) referred to "strategic competence" as the set of mechanisms by which strategies are used in communication. Bachman's conceptualization of strategic competence draws on the work of cognitive psychologists (e.g., Clark & Clark, 1977), and on Faerch and Kasper's (1983) psycholinguistic model of speech production. This model describes oral production as consisting of a planning phase and an execution phase. The *planning phase* depicts how learners assess the communicative situation by considering their communicative goal and the communicative resources they have to reach this goal. The *execution phase* depicts how learners draw on neurological and physiological resources to produce utterances designed to resolve communicative problems.

Bachman (1990) extended Faerch and Kasper's (1983) depiction of strategic competence in oral production to include strategies in instances of *all* language use. He also broadened the model to include an *assessment phase* of strategy use alongside the planning phase and the execution phase. In Bachman's conceptualization of strategic competence, an examinee might be asked on an exam to describe a defining moment in her life. She first mentally assesses, in light of her available grammatical resources, the information she needs for telling a story (the assessment phase). She then uses topical information and grammar to formulate a mental plan for the story (planning). Finally, she uses psychophysiological mechanisms to tell the story in real time (execution).

More recently, Bachman and Palmer (2010), drawing on Sternberg's (1988) triarchic theory of intelligence, characterized strategic competence as "higher-order metacognitive strategies that provide a management function in language use, as well as in other cognitive activities" (p. 48). They operationalized strategic competence with the help of three metacognitive strategies: (1) *goal-setting* (deciding what one is going to do); *appraising* (taking stock of what is needed, what one has to work with, and how well one has done); and *planning* (deciding how to use the resources one has) (p. 49).

Bachman (1990), and later Bachman and Palmer (2006, 2010), argued convincingly that strategic competence influences test score variation, stating that test performance is not only a function of the examinee's L2 knowledge, but also a function of the cognitive demands of the task. For example, a listening item requiring examinees to understand information explicitly stated in the text might be considered easier than a listening item requiring examinees to write a summary of a graph. This might be justified by evidence that the two students with similar scores on other test tasks performed differently on the graph summary. Also, when interviewed about the strategies used to answer the graph summary, one student might report having a lot of experience with summarizing graphs, thereby

displaying a well-organized set of strategies for this task. The other might report no such experience. Thus strategic competence would surely be considered an integral part of the measured construct for this task (L2 knowledge and strategic competence), even though it might not have been intended that way.

In sum, Bachman and Palmer took a *strategic competence approach* to characterizing cognition and language assessment. They highlighted the importance of metacognition and its role in regulating how examinees set goals, formulate plans, and appraise their work. The idea of the importance of metacognition and of its ability to regulate action has endured: today metacognition is considered a crucial component of effective, flexible thinking and competent performance. Bachman and Palmer's work has since inspired many researchers to investigate the kinds of strategies examinees use on language tests and their relationship with performance.

The Cognitive Processing Approach to Cognition and Language Assessment

While the strategic competence approach to cognition clearly accounted for the regulatory or metacognitive processes in information processing, this approach represented only one set of cognitive activities underlying L2 performance—executive processing. In other words, the strategic approach accounted for *thinking* strategies such as *deciding* to use repetition in order to retain information in STM (a metacognitive strategy), but it did not account for *doing* strategies such as *using* repetition to retain information in STM (a cognitive strategy). By excluding the cognitive strategies, the strategic competence approach ignored other mental processing components critical to L2 test performance. According to Dehn (2008), such components are phonological processing (the encoding of phonemes), auditory processing (the ability to perceive, analyze, synthesize, and discriminate auditory stimuli), visuospatial processing (the ability to perceive, analyze, synthesize, manipulate, and transform visual patterns and images), and so forth. In other words, cognitive processing certainly includes metacognition, but it also characterizes how the human mind perceives new information and transforms it into meaningful representations (*encoding*), holds information so it can be stored (*retention*), and activates and accesses the information when needed (*retrieval*), so that a response can be mentally organized (*response preparation*) and produced in task completion (*response generation* or *output production*). Each stage in this sequence constitutes a different mental representation and may short-circuit comprehension, production, or in fact learning. Thus the strategic competence approach failed to account for the different stages of, and for the processes associated with, comprehension or production; it also ignored the role that attention, memory capacity, and processing speed might play in L2 test performance.

An early attempt to define test-taking behaviors within a cognitive-processing approach to cognition was Oller (1979). Influenced by Carroll's notion of integrative tests involving both linguistic and cognitive factors, Oller (1979) rejected the notion that L2 proficiency involved only the accumulation of individual components of language, arguing instead that L2 proficiency involved the integration of these elements in L2 performance. He also maintained that L2 proficiency was

intrinsically involved in the ability to make moment-by-moment predictions about what an interlocutor was likely to understand or say in interaction, especially in context-reduced situations. He further claimed that the capacity to make such predictions involved perceptual processing, since the interlocutor had to process incoming input and to predict future output. Thus the integration of several linguistic resources to predict meanings in context-reduced situations was the basis of Oller's "pragmatic expectancy grammar." It also justified his notion of L2 proficiency as a unitary, general factor consisting of integrated L2 knowledge and perceptual processes—a view supported by Hymes (1972) and Jakobovics (1970) and still debated in the psycholinguistic literature.

Oller's notion of "pragmatic expectancy grammar" was a departure from behaviorism in favor of *perceptual processing* as an approach to understanding the mechanisms underlying assessment. Rather than focusing on the accumulation of discrete elements, he explained "pragmatic expectancy" in terms of the grammar and perceptual processes needed to enable individuals to make predictions and inferences about meaning conveyance during language use. His ideas about cognition were influenced by Neisser's (1967) work on perceptual processing, where an individual decodes and analyzes input by creating syntheses of intended meanings, which are later confirmed in interaction.

Thus Oller (1983) took a cognitive-processing approach to characterizing cognition and language assessment. While his ideas about the full integration of L2 knowledge and perceptual processing in a model of proficiency were eventually rejected, his approach to cognition provided an early glimpse into how processing theory might explain the mechanisms underlying test performance. Unfortunately he did not elaborate on how to capture processing information in L2 tests, aside from recommending integrative test tasks.

Influenced by the strategy research in L2 assessment (Bachman, 1990) and pedagogy (O'Malley & Chamot, 1990), Purpura (1997) endeavored to investigate the relationships between cognitive processing and test performance. Adopting a cognitive-processing approach, he first examined the links between metacognitive and cognitive strategy use and the different stages of human information processing, and then investigated the relationships between these processes and L2 test performance. Before describing this research, let's review what information processing is.

Information processing refers to how humans use the mind's cognitive architecture (i.e., mainly, WM and LTM) to control how information flows and is processed from sensory input to storage, access, and retrieval from memory structures for the generation of a response to a task (Gagné, Yekovich, & Yekovich, 1993). Early models of information processing identified the following types of processes: selective perception, decoding/encoding and storage, retrieval, response organization, and executive control (i.e., metacognition)—as seen in Figure 86.1.

Let's examine this model with a listening item on a test passage designed to measure an examinee's ability to understand the stages of the desalination process (i.e., a successive processing). The examinee hears a brief monologue about the process of desalination (input), followed by a question (more input) such as: *After the brackish water is heated, what happens to the water?* To process the input, s/he needs to properly hear and attend to the input (sensory receptors and attention

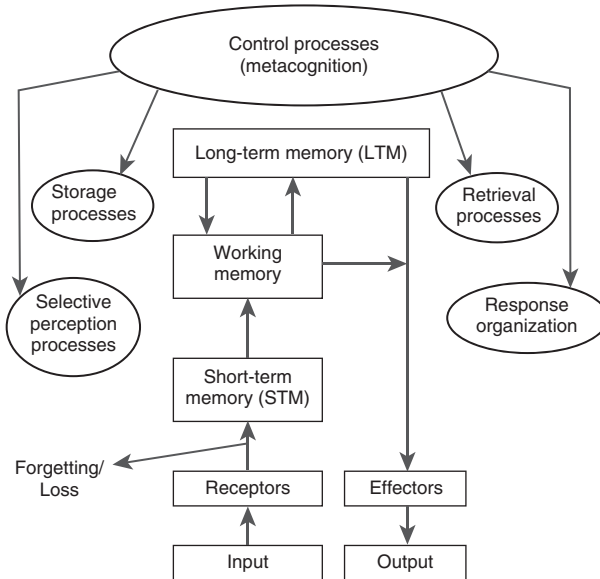

Figure 86.1 Basic components and processes of information processing. From Gagné, Yekovich, & Yekovich (1993), p. 40. ©HarperCollins College Publishers

control). This information is then held briefly in STM, where selective perceptual processing of speech-like, visual, and spatial information begins. In other words, information in the input is held long enough, so that phonological and auditory processing can begin in WM. At the same time, extraneous information in the input and other thoughts are ignored (inhibition), so that the focus of attention can be maintained. In WM sounds are parsed, decoded for meaning through interaction with knowledge structures in LTM such as L2 knowledge and topical knowledge structures (encoding), and held for further processing (storage). If the examinee already knows something about desalination, the information in the passage and the question are likely to be easier to retain in WM. The examinee then needs to match the information in the passage and the question with information in LTM, so that s/he can retrieve the appropriate information (retrieval), organize a response mentally (response organization), and respond to the question through the effectors (output). In sum, information processing is seen as a mental and neurological process in which the mind controls the information flow through a series of sequential operations.

Purpura (1997) used Gagné et al.'s (1993) model of cognition to propose a taxonomy of cognitive competence in which metacognitive and cognitive strategy use are directly aligned with the stages of information processing. In this taxonomy, *metacognitive strategy use* was conceptualized as metacognitive processes operationalized by *thoughts* associated with (1) assessing the situation (e.g., planning or goal-setting strategies), (2) monitoring performance as it occurs, (3) evaluating performance after the fact, and (4) mentally testing one's performance. *Cognitive strategy use* was characterized in terms of four underlying processes operationalized by *actions* associated with (1) attending (e.g., focusing),

(2) comprehending input (e.g., clarifying, verifying, analyzing inductively), storing/memory (e.g., associating, repeating, rehearsing, summarizing, applying rules, transferring from L1 to L2), and retrieval/using (e.g., transferring from L1 to L2, inferencing, linking with prior knowledge, applying rules, practicing naturalistically). This taxonomy was used to construct and validate an 80-item questionnaire designed to measure metacognitive and cognitive strategy use (Purpura, 1997).

Purpura administered this questionnaire, together with a 70-item test of L2 grammar/vocabulary and reading, to 1,382 examinees in order to investigate the underlying cognitive processes of L2 test performance. He found that the cognitive and metacognitive processes in these questionnaires were generally well measured by the strategy types and that some strategies measured only one process (e.g., "repeating/rehearsal strategies" seem to be strong indicators of the memory/storing processes), whereas others measured several processes (e.g., "applying rules" might be used to understand input, to remember or store it, or to retrieve it from LTM during test performance). The study also showed that the cognitive processes were highly correlated. Finally it was found that examinees use metacognitive processes to control cognitive processes, which appear to be directly responsible for guiding the performance. This study provided clear empirical justification for including both metacognitive and cognitive processes in a model of cognitive competence.

To illustrate, imagine that an examinee rereads her essay and finds a grammatical error (metacognitive strategy), so she decides to revise it (metacognitive strategy). This decision makes her access her L2 knowledge to correct the error (cognitive strategy). This examinee's ability to use metacognitive processes to drive cognitive actions appears to make her more likely to perform well on L2 tests. In contrast, imagine the performance of an examinee who does not take the time to look over her work (metacognitive strategy), or who begins writing a story (cognitive strategy) without formulating a plan (metacognitive strategy).

Purpura (1997, 1998) took a clear cognitive-processing approach to characterizing cognition and language assessment. His work demonstrated that specific clusters of strategies were indeed associated with the different stages of processing. In other words, an inferencing strategy could be invoked at the comprehending stage of processing (e.g., inferencing to *understand*), at the storing/memory stage (e.g., inferencing to *remember*), and at the retrieval/using stage (inferencing to *retrieve, organize a response, and use in a response*). Purpura's work also showed that metacognitive processes strongly regulated the choice of cognitive processes, which in turn affected performance.

The Social Approach to Cognition and Language Assessment

The cognitive processing approach to cognition and assessment focuses on the contents of an individual's memory and its role in how examinees process L2 information on tests so as to be able to generate responses in relation to some task. This approach highlights the thinking processes underlying L2 performance, which individuals resort to in order to complete assessment tasks, whether or not interaction with other interlocutors is required.

The social approach to cognition and language assessment assumes, however, that performance on L2 tests is a social activity, taking place in sociocultural context, where individuals in interaction share a mental space by jointly participating in the co-construction of meaning, knowledge, and complex thinking (e.g., problem solving, decision making, argumentation, exploration, explanation, extrapolation). The co-construction of performance may transpire between two examinees in talk, between examinee and rater, or even between examinee and writer (McNamara, 1997). Cognition in the social approach is seen as socially distributed. For example, when examinees are asked to solve a problem, their interaction is a manifestation of how they jointly attend to, understand, and transform the information into various representational states in order to generate a joint solution. Therefore, from the social perspective, assessment involves observing and analyzing how examinees use language and other artifacts (e.g., pencils, paper) to solve problems.

Probably the best example of assessment from a social approach angle is dynamic assessment (DA). Rooted in a sociocultural theory (SCT) of mind (Vygotsky, 1978), DA refers to an interactive approach to assessment (especially in instructional contexts) in which an assessor intervenes during the course of assessment so that learning gaps can be closed and mental processes for efficient problem solving can be promoted. Examinees are also evaluated on their ability to respond to interventions. This approach assumes that self-regulated or autonomous learning is *mediated* (assisted) through language, especially in the form of interaction with a more capable speaker, and through other artifacts (e.g., books). Mediation by a more capable person (an assessor) is assumed to lead to the *internalization* of new information, higher levels of functioning, and eventually a change in the interactive quality of assistance (Lantolf & Thorne, 2007). In short, this approach, while focusing on the social dimension, acknowledges that interaction can produce cognitive development. Poehner describes internalization as follows:

In SCT, the development of higher forms of consciousness, such as voluntary control of memory, perception and attention, occurs through a process of internalization whereby these functions initially occur as interaction between human beings but are then transformed into cognitive abilities with the result that “the social nature of people comes to be their psychological nature as well.” (Poehner, 2008, p. 5)

Internalization is facilitated by the ability of examinees to *imitate* how other humans perform activities. Finally, DA takes stock of the examinee’s actual developmental level, observed in problem solving in relation to his/her potential level of development with respect to some learning gap, assuming mediation. While DA has not gained much traction in L2 assessment, this approach holds great promise, in my view, for informing teachers about the nature of scaffolded development deriving from an examination of dialogic interactions between class participants during unplanned, spontaneous assessments.

Finally, most L2 testers would agree that the social dimension of L2 performance, especially as this performance relates to tasks that require interaction, is a critical area of consideration. Most would also agree that examinees, being required to perform complex cognitive tasks in paired assessment activities, engage in an

intricate web of shared L2 ability and distributed cognition—and this is emblematic of real-life participatory practice. However, I would argue against a uniquely social approach to cognition and language assessment just as I would against a uniquely cognitive approach; I would favor in these instances a *sociocognitive approach* to cognition and language assessment.

In other words, individuals have the ability to process input, to reason, and generate meaning alone, in nonreciprocal and nonadaptive contexts, as is the case in many learning and assessment situations. These contexts highlight the need for metacognitive, cognitive, and perhaps affective strategy use. However, individuals also need to be able to process input, to reason, and to generate meaning in contexts that include the physical, virtual, or assumed presence of an interlocutor. In these situations the participants' L2 output and cognitive processing are conditioned, in a reciprocal and adaptive way, by the other's output in terms of propositional content, interactional features (e.g., turntaking), and their social characteristics (e.g., relative power, social distance). These contexts emphasize the need not only for metacognitive, cognitive, and affective strategy use, but also for interactional (e.g., turntaking) and social strategy use (e.g., cooperating), thereby making paired assessments cognitively more complex. In my opinion, a broad model of cognition and language assessment should embrace all the possible sociocognitive parameters.

In the next section I will review some of the empirical research on cognition and language assessment.

Current Research on Cognition and Language Assessment

Several researchers (Messick, 1993; National Research Council, 2001) have asserted the importance of cognitive models in characterizing test constructs, operationalizing test tasks, and generating inferences about examinees from performance, including inferences that support claims about thinking processes. In this section I first discuss studies concerned with the extent to which tasks on L2 tests engage examinees, mentally, in ways that are congruent with the intended test construct. I then examine research concerned with the degree to which cognitive factors on L2 assessments contribute to performance. A third set of studies address concerns related to the extent to which the cognitive component accounts for the variability of test performance across groups. Finally, I discuss studies of rater cognition and of its effect on score assignment. In each area of inquiry, researchers have adopted one or more of the approaches to cognition and assessment described above, with varying insights.

Cognitive Mechanisms Engaged During Task Performance

L2 testers have long been concerned with the extent to which tasks on tests engage examinees, mentally, in ways that represent the intended test construct—the assumption being that cognitive processes accessed in test performance should resemble those used in real-life tasks, just as the knowledge, skills, and ability needed to complete test tasks should mirror the proficiency needed for real-life

task completion. Evidence of how examinees arrive at their responses provides compelling support for the meaningfulness of test scores, especially as this relates to the cognitive processes intended by assessment tasks, but also due to the potential that this information holds for influencing test development.

Several studies have endeavored to examine the cognitive mechanisms engaged in during task performance. Most require examinees to perform a concurrent verbal protocol in which examinees, after training, are asked to verbalize the strategies they are using while performing some task (Cohen, 2011). Some studies also collect data retrospectively by asking examinees to review the recordings of the verbalizations in order to comment spontaneously on their verbal reports and to respond to specific questions. The data from these reports are then transcribed and coded according to some preliminary coding rubric, which is modified iteratively during the course of the analysis. The coding rubrics reflect the model of cognition referenced in these studies.

Early studies examining the mental processes of test takers while taking L2 tests took a *learner strategies approach* to cognition, as explained above. These studies often focused on the strategies examinees claimed to invoke while performing tasks representing different test methods. For example, MacKay (1974) investigated the strategies that L1 children used in taking a reading test and discovered a mismatch between the test input and the reasoning processes used to obtain answers related to test graphics. Anderson (1989) examined the reading strategies of L2 adults using a retrospective verbal protocol, and found that 47 strategies were reported. Similar studies examined the strategies involved in performing cloze tasks (Alderson, 1983), summarization tasks (Cohen, 1994), and other tasks. Finally, Cohen and Olshtain (1998) examined the strategies that advanced L2 learners used in producing oral speech acts. Using videotaped samples and retrospective verbal protocols with probing questions, they found that the examinees identified the speech act they needed to use, but often failed to plan out the language needed to communicate. When they did plan their speech act utterances, they did so in several languages. Finally, examinees used different strategies to search for linguistic forms, but they did not attend much to language. This study offered an interesting array of strategies used in oral production, but with no reference to how they related to a model of cognition or L2 proficiency.

A more recent study rooted in a learner strategies approach was performed by Cohen and Upton (2007). As part of the validation efforts of the Test of English as a Foreign Language (TOEFL), they examined the underlying response processes that examinees engaged in while responding to three reading item types of the LanguEdge Courseware (Educational Testing Service, 2002). More specifically, they used verbal reports to determine if examinees used academic reading skills rather than test-wiseness strategies to respond to (1) multiple choice (MC) items designed to measure *basic comprehension* and *inferencing*, and (2) multiple selection (MC) items intended to measure *reading to learn*. Their coding rubric contained: (1) reading strategies (e.g., “plans a goal for the passage”); (2) test management strategies (e.g., “goes back to the question for clarification”); and (3) test-wiseness strategies (e.g., “uses clues in other items to answer an item”). They found that examinees used several academic-like reading and test management strategies instead of test-wiseness strategies to perform the tasks. More specifically, the

authors identified several trends in the verbal protocols related to answering: (1) basic comprehension vocabulary items (e.g., jumping immediately to the word in the context of the passage before looking at the options, in order to try to get a sense of the word's meaning); (2) inferencing items (e.g., returning to the passage to look for clues to the answer); and (3) reading-to-learn items (e.g., reading the option(s) before going back to the passage).

Cohen and Upton's (2007) study supported the claim that the TOEFL tasks induced construct-relevant strategies to perform academic reading and test-taking skills, and it demonstrated that examinees used several strategies related to test management. However, as the study was not rooted in strategic competence or in a model of information processing, it is unclear how the reported strategies explained response processing other than through trends found in the data.

Other studies examining the mental processes occurring during test performance have adopted a *strategic competence approach* to cognition. In this approach researchers drew on one of the many strategy taxonomies (e.g., O'Malley & Chamot, 1990; Oxford, 1990; Purpura, 1997) to generate a list of strategy types (e.g., metacognitive, cognitive, social, affective, compensatory, test-wiseness). The verbal report data were then coded for these strategy types before further analyses were carried out.

For example, Barkaoui, Brooks, Swain, & Lapkin (2012), again as a part of the TOEFL validation efforts, investigated the strategic behaviors that examinees reported using while taking the TOEFL. They videorecorded response processes while examinees took the integrated and independent skills tasks in the speaking section of the test. Immediately after taking the test, each examinee watched the video and engaged in a video report through stimulated recall. The data were then transcribed and coded. With the help of a *strategic competence approach* to cognition, 49 strategies were identified, coded, and categorized as communication strategies, cognitive strategies, metacognitive strategies, and affective strategies on the basis of several taxonomies. Unfortunately no attempt was made to align these strategy types explicitly with a model of cognitive processing. Findings showed that the integrated tasks elicited a greater variety of strategies than did the independent tasks, and that strategies within a task type elicited clusters of strategies similar to those elicited across task types. Also, unsurprisingly, no relationship was found between the total number of strategies and the total test scores, since several studies had shown that test performance is not necessarily a function of the quantity of strategies used, but rather a function of the efficiency with which strategy clusters are used. Finally, this study raised several questions about the relationship between metacognitive strategy use and the other strategy types—results that, in my opinion, are an artifact of the study method.

Finally, other studies examining the mental processes occurring during test performance have adopted a cognitive-processing approach to cognition. Stemmer (1991), for example, examined the mental processes that examinees reported using while taking a C-test.² The C-test task is a problem-solving task thought to invoke both low-level processes like word perception and recognition and the higher-level processes of reading and comprehension. Unlike previous studies, which simply codified lists of strategies, Stemmer viewed strategies as "goal-oriented

and problem-oriented, conscious and unconscious behaviors” related to information processing. In other words, she used a cognitive-processing approach to examine task engagement by relating the strategic behaviors elicited in problem-solving tasks to the components of memory (STM, WM, LTM), and to how information is assumed to be processed in an information-processing model of cognition. She also discussed assumptions about how L2 knowledge is represented and stored in WM and retrieved from LTM during task engagement.

After training examinees in the verbal protocols, Stemmer (1991) audiorecorded the verbalizations of 30 participants completing a C-test. Immediately afterwards the examinee and the interviewer listened to the recording, while the examinee spontaneously commented on his response behaviors. The interviewer also asked questions. The C-test data were scored and submitted to quantitative analysis. The verbalization data were transcribed, coded, and submitted to logical task analysis and interpretive analysis. Stemmer (1991) found that, instead of measuring text comprehension, the C-test actually measured low-level processing through several local recall strategies. She also found that the task mainly measured propositions at the phrase or sentence level. Finally, the more difficult texts seemed to reduce the number of automatic retrieval strategies while increasing the overall number of strategies and confirming that processing for low-level examinees is much more complex than processing for high-level examinees (Purpura, 1998). This exemplary study used a clear cognitive-processing approach to examine cognition and language assessment.

Cognitive Mechanisms and the Internal Structure of L2 Assessments

Besides examining the mental mechanisms of task engagement, L2 testers have investigated claims regarding the internal structure of L2 assessments and the extent to which score variation is dependent upon cognitive processing. These studies have usually taken a cognitive-processing approach to cognition and assessment, where the components of the mind’s cognitive architecture and the functions of these components (e.g., input processing, output processing, executive processing) are considered integral parts of task performance (Dehn, 2008). In this approach, metacognitive processes are believed to regulate the cognitive ones through the stages of processing input and of generating output in task performance. Also, this perspective acknowledges the limited capacity of WM, the role of attention, and the importance of processing speed.

Purpura (1997), described above, was the first to situate processes and strategy use within a model of information processing and to model the statistical effects of cognitive competence on L2 test performance with a single group of L2 test takers. In a later study, again taking a cognitive-processing approach to cognition, Purpura (1998) modelled the effects of strategy use on L2 test performance across high and low ability test takers. Examining these effects for each group separately before examining them simultaneously, he found that metacognitive strategy use was identical in all models, indicating that executive processing was an important part of test performance for both high and low ability groups. The models for cognitive strategy use, however, appeared somewhat different, in that the high ability group model was much less complex than the low ability group model,

suggesting that activation and retrieval from LTM were automatic for the high ability group, whereas the low ability group appeared to find difficulty in processing the test information. Finally, while some evidence of cross-group equivalence was observed, most tests of invariance across groups could not be supported, which suggested that the effect of metacognitive strategy use on cognitive strategy use was variant across the groups.

Drawing on Purpura (1997), Phakiti (2003a) also took a cognitive-processing approach to cognition in order to investigate the relationships between metacognitive and cognitive strategy use and L2 reading test performance. Using strategy questionnaires, retrospective interviews, and an 85-item reading test, he also found that the use of metacognitive strategies regulated the use of cognitive strategies, which in turn influenced reading test performance. Similarly, he found these processing differences to hold across highly successful and unsuccessful test takers. However, when he modeled metacognitive and cognitive strategy use across gender differences, he found that two groups, for all practical purposes, did not differ (Phakiti, 2003b).

In an interesting extension of this work, Phakiti (2007) argued that strategic competence might more accurately be conceptualized as trait and state strategy use. *Trait strategy use* is the equivalent of strategic competence in LTM and is engaged in context-free situations. Trait strategy use, Phakiti claimed, was captured by asking examinees to report generally on the strategies they used to attend to, understand, remember, retrieve, and evaluate their L2 performance. *State strategy use* is defined as the behaviors individuals use when asked to report on the processes and strategies they invoke to respond to specific assessment tasks. Phakiti saw state strategy use as online regulation. He then administered the strategy and reading instruments to 586 test takers, finding that trait strategy use strongly regulated state strategy use, which further influenced reading test performance.

I believe the distinction between trait and state strategy use is important, since learners, when asked to complete a specific task, seem to initially invoke “domain-specific strategies to solve problems” (National Research Council, 2001). These strategies constitute algorithms specific to the domain of interest and allow individuals to solve problems with a relatively high degree of processing speed. Also, when learners are not familiar with the problem or have difficulties applying learned routines, they revert to domain-general strategy use, which might involve means–ends analysis, analogy, and, as a last resort, trial and error (Newell & Simon, 1972).

Several recent studies have examined the relationships between cognitive processing and reading, writing, and speaking test performance (e.g., Van Gelderen et al., 2004; de Jong, Steinel, Florijn, Schoonen, & Hulstijn, in press). Taking a cognitive-processing approach to cognition and language assessment, these studies also included tasks designed to measure speed of processing with respect to linguistic information in the input. They hypothesized visual word recognition and sentence verification to be predictors of reading ability, and picture naming and sentence building to be predictors of writing and speaking ability. A common finding from this work was that test score variance seems to be attributed not only to declarative knowledge structures (grammar and vocabulary), but also to speed of processing. In a later study, Hulstijn, Van Gelderen, & Schoonen (2009) found

not only that speed of processing and communicative adequacy in speaking test performance were explained by increases in linguistic knowledge, but also that metacognitive knowledge was an important determining factor of these speaking abilities.

Finally, in an interesting study examining the determinants of successful listening proficiency, Andringa et al. (2012) noted that successful listening proficiency involved the ability to decode speech, segment it, recognize words, and interpret the utterances by means of thematic and syntactic analyses—all this before being able to integrate utterances into an ongoing discourse for later action. Taking a cognitive-processing approach to cognition, they sought to examine the relationship between cognitive functioning (especially the imitations of WM) and the listening ability. Cognitive functioning was operationalized by several subcomponents (e.g., digit span; nonverbal intelligence). The authors also examined whether the cognitive mechanisms underlying listening were influenced by nativeness, age, and level of education. Then, testing 120 younger learners (20–30 years of age) and 120 older (60–75) Dutch speakers, of which half had a higher educational background, they found that, for all the groups, the models depicting the factors underlying listening proficiency were the same, but the degree to which the components contributed to proficiency varied.

In sum, several studies have examined the internal structure of exams within and across groups. Most have focused on the strategic aspects of cognitive functioning—which are typically referred to as executive processing (Dehn, 2008) and are operationalized in terms of metacognitive and cognitive strategy use. Others have also considered processing speed as function of test performance. Surprisingly, to my knowledge no studies have examined the role of other types of processing (e.g., phonological, auditory, visuospatial, sequential, simultaneous), fluid reasoning (e.g., deductive, inductive), or attention on test score performance.

Cognitive Mechanisms and Rater Performance

Besides looking at the cognitive mechanisms of test takers, L2 testers have long been concerned with the validity of scores on performance tasks assigned by raters in light of the cognitive attributes of these raters and with the processes by which raters assign scores. Bejar (2012) described the rating process in terms of a scoring rubric that raters are trained on, so that they can formulate a mental scoring rubric in their mind. The process of scoring responses, then, requires raters to form a mental representation of the response, so that it can be compared with the mental image of the rubric. The assigned score involves, among other variables, the quality of the response, the quality of the mental rubric, and the quality of the representation of the response, together with the information that has been processed and stored during the rating process and, I would add, together with the rating style of the judge. In sum, the rating process places extremely high mental demands on raters, given the number of cognitive components and functions engaged in scoring and the possibility of introducing subjectivity into the rating process, which would present a serious threat to validity.

In examining rater cognition, Crisp (2012) used verbal protocols to investigate the scoring judgments of 13 teachers across three subjects, in a high stakes

assessment of a school-based project work. In addition, nine professional raters were asked to standardize a set of project scores while verbalizing their thoughts. Using a strategies approach to rater cognition, Crisp (2012) identified the following features of rater cognition: (1) planning and orienting; (2) reading and understanding; (3) task realization; (4) social and emotional reactions; (5) concurrent evaluation; (6) overall evaluation/score consideration. She also found that reading strategies, emotional and social reactions, and the evaluation of the responses aligned with the scoring criteria and that the judgment processes of teachers and professional raters appeared to be similar.

While many studies in L2 testing have investigated rater attributes and their thought processes while scoring performance (e.g., Brown, 2005; Lumley 2005; Kim, 2011), most have examined weighted judgments of examinee performance in terms of the salient features that raters attend to. These studies have provided insights into a range of mental activities. However, to my knowledge, no study to date has taken a cognitive processing approach to examining the rater judgment process. What are the processes and strategies invoked while raters are attempting to understand response input, formulate a mental representation of the response, compare the response representation with that in the rubric, and evaluate the response in those terms? Or how do raters inhibit biased thinking (an attentional variable) while scoring? In sum, many questions about this interesting aspect of cognition and language assessment remain to be answered.

In the next section I discuss ongoing challenges and future directions in examining issues of cognition and language assessment.

Challenges and Future Directions

As we have seen, many researchers have pursued research focused on gaining an understanding of the cognitive processes underlying assessment. This research has served to inform construct definition, test task design, and test scoring; it has also been used to support validity claims about cognition and assessment. As we move forward, what are the ongoing challenges in pursuing this work, and what would some of the new directions be?

One persistent challenge involves the methods available to the researcher to identify and document claims about examinee (or rater) cognition. How can we obtain evidence of the cognitive mechanisms being resorted to during test performance, and how do we utilize this information to infer what is happening inside a person's head? Furthermore, how do we relate processing to L2 development?

Many testers have successfully used observation of performance, verbal protocols, questionnaires, and oral interviews to gather cognitive-processing information about assessments. Each of these methods has its advantages and disadvantages. For example, while some researchers maintain that verbal protocols provide rich accounts of examinee processes, accounts that allow us to judge the meaning of test scores and the quality of the items, others criticize these reports for the challenges they present to the examinees by verbalizing the thoughts they have in the course of responding to items, or for the effect that consciously verbalizing behaviors might have on performance. Also, the analysis of these

verbalizations can be highly subjective. In short, no method provides a fully objective, comprehensive, and conclusive picture of cognition.

An alternative to these traditional methods is digital eye-tracking analyses, where eye movements are recorded during stimulus processing, the assumption being that the location and length of eye fixation on input correspond to visual attention and processing. Unfortunately few studies in L2 assessment have utilized this method.

Another alternative for probing and modeling the cognitive processes underlying assessments is the use of computer-tracking programs in assessment contexts. This is where examinees can use dictionaries, the Internet, or word-processing tools to write essays, and where logs of their computer behaviors (i.e., keystrokes, Internet access patterns, speed of processing) are unobtrusively gathered and later analyzed for trends related to cognitive supports, cognitive processes, and performance.

Another persistent challenge relates to the complex nature of L2 use and to the role that cognitive factors play, alongside other variables, in task completion. As seen in Figure 86.2, several components of L2 ability are engaged and interact in L2 use, making it difficult to isolate cognitive factors from other factors in L2 use. For instance, an examinee performing a writing task must use L2 knowledge, topical knowledge, and cognitive mechanisms, all mediated by personal attributes (e.g., anxiety), in order to complete a task that requires him/her to speak. Without examining all these interacting variables in task engagement, how can we ever be sure what contribution cognitive factors have on performance?

Still another challenge springs from the complex nature of cognition and of the way in which we might characterize a cognitive model in L2 assessment that could allow us to support claims about the cognitive processes of examinees during test performance. Given that there is no one unifying theory of cognition or learning in cognitive psychology, the selection of such a model to inform assessment can be problematic. Witness to this are the many approaches to cognition in L2 assessment that have been used to examine test-taker processes, many of which

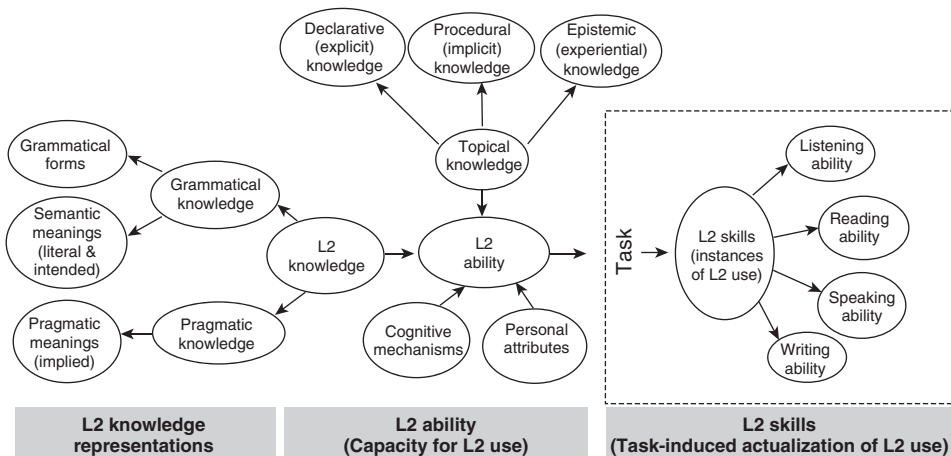

Figure 86.2 The role of cognitive factors in L2 task engagement

subscribe to no explicit theory of cognition or make no attempt to align cognitive behaviors with the mind's cognitive architecture.

Since the 1960s, however, the one theory that seems to have had most traction in L2 assessment is information processing—a theory that is supported by evidence from extensive research in cognitive psychology and currently by research in neuroscience, where brain-scanning technology is used to study how processing transpires in the brain (Dehn, 2008). Information-processing theory has also been the basis of numerous studies, but how might a model of information processing be related to a model of L2 processing? And how do processes and strategies fit into such a conceptualization?

In an attempt to answer these questions, Purpura (2012) proposed an integrated model of information processing as a basis for understanding the cognitive mechanisms underlying L2 performance. Drawing on the work of Gagné et al. (1993), Dehn (2008), and Baddeley, Eysenck, and Anderson (2009), he first specified the way in which regulatory processes in the brain appear to control how L2 input from L2 assessments might be initially processed in STM, how it utilizes WM to access and retrieve different types of information from LTM, and how the retrieved information is organized to produce a response, as seen in Figure 86.3.

Purpura (2012) then explained how information processing might be applied to L2 processing—that is when examinees taking tests are engaging in input processing, central processing, and output processing in order to generate responses. For example, information on an assessment (test input in the form of a question) is understood by utilizing comprehending processes (e.g., parsing, decoding). The understood request from the question is held in WM by means of

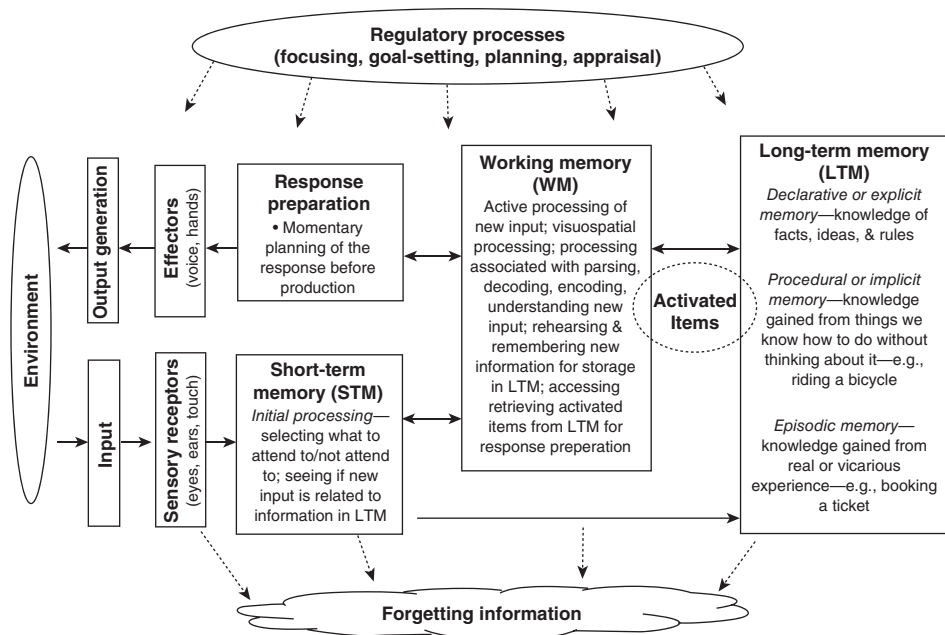

Figure 86.3 The architecture of human information processing. Adapted from Purpura (2012)

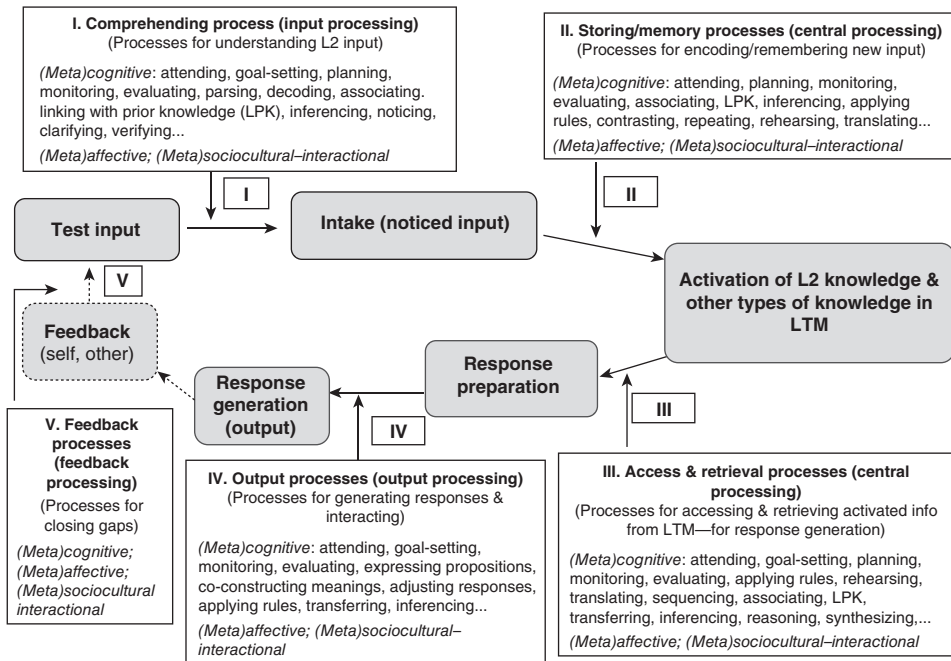

Figure 86.4 The interface of cognitive competence and L2 processing in assessment. Adapted from Purpura (2012)

storing/memory processes. This activates knowledge structures in LTM so that the response to the question can be accessed, retrieved by using retrieval processes, and held again in WM until a response can be prepared and eventually generated by means of output processes.

The final challenge in this conceptualization relates to the nature of strategy use while the examinees taking tests are engaging in input processing, central processing, and output processing in order to generate responses. Each stage of processing the response to the test question potentially involves a range of strategies. These can be metacognitive strategies designed to regulate cognitive ones (e.g., revising), meta-affective strategies intended to control affective ones (e.g., coping), and meta-sociocultural and meta-interactive strategies designed to regulate socio-cultural (e.g., cooperating) and interactive ones (e.g., managing turntaking) (Oxford, 2011). The overall conceptualization is presented in Figure 86.4.

In conclusion, this chapter described, in considerable detail, the role that cognitive factors play in L2 assessment. An understanding of the nature of cognition in L2 assessments is important because this information allows us to improve the quality of our tests. It is also important for understanding performance in L2 assessment contexts with respect to the mind's cognitive architecture and its functioning.

Language Acquisition and Language Assessment

Yasuhiro Shirai

University of Pittsburgh, USA

Mary Lou Vercellotti

University of Pittsburgh, USA

Introduction

The main goal of language acquisition research is to uncover what the language learner knows and how language knowledge develops over time. Language assessment is especially important in attaining this goal. Of course, language learning happens inside the learner's mind and is unavailable for direct observations. Therefore, all measures of assessment are indirect, and language knowledge and language acquisition must be inferred from the results of appropriately chosen assessments. This chapter describes assessment methods used to assess first and second language acquisition. There are some fundamental differences between first and second language acquisition in terms of assessment because first language learners are cognitively immature while second language learners have the advantage (or sometimes the disadvantage) of an already existing linguistic system. In most cases, however, the methods described in this chapter are used in both contexts, occasionally with some modification. In a few cases, a method is only used in one domain, which will be noted. For instance, habituation paradigms have been designed to study prelingual learners, and are therefore only used in first language acquisition studies, while assessments of oral fluency are more frequently taken in second language acquisition. This article reviews how language acquisition researchers have used different methods and criteria in determining that acquisition has taken place.

The assessments are discussed as two main types: methods to assess natural production data and methods with structured elicitation. Natural production data are authentic language samples which can be used to unobtrusively assess what learners have actually produced in the real world. Researchers, however, often directly ask for language samples or other information to conduct focused assessments on particular linguistic structures or linguistic subsystems. Although

natural/elicited is a useful dichotomy for organization of assessment methods, in reality many assessment methods are a blend of natural and structured elicitation as researchers balance the need to have some experimental direction while maintaining a pragmatically relevant context for the learners to produce the language samples.

We first review four types of criteria often used to analyze (oral and written) natural production data, which have been most often used in language acquisition research: accuracy measures, complexity measures, fluency measures, and holistic measures. Researchers have also used more structured data collection methods, which include comprehension tasks, judgment tasks, and elicited production tasks. These methods, in most cases, constitute a type of accuracy data in the sense that these batteries have “correct” targets judged from the adult native speaker’s norm to which learner data (both first language and second language) are compared.

Standardized tests such as Test of English as a Foreign Language (TOEFL), International English Language Testing System (IELTS), Test of English for International Communication (TOEIC), American Council on the Teaching of Foreign Languages Oral Proficiency Interview (ACTFL OPI) (among many others) utilize some aspects of the above criteria in combination. Finally, issues in measuring acquisition and some future directions in language assessment in acquisition are discussed.

Natural Production-Based Measures

Researchers have extensively used the language data produced by learners who have choices in what they produce and how to produce it. Naturalistic data allow researchers to study language in normal use in order to determine what has been acquired.

Brown (1973) investigated the acquisition of English by three children in a landmark longitudinal study that described the developmental profile of various English grammatical structures by analyzing transcribed audiorecordings of children’s spontaneous speech. In this study, he used two major criteria to assess children’s acquisition: supplied in obligatory context (SOC) and mean length of utterance (MLU), which are representative measures of accuracy and complexity, respectively. Both these measures have become standard to evaluate children’s language development and are still used today, mainly in first language acquisition.

Accuracy Measures

SOC is a measure that calculates how frequently the learner can supply a particular linguistic element in the contexts in which its use is obligatory. Brown (1973) set 90% as the point of acquisition; that is, if the learner can supply the form in 90% of the contexts for which the researcher determined a particular linguistic item should be used, it is considered to be acquired. This 90% has become the standard in the field and has also been used in second language (L2) acquisition

(e.g., Dulay & Burt, 1974). However, there is not an absolute cutoff point to ascertain acquisition, and others (e.g., Hyams, 1986) used 80%.

Another important measure for accuracy is target-like use (TLU). This measure is often used in second language acquisition as a variant of SOC. The merit of TLU over SOC is that it considers the degree of overuse as a factor when calculating accuracy. Suppose a learner uses *-ing* for all verbs, the learner's SOC score for *-ing* would be 100%, which indicates perfect acquisition. However, this, of course, may be faulty. To address the issue of overuse, L2 researchers (Stauble, 1978; Pica, 1983) proposed an alternative method to calculate accuracy, in which the number of times the form is overused is added to the denominator. For example, if there are 50 obligatory contexts for *-ing*, and the learner uses *-ing* 40 times, the accuracy will be 80% in SOC. In addition, if the learner overuses *-ing* 30 times, then accuracy would be 50% in TLU. This more accurately assesses the mastery of *-ing* for this learner.

It is interesting to note that SOC was sufficient for first language (L1) acquisition of English, but not for L2 acquisition. This is probably because in L1 acquisition, the overuse of grammatical morphemes is rare (Brown, 1973) while in L2 acquisition it is much more extensive, and thus it was necessary to propose TLU as improvement for measuring accuracy.

Complexity Measures

Complexity measures often used include MLU, subordination ratios, and productivity measures (e.g., type frequency), developmental sentence scoring (DSS) and index of productive syntax (IPsyn). These measures can be classified into two types: general complexity measures and difficulty-based measures. General complexity measures include MLU, subordination ratios, and productivity measures, which do not presuppose one grammatical item more difficult than others, while difficulty-based measures assume that some items are more difficult than others and that the use of difficult items shows a higher level of language development.

General Complexity Measures MLU (Brown, 1973) is the most widely used complexity measure in first language acquisition, especially at the early stages of development. At these stages, the average number of morphemes used in an utterance is a fairly reliable measure of language development. This measure is used in various languages, although some issues have been raised about its use with languages that allow the deletion of elements (e.g., Japanese, which allows frequent deletion of arguments and case particles, Miyata et al., 2013) and its use beyond a certain age (see Yip & Matthews, 2007, for discussion of problems with MLU). Use of MLU as a measure of proficiency (e.g., comparing child L2 learner and adult L2 learners) is also questioned (Unsworth, 2008).

At later stages of language acquisition, researchers usually want to analyze how learners combine smaller linguistic units (e.g., clauses) to form the longer, more complex linguistic units (e.g., sentences), in addition to merely a measure of length. Therefore, a subordination ratio (e.g., the number of clauses per sentence-length unit) has been employed to measure language complexity in a variety of L1 and L2 learner data.

Some language samples, however, are not produced in easily identifiable sentence-like units so researchers must decide how to segment the data before calculating these general complexity measures. For instance, Hunt (1970, p. 4) defined a minimal terminal unit (T-unit) as “one main clause plus all subordinate clauses and non-clausal structures attached to or embedded in it” to be used to segment L1 learners’ written texts (which had issues such as run-on sentences). After segmenting a text into T-units, the researcher can analyze the sentential complexity, both in the mean length of the T-units and by a subordination ratio (e.g., clauses per T-unit).

Researchers have found problems with applying the T-unit and calculating measures based on the T-unit on other (especially oral) language samples, so alternate units have been proposed. For instance, when analyzing conversational data, researchers might analyze communication units (c-units) which may not be full syntactic clauses but which successfully communicate a proposition (e.g., *yes* to a direct question). Regardless of the specific unit chosen, researchers often measure complexity generally as the mean length of the unit (in morphemes or in words) and with a measure of subordination (e.g., clauses per unit, finite verbs per T-unit).

Productivity measures assess lexical diversity and grammatical diversity. Lexical diversity is often measured by type–token ratio (TTR), which is calculated by the number of different words (types) divided by total number of words used (tokens). If the learner uses a variety of words without repeating the same words, the TTR will be high (closer to 1), which indicates high lexical diversity. This measure has a limitation when comparing texts, in that the length of the text greatly influences the score because as more language (written or oral) is produced, it is more likely that the same words, especially common function words (e.g., *a*, *the*, *is*) will be repeated. For instance, if one sample has 80 types and 200 tokens, its TTR is .40, while a sample with 100 types in 400 tokens has a much lower TTR of .25. In response, researchers have developed numerous variations of TTR, such as Guiraud’s TTR which substitutes the number of tokens with the square root of the tokens, in order to adjust for the impact of longer texts (in the denominator of the equation).

Another measure of lexical diversity that has been widely used (in L1 acquisition) is MacArthur Communicative Development Inventories (Fenson et al., 1993), in which a parent responds to a checklist of words, in order for researchers to measure how many different words the child can produce (and understand). This inventory has been adapted and used in more than 60 languages (Dale, 2011). Checklist measures of lexical diversity are also widely used in L2 acquisition (e.g., Paul Nation’s Vocabulary Levels Test; Nation, 1990), although in this case it is the learner that checks the list, not a parent. (It should be noted that these measures are not production-based measures when the checklists reflect the words the learner only understands.) Measures of grammatical diversity determine the degree to which a particular grammatical structure can be used in different contexts, that is, the degree of productive control of the structure. Type analysis (e.g., Choi, 1991; Shirai, 1998) is intended to guard against the overestimation of a learner’s competence due to formulaic production. That is, even if a learner produces many instances of a particular grammatical form (which results in a high

score in the SOC analyses) but in only a single memorized form (e.g., *It's time to eat!*), one cannot be sure of the learner's ability to produce the form productively in different linguistic contexts. Pienemann's (1998) processability theory uses an example of a productivity measure called emergence criteria, in which the production of a structure in different contexts is considered evidence of attainment in particular developmental stages in second language acquisition.

Difficulty-Based Complexity Measures This group of measures presupposes different levels of difficulty assigned to various linguistic items, usually considering data-based research. Developmental sentence scoring (DSS; Lee, 1974) and IPsyn (Scarborough, 1990) are two major ones. These assessment systems classify different grammatical items into various levels of difficulty and give more points for producing difficult items. The resulting score represents the current level of language development of the child. This type of measure has been widely used in clinical assessment of language development for first language acquisition, and has been computerized to conduct automatic assessment of children's language based on transcription of short discourse of 50 sentences or so. Computerized Language Analysis (CLAN), which is a software program to analyze language corpus data, includes DSS and IPsyn to calculate children's level of language development (MacWhinney, 2000), as well as other measures mentioned in this chapter such as MLU and TTR.

Fluency Measures

No matter how complex or accurate the language a learner uses, it can be argued that the language is not fully acquired if the learner speaks very, very slowly, with a lot of false starts and pauses. Therefore, to fully measure acquisition, fluency has to be assessed. Although learners can be described as fluent readers (reading without hesitations or mistakes) and fluent writers (writing quickly and productively), using "fluent" to describe performances in these modalities makes it difficult to separate "fluency" from "proficiency." Therefore, researchers have recently reserved "fluency" for oral production, but so far researchers have not agreed upon standard measures of fluency, and they have used many different measures. Some common temporal measures of fluency include speech or articulation rate, pausing information, and the quantity of speech.

Speech rate (calculated as syllables divided by total time) and articulation rate (syllables divided by total time excluding pauses) can be calculated in order to measure speed fluency. Although commonly used, speaking rate and articulation rate are subject to individual differences (e.g., some people simply talk faster than others) and do not capture all aspects of language performance fluency, so other measures of fluency—pausing information and quantity of speech—have also been used.

Pausing information is considered an important factor of oral fluency because fluent speech is expected to be normally paced, without many hesitations or long pauses. More fluent speakers may take shorter pauses, fewer pauses, or fewer shorter pauses. The mean length of pause (calculated by dividing the total pausing time by the total number of pauses, or by averaging the length of all pauses) shows

how much time the speaker takes, on average, to plan upcoming utterances. Obviously, a shorter mean length of pause indicates higher fluency.

Quantity of speech assesses the amount of speech the learner can produce. It has been measured with phonation time ratio (speaking time divided by total time) and with length of fluent run (the speech produced between pauses). Mean length of fluent run is calculated as the average number of continuous syllables or words that are produced between the pauses. For instance, a speaker who averages five syllables (e.g., *we went to the beach*) before pausing is more fluent than a speaker who pauses after producing only two or three syllables (e.g., *we went . . . to the beach*).

Holistic Ratings

Language acquisition researchers may assess all aspects of the language in total with a qualitative holistic rating, rather than assess the accuracy, complexity, and fluency separately with quantitative measures. Examples of holistic ratings are an essay (or other language sample) given simply a letter grade (e.g., "A," "B") or a second language learner labeled as "novice," "intermediate," "advanced," or "superior," as in the OPI. Often, holistic labels are used to describe the proficiency of learners in second language acquisition research.

Since it is difficult to know what makes a language sample an "A" rather than a "B" or what makes a learner "intermediate" or "advanced," ratings can be guided by an analytic rubric. Analytic rubrics usually list the components to be assessed separately, which allows the assessor to give a score (e.g., 1–5) or description (e.g., "many long pauses," "some pausing," "normally paced") to each component (e.g., accuracy, complexity, fluency) and allows learners to see their relative strengths and weaknesses. This type of assessment is often easier to make because the assessment can be completed without calculating specific measures (e.g., TLU, subordination ratios, mean length of pause), although they may not be reliable or comparable unless standardization is thoroughly done, as in the case of ACTFL OPI.

These four types of measures of acquisition (accuracy, complexity, fluency, and holistic ratings), as noted above, are primarily applied to performance data in which the learner has relative freedom in what structures to use in speech or writing. In other words, these measures allow researchers to analyze unstructured language use data to measure whether particular aspects of language are acquired, and if so, to what extent. One major advantage of these methods of assessment is ecological validity. That is, one can assess the learner's language ability in a rather natural environment under normal circumstances.

A major limitation of these natural production-based measurements is that the target of your research may not frequently occur naturally. Suppose you are trying to find out whether a learner has acquired structure X, but this structure is extremely infrequent in occurrence and even if you collect hundreds of hours of data, it is used only once or twice. In this case, it is very hard to come up with any firm conclusion regarding the mastery of the structure by the learner. Hence, more structured elicitation methods are often needed to more efficiently test the knowledge of the structure, to which we now turn.

Structured Elicitation Measures

In addition to the natural production-based acquisition measures discussed above, more structured elicitation measures have been used. These mainly include comprehension tasks, judgment tasks, and production tasks. The distinction between these is not clear cut because some tasks involve more than one language skill. For example, there are cases where learners are asked to manipulate verb forms within discourse (e.g., a cloze type test), in which case what is tested is both reading comprehension and ability to produce the correct verb form. We will discuss below three major types of structured elicitation measures with this caveat in mind.

In terms of the classification we have discussed so far, these measures, in most cases, represent accuracy-based measures because the learner's (both L1 and L2) response is compared with a "correct" native speaker norm. It is theoretically possible, however, to analyze the data obtained in structured measures regardless of whether they are correct or not. For example, in the spirit of interlanguage analysis which assumes the autonomous nature of learner language (Bley-Vroman, 1983), Bardovi-Harlig and Reynolds (1995) analyzed a cloze type verb-form manipulation task, looking for associations between the past tense form and verb semantics, disregarding whether the answers were correct or not.

Regardless of whether the researchers use a target-based accuracy perspective, structured measures have particular linguistic target(s) that researchers would like to investigate. The obvious strength of structured measures is that they can readily test the target items that the researchers want to investigate through an experimental battery.

Comprehension-Based Measures

Comprehension measures are used often both in L1 and L2 acquisition research. There are many variations, but a commonly used method is forced choice—there may be two, three, or more choices, and the learner is supposed to choose one that matches (or does not match) the linguistic stimuli that have been presented. This way, researchers can investigate whether the learner understands the target linguistic stimuli, be it phonetic, lexical, grammatical, or pragmatic. The linguistic stimuli are often matched with pictures or images, but they can also be matched with another linguistic stimuli, or actual behavior. For example, children are often asked to "act out" what they just heard—using puppets and props.

Let us take an example of aspectual marking. Suppose a learner is using the progressive and past tense forms in English productively. One is tempted to conclude that the learner has adult-like control of these grammatical items. However, to truly test if he or she has adult or native-like control, it is necessary to test their sensitivity to grammatical contrast. In this case, using *John is walking to the store* versus *John walked to the store* as linguistic stimuli, researchers can test the learner by asking them to match the sentences with contrasting pictures representing John in the process of walking to the store and John already at the store.

Sensitivity measures comprise a distinctive branch of comprehension-based measures, which is often used in research with very young children. These are

often used with habituation paradigms (such as preferential looking, heart rate, sucking rate, head-turn, etc.) which rely on children's nature of paying attention to novel stimuli. In this paradigm, children are typically exposed to stimuli until boredom, and then the infant is presented with the new stimuli. If they are sensitive to the difference between the old stimuli and the new stimuli, they will change their response, resulting in a longer looking time, a faster heart rate, a change in their gaze direction, etc. This is another method of testing learners' linguistic competence; for example, whether they are sensitive to certain phonemic distinction. Although this is not testing children's comprehension ability per se, what is tested here is whether they can process linguistic stimuli in some way. These sensitivity measures have greatly advanced our understanding of very young infants, especially prelingual infants, because we can test them before they produce any language.

The self-paced reading task is a type of comprehension data analysis, but the major focus here is the process involved in reading comprehension. Here, the time-course of the reading process is recorded online, and by checking at what point(s) the readers tend to slow down, researchers infer their problems in reading and, by extension, their linguistic knowledge. In L2 research, self-paced reading has often been used to test learners' sensitivity to grammatical errors. When encountering a grammatical anomaly (e.g., subject-verb agreement error), native speakers will slow down, attempting to resolve the unexpected form, but learners may show a lack of sensitivity to the anomaly (meaning that they do not notice the grammatical error) by not slowing down. In the same vein, eye-tracking data can be used to infer when learners pause or regress while reading or listening to a passage. (In fact, eye-tracking can be used while learners are engaged in production as well, so it is not exclusively a comprehension-based measure.) These measures were originally used in psycholinguistic research with adult native speakers, but have been increasingly used in L2 acquisition research (and less so in L1 acquisition).

Judgment-Based Measures

The most frequently used measure in this category is a grammaticality judgment task. This acquisition assessment task mirrors the basic method used in linguistics where native speakers' intuition about grammaticality is mainly used to construct theories and hypotheses about their linguistic competence. Some researchers call this a "comprehension measure" because, in order to judge grammaticality, one has to comprehend the sentence in question. However, one can judge grammaticality of a sentence without understanding the sentence (e.g., *I moopes to the jikekeket.*)

Obviously, this method is not easy to apply for children, and therefore it has been predominantly used in adult L2 acquisition research, especially by the researchers employing a generative grammar approach (e.g., White, 1985). In the domain of semantics, the term acceptability judgment is sometimes used, simply because it is preferable to avoid the term "grammatical" for semantic anomaly (e.g., Shirai & Kurono, 1998). Generally, grammaticality judgment tests are conducted in written form, but auditory grammaticality judgment tests are sometimes used (e.g., Johnson & Newport, 1989).

Similarity judgment tasks produce slightly different judgment data and access learners' mental representation in an indirect way. Kellerman (1978), for example, asked learners to judge similarities among different senses of the polysemous verb "break" to investigate how the different senses are represented in their mind. By analyzing similarity judgment data using statistics (such as cluster analysis and multidimensional scaling), one can see how learners represent linguistic items in their minds.

Lexical decision tasks can be considered judgment data, although in this case the focus is how fast a learner can make a decision on whether a word presented to them is an extant word or a nonword. By manipulating what precedes the presentation of the target word, one can identify whether there is a priming effect (e.g., presenting *butter*, rather than semantically unrelated *desk*, makes subsequent decision of *bread* as a word faster). If a learner shows priming just like native speakers, it can be inferred that the learner's linguistic representation is similar to that of native speakers.

Production-Based Measures

As noted above, the advantage of using structured measures is that they can readily test the target item(s) that the researcher is investigating, and more structured elicitation is essential if one wants to investigate linguistic items that do not occur frequently in naturally occurring discourse. A good example is the acquisition of relative clauses, which has been extensively investigated in first language acquisition. This area almost exclusively used structured measures both in comprehension and production presumably because young children do not produce many relative clauses in naturally occurring discourse. It is only since large-scale computerized corpora on the Child Language Data Exchange System (CHILDES; MacWhinney, 2000) have been available that research using natural production data on relative clauses has advanced (e.g., Diessel & Tomasello, 2000; Ozeki & Shirai, 2007). In second language acquisition as well, research on the acquisition of relative clauses is dominated by experimentally elicited data, such as grammaticality judgment and sentence combination (see Shirai & Ozeki, 2007, for an overview).

Even with the development of computerized large corpora, however, some items occur only infrequently. Furthermore, naturally occurring discourse allows the learners to avoid (whether consciously or unconsciously) linguistic items they are not very comfortable using (Schachter, 1974). Even if they are able to use a particular structure (e.g., subjunctive) if forced, learners may opt for alternative forms (they feel more comfortable with producing) that achieve the same (or approximate) communicative goal. In other words, naturalistic data can tell us what learners *do* do, but not necessarily what they *can* do (Weist, Wysocka-Stadnik, Buczowska, & Konieczka, 1984).

Elicited imitation is somewhat in between comprehension and production, but since the learners' production is what is analyzed, it is included in this category. The procedure is that the learner listens to a linguistic stimulus (normally a sentence) and tries to reproduce it exactly as they heard it. The assumption is that the learner cannot reproduce it as is if it is beyond their linguistic control, and their current linguistic knowledge will manifest itself. This method has been used in

both first (Slobin & Welsh, 1973; Lust, Flynn, & Foley, 1996) and second language acquisition (Jeon & Kim, 2007; see Vinther, 2002, for an overview), although it is somewhat unclear exactly what this method is eliciting.

Elicited production can take many forms. The most common method both in first and second language acquisition is a picture description task. Learners are asked to describe a scene (or a sequence of scenes) in either spoken or written form, which attempts to elicit the use of a particular linguistic item. Instead of pictures, other visual images (e.g., video clips) are sometimes used. Other times auditory linguistic stimuli (e.g., a story told or read), rather than visual stimuli, are given, and the learner is asked to convey the same storyline (retell the story).

The Discourse Completion Test (DCT) and role plays, often used in L2 pragmatics research, are other examples of linguistic stimuli used to elicit production data (e.g., Sasaki, 1998). DCT gives a context which describes a particular sociolinguistic situation (formal vs. informal, etc.) and the learners are asked to write what they are going to say by completing the discourse segment. For role plays, learners are also provided with a particular context and asked to perform a speech event or act.

Finally, it should be noted that the distinction between elicited and naturalistic production is not clear cut, and tasks fall along a continuum as briefly mentioned at the outset. For instance, the language produced in response to a general topic allows the learner more freedom in which linguistic structures to use than a picture prompt, where the learner still has flexibility but is more constrained to the events in the pictures. And even within elicited production tasks, some tasks still allow flexibility in the learner's response. For instance, a researcher can collect interview data with a particular research question in mind, but the interview can be conducted without making it clear what the linguistic target is so that learners will not monitor their speech. In this case for learners it is very close to natural conversation, but for the interviewer it is more of a structured elicitation. For example, Shirai and Kurono (1998) did an interview to analyze tense-aspect forms used by L2 learners, and therefore included topics about the learners' present, past, and future plans, without telling the learners which particular linguistic forms they are interested in.

Introspective Data

As a supplement to the above three major types of structured data collection, researchers sometimes ask the learners what they are thinking as they engage in the task at hand (think aloud) or after it is over. These data can be used as additional information to infer learners' linguistic knowledge. Of course, not all of our linguistic knowledge is accessible to our verbalization, and learners may "make up" what they think was happening, especially in the case of retrospective post-interview after the task (stimulated recall), but at least some aspects of learners' knowledge can be uncovered by this method.

Standardized Tests

Standardized tests, such as TOEFL, IELTS, TOEIC, ACTFL OPI (among many others), which are the major foci of this companion volume and are dealt with in

depth in other chapters, utilize some aspects of the above measures in combination. Let us take the example of the traditional paper version of the TOEFL tests. The listening comprehension section is a comprehension-based measure, obviously, and uses spoken stimuli to be matched with one written choice out of four. The reading comprehension section is similar except that the linguistic stimuli are all written. The structure (grammar) section consists of multiple choice items and requires learners to give grammaticality or acceptability judgments of the four choices in order to choose one that is correct or incorrect. ACTFL OPI is based on production, and is in between natural production and structured elicitation. However, the learner needs to understand speech by the interviewer, and therefore comprehension is also tested.

The difference between language testers and language acquisition researchers, generally speaking, is that the former are not necessarily interested in specific aspects of language ability but in the combination of different components and what the learners can do in total, while language acquisition researchers are more interested in particular linguistic aspects. This, however, is again more of a continuum. For example, if one uses a discrete-point test, then language testers are more interested in ability with regard to particular linguistic items.

Challenges

There are many issues involved in using these measures. They include arbitrariness of determining the thresholds, the difficulty of operationalizing constructs, and theoretical issues of what constitutes knowledge representation.

In earlier studies of first and second language acquisition conducted in the 1970s, the 90% threshold was determined to be a point where learners are considered to have acquired the particular linguistic item. But this is rather arbitrary, and it could be set at 95%, 85%, or 80%. Likewise, researchers have chosen different lengths of silence to qualify as a pause (e.g., 200 milliseconds, 250 milliseconds, 400 milliseconds), and any choice is arbitrary because there is no objective length to qualify as a “pause” needed for speech planning. Determining a standard for this purpose has the advantage of comparability with similar studies. The disadvantage is that the nature of the cutoff may alter the results. Thus, in addition to one threshold, it is possible to analyze the data using different criteria. If different thresholds yield the same results, the results are quite stable with regard to the particular data being analyzed. If not, one has to think about the reason why.

It is not an easy task to identify what a learner (or group of learners) knows about linguistic structures. This is because all we can do is to infer from behavior what is in the mind. If we want to test declarative facts such as whether someone knows Mr. X, then it is more or less straightforward—either he knows Mr. X or not. In the case of knowledge of language, one cannot always say (or be aware) that a learner knows a particular structure because it is the nature of language knowledge that it is mostly implicit. One may be aware of it through conscious reflection or instruction, but essentially it is implicit in first language acquisition. In second language acquisition the degree is somewhat different and both declarative or explicit knowledge and implicit knowledge coexist for instructed learners.

This dual structure of language knowledge makes it particularly difficult for researchers to understand what has been acquired and known by learners.

One major obstacle for identifying what a learner knows is task variation. This has been a major focus in L2 acquisition research since the 1970s when it was found that the same learners show different linguistic behaviors depending on the task. The great deal of attention paid to task variation in L2 research is probably due to the conspicuous dual structure of language knowledge for L2 acquisition; that is, explicit and implicit knowledge coexists and the degree to which explicit knowledge (or conscious monitor) is applied varies greatly depending on the task (spoken, written, judgment, etc.). In contrast, L1 acquisition is primarily driven by implicit learning processes, and therefore task variability is far less extensive. Thus, the notion of triangulation is important—that is, by using different tasks (or multiple arbitrary thresholds), one can validate the results found in one task. If one gets support from multiple tasks, the results give us a good indication of learners' knowledge. If not, then researchers need to address the issue of task condition for a particular behavior to appear. One important consideration is the issue of ecological validity discussed above. When a learner is engaged in naturalistic language use, it at least shows what the learner is capable of producing spontaneously. In other words, we can be reasonably sure that the data reflect the learner's natural competence. In contrast, when we experimentally elicit data, we need to be very careful about the interpretations. Since experimental settings and tasks are not what learners are used to dealing with, it is possible that the data cannot adequately reflect the linguistic knowledge that the researchers wanted to study. One example of such failure is observed in a study on the acquisition of relative clauses. Tavakolian (1981) suggested that instead of processing the stimuli as relative clauses (*the boy that saw the man chased the girl*), children were comprehending them as if they were conjoined clauses (*the boy saw the man and chased the girl*). This is the inherent danger of experimental tasks: while natural production data cannot push learners to their extreme, structured experimental devices tend to include tasks that are unnatural to learners. This may result in behavior that is unexpected by researchers or result in unreliable findings. When we look at sentences that were used in relative clause experiments for children in the 1980s, we are struck by how complex they are—even for adult native speakers of the language. To avoid this danger, Diessel and Tomasello's (2005) elicited imitation experiment used the type of relative clauses that are actually produced by children in their naturalistic interaction. This is just one example of an improvement in the method to elicit data that are truly reflective of learners' actual competence, not the task-specific oddity. To avoid overinterpretation, or more sophisticated interpretation of the results, introspective data can be quite useful. Other researchers have found a middle ground between truly naturalistic data and the most directly elicited responses.

Finally, there is the age-old issue of competence versus performance. The assumption here is that there is a stable linguistic representation called competence, which is accessed in various types of linguistic performance such as speaking, listening, grammaticality judgment, etc. In the case of adult native speakers, their judgment is more or less stable, but, when it comes to learners, it is not as

stable, so we refer to many other different measures to make our best guess about these learners' knowledge. This methodological problem aside, what is it that we are trying to measure?

As noted above, in second language acquisition, there are usually two knowledge structures involved—explicit knowledge and implicit knowledge. Which one do we want to assess? Generally speaking, language acquisition researchers are trying to get at the latter, but is that possible? To get at the implicit knowledge, L2 researchers try to collect monitor-free production data, which most closely reflect the learner's stable, real competence. This is generally assumed to be elicited successfully if the learner's focus is on communication so that their explicit knowledge cannot come into play to "contaminate" their production. Other methods can also aim at L2 implicit knowledge pure and simple (not contaminated by conscious monitor); for example, online tasks such as priming experiments can be used to investigate the learner's implicit knowledge. However, the kind of target knowledge one can assess using these online methods is limited, and indeed it does not have ecological validity in the sense that priming does not give us so much information regarding what learners can do in terms of actual language use.

Future Directions

Language acquisition researchers must continue to employ multiple measures to assess acquisition because of the multifaceted nature of both language ability and of language acquisition research. Different researchers from different orientations have different research questions, and they need to address and establish their own paradigms within which accepted methodologies and standards are established. By employing various measures that are available, researchers must make the utmost effort to improve our understanding of learners' language ability, which is complex and interrelated in both first and (especially) second language acquisition. Technology has enabled new methodologies to research language knowledge and acquisition, such as use of large corpora, computer modeling, and neuroimaging techniques (e.g., functional magnetic resonance imaging, fMRI; event-related potentials, ERPs), which help us deepen our understanding of the nature of language knowledge. For instance, ERPs are online processing measures that can give insight to lexical and syntactic processing, including revealing language acquisition. Additionally, with large L1 and L2 datasets collected, more research can be done to explore individual differences and universal patterns in acquisition, complementing earlier research based on case studies. Needless to say, we should also try to enhance the reliability and validity of our measurements.

Bilingual Assessment

Usha Lakshmanan

Southern Illinois University, Carbondale, USA

Introduction

Bilingualism is present in practically every country, across all classes of society and age groups. For a majority of the world's population, bilingualism is an integral part of everyday life (Grosjean, 2010). Bilingualism has existed since ancient times, as a result of language contact between speakers of different languages. In the 20th century, the expansion of educational opportunities to the masses and an increase in immigration of a linguistically diverse population, especially to countries such as the USA and Canada, promoted growth in numbers of bilinguals. Recently, the rise of global economies and rapid advances in information technology have also contributed to this growth. For example, English is an international lingua franca and a majority of the speakers of English in the world are second language speakers of English.

A popular misconception is that monolingualism is the norm and bilingualism is a rarity (Grosjean, 2010). Mainstream linguistic research has largely focused on the monolingual speaker, often an idealized monolingual native speaker, of high status languages, especially English. Since the 1990s, however, there has been a surge of interest in researching bilingualism. This change in perspective stems partly from the recognition of the potential value of bilingualism to help shed light on theories of language acquisition and language use, and theories of the interaction between the linguistic and nonlinguistic aspects of human cognition (Yip & Mathews, 2007). Additionally, the impetus of research on bilingualism stems from practical concerns, such as the education of linguistically and culturally diverse children and the identification and treatment of language disorders in bilinguals. A task confronting researchers and professionals in educational and clinical settings is the development of appropriate practices for assessing bilinguals (García, 2009).

The purpose of this chapter is to provide an overview of issues central to bilingual assessment. The chapter is organized as follows: It sets the stage by highlighting the complexities involved in the definition and classification of bilinguals and the primary factors motivating bilingual assessment. Next, it analyzes the problems with previous approaches to the assessment of bilinguals, examines the change in perspective underlying current conceptualizations of bilingual assessment, and presents highlights of current research on bilingual assessment. The chapter concludes with a consideration of the challenges that remain and future initiatives necessary to meet these challenges.

Defining and Classifying Bilinguals

The assessment of bilinguals is a difficult task because of the complex nature of bilingualism. There is no consensus regarding how to define the term “bilingual” (Baker, 2006). Conservative definitions emphasize native speaker ability or “native-like control” of the two languages as a strict criterion. Other definitions emphasize language use rather than fluency or proficiency; under this view, a bilingual speaker is one who uses two languages on a regular basis. In actuality, bilinguals rarely achieve full competence in both languages, and, typically, one of the languages (often the L1) is more dominant, although the dominance can shift over time to the other language (Yip & Mathews, 2007). Likewise, despite knowing two languages, bilinguals may use only one on a regular basis or one only for listening and reading but not for speaking and writing. In relation to fluency, bilinguals can fall anywhere along a continuum ranging from full competence in one language plus limited knowledge of a second, to apparently full competence in all skills for both languages; similarly, in relation to language use, bilinguals fall anywhere along a continuum ranging from regular use of one language plus limited use of a second, to regular and frequent use of both languages.

The classification of bilinguals into different types is often necessary in research, educational, and clinical settings. Based on age at onset of exposure to a second language (L2), we can distinguish between “early” bilinguals and “late” bilinguals. In early bilingualism the acquisition of an L2 occurs during childhood, whereas in late bilingualism it occurs during adolescence or adulthood. Childhood bilingualism can be “simultaneous” or “sequential” (Lakshmanan, 2009). Simultaneous bilingual children acquire their two languages concurrently from birth (or one language from birth and a second soon thereafter). Sequential bilingual children (i.e., child L2 learners), acquire their L2 after the age of three years, when the basic grammatical properties of their L1 have been established for the most part. Child bilinguals can be further differentiated based on whether they are typically developing children or children with language difficulties, such as specific language impairment (SLI) (Paradis, Genesee, & Crago, 2011). Language balance or dominance is another variable used to distinguish bilinguals. Balanced bilinguals are equally proficient in their two languages. Although the term “balanced” does not necessarily entail a high level of fluency or proficiency in both languages, it is in this sense that the label has generally been used (Baker, 2006). Typically, one language (often the L1) is more dominant. Many bilingual children in the world live in a subtractive bilingualism context, where their L1 (a minority

language), fails to be valued or supported in school, as the medium of education is in the majority language (i.e., their L2). In such cases, the L2 may become the stronger language over time.

Even in bilingual populations involving the same language pair and the same or similar age at onset of exposure to the two languages, there can be individual variation in relation to several factors (Paradis et al., 2011). These factors include the quantity and quality of input as well as the dialectal variety (e.g., standard/mainstream vs. nonstandard/vernacular); the contexts of acquisition (via immersion in a natural setting vs. a formal instructional setting); the extent to which, and the contexts and functions for which, the two languages are used; the status of language mixing or switching (i.e., the alternate use of the two languages in the same utterance or conversation); the sociopolitical and economic status of the two languages (minority language vs. majority language) and attitudes toward the two languages at the local, national, and global levels; and the motivation for bilingualism (i.e., “elective” vs. “circumstantial” bilingualism).

Why Assess Bilinguals?

The assessment of bilinguals is necessary for research purposes and from a practical perspective (i.e., in educational and clinical settings). Researchers assess bilinguals in order to understand a range of effects (positive and negative) of bilingualism on individuals, in relation to language development, language knowledge, and language use and the cognitive processes underlying them, as well as its impact on nonlinguistic aspects of cognition (e.g., intelligence, memory, and executive function). In order to address these issues, appropriate assessment methods are necessary for various tasks, such as the selection of participants and conducting comparisons across the two languages of the same individual, as well as between different groups, such as monolinguals versus bilinguals, fluent versus nonfluent bilinguals, L1-dominant versus L2-dominant bilinguals, early versus late bilinguals, simultaneous bilingual children versus child L2 learners and adult L2 learners, healthy bilinguals versus language-impaired bilinguals. In the educational sphere, for both child and adult bilingual populations, appropriate language assessment practices are necessary for placing students at the appropriate grade or level, for purposes of remediation as well as for assessing curriculum-based learning. Many countries in the world, especially the USA and Canada, have witnessed a substantial increase in the number of linguistically and culturally diverse children in schools. These children typically receive their education in the majority language (or mainstream dialect) of the country (i.e., their L2). A cause for concern is the over-referral of linguistically and culturally diverse children among those diagnosed for special education classes. Nonbiased or least biased assessment materials and procedures are crucial for teachers and speech language pathologists to distinguish between normally developing bilingual children and children with a genuine language disorder. Otherwise, there is a danger of over-identification, where typically developing minority language children are mistaken as being language impaired, and underidentification, where minority language children with language impairment are mistaken for typically developing child L2 learners (Bedore & Peña, 2008; Paradis et al., 2011). The development

of appropriate bilingual assessment practices is crucial for the accurate diagnosis and effective treatment of acquired language disorders such as aphasia or language loss resulting from stroke or injury to the brain (Paradis, 2011). Nonbiased assessment is also important from the parents' perspective, on a range of issues: whether to raise one's child bilingually or not, whether to continue to use the L1 within the home, whether or not the language delay or difficulties currently experienced by their child is cause for serious concern (Paradis et al., 2011). Additionally, bilingual assessment is needed for occupational purposes, such as the selection of bilingual teachers and interpreters.

Previous Conceptualizations

A challenge facing researchers, educationists, and clinicians when assessing bilinguals is how not to underestimate or overestimate the bilingual individual's linguistic abilities. Historically, the assessment of bilingual children and adults has tended to follow monolingual norms (Baker, 2006; García, 2009). The monolingual bias is still evident today, even in countries supporting strong forms of bilingual education.

Fractional View of Bilingualism and Single Language Assessment

The monolingual bias in assessing bilinguals stems from a fractional view of bilingualism, which stresses perfect competence in each of the two languages as a strict criterion for bilingualism (Baker, 2006). Historically, in the USA and several other countries, the sociopolitical context of schools and society has generally been negative toward bilingualism, which continues to persist today. Parents of minority language children are often advised to use only one language (typically, the majority language of the country, which is the children's L2) within the home, because of the myth that bilingualism can lead to language deficits (e.g., language delay) as well as nonlinguistic deficits (e.g., lower intelligence).

An outcome of the fractional approach and the negative attitudes to bilingualism is that bilinguals tend to be assessed only in one of their two languages, typically the L2, which is often a high status language, such as English. This is problematic because, as that language may be their weaker language, they are at risk of being misidentified as being language impaired (Gutiérrez-Clellen, Restrepo, & Simón-Cerejido, 2006).

Standardized Tests and the Use of Monolingual Norms

In standardized tests, frequently used in educational and clinical settings, the norming is typically based upon a monolingual native speaker population. The use of such standardized assessment measures may be inappropriate when assessing bilingual children (Saenz & Huer, 2003; Roseberry-McKibbin & O'Hanlon, 2005). The task may be unfamiliar to the child because of culturally different child-rearing practices (Peña & Quinn, 1997), or the language of the task may represent a mainstream dialect or high variety, different from the vernacular variety the child is

used to (de Villiers & de Villiers, 2010). Furthermore, standardized testing typically entails discrete item testing of single measures such as vocabulary and grammar, rather than the use of language for authentic communication (see Del Vecchio & Guerrero, 1995, for a review of standardized tests used with English language learners, such as the Bilingual Syntax Measure, Language Assessment Scales, IDEA Proficiency Tests, and the Woodcock–Muñoz Language Survey).

One reason for single language assessment of bilingual children is the nonavailability of standardized assessment measures in many languages, besides English and other high status languages. However, this situation has begun to change and standardized assessment measures are now becoming available for certain other languages. But as the norming is typically based on monolinguals, it can lead to faulty comparisons between the linguistic abilities of bilingual children and monolingual children. For example, monolingual norm-referenced assessment tools, such as communicative development inventories (CDIs), have been used to estimate bilingual toddlers' vocabularies in each of their two languages. A common finding is that the bilingual children are disadvantaged in comparison to monolingual children in each of their two languages. When a strict definition of the term "bilingual" is adopted, the expectation is for bilingual children to demonstrate knowledge of words in *each* of their two languages, according to monolingual age-expected norms. Accordingly, the total vocabulary score is determined separately for each of the two languages of bilingual children. However, as bilingual children do not necessarily use their two languages in the same contexts, they may have fewer translation equivalents; they may know words only from one language for certain concepts and words only from the other language for other concepts, and fewer words in both languages for the same concept. Some labels may be lacking in one of the languages, because of crosscultural differences. When the total vocabulary score computed for comparing the bilingual children with monolingual norms is based upon scores for each language considered separately, bilingual children tend to display smaller vocabularies in each of their two languages than monolingual children of the same age (for discussion, see Pearson, Fernandez, & Oller, 1993).

A similar "comparative fallacy" is also present in more authentic forms of assessment (Lakshmanan & Selinker, 2001). Since its beginnings, research on language development (especially L2 development) in "early" and "late" bilinguals has used spontaneous (and experimentally elicited) speech samples gathered from bilinguals for investigating the acquisition of certain linguistic elements, such as grammatical morphemes. The speech samples are analyzed for correct suppliance in obligatory contexts. A problem associated with the analysis of accuracy in usage is the adoption of a very high criterion (e.g., 80–90% accurate suppliance in obligatory contexts). The emphasis on *absolute accuracy* rather than *patterns* of language use in relation to monolingual native speaker norms could result in an underestimation of bilingual speakers' knowledge of the L2. Another problem relates to the identification of obligatory contexts based upon monolingual "native speaker" norms, which could result in overestimating the number of obligatory contexts. In relation to past tense marking, the inherent semantics of the verb and pragmatic factors (such as foregrounding and backgrounding of information) have been shown to play a role in language development in

relation to whether a verb is overtly past tense marked or not. Failure to take into consideration the semantic and pragmatic factors from the perspective of the L2 speaker could lead to an overestimation of obligatory contexts for past tense marking and to an underestimation of the percentage of accurate use (for discussion, see Lakshmanan & Selinker, 2001).

A related issue concerns the variety of the L2 that is used as a yardstick. Typically, in relation to L2s such as English, varieties that encompass the Inner Circle (e.g., mainstream American English or British English) are assumed to be the target; in many cases, the bilingual speakers may be exposed to a different variety, often a home-grown variety, such as Indian English in India. Failure to accommodate the assessment to the local language variety can lead to erroneous results (for dialectal considerations in assessment, see Gutiérrez-Clellen & Simón-Cerejido, 2009).

Translation

As stated above, one problem in assessing bilinguals in each of their two languages is the nonavailability of standardized tests in languages other than English. A common solution to this problem is to directly translate the test from English to the other language. However, translated tests are inappropriate for use with bilinguals. This is because the translated version in the other language may not be equivalent to the original test in English because it ignores important crosslinguistic differences (Bedore & Peña, 2008; Paradis, 2011). For example, English distinguishes third person personal pronouns in terms of gender (he/she/it), whereas in other languages, such as Mandarin, there is no gender distinction. In some languages, such as Tamil, first person plural pronouns are distinguished on the basis of an additional feature (i.e., inclusive “we” versus exclusive “we”); this feature would not be captured in a direct translation from English, which does not distinguish formally between the inclusive and exclusive interpretation.

The problems underlying direct translation become particularly apparent in clinical settings. The clinical markers for a particular type of language impairment (e.g., SLI, Broca’s aphasia) may differ based upon the language-specific properties of the two languages (Bedore & Peña, 2008; Paradis, 2011). For example, English-speaking children with SLI demonstrate difficulties with tense marking, evidenced by their use of nonfinite verb forms. Spanish-speaking children with SLI have less difficulty with tense marking and more difficulties with articles and clitic pronouns (Gutiérrez-Clellen et al., 2006).

Confounding Variables: Language Dominance and Language Mode

As stated earlier, typically, one of the two languages of bilinguals is stronger than the other. The stronger language is usually the L1, although in children language dominance can shift from the L1 to the L2. In studies comparing the effects of language dominance on linguistic and nonlinguistic cognitive abilities as well as the influence of each language upon the other, language dominance functions as a control variable (i.e., independent variable). However, a problem is that, even in research studies where language dominance is not the focus of investigation, it could nevertheless be present as a confounding variable. For example, an issue that

has received considerable attention within bilingualism is the critical period effects in L2 acquisition. Such research typically involves the comparison of early bilinguals with late bilinguals, with respect to their ultimate L2 attainment of phonology and morphosyntax; a group of native speakers of the target L2 serve as controls. Some studies have used retrospective methodology (e.g., Johnson & Newport, 1989). The categorization into “early” and “late” bilinguals is based on the bilinguals’ age of arrival in the target L2-speaking country, which is assumed as the age at onset of exposure to the L2. A key finding is that early bilinguals outperform late bilinguals with respect to ultimate L2 attainment. In addition to age at the offset of the critical period (puberty), Johnson and Newport proposed a second cutoff point of age 7, as only those who began acquiring the L2 between the ages of 3 and 7 years performed similarly to monolingual native speakers. A methodological flaw is that language dominance is a confounding variable and interacts with the control independent variable of age at onset of L2. Crucially, for the group with the earliest age at onset of L2 acquisition, their language dominance may have shifted to the L2, accompanied by L1 attrition (Lakshmanan, 2009).

Language mode has largely been ignored when assessing bilinguals. When bilinguals converse with monolinguals, they use one of their two languages (Language A or Language B) depending on the monolingual interlocutor; that is, they are in a monolingual mode, where only one of the languages is active and the other language is inactive (although the other language may not be completely deactivated). However, when interacting with bilingual speakers of the exact same languages, their communication is complex, and can shift along a continuum ranging from the monolingual mode (in either Language A or Language B) to a bilingual mode, with both Language A and Language B fully activated (Grosjean, 2010). In the bilingual mode, code switching can occur as well. A problem when assessing bilinguals is that the context could be one that promotes a bilingual mode of interaction, where both languages are fully active, as would be the case when the other interlocutor is also a bilingual speaker of the same two languages. If the purpose is to evaluate the bilingual’s use of one language (e.g., the L2), a potential problem is how to distinguish between true instances of language transfer from instances of borrowing or code switching. What appears to be language interference may actually be borrowing or code switching, a natural phenomenon for many bilinguals when interacting with other bilinguals (Grosjean, 2010; Lakshmanan & Selinker, 2001).

In the assessment of bilingual children, the full potential of their bilingual linguistic abilities is rarely tapped. Even in those cases where children are evaluated in both languages, as the languages are considered separately, children’s abilities in weaving in and out of their two languages (i.e., code switching or translanguaging) are typically not assessed (García, 2009).

Current Views or Conceptualization

Since the beginning of the 21st century, the growth in research in bilingualism has contributed greatly to an improved understanding of bilingualism, which in turn has helped develop least biased approaches to the assessment of bilinguals.

Holistic View of Bilingualism

Central to current conceptualizations of bilingualism is a holistic view of bilingualism, according to which a bilingual is *not* two monolingual speakers within the same person (Baker, 2006; Grosjean, 2010). Under this approach, the adoption of monolingual norms for assessing bilinguals is clearly inappropriate. Bilinguals tend to be more dominant in one of their two languages; nor are their linguistic abilities in each language exactly like that of monolingual speakers. In addition, the two languages are often functionally differentiated. Furthermore, code switching or “translanguaging” is also common in many bilingual communities and, far from being a limitation, is a valuable communication resource (Arias & Lakshmanan, 2005; García, 2009).

Language History and Language Use

A holistic view of bilingualism emphasizes the importance of taking into account the heterogeneous nature of bilingualism. Healthy bilingual speakers of the exact same languages, with similar ages at onset of acquisition of the L2, can differ in their bilingual abilities, because of variation in relation to other linguistic and non-linguistic aspects of their language history. An important implication of the holistic approach to bilingual assessment is that, even where the focus of attention is on the performance of bilinguals considered as a group, one cannot lose sight of the unique individual profiles represented within that group. Whether the assessment is for research or for diagnostic/interventionist purposes, information about the bilingual individuals’ language acquisition history and language use will be useful in interpreting their performance on specific language tasks. For adult bilinguals, such information is usually obtained through a bi/multilingualism questionnaire. In addition to questions about their language history and language use, they are also asked to rate each of their languages in relation to fluency or proficiency and language strength. However, it is important to provide the questionnaire in each of the two languages. The bilingual’s selection of one of the two language versions of the questionnaire can provide information about the bilingual’s covert language attitudes and language preference. For very young bilingual children, information about their bi/multilingualism should be sought by talking with their parents or caregivers as well as with their teachers (Gutiérrez-Clellen & Kreiter, 2003; Paradis et al., 2011). Additionally, in the case of children, it will be necessary to obtain such information more than once, given the potential for changes over time in the frequency of use of each language as well as language dominance (Chong, 2011).

Assessing Bilinguals in Both Languages

A positive outcome of the holistic approach to bilingualism is that both languages of the bilingual are considered equally valuable for assessment purposes. No doubt, in the case of healthy adult bilinguals, who elected to learn an L2 for educational or occupational purposes, assessing only their L2 may be a reasonable option. In research settings, where the purpose is to address issues such as language transfer, assessing both languages would be preferable. In the case of

circumstantial bilinguals, especially children, it is necessary to assess both languages. An example of an attempt at considering two languages holistically is the Bilingual Verbal Ability Test (BVAT) (Muñoz-Sandoval, Cummins, Alvarado, & Ruef, 2005), available in English, Spanish, and 16 other languages, which assumes that bilinguals have a unique linguistic configuration, rather than two language-specific configurations. Assessing only one language could lead to one of two scenarios. The child could be mistaken as being language delayed or language impaired, because the language assessed represents her weaker or less proficient language. Alternatively, it could result in a case of “missed identity,” where the child’s language difficulties are confused with those experienced by a typically developing child L2 learner, even though language impairment may be the underlying cause for the child’s linguistic deficits (Bedore & Peña, 2008; Paradis et al., 2011). Recent research indicates that bilingual children with language impairment demonstrate language difficulties in both of their two languages, although the difficulties may not involve the same grammatical aspects across the two languages, because of crosslinguistic differences (Gutiérrez-Clellen et al., 2006). Likewise, when using the Bilingual Aphasia Test (BAT) to assess bilingual aphasic individuals, examining both languages is crucial, for diagnosis of the specific type of aphasia as well as for the purposes of language therapy (Paradis, 2011).

Standardized Tests, Renorming, and the Principle of Equivalence

A problem that persists even when standardized tests are used to assess bilingual children in each of their two languages is the issue of norming. This is because, in standardized testing, the norming for each language is based on monolingual children. This overlooks an important difference between bilingual acquisition contexts and monolingual acquisition contexts. In terms of the overall quantity of the input (i.e., in both languages considered together), bilingual children may be no different from monolingual children. However, the total quantity of the input available to bilingual children in *each* of their two languages is inevitably greatly reduced compared to the total quantity of the input available to their monolingual child counterparts (Yip & Mathews, 2007). In the past, failure to take this difference into account in scoring procedures for standardized tests used to assess bilingual children led researchers to compare bilingual children’s linguistic abilities unfavorably with those of monolinguals. For example, as discussed above, in relation to vocabulary measures, a total score computed separately for each language of the bilingual child often formed the basis of comparisons with monolingual norms. A less biased scoring procedure would be to adopt conceptual scoring, where an overall “conceptual” score is computed for both languages considered together. This involves scoring for the total number of *concepts* expressed rather than scoring for vocabulary specific to each language per se and giving credit only once for words representing the same concept across the child’s two languages (i.e., translation equivalents). When conceptual scoring for vocabulary measures is employed, bilingual children are shown to be no different from monolingual children (Pearson et al., 1993; Bedore, Peña, García, & Cortez, 2005).

In those cases, where standardized tests are available only in one language (especially the L2), renorming the test using the target population has sometimes

been used in educational and clinical settings as an alternative (Saenz & Huer, 2003). An appropriate norming group should comprise individuals of the same ethnic, cultural, and linguistic backgrounds, age, gender, and educational level. Renorming is advantageous in contexts where the target group at issue is a relatively large and homogeneous one. This requirement must be met in order for one to conclude that a particular student who obtains a low score on the renormed test also ranks considerably below her peers who share the same background. However, a disadvantage of renorming is that the norms for the target bilingual population at issue may be lower than the norms for the monolingual group tested during initial standardization of the test, which can lead to the stereotyping of the group as being linguistically less capable than other mainstream groups.

Current approaches to the assessment of bilinguals stress the importance of the principle of equivalence, especially when comparing the linguistic abilities of a bilingual individual in each of their two languages. In other words, *adaptation* to local norms rather than literal translation would be more appropriate (Bedore & Peña, 2008; Paradis, 2011). In order to ensure that each task measures the same capacity as the original (and all other versions), the stimuli should be selected on the basis of similar complexity rather than for being actual translations from the original. The importance of this procedure is readily apparent in phonological assessment. A task in the English version, based on rhyming words or minimal pairs, will be clearly inappropriate for any other language. In some languages, certain constructions (e.g., passive or relative clauses) may be rarely used or, even if frequent, may be less complex. Syntactic structures differ across languages in relation to form and frequency of occurrence and also in relation to the contexts of use. Observance of the criterion of crosslinguistic equivalency will have certain consequences on versions adapted from the original. In certain cases, the form of the stimulus sentences will differ across languages in proportion to the structural distance between them. Moreover, the content will also likely differ across the two testing conditions. For example, in a verbal auditory discrimination task, where the purpose is to assess the ability to distinguish between minimal pairs, translation equivalents of the original stimulus words cannot be used and a new set of phonologically comparable minimal pairs will be needed for the other language. Similarly, when assessing listening comprehension of a story, it is necessary to use a different story in each language. As bilinguals are often assessed consecutively in each of their two languages, using a story different in content (i.e., different story and different lexical items), but *equivalent* in terms of the relevant dimensions (i.e., information load, grammatical complexity, and discourse structure), will help avert a situation where the bilingual individuals use their recollection of the story they heard in the previously tested language.

Current Research

The focus of current research in bilingual assessment, especially in relation to bilingual children, has been to develop alternatives to existing standardized language measures, which lack validity because of their monolingual bias.

Standardized Language Measures and Bilingual Norms

One option is to develop standardized dual language measures for specific language pairs for use with the target bilingual population. An example of this type of language test is the Bilingual English Spanish Assessment Battery (BESA: Peña, Gutiérrez-Clellen, Iglesias, Goldstein, & Bedore, 2011). Its purpose is to identify language impairment in Spanish-speaking children as well as Spanish-dominant bilingual children, ranging in age between 4 and 7 years. However, the development of language assessment batteries based on bilingual norms will only be feasible when the target population is sufficiently large.

Dynamic Assessment

In dynamic assessment, the focus is on determining the ability of the child to transfer newly acquired knowledge from one task to another (Gutiérrez-Clellen & Peña, 2001). Crucially, dynamic assessment provides the child with an opportunity to learn when provided with instruction. While dynamic assessment is not new, it has only recently begun to be adopted by speech language pathologists and other professionals involved in the care and education of linguistically and culturally diverse children. A popular variant of dynamic assessment involves the use of a three-step TEST-TEACH-RETEST approach (Gutiérrez-Clellen & Peña, 2001). The initial testing phase involves the administration of a standardized test. In the second phase (i.e., the instruction phase), the child participates in a “mediated learning experience.” The goal of the instructional phase is not to teach the child answers to specific items on the test but to help the child have a clearer understanding of the principles underlying the language test as well as the strategies to use to respond. After the instructional phase, the child is reassessed using the same language measures. The focus of interest in dynamic assessment is not on what the child already knows or has learned but on *how* the child learns. The child’s performance on the first test and the second one is compared, based on the scores received as well as their “modifiability” (i.e., changes evidenced as a result of instruction). The evidence from studies of the use of dynamic assessment as a diagnostic tool for language impairment indicates that typically developing children tend to demonstrate higher levels of modifiability and score changes as a result of the instructional phase, compared to children with language impairment.

Language Sampling

An important source of information about language development that researchers have historically relied upon is spontaneous speech samples gathered from the participants. Spontaneous speech data are still used in research on language acquisition, in relation to monolingual and bilingual children. In contrast, in clinical settings standardized tests have been the norm. Recently, however, speech language pathologists and other professionals involved in the care and education of linguistically and culturally diverse children have begun to recognize the value of spontaneous language samples for addressing clinical aims (Gutiérrez-Clellen,

Restrepo, Bedore, Peña & Anderson, 2000; Gutiérrez-Clellen & Simón-Cerejido, 2009). Recent research on the assessment of Spanish–English bilingual children in the USA has shown that standardized testing, even when carried out in both languages of the children, tends to be of limited clinical accuracy and provides insufficient information to plan language intervention. In contrast, spontaneous speech samples obtained from the child in her two languages can help identify language impairment with higher accuracy. One advantage is that language samples can be gathered from the children in a variety of familiar contexts (e.g., in the home, playground, or classroom). The help of a bilingual interpreter who knows the child’s primary language will be necessary to gather the language samples and evaluate the child’s ability to use language to function in daily life situations.

To elicit spontaneous speech samples for the purpose of language assessment, researchers, teachers, and clinicians can also collect narratives in each of the child’s two languages. A popular method is to use a wordless picture storybook to elicit spontaneous narrations. The child is asked to view the pictures in the book and then tell the story. Another method to elicit narratives is the story recall task. The child listens to a story being read to her and is asked to retell the whole story. The audiorecorded narratives are transcribed and analyzed for vocabulary and grammar as well as for narrative structure.

Narrative skills are increasingly important in school contexts, as children need to comprehend larger and more complex discourse. Assessing children’s oral narrative production can help shed light on their academic readiness in relation to their language-based skills. Studies with monolingual children have shown the significance of children’s narrative development for the acquisition of literacy skills. There are relatively fewer studies on narrative development in bilingual children (Gutiérrez-Clellen, 2002; Fiestas & Peña, 2004; Chong, 2011). The findings of existing studies suggest that typically developing bilingual children, including children who are fluent in two languages, may not show equivalent levels of narrative proficiency in their L1 and L2. In more complex tasks, such as “story recall,” children may demonstrate better performance in one language. Children may also differ in relation to the language (L1 or L2) in which they demonstrate better narrative skills. In less demanding tasks (e.g., narration of a wordless picture book), however, bilingual children are able to successfully use their grammatical knowledge in each language without apparent difficulty and perform similarly across their two languages in relation to overall narrative quality. Furthermore, the evidence suggests that children who appear to be limited in one language are capable of producing adequate grammar, appropriate narrative structure, and overall narrative quality in that language when their spontaneous narratives are analyzed. Crucially, the fact that a child is still in the process of learning an L2 does not necessarily preclude her appropriate use of narrative structure on spontaneous storytelling tasks. Thus both story recall and spontaneous narratives are useful, for different reasons, in assessing bilingual children’s linguistic abilities in educational as well as clinical settings (Gutiérrez-Clellen, 2002).

An important criterion for the elicitation of language samples is the age of the bilingual speakers at the time of testing. The task used to elicit language samples should not be too difficult for young children or too easy for older children and

adults. Maintaining a balance between these two standards, particularly when the purpose is to compare the linguistic ability of children and adults, is a challenge (Unsworth, 2008).

Mean length of utterance (MLU) is a measure commonly used by language acquisition researchers to examine children's early morphosyntactic development. MLU is the average length of a child's utterances computed across numerous utterances in that child's spontaneous speech sample. In relation to simultaneous bilingual children, MLU, as a measure of linguistic proficiency, has been used to compare the development of their two languages and also to compare the rate of development in each language with monolingual norms (Paradis et al., 2011). Some researchers have used MLU (MLU_W or MLU_M) to identify the bilingual child's dominant language at a given age. MLU_W is based on the number of words and MLU_M is based on the number of morphemes per utterance. A potential problem in computing the MLU of bilingual children using one measure (e.g., MLU_W) is the likelihood of underestimating the MLU of one of the two languages, in the case of language pairs which represent different morphological types (e.g., richly inflected languages such as Spanish and Tamil vs. poorly inflected or isolating languages such as English and Chinese) (Yip & Mathews, 2007). In such cases, computing the MLU based on both methods would be necessary, in order not to violate the principle of structural equivalency.

MLU is a reliable measure of grammatical complexity for very young children but not for older children and adults. Recently, the field of second language acquisition has witnessed a growing interest in comparing child L2 development with adult L2 development. An alternative measure of grammatical complexity recommended for comparative purposes is mean verbal density, which refers to the average number of finite and nonfinite (auxiliary and lexical) verbs computed across numerous utterances in an individual's spontaneous speech sample (Unsworth, 2008). Mean verbal density has also been used to compare L1 and L2 development in sequential bilinguals. However, as in the case of MLU, when using verbal density for comparing grammatical complexity across a bilingual individual's two languages, one should take into account the crosslinguistic differences between the two languages in the language pair. For example, auxiliary verbs, in English-type languages are independent morphemes, whereas in agglutinative languages, such as Korean and Tamil, they are suffixes bound to the verb stem. The method that will work for English-type languages (i.e., counting only independent units) will lead to an underestimation of the verbal density in relation to Korean (Chong, 2011).

Another problem when analyzing bilingual children's spontaneous speech samples concerns the treatment of code mixing or code switching. Should mixed utterances be included when computing for measures of grammatical complexity? If the language switch involves only a single word switch (e.g., nouns), it may be possible to assign the utterance to one of the two languages, on the basis of the language of the verb. However, the mixing may be such that categorization based upon the language may be difficult. An appropriate procedure would be to compute the MLU of the mixed utterances as well, as ignoring them may lead to an underestimation of the child's linguistic proficiency. Code switching can be a valuable communication resource for bilingual children and a bilingual child's

code-mixed utterances may also represent MLU values that are higher than the values for each of her two languages (Arias & Lakshmanan, 2005).

Language-General Measures and Processing Capacity

A problem with using language-specific measures when assessing bilinguals is that there is always a potential for bias, as they probe certain aspects of linguistic knowledge (e.g., vocabulary items or grammatical rules). In order to address this problem, researchers have begun to develop language-general measures for assessing bilinguals, especially simultaneous and sequential bilingual children, in educational and clinical settings (Paradis et al., 2011). Such measures seek to assess the children's language-processing capacity by investigating their use of linguistic and nonlinguistic mechanisms, which are thought to be language general (and also dialect neutral) in nature. Examples of processing-dependent measures include digit repetition, real word repetition (in the L1 and L2), nonword repetition (Windsor, Kohnert, Lobitz, & Pham, 2010), as well as tests assessing children's ability to "fast-map" the meaning of a novel word from its linguistic context (Seymour, Roesper, de Villiers, & de Villiers, 2005; de Villiers & de Villiers, 2010). Language-general measures tend to be less biased against bilingual children. They can be effectively used to determine whether the referred bilingual children have genuine language impairment or whether they are simply demonstrating a language difference and have a typical underlying language-learning ability. Typically developing children generally do not demonstrate difficulties with such processing-dependent measures, whereas children with language impairment do (Roseberry-McKibbin & O'Hanlon, 2005).

Psycholinguistic tools are currently being developed as part of the Hawaii Assessment of Language Access Project (HALA: O'Grady, Schafer, Perla, & Lee, 2009) for the early diagnosis of language loss in bilinguals, which will be useful in language revitalization and maintenance programs. The tasks in the HALA inventory exploit the fact that the speed with which bilingual speakers access lexical items and structure-building operations in their two languages provides a sensitive measure of relative language strength (i.e., dominance).

Challenges

The implementation of nonbiased and less formal alternatives to bilingual assessment can be challenging for several reasons. As standardized testing is highly valued in mainstream society, it is unlikely that more informal assessment methods such as dynamic assessment, language samples analysis, and language profiles can entirely supplant formal standardized testing when assessing bilinguals. On the contrary, the use of standardized assessment measures with bilingual populations will likely continue in research, clinical, and educational settings. From a holistic perspective, the recommended practice is to assess bilinguals in each of their two languages. This can be challenging particularly in relation to norm-referenced tests. Standardized tests have been developed only for English and a few other high status languages and are not available for all potential language

pairs. Additionally, even for language pairs where such measures are available, adaptation to local bilingual norms is crucial. Given time and financial constraints, adaptation to local bilingual norms may be feasible only in situations involving a large number of bilinguals with the same language pairs. An additional challenge is posed by the crosslinguistic equivalence requirement. Language is dynamic and varies across space and time. Standard descriptions of the grammar of the target languages may not truly reflect local norms. In order to avert a potential bias, the assistance of bilingual cultural brokers, from the same community as the target bilingual assessees, is needed in such cases (Martin, Krishnamurthy, Bhardwaj, & Charles, 2003).

Less formal alternatives to standardized assessment, such as dynamic assessment and language samples analysis, are potentially valuable in ensuring least biased assessment practices. However, mainstream society may find such approaches less acceptable because of their variability. An ongoing challenge is how to raise their value in relation to reliability and validity, and make them more acceptable. At the very least, this would require clarity of the teaching/learning objectives and expectations about learner performance, with the assurance that consistent criteria will be used in assessment.

Language-general measures (e.g., fast mapping, processing capacity) hold great promise for nonbiased assessment practices in the future. However, such language-general measures are available only for a few aspects (e.g., phonology, vocabulary, and language dominance). A challenge for the future is to develop language-general measures for the assessment of other aspects as well.

Implementation of new solutions to old problems is likely to meet with resistance because of firmly entrenched attitudes and habits. A continuing challenge to the implementation of less formal alternatives to the assessment of bilinguals is how to raise the awareness of the key stakeholders such as teachers, speech language pathologists, and parents of bilingual children about the need for nonbiased approaches to bilingual assessment. As a large part of bilingual assessment involves school contexts, the training and support of teachers are crucial for the successful implementation of less formal approaches to language assessment.

Future Directions

In order to facilitate successful implementation of holistic approaches to bilingual assessment, curricular reforms to educational and training programs are necessary to raise awareness and promote understanding among potential teachers and speech language pathologists of the value of less formal and least biased alternatives to the assessment of linguistically and culturally diverse populations. Sustained efforts to bring in greater consistency to less formal alternatives to bilingual assessment can help facilitate their acceptance within the mainstream. The establishment of a computerized database of the language profiles of bilinguals for different language pairs would partially help address the variability problem. At the same time, given the value placed upon standardized tests in society, further research on the adaptation of standardized measures for use with specific language pairs, where such measures are currently unavailable, as well as continued

efforts to adapt existing standardized tests to local bilingual norms will be necessary. Further research is also needed to develop language-general assessment measures for linguistic aspects for which such measures are lacking, such as morphology and syntax. For research purposes as well as curriculum-based assessment, there will, for obvious reasons, continue to be a need for the development of appropriate language-specific measures for use with bilingual populations.

In order to facilitate successful communication within bilingual communities as well as within today's global world, further research is needed to help develop language assessment measures that value code switching and translanguaging. Another area that can benefit from future research relates to the use of language brokers. The services of language brokers are frequently used in the treatment of bilingual aphasic clients; there will likely be an increasing need for the use of language brokers in other clinical settings, as well as in educational and research contexts. There is a need for research on how the use of language brokers can influence bilingual assessment outcomes.

Classroom-Based Assessment Issues for Language Teacher Education

Constant Leung
King's College London, England

Introduction

Assessment as an integral part of teacher education has received increasing attention in recent years. Although teachers have always been involved in assessment activities in their professional work, traditionally teacher education has generally not given assessment literacy—that is, the professional knowledge and repertoire regarding assessment—a great deal of curriculum prominence. Recent developments in education and assessment reforms have, however, pointed to the need for teachers to have a good grasp of assessment issues. Furthermore, the current trends toward increasing accountability in public services have been reflected in greater use of the assessment of student attainment as an index of effective pedagogy and cost-efficient educational provision. With few exceptions, practicing teachers are required to administer externally produced tests as well as to carry out teacher-led assessment. The more they understand the educational and technical issues involved, the better they are able to make principled decisions that would lead to beneficial uses of assessment, especially classroom-based assessment, in their professional practice. For these reasons assessment literacy is now a very important aspect of teachers' professional repertoire (see Inbar-Lourie, 2008, for a further discussion).

For reasons of clarity this chapter will focus on classroom-based assessment issues for teacher education with reference to teachers working in the broad field of English language teaching (ELT); the conceptual issues raised in this discussion are, however, relevant to language teacher education more generally. ELT teachers work in a range of diverse contexts in different world locations. Some work in conventionally labeled foreign language contexts (e.g., universities and schools in parts of Africa, East Asia, and South America), some in places such as Hong Kong and Singapore, where English is regarded as a second language, and yet others in

international schools (in all parts of the world) where English is used as the medium of instruction. In many educational jurisdictions in places such as Australia, England, and USA, where a significant number of students come from linguistically diverse backgrounds, ELT can be provided as part of mainstream content lessons. The discussion will be oriented toward giving an account of some of the key issues related to teacher-led classroom-based assessment that are relevant to preservice and in-service additional/second language teacher education. This chapter will not address classroom-relevant issues related to peer and (student) self-assessment (but see cross-references at the end of this chapter). The term “assessment” is used inclusively in this discussion, to refer to all the types of measuring, monitoring, and evaluating student learning and attainment that are carried out by teachers; the narrower terms “test” and “examination” will be used, where appropriate, to indicate the use of particular assessment instruments.

Classroom-Based Assessment in Teacher Education: Some Key Issues

Classroom-based assessment has been a major focus in many curricular reforms in different parts of the world (see Davison & Leung, 2009). At the same time assessment is being increasingly recognized as an important part of the ELT teacher education curriculum. For instance, the Cambridge ESOL (English for speakers of other languages) Delta syllabus (University of Cambridge Local Examinations Syndicate, 2007) assessment is in two of its three modules. Out of a 47-page statement, the TESOL/NCATE standards for initial teacher education programmes (Teachers of English to Speakers of Other Languages, 2010) devote some 12 pages to specifying the types and levels of knowledge in assessment for trainee teachers. In general most teacher education curriculum statements cover issues such as formative and summative assessment purposes, technical concepts such as validity and reliability, and professional considerations such as appropriate choice of externally produced assessment instruments and practicality. Classroom-based assessment tends to be subsumed within these topics, with the exception of the TESOL/NCATE curriculum statement (Teachers of English to Speakers of Other Languages, 2010), which provides a separate subsection on “Classroom-Based Assessment for ESL” within the “Assessment” domain. The inclusion of a separate subsection on classroom-based assessment signals a growing awareness that this is an important area of professional knowledge and practice. For reasons of scope, this discussion will focus on four major issues: purposes of assessment, validity and reliability of assessment, perspectives on language and language learning, and the relationship between language and curriculum content. The overall aim is to help produce a teacher education agenda that would promote teachers’ assessment literacy. The discussion will be broadly framed within a classroom-based assessment perspective.

Purposes and Uses of Assessment

Assessment has been conventionally seen as serving two main purposes: formative and summative. Assessment activities in themselves are essentially

purpose-neutral; it is the way(s) in which we make use of the assessment process and outcome that would render them purpose-bound. For instance, the scores of a teacher-made vocabulary test administered at the end of a reading course could be used to indicate how much (or how many words) students have learned and retained. This would be a summative use of the test. At the same time, it is possible to use the results of the same test as a basis to work out what has and what hasn't been learned and why, and to develop alternative teaching strategies to try to improve future teaching and learning. This "assessment-to-teaching/learning" orientation would serve a formative purpose.

The term "assessment" in formal education generally signals particular moments within the curriculum when teaching, learning, and other related activities come to a halt, and students' performance is being checked and evaluated in specially designed activities. End-of-year school examinations and termly tests are examples of these set-piece activities. This conventional notion of assessment still holds for formal summative assessment. However, in the past 15 years or so the developments in formative assessment have added a process and learning orientation. This orientation to formative assessment is often discussed under the banner of assessment for learning. The influential Assessment Reform Group's (2002, p. 2) ten principles of assessment for learning, for instance, include the following:

- Assessment for learning should be part of effective planning of teaching and learning. A teacher's planning should provide opportunities for both learner and teacher to obtain and use information about progress towards learning goals . . . Planning should include strategies to ensure that learners understand the goals they are pursuing and the criteria that will be applied in assessing their work. How learners will receive feedback, how they will take part in assessing their learning and how they will be helped to make further progress should also be planned.
- Assessment for learning should focus on how students learn. The process of learning has to be in the minds of both learner and teacher when assessment is planned and when the evidence is interpreted. Learners should become as aware of the "how" of their learning as they are of the "what."
- Assessment for learning should be recognised as central to classroom practice. Much of what teachers and learners do in classrooms can be described as assessment. That is, tasks and questions prompt learners to demonstrate their knowledge, understanding and skills. What learners say and do is then observed and interpreted, and judgements are made about how learning can be improved. These assessment processes are an essential part of everyday classroom practice and involve both teachers and learners in reflection, dialogue and decision making.

Active open dialogic interaction between teachers and pupils seems to lie at the heart of this approach to formative assessment; from a teacher's point of view this kind of assessment is embedded in ordinary teacher-student interaction. The formativeness resides in the efforts made by the teacher to make use of the information given by the student as a basis of developing additional and/or alternative teaching strategies and of providing learning opportunities. When teachers engage

students in learning activities and analyze their performance with a view to determining how much or how well the target content (in terms of language or other subject knowledge or both) has been learned, they are effectively conducting a diagnosis of what has been learned or achieved (as part of their formative assessment). The diagnosis can be used to form the basis of teachers' pedagogic guidance for further learning. Perhaps it is worth highlighting the point that diagnosing student learning can take place as a one-off teacher-centered event that takes place at planned moments, or it can be built into teaching activities on an ongoing basis, with students playing an active part through dialoguing with others and reflecting on their own work (see Fox & Hartwick, 2011; also see Read, 2008, for a further discussion on diagnostic assessment).

Rea-Dickins (2006) provides an empirical account of how language teachers, working in collaborative teaching situations with subject teachers, orient toward different purposes in planned assessment and informal "assessing while teaching" activities. She notes that both the summative and the formative orientations may be observed during the moments when teachers carry out the assessment of student performance in the classroom. From the point of view of teacher education, particularly initial teacher education, an important point to emphasize is that formative and summative purposes are not tied to specific activities—the marks of an end-of-term teacher-made test can be used for both formative and summative purposes, just as teacher assessment of students' knowledge and understanding carried out during teaching can be both formatively and summatively oriented.

Validity and Reliability in Classroom-Based Assessment

Issues of validity are key to the consideration of quality in assessment. There is a considerable body of research literature devoted to these issues, particularly in relation to large-scale psychometrically oriented standardized assessment in the form of tests and examinations (e.g., Messick, 1989; Stoyhoff & Chapelle, 2005; McNamara & Roever, 2006; Bachman, 2010). Broadly speaking, validity refers to the extent to which an assessment can be justified in terms of a number of considerations such as: whether an assessment taps into the knowledge and skills that it claims to be focusing on (this is generally referred to as construct validity); what interpretation and use is made of the assessment outcomes; what consequences the assessment may have on the key stakeholders (e.g., the students); and so on. Traditionally reliability—accuracy and consistency in sampling and reporting student performance—is seen as a key quality in any assessment (and it is a separate consideration from validity). From the point of view of classroom-based assessment, reliability issues should be seen in conjunction with the focus of the assessment and its intended purpose(s) and use(s). There is a case for suggesting that, for classroom-based assessment, reliability and validity work hand in hand, as the following discussion will indicate.

In planned and specially designed teacher-made summative assessment activities that attempt to establish what has been learned, for example an end-of-term test, it would be important to be clear about what is meant to be assessed (i.e., what is the construct?), and how the chosen focus of assessment is being

translated into the test itself. For instance, in developing a test on speaking and listening, one might ask questions such as:

- What counts as listening and speaking (in a specific curriculum context)? Listening to and giving a monologic talk (e.g., a lecture)? Listening and responding to a recorded multiparty conversation? Listening to (and watching) a videorecorded conversation and responding to questions from the teacher? Listening to others while participating in a live discussion?
- What content should be included in listening tasks? Should the tasks be on topics covered in the course? Or should they be general topics appropriate for the age and for the stage of language development?

There isn't a single, universal correct answer to any of the above questions; the important consideration is fitness for purpose. Language teachers in academic language programmes at university are likely to have different concerns and priorities from those of teachers who are in school content classes, teaching English collaboratively with content teachers. The test tasks should reflect the aim and content of the teaching programme concerned. Furthermore, interpreting the value of the outcomes of such teacher-made tests should take account of intended use(s). If the purpose of the test is to sort students for a particular purpose, for instance to identify students with relevant background knowledge to fill ten places for a general language course at a particular level, then it would be sufficient to use the test scores from a relevant programme to establish the students' attainment relative to one another. The ten students with the top ten highest scores would be allocated the ten places, even if the students concerned may not compare favorably with past or future cohorts. However, if the intended use of a test is to find suitable candidates for a competition, say in oratory, then it would be necessary to identify those students who have the attributes that the competition is known to require. In other words, a stronger criterion-based consideration would need to be applied. One of the advantages of teacher-made tests over externally produced tests is that teachers, by using their local knowledge, are generally better placed to develop tasks that would tap into their students' achievements. On the other hand, the close relationship between teacher-influenced content and teacher-made tests may be a limiting factor in validity, because the teaching may only have covered the content partially or from a particular perspective.

When teachers carry out formative assessment as part of teaching in an informal way, validity issues become more complex. When a teacher asks probing questions in order to find out about students' knowledge, the live and contingent nature of this kind of "on the run" assessment may lead to an unexpected change or detour in topic. For instance, an elicitation question such as "What is the capital city of China?" might yield a variety of responses from students. While for summative assessment purposes there is only one acceptable and correct answer to this question, formatively the answers provided by students are the entry point for further action. A correct answer may be the result of a lucky guess, an incorrect answer might be triggered by a momentary confusion over the different capitals at different historical periods or the different Anglicized names being used, and so on. On receiving an answer, the teacher might ask a further question such as "why?"

in order to elicit further information that might help establish the underlying reason(s). The point here is that the formative imperative cannot be served adequately just by having a well-defined construct in terms of desired knowledge and skills. To conduct formative assessment that is embedded within classroom interaction effectively, the teacher should offer students opportunities to express the basis of their answers; and s/he should use this information to design alternative teaching strategies and learning activities where necessary. Thus the validity considerations discussed earlier in relation to teacher-made tests or examinations would not be sufficient for classroom-embedded formative assessment, the validity of which depends, additionally, on improved learning outcomes. Colby-Kelly and Turner (2007) use the metaphor of “assessment bridge” to highlight this distinct relationship between assessment, teaching, and learning. Also see Davison and Leung (2009).

The discussion so far has addressed some of the key concerns regarding assessment purposes and validity. There are, however, two other conceptually relevant issues that should be taken into account when developing teachers’ professional repertoire in classroom-based assessment: view(s) on language and language learning and assessment; and the relationship between content meaning and language.

Perspectives on Language and Language Learning

Teachers’ beliefs and perceptions of what counts as language and language learning can bear on their assessment practices. Language learning can be understood in a variety of ways from different theoretical perspectives. For instance, a behaviorist view would suggest that learning is a form of response to external stimulus; a cognitive view of learning would foreground the importance of understanding and problem solving by individual students; and a sociocultural perspective would emphasize the importance of the interaction between the individual learner and the social environment (including other people’s actions in any given social situation). At the same time language can be conceptualized at a number of levels and in a variety of ways. For instance, a grammar-oriented teacher may regard language as primarily consisting of a set of rules at the lexical (e.g., spelling and tense inflection) and syntactical levels (e.g., active or passive voice); a discourse-minded teacher, on the other hand, may see language as a set of resources for meaning making that can embody social values and power relationships. (For a further discussion see James, 2006.)

At any one time language teachers, like other subject specialists, tend to hold particular views on language and language learning, some of which may be espoused and some may be implicit (Rea-Dickins, 2008). In various combinations, these epistemological views held by teachers can impact on their pedagogic and assessment practices. For instance, a grammar-oriented teacher who sees learning in behaviorist terms would tend to favor the vocabulary and sentence level work presented in discrete-point material for practice. A discourse-oriented teacher aligned with a sociocultural view of learning is likely to organize language-learning tasks as group work in which the teacher would act as expert informant and the students would be encouraged to participate in discussions and to build

on them in order to set their own objectives and tasks. In each of these cases the teacher's epistemological position and the associated pedagogy would impact on his/her assessment priorities. The grammarian would likely be focusing on the learning of discrete points of language (e.g., third party verb inflection in the present tense); the socioculturalist would be interested in assessing the language learning outcome, say, a piece of writing, against the backdrop of the students' current levels of proficiency and use of the available resources—such as a teacher's exposition of ideas, learning materials, and discussions with peers. So both the process and the product would be part of the assessment.

The examples above are illustrative. In practice teachers often hold a complex of views regarding language, language learning, and other education-related matters. In a study of assessment practice, for example, Leung (in press) reports that the participant teachers applied a range of criteria when marking English language learners' writing:

Skills: using grammatical rules correctly

Process: making use of recommended process in writing (e.g., drafting and revision)

Genre: using appropriate text types and language expressions for particular audiences

Effort: evidence of a student trying hard

Second/additional language: being mindful of the limits to the amount of language learning possible at any one time, thus accepting some unclear language expressions.

From the point of view of teacher education, it is important that the relationship between these language-related views and assessment be made explicit. A degree of conscious understanding of this relationship would be important for any reflection on the merits and problems in one's own classroom-based assessment practices. Furthermore, such knowledge would also help teachers to analyze and understand the often implicit language models and assumptions underlying externally produced tests and assessment frameworks. This would in turn enable them to make informed decisions as to how best to support their students' overall language learning and their preparation for assessment on the one hand, and how to avoid "teaching to the test" on the other (see Stiggins, 2001, for further discussion).

Relationship Between Curriculum Content and Language

The way language is construed has an impact on how the relationship between language and curriculum content is handled in assessment. It is noncontroversial to say that meaning is expressed through language. Furthermore, the communicative approach that has been predominant in English language teaching worldwide in the past 30 years has tried to focus on meaning in context. In turn, large-scale public language-testing systems such as International English Language Testing Systems (IELTS) have been designed to address language proficiency in specific contexts—the use of English in academic contexts, in this case. So, at the level of

broad conceptualization, there is an acknowledgment of the links between language and curriculum content meaning. In practice this means that academic English, for instance, is assessed through test items that represent some form of decontextualized proficiency. The actual relationship between wording (what is actually said or written in real contexts) and meanings in particular subject areas has, however, remained underarticulated. For classroom-based language assessment this state of affairs is unhelpful. Teachers, from their professional experience, know that it is possible to communicate the meaning of any curriculum content in a variety of formal and informal ways. Gibbons (1998: 101) offers an illustrative example:

Text 1 (working on the topic of magnetism, spoken by three 10-year-old students while doing an experiment using metal and non-metal objects):

1. this . . . no it doesn't go . . . it doesn't move . . .
2. try that . . .
3. yes it does . . . a bit . . . that won't . . .
4. won't work it's not metal . . .
5. these are the best . . . going really fast.

Text 2 (spoken by one student about the action, after the experiment):

we tried a pin . . . a pencil sharpener . . . some iron filings and a piece of plastic . . . the magnet didn't attract the pin but it did attract the pencil sharpener and the iron filings . . . it didn't attract the plastic.

Text 3 (written by the same student):

Our experiment was to find out what a magnet attracted. We discovered that a magnet attracts some kinds of metal. It attracted the iron filings, but not the pin. It also did not attract things that were not metal.

All three texts can be said to be about magnetism, but they differ in the lexical and grammatical resources being used. From the point of view of language assessment the teacher would need to address questions such as: Is the assessment at hand concerned with interactional talk, spoken (monologic) reporting, or written formal reporting? Effective classroom-based assessment, for both formative and summative purposes, would require a clear and explicit sense of the language resources students are expected to use in curriculum-based tasks.

Concluding Remarks

Current developments in curriculum reform and innovation in different world locations call for increasing teacher expertise in formative and summative assessment. The discussion in this chapter suggests that additional or second language teacher education should address some of the key concepts, such as validity and reliability, but should do so in ways that would sensitize teachers to the specific

affordances and purposes of classroom-based assessment. Furthermore, given that classroom-based assessment is often carried out at close proximity to pedagogy and learning, teacher education should promote a higher level of awareness of the relationship between teachers' own beliefs and perspectives on matters such as "what is language?" and "how is language/how should language be taught/learned?" and their assessment practices. In both preservice and in-service phases, teacher education programs can help develop a higher level of expertise in this increasingly important area of teacher professionalism.

Program Evaluation and Language Assessment

Brent A. Green

Salt Lake Community College, USA

Introduction

Like modern language assessment, program evaluation has developed into a professional and academic discipline over the past 40 years in response to the call for accountability in publicly and privately funded enterprises across a broad range of disciplines (Shadish & Luellen, 2005). In addition to a call for accountability in social programs, the accountability waves that have hit elementary, secondary, and higher education over the past decade have pushed program evaluation beyond a designation of just applied social science methodology to an understanding of the intellectually challenging problems which are raised in program evaluation theory and practice (Shadish, Cook, & Leviton, 1991).

While language assessment theory and practice have been centered primarily within the realms of language education programs and language acquisition research, program evaluation theory and practice often has a broader scope. An examination of theoretical perspectives from the field identifies theoretical origins stemming from accountability and social inquiry (Alkin & Christie, 2004).

Regardless of the orientation and history, both fields, language assessment and program evaluation, focus primarily on the practice of obtaining information that is used to make decisions in a variety of contexts. In educational contexts, educational assessments drive decisions that can impact a broad range of stakeholders. Norris (2008, p. 2) discusses these decisions and their impacts below.

On the basis of assessments, students will be accepted, placed, promoted, informed, instructed, motivated, and rewarded, or they will be denied access, retained, misplaced, misled, discouraged, and embittered. Teachers will be hired, promoted, supported, encouraged, and developed, or their contracts may not be renewed. The public, and education policy makers will be thoroughly informed or they will be wilfully (and often willingly) deceived . . . educational institutions, schools, and

programs will be accredited and funded, or not. Standards and curriculum will be challenged, evaluated, endorsed, revised, or dismantled. Instruction will be supported, developed, and improved, or it will be degraded, undermined, and ignored.

Likewise, program evaluation relies on information gathered through assessments and other means to make decisions about various programs and their stakeholders. Similar to the impact of assessments above, program evaluations carry significant implications and can result in policy and program decisions affecting a variety of stakeholders.

Given these similarities, what might a closely aligned discipline, like program evaluation, have to offer language assessment theory and practice? In the first issue of the language-testing journal, *Language Assessment Quarterly*, Alister Cumming (2004) calls for the continuation and extension of three directions that he feels are integral to language assessment. The directions he lists are to

1. broaden the scope of inquiry and contexts that inform knowledge about language assessment;
2. deepen the theoretical premises and philosophies of language assessment; and
3. consolidate through systematic, critical reviews the information base about prior research on language assessment. (p. 5)

A careful examination of program evaluation theory and practice can certainly help broaden the scope of inquiry and deepen the theoretical premises and philosophies of language assessment.

Among other things, a program evaluation perspective on language assessment may help assessment researchers and practitioners gain a clearer understanding of stakeholder and agent of reform roles in assessment reform contexts and the issues surrounding assessment misuse. In addition, a program evaluation perspective on language assessment can provide insight into contextual factors and decisions based on assessment results within a given program. Norris (2008) describes this process below.

Educational assessments cannot be adequately defined without addressing: (a) who uses them, (b) what kinds of information they provide about whom or what, (c) why and how that information is sought, (d) what decisions and actions are taken on their basis, and (e) what consequences are intended (and not intended) to occur as a result. (p. 73)

These processes and key questions have been the topic of research in program evaluation for many years. Language assessment theory and practice which focuses on these areas is still coming of age. A careful examination of these program evaluation processes can inform current language assessment theory and practice.

Previous Views or Conceptualization

Most historical overviews of program evaluation identify the historical trends which have occurred in program evaluation over the past century (see Guba &

Lincoln, 1989; Shadish, Cook, & Leviton, 1991; Rossi, Freeman, & Lipsey, 1999). While Shadish, Cook, and Leviton (1991) among others, trace evaluation back to the beginnings of human social interaction, most histories place the beginning of modern program evaluation in the mid-20th century corresponding to the rapid economic growth after World War II, the interventionist role of the US government, and the expansion of publicly funded social programs. Because these programs were funded by government dollars, there was pressure to demonstrate that they were contributing in positive ways to society and that the public was getting a good return on their investment (Kiely & Rea-Dickins, 2005).

The early methods used for determining the effectiveness of educational programs had their roots in the work of Ralph Tyler's (1942) objectives-based evaluation. Tyler's framework for evaluation focused primarily on the following procedures: (a) formulating a statement of educational objectives and classifying them into major types, (b) defining objectives in terms of behavior, (c) identifying situations in which students display these types of behavior, (d) selecting and trialing methods for gathering evidence, (e) selecting the more promising methods for further development and improvement, and (f) devising a means for interpreting and using the results of the various instruments of evaluation (Christie & Alkin, 2005, p. 281).

While Tyler's approaches to evaluation gained significant ground in the 1960s and early 1970s, Christie and Alkin (2005) discuss some of the reasons why objectives-based evaluation, at least in educational contexts, came under intense scrutiny. The first was the time-consuming nature of writing detailed objectives and then writing assessments that would measure the objectives. In fact, some teachers were spending so much time on the objectives that they had very little time to teach. The second criticism was the emphasis on measuring objectives rather than judging the merits of the program. This approach failed to capture the unintended aspects of the program, describe the variation in program contexts, and assess the relationships among the objectives. Finally, it was found that a focus on specific objectives could deter teachers from teaching a broad curriculum.

Tyler's focus on educational outcomes was a direct result of his interest and research in educational evaluation. Program evaluation research and practice for a diverse range of early studies continued to increase the knowledge base of evaluation. Psychologists and educators contributed to the knowledge of conducting experimental evaluations. Anthropologist evaluators focused on qualitative methods, and management evaluators focused on management information systems. (Shadish & Luellen, 2005).

According to Shadish and Luellen (2005) early evaluation theory and practice expanded and diversified as knowledge databases grew. New theories began to address the politics of applying methods and examined how research fit into social policy. These theories helped researchers focus on five fundamental issues of program evaluation as expressed by Shadish and Luellen (2005, p. 186).

- (a) how social programs and policies develop, improve, and change;
- (b) debates about the best ways for constructing knowledge about social programs;
- (c) the ways that value can be attached to program descriptions in a highly charged political

process; (d) how social science information is used to modify programs and policies; and (e) the tactics and strategies evaluators following in their professional work, especially given the constraints of time and money that they usually face.

Current Views or Conceptualization

As mentioned above, modern evaluation theorists and practitioners subscribe to a diverse range of perspectives and foci. Norris (1998) identifies six routine approaches to evaluation which he believes represent modern evaluation practice: experimentalism, the objectives/achievement model, performance indicators, self-study, expert or peer review, and inspection.

Alkin and Christie (2004) provide a useful framework for classifying modern evaluation theory. In their framework, represented as an evaluation theory tree, they identify three branches, methods, valuing, and use, with each branch growing out of a common trunk of accountability and systematic social inquiry and fiscal control.

The methods branch is classified as the “evaluation as research, or evaluation guided by research methods branch” (Alkin & Christie, 2004, p. 12). Methods-focused evaluators are concerned primarily with obtaining information that can be generalizable to broader contexts or in some way facilitate the construction of knowledge bases. In other words, the role of the evaluator is to ensure that data are collected and analyzed in such a way that results can be generalized to broader populations or gathered in a manner which contributes to greater understanding of social phenomena. Alkin (2004) lists the early work of Campbell (1957) as the fundamental source for experimental and quasi-experimental design within the methods branch.

Evaluators who primarily focus on their roles of making appropriate judgments or the placing of value on data as central to the evaluation process are listed on the valuing branch of the evaluation theory tree. According to Alkin and Christie (2004), “Theorists on this branch believe that what distinguishes evaluators from other researchers is that evaluators must place value on their findings and, in some cases, determine which outcomes to examine” (p. 32). The evaluator most associated with the valuing branch is Michael Scriven (1967). The following quote from Scriven (1986, p. 19) helps illustrate the job of the evaluator in the valuing branch. “Bad is bad and good is good and it is the job the evaluators to decide which is which.”

The third branch, the use branch, focuses mainly on how evaluation information will be used by stakeholders to make important decisions. According to Alkin (2004), this class of theories is “concerned not only with designing evaluations that are intended to inform decision making, but . . . [is also intended] to ensure that evaluation results have a direct impact on program decision making and organizational change” (p. 44). In this type of decision-oriented approach, when the results of an evaluation are shared with stakeholders, it is expected that they will use those results to promote change. Alkin (2004) cites Stufflebeam’s (1983) context, input, process, and product (CIPP) model as one of the most well-known utilization-focused theories.

A use-focused evaluation places primary emphasis on stakeholders. In program evaluation, stakeholder involvement refers to stakeholder participation in one or more aspects of the evaluation process (see the list of stakeholder factors below).

Stakeholder factors

Involvement in decision-making processes

Confidence in abilities to use research procedures

Sense of ownership

Engagement

Self-determination

Feelings of equitable distribution of power relationships

Collaboration

Self-inquiry about basic assumptions, beliefs, and practices

According to Greene (2005) stakeholder involvement is more than “providing information or responding to data gathering instruments” (p. 357). Stakeholders who are involved in an evaluation process contribute to important decisions regarding evaluation planning, implementation, and use.

Shulha and Cousins (1997) have observed that, when researchers have focused on involving stakeholders in the decision-making processes, positive outcomes often result in not only the process, but also personal learning and program practices.

In addition, other researchers (Ayers, 1987; Greene, 1988; Cousins, 1995) have observed how participation in evaluation gives stakeholders confidence in their ability to use research procedures, confidence in the quality of the information that is generated by use procedures, and a sense of ownership in the evaluation results and their application. Finally, studies by Fetterman (1994) and Fetterman, Kaftarian, and Wandersman (1996) identify engagement, self-determination, and ownership as important elements in evaluation contexts where stakeholders are concerned about the political actions concerning their programs.

Shulha and Cousins (1997) also discuss among the emerging practices in the use branch of evaluation a move toward an understanding and more equitable distribution of power relationships that lead to more “jointly negotiated decision making and meaning making” (p. 200). Regarding what has been learned from stakeholder research, Shulha and Cousins (1997) found several studies which report positive reactions to evaluation in contexts where evaluators worked closely with stakeholders in a collaborative model.

Following current trends in use-focused evaluation, two evaluation use researchers, Hallie Preskill and Rosalie Torres (Torres, Preskill, & Piontek, 1996; Preskill & Torres, 1999, 2000; Torres & Preskill, 1999, 2001), have spent a considerable amount of time and effort describing a process in which stakeholders are the key decision makers who are ultimately responsible for change. In their approach, evaluation’s primary purpose is to support the kind of organizational learning that can ultimately lead to effective decision making and improvement in department, programmatic, and organization-wide practices. In essence, their approach seeks to establish a “community of practitioners who inquire daily about their progress

and use their learning to improve themselves and the organization" (Preskill & Torres, 1999, p. xix).

Since it is the stakeholders who are the central participants in the evaluation process, it is they who are articulating, reviewing, and comprehending the information needed to make lasting organizational change. Stakeholder involvement is intended to "increase their buy-in to the evaluation, their understanding of the evaluation process, and ultimately, their use of the evaluation findings" (Preskill & Torres, 1999, p. 388).

While there are many practical models of use-based approaches which focus on the decisions and learning of the stakeholders which have been proposed, given the primary focus on the stakeholders and opportunities for individual and organizational learning, Preskill and Torres's (1999) evaluative inquiry seems particularly promising for use in language assessment reform settings. While there has been a general call in language-testing literature for more stakeholder involvement in language test development (see Hamp-Lyons, 2000), there have been no clear procedures on how this might be carried out within actual language assessment reform contexts. Since the main focus of the evaluation use branch is on information used to support stakeholder decisions, this is one area that can specifically inform the processes of language assessment reform.

Use-focused program evaluation research has also examined the role(s) of the evaluator. Literature in use-based program evaluation and educational innovation addresses some of the issues related to the individual(s) who are promoting the reform. Two bodies of work by evaluation theorists Hallie Preskill and Rosalie Torres, and Everett Rogers, an innovation theorist, are discussed below.

In Preskill and Torres's (1999) evaluative inquiry approach, the evaluator is the one who facilitates change. This person not only provides knowledge about research designs and how to analyze results, but also, and perhaps more importantly, focuses stakeholders' attention on important issues through the "collective action of dialogue, reflections, asking questions, and identifying and clarifying individuals' values, beliefs, assumptions, and knowledge" (p. 2). As individuals and teams share their learning from evaluative inquiry with others, Preskill and Torres believe the organization learns. They also believe that when evaluators help organizations apply the results of evaluative inquiry to their pressing issues, organizations can improve their practices, processes, products, and services. While Preskill and Torres's discussion is specific to program evaluation, it seems that these principles might easily transfer as language test reformers attempt to promote change in specified contexts.

Rogers (1995) defines a change agent as "an individual who influences clients' innovation decisions in a direction deemed desirable by a change agency" (p. 335). In his view the change agent can work toward one of two key goals: she or he can either promote the adoption of new ideas or slow the process to prevent undesirable effects.

Rogers (1995, p. 337) lists seven roles for change agents in the process of introducing an innovation in a client system: (a) to develop a need for change, (b) to establish an information-exchange relationship, (c) to diagnose problems,

(d) to create an intent in the client to change, (e) to translate an intent to action, (f) to stabilize adoptions and prevent discontinuance, and (g) to achieve a terminal relationship.

In addition, he notes one of the dangers of a change agent's zeal in promoting change is the short-rangedness of his or her goals to press the rate of adoption of innovations. Rogers states that it is better for change agents to look instead to self-reliance of clients as the primary goal of the change agency. In the long run he feels this will benefit the overall system (p. 357). Again, in many local assessment settings, these ideas can help the persistence of assessment practices that meet program goals and allow for valid score interpretations and decisions made of individual test results. The list below summarizes the key characteristics of agents of reform as discussed in the program evaluation and innovation theory literature.

Characteristics

- Facilitates change by focusing stakeholder attention on important issues
- Gets stakeholders to dialogue, reflect, ask questions, and identify and clarify their values, beliefs, assumptions, and knowledge
- Develops a need for change
- Establishes an information-exchange relationship
- Diagnoses problems
- Creates an intent in the client to change
- Translates an intent to action
- Stabilizes adoptions and prevents discontinuance
- Achieves a terminal relationship
- Develops a need for change
- Promotes stakeholder self-reliance

We now turn to a discussion of evaluation approaches specific to language assessment reforms in local settings. While language program evaluation methods have been well documented in the literature (see Brown, 1989; Lynch, 1990, 2003; Rea-Dickens & Germaine, 1998; Kiely & Rea-Dickens, 2005), Norris (2008) and Green (2010) engaged use-focused program evaluation principles in helping educators examine the utility and worth of their assessment practices in local settings.

Green (2010) focused his research on the role of program evaluation, innovation theory, and modern language assessment theory in a local assessment reform setting. His main research goal was to identify key factors associated with an English as a second language (ESL) test reform project at a small liberal arts university. Using case study methodology, his findings indicated that an evaluator (agent of reform) who engages the stakeholders using utilization-focused program evaluation principles can provide clear guidance in the areas of stakeholder involvement and the utilization of assessment processes and results to help participants respond to change. His model, which represents the interactions of the key factors is represented in Figure 90.1.

This figure visually represents key factors and their interactions in the examination of language test reform within a local context. The three factors related to

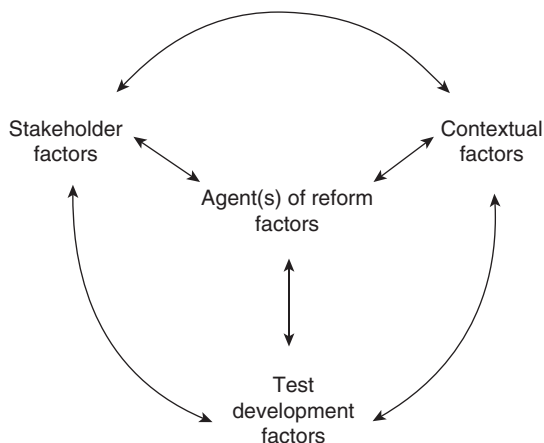

Figure 90.1 Key factors in test reform (Green, 2010). © Lambert Academic Publishing

stakeholders, context, and test development are shown encircling the agent(s) of reform. The double arrows on the periphery represent the interaction among the stakeholders, context, and test development while the double arrows within the circle represent the interactions among the stakeholders, context, and test development as they are negotiated by the agents of reform.

Norris's (2008) multi-year case study work with a German as a foreign language department at Georgetown University, USA demonstrates how use-focused program evaluation approaches were applied in meeting the assessment needs of the German program and its stakeholders. The term he uses to describe his methods is *validity evaluation*, an approach based largely on the principles of evaluation use methodologies. Like Green (2010), Norris discovered that utilization-focused methods were instrumental in getting stakeholders to improve their assessment practices which positively impacted program and individual course outcomes.

Additionally, there has been a growing body of literature which has focused on the consequences or impact of high stakes tests in a variety of contexts. However, there have been no attempts to look at the role of test development and validation in reform settings. According to Bachman (2005, p. 1) one of the shortcomings of recent validity research in language testing and educational measurement is the failure to provide a clear set of principles and procedures for linking test scores and score-based inferences to test use and its consequences. So, in spite of a body of testing literature that examines validity (Messick, 1989; Bachman, 1990), ethical test use (Lynch, 2001; Kunnan, 2003), argument-based frameworks (Kane, 1992; Mislevy, Steinberg, & Almond, 2002) and critical language testing (Shohamy, 2001) until recently there was no set of procedures which linked test scores and score-based inferences to test use and the consequences of test use. Bachman (2005) has attempted to remedy this situation by suggesting the use of Toulmin's (2003) argument structure as a possible mechanism for linking these important areas.

However, even modern validation argument theories such as those proposed by Bachman (2005) and Bachman and Palmer (2010) can benefit from an understanding of the participatory nature of change within a given assessment system. What is missing from Bachman's framework is an approach for engaging stakeholders in the process that will encourage learning and change. Again a program evaluation use framework can be useful in helping stakeholders make appropriate decisions when presented with an assessment argument for the validity and interpretation of assessment results (see Kunnan, 2010, for challenges to the use of Toulmin's argument structure for test fairness).

There is more that language assessment researchers can do to examine the stakeholder and contextual factors in local assessment settings. Regarding what we have learned from program evaluation research on context in program evaluation, Shulha and Cousins (1997) state

It is clear . . . that both empirical and conception research on the nature, causes, and consequences of utilization has become immersed in issues of context. The evidence suggests that the more evaluators become schooled in the structure, culture, and politics of their program and policy communities, the better prepared they are to be strategic about the factors most likely to affect use. (p. 207)

Traditionally, practitioners interested in language test reform have focused on the qualities within an examination which result in either positive or negative impacts on participants, institutions, and society. This is evident in a growing number of college entrance exams in Asia and other countries which have been modified to include English oral components with the primary purpose of encouraging oral skill instruction and development in these countries. The expectation is that there will be a direct causal link between the test and the behavior of the participants (e.g., teachers, test takers, administrators, etc.). Many hold the view that good tests equal positive impact, and bad tests equal negative impact. However, recent research on these issues in language testing has demonstrated that this is an overly simplistic view, and has revealed a picture that is much more complex. Alderson (2004) discusses the challenges of dealing with the complexities of the change process when testing innovations are proposed. He states that "studies need to take careful account, not only of the context into which the innovation is being introduced, but all of the myriad forces that can both enhance and hinder the implementation of the intended change" (p. xi). He goes on to cite Wall's (1999) Sri Lankan study which demonstrates how innovation theory and its application increase our understanding of the "hows" and the "whys" of language test impact. An understanding of how use-focused program evaluation theory examines contexts can help assessment researchers consider contextual factors in specific language assessment reform contexts.

Finally, we examine research on evaluation use and misuse as a guide to help understand parallel phenomena in language assessment research and practice. As evaluators strive for more process-oriented approaches to evaluation with a focus on collaborative methods of engaging stakeholders in the evaluative processes, several researchers (Alkin & Coyle, 1988; Shulha & Cousins, 1997;

Christie & Alkin, 1999) have raised the question of whether or not the evaluator can maintain a bias-free stance when faced with pressure from the program community.

According to Shulha and Cousins (1997) “the question of understanding the complexities of, and the potential for, patterns of misutilization is especially pivotal in situations where evaluators work closely with program stakeholders” (p. 201). Alkin and Coyle (1988) distinguish between evaluation misuse and mis-evaluation of evaluation results. For them the responsibility for evaluation misuse resides with the users of the evaluation results while the responsibility of mis-evaluation lies with the evaluators.

What is enlightening about this discussion is the fact that evaluation literature focuses on the practices and principles of the evaluator and others engaged in the evaluation process. According to Christie and Alkin (1999) “misutilization examines evaluation ethics through a different lens. Here, we consider the ethics of those using the evaluation, be it the commissioning of an evaluation, the evaluation process itself, or the evaluation findings” (p. 1). House (1995) argues that, even with standards and guidelines in place, there will always be disputes about what constitutes good evaluation. Likewise, language assessment professionals, in spite of standards and guidelines, have been known to argue over what constitutes good assessments. The discussion of evaluation misuse and mis-evaluation from a program evaluation perspective is a framework that language assessment developers and users should access and consider examining.

Challenges

One of the greatest challenges of a program evaluation perspective in language assessment is that there is still much we do not know about processes of change which evaluations and assessments bring about. Taut (2008) sees an insufficient empirical base as the greatest challenge for understanding the conditions under which stakeholder involvement works. She states that

We need even more rich, detailed descriptions of successful and unsuccessful evaluations involving stakeholders. These descriptions should include detailed characterizations of the evaluation process, the stakeholders, evaluator behaviors, and the context to provide a better understanding of the complex interplay between these factors and to eventually derive more robust lessons learnt for factor combinations that are more common in practice. (p. 229)

While program evaluation research from the past and present is adding to the knowledge bases, more research is needed to understand how contexts, stakeholders, and evaluators interact and engage within assessment contexts. These key players and the interactions need to be essential components of future language assessment research. As knowledge bases increase, and more assessment researchers engage in program evaluation-based research, it is hoped that there will be more studies reporting on practical issues in actual test development and reform settings.

Future Directions

As mentioned above, perhaps the most promising aspect of program evaluation theory and practice is its role in promoting change in a wide variety of contexts. While language assessments have been used as levers for change (Pearson, 1988) for many years, one of the greatest challenges of language assessment is the practical application of assessment-based theory in local contexts. Program evaluation can help with the understanding of how language teachers can create assessments that allow for valid interpretations and decisions. Bachman (personal communication, April 28, 2012) believes that there is a need for language assessment researchers helping teachers understand and correctly apply the fundamentals of classroom-based assessment.

In short, program evaluation theory and practice outlines the processes of assessment reform which can help classroom teachers understand and use test results to make the kind of decisions they need to about their curriculum, programs, and students. In addition, what is needed in educational programs which deal with assessment reform is agents of reform who are equipped with the tools of use-focused program evaluation theory and practice, and who can help stakeholders understand assessment purposes, validate score interpretations and decisions, and promote beneficial change within local contexts.

The Interface of Language Assessment and Forensic Contexts

Margaret van Naerssen

Immaculata University, USA

Introduction

Where immigrant and refugee populations are increasing, and where a language assessment community is active, professionals in language assessment are being called to apply their expertise in legal and forensic contexts (e.g., law enforcement contexts). Language assessment experts bring valuable expertise. Still, initially there is, too often, limited awareness of the specific demands of forensic contexts. This can trip up the most qualified examiner. This, in turn, can result in (a) potential misapplications of language assessments and (b) court challenges to one's expertise. This can also affect the perceived value of language assessment by the court. One does not simply test, report a score or descriptors, and then jump to the legal question.

More positively, the uniqueness of each case is an opportunity for flexible and creative thinkers to (a) determine how to appropriately link specific evidence to legal questions; (b) creatively draw on experience communicating clearly with those outside language assessment, and work on very real-world problems.

Purposes

The theme of this chapter is the interface of language assessment and forensic contexts. The immediate purpose is orienting those new to forensic contexts and supporting those already occasionally working in legal contexts but who have lacked time to further explore issues.

One long-term goal is for experts to inform jury members and those in the legal community about non-native speaker (NNS) language issues. Another is to promote more appropriate use of language assessment, strengthening the interface of language assessment and forensic contexts.

Scope

This chapter begins with common contexts in which language assessment might be needed. This is followed by a review of certain linguistic and assessment concepts and their relevance to legal contexts. Interface is then illustrated through cases and discussions of four broad topics:

- linking assessment data to legal questions,
- evidence argumentation and practical considerations,
- connecting language assessment to other legal contexts, and
- exploring challenging issues.

Focus is on interactive oral communications related to “live” cases. The US legal system is the primary frame of reference though there are references from other countries. L1 refers to first language, L2 to second language, though a person may be an NNS of more languages. LEO is commonly used for law enforcement officers in the USA. LAE for language assessment experts is the author’s invention.

Forensic Contexts and Second Language Proficiency

This section begins with common forensic contexts in which language assessment might be needed. This is followed by a review of selected linguistic and assessment concepts and their relevance to legal contexts.

Common Legal Contexts

Three general communication contexts are introduced here to suggest a potential range of NNS cases: (a) communications in alleged criminal activities, (b) interactions with law enforcement, and (c) communications during case preparations and trials.

First, with NNS communications (oral or written) in alleged criminal activities, both receptive and productive abilities are considered: (a) the ability to understand enough to be held responsible for a decision to participate (or not) in alleged criminal activities, and (b) the ability to make one’s self understood accurately enough that meanings and intentions are clear. In the second context, in law enforcement communications, key communication concerns include the ability to

- accurately make one’s story understood during pre-arrest interactions,
- understand legal rights when given a police caution or during a search request,
- accurately make one’s story understood during law enforcement interviews, and
- understand the details of formal statements resulting from law enforcement interactions, with language evidence typically from police reports, confession statements, and recordings of communications with law enforcement.

A third context involves communications during case preparations and trials. Concerns include (a) the adequacy of legal counsel without an interpreter, and (b) the ability to accurately make one's own story understood during preliminary hearings and trials.

A key concern for all contexts is whether communications reflect truthful or deceptive language proficiency—either by a defendant to gain advantage in alleged criminal activities and legal proceedings, or by a native speaker pretending to be an NNS. (See also Chapter 15, Assessing Translation; Chapter 22, Language Testing for Immigration to Europe; Chapter 23, Language Testing for Immigration and Citizenship in the Netherlands; Chapter 24, Assessment in Asylum-Related Language Analysis.)

Linguistic and Forensic Concepts

Readers probably already understand the basic concepts below. They are placed here only to provide (a) a common frame of reference for the issues discussed, and (b) a convenient source of definitions if needed in court for grounding one's methods and findings. Of course, experts may prefer other definitions.

Linguistics is the scientific study of human language from various perspectives, including as one "window into the mind," and as a vehicle for communication in social interaction. Linguists view human languages as systems. A ballistics expert, by looking at patterns on targets, projectiles, and residue, can frequently determine the type of gun, the shooter's position, etc. Like experts in other forensic sciences, linguists look for patterns and inconsistencies in language evidence.

Applied linguistics is the application of theories and knowledge from linguistics to help solve problems in the real world. Sample disciplines include second language acquisition, sociolinguistics, second language testing, and acoustic phonetics.

"The presentation of expert linguistic evidence in court is often referred to as forensic linguistics" (Eades, 2010, p. 234). It can also include language in police work. More broadly it "refers to the linguistic study of language in the legal system" (p. 234). Sources of references on forensic linguistics include the International Association of Forensic Linguistics (IAFL, *n.d.*).

Language Proficiency and Assessment Concepts

Readers are familiar with language proficiency and language assessment concepts. They are given here to provide a common frame of reference for linking them to forensic contexts.

It may be advantageous to use a definition of *language proficiency* with some official government standing. Ad hoc definitions may have less credibility. The one given below is from the US Office of Civil Rights. LAEs, of course, might choose other definitions they feel comfortable with. A definition provides features for use in analyses. The expert might parse the definition into very simple components, and give concrete examples, to further understanding by attorneys, judges, or jury members. ("Student" can refer to any NNS.)

Language proficiency refers to the degree to which the student exhibits control over the use of language, including the measurement of expressive and receptive language skills in the areas of phonology, syntax, vocabulary, and semantics and including the areas of pragmatics or language use within various domains or social circumstances. Proficiency in a language is judged independently and does not imply a lack of proficiency in another language. (Office of Civil Rights, US Department of Education, *n.d.*)

Language assessment, an applied linguistics discipline, draws primarily from linguistics (the scientific study of human language) and the scientific field of testing theory and development. In the USA, the “reliable foundations” of an expert’s field and methods are important for court acceptance.

Frequently an LAE is involved with (a) the assessment of large populations in high stakes testing, (b) local assessments for program placement and achievement testing, or (c) work-specific language assessment. Assessment generally is of current abilities, achievement in specific training, past and current performance, or for predicting abilities to use the language in future settings.

In forensic contexts, language assessment is a tool in the legal process to examine language evidence. In contrast to the above-mentioned conditions, language evidence has been produced in the past by a specific person for specific communications. There is usually only one examinee. Thus, language tests for large populations or for specific programs have limitations when used with an individual for specific legal issues.

Informal surveying suggests that in many countries the idea of having LAEs work on legal cases simply has not arisen. The NNS population may not have reached a “significant” level. The language assessment community and country may have other priorities. Language proficiency requirements in some immigration policies may be seen as having “disposed of the problem.” Last, the use of interpreters is seen as an adequate solution: “What else is needed?!”

Linking Data to Legal Questions

It is critical to keep an eye on the legal question while developing relevant linguistic questions. For any research, developing the right questions, given the evidence one can collect, is probably the most difficult part of a case. However, it is too easy to simply give a test, report test results, then give a general opinion on the person’s ability to communicate in X setting.

Learning to Develop Links

This reflective, first person narrative shows how the legal question drives analysis of language evidence and assessment data. It also shows an emerging understanding of the relation between legal and linguistic issues of a newcomer to forensic linguistics.

Case: Perjury and Fraud The defendant, Mr. K, went to his insurance company to file a claim for roof repair costs from snowstorm damage. Mr. K was an NNS with

limited English speaking skills. Not realizing the visit would become a legal situation, he had no interpreter or lawyer. However, it became a formal interview with the insurance company attorney, along with a legal reporter transcribing a “deposition-like” interview of about 1.5 hours, without audiorecording. The insurance company then reported to the police department antifraud unit which followed up with surprise home visits.

An attorney wanted to know if his client, Mr. K, had English problems. On a police report was a note indicating his wife had interpreted. Then I learned Mr. K had been charged with perjury and insurance fraud. The attorney wanted to know if his client might have been lying or pretending not to understand several questions in a 79-page transcript of an interview in the insurance office.

Though new to forensics work, my professional instincts alerted me. I told the attorney not to show me the transcripts before I tested Mr. K. As the case involved an oral interview, I administered an ACTFL-like oral proficiency interview. My assessment was “borderline novice-high/low intermediate,” and I submitted descriptors for the relevant and adjacent levels.

I was then asked to check two pages in the insurance interview for possible evidence of lying or faking comprehension. I said two pages were not enough. I had translated the legal question into a linguistic one: *Is the language in those legally critical areas generally consistent with Mr. K's language use elsewhere?* The attorney was concerned about money for my extra time, but I insisted.

Reading over the transcript, I still was not quite sure what I was looking for or would find. With technical help I did some digital searches. I then reported that Mr. K's English proficiency reflected in the transcripts appeared to be generally consistent with my assessment. The attorney was not satisfied but did not explain why. I also wondered if there was more. I was his first linguistics expert so we were both new to the process. It also appeared the attorney still was convinced Mr. K was lying. So, since I was “the expert,” I was on my own.

I returned to the attorney's concern: lying, perjury. I found a legal definition of perjury in my son's law school textbook. Four conditions of perjury are (a) understanding the question, (b) intending to deceive, (c) deceiving, and (d) connecting the deception to the main charge. I suddenly realized: the first condition! Had Mr. K adequately understood the questions surrounding the insurance claim?

The insurance attorney had conducted the interview like a trial, cross-examining, using complex questions, and crisscrossing through time, all especially difficult for an NNS testing at a low proficiency level. Mr. K's responses were not sufficiently related to the insurance attorney's wide-ranging questions, thus were seen as lying.

Without much time, I needed to focus. What linguistic evidence was there of Mr. K's comprehension of *key* questions? Looking at the topics and apparent communication breakdowns, I noticed a pattern. When a specific date was mentioned Mr. K seemed to understand or at least negotiated some understanding. However, when a specific date was not mentioned, might Mr. K have been answering as if thinking of February 5, the date of the snowstorm? That was why he was at the insurance company! Using this assumption, his responses now made sense.

I was then able to show it was highly likely that a person with his tested language proficiency level would have had difficulty understanding the key

questions. The first test of perjury had failed. No evidence of fraud-related perjury. The attorney took it from there: no evidence of fraud.

Examining More Concepts

To help link language assessment to legal contexts, relevant characteristics of *language* and *linguistic* evidence are introduced. Also, key assessment principles, *reliability* and *validity*, are tied to forensic contexts.

Language Evidence Language evidence includes audio, telephonic, video, or digital recordings of communications (covert or overt) as well as written communications (print or digital). LAEs may be able to use relatively long stretches of naturalistic communication by an NNS as one point of reference. Audio-videorecordings might provide viable samples, with some limitations.

Video- and audiorecordings are used by LEOs, for example, in Australia, Canada, England and Wales, and the USA. Factors affecting use vary including by civil structure and jurisdiction, type of crime, and whether the person is a suspect or witness. Boetig, Vinson, and Weideleceember (2006) argue that US law enforcement agencies should consider the benefits of electronically recording interrogations.

As transcripts of audiorecordings of live interactions are not the same as spoken language, in the USA transcripts are not considered *direct* evidence. LAEs are aware of how omissions and inaccuracies can change meanings. Transcribing accurately can be especially challenging with NNSs. Attorneys, the judge, and jury need to be reminded of these limitations. These concerns about accuracy also apply when court transcripts are used in appeals (Walker, 1986; Benmaman & Framer, 2010). Nevertheless, transcripts can be used as *tools* to assist the fact finders (*United States v. Reed*, 1989).

Given concerns about transcripts, experts should ask for audiorecordings, though they might not be easy to obtain. Jail calls from prison might be available. It is generally not the practice for private legal stenographers to release their audiorecordings. If no audio is available of law enforcement communications, the expert can ask "Why not?" This at least highlights a critical gap in evidence. Also, if an interpreter was involved in LEO questioning (e.g., NNS's L2 is English), and if there is no audio of the interview, then the reporter's transcript, in English, is the only record of the interview. It is then, a record of the interpreter's English, not the NNS's.

Linguistic Evidence Linguistic analyses involve examination of aspects of a language system. Findings of analyses, grounded in principled theory and practice, become linguistic evidence. In conversation analysis one might look at who initiates a topic, and how the other person responds, as evidenced in language choices and patterns. This is especially useful for analyzing evidence from an undercover entrapment operation (Shuy, 2005). In NNS cases findings from language assessment can also become linguistic evidence. "Language evidence" does not equal "linguistic evidence." These two terms are sometimes loosely interchanged. The expert should be rigorous with correct usage.

In defining linguistic evidence, it is also useful to say what it is not. Simply because analysis is done on a language sample does not mean it produces linguistic evidence. First, other information can be found in language samples, for example, eyewitness accounts might contain descriptions of sensory perceptions—what was heard or smelled. Behavioral analysis experts may then see clues about the truthfulness of eyewitness accounts. Second, anecdotal comments by a non-linguist about a person's language skills are not linguistic evidence.

Assessment Principles LAEs may be especially concerned about the reliability of high stakes testing with large examinee populations. In contrast, validity in legal cases may be of greater concern as there is almost always only a single subject. Legal questions usually involve specific communication events. These frequently are not at all similar to tasks commonly found on standardized tests. For example, a multiple choice L2 grammar test is not valid for testing someone's ability to interact in a police stop. Reliable tests might lack validity for a specific case. However, by placing validity over reliability, LAEs should be prepared to demonstrate to judges that validity is also a key principle in language assessment. It may, in fact, override the weight of reliability rates.

Arguing Evidence

LAEs bring the critical tool of logical reasoning for linking linguistics to legal issues. The expert may be asked by the NNS's attorney to evaluate existing language evidence in terms of the legal question and do some language assessment. Alternatively, the expert may be hired by the opposing counsel to evaluate another expert's report. Evidence argument is discussed here as a tool in NNS cases. In NNS cases validity can be a key link in argumentation.

Evidence Argumentation

Experts are expected to ground their work in the principles and research of relevant fields. Fortunately, the language assessment field offers useful theoretical models for forensic contexts (e.g., Mislevy, Steinberg, & Almond, 2003).

While readers may already be well grounded in evidence or assessment argumentation, a brief review here ties it to forensic contexts. McNamara and Roever (2006) present Mislevy's assessment argumentation. The argument categories are: *Evidence* (observations, assessment data) → *Assessment argument* (relevance of data, value of observations as evidence) → *Claims about test takers* (relevance of data, value of observations). The Evidence Argument table (McNamara & Roever, 2006, p. 19) is particularly helpful. They advise beginning with the *Claims*. Applying this in a forensic context might mean starting with a claim about a suspect, derived from the legal issue, for example, "It is highly likely that the defendant was not able to read and understand the law enforcement agent's summary of the interview." Now returning to the beginning, language assessment data, observations, and other samples of language evidence are collected under *Evidence*.

The *Assessment argument*, between the *Evidence* and *Claims*, forces the expert to be clear about the quality of the links to the *Claims*, for example, looking at validity of assessments and gaps in argumentation. This may trigger the need to (a) gather more background information, (b) reword the claim, (c) discard initial invalid assessment data, (d) examine the test descriptors, and (e) reconsider weighting for validity and reliability. If a standardized test has been used, the expert might decide the scores are only of limited relevance, and that additional assessment tasks could strengthen the link to the *Claim*. Even while trying to build a stronger linkage, the limitations of the added tasks should also be considered.

This approach strengthens an expert's position to form a professional opinion on the *Claims*. The LAE might also determine that a *Claim* cannot be supported. If an evidence argumentation approach is clearly presented in a court, this may resonate with judges as it parallels their training in legal argumentation. This approach can also prepare an expert to testify in court, and, especially in an adversarial legal system, to be ready to defend findings, be aware of possible gaps, and acknowledge limitations (van Naerssen 2009).

Practical Considerations

In this section three practical topics are covered: (a) creating additional language assessment tasks, (b) doing prison assessments, and (c) recording oral assessments.

Additional Tasks An LAE might feel uncomfortable creating additional tasks that may not have been widely tested. Thus, this should only be done if experts have confidence in their expertise in language assessment (and related fields). The judicial calendar drives events, usually not allowing for research studies or experiments.

While tasks may be devised at short notice, the expert still needs to ground the tasks. Some tasks initially developed for L1 and L2 development research might be adapted, for example, an unplanned fast writing task which gives a snapshot, at a general level, of the current language development level (Kroll, 1990). Story retelling-type tasks, with appropriate evaluation criteria, might be useful.

Prison Assessments When examinees are prisoners, assessment requires planning and prioritizing. A prison visit is probably the only chance to meet with the defendant. After meeting the defendant, it is then easier to think, "This is simply another language assessment." Below are some reminders.

- Find out what cannot be taken or worn into the prison.
- Check with the attorney about the visitor schedule.
- Allow time for being processed through security.
- Remember that personal items are locked up before entering the prison.
- Listen to the security guard's precautions.
- Keep the attorney's contact information with you.

Do not count on extra time. Also, if assigned an area with a barrier between you and the defendant, and if the defendant is not considered dangerous, your attorney might prearrange for you to be on the prisoner's side, creating a more "natural" setting.

Recording All oral assessment tasks should be audiorecorded for subsequent review. However, this recorded language, now evidence, can also be requested by the opposing counsel. (This happened once to van Naerssen. Transcription notes were also requested but not turned over: they were informal, not easily legible, not direct evidence, and, in that setting, were "protected work product.") While an assessment expert may be reluctant to turn over data, if it is additional evidence, it does not belong to the expert.

Resources for many other practical suggestions for linguistics experts include, among others, Shuy (2006) and Coulthard and Johnson (2007).

Juggling Validity and Reliability

If additional language testing is needed, LAEs normally look for assessment instruments that are (a) generally related to the communication skills in the legal question, (b) grounded in theory and research, and, importantly, (c) normed on a population that is roughly similar to that of the NNS. Using one such "grounded" instrument then allows the LAE to add other more appropriate assessment tasks to strengthen the validity of the assessment. An "accepted" oral proficiency interview, done by phone, is highly vulnerable to reliability challenges.

While validity for additional tasks is important, close simulations of key communication situations in the case should be avoided. Outside of introductions and explanations of the purpose of meeting the NNS, communications should be strictly limited. Extended warm-up conversations to get to know the NNS or conversations about the case (which might trigger more natural, spontaneous language) could compromise the objectivity of an assessment. However, a topic from an oral interview protocol could be fed into another task to trigger relatively unmonitored language use.

If challenged in court about why an examiner did not spend time getting to know the defendant, here are two successful responses. First, "Getting to know the defendant might subconsciously affect my reliability as an objective examiner." Second, "Such communications would be beyond the scope of my assignment. My job was only to objectively assess the defendant's language proficiency using principled procedures."

Common myths about NNSs also affect the quality of assumptions in "evidence." LAEs need to "unpack" these myths, for example, "*An adult living and working in the US for 10 years should be able to understand and speak English. If such a person claims not to understand English (or only a little), the person is lying*" (van Naerssen, 2007, p. 97, emphasis added). Research shows that for adults the length of residence (LOR) alone is not a valid predictor of language proficiency. The type of exposure and amount of interaction also affect proficiency, if that interaction results in comprehensible input (Krashen, 1982).

Wennerstrom (2011) discusses why judges might become “LAEs” when determining the need for a court interpreter; they usually are not trained in assessment. Their decisions are affected by legal responsibilities and by their own personal beliefs. (Also see van Naerssen, 2007, 2010, in press, on myths.)

Connecting With Other Contexts

In this section we see how language assessment interfaces with other contexts, for example, by looking “locally” from a law enforcement perspective, and by connecting with wider legal systems, as assessment principles can cross systems.

Law Enforcement

Language proficiency probably is more frequently raised by defense attorneys than by the government. Thus, forensic linguistic experts should try to avoid being seen as “biased for the defense.” By becoming acquainted with the law enforcement side, we can “balance” our experience and add insights on language evidence. To better understand the perspectives of local police officers, the author participated in a citizens’ police academy which also led to dialogs with LEOs about NNS issues.

As some people in society do try to deceive LEOs, including NNSs, some LEOs might question certain groups of NNSs. LEOs might also carry common myths about NNSs. Still, awareness by LEOs about language learning and NNS communication challenges may help LEOs reduce, to some extent, miscommunications and potential errors in judgment.

In the daily work of an LEO, one common event is the traffic stop resulting from observing a vehicular violation, for example, an expired license or speeding. If an NNS contests a violation or procedures, claiming lack of understanding, language assessment might be used to support the claim. However, the conditions of a stop frequently are not conducive to documenting proficiency. As a result of exchanges during three “ride alongs” in patrol cars, the author realized that some of her ideas about documenting communications and interpreting support were quite impractical!

Wider Legal Contexts

The US Federal Rule of Evidence 702 is the focus of this section. It affects whether an expert is allowed by the judge to testify, and about what.

Rule 702 Testimony by Experts

If scientific, technical, or other specialized knowledge will assist the trier of fact to understand the evidence or to determine a fact in issue, a witness qualified as an expert by knowledge, skill, experience, training, or education, may testify thereto in the form of an opinion or otherwise, if (1) *the testimony is based upon sufficient facts or data*, (2) *the testimony is the product of reliable principles and methods*, and (3) *the witness has applied the principles and methods reliably to the facts of the case*. (Article VII. Rule 702, Federal Rules of Evidence (FRE), December 1, 2009, my emphasis)

Rule 702 (“Daubert”) expanded the scope of expert knowledge allowed. It goes beyond “scientific” (as required by Frye standards, *Frye v. United States*, 1923) to include “technical or other specialized knowledge.” It also removed the requirement that expert opinion based on a scientific technique is admissible *only where the technique is generally accepted as reliable in the relevant scientific community*. Innovation is allowed as long as three Rule 702 criteria are met.

The judge is the gatekeeper, determining whether to allow experts to testify. The judge uses the principle of *relevance* to ensure the expert’s testimony is relevant to the legal issue in the case. The judge uses *reliability* to determine whether the methods used by the expert rest “on a reliable foundation” and are applied reliably to the facts at hand.

FRE 702 superseded *Frye* as the standard for admissibility of expert evidence in federal courts. As some states still adhere to the Frye standard or a hybrid, experts in state courts should check the applicable standard (see United States Courts, *n.d.* and National Center for State Courts, *n.d.*).

Some judges may still think in terms of Frye standards: error rates and the “generally accepted” criterion. Thus, an expert might be asked about the known or potential error rate in one’s field. Having an error rate appears to be a marker of whether a field is seen as “scientific” enough for the expert to be allowed to testify about any findings. In language assessment there can be various responses, from test reliability rates to inter-rater reliability rates. The concept of scaling may be unknown to a judge.

When introducing language assessment as a field, this could be an opportunity to introduce and stress the importance of validity as a core assessment principle. Validity could also be tied to relevance. This could then be used to bridge to the argument that a test should be valid for the communication situation in question.

No test is perfect. Experts should be prepared for criticisms of assessments. Any criticism of a test, from the Internet, can be thrown at an expert. An unprepared expert risks having carefully done assessments destroyed before even having a chance to testify.

If a language test has been accepted by another court, this improves the chance of acceptance. However, as “language proficiency” commonly does not appear in judicial opinions, “court acceptance” might not appear in database searches. A challenge might be “no evidence of X assessment being accepted in federal courts!” Networking with others allows the LAE to be ready with specifics.

A comparison of rules on admissible evidence in three countries, Australia, the UK, and the USA, can be found in Coulthard and Johnson (2010). The Law Commission (2011) report refers to current concerns in England and Wales about expert evidence.

Challenges

Three challenging areas that an LAE might face are given here: (a) building social context for evidence argumentation, (b) examining “police caution” contexts; and (c) trying to assess truthful versus untruthful language performance.

Building Context

Except for on-the-job assessments, formal assessments usually take place in isolation from the actual contexts of examinees' communication needs. Validity of an assessment can be increased through simulating the relevant contexts (but recall the earlier caution).

Without direct insights on the context, the examiner may have only debatable contextual information. Conversation analysis can help reveal a theory about what might have happened. Gibbons combined discourse analysis and the Australian Second Language Proficiency Rating Scales for an oral proficiency interview (2003). LAEs can also draw on research on dynamics in oral assessment interviews. Forensic linguists, some trained in both linguistics and law, applying sociolinguistic and cultural insights also include, for example, Eades (2010). A valuable reference is Benmaman and Framer (2010) on how demands on the NNS defendant in the complex courtroom environment differ from in a one-on-one meeting (2010). (Also see Chapter 7, *Assessing Pragmatics*.)

In 2011, van Naerssen developed a strategy for building context in a case about the need of a NSS for an interpreter. In addition to research on language in trials, three externally recognized context descriptions were used: (1) the special education due-process hearing (from state administrative law), (2) mediation (mediation handbook), and (3) a deposition (from a standard legal reference).

To analyze these sociolegal contexts seven social context factors commonly used in sociolinguistics were: (a) persons involved, (b) relation of these persons to each other, (c) purposes of the communications, (d) specific setting, (e) mode (oral, written), (f) degree of formality, and (g) length of communications. These factors and the sociolegal contexts were used to create a grid. Details from the context descriptions and the case were added.

Second or foreign language pragmatic awareness is part of an NNS's communicative competence (Canale & Swain, 1980; Savignon, 1991). This awareness is considered a very challenging aspect of language learning, requiring extensive opportunities to develop (Kasper, 1997). The language needed in informal settings about everyday needs is different from the heavier language demands in legal proceedings. Thus, van Naerssen was then able to link language assessment findings to the likely difficulty in these sociolegal contexts.

Police Cautions

This section focuses on legal aspects a linguist or LAE might need. Readers should consult local legal authorities: the author is not legally trained.

Police cautions involve making individuals aware of their legal rights. Typically they also include an acknowledgment by individuals that they have understood what has been said regarding their rights, and second, a willingness to waive these rights if they choose to do so. If these rights are not given, or not understood, there may be legal consequences which can affect the legal status of any evidence gathered after the cautions. Knowledge of rights is cultural knowledge, adding to the complexity level of a caution.

Two contexts are discussed here: the rights surrounding “drinking when intoxicated” (DWI) and those surrounding an arrest.

DWI Communications around a DWI can be complex. One or more tests might be done testing for signs of intoxication, e.g., “the walk.” Rules vary by jurisdiction. The “walk” involves walking in a line and turning around, following instructions in language that may not be easily comprehensible to the NNS motorist, even with accompanying gestures. As learning about one’s rights is part of a motorist becoming licensed, knowledge of the law is assumed, yet might not be remembered. The law may require LEOs to inform motorists of the “right to refuse” and of the consequences.

In the State of New Jersey in the USA, the State Supreme Court in 2010 ruled that a person stopped for DWI has the right to be informed of the obligation to submit to a breath test—in the L1. Now LEOs in New Jersey can supply printed and recorded translations of the instructions and warnings to NNSs. New Jersey became the first state in the USA to initiate this requirement. Rules also vary by country (see US Department of Transportation, 2000).

Post-Arrest Questioning The second set of rights surround LEO questioning after a person has been arrested. Comments are based on the US context; however, an international reference is also provided.

In the USA, the exact wording of the police caution statement (“Miranda rights”) is not specified in the Supreme Court’s decision. Law enforcement agencies have created basic sets of statements that can be read to an accused person prior to any questioning. Every US jurisdiction has its own regulations regarding how the rights must be said. An expert is advised to request a copy of the actual wording for a specific case. One variation is given below.

You have the right to remain silent. Anything you say or do can and will be held against you in a court of law. You have the right to speak to an attorney. If you cannot afford an attorney, one will be appointed for you. Do you understand these rights as they have been read to you?

The warning must be “meaningful”: the suspect must be asked if he understands his rights. Firm answers of “yes” might be required. Some jurisdictions require an officer to ask “Do you understand?” after each sentence in the warning. An expert should ask for the rules about acceptable responses and waivers, the language and mode of delivery, and availability of an audiorecording, and other contextual information.

The Supreme Court decision also requires that any waivers be done following the “knowingly, voluntarily, and intelligently” standard. “Knowingly” and “intelligently” can be useful hooks on which to hang language proficiency arguments. (See Briere, 1978; Ainsworth, 1993; Shuy, 1997; Einesman, 2010, pp. 587–628; van Naerssen, in press, on case law surrounding Miranda on cultural and linguistic issues of NNSs.)

Many countries have adopted the tenets of the 1966 International Covenant on Civil and Political Rights, with variations in actual implementation. Of relevance

here are the Article 14 tenets on rights of individuals under criminal charges (Office of the United Nations High Commission for Human Rights, 1976).

Truthful or Less Than Truthful Proficiency

In this section judgments about NNS language are explored, followed by four assessment strategies. An LAE should assume *both* the possibility of “faking” *and* that the person is communicating using truthful language skills. Claims of low English proficiency tend to occur around communications involving police cautions and interviews or interrogations. (See van Naerssen, 2007, drug trafficking case.)

Judgments About NNS Language Myths and labels about NNSs’ language use can lead to errors in judgment which can then affect how an NNS is treated legally. Myths represent a lack of understanding about NNS language use and language learning and may reflect attitudes and negative stereotypes about NNSs. “They lie about their comprehension of English.” “If they’ve been in the US for 10 years and haven’t learned English, they’re lazy.” “Broken English” might suggest something is wrong with the person.

LEOs encounter persons with criminal intent that deceive. Concerned about enforcing the law and public safety, LEOs need to make quick assessments and decisions. When LEOs encounter NNSs, they have still another layer of issues to consider, complicating their mental checklists. Experienced LEOs, like other professionals, develop some intuitions about populations they serve. Sometimes those intuitions are accurate. They may even develop tricks for catching a person unaware, to test for English comprehension.

LEOs are also trained not to make firm assumptions based on inadequate evidence. However, if an NNS uses some survival L2 words, some LEOs might assume the NNS can also understand and use more complex language. This is not adequate evidence about overall language proficiency. Unfortunately, errors in judgment are sometimes made. Fortunately, forensic linguistics experts can examine the evidence, add assessments, and provide professional opinions. Thus, they can assist the judge and jury in determining whether an error in judgment has been made about an NNS’s language proficiency.

Several labels have been used for what NNSs do when pretending to have a lower than truthful language proficiency: *untruthful*, *deceitful*, *faking*, *feigning*, and *malingering*. An NNS guilty of a charge might falsely claim lack of comprehension of the language of legal procedures to try to have evidence against him or her dropped. *Intentional underperformance* is distinguished from *underperformance*, possibly the result of stressful conditions and exhaustion. *Malingering* is used technically by psychologists, identified by testing.

On the other side, for an NNS that appears to be truthful regarding language proficiency, simple antonyms, *truthful* or *not faking*, are used. However, this is probably not adequate for more accurately reflecting what an NNS may be doing. An NNS may clearly have no comprehension, or may be struggling. A third category may appear ambiguous to the layperson: an NNS appears, in spots, to

understand, but actually probably does not understand as much as might be assumed. The NNS may just be trying to cope.

Eggington and van Naerssen have explored common concerns in NNS legal cases, including untruthful language use. Eggington, Cox, and Wood (2011) reported on research to examine language used in “police” interviews following viewing an automobile accident video. Recordings of the interactions were analyzed. They examined what L2 speakers do when engaged with a native speaker, including giving feedback cues that can give the impression they are comprehending when they may not be. “They are faking comprehension as an ultimate comprehension strategy.” What label then most accurately represents what NNSs might sometimes be doing?

This ambiguous language use suggests two areas of research. First, Canale and Swain (1980) identified, as a component of communicative competence, “strategic competence,” which includes the need to compensate for communication breakdowns. This might be due to “limiting conditions” or to “insufficient competence.”

The other area is L2 learning strategies. Rubin, an expert on L2 learning strategies, observed that when language learners use compensatory strategies, they are compensating for their known lack of skills (personal communication, August 7, 2011). Rubin then referred to Cohen’s learner strategy work. Language learning strategies encompass both L2 *learning* and L2 *use*. In his 1996 paper Cohen defines language use strategies as those which “focus primarily on employing the language that learners have in their current interlanguage.” This early definition, using “current interlanguage,” best fits forensic contexts in which language development patterns are being examined. Cohen (2011) suggests language use strategies include retrieval, rehearsal, coping, and communication strategies. Coping strategies include both compensatory and cover strategies. Learners use compensatory strategies “to allow them to compensate for a lack of some specific language knowledge.” Cover strategies involve “creating an appearance of language ability so as not to look unprepared, foolish, or even stupid” (Cohen, 2011, pp. 13–14).

The thinking of both Canale and Swain and Cohen points to a similar cluster of strategies which suggests a category for language use in legal situations in which an NNS appears, on the surface, to understand, but may really have more limited proficiency. Additionally, their theory and research could support the use of this cluster of strategies in court testimony.

Detection Strategies For attorneys using low proficiency as an argument, the primary challenge is likely, “How do you know he wasn’t faking?!” Linguists have not yet solidly demonstrated expertise in detecting deceit.

Still, it is highly unlikely a person could successfully deceive throughout lengthy samples of unplanned communications, especially at different times. Experts in language acquisition, sociolinguistics, and assessment can detect consistencies and inconsistencies. Interviewing film star speech coaches might provide insights on time and effort needed to successfully change language use practicing with scripts. Below are four possible detection strategies.

Strategy 1. Identify two or more substantial stretches of communication by the NNS in as unplanned and natural contexts as possible, preferably formal case evidence. Additional tasks can also strengthen analyses.

Strategy 2. When language evidence from a case is limited, additional lengthy language samples from language assessments allow comparisons.

Strategy 3. In the absence of substantial language evidence, gather at least two substantial, relatively comparable language samples through assessment. This may involve arguing for time or money for a second examiner if the nature of the case warrants this.

Strategy 4. Appeal to cognitive psychology for a “window into the mind” involving a cognitive-processing task. Canadian psychologist Bialystok (2001) indirectly pointed the way when reporting on a study involving a story re-tell task to examine domains of proficiency in bilingual children. However, one drawback is that an adult, intending to deceive, could simply say, “I didn’t understand.”

To try to sneak into the mind of the NNS, an alternating language story re-tell task was developed and used in a federal case in combination with an oral proficiency interview. It has since been revised and further tested on 18 participants, including two “fakers” (van Naerssen, 2011).

Future Directions

With the rise in legal cases calling for language assessment, there is a need to increase credibility in the potential of appropriately done language assessment. For LAEs this involves

- continuing to strengthen tools for forensic settings;
- providing creative, appropriate approaches;
- learning more about local and wider legal contexts;
- communicating clearly to others in critical decision-making roles; and
- raising awareness about the nature of NNS language use and language learning.

Finally, applied linguists can introduce the legal community to our codes of ethics and best practices: the ILTA Code of Ethics (2000) and the pending IAFL template for a statement of professional ethics for expert consulting and code of ethics.

Language Testing in the Dock

Glenn Fulcher

University of Leicester, England

Introduction

Language testing becomes embroiled in litigation whenever an individual from an identifiable subgroup of the test-taking population feels that they have been unfairly treated (Childs, 1990; Fulcher & Bamford, 1996). This normally means they believe that their score does not reflect their true ability. This state of affairs arises when a decision taken on the basis of a test score (and associated documentation) may deny them access to education, employment, or some other economically desirable opportunity. In technical terms, they believe they are a false negative: Their observed score was below the pass mark or cut score for an intended decision-making purpose, but their true score is higher.

This chapter investigates the relationship between language testing and the law. This begins with a consideration of the role of high stakes testing as a social tool designed for allocating resources, and the values underlying current practices. When decisions are made about the future of individuals using tests, the question asked is whether these are “fair” or “just.” Test takers may question the outcome of the test and litigation may follow. A range of situations are considered in which fairness or justice may be questioned and litigation has occurred, or is likely to take place. Illustrative cases are discussed in order to explore emerging themes. These cases are drawn almost exclusively from the USA, with a smaller number from Europe, because these are the regions in which testing and assessment have been explicitly related to issues of discrimination, either in primary legislation or through precedent. Searches in legal databases such as Westlaw and Lexis Library reveal very little legal activity around testing and assessment in other countries, with the single exception of the prosecution for fraud of test takers or officials in cases of cheating.

The research reported in this chapter and the synthesis of key legal issues as they relate to testing and assessment are a key resource for institutions and

individuals involved in assessment development, test use and administration, and score reporting.

High Stakes Decisions

High stakes testing is an enterprise explicitly designed to classify or select individuals for decision-making purposes. For Plato (1987, p. 190), testing was used to ensure that members of the Republic could “devote their full energy to the one particular job for which they are naturally suited.” This meant using tests and assessments to maintain social castes and ensure that only the most able guardians became rulers. In ancient China, testing was the tool of choice to reduce the power of the aristocracy over the state, while maintaining traditional values in what knowledge was taught to the administrative classes (Miyazaki, 1981). These two examples illustrate the union of merit, social standing, and income, mediated by testing and assessment, that is foundational for the cultures of both East (Zeng, 1999) and West (Roach, 1971).

As a powerful social tool that allocates resources to individuals and brings opportunities in life, testing is also a value-laden enterprise. Our choices in how to use tests reveal our political and philosophical preferences (Fulcher, 2009), clearly exemplified by the haste with which the German Nazi party seized control of the examination system upon coming to power in 1933 (Cecil, 1971). This is clearly an extreme case, but it serves to demonstrate most vividly how testing and assessment, perhaps more than any other social tool, are both governed by, and revealing of, our beliefs and values.

E. M. Forster is reputed to have said:

As long as learning is connected with earning, as long as certain jobs can only be reached through exams, so long must we take this examination system seriously. If another ladder to employment was contrived, much so-called education would disappear, and no one would be a penny the stupider.

The meritocratic view of the world that links effort to material success, and back to motivation to learn, is taken for granted today. It also provides the backdrop to notions of fairness and how perceived unfairness may be challenged.

Values and Fairness

What we value in our testing and assessment practices, and therefore how decisions are made, is intimately related to society’s current sense of what is “fair.” This is inherent when decisions are made that favor some—the successful—and disadvantage others—the unsuccessful. What we ask is “Is the decision fair?”

This raises the question of what “fairness” is, to which there are many different answers on offer. Messick (1988, p. 2) says:

In general, fairness implies impartiality, and the question arises as to how fairness is manifested in educational and psychological measurement. In particular, the impartiality entailed in test fairness is achieved through comparable construct validity

across individuals, groups, and settings. That is, score levels should have the same meaning and consequences in different population groups and environmental contexts. This does not imply that fair test use yields equal group outcomes, however, because fair tests may validly document unequal outcomes resulting from, among other things, unequal opportunities to learn as well as differential experiences in learning and development.

While “fairness” is notoriously difficult to define for the purposes of assessment (Kunnan, 2000, 2004; Camilli, 2006; Xi, 2010), its use in daily life is not (Walters, 2012, p. 469). In line with Messick, it is taken to mean “just and honest,” “impartial,” “unprejudiced,” and “free from discrimination.” For legal purposes, this is the heart of the matter. The law asks the question: “Does the process of assessment lead to discrimination against a subgroup of the test-taking population?” Much of the interface between assessment and the law is therefore concerned with discrimination. However, as Walters (2012, p. 470) points out, “What most language testing views of fairness have in common is a desire to avoid the effects of any construct-irrelevant factors on the entire testing process, from the test-design stage through post-administration decision making.”

This is the second principle that informs legal practice. Messick (1989, p. 34) describes construct irrelevance in terms of assessment contexts where “the test contains excess reliable variance that is irrelevant to the interpreted construct.” This means that the scores of some individuals or groups may be artificially low because of what Carroll (1961/1965, p. 319) called “extraneous variables.” Such variables may range from the conditions under which a test is administered, to test content that requires particular background knowledge, or sensitive content that is likely to cause offence or distress. The test is therefore seen as parallel to a controlled experiment for the findings to be meaningfully interpreted (Fulcher, 2010, pp. 254–60).

It is here that legal issues and litigation intersect with assessment theory and practice. If testing and assessment are used for classification and selection, the outcome of which is to distribute scarce resources and opportunities, it is inevitable that the fairness of the system will be questioned primarily by those who are classified unfavorably, or are not selected. The law becomes interested in testing and assessment whenever it is asserted that practices are biased, prejudiced, or discriminatory.

Messick (1989, pp. 86–7) discusses the question as part of his conception of validity under the heading of the consequential basis of test use, which he explicates in terms of distributive justice (Rawls, 1971). Claims of injustice or unfairness may be targeted at:

- the rules by which the distribution is made;
- the implementation of the rules;
- the decision-making procedures;
- the values underpinning the rules or procedures.

Examples of such claims will be investigated within a legal classification of the grounds for litigation, beginning with the most important, which is discrimination

and bias. The vast majority of legal cases associated with testing and assessment fall into this category.

Discrimination and Bias

Discrimination is defined as denying equitable treatment, rights, benefits, or access to social goods, on the basis of a protected characteristic. This has two parts: what may not be denied, and those to whom it may not be denied. Most countries legislate to cover both parts. With regard to the first, the most relevant categories to language assessment are employment and education, although in Europe this is now impacting upon marriage and rights of residence (see the discussion below of *Chapti, Ali, & Bibi v. The Secretary of State for the Home Department*, 2011). With regard to the second, a protected characteristic is an identifiable attribute showing an individual to be a member of a particular group, which may not be used as a basis for decision making. Under the 2010 Equality and Diversity Act in the United Kingdom, for example, protected characteristics included: age, disability, gender, gender reassignment, marriage or civil partnership, pregnancy and maternity, race, religion or belief, and sexual orientation. With these two aspects of discrimination clarified, it is possible to proceed to consider what would count as bias in language testing.

Cole and Moss (1989, p. 205) define bias in the following way:

An inference is biased when it is not equally valid for different groups. Bias is present when a test score has meanings or implications for a relevant, definable subgroup of test takers that are different from the meanings or implications for the remainder of the test takers. Thus, *bias is differential validity of a given interpretation of a test score for any definable, relevant subgroup of test takers.* (Italics in original)

From a legal perspective, bias is an unequal outcome on a test for a subgroup of the test-taking population that is identified by a protected characteristic, *because of construct-irrelevant (extraneous) factors*, and affects access to education or employment, or restricts civil rights. The following sections discuss the two protected characteristics that have attracted legal attention in the field of testing and assessment.

Race

The earliest legal cases were brought in the USA after the passage of the Civil Rights Act of 1964, of which Title VII abolished discriminatory employment practices, and the Fourteenth Amendment (see Phillips & Camara, 2006, for a detailed discussion of Title VII). *Hobson v. Hansen* (1967, 1969) set the trend, claiming that state tests systematically and unfairly placed Black children in remedial educational provision (Reschly, Kicklighter, & McKee, 1988a, pp. 16–17). In all subsequent cases in which the defendants were unable to show that bias was not the cause of observed differences between groups, the petitioners would win, as in the landmark case of *Larry P. v. Riles* (1984). As a result of this case, the use of IQ

tests was banned in the USA due to the larger number of Black students classified as mentally retarded (Prasse & Reschly, 1986; Reschly et al., 1988a, 1988b, 1988c; MacMillan & Barlow, 1991). In *Larry P. v. Riles* the court ruled that no attempt had been made to validate the use of the test (and hence comparable score meaning) for ethnic minorities, and that test content was culturally biased against them.

Perhaps the most important case in the USA was *Golden Rule Insurance Company v. Washburn/Mathias* in 1984. In 1975 the State of Illinois introduced an insurance agent licensing test that had been developed by the Educational Testing Service (ETS). The plaintiffs argued and eventually proved that the pass rates of White and Black test takers were of the order of 83% and 59% respectively. This was ruled discriminatory, and as a result testing agencies in the USA were obliged to report test statistics broken down by race, and to conduct some form of differential item functioning for individual test items by ethnic group. Most importantly, it became a requirement to define the domain from which test content was derived, and select questions written to domain specifications on the basis of (a) achieving predetermined minimum facility values for all test takers, and Black and White test takers separately, and (b) achieving a predetermined maximum difference in facility values for Black and White test takers (Shapiro, Slutsky, & Watt, 1989).

However, as indicated in the above quotation from Messick, a difference in scores between test takers classified by protected characteristics is a necessary, but not sufficient, condition for the identification of bias. The observed (statistically significant) difference must be traced to a source of construct-irrelevant variance for bias to be proved. This principle was established in two important cases. In *Wards Cove Packing Co. v. Antonio* (1989) it was alleged that the salmon packing company had discriminatory appointments processes because low-paid cannery jobs were mostly filled with non-Whites, whereas more highly paid non-cannery jobs were filled with Whites. The statistically significant difference, however, was held to be irrelevant, because the most appropriate space of events for an analysis of the probability of this distribution was not the employees of the packing company, but the population from which the workforce was drawn. That is, if the distribution of qualifications and abilities in the population was represented in the workforce, the unequal distribution would not be evidence of bias in selection processes. It may very well tell the authorities something about the social and educational opportunities available to the different ethnic groups, but not about assessment bias. Furthermore, the only way to achieve equality in this case would be to introduce ethnic quotas, and this would lead to having unqualified individuals in non-cannery jobs. It was established that for the plaintiffs to be successful they would have to show that "specific practices by the state or the testing company caused the discrimination and had a specific impact on minorities" (Hood & Parker, 1991, p. 604). The second case is that of *Debra P. v. Turlington* (1981), in which it was argued that the State of Florida's Student Assessment Test (SSAT II), a test of functional literacy, discriminated against Blacks. The evidence was that fewer Blacks than Whites passed, and they were not therefore awarded a High School Diploma. The State of Florida undertook a survey of all schools to discover what teachers had done to prepare pupils for the test, and of students to find out if they thought they had been properly prepared. The court ruled that there was no evidence of bias in the test, and that all pupils had been given

appropriate opportunities to prepare. Thus, any attempt to produce equal pass rates would constitute a threat to the value of the High School Diploma. In this case the variance associated with differential outcomes was deemed to be construct relevant.

These important cases have established the principle that equality of opportunity at the moment of testing is of primary concern, rather than equal outcomes. The legal issues arising from these cases may be summarized under the following three categories, annotated with reference to other relevant litigation.

1. The predictive aspect of validity. *Wards Cove Packing Co. v. Antonio* was also concerned with the relation between the method of assessment and the outcomes. However, it placed the burden of proof on the plaintiff. This was a change from the principle laid down in *Griggs v. Duke Power Co.* in 1971, that the burden of proof lay with the employer. Duke Power Co. had introduced the requirements of a High School Diploma and IQ testing for entrance to higher paid jobs, thus discriminating against Blacks in the population who had had an inferior education. A study showed that White employees who had been employed prior to the new requirements performed just as well as employees appointed after the introduction. It was concluded that the Diploma and the tests were not related to job performance and were therefore likely to discriminate against ethnic minority applicants. The court ruled that, if differential impact could be demonstrated, the burden of proof lay with the employer to justify the use of assessments as a "business necessity" (Crow, 2004). The Civil Rights Act of 1991 reinstated the Griggs principles, thus establishing "disparate impact" as grounds for litigation. This has not been used as much as direct impact as grounds for litigation in succeeding years (Shoben, 2003), but it has established the principle that any assessment used for employment decisions must be shown to be directly relevant to, and predictive of, workplace performance.
2. The content aspect of validity. *Wards Cove*, *Griggs*, and other cases already mentioned illustrate the necessity for tests that are used for employment decisions to demonstrate content that is directly related to the domain of interest. In the Golden Rule case, plaintiffs claimed that

The test allegedly contained many questions subject to different interpretations and different answers by individuals experienced and competent as insurance agents and brokers. Additionally, the exam allegedly tested levels of cognition of subject matter substantially and rationally unrelated to a determination of an applicant's competency as an insurance agent or broker. The plaintiffs alleged that the test was given without any job validation to determine whether in fact it appropriately measured competency to engage in the business of an insurance agent or broker, and was not fairly designed to measure an applicant's competency. Instead, the test served as a method of artificially limiting and controlling the number of individuals entering the business of insurance agent or broker without regard for competency. (Shapiro et al., 1989, p. 244)

This aspect of interface between language testing and the law is relevant to debates around the relevance of general language tests for domain-specific

decisions, and the use of tests for specific purposes for which they were not designed (see test retrofit, below).

3. Test preparation. The Debra P. case has particular relevance to test preparation. First, the ruling established the principle that, if a new test is to be introduced or significant modifications are to be made to a test, the test developer must leave a reasonable period of time between publishing information on the changes and their introduction to allow teachers and learners time to adjust. The principle should be that the changes themselves should not become a source of construct-irrelevant variance. Second, that what is tested should be adequately reflected in educational materials and texts, thus providing equality of learning opportunity for all.

Disability

The second major area of concern to the law is the provision of equal opportunities for any test taker with a physical or learning disability. This is often enshrined in primary legislation. In the USA, this is the Americans with Disability Act, and in the United Kingdom the Disability and Equality Act. Legislation requires test providers to offer accommodations to any individual whose score on a test may be negatively affected by a disability unrelated to the construct of interest (Abedi, 2012). The most frequently granted accommodation is extended time, but may also include:

- someone to read the instructions or text in the test;
- amanuensis for those unable to write or type responses;
- Sign Language interpreter for spoken information;
- audiorecordings of written texts;
- braille;
- large print versions;
- selectable font type and size (in computer-based tests);
- selectable colors (in computer-based tests).

The issue of construct-irrelevant variance is equally pertinent to disability. First, if a disability is construct relevant there is a case for denying an accommodation. If the test is one of listening, for example, it is arguably the case that Sign Language should not be offered as an alternative for the deaf as the construct definition is changed. Second, any accommodation offered to a test taker with a disability should not also significantly increase the scores of a test taker who does not suffer from that disability. Under this scenario the accommodation itself impacts upon the construct. This particularly affects increased time, which may lead to all test takers improving their scores (Lovett, 2010). Accommodations are not always effective (Abedi, 2012), and so care should be taken in their use. Changes in the construct can result in score interpretations that are not equally valid across groups, thus introducing rather than eradicating discrimination.

However, the provision of accommodations has not been the focus of legal attention. Rather, it is the practice of “flagging.” This is the procedure of noting on a score report the fact that a test taker has taken the test under a nonstandard condition, such as an accommodation, when there is no validation evidence to

suggest that the construct has not been altered. The double negative is important here: If a non-disabled test taker may have benefited from the accommodation, the score obtained by the disabled test taker *may not* be completely comparable with that obtained by a non-disabled test taker obtained without the accommodation. The score is therefore “flagged” for the score user, who is thereby warned of a potential problem with interpretation.

Flagging first came before the US courts in the case of *Doe v. The National Board of Medical Examiners* in 1999, but it was *Breimhorst v. Educational Testing Service* (ETS) in 2000 that led to widespread changes in testing practice. Mark Breimhorst took the Scholastic Aptitude Test (SAT) with the accommodation of a track ball and additional test-taking time, with the purpose of applying to business school. His score card was flagged with the accommodations. Under the Americans with Disabilities Act, the first argument of the plaintiff was that flagging was an act of discrimination as it identifies and stigmatizes the test taker as disabled. Further, the act of flagging is contrary to the reason for providing the accommodation in the first place: to remove any effect of the disability from the score. In other words, the act of flagging by ETS suggests they suspect that their accommodations compromise the validity of their own test scores. Finally, the plaintiff argued that the policy of flagging intimidated the disabled into not requesting accommodations due to the knowledge that their disability would be disclosed through the flag. The court ruled that flagging violated the Americans with Disability Act.

Following this ruling the College Board, which owns the SAT, established the “Blue Ribbon Panel” of experts to make recommendations on flagging. In their review Gregg, Mather, Shaywitz, and Sireci (2002) found that there was not sufficient validation evidence to suggest that scores from standard and accommodated administrations were comparable, but nevertheless recommended the abolition of flagging:

Many students are reluctant to request extended time on the SAT I because the presence of the flag forces them to reveal a disability. Since the overwhelming majority of students who request extended time demonstrate learning disabilities, the presence of a flag denotes a special personal characteristic of the examinee—a learning disability. The detrimental effect of such a designation is further supported by findings that students with learning disabilities with flagged scores are under admitted to colleges. Thus, flagging appears to single out and treat the group with learning disabilities unequally, to diminish fair chances for college admission, and to discourage the use of a mandated ADA accommodation. . . . The Majority concluded that there are situations when it is necessary to treat people differently in order to treat them equally, and that this is one of them. (Gregg et al., 2002, p. 10)

The recommendation was implemented in 2003, bringing flagging to an end. However, Leong (2005) reports on the unintended consequences of the abolition of flagging: the increased incentive for those without disabilities to seek diagnosis as learning disabled in order to gain additional testing time. Applications for psychological assessment have risen significantly since 2003, primarily among those with the ability to pay, in the knowledge that the additional testing time will never be revealed. Leong expresses the concern that this provides additional advantages to those with the socioeconomic backgrounds to manipulate the

system. She suggests that the only solution to the problem is to make all tests nonspeeded so that a time accommodation is not required, but suspects that the resource implications will deter test providers for the foreseeable future. In the meantime, testing agencies are tightening up on the kind of evidence for disability that they will accept before allowing accommodations.

Test Design and Retrofit

This section identifies two design issues that have arisen in some court cases: the use of inappropriate samples, and the use of tests for purposes different from those envisioned at the time of test design. This is likely to become an area of further concern and legal challenge in the future as testing agencies come to rely on standard-setting techniques as a defence for a change in test purpose without paying attention to the need for test retrofit.

Selection of Samples for Pretesting and Standard Setting

The law becomes interested in test design processes when a test or assessment is used to make high stakes decisions about a population that was not intended, and not adequately represented in a sample used for preoperational testing (prototyping and piloting). In the case of *Larry P v. Riles* (1984), for example, the tests in question had been pretested on an all-White population, but subsequently used to make decisions about ethnic minority children.

This problem is exacerbated in standard-setting studies where the purpose of the test is being changed. The clearest example is in the use of academic English tests to make high stakes judgments about the communicative abilities of health professionals. Failure to reach cut scores on these tests can result in nurses being refused professional status (Castledine, 2000), or medical doctors being required to spend long periods of time studying language not directly related to the medical domain (Cacanus, 2002). Such stories reach the popular press, as well as the courts. Some examination boards have resorted to standard-setting practices in order to legitimize the new test use. O'Neil, Buckendahl, Plake, and Taylor (2007, p. 295) explicitly state that standard setting is used to establish a "legally defensible passing standard on the test."

Standard setting is primarily a policy judgment informed by perceptual data, as frequently acknowledged by practitioners in the field:

a passing standard is a function of informed professional judgment that relies on the panelists' content expertise and their experience with the abilities of the target examinee population. There are no passing standards that are empirically correct. A passing score reflects the values of those professionals who participate in its definition and adoption, and different professionals may hold different sets of values. (O'Neil et al., p. 299)

Content experts were asked to make judgments about whether minimally competent health practitioners would answer a test item correctly. The average

responses with the error estimates were used to arrive at cut scores. As part of the process the panellists were shown item statistics from operational test data to help them modify their judgments. These data were drawn from the IELTS population at large (O'Neil et al., p. 304). They did not reflect the performance of medical personnel on the test, nor was there any group difference information regarding successful and unsuccessful practitioners on the target criterion.

This use of standard setting would not provide the test users with a "legally defensible passing standard" were it to be challenged in the courts because of the very different samples, but the problem is much deeper than this.

"Repurposing" and Retrofit

The use of a test for a new (unintended) population, as in the case described above, is sometimes referred to as "repurposing" the test (Wendler & Powers, 2009). The content aspect of validity becomes critical in order to ensure that it is directly relevant to the domain of inference (Shapiro et al., 1989, pp. 223–4, 244) in order to avoid bias, as shown in the Griggs, Wards Cove, and Golden Rule cases.

As we saw in the previous section, the data that support a standard-setting judgment when attempting to repurpose a test are usually the perceptions of individual experts (language testing and content) of the likely outcome of a response to a given item by minimally competent practitioners. In the case of health professionals the IELTS has no content that is relevant to the specific needs of this population as outlined in table 3 of the paper (O'Neill et al., 2007, p. 303). For example, there are no reading tasks that measure the ability to understand medication lists or diagnostic reports. Expert judges are therefore being asked to decide how well a minimally competent nurse could perform on generic first year university academic tasks, and an inference is being made from that judgment to how well they would perform medical communication tasks in a hospital or surgery.

This assumption would not stand up in court. It has recently been argued that any use of a test for a new population and decision context should be subject to retrofit procedures (Fulcher & Davidson, 2009; Fulcher, 2012). The minimum requirement of retrofit practice is that a new validation argument is constructed to support the use of the scores for the new intended use (AERA, 1999, pp. 17–18, Standards 1.1 and 1.4). However, it is much more likely that significant changes are required to test specifications and content in order to make that argument plausible.

Missclassification

The legal system has recognized that test scores do not provide certainty. Even if there is sufficient validation evidence for the use of a score for an intended purpose, there are always sources of unreliable variance. The legal system, at least, has heard the message of "inescapable error" (Spolsky, 1997, p. 246).

While test takers may be misclassified, there is also a notion of reasonable and unreasonable measurement/classification error. If the reliability of a test is known

and published, it is unlikely that a challenge to a score would succeed if it fell within known error ranges and the rationale for establishing cut scores for specific decisions had been articulated in terms of the effects of false positives or false negatives on both individuals and the wider public. However, if it can be demonstrated that sources of error have not been identified and adequately dealt with, legal challenges are likely to succeed. The main areas for legal concern include taking appropriate measures to establish defensible cut scores (as discussed above), producing rating scales/scoring procedures that are not ambiguous or difficult to use, and training human raters to make consistent and construct-relevant decisions (Kleinman & Faley, 1985).

Any such claim must be related to an instance of disadvantage. One such case was reported in the *Pakistan Times* (2009): Dr. Jaffrey took an IELTS test during 2008 in order to apply for an Australian work visa. The score was below that required under Australian immigration law and Dr. Jaffrey appealed. Cambridge Assessment had the test rescored and the band was raised as a result, but not before the date for issuing the visa had passed (*Dr. Syed Jaffer Abbas Jafri v. The British Council and Others*, 2009). This case was unfortunately not heard; court records suggest that the lawyers and plaintiff did not appear at the required hearings and the case was dismissed. Similar misclassification concerns have been aired by judges in Australia (Lane, 2011) in cases where there was prima facie evidence that IELTS scores may have been unreliable, particularly where the plaintiffs had acquired degrees from English-medium universities. However, in all such cases to date judges have ruled that internationally recognized tests are at least more likely to be reliable than other measures of proficiency.

Although no successful cases have been brought under the heading of misclassification because of unreasonable measurement error, this may be because language-testing experts have not been called as expert witnesses. This is an area in which future litigation may be successful unless test providers conduct and place into the public domain classification reliability data and risk estimates.

Immigration

A closely related area is that of immigration. The use of language tests to restrict immigration is rapidly growing around the world (Kunnan, 2012), and has proved to be highly controversial, not least because it is difficult to clearly identify key ethical principles upon which stakeholders can agree (Bishop, 2004). However, from a legal perspective the key issue is likely to revolve around discrimination. The most important case to date is that of *Chapti, Ali, and Bibi v. The Secretary of State for the Home Department* (2011) in the UK. In 2010 new legislation was passed that required spouses of UK citizens to demonstrate a working knowledge of English before they were allowed to remain in the United Kingdom. In this case it was claimed that the use of language tests for this policy purpose was an infringement of Articles 8 and 12 of the European Convention on Human Rights, which protect the right to marry and live together. It was further claimed that the law was discriminatory because it would have differential impact on spouses from

poor educational backgrounds, and countries where access to English-learning opportunities are limited.

The key aspects of the defence were that Article 8 does “not oblige a state to respect the choice by married couples of the country of their matrimonial residence” (*Chapti, Ali, and Bibi v. The Secretary of State for the Home Department*, 2011, section 5), and as the plaintiffs had not lived with their spouses in the United Kingdom at the time of marriage the requirement that they pass a language test did not interfere with their married life. Evidence considered in favor of the defence included reports on the need to speak English for social integration, the cost of translation services for non-English speakers in public services, and research into employment rates among non-English-speaking immigrants. The central argument therefore was that there are good social reasons for using language tests to deny residence, and no violation of human rights had occurred. The entire case deserves close reading by applied linguists and language testers for the nuanced approach to the use of language in policy aims. However, the judge, Mr. Justice Beatson, commented in relation to discrimination:

I first deal with direct discrimination. I have concluded (at [82]–[84]) that the aim of requiring a minimum level of English from those seeking entry as spouses of British citizens and other persons settled in the United Kingdom is a legitimate aim. Those who can speak English will have no difficulty in meeting it. Non-English speakers are not in a relevantly similar position to English speakers and it is rational to exempt those who do speak English to the required standard from the test. A lack of English is not an immutable characteristic like race or gender. A distinction based on it should not be regarded in the same way as they are; that is, accorded a “specially protected status”, “special vigilance and a vigorous reaction”, and require “very weighty reasons” in order to be justified (*ibid.*, 128).

I turn to indirect discrimination. For the reasons in [140], I have not determined whether the new rule constitutes indirect discrimination on the ground of gender. In relation to the other categories, I have concluded that, while the rule has a disparate impact on some, that disparate impact arises from personal circumstances such as financial means, education or knowledge of English, and does not amount to discrimination contrary to Article 14 (*ibid.*, 139).

These observations led to the ruling that the purpose served by the language tests was legitimately in the public interest and did not represent direct discrimination because it was not targeting a protected characteristic. Although there was evidence of indirect discrimination, this does not contravene human rights; it merely reflects the fact that those from disadvantaged backgrounds find it harder to obtain a share of the limited resources available. In legal terms, it may be of great social concern, but using a language test to limit their rights of residence is neither direct nor indirect discrimination.

There is evidence that this use of language testing spreads rapidly in times of economic turmoil, and is therefore a topic that will dominate the pages of journals and newspapers for many years to come. The reasoning in this landmark case should be carefully studied and re-evaluated in the light of new research and practices.

The Unusual Case of False Positives

There have been no legal cases to date regarding a test taker receiving a score higher than they should have done as a result of unreasonable error. In other words, they should have received a score below some cut score for decision making, but nevertheless “passed.” It is not hard to see why this is the case given previous discussion: There is no possible basis for a claim of discrimination.

Passing Due to Error or Misuse

However, testing agencies and other professional bodies should not discount the possibility that litigation may happen at some point. The example of using IELTS to certify nurses and doctors to practice in the United Kingdom is apposite. The call for testing health professionals from the European Union working in the British National Health Service was a direct result of the death of a patient at the hands of a German doctor who did not have the language skills necessary to practice in the UK. New legislation establishes systematic language testing with decisions to be taken by “responsible officers” (BBC, 2012). The General Medical Council (GMC) has been given responsibility for the new system, and a tender to establish appropriate cut scores on the IELTS issued.

It is almost inevitable that a health professional who has achieved the cut score will at some point in the future be responsible for an error that will lead to medical tragedy. The family or a patient support agency may bring a case against the health professional, the GMC, or one of the responsible officers, on the grounds that the health professional was not able to communicate with the patient, understand medical records, or write out prescriptions or notes. Content and cut score issues will immediately be the evidential focus of the litigation, in addition to the reliability of classification. However, the challenge will be that the individual was a false positive, and should not have passed the test. Similar scenarios can be imagined for other high stakes decision contexts, such as pilots and air traffic controllers. False positives, in these cases, may clearly not be in the public interest.

Language testers and test providers should be very wary of the possibility of litigation related to false positives. A failure to take into account potential consequences could lead to those who conduct the standard-setting studies to be held personally responsible, and the test provider could face penalties for failure to advise what a test should not be used for.

Cheating

Cheating is an attempt to create false positives by an act of dishonesty on the part of a test taker, individuals employed by a testing agency, or their representatives. It is usually dealt with under fraud legislation. Cheating usually takes place in high stakes contexts where the fear of being prosecuted is outweighed by the desire for economic or social benefits to be accrued by achieving a test score that appears unobtainable (Fulcher, 2011a).

Cheating takes many forms, such as the use of electronic devices to receive answers from outside the test venue, smuggling crib sheets into the test venue, and transmitting questions over time zones. Most recently the provision of “ghost writers,” test-taker substitutes, has grown into a substantial business activity. On the provision side, there have been a number of cases of teachers changing student answers after the test, and providing copies of test papers prior to the test. The range of activities that attract prosecution is discussed and illustrated in Fulcher (2011b).

Test providers and those responsible for test delivery attempt to reduce the number of false positives created in this way by developing test security procedures that guarantee test confidentiality and ensure test-taker identity and score integrity throughout the assessment process. While there are numerous prosecutions of test takers and individuals who abuse the system each year, there have been no cases in which a test provider has been prosecuted for poor security systems. However, as language test use grows as a component of immigration policy, border agencies increasingly produce lists of tests that providers claim are “secure.” This has pushed providers to invest in new security measures, such as biometric identification. It is therefore at least possible that lapses in security that allow false positives may attract prosecution in the future.

Standards and Codes

Most of the issues raised in this chapter are covered to varying degrees by the standards and codes that have evolved to guide testing and assessment practice. Individual testing agencies produce standards for use within their own institutions, and internationally recognized standards are produced by organizations such as the International Language Testing Association (ILTA). However, it is the *Standards for Educational and Psychological Testing* (AERA, 1999) and its predecessors that are frequently cited in court. In many cases, including those involving flagging such as *Doe v. The National Board of Medical Examiners* (1999), the interpretation of the *Standards* has been a critical element in legal argument. It behoves testing and assessment producers to pay close attention to the *Standards*, and to develop research agendas that address the key questions upon which they are most likely to be at risk from litigation.

Conclusions

The law is relevant to language testing and educational assessment primarily when test use and interpretation give rise to the possibility of discrimination in decision making. Whenever discrimination is suspected, specific aspects of current practice and test data become evidence in legal proceedings that challenge the fairness of outcomes. Litigation is usually motivated by the potential loss associated with unjustifiably low scores. In the future there is additional potential for litigation to be associated with damage to the public good through misclassification.

Basic procedures to avoid bias and discrimination are built into routine testing and assessment practice, including content sensitivity and bias reviews during test development, and evaluation of differential item functioning in operational testing. New practices such as those associated with test retrofit (Fulcher & Davidson, 2009; Fulcher, 2012) will add to the language-testing tool kit.

When institutionalized, these will inevitably provide some defence against a charge of discrimination. However, it is unclear whether test providers, individual language-testing researchers, or nominated “responsible officers” have considered the breadth of potential sources and reasons for litigation in the field. With issues of fairness and accountability permeating every aspect of our societies, and the growing use of language testing in such a wide range of policy contexts, the escalation of litigation is inevitable. The research and synthesis of legal issues presented in this chapter, and an awareness of the relevant standards and codes, should inform a risk-aware approach to professional practice.

The Influence of Ethics in Language Assessment

Bernard Spolsky

Bar-Ilan University, Israel

The Power of Tests

A flurry of ethical concerns among members of the language-testing community at the end of the 20th century resulted in heated discussions on lists such as LTESL-L and at symposia such as the one held at the AILA (International Association of Applied Linguistics) Congress in Finland in August 1996 (Davies, 1997a), leading to the adoption of codes of ethics and good testing practice by the International Language Testing Association and by regional language-testing organizations. This recognition of ethics was sanctioned in large measure by the inclusion of the notion of consequential validity under the heading of validity: Once a leading psychometrics scholar (Messick, 1980) had taken this step, it proved possible to add the use of tests to their form as an appropriate topic for language testers to debate.

There is a power imbalance in questions. Normally, when we ask a question, we are in the power of the person we ask, who may choose not to answer or to lie. The fact that examiners already know the answers to the questions they ask means that they have power over the examinees. From their beginnings in imperial China, tests and examinations have been tools for the powerful to control the less privileged or to select among them. The imperial Chinese examination was developed over 2,000 years ago as a method of winnowing out highly educated scholars to be candidates for magisterial positions, relieving the emperor of the dangerous nepotism that existed when magistrates were selected by important aristocratic rivals. Recognizing this, during the period of Mongol rule, Kublai Khan abolished the examination and replaced it with a system that gave priority to Mongols. Under the elaborate and expensive imperial examination system that developed over the centuries, those candidates who came to the top could be assumed to be independent of outside influence but still loyal to the emperor who personally supervised the examinations (Miyasaki, 1981). Given the vast gap

between chief examiner and candidate, nobody would dare to claim bias, nor was there much sympathy for all those who failed the selection process, which was aimed at a meritocracy, intended to produce a tiny elite out of a mass of potential examinees. The examination should be fair, but there was no concern for ethics, reliability, or validity.

In 19th-century England, the same considerations of effectiveness impelled Thomas Macaulay to propose adopting the Chinese system to choose cadets for the Indian civil service. He argued that a mammoth examination, which would include Latin, Greek, German, Italian, mathematics, and Sanskrit, was appropriate in a situation where the men most qualified for public office as English judges and governors-general of India usually turned out to have been at the top of the competitive examinations at Cambridge and Oxford. The leader of the opposition agreed to “a principle unknown in this country, but which was said to prevail in China, and therefore might be named the Chinese principle, namely, that of unlimited intellectual competition for admission to civil office” (Hansard, 1853, p. 620). While some doubts were expressed—some speakers questioned the ability of an examination given to a young man to predict his future and noted the difficulty of administration and the failure to take character and ability into account—the system was finally adopted in 1853, and by 1858 the first examinations were held. They were believed to have been validated by the fact that 101 of the successful candidates in the first decade turned out to have been educated at the University of Oxford, 80 at the University of Cambridge, 37 at the University of London, 27 at the University of Edinburgh, and 76 at Trinity College Dublin; in addition, one Brahmin passed. It was assumed that the examiners would be fair, and that the examination would be “felt fair” to use the language still used by the secretary of the University of Cambridge Local Examinations Syndicate in the 1980s before more elaborate statistical techniques for achieving reliability became widely accepted.

Although there had been earlier European uses of examinations in schools, such as the citizen-controlled medieval exams at Treviso (Spolsky, 2005) that were not unlike the public examination “by all Commers” in Harvard College in the USA in the 17th century (Buck, 1964), the introduction of testing into schools in Europe has been attributed to the Jesuits who applied the Chinese model to their schools as a method of ensuring that class teachers followed the centralized syllabus. In France, the system spread to secular schools, survived the French Revolution, and was enthusiastically adopted as a method of central control of education by Napoleon (Madaus & Kellaghan, 1991) and his successors. Readers will notice the renewed current attraction of politicians, businessmen, and the US Department of Education to testing as a method of asserting the control of the federal government over an area constitutionally left to the states.

In the 19th century, examinations became “a major tool for social policy” (Roach, 1971) in England as well as in France, and were mocked in a Gilbert and Sullivan opera (Gilbert, 1882):

Peers shall teem in Christendom,
And a Duke's exalted station
Be attainable by Com-
Petitive Examination.

Besides this ironic celebration, there were serious critics. One of the most outspoken was Latham (1877), who saw examinations as “an encroaching power” that was blurring distinctions between liberal and technical education and making teaching narrow and subordinate to examinations. Examinations, he said, should be concerned with use, but with different examiners there could be different results. This attack on the technology of testing was meant to be handled by quantification of scores, which could lead to precision in ranking, would set norms, and would allow for comparing results. But this too was questioned, in two pioneering papers presented to the Royal Statistical Society (Edgeworth, 1888, 1890). Edgeworth examined the statistical nature of examination results, noting the existence of a normal curve of distribution with inevitable problems produced by variations in examiners’ judgments, the health of candidates, and the suitability of questions. He concluded that there was “unavoidable uncertainty” (1890, p. 660) and a need therefore to report and interpret results carefully; he consequently preferred the Oxford system of classes of passes to the Cambridge attempt to rank candidates.

Reducing Uncertainty

The testing profession accepted “uncertainty” but not “unavoidable,” and set out professionally (and ethically, if erroneously) to reduce uncertainty: Psychometrics found technical methods of achieving more accurate, reliable, and stable results; this became the thrust during the next century. The English toyed with objective testing after World War I, but went back soon to more subjective approaches so that, by the mid-1930s, their examinations were a target for ineffective attacks by the British educationalist Phillip Hartog (Hartog & Rhodes, 1935) and criticism by visiting American psychometrists (Monroe, 1939). British acceptance of objective tests was recognized in the Education Act (1944), a measure introduced by the Conservative politician R. B. Butler which established the 11 Plus examination to determine what kind of secondary education a pupil was qualified for. In the USA, enthusiastic but inaccurate descriptions of army mass recruit intelligence tests (Yerkes, 1921) encouraged the spread of the testing movement and its exploitation by a new industry: By 1923, half the business of the Teachers College Bureau of Publications was in tests and scales (Joncich, 1968, p. 57). The College Entrance Examination Board, under the leadership of Brigham, who had by then disowned his controversial positions on IQ (Brigham, 1923), was setting up the Scholastic Aptitude Test which came to dominate admission to American universities.

Standardized testing was introduced to the area of language during the work of the Modern Foreign Language Study. The testing served the profession rather than the pupils. This is best illustrated by the so-called prognostic tests (Henmon et al., 1929), the purpose of which was to ensure that pupils who were potential dropouts could be kept out of foreign language classrooms: The goal was to prevent “mortality” (Cheydleur, 1932). This kind of test, renamed “aptitude,” was later developed by John Carroll (Carroll, 1962) in order to save government intensive language programs the expense of bringing unqualified students to the two-day preliminary trial session that would determine admission.

By the mid-1950s, when Carroll organized a pioneer meeting on language testing (Carroll, 1953) and wrote a valuable state of the art paper that unfortunately was never published (Carroll, 1954), the language-testing profession was starting to take shape, and was ready to tackle a major enterprise: the development of an English language proficiency test. The motivation was the interest of government rather than students. This was in fact the third time the US Immigration Service had approached the testing profession to deal with a loophole in the Immigration Act of 1924 that was intended to limit immigration as much as possible to people from northern Europe. The Act provided visas for foreigners whose stated purpose was to study in the USA; many took advantage of this exception as a way of getting into the country, and the commissioner of immigration called for the development of a method certifying "the exact knowledge of the English language" of applicants (the memorandum is in the Educational Testing Service archives). As a result the College Entrance Examination Board, on the advice of two commissions, prepared the first form of an examination and administered it to 30 candidates in Europe and Asia in 1930 (College Entrance Examination Board, 1930). The following year, 139 candidates (82 in Moscow) took the examination but, with the depression, only 17 candidates were tested in 1933 and 20 in 1934. The attempt to control immigration by testing then languished, nor was the test available in 1938 when a test was sought to establish the English proficiency of Jewish doctors and lawyers seeking to emigrate from Nazi Germany.

Perhaps this is an appropriate place to mention a program with no claim to ethicality, the Australian immigration test, where customs officers had been instructed to give dictation tests in a language that an undesired immigrant clearly did not know (Davies, 1997b). Similar use of language testing to control immigration has now spread to many European countries, leading to the recent publication of several papers and collections dealing with the ethical issues (Eades, Helen, Siegel, McNamara, & Baker, 2003; Bishop, 2004; McNamara, 2005; Extra, Spotti, & Van Avermaet, 2009; Hogan-Brun, Mar-Molinero, & Stevenson, 2009; Slade & Mollerling, 2010).

After World War II, the US Department of State once again asked the College Board for an English Proficiency test. The Board set up an advisory committee in 1946 which included Charles Fries from the University of Michigan, who brought his doctoral student Robert Lado with him. The committee designed a test to be offered at US universities, through the Department of State (which in the event did not cooperate; Saretsky, 1984), and at overseas centers. Only one version was prepared, and small numbers of candidates took the test in the USA and South America. A review by Charles Langmuir in *Buros* (1959) raised serious questions about the quality of the test: Foreign students had to study the practice book for a week, undergo five hours of testing in two sessions, and wait for the results of a long scoring procedure. There were no normative or validity studies, but, while the experiment clearly failed, it gave some idea of the possibilities of such a test.

The third initiative a decade later was more successful and, after a memorable meeting in 1961 (Center for Applied Linguistics, 1961) which included a landmark paper by Carroll (1961), the Test of English as a Foreign Language (TOEFL) was born, developed, nearly went bankrupt, and was captured by the College Board and Educational Testing Service (ETS); it later became a major income source for

ETS, encouraged competition from the University of Cambridge Local Examinations Syndicate, and launched the English language-testing industry (Spolsky, 1995). The early validity studies consisted mainly of comparison with other available tests. ETS was in fact persuaded by language testers on the committee of examiners to make clear the ethical need for local validation studies and did at one stage ask users how many did this, but few responded positively, a sign of the difficulty of imposing ethics on users. The original motivation remained the same—to control the immigration loophole—but the immediate focus was to provide a secure standardized test with regular new forms that precluded cheating as much as possible. Again, the test served the interests of the users of test results more than the interests of the test takers.

Building an English-Testing Industry

Clark and Davidson (1993) provide a good metaphor of the move from cottage industry to consolidated enterprise. The Educational Testing Service, the owner of the Test of English as a Foreign Language, is an excellent illustration. But the process goes back much further; in the 1920s in the USA, many small testing units set up by psychologists and academics came under the control of larger corporations and publishers, who quickly added a business motivation that dominated practical and ethical concerns. ETS was founded in 1948. The work of the College Entrance Examination Board, conceived in the last decades of the 19th century and founded by a dozen Eastern elite US colleges in 1900, had grown and become more complex in the mid-years of the 20th century. It added research in test development in the 1930s, and during World War II was active in government work: Over half a million men took the Army–Navy Qualifying Test in 1944. It soon became too complex to be managed by what had started as a group of college professors trying to maintain admission standards. James Conant, president of Harvard from 1933 to 1953, was one of those who proposed a unified testing agency. He chaired the committee on the topic set up in 1946 on the initiative of the Carnegie Foundation. There was some reluctance within the College Board, but in 1947 the Board handed over tests worth hundreds of thousands of dollars and part of its capital to the newly established Educational Testing Service. ETS was to be a “non-profit, non-stock corporation without members,” which protected it from takeover by publishers (Harcourt Brace Jovanovich had swallowed the Psychological Corporation, and McGraw-Hill had taken over the California Test Bureau). The governing board was to select its own successors. Chartered under the New York Board of Regents as a nonprofit body (though situated in Princeton, New Jersey), it was exempted from federal income tax. It received a \$750,000 grant from Carnegie and testing assets from the American Council of Education (worth \$185,000) and the College Board (worth \$300,000). It designed and owned its tests, but operated them for the College Board or for ad hoc boards it created for each test. The result of this clever arrangement was that ETS came quickly to dominate US testing. It had its critics, but reading the Nader report (Nairn, 1980) one realizes how difficult it was to monitor or interfere with its operation.

ETS worked with the College Board to take over the newly created Test of English as a Foreign Language in 1964, and then persuaded the Board to give up its share of a losing business that shortly after turned into ETS's major source of income (Spolsky, 1995, pp. 269–79). One can see the business motivation in early decisions. The design of TOEFL was dictated by an ETS expert who was at the time leading a drive inside ETS to add a writing sample to the SAT but who persuaded people not to include a writing test in TOEFL because of the cost of overseas airmail, and to keep away from oral testing because of expense. Once David Harris and Leslie Palmer, the two language testers who ran the program for the first four years, had returned to academic life, ETS replaced them with a business manager who controlled policy. Essentially, the psychometric expertise of ETS was available to carry out research justifying policy—in the course of time, a large body of such studies was published, and language testers were appointed to an advisory board, which met rarely. As time went on, outside pressures forced ETS to add writing and oral tests, but using a modified form for secondary school pupils added to income; at the end of the century, a promise to revise the test was delayed so as to try out the economic value of computerization.

Business motives also led to an attempt to get into the European market, arousing the competitive spirit of the major British testing institution, the University of Cambridge Local Examinations Syndicate (UCLES). Cambridge had been in the English-testing business for many years, under the firm grip of traditional non-objective approaches. The word “objective” remained in inverted commas in the minutes of their committees into the 1960s. In 1988, challenged by the competition, UCLES funded a study intended to permit easy comparison of TOEFL and UCLES test results, only to be deeply shocked by the finding that its tests were psychometrically questionable. UCLES undertook major administrative restructuring, hiring language-testing experts and appointing them to run the English tests in what soon became an independent program. Before the reform, UCLES was headed by an engineer and wondered what to do with its profits, but, since then, it has invested in hiring more highly qualified language testers and published a series of books describing its extensive program of research and development. An intriguing method of minimizing competition was initiating the Association of Language Testers in Europe (ALTE) in 1989. In fact, this is not an association of language testers but, to quote its Web site, “an association of institutions within Europe, each of which produces examinations and certification for language learners. Each member provides examinations of the language which is spoken as a mother tongue in their own country or region.” By restricting membership to Europe and limiting admission, the only two members entitled to offer English tests are University of Cambridge ESOL Examinations (formerly a division of UCLES) and Trinity College London; this clearly kept out the major competitor, the Educational Testing Service, and prevented any other European language-testing organizations from competing in offering English tests. Its code of ethics will be described later, but simply note this as another case where business interests were stronger than ethical or professional considerations.

Corporate interests do not allow stagnation, however, as the recent entry of a new major player into the English-testing field shows. It was reported in the *New York Times* in an article by Eric Pfanner (September 7, 2009) that

Pearson, the British publishing company, has developed a test for English as a second language, seeking to compete with two nonprofit groups that currently dominate that fast-growing market. The company plans to announce Tuesday that it will start selling the Pearson Test of English Academic in October. It will compete with the Test of English as a Foreign Language, or TOEFL, which is managed by an American organization, the Educational Testing Service, and with the International English Language Testing System, or IELTS, run by a British–Australian group. Pearson estimates that about two million such tests are taken annually, mostly by business-school applicants and job seekers. With demand surging in places like India and China, the number of tests taken has doubled over the last four years, Pearson says. Pearson said prices of its test would range from \$150 to \$210, depending on the country, roughly in line with its competitors. That means such tests, over all, generate several hundred million dollars in annual revenue.

There are thus now three major competing businesses aiming to control the huge and profitable English-testing market.

Introducing and Codifying Ethics

Discussions of ethics in language testing were foreshadowed in papers like Spolsky (1967), which raised the question of test impact rather than psychometric qualities. This conference paper noted the requirement of English proficiency as a criterion for admitting foreign students to US universities, suggesting that this excluded applicants lacking the middle-class or establishment backgrounds which in their countries of origin would permit secondary education at institutions with strong English programs. This was a novel point of view, for most language testers at this time took for granted that their job was to develop efficient gatekeeping tests with no thought of who was being excluded. For instance, Spolsky (1968) was still concerned with validity seen as the problem of defining language proficiency, a question concerning construct rather than use and impact. Only a decade later did Spolsky (1981) return to the ethical question, at a testing conference hosted by a German military language-testing agency, arguing that tests, like medicines, should be labeled “use with care.” Stevenson also noted the uncertainties that research had raised about the nature of language proficiency (Stevenson, 1985), and argued therefore for the need for international standards for language tests. Canale (1988) proposed a natural-ethical approach to language testing. As the discussion continued at meetings and on e-mail lists, Stansfield (1993) proposed professional standards and a code of ethics. Leadership in this area had been provided by the American Psychological Association (APA), which included professional practicing psychologists; in 1992, APA adopted a code of ethics which included a section on test construction.

In response to the widespread discussion, the International Language Testing Association set up a taskforce on testing standards, which reviewed over 100 documents and in a report described the variation in international practices (International Language Testing Association, 1995). Discussion continued on the Internet, at meetings, and in journal articles and formal symposia toward the end of the century.

An important symposium took place in Finland at the AILA Congress in 1996 (Davies, 1997a). Spolsky (1997) argued that tests had always been used for political and social control. However, given their “unavoidable uncertainty” and probable unfairness, language testers should remain skeptical about their precision and power of prediction; those who use test results for decision making should gather as much information as possible.

In Australia, tests continued to be used for political ends: Hawthorne (1997) described the access test (Australian Assessment of English Proficiency) used to regulate the flow of migrants and STEP (Special Test of English Proficiency), intended to keep out asylum seekers. Political aims affected test design, administrative procedures, and the outcomes of testing. Another example of ethically questionable testing procedures in Australia for speakers of languages other than English (LOTE) was reported by Elder (1997): The state of Victoria compensated those who were learning a foreign language for the “bias” in favor of heritage speakers of the language (but did not compensate LOTE learners of English for the bias against them). Looking at testing policy at a South African university, Norton and Starfield (1997) noted that lack of English proficiency was sometimes penalized in examinations in other subjects; it would be fairer if speakers of English as a second language were informed how much of the score is given for knowledge of content and ideas and how much for expression in English. Expressing ideas she had previously expressed on e-mail lists, Hamp-Lyons (1997) showed the link between the washback of a test and its impact, relating this to Messick’s theory of construct validity. Rea-Dickins (1997) reviewed a wide range of tests to consider the contributions that stakeholders (learners, parents, teachers) were allowed to make to test development and evaluation, and the relation between testing experts and government, arguing that stakeholders need to be better informed on testing. Lynch (1997) defined ethicality in terms of harm, consent, confidentiality of data, and fairness, and examined the Victorian assessment project in these terms. Davies (1997c) argued that the ethical foundations of testing (as of the social sciences) were dependent on professionalization. Professions like medicine and law establish contracts with the public and at the same time protect their members. The intrusiveness of language testing and the application of norms raise ethical questions; consequently, alternative methods need to be considered and validity of test scores needs to be shown. But the language-testing profession has weak sanctions. It needs to set up an “ethical milieu” by professionalization, which involves training standards, professional associations and journals, codes of practice, and explicit qualifications for language testers. Shohamy (1997) repeated arguments she had expressed at greater length in an earlier book (Shohamy, 1993): Tests are powerful and unfair; the use of tests for control is unethical; language testers need to remain vigilant.

Codes of Ethics

The ILTA working group subsequently drafted a code of ethics which was approved by the association in March 2000 (International Language Testing Association, 2000). The ILTA code of ethics sets out “fundamental principles”: respect for the

humanity and dignity of test takers and their needs, values, and cultures; confidentiality of data; research guidelines; avoidance of misuse; development of professionalism; integrity of the profession; need to educate society on quality assessment; recognition of social obligations; and consideration of potential effects, to the extent that a language tester might withhold services as a matter of conscience.

Over the next few years, codes of ethics spread and blossomed (Jia, 2009). ILTA developed guidelines for practice, drafted and circulated and finally approved in 2007 (International Language Testing Association, 2007). They are more precise, as Jia notes, in setting “minimum standards of conduct”:

The ILTA Guidelines for Practice spell out some basic considerations for good testing in all situations as well as on some special occasions. They mention the responsibilities and rights for the following stakeholder groups: test designers, test writers, institutions preparing or administering high stakes examinations, those preparing and administering publicly available tests, test users and test takers. The fundamental rationale for the ILTA Guidelines for Practice is to promote test validity, reliability, and test fairness. (2009, p. 4)

They stress the need for a clear statement of the construct underlying the test, call for pretesting or IRT analysis before results are issued, encourage the use of scoring guides and the training of scoring, expect accurate scoring and equal conditions of administration, and require test security. Institutions are expected to use qualified test designers, advertise their purpose and scoring method, and guarantee accuracy of scoring, appropriate facilities, and equated forms. Publicly available high stakes tests should define the target candidates and the test construct, publish reliability and validity reports, provide interpretable results, avoid false claims, and provide a manual or handbook. Users of test results should be able to explain their relevance, fairness, accuracy, and limitations. For norm-referenced tests, the population on which they were standardized should be reported; for criterion-referenced tests, expert opinion should be given; and for computer-adaptive tests, the rationale should be explained and the sample large enough for IRT analysis. Native speakers should check items. The code of good testing practice of the Japan Language Testing Association, adopted in 2003, closely follows the ILTA guidelines. The TESL Canada ethical guidelines are also based on the ILTA guidelines and others.

The model adopted in 2006 by another professional group of language testers, the European Association for Language Testing and Assessment, was aimed at three populations: “those involved in: the training of teachers in testing and assessment, classroom testing and assessment, and the development of tests in national or institutional testing units or centers” (European Association for Language Testing and Assessment, 2006). Rather than providing statements, it consisted of a set of questions to be considered by trainers and testers, such as what the purposes of the assessment are, who designs it, and what use is made of the results. As befits an organization sponsored by the European Commission, it now provides its guidelines in 35 European languages.

As an association of testing institutions rather than of testers, ALTE has taken a technical and professional approach to setting standards. It sets out a code of

practice (Association of Language Testers in Europe, 2001) and a quality management system for checking the internal auditing of standards. This system, established by ISO (International Organization for Standardization), aims to increase business efficiency and in future will be able to form the basis for a method of auditing of the standards met by member organizations. Once this is done, some method of enforcing or evaluating the application of the codes, an essential component missing from the approaches of language tester organizations, would be added, but Van Avermaet, Kuiper, and Saville (2004) doubt if this is feasible. In the meantime, the code serves ALTE members as guidance rather than regulation.

The three big English-testing businesses each have statements of ethics. Cambridge will also have a monitoring system when the ALTE system is in place. The Educational Testing Service adopted its standards of quality and fairness in 1981, under pressure from legal actions, and has revised them regularly; the latest revision dates from 2002 (Educational Testing Service, 2002). The standards are divided into 13 headings: development procedures, suitability, customer service, fairness, uses and protection of information, validity, assessment development, reliability, scaling and equating, assessment administration, reporting, assessment use, and test takers' rights and responsibilities. Each testing program is audited by the ETS office of professional standards compliance to ensure that it meets the standards. There appears to be a strong concern in the ETS standards for "fairness," which looks in fact like what is called "political correctness": avoiding language or topics which may give offence to a group or be controversial. This may well have been a reaction to external criticisms citing items from tests that, since legal requirements in the 1980s, have needed to be published. The third, Pearson Language Testing, is a division of Pearson Education; its president is experienced in publishing, but its vice-president for test development is a leading language-testing scholar and three other senior managers have had experience at IELTS and Cambridge ESOL. It has a code of business conduct and pledges to abide by ILTA and EALTA and APA standards. All employees are expected to renew their pledges annually. Its tests are regularly monitored: Language testing is a subdivision of Edexcel, which has a standard vetting and auditing procedure (John de Jong, personal communication, February 16, 2011).

Codes and Beyond

In the last two decades of the 20th century, language testing came under the influence of demands for standards and ethics, an influence responded to by the three big testing businesses, ETS, Cambridge, and Pearson. At the same time, professional associations of language testers started to develop and publish their own codes of ethics and good practice. The discussions continue. Fulcher, while clearly not yet convinced that language testing had solved basic problems (Fulcher, 2004a, 2004b), saw the symposia and codes as a valuable step in answering the questions raised by Edgeworth and Messick 100 years apart (Fulcher, 1999). Byram (2000) included in his article on assessment a reference to growing concern for ethics and accountability. Bachman (2000) called for a program of validation including

concern for ethical test use. Kunnan (2005), recognizing the importance of Messick to the inclusion of fair use in standards, set out the wider social and political context of testing. He noted the questioned gatekeeping functions of tests for immigration and citizenship, and commented on bias studies and the use of computers. In the USA, he said, an important factor has been the development of a legal framework for challenging standardized tests as discriminatory if they lack due process by giving advance notice of the nature of the test or if they fail to make accommodation for disabilities.

But the issue remains open. A paper by Schwandt and Jang (2004) argued that language testing is a social-political-cultural practice. There are, they proposed, two approaches. The "interpretive turn" is raising some basic questions, but the dominant view is that language can be objectified and studied scientifically. Language testing has developed within psychometric theory and practice, framing criteria of reliability and validity, and has grown into big business. From a psychometric point of view, language testing is empirical, but to ask questions about use and users is normative, not subject to empirical proof. The two streams do not intersect. Schwandt and Jang contrast Bachman (2000), who sees language-testing history as advances in theory and practice, and Spolsky (1995), who concentrates on the external nontheoretical social, political, and institutional forces which shaped practice.

Increasingly, books on language testing include ethics. In an important extension of a psychometric approach, McNamara and Roever (2006) add the social dimension. Davidson (2010) notes that a new textbook by Douglas (2010) features ethical questions in several chapters, and bases exercises on the ILTA guidelines which it includes. Two of the five articles in a recent issue of the journal *Language Testing* deal with the impact of tests, and one review deals with three books on language testing of immigrants and citizens, showing the growing concern for ethical questions.

At a time when one of the major issues in debates about US education concerns the emphasis on testing as the means to take control of the system, the issue of the best way for ethics to influence language testing remains open. Some are satisfied: Davies (2008) takes a pragmatic position, pointing out that language testing does not have the claim to professionalism of law and medicine, but can make a claim to accountability by developing a code of ethics, as its professional associations have done. But, just as architects have no responsibility for the use to which their buildings are put, so language testers cannot be blamed for the misuse of tests.

As we have seen, the most serious auditing of standards has been promised but not yet implemented by ALTE which is an association of testing organizations rather than of language testers. For the rest, one has to rely on the personal ethical standards of language testers and their application of these standards in their work for other agencies. Language testers are increasingly aware of ethical problems, as might be illustrated in Kunnan and Davidson (2004). But wider implementation remains a problem. It could be improved by a system of certifying or recognizing tests which have independent auditing of ethical standards, an issue currently being discussed by language testers. At the same time, this leaves a major gap, for there is no way to control the use made of test results or guarantee

the wider acceptance of assessment literacy (Taylor, 2009). We can deplore or decry governments that use language tests to control migration and block asylum seekers, or education departments which misuse tests given to pupils to judge teachers, or school systems and politicians who believe that testing can replace teaching. But language tests, like guns in Arizona, remain unregulated, and one can only hope that codes of ethics will have more influence than religious codes in avoiding misuse.

Ongoing Challenges in Language Assessment

Lyle F. Bachman

University of California, Los Angeles, USA

Introduction

In considering the challenges that face the field of language assessment in the early decades of the 21st century, it is clear that many of those that have persisted over the years continue to engage us. At the same time new challenges, engendered in part by our own accomplishments and the progress made over the past half century and in part by changes in the economic, social, and educational contexts of the 21st century, assure us that the field will continue to be a vibrant and exciting one. Thus, while the field has matured both in the breadth of research questions it addresses and in the range of research approaches at its disposal for addressing them, it still grapples with the questions that are fundamental to our enterprise. What is the nature of language ability? How can we assure that the interpretations about test takers' language ability at which we arrive on the basis of assessment results are meaningful to them and other stakeholders? How can we assure that these assessment-based interpretations generalize to language use situations beyond the assessment itself? To what extent can we justify the uses for which our assessments are intended? To what extent do our assessments, the uses to which they are put, and the consequences of these uses respect the individual rights and the societal and educational values of those who are affected by these uses and consequences?

Addressing these questions has led to a better understanding of their complexity, their persistence, and the importance of continuing to address them through research. We now have a broader and more inclusive view of language ability, along with a wide range of methodologies—both quantitative and qualitative—that we can employ in the development of practical language assessments and in basic research. We also have a clearer understanding of the social and political contexts within which the uses of language assessment are embedded and a firmer

grasp both of the ethical issues involved in using language assessments and of how these contexts and issues need to inform and shape what we do. In short, the field is in a much better position to deal with the issues of developing and using language assessments in the real world than ever before.

At the same time, it is important to realize that theoretical frameworks of language ability, sophisticated research methods, social theory, and moral, ethical, and philosophical explorations all provide, at best, general guidance for the craft or practice of language assessment, which is to develop language assessments whose intended uses can be justified to those whose lives will be affected by these uses. The richness and complexity of the theoretical and methodological frameworks that now underlie our practice heighten the single most important and continuing challenge for language testers: how to discharge our duties *responsibly*—both methodologically and ethically—as we develop and use language assessments in the real world.

New challenges for the field have also arisen from the increasing worldwide demand for individuals with high levels of language ability. These demands are twofold: (1) huge and growing numbers of students worldwide whose native language is not the language of instruction and who may need to learn the majority or “official” language of a country in order to become fully functioning members of the society; and (2) globalization and the increasing demands for employees who can function in multilingual work settings. Along with these growing demands for high-level users of languages has come an increasing demand for accountability in language teaching (see below). Governments, from nations to states to school districts to local schools, are increasingly requiring that educational institutions and teachers be held accountable for the levels of language ability attained by learners, given the resources—human as well as time, space, and money—that have been expended. Similarly, corporations and businesses are increasingly expecting educational institutions—schools, colleges, and universities—to produce potential employees whose language ability is sufficient for them to function in a multilingual workplace. These demands for accountability reinforce schools’ and teachers’ normal interest in providing instruction that is more effective and appropriate for enhancing their students’ learning. In virtually all such situations, the tools for collecting information that will inform decisions—both accountability decisions and instructional ones—are language assessments.

Growing numbers of “young language learners” in schools pose challenges for classroom language assessment as well as for high stakes accountability assessment. For classroom language assessment, the challenge is how to apply the knowledge we have acquired (1) to develop assessments that will serve the purposes of learning and instruction; and (2) to provide training in language assessment for classroom language teachers. For accountability assessments, the challenge is how to apply the knowledge we have, as *language* testers, to inform the kinds of assessments that are made of students’ achievement not only in the language of instruction, but also in other areas, such as math and science, where the language of the assessment may not be the native language of the test takers.

The displacement of huge numbers of individuals across countries and continents, whether voluntary or involuntary, due to political unrest, economic

hardship, or personal circumstances, presents another kind of challenge for the field. In many such situations governments require those seeking to immigrate to demonstrate proficiency in a particular language. In the case of individuals who are voluntarily intending to immigrate in order to seek employment, governments typically require them to demonstrate proficiency in the dominant or official language of the country. In cases where individuals are involuntarily seeking political asylum, governments may wish to determine what their native language or dialect is in order to make a decision about granting them asylum. Again, the instruments that are used to collect information to support these decisions are language tests.

In this chapter I will describe what I regard as issues of continuing concern, as well as the new challenges that the field of language testing is facing—or will face in the years to come. I will then briefly describe an “assessment use argument” as a conceptual framework for problematizing many of these issues and for providing a principled basis for bringing together the rich diversity of research approaches at our disposal in order to investigate them empirically. I will conclude by pointing out that these challenges also offer opportunities for those language testers in the 21st century who are willing to address them.

Issues of Continuing Concern

Several issues have concerned language testers for the past decade or so: (1) the validity of score-based interpretations and the nature of the construct we want to assess—language ability; (2) ethics and professionalism in the way we develop and use language assessments; (3) the role of language assessments in accountability decisions; and (4) the impact of assessments on instruction.

The Validity of Assessment-Based Interpretations: The Nature of Language Ability

A major requirement of any language assessment is that the interpretations we make about test takers’ language ability on the basis of assessment results be valid. What this requirement entails is that the assessment results can be interpreted as indicators of the areas of language ability we want to assess, and of very little else. In the past 30 years the conceptualization of validity has evolved considerably, but central to all of these conceptualizations is the notion that the test developer and/or test user have defined the construct or ability that is to be assessed. For language tests, this construct is language ability. Thus one major area of inquiry continues to be the nature of language ability. In the past 35 years the field has seen a move from viewing language ability/proficiency as a unitary or global ability (e.g., Oller, 1979) to a view that language ability is multicomponential (e.g., Canale, 1983; Oller, 1983; Bachman, 1990; Bachman & Palmer, 1996). The dominant view in the field continues to be that language ability consists of a number of interrelated areas such as grammatical knowledge, textual knowledge, and pragmatic knowledge and that these areas of language knowledge are managed by a set of metacognitive strategies that also determine how language ability is realized in language use or in the situated negotiation of meaning (Bachman, 1990; Bachman

& Palmer, 1996; Purpura, 1998; Chapelle, 1998, 2006; Phakiti, 2003, 2008). Researchers who focus more closely on the nature of the interactions in language use have argued that the view of language ability as solely a cognitive attribute of language users ignores the essentially social nature of the interactions that take place in discourse. These researchers argue that language ability resides in the contextualized interactions or discursive practices that characterize language use (e.g., Chalhoub-Deville, 1995, 2003; McNamara, 1997, 2003). More recent research with paired and group interviews—which are oral assessments in which two or more test takers speak with each other rather than with, or in addition to speaking to, an examiner—suggest that, while such assessments can engage test takers in interactive language use, actually measuring the interactional competence of individual test takers can be problematic for both methodological and ethical reasons.

In a critical review of this debate, Bachman (2007) identifies three different approaches to defining language ability: (1) ability-focused, (2) task-focused, and (3) interaction-focused. He concludes that the theoretical issues raised by these different approaches to defining the construct, language ability, are challenging both for empirical research in language testing and for practical test design, development, and use. For language-testing research, these issues imply the need for a much broader methodological approach, involving both quantitative and qualitative perspectives. For language-testing practice, they imply that focus on ability, task, or interaction, to the exclusion of the others, will lead to weaknesses in the assessment itself or to limitations on the uses for which the assessment is appropriate.

A closely related issue is that of the extent to which language ability includes topical knowledge. The effect of test takers' topical or content knowledge on language test performance is well documented in the language assessment literature (e.g., Alderson & Urquhart, 1985; Douglas, 1997), and the dominant view has been that this is a source of bias in language tests. That is, in designing a language test and in interpreting scores from such a test, it is either generally assumed or specifically stated that "language knowledge" or "language ability" is what we want to assess, and not test takers' content knowledge. An alternative, or perhaps complementary, view has been articulated in the area of language for specific purposes (LSP) assessment. According to this view, what we want to assess is what Douglas (2000) has called "specific purpose language ability," which is a combination of language ability and background knowledge. Davies (2001) has argued that LSP assessment has no theoretical basis but can be justified largely on pragmatic grounds. Bachman and Palmer (1996) have argued that whether one includes topical knowledge as part of the construct to be assessed in a language test is essentially a function of the specific purpose for which the test is intended and of the levels of topical knowledge that the test developer can assume test takers to have.

As John B. Carroll (1973) noted 40 years ago, questions about the nature of language ability and the validity of score-based interpretations will be a perpetual concern for language testers. In terms of ontology, there will always be debates about whether language ability actually exists in the "real world" and, if so, where, while in terms of epistemology researchers will undoubtedly debate approaches to understanding precisely what language ability is (see Bachman,

2006a for a discussion of these issues). Furthermore, as Bachman (2007) has pointed out, the field has seen numerous approaches to defining this construct, and we are not likely to see universal agreement on any particular “model” in the near future. Nevertheless, in terms of practical research and development aimed at providing language assessments that can be justified to stakeholders, language testers will be well advised, in my view, to use these philosophical and theoretical issues more as general guidelines for informing the way the construct of language ability is defined for any particular language assessment and less as scientific theories of language ability that can somehow be verified through research and development. The question of validity, then, is not whether, or to what extent, a given test score can be seen to be an indicator of some abstract theoretical model of language ability, but rather whether score-based interpretations are meaningful and can be justified to stakeholders.

Issues of Ethics and Professionalism in Language Assessment Use

Although validity and validation continue to form a major area of focus in language assessment research (e.g., Bachman, 2005), this is no longer the sole, or even the dominant, concern of the field. Language testers are investigating difficult questions about how and why language assessments are used, about the ethical responsibilities of test developers and users (e.g., Stansfield, 1993; McNamara, 1998, 2001), about fairness in language assessment (e.g., Elder, 1997; Kunnan, 2000a, 2004), about the impact and consequences of assessment use (e.g. Shohamy, 2001), particularly on instructional practice (e.g., Alderson & Wall, 1993, 1996; Cheng, 1997; Wall, 2005), and about the societal values that underlie such use and the larger sociocultural contexts in which language tests are used (e.g., McNamara & Roever, 2006).

Language testers are still debating issues of fairness and professionalism and will no doubt continue to do so for the foreseeable future. And while to some this ongoing debate may reflect a lack of progress and consensus in the field about these critical issues, I view it as healthy for a number of reasons. First, it reflects the intense commitment of language testers to assuring that language assessments are developed professionally and used fairly. Second, it engages language testers with other discourse communities—such as philosophers, who are grappling with ethics—and with other professions—such as medicine and law, which must also deal with issues of professional ethics. Finally, what I find extremely encouraging is that these two strains of research and concern are coming together in a growing body of research that investigates both the validity of score interpretations and the consequences of assessment use (e.g., papers in Kunnan, 2000b; Bachman, 2005; Bachman, 2006b).

Language Assessment for Accountability

The assessment demands of No Child Left Behind (NCLB) in the US (United States Congress, 2001) have greatly increased the pressure on states to develop more useful assessments, both for accountability and in the service of classroom language learning. In neither area, in my view, have language testers been adequately

involved. Of particular concern to language testers and other applied linguists should be issues of assessing the English language development and academic achievement of English language learners (ELLs).

Recent initiatives on the part of the US government to increase that nation's capacity in foreign languages are also placing great demands for useful assessments of foreign languages, particularly the less commonly taught languages (US Department of Education, US Department of State, US Department of Defense, & Office of the Director of National Intelligence, 2006). As increasingly larger amounts of government resources are likely to be going into foreign language instruction in the coming years, at all levels, from federal, state, and local authorities, there will most likely be a concomitant need for greater accountability. In K-12 education an accountability mechanism is already in place, through NCLB; for better or worse, one can expect that, as the federal government invests more heavily in language instruction at this level, an accountability mechanism will be required and that this will necessitate the development of assessments of foreign language proficiency that meet accepted professional standards for validity and impact.

Similar demands for the involvement of individuals with expertise in language assessment can be found in countries around the globe, where governments and institutions are applying increased pressure on language testers to develop language assessments whose results can be meaningfully interpreted on a common scale of language ability. In Europe, for example, governmental policy is driving massive efforts to develop language assessments in all 14 languages of the European Community, as well as requiring that high stakes language assessments be reported on a single scale: the Common European Frame of Reference (Council of Europe, 2001). Similar efforts are being implemented in many other countries, where the need for high stakes accountability assessments is being driven by the demand for individuals with higher levels of language ability (see, for example, the papers in Martyniuk, 2010).

The worldwide demand for high-level users of a wide range of languages is unlikely to diminish in the foreseeable future; this demand will continue to create a need for accountability; and this need, in turn, will inevitably sustain the ongoing need and demand for language assessments. In my view, in their rush to meet the political demands of governments and other institutions for language assessments, language testers in general have not adequately considered the issues of professionalism and fairness discussed above. For example, rather than asking governmental agencies or institutions questions like "*Why* do you want us to report our test results on a common international scale?" or "*How* can we *justify* doing this?," language testers are taking the easy way out and making claims about their assessments that may or may not be justifiable, merely in order to satisfy the political agendas of governments and institutions.

Impact on Instruction

The impact of language assessments on instruction (also referred to as "wash-back") was for many years considered to be relatively straightforward: "good" assessments would cause teachers to follow "good" instructional practice, while "bad" assessments would cause teachers to follow "bad" instructional practice. It

may be implicitly recognized that language tests can have a positive impact on instruction by promoting instructional practices that teachers and educators consider to be appropriate and effective for learning. Nevertheless, much of the discussion around washback (a process also referred to as “backwash”) has focused on the negative effects of assessment on teaching, notably its leading to instructional practices that teachers and educators believe are detrimental to learning, such as the phenomenon of “teaching to the test” and the “narrowing of the curriculum.”

It was not until language-testing researchers rigorously investigated washback empirically that the field began to realize the complexity of this phenomenon. Two large-scale studies, both of which investigated attempts planned by governments in two different countries to engineer changes in English teaching curricula and in instructional practice through changes in public English examinations, were instrumental in demonstrating to the field that washback is neither simple nor straightforward. The first study was Wall and Alderson’s pioneering research into the impact of introducing a change in the English part of the secondary school-leaving examination in Sri Lanka (Alderson & Wall, 1993; Wall & Alderson, 1993). This study revealed that washback works in different ways and to varying degrees on different parts of an educational system—classroom teachers, curriculum developers, and textbook publishers. The second large-scale study of the impact of language assessment was Cheng’s (1997) research into the impact of introducing a test of English language speaking into the secondary school-leaving examination in Hong Kong. Her results supported Wall and Alderson’s findings in general and extended them to demonstrate that both classroom teachers and students differed in their perceptions of reactions to the new examination. Many of the issues raised by the Sri Lankan study were addressed in a special issue of *Language Testing*, guest-edited by Alderson and Wall (Alderson & Wall, 1996). Bailey (1999) provides a review of the research into and conceptualization of washback.

As a result of this research and theorizing, the complexity of washback is much better understood, and the field has a much better conceptual base upon which to continue empirical research into this vital area of language assessment. What language testers might want to consider, in my view, is finding ways in which this understanding can be used to inform policy about the use of language assessments in instruction, particularly about its use to engineer educational reform.

New and Recent Challenges

Several new and recent challenges face the field of language assessment: (1) the role of assessment in language classrooms, (2) training classroom teachers in language assessment, and (3) language assessment for citizenship and naturalization.

Classroom Assessment

If we consider the numbers of individuals around the world who are studying languages in classrooms—between about 1 and 2 billion people

are studying English alone worldwide (Graddol, 1997, 2006)—in conjunction with the finding that teachers spend significant amounts of time assessing their students—subject matter teachers in schools up to 40% and ESL (English as a second language) teachers about 25%—we quickly realize what a huge enterprise and undertaking classroom assessment is.

Nevertheless, language testers have been only marginally involved in issues of classroom assessment in schools and adult education, and this is still not considered “mainstream language testing” by many. In the past decade, however, classroom language assessment has emerged as one of the most exciting and challenging areas in our field. In this short time the field has seen a move from virtually no interest in school-based or classroom assessment to a growing interest and body of research and practice in this area.

Language testers have also become increasingly involved in two areas of classroom assessment: the assessment of young language learners; and the role and function of assessment in the language classroom. Seminal research in the assessment of young learners can be found in two special issues of the journal *Language Testing*, both edited by Rea-Dickins (2000, 2004), and in a special issue of the journal *Language Assessment Quarterly* edited by Brindley (2007).

The role and function of assessment in the language classroom have been discussed from two perspectives: that of formative assessment and that of so-called “dynamic assessment.” *Formative assessment* can be defined broadly as assessment that takes place during instruction and learning and is intended to provide feedback for the improvement of both. It contrasts with *summative assessment*, which typically takes place at the end of instruction and learning and is intended to provide feedback for making decisions about advancement, progress, or certification. Drawing on work on formative assessment in the field of educational measurement (e.g., Black & Wiliam, 1998), a number of language-testing researchers have discussed the tension between high stakes accountability summative assessments on the one hand and teacher-based classroom assessments on the other; and they argue for increased emphasis on teacher-based formative assessment in the language classroom (e.g., Brindley, 1998; Leung, 2004; Leung & Mohan, 2004; Leung & Rea-Dickins, 2007).

Drawing on research in second language acquisition and on Vygotskian psychology, some researchers have discussed what is called “dynamic assessment,” arguing that this form of assessment incorporates what is known about learning in general and language learning in particular and should therefore be the preferred mode of assessment in language classrooms (e.g., Lantolf & Poehner, 2004, 2011). Lantolf and Poehner (2004) further suggest that formative assessment might be reconceptualized within the principles of dynamic assessment.

A slightly different approach to the roles and functions of assessment in the language classroom is proposed by Bachman and Palmer (2010), who describe classroom assessment in terms of features, mode, characteristics, and purpose. They distinguish two modes. The *implicit mode* of assessment is fully integrated with teaching, being characterized as continuous, instantaneous, and cyclical; it is a mode in which the teacher and students are essentially unaware that assessment is taking place. This mode corresponds closely to “dynamic

Table 94.1 Modes of assessment (Bachman & Palmer, 2010, p. 29). © Oxford University Press

<i>Mode</i>	<i>Characteristics</i>	<i>Purpose</i>
Implicit	Continuous	<u>Formative</u> decisions, e.g.:
	Instantaneous	Correct or not correct student's response
	Cyclical	Change form of questioning
	Both teacher and students may be <u>unaware</u> that assessment is taking place	Call on another student Produce a model utterance Request a group response
		<u>Summative</u> decisions, e.g.:
Explicit	Clearly distinct from teaching	Pass/fail decision based partly on classroom participation or performance
	Both teacher and learners aware that assessment is taking place	<u>Summative</u> decisions, e.g.:
		Decide who passes the course Certify level of ability
		<u>Formative</u> decisions, e.g.:
		<i>Teacher:</i> move on to next lesson or review current lesson <i>Teacher:</i> focus more on a specific area of content <i>Student:</i> spend more time on a particular area of language ability <i>Student:</i> use a different learning strategy

assessment." The *explicit mode* of assessment is clearly distinct from teaching; both the teacher and the students being aware that assessment is taking place. The authors argue that both modes of assessment can serve the purposes of both formative and summative decisions. They illustrate these distinctions in Table 94.1.

Training Classroom Teachers in Language Assessment

Although there are dozens of textbooks in both language assessment and educational measurement that claim to be "practical" and written for teachers, it is widely recognized that teachers are generally neither knowledgeable about nor well trained in assessment. And, while courses in language assessment are offered at many colleges and universities around the world, nevertheless, as Brown and Bailey (2008) conclude at the end of their article reporting the results of two surveys of individuals who teach such courses, "there is still much we do not know about how language testing is being taught in language teacher training programs around the world, and how it should be taught" (Brown & Bailey, 2008, p. 373). Furthermore, Leung (2004) points out that assessment is not generally part of the preservice training of language teachers.

What language teachers believe about assessment and what they actually do when they assess in the language classroom have been extensively researched. To date, however, there have been very few studies, in the language-testing literature, about how language teachers are trained in assessment. This is so despite numerous calls, in the language assessment literature, for the need to build teachers' capacity in language assessment. Thus, as Brown and Bailey (2008) note in their

review, most of what is known about teacher knowledge of and training in assessment comes from the field of educational measurement.

Two areas of research and discussion in the literature on training teachers in educational measurement and language assessment are (1) determining what constitutes teachers' assessment knowledge and the degree to which teachers have it and (2) developing and evaluating training programs aimed at helping teachers acquire knowledge of assessment.

Despite the huge demand for teachers who are competent in assessment, and despite calls from the field itself for the need to train teachers in language assessment, the field of language assessment clearly lags far behind its sibling discipline, educational measurement, not only in terms of understanding what language teachers know and need to know about assessment, but also in terms of developing appropriate programs for training classroom teachers in it. Virtually every article in the field that addresses these issues concludes that little is known and more research is needed. Given the huge numbers of language teachers worldwide, addressing these issues will indeed be a daunting challenge for the field.

Language Assessment for Immigration, Citizenship, and Asylum

As Shohamy and McNamara (2009a) point out in their editorial introduction to a special issue of the journal *Language Assessment Quarterly* on the use of language tests for immigration, citizenship, and asylum (hereafter ICA), this relatively recent area of concern and interest among language testing researchers is an outgrowth of the more general concern, discussed above, in professionalism and ethics in language testing. And, while a number of language-testing researchers (e.g., McNamara, 2001; Shohamy, 2001) have been writing about this issue for quite some time, it has only come to the forefront of language testing research in the past half decade. Most of the papers that have been written on this area of concern appeared in 2009, when two volumes, one edited by Hogan-Brun, Mar-Molinero, and Stevenson (2009), and another by Extra, Spotti, and Van Avermaet (2009), along with a special issue of the journal *Language Assessment Quarterly* (Shohamy & McNamara, 2009b), appeared. An excellent review of these three collections can be found in Lee (2011).

Two very general sets of issues have been discussed in the rapidly emerging literature: (1) language ideologies and ideologies of national identity; and (2) the qualities of and justification for specific assessments. A number of researchers have critically analyzed the ICA policies of governments, questioning the language ideologies and ideologies of national identity that underlie them (e.g., Blackledge, 2009) as well as the use of language as a requirement for ICA (e.g., Shohamy, 2009). Others have criticized specific language tests, which are used for ICA, either from the perspective of fairness issues (e.g., Eades, 2009) or from that of the technical qualities of the assessment or both (e.g., Kunnan, 2009). Yet others have argued strongly that both the specific assessment that is being used for ICA and the rationale for it are justified (e.g., de Jong, Lennig, Kerkhoff, & Poelmans, 2009), while others have taken a more neutral, proactive approach.

The consideration of the issues to be faced in developing and using language assessments for ICA raises many of the same now familiar ethical questions about

the role and position of language testers in developing assessment that could be used for purposes they themselves may either question or disagree with. Many of these questions are raised by Shohamy and McNamara (2009a, 2009b). To what extent should, or can, language testers themselves become involved in the setting and implementation of public policy? To what extent, and how, can language testers best apply their knowledge and skills to developing language assessments that can be justified for ICA? Addressing these issues will clearly be a challenge for the field.

Justifying the Uses of Language Assessments

Given all these different uses of language assessment, and given the fact that many of them are high stakes—that is, involve making decisions that have major, life-affecting consequences for test takers and other groups of stakeholders—the critical question faced by language testers is: To what extent can we justify the uses for which our assessments are intended? To what extent do our assessments, the uses to which they are put, and the consequences of these uses respect the individual rights and the societal and educational values of those who are affected by these uses and their consequences? As the demands for language assessments have increased and have become even more diverse, there is a growing demand for language testers themselves to be accountable to stakeholders—those who are affected by the uses of language assessments and by the decisions made on the basis of these assessments.

Assessment Justification

Starting from the premise that test developers and decision makers need to be accountable to stakeholders—those individuals who, or those programs or institutions that, will be affected by the uses of the tests—Bachman and Palmer (2010) describe *assessment justification* as the process of providing a rationale and evidence to justify the use of a particular assessment.

Assessment justification includes both a rationale for the assessment and evidence to support this rationale. At the heart of assessment justification is what they call an “assessment use argument” (AUA). Drawing on argument-based approaches to validity in educational measurement (e.g., Kane, 2001; Mislevy, Steinberg, & Almond, 2002), Bachman and Palmer (2010) describe an AUA as a conceptual framework for linking inferences from assessment performance to interpretation and use. An AUA explicitly states the interpretations and decisions that are to be based on assessment performance, as well as the consequences of using an assessment and of the decisions that are made. Bachman and Palmer argue that an AUA provides an overarching inferential framework to guide the design and development of language assessments and the interpretation and use of language assessment results. An AUA consists of a series of claims that can be illustrated as in Figure 94.1.

The arrows between the rectangles go both ways to illustrate that the claims, which may also be stated as questions, serve as a guide both for test development

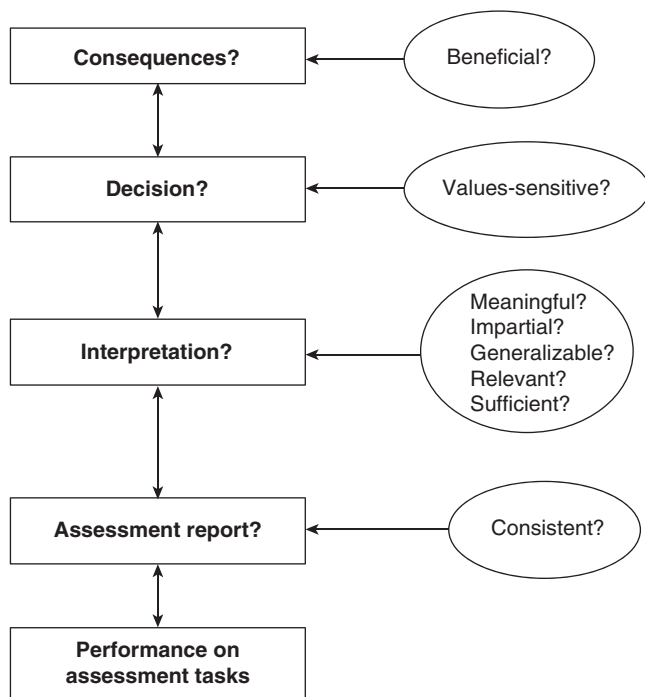

Figure 94.1 Assessment use argument (after Bachman & Palmer, 2010, p. 104) © Oxford University Press

and for the interpretation and use of assessment results. In using an AUA for designing and developing an assessment, the developer would first ask what the consequences of using the assessment might be and to what extent they would be *beneficial* to stakeholders. Then she would consider the decisions to be made and whether these are *sensitive* to existing societal values¹ and *equitable* toward different groups of stakeholders. Then she would consider the interpretations that are needed to make the intended decisions and the extent to which these interpretations will be *meaningful* with respect to a general theory of language ability, a needs or task analysis of a language use setting, or a particular learning syllabus: *impartial* to all groups of test takers; *generalizable* to the intended target language use domain; *relevant* to the decision to be made; and *sufficient* for the decision to be made. Finally the test developer would consider how to assure stakeholders that the assessment results (i.e., scores or descriptions) are *consistent* across different aspects of the measurement procedure (e.g., items, tasks, raters, forms).

In interpreting test takers' performance on an assessment, the assessment user would consider the inferences that are based on this performance. She would consider the consistency of the assessment report, the meaningfulness, impartiality, generalizability, relevance, and sufficiency of the interpretation, the values-sensitivity and impartiality of the decisions, and the beneficence of the consequences.

While the claims of an AUA constitute the conceptualization that is needed either to design an assessment or to interpret and use the results of an assessment, these claims need to be supported in order to justify using the assessment for a particular purpose. This support is provided in the form of warrants, which are propositions we use to justify the inference from one claim to the next (Bachman, 2005, p. 10). A warrant to support an inference from a score to an interpretation, for example, might be that the ratings derived from observing test takers' performance are consistent both across different raters and across multiple ratings by the same rater. Warrants supporting an inference from an interpretation to a decision might consist, for example, of the following:

- relevant legal requirements and existing community values are carefully considered in the decisions that are made (values-sensitivity warrant);
- stakeholders who are at equivalent levels on the construct to be assessed, as indicated by the interpretations of their assessment reports, have equivalent chances of being classified in the same group (equitability warrant).

Warrants, in turn, must be supported by backing, which comprises evidence from empirical research, documentation, regulations, laws, and community or societal values. The backing for the consistency of ratings, for example, might include classical inter- and intra-rater reliability estimates or variance components and dependability estimates from a generalizability study. The backing for the warrants of values and equitability, for example, might consist of:

- laws, regulations, policy, surveys of and focus group meetings with stakeholders;
- decision rules described in the assessment specifications; standard-setting procedures for setting cut scores; studies of the relationship between assessment performance and classification decisions.

Since it is the use of a *specific* assessment that needs to be justified, assessment justification is inherently a local process. Thus the AUA for a particular assessment provides a "local theory" that makes explicit claims about the roles of consequences, decisions, interpretations, and assessment reports in the assessment and identifies the evidence that needs to be collected to support these claims. The purpose of an AUA is thus *not* to falsify some general theory of language ability or a particular approach to designing language tests. Rather the purpose is to provide for, and to support empirically, a coherent argument capable of convincing the stakeholders that using the assessment will help promote the intended beneficial consequences.

The AUA also identifies appropriate methodologies for collecting evidence and thus embraces a multiplicity of methodological approaches, both "quantitative" and "qualitative."

Bachman and Palmer argue that the process of assessment justification, including the articulation of an assessment use argument, offers a conceptual framework for guiding both the development and the use of language assessments. It is this process that enables test developers and decision makers to be held accountable for the uses for which the assessments are intended. The authors further argue

that the process is applicable to a wide range of situations, from large-scale standardized tests to classroom assessments, and to a wide variety of purposes, from high stakes summative decisions about certification, entrance, and selection to low stakes formative decisions about improving teaching and learning.

Conclusion

The immediate and the long-term prospects for language testing (considered as a field) are filled with opportunities and challenges. I believe that the greatest challenges language assessment as a field faces are *not* in the cerebral spheres of validity theory, sociopsychological theory, postmodern critical social theory, or moral philosophy. Nor are they to be found in sophisticated statistical and measurement models or in ever refined approaches to naturalistic observation. Rather the challenges that we, as language testers, face are in the “real-world” arenas where language tests are being used to make decisions about individuals and institutions.

Turning these challenges into accomplishments will depend upon the willingness and capability of language testers to apply the knowledge and skills acquired over the past half century to the urgent practical assessment needs of our education system—from kindergarten to university and adult school—and of our society. It will also depend upon our willingness to leave the comfortable confines of the academy and join our colleagues in education and measurement to toil in the fields of practice. I believe that language testers have a unique combination of knowledge and skills, as well as a growing understanding of the issues involved in addressing the validity of interpretations and the consequences of test use. If we can but apply this expertise to the practical problems of assessment in our education systems and in our society, we are in a position to provide leadership and to contribute greatly to making our meritocracy fair and equitable.

Note

- 1 One of the thrusts of critical applied linguistics, as well as so-called “critical language testing” is that existing community values may themselves be inequitable and hence need to be constantly scrutinized, particularly by those who will be affected by the decisions that are made.

English as a Lingua Franca

Jennifer Jenkins

University of Southampton, England

Constant Leung

King's College London, England

Introduction: The Changing Global Role of English

During the past few decades, largely as a result of its position as the main language of globalization, English has undergone a major demographic transformation. Up until then, it was spoken primarily as a native language in the Anglophone countries, and as a nativized language in the postcolonial countries, as well as being learned as a foreign language (i.e., for communication between native and non-native speakers) in many other parts of the world. Nowadays, however, its most extensive use is as a lingua franca among speakers from different first languages, particularly, but not exclusively, non-native English speakers from countries with no history of British colonization.

A substantial body of empirical research into English as a lingua franca (henceforth ELF) conducted over the past 20 years or so has identified a number of linguistic features that differ from native English. More recent research has demonstrated that ELF is also characterized by extensive contingent variability, with speakers accommodating their language to an extent not found in other language use in order to make it appropriate to the diverse interlocutors engaged in the interaction in hand. ELF thus presents a twofold problem for English language teaching and testing. First, the prolific global growth in ELF use, which is predicted to continue for several decades (e.g., Graddol, 2006), calls into question the prioritizing of standard native English grammatical and pragmatic norms in evaluating the competence of the majority of non-native learners. For, as Tomlinson (2010, p. 299) points out, these norms represent a kind of English that they “do not and never will speak.” Second, ELF’s inherent variability implies not only that language yardsticks need to be updated, but also that new approaches to language modeling and norming in assessment are needed if we are to be able to judge whether ELF users’ English is fit for purpose. In the discussion that follows,

“assessment” will be used as a superordinate term, and the narrower term “testing” will be used where appropriate.

In the next section, we consider a high stakes language assessment framework, the Common European Framework of Reference for Languages (CEFR), and a sample of tests that are widely used around the world: International English Language Testing System (IELTS), Test of English as a Foreign Language (TOEFL), Test of English for International Communication (TOEIC), and the more recent Pearson Test of English (PTE) and PTE (Academic). In the third section we turn to ELF, report some of the key findings of empirical ELF research, and consider what these findings imply for conceptualizations of English. We go on in the fourth section to explore the implications of ELF for the testing of English, and, in the final section, to consider the challenges involved in, and possible future directions for, (research into) the assessment of English if it is to embrace ELF.

Current Approaches to Testing English

We start with the Common European Framework of Reference for Languages. Although, as its name suggests, the CEFR was originally devised for the teaching and assessment of second or foreign learners’ proficiency in European languages, it has been widely adopted and “is being used as a crucial reference point . . . well beyond Europe: for example in North and South America, Australia and Asia” (McNamara, 2011, p. 5). Indeed, Cambridge ESOL, whose suite of exams is aligned to the CEFR, describe it as an “internationally recognised framework” (www.cambridgeesol.org). According to the CEFR, candidates are assessed on a range of skills against six levels, from A1 (the lowest), through A2, B1, B2, and C1, to C2 (the highest), according to the degree of linguistic complexity involved at each level. In each case, the descriptors for the six levels are identical regardless of the specific language being tested, while the wording of the descriptors for the highest level implies that ultimate achievement in the CEFR corresponds to native-like proficiency in the respective language. For example, on the “C2—Overall” scale, the candidate “can express him/herself spontaneously, very fluently and precisely, differentiating finer shades of meaning even in more complex situations” (Council of Europe, 2001, p. 24). In terms of the “qualitative aspects of spoken language use,” at C2 the candidate’s range includes “a good command of idiomatic expressions and colloquialisms” (p. 28). As regards listening skill, the C2 candidate has “no difficulty in understanding any kind of spoken language, whether live or broadcast, delivered at fast native speed” (p. 66).

While the CEFR is intended as a proficiency framework for languages in Europe including English, the tests we will now consider are specific to English. The newest of these is the Pearson Test of English (Academic), which is becoming widely used to assess suitability for study in English-medium higher education, primarily but not exclusively in mother tongue English countries. This is how a Pearson representative describes the way in which the test was designed:

To create an international exam we started by hiring item writers from the UK, the US and Australia . . . Because we are not using a single standard model of English

we can grade all non-native students on a single scale. The first thing we look for is comprehensibility—are they understandable to the native speaker? (*EL Gazette*, September 2008, p. 10, quoted in Jenkins, 2008)

The “international” nature of the PTE presumably resides in the fact that it draws on a range of native English varieties (rather than only one native variety), and that it is concerned with non-native speakers’ intelligibility to native speakers of all these varieties (rather than only with, say, native speakers of British English). We will return to this issue.

We turn now to another test frequently used to evaluate suitability for English-medium study in higher education, the International English Language Testing System, owned and run jointly by the British Council and Cambridge ESOL in the UK, and IDP (International Development Program) Education in Australia. IELTS state on their Web site (www.ielts.org) that theirs is “the world’s most popular high stakes English language test” and that “over 1.4 million candidates take the test each year to start their journeys into international education and employment.” Like the PTE, this test assesses candidates in terms of the proximity of their academic English skills to those of native English speakers.

The same is true of other tests that claim “international” currency and that are used for university entry, including TOEFL and TOEIC. TOEFL’s name makes clear that it is testing “EFL” (i.e., by definition with native English as the target). However, its Web site (www.ets.org/toefl) states that it is “the most widely respected English-language test in the world,” implying that it sees itself as international. TOEIC, on the other hand, actually includes the word “international” in its name. These two tests are run under the auspices of ETS (Educational Testing Service), which is based in the USA, and which claims on its Web site (www.ets.org) to be “the world’s premier educational testing organization.” Its assessment director, Trina Duke, gave a talk on TOEIC with the title “Assessment of English as an International Language,” at the 4th International ELF Conference in Hong Kong (May 2011). In her talk she pointed out that TOEIC accepts non-native English-speaking raters provided that they first pass an English language test, but added (when asked) that native speakers are not required to take any such test, only to demonstrate that they are “comfortable” with English. Evidently, TOEIC, like the other tests discussed above, is “international” in the sense of being *used* (marketed and administered) internationally rather than in the sense of reflecting international *use* (the diverse ways in which English is used internationally).

Of course the largely native speaker-oriented perspective adopted by the large international English language-testing organizations represents just one view, albeit a very powerful one. Some test developers and researchers have explored other approaches. For instance, Brown and Lumley (1998, p. 94) developed a test of English proficiency for teachers of English in Indonesia in which “the native speaker was not set as the ‘ideal’”; they consciously tried to incorporate appropriate local cultural content and English language usage (also see Hill, 1996, for a discussion on the case for using local non-English native speaker raters). There has also been research into shared first language advantages in language testing, for example Harding (2012) investigates whether test takers from a particular first language background gain advantage when listening to English passages

delivered in their own accents (e.g., Japanese test takers listening to Japanese-accented English passages). These are interesting efforts designed to move beyond the confines of English native speakerdom in language testing. However, the use of ELF involves speakers from diverse linguacultural backgrounds. They are not necessarily oriented towards a particular variety of English (native or otherwise); they use ELF to communicate with one another, to get things done, and to socialize. Therefore the language assessment issues raised by ELF transcend questions of proficiency conceptualized in terms of a stable variety; they are concerned with what counts as effective and successful communication outcomes through the use of English that can include emergent and innovative forms of language and pragmatic meaning (also see Chapter 81, Spoken Discourse).

In the next section we explore ELF research and its implications for the way we conceptualize the English language in its global contexts. We then return in the fourth section to the testing of English, in order to consider the issues that ELF raises for the kinds of tests discussed above.

ELF Studies and Their Implications for Conceptualizations of English

The earliest empirical ELF research was that of Jenkins, who in the late 1980s began exploring the ways in which non-native English interlocutors from different first languages adjusted their pronunciation in order to render their speech more mutually intelligible.¹

She found accommodation at the phonological level to be a crucial aspect of ELF communication, while also identifying a “lingua franca core” of target features that contribute to mutual intelligibility, along with a larger “non-core” in which speakers can “safely” replace a target item with their preferred (often first language-influenced) variant (see Jenkins, 2000).

The next major development was Seidlhofer’s (2001) call for corpus descriptions of ELF communication. Practicing what she preached, Seidlhofer set up VOICE (the Vienna-Oxford International Corpus of English, www.univie.ac.at/voice) in 2001. It now numbers over a million words, all meticulously transcribed, many with speech files, and available online for free download. As a result of the wealth of new empirical evidence available in VOICE, Seidlhofer and her team were soon able to identify a number of lexicogrammatical ELF features that differ from native English use and are communicatively effective in ELF communication. These features include the use of count nouns where they are uncountable in native English (e.g., *informations*), zero marking of the third person present tense *-s*, and the use of an all-purpose tag question such as *isn’t it?* or *no?* (Seidlhofer, 2004). Seidlhofer presented these features as a set of hypotheses rather than as definitive ELF features, but they have nevertheless proved remarkably durable, being repeatedly identified in subsequent empirical ELF studies (e.g., Dewey, 2007), and thus likely to indicate language change in progress among ELF users.

Soon after VOICE had been launched, Mauranen established the ELFA corpus (English as a Lingua Franca in Academic Settings, www.helsinki.fi/englanti/elfa/elfacorpus) (see Mauranen, 2003) which focused, as its name suggests, on one particular—and highly prevalent—global context of ELF use, higher education.

Like the VOICE researchers, Mauranen and her ELFA team have since identified a number of lexicogrammatical features that differ from native English use. These include some of the features that have been identified in more general ELF corpus studies, as well as others that appear to be specific to academic settings. An example of the latter is the extending of an attention-catching function to the progressive involving its use where native speakers would typically use a stative verb, e.g., *are belonging* rather than *belong* (Ranta, 2006).

Another major branch of ELF research is pragmatics. Some of the pragmatics research focuses on miscommunication, particularly the preempting, negotiation, and resolution of nonunderstanding by means of various kinds of accommodation strategies. This research has tended to find that miscommunication is less frequent than in traditional EFL communication, and that when it occurs, it is dealt with discreetly in ways that do not interrupt the flow of conversation (Pitzl, 2005) by strategies such as repetition, clarification, and paraphrasing.

Studies of ELF pragmatics also focus on the ways in which speakers exploit their plurilingual resources, particularly by means of code switching. For example, Cogo (in Cogo & Dewey, 2006, p. 68) demonstrates how a French speaker uses the French expression *fleur bleue* for the English idiom *cheesy* in order to signal his cultural identity rather than to explain the meaning of *cheesy* to his German and Italian interlocutors. Other studies demonstrate how ELF speakers code switch into the languages of their interlocutors in order both to signal their plurilingual identity and to promote solidarity. These kinds of code switching enrich communication and have nothing to do with the lexical gaps that are so frequently cited in the traditional EFL literature as the prime motivation for code switching.

More recently, in line with the increasing availability of ELF data, there has been a growing realization that, despite the observed regularities in ELF forms, ELF communication is inherently more fluid, flexible, dynamic, and ad hoc than traditional language varieties used by traditional speech communities. As a result, the focus of research has shifted from features to the underlying processes that motivate their use and, in turn, to the need for new conceptualizations of language. For, as Seidlhofer (2009, p. 238) points out, the terms “language variety” and “speech community” are “still used in the same way as they were long before the days of mass international travel, let alone electronic communication”; and “at a time of pervasive and widespread global communication, the notion of community based purely on frequent face-to-face contact among people living in close proximity to each other clearly does not hold any more.” Or, to put it another way, ELF “is a use- and context-driven phenomenon not primarily tied to any particular ethnic or racial group, nation, or geographic space” (Leung & Lewkowicz, 2006, p. 229). The (teaching and) testing of English therefore needs to reflect this reality if it is to be relevant to the ways in which the majority of non-native English learners will use the language in their future lives. Let us now consider how testing currently measures up.

The Implications of ELF for Testing English

The tests we described above (second section) all claim international status. This, we argued, relates to their international spread as well as to the use of test

developers from a range of native English countries in the case of the PTE, and the use of non-native raters (provided they first pass a test) in the case of TOEIC. On the other hand, their interpretation of “internationalness” reflects a particular set of values and perspectives. For instance, the tests are all predicated on the notion of “foreign language,” according to which the learner and, therefore, test candidate is assumed to be learning the language in order to communicate with its native speakers, often for occupational or academic purposes. Consequently, the ultimate goal of learning is seen as a standard native variety of the target language. Any differences in forms from those that would be used by the notional native speaker of a standard variety of the language are thus regarded as learner errors in need of remediation.

Seidlhofer (2011, p. 18) sums up the characteristics of English as a foreign language (EFL) as follows: its linguacultural forms are “pre-existing, reaffirmed,” its objectives are “integration” and “membership in [a native speaker] . . . community,” and the processes involved in its learning are “imitation” and “adoption.” She contrasts these characteristics with those of an ELF perspective, whose linguacultural forms are “ad hoc” and “negotiated,” whose objectives are “intelligibility” and “communication in [a non-native speaker] . . . or mixed [non-native speaker–native speaker] . . . community,” and whose processes involve “accommodation” and “adaptation.” From this perspective, differences from native English forms are not automatically errors. More importantly, those forms that according to traditional approaches are said to have fossilized may, by contrast, be considered evidence of English language change in progress. Indeed, Widdowson (2011) argues that from an ELF perspective “it is the [traditional] norms that are the fossils.”

Despite claims to the contrary (e.g., Elder & Harding, 2008, argue that intercultural skills are already addressed in testing; Taylor, 2002, states that Cambridge ESOL “has been grappling with these issues for some time”), up to now, it is almost exclusively those scholars working with a critical perspective who have engaged with ELF (see, for example, Lowenberg 2002; Canagarajah, 2006; Leung & Lewkowitz, 2006; McNamara, 2009, 2011). Others seem to consider themselves to take a “liberal” approach in relation to ELF, but turn out, on closer inspection, to largely regard ELF as a surface level phenomenon, or to fall back on the established certainties in psychometrically oriented language testing that have been built up in the past 40 years or so (e.g., Elder & Davies, 2006; Taylor, 2006; Elder & Harding, 2008). This is implicit, for example, in Taylor’s (2006) response to an article by Jenkins (2006a) on the implications of ELF for testing. Instead of engaging seriously with Jenkins’s points about the changing global demographic of English and the contemporary importance of successful accommodation skills over narrow versions of “correctness,” Taylor presents Cambridge ESOL’s standard response and argues, for instance, that tests of standard native English fulfil test takers’ and users’ expectations, and implies that an ELF approach patronizes learners and teachers (see Jenkins, 2006b). Others suggest that those scholars arguing for an ELF orientation to testing are politically motivated “bleeding hearts.” In this respect, Canagarajah (2006, p. 241) argues that “debates in English-language testing should not be conducted with the condescending attitude that we scholars are just trying to be kind to those non-native speakers outside the inner circle.”

Current tests of English, then, continue to focus narrowly on native English norms, while no substantial adjustments have been made to the basic assumptions of what English is. Decisions of momentous importance in people's lives are thus taken on the basis of their ability to pass tests such as IELTS and TOEIC which are grounded in kinds of English that are often insufficient and inadequate in relation to their situated language practices (Leung & Lewkowicz, 2012). Even when students are hoping to study in universities in native English-speaking countries, the communities they will circulate in are largely lingua franca groups made up of other students from a range of first language backgrounds. These days, even many of their lecturers are not native English speakers. Universities in the UK and USA that like to call themselves "international" need, therefore, to think more carefully about the linguistic implications of their proclaimed international status, including whether their *native* English-speaking staff and students would benefit from developing greater intercultural language skills for use on campus and beyond (see Jenkins, 2013).

Many of these issues have not been given sufficient attention in language assessment research. An exception, however, is the work of Kim, a doctorate currently being completed at the University of Melbourne. Kim is investigating attitudes within the Korean aviation industry to the English language-testing policy of the International Civil Aviation Organization (ICAO). At present, her findings are only available in short articles (e.g., Kim & Elder, 2009) or in secondary sources (e.g., McNamara, 2011). Nevertheless, they already indicate that a substantial amount of miscommunication between pilots and air traffic controllers is not the fault of the non-native English speaker but arises from the native English-speakers' inability to accommodate to their ELF interlocutors, that the test is insufficiently oriented to the international (i.e., ELF) community for whom it is designed because of its privileging of native English norms, and that native English speaking pilots need to be trained and tested in ELF communication. This study has much to offer others researching English language testing, and it is to be hoped that they will follow its example.

From an ELF standpoint, a fundamental problem with second language assessment is that the basis of its language modeling and norming has failed to keep in touch with contemporary developments in English. At a very broad theoretical level, the second language assessment community tends to regard the notion of communicative competence as the bedrock of their paradigm (e.g., Bachman, 1990). Assessment frameworks such as the CEFR and tests such as IELTS and TOEFL all claim such affiliation. This concept, as first elaborated by Hymes some 40 years ago (1972), suggests that competence in language use is more than just having a knowledge of lexicogrammar and abstracted pragmatic conventions; it also involves the use of such knowledge with reference to social purposes in actual contexts of communication. According to this Hymesian view, communicative competence should be empirically derived—that is, what counts as effective communication should be based on observations of what people actually say and do. The Hymesian ethnographic impulse will continue to serve us well in future for as long as we pay close-up attention to the ways in which users of English in multiethnic and transcultural interactions make use of its lexicogrammatical (and other semiotic) resources to serve their pragmatic real-life

purposes. In a world where this kind of lingua franca use of English is fast becoming the default scenario, language assessment has no alternative but to return to its empirical roots.

Implementing ELF Assessment: Challenges and Possible Future Directions

Apart from the harmful impact that current language-testing ideology has on candidates and their life chances, it also has a negative impact on the English language itself. As McNamara (2011, p. 1) points out, the testing status quo “makes us less able to respond to . . . the fact that communication in the globalized workplace takes place using English as a lingua franca.” The washback effect, then, is that testing promotes an outdated view of communication in English as relatively fixed and native-normative, whereas a major result of the globalization of English is that the language in its global contexts has become relatively fluid, flexible, contingent, and often non-native-influenced. Testing is therefore preventing learners from exploiting the potential of the English language and their own resources as multilingual English speakers, and thus holding up English language change.

The challenge for English language testers, then, is to move away from their narrow focus on native-like correctness. Instead, they need to start taking proper account of the global sociolinguistic reality that is ELF, and to find effective ways of testing the receptive and productive skills relevant to that reality. While we understand their argument that ELF is not yet sufficiently described to be able to use it as the basis for testing English, we do not condone it. ELF researchers have for several years pointed out that testers could, for example, refrain from penalizing the use of forms that are emerging as potential ELF variants, reward the successful use of accommodation strategies even where the result would be an error in native English, and penalize the use of forms that are not mutually intelligible in ELF, such as native English idioms (Jenkins, 2006a). But more than this: now that there is clear evidence of the extent of ELF’s fluidity and flexibility, testers need to devise new approaches altogether to assessing English, so that, as we argued in our introduction, they can assess whether ELF users’ English is fit for ELF use, and the extent to which contingent uses of ELF in context have facilitated communication. It is to this end, we believe, that they should now be directing their main English-related research effort.

McNamara (2011, p. 8) contends that “we are at a moment of very significant change, the sort of change that only comes along once in a generation or longer—the challenge that is emerging in our developing understanding of what is involved in ELF communication.” He goes on to argue that the effect of this change on language testing will be comparable with that of the “communicative revolution.” Just as the “communicative revolution” posed questions that ultimately increased our understanding of what counts as socially appropriate language repertoires and conventions of use (from particular speaker community standpoints), ELF research is pointing to the need to better understand what communication may comprise in terms of participant-driven uses of English as a linguistic resource in

contemporary conditions. Researchers in language assessment, with their well-established know-how, can make an important contribution to this hugely challenging task.

SEE ALSO: Chapter 81, Spoken Discourse

Note

- 1 Space constraints inevitably mean that our account of the vast amount of ELF research that has been conducted, particularly over the past decade, is somewhat truncated. A fuller account of the key studies and findings is available in a recent state-of-the-art article on developments in ELF research (Jenkins, Cogo, & Dewey 2011).

Assessing English in Australia and New Zealand

Kathryn Hill

University of Melbourne, Australia

Rosemary Erlam

University of Auckland, New Zealand

Introduction

Australia and New Zealand share many similarities in addition to geographical proximity. In particular, both countries share a history of English colonization and monolingualism. However, in recent decades the two countries have experienced a significant increase in migration from non-English-speaking background (NESB) countries resulting in an increasing demand for English as a second language (ESL) assessment and reporting tools. Beginning with Australia, this chapter attempts to provide an overview of ESL or English as a foreign language (EFL) assessment in the respective countries in relation to immigration and settlement, education, and professional accreditation respectively. Brief descriptions of the relevant assessment procedures as well as references to associated research are provided as appropriate.

Australia

Immigration and Settlement

This section describes the ESL assessment procedures used for immigration visa applications (screening) and for English language support programs (settlement) for recent immigrants to Australia.

Immigration English language requirements for migration to Australia only apply to applications made under the skilled migration category, or “stream,” where applicants hold qualifications in an occupation listed as “in demand” (Australian Government Department of Immigration and Citizenship, *n.d.a*). For

this stream applicants need to score a minimum of 65 migration “points,” based on a combination of experience, qualifications, and age in addition to English language proficiency. In 2011 the *threshold* English language requirement for these applicants was increased to “competent” English, defined as an average score of 6.0 on the International English Language Testing System (IELTS) (IELTS, *n.d.*). Citizens of the United Kingdom, Canada, New Zealand, the United States of America, or the Republic of Ireland are exempted from this threshold requirement. However, in order to claim *additional* points for English language ability all applicants, regardless of origin, need to provide evidence of “proficient” (IELTS 7.0) or “superior” (IELTS 8.0) English language ability.

At present the only tests approved for immigration purposes are the academic module of IELTS and the Occupational English Test (OET) (for overseas-trained health professionals only) (Occupational English Test, *n.d.*). However, consideration is currently being given to additional tests recently approved for student visa applications, namely the Test of English as a Foreign Language (TOEFL) (ETS) (TOEFL, *n.d.*), the Pearson Test of English Academic (PTE) (Pearson Test of English Academic, *n.d.*) and the Cambridge English: Advanced test (Certificate in Advanced English; CAE) (Cambridge ESOL, *n.d.*). See McNamara (2009) for a discussion of the history of language testing in Australian immigration policy.

Settlement Close to 170,000 migration visas were granted in the year 2010/11, with significant increases in arrivals from China (29,547) and India (21,678) respectively. In addition, almost 9,000 humanitarian visas were granted, with the majority of recipients originating from NESB countries in Asia, Africa, and the Middle East (Australian Government, 2011). To assist with settlement the Adult Migrant Education Program (AMEP) provides up to 510 hours of free English language tuition to eligible migrants in over 250 locations (Australian Government Department of Immigration and Citizenship, *n.d.b.*)

The AMEP curriculum is based on the Certificates in Spoken and Written English (CSWE), which are offered at five levels, from “absolute beginner” (Level 0) to “advanced” (Level 5) (AMEP Research Centre, *n.d.*). The International Second Language Proficiency Ratings (ISLPR) is used for initial placement into the CSWE course. The ISLPR assesses speaking, listening, reading, and writing in a one-to-one interview and takes approximately two hours to complete. Results for each component are reported using a nine-point scale (ISLPR, *n.d.*).

Achievement on the CSWE is assessed using a bank of moderated assessment tasks (Slatyer, 2003). On completion of the CSWE graduates receive a “certificate” or “statement of attainment.” These can be mapped onto the Australian Core Skills Framework (ACSF) (Department of Education, Employment and Workplace Relations, 2008), which aims to provide a nationally consistent mechanism for reporting outcomes in adult English language, literacy, and numeracy programs (Australian Government, *n.d.a.*)

Education

This section provides an overview of the ESL assessment procedures currently approved for international student visa applications as well as those used for

Table 96.1 Scores for Level 3 and 4 applicants

	<i>Vocational courses</i>	<i>University courses</i>
IELTS	5.5	6.0
TOEFL iBT	46	60
PTE Academic	42	50
CAE	47	52
OET	Pass	Pass
TOEFL PBT	527	550

“domestic” NESB students in tertiary, vocational, and school education respectively.

Student Visas IELTS, TOEFL, PTE (Academic), and CAE are all accepted for student visa purposes. However, test score requirements vary according to the applicant’s assessment level (based on an estimated “immigration risk” for citizens of that origin) and education sector (ELICOS, vocational, tertiary). The scores required for Level 3 (e.g., applicants from Iran) and Level 4 (e.g., applicants from India) for vocational, or nonaward, and university courses have been provided in Table 96.1 as an example.

English language entry requirements for the school sector are as accepted by the educational institution (Australian Government Department of Immigration and Citizenship, *n.d.c*).

Tertiary Education

Admission: IELTS, TOEFL, and PTE are the most commonly accepted tests for university admission in Australia although the specified requirements vary slightly across institutions, disciplines, and course levels (e.g., undergraduate vs. graduate courses). For example, the Australian National University requires a minimum IELTS 7 (with at least 6 in each component), TOEFL 570 (paper-based), or PTE (Academic) 64 (with a minimum score of 55 in each section) for “regular” courses and a minimum IELTS 7 (with at least 7 in writing), TOEFL 600 (paper-based), or PTE (Academic) 70 (with a minimum score of 60 in each section) for undergraduate law and medicine. As this example demonstrates, the English language level required for admission to university-level courses is typically higher than those required for international student entry visas.

Diagnostic Assessment: An increasing number of Australian universities have introduced post-entry diagnostic English assessment procedures. For example, undergraduate students at the University of Melbourne scoring less than 7.0 on IELTS, less than 100 on TOEFL (IBT), or the minimum score in an approved high school English test (e.g., ESL in the Victorian Certificate of Education), are required to take the Diagnostic English Language Assessment (DELA) at the time of enrollment. DELA comprises tests in academic reading, writing, and listening and takes approximately two hours to complete. In addition to their test scores, candidates may receive recommendations for additional language support (in the form of credit-bearing or noncredit courses) (University of

Melbourne, *n.d.*). For publications relating to DELA or the associated program in New Zealand, Diagnostic English Language Needs Assessment (DELNA), see University of Melbourne Language Testing Research Centre (*n.d.*).

Vocational Education The Language, Literacy and Numeracy Program (LLNP) provides up to 800 hours of language, literacy, and numeracy training to Australian residents identified as having difficulties finding employment due to poor literacy skills or inadequate English language ability. The Initial Language stream is solely for NESB clients while the Basic and Advanced Language or Literacy/Numeracy streams accommodate both language and literacy and numeracy clients. Pre- and post-training assessments are reported on the Australian Core Skills Framework (ACSF) based on a combination of competency and skill assessments, observation, interviews, and evidence of prior learning (Australian Government, *n.d.b.*).

School Education

Admission: Generally speaking, international students do not require evidence of English language proficiency for enrollment in Australian government schools. However, the Australian Education Assessment Services (AEAS) test is used by over 200 independent (or “private”) schools for selection purposes and by government schools in New South Wales, Victoria, and Queensland for diagnostic purposes. It comprises mathematical reasoning and nonverbal general ability as well as English language tests for Years 4 to 6, 7 to 9, and 10 to 12 respectively. The English language tests (developed by the Language Testing Research Centre, University of Melbourne) comprise spelling (Years 4 to 9 only), vocabulary, reading, writing, listening, and speaking tests (AEAS, *n.d.*). Depending on their scores, applicants may be required to undertake additional English tuition prior to commencing their studies.

Diagnostic Assessment: The National Assessment Program—Literacy and Numeracy (NAPLAN) was introduced in Australian schools in 2008. Every year, all students in Years 3, 5, 7, and 9 are assessed on the same day using national tests. NESB students who have been resident in Australia for less than a year before the test date may be exempted. The tests cover reading, writing, language conventions (spelling, grammar, and punctuation), and numeracy (NAPLAN, *n.d.*). Test design for the language components is informed by the Ministerial Council for Education, Early Childhood Development and Youth Affairs national Statements of Learning for English (MCEECDYA, 2005). Individual results are reported against the national average and the middle 60% of students.

Assessment of Achievement: In the compulsory years of education (K-10) English language assessment is wholly school based and governed by the curriculum and standards frameworks operating in each state and territory. Details of the English as a second language companion to the Victorian Essential Learning Standards (VELS), for example, can be found at Victorian Essential Learning Standards (*n.d.*).

English (e.g., English/ESL, English literature or English language) is a compulsory component of senior high school certificates in most states and territories.

Students are eligible to enroll in an ESL subject if their first language is not English, they have been resident in Australia for less than five years (or seven years in Victoria and Western Australia), and English has not been the main language of instruction for more than five (or seven) years prior to the start of the year in which the subject is to be taken. Information about the Victorian Certificate of English/ESL can be found at Victorian Curriculum Assessment Authority (*n.d.*).

Professional Accreditation

This section focuses on ESL assessment for professional accreditation using the example of overseas-trained health professionals and teachers. In both cases exemptions may be granted to applicants who have undertaken their secondary school education and pre-service training, or both, in Australia or another predominantly English-speaking country (New Zealand, Canada, Republic of Ireland, South Africa, United Kingdom, and United States of America), or who have significant relevant work experience in one of these countries.

Teachers English language testing is required for teachers who have not completed their training in Australia or another English-speaking country. All Australian states and territories accept one or more of IELTS (academic module), the Professional English Assessment for Teachers (PEAT) (University of New South Wales, *n.d.*), and the ISLPR (Version for Teachers). The relevant score requirements for each test are provided in Table 96.2.

Overseas-Trained Health Professionals Despite recent efforts to increase the number of medical courses and government-funded student places, Australia is still heavily reliant on the importation of overseas-trained health professionals from a diverse range of backgrounds. Many of these are already working on restricted temporary resident visas and English language assessment is only required for applicants seeking formal recognition of their qualifications in Australia. With some minor variations across specialties, overseas-trained health professionals currently require a minimum score of 7.0 on IELTS (academic module) or B on the OET. The English language requirements can also be satisfied through successful completion of either the Professional and Linguistics Assessments Board (PLAB)

Table 96.2 ESL tests for teacher accreditation (by state)

	<i>IELTS</i>	<i>ISLPR</i>	<i>PEAT</i>
New South Wales	–	–	A
Victoria	7	4	A
Queensland	7	4 (S,L,R) 3+ (W)	–
South Australia	7.5	4	A

Western Australia	7.5	4	A
Australian Capital Territory	7.5	–	A
Tasmania	7	–	A

examination (General Medical Council, *n.d.*) in the UK or the New Zealand Registration Examination (NZREX) (Medical Council of New Zealand, *n.d.*).

New Zealand

With a population of only 4.5 million (compared to 22 million in Australia) New Zealand has fewer resources to devote to the area of ESL assessment than Australia. Furthermore, with approximately three-quarters of New Zealand's population living in the North Island, areas of the South Island tend to be relatively under-resourced.

Immigration and Settlement

New Zealand was once described as one of the world's most monolingual countries (Bell & Holmes, 1991). The dominance of the English language and culture was, however, first eroded by significant immigration to New Zealand from the Pacific Islands in the 1950s. Immigrants from Niue, the Cook Islands, and Tokelau have constitutional rights of residence, while those from Samoa enter under an annual quota system. Increases in immigration subsequent to the 1987 Immigration Act, in particular from Asia, again brought changes to the face of New Zealand society.

Immigration In recent years the level of immigration to New Zealand has been especially significant. For example, in 1986, 17% of workers were born overseas but by 2006 this had risen to 24% (Callister & Didham, 2010). Migrants to New Zealand are only required to meet English language requirements if they apply under the "general skills" and "business investor" categories. Prior to 1995, assessment interviews were conducted by immigration officers to establish whether the applicant had the comprehension of an 11-year-old child (Read, 2001). Since 1995 this procedure has been replaced by IELTS (general training module). Score requirements have varied but principal applicants in the skilled migrant category currently require an average of 6.5 on IELTS, or some other evidence of English proficiency (e.g., ongoing skilled employment in New Zealand), while their dependents need to obtain an IELTS level of 5.0. Applicants scoring below these levels may be required to pre-purchase English language tuition. However, requirements for the "general business" category vary according to the size of the applicant's investment portfolio. For example, applicants investing NZ\$10 million do not need to satisfy any language requirements, while those investing NZ\$1.5 million or more only require a score of 3.0 on IELTS (Department of Labour, 2005).

Settlement New Zealand does not have a national language support program resembling Australia's AMEP. The Centre for Refugee Education uses a range of formal and informal assessments to establish the preliminary language needs of refugees. Otherwise assessment of the needs of new arrivals has been somewhat fragmented. From 2004 to 2009, assessment and access specialists were funded by the Tertiary Education Commission to provide free English language assessments

to anyone from an NESB and to make recommendations for language training and possible employment options. However, since 2009 assessment centers have had to source their own funding and there are currently no services available in the South Island. The ISLPR is the mostly commonly used assessment tool in the North Island.

Education

Student visas For overseas students planning to study in New Zealand there is no English language entry requirement that must be met in order to obtain a visa, but applicants must have an offer of a place from an educational provider. These providers set their own English language entry requirements.

Tertiary Education

Admission: Entry requirements vary across universities and programs. The Universities of Otago, Waikato and Canterbury, for example, require a minimum score of 6.0 on IELTS for most undergraduate programs. While IELTS is usually preferred, TOEFL, CAE, or the Advanced Placement International English Language (APIEL) exam (College Board, *n.d.*) are also accepted and most universities will accept graduates of a foundation studies program or an English for academic purposes program from an affiliated language school.

Diagnostic Assessment: Currently the University of Auckland has the most comprehensive approach to diagnostic assessment in the form of the Diagnostic English Language Needs Assessment (DELNA). All newly enrolled undergraduates (irrespective of language background) are required to take an online screening assessment (speed reading and vocabulary) with those scoring below a certain level required to complete additional assessment in reading, listening, and writing. In a recent new initiative, PhD students now also complete DELNA. More detailed information about English language assessment in New Zealand universities can be found in Read and Hirsh (2005).

Vocational Education As mentioned above, assessment and access specialists provide advice about education and vocational training options, although currently this service is only available in the North Island. Since 2008 a set of learning progressions for adult literacy and numeracy, in conjunction with an online assessment tool, comprising reading, vocabulary, writing, and numeracy tests have been used by some ESL providers (National Center of Literacy and Numeracy for Adults, *n.d.*). While not primarily devised as an assessment tool, the learning progressions aim to provide teachers and managers of adult learners with the information they need to develop their own curricula, teaching and assessment tools. They can also be used to establish eligibility for program funding. The learning progressions are linked to the national assessment system.

School Education

Admission: As in Australia, English language entry requirements for the school sector are as accepted by the educational institution. International students may only be enrolled in schools which are signatories to the Code of Practice for the

Pastoral Care of International Students, which acts to ensure that international students are adequately cared for.

Diagnostic Assessment: The main purpose of diagnostic English language assessment of domestic NESB students is establishing eligibility for Ministry of Education funding. English as a second or other language (ESOL) funding assessment is conducted by classroom teachers using guidelines for “effective assessment procedures” provided by the Ministry of Education (2004, p. 3). Teachers rate students’ proficiency in speaking, reading, listening, and writing as “well below,” “below,” or “close to” that of the national cohort of students at the same educational year level. Students scoring below the funding benchmark are deemed eligible for ESL funding. Ministry of Education verifiers visit schools to ensure the accuracy of assessments and that students are receiving appropriate support. International fee-paying students (approximately a third of all ESL students in 2009) are not eligible for funding.

While the ESOL funding assessment provides some information about learning needs the English language learning progressions, or ELLP (Ministry of Education, 2008), have been developed more especially for this purpose. Teachers are encouraged, using multiple sources of evidence, to match students’ performance against descriptors in each of the four skill areas, thus completing an ELLP matrix. The matrix can be used to establish a student’s learning needs but also to track the student’s progress and to identify future learning goals (National Migrant, Refugee and International Team, Ministry of Education, personal communication, April 5, 2011).

Assessment of Achievement: The ELLP can be used as a benchmark for reporting progress for NESB students from Years 1 to 8, in the place of the standardized tests, which are norm-referenced for students whose first language (L1) is English and which compare students to National Standards. The national qualification for senior secondary school students (Years 11–13) is the National Certificates of Educational Achievement (NCEA), a criterion-referenced assessment. Students complete “unit standards,” which are competency based and “achievement standards,” which are New Zealand curriculum based. NESB students can complete ESL unit standards over a range of four levels. While these ESL unit standards do not currently fulfill the literacy requirements (credits in English or *te reo Māori*) necessary for university entrance, they do scaffold students toward achieving these requirements.

Professional Accreditation

Teachers A range of tests are accepted for NESB teacher accreditation in New Zealand (New Zealand Teachers Council, *n.d.*). Applicants require a score of 7.0 on IELTS (academic module), 4 for each skill on ISLPR (version for teachers), Band A on PEAT, Grade B on the CAE, or a pass on the Certificate of Proficiency in English (CPE).

Overseas-Trained Health Professionals As in Australia there has been a significant increase in the number of overseas-trained health professionals working in New Zealand. In 2006 for example, 52% of doctors working in New Zealand trained overseas (Callister & Didham, 2010). The English language requirements for

accreditation of overseas-trained health professionals are the same as for Australia though the OET is used more widely than IELTS.

Conclusion

Table 96.3 provides a summary of the tests mentioned in this chapter.

Table 96.3 Summary of assessment procedures (Australia and New Zealand)

	<i>International students</i>		<i>Immigration</i>		<i>Teachers</i>		<i>Health professionals</i>	
	AUS	NZ	AUS	NZ	AUS	NZ	AUS	NZ
IELTS	✓	✓	✓	✓	✓	✓	✓	✓
CAE	✓	✓	?			✓		
PTE	✓		?					
TOEFL	✓	✓	?					
APIEL		✓						
ISLPR				✓				
OET	✓		✓				✓	✓
PEAT					✓	✓		
ISLPR (<i>teachers</i>)				✓	✓	✓		
CPE						✓		

One notable trend is the use of tests of academic English for an increasing range of purposes. IELTS, for example, which was originally designed to assess whether international students had a sufficient level of English for university study, is now also being used for immigration, professional accreditation and employment purposes. This is despite the availability of high quality specific-purpose tests. The OET, for example, was specifically designed to assess the English language proficiency of overseas-trained health professionals intending to migrate to or practice in Australia (Lumley, Lynch, & McNamara, 1994; McNamara, 1997; Wette, 2011). In 1998, IELTS completely replaced the Australian Assessment of Communicative English Skills (**access**): a specific-purpose English proficiency test for immigration selection in Australia (Brindley & Wigglesworth, 1997). See McNamara, Iwashita, and Hill (2003), Ingram (2005, 2011), and O'Halloran (2011) for a more detailed discussion of these issues.

Introduction to Volume IV

This volume presents chapters on language assessment practice from around the world. In the first part, current practices in EFL and ESL assessment are presented. These chapters include English as a lingua franca, and assessing English in Australia and New Zealand, North America, Mexico and Central America, the Middle East and North Africa, South, East, and Southeast Asia, South America, and Europe. In subsequent parts, language assessments in over 35 languages are presented. These chapters present some salient features of the language, language teaching and policy, and language assessment. The languages covered are from Africa, North and South America, the Middle East and South Asia, Southeast and East Asia, Australia and New Zealand, and Europe. While linguistic studies of the world's important languages are commonplace, these chapters are arguably the first chapters to be written from an assessment perspective.

Assessing English in North America

Samira ElAtia

University of Alberta, Canada

Introduction

Historically, socially, and politically, both Canada and the USA are choice countries for work, education, and permanent immigration; they are labeled and referred to as “receiving countries.” As such, diverse linguistic groups from around the world come to North America,¹ and, in order to function and to get established in the new home country, mastering English becomes a necessity and is, in some instances, mandatory. Consequently the field of English as a second language (ESL) for either learning or assessment has grown tremendously in the last century and a half.

English is the dominant language in North America because of historic ties with the United Kingdom.² Consequently, ESL teaching and assessment are heavily present in North America and for different purposes: proficiency, achievement, competence, and diagnosis. The ESL assessment population can be divided into three major categories. First, the immigration category includes adults and their families whose first language is not English, and who are intending to permanently relocate to or who have already settled in North America. Second, there is the education category which can be further divided into three separate assessment subcategories: students who need to demonstrate their language abilities to be admitted to institutions of higher education, students who need to be placed at the right level according to their language proficiency, and students who are learning English in North America and need to take achievement tests. Third, the category of migrant workers is composed of individuals seeking employment either temporarily or permanently in North America.

There is constant demand for ESL assessment in North America, and to address this growing need, several educational and commercial, for-profit and not-for-profit organizations have been established. Some of the universities that

receive a large number of international students have been developing their own language tests and are establishing their own assessment procedures and tools to monitor the English language acquisition process and rating scales. All of these language tests have led to a wealth of research on ESL assessment centered on finding better, more efficient, valid, and reliable methods to address the needs for ESL assessment of the various groups of examinees in North America.

The North American Context

The teaching and assessment of ESL in North America has become a field in its own right with its own scholarly societies and journals. Teachers of English to Speakers of Other Languages (TESOL) is the largest and most prominent society, starting in the USA in the 1960s (Alatis, 2012). There are also regional teaching English as a second language (TESL) and teaching English as a foreign language (TEFL) organizations across North America, whose main objective is to address needs in ESL assessment and learning. The importance given to ESL assessment in North America is mirrored in the *Standards for Educational and Psychological Testing* (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 1999)³ where a subsection is entirely devoted to special considerations when assessing individuals for whom English is not a native or a first language. The *Standards* constitutes an important link between the USA and Canada as, first, it provides information useful in both national contexts, and, second, it recognizes an important component in assessment, that of the ESL population. However, even though the countries are in line with each other when it comes to practices, they are quite different when it comes to language legislation and hence language assessment needs.

Canada is an officially bilingual (English and French) country. As such, there are federal and provincial regulations and laws that govern the use of English, be it for administrative functions or for business and education. Some Canadian provinces are English dominant, with government administrative services, education, and assessment available in French. In Quebec, French is the dominant language, and in New Brunswick, a bilingual province, residents must generally be able to function in both official languages. Regardless of the position of English in each province, ESL assessment must be offered to whoever requests it and must address the needs of specific individuals.

In the USA, unlike Canada, English does not have an official status at the federal level, but it is recognized as the language of the country. There are no regulations or laws governing or restricting the use of English at the federal level as yet. However, many states, such as California (Legislative Counsel of California, *n.d.*) and Arizona, have declared English the official language of the state and adopted laws to regulate the use of English in the workplace, the legal system, and the education system. One outcome of these laws has been the need to provide ESL assessment to the growing Hispanic population. This demographic has specific ESL assessment needs that have produced an assessment scenario unique to the USA.

ESL Assessment for Immigration

In Canada

Citizenship and Immigration Canada (CIC) regulations stipulate that applicants for immigration⁴ must demonstrate their proficiency in English⁵ by taking the International English Language Testing System (IELTS) examination with one of three designated agencies—Education Australia, the British Council, or the Local Examination Syndicate at the University of Cambridge (UCLES).

The IELTS language exam is calibrated with the Canadian Language Benchmarks (CLB) (Centre for Canadian Language Benchmarks, 2011) scaled from 1 to 12 according to a candidate's English language proficiency. CIC requires a benchmark of 7. Candidates take a test for four different skill sets—listening, reading, writing, and speaking—after which their benchmark in each category is converted to a series of points. "Points earned" on the IELTS exam count towards the language factor on an immigrant's application; immigration candidates have an increased possibility of being admitted if their IELTS score is high. Since June 26, 2010, all skilled immigrants intending to find work in Canada are required to take an English language test, regardless of whether they are native English speakers or not (Citizenship and Immigration Canada, *n.d.*).

In the USA

The USA has its own naturalization test, which is administered and evaluated by the US Citizenship and Immigration Services (USCIS). According to requirements in Section 312 of the American Immigration and Nationality Act (INA), the naturalization test assesses applicants on their English speaking, reading, and writing abilities. For more information on this test, see Kunnan (2009). Unlike the IELTS used in Canada, the scoring system is less formal and more subjective, and is based on a pass–fail result determined by the USCIS officer examining the applicant. The naturalization test also includes a section on general knowledge of US government and history.

ESL Assessment for Studies in North America

ESL assessment for education purposes in both Canada and the USA includes various categories: students who must show a certain level of competence in English in order to be admitted to a program of study, students who are learning English in a North American institution and must show their progress, and school-age children (mostly elementary students),⁶ who learn English in North American schools. For children of immigrants who are living in either Canada or the USA, the term English language learner (ELL)⁷ has been used widely. It connotes young populations who are learning English within a regular school program and whose deficiency in English is being addressed during their academic schooling from elementary to secondary schools, grades K to 12.

In Canada, each province has designed its own ESL program for new English language learners in public schools, targeted primarily at immigrant children. Ontario assists ESL students according to four defined levels of language proficiency based on the CLB. ESLs students are distinguished from English learning development (ELD) students,⁸ who have had significant gaps in their schooling and are themselves categorized according to four different levels of language proficiency of the CLB.

In the USA, school districts across the country have established a variety of ESL assessment procedures for ELLs (mostly children of immigrants). For instance, in Michigan, the Monroe Public School district has set out a comprehensive ELL program for students whose first language is not English. The goal of the program is to support all children in their efforts to communicate effectively in English and to understand how to use the language in appropriate social and cultural contexts. Candidates for the ELL programs are first identified through the district's Home Language Survey or on a teacher's recommendation; they subsequently take a language proficiency test, Michigan's English Language Proficiency Assessment (ELPA) Screener. ELL students continue to take this test yearly so that their progress can be tracked until such time as they place out of the program.

In several US states, and depending on the level of schooling and required courses, ELL students leave their regular classes on a flexible basis to study ESL during the day. In the regular classroom, teachers are trained to accommodate ELL students through the use of specially designed content. If, on the other hand, students are able to take classes in their native language, bilingual assistants with the proper training may be available to simultaneously support them in English language learning. Beyond the commitment of individual school resources, the school districts provide training and supervision to both paid and volunteer ELL tutors.

At the postsecondary level, most North American universities offer more or less the same context of study and have similar requirements for English language competence. Students either apply to be admitted directly to a program for which they need to demonstrate English proficiency before being accepted, or they apply to an English language program to learn English and subsequently apply for admission to an academic program.

The students applying for higher education are not necessarily international students who are foreign citizens to the USA or Canada. Some are citizens but have lived and been schooled in other countries where English was not the dominant language. These include children of military and diplomatic personnel as well as expatriates working abroad. Moreover, in Canada, students from Quebec,⁹ for instance, are required to demonstrate a certain competence in English when applying to English institutions either in Canada or the USA.

In general, a student applying to study at an institution of higher education is exempted from sitting for any ESL assessment if she or he comes from an English-speaking country or has studied in an accredited or a recognized high school or a program that uses English as the language of instruction. In these instances, tests from the Organization of the International Baccalaureate (IB) are recognized as a proof of English proficiency. Some universities require an IB score of 5 or higher in the subjects of English A1 or English A2.

For non-English-educated students, institutions may require several English language tests as ways to assess their competence. In this respect, two tests are

universally recognized and acceptable: IELTS and Test of English as a Foreign Language (TOEFL).

On average, universities need a minimum of 550 on the paper-based TOEFL and 75 on the Internet-based TOEFL for admission to undergraduate and graduate programs. Educational Testing Services (ETS), an American not-for-profit organization, oversees the development and administration of the TOEFL around the world. The TOEFL dates back to the mid-20th century and is a product of the same merit-based system that gave birth to the SAT exam and other standardized objective tests. (Spolsky, 1995, provides more in-depth historical analysis on the College Board, ETS, and the birth of the TOEFL.) The TOEFL is divided into four sections: reading, writing, listening, and speaking. Universities are encouraged by ETS to establish their own acceptable score in each of these categories rather than for the whole test score.

Cambridge ESOL (formerly known as UCLES) in England oversees the development and the production and administration of the IELTS. Almost all universities that require a proof of English proficiency recognize both the TOEFL and the IELTS. A score at the band of 5 or higher is generally the required minimum IELTS result in order to be admitted to a North American institution of higher education.

There are other large-scale standardized tests that are accepted for ESL assessment. These include the Pearson Education Test of Academic English, the Michigan English Language Assessment Battery (MELAB), and the Berlitz English Language Proficiency Exam, which is accepted by mostly military educational institutions. Some universities that receive a large number of international students have developed their own English tests for placing students upon their arrival and for measuring their achievement after a period of language study. The Michigan State University English Language Test (MSU-ELT) at Michigan State University, the English Placement Test (EPT) at the University of Illinois, and the English as a Second Language Placement Examination (ESLPE) at the University of California are examples.

The Canadian Academic English Language test (CAEL), developed at Carleton University in Canada, aims to assess students' pre-entrance competence in academic English. The CAEL assessment is an English language proficiency test and a band score of 60 or more in the CAEL indicates satisfactory English.

Along with ESL tests, universities in North America may accept a score in the critical reading part of the SAT (originally Scholastic Aptitude Test) or the English part of the ACT (originally American College Testing); as well as the International General Certificate of Secondary Education (IGCSE) in the English language exams. Furthermore, for the USA, there is a special requirement for students coming from Puerto Rico, who may submit the official score report of the Prueba de Aptitud Académica (PAA) as a proof of their English language competence.

ESL Assessment for Employment

A recent amendment to Canada's Immigration and Refugee Protection Regulations requires all business class applicants for permanent residence to provide results of English or a French language proficiency exam along with their applications. The English exams can be either the aforementioned IELTS or the Canadian

English Language Proficiency Index Program (CELP/IP); both are only valid if conducted by a third party organization preapproved by the Minister of Citizenship, Immigration, and Multiculturalism.

Along with these general conditions, the regulations governing the accreditation process for some professional designations require workers to submit to additional English language testing for technical purposes before they can be officially certified in Canada. For example, all applicants for jobs in aviation—from air traffic controllers to flight attendants—must take the Aviation Language Proficiency Test (ALPT). This exam includes vocabulary and jargon specific to the field of aviation; it measures applicants' comprehension, speaking, and general communication skills. Pharmacy technicians must also meet certain language proficiency criteria, as set out by the National Association of Pharmacy Regulatory Authorities (NAPRA), in order to obtain their licenses. Officers of Canada's Food Inspection Agency (CFIA) are further assessed according to their proficiencies in English, French, or both languages. Medical doctors need to submit either an IELTS or a TOEFL before they are granted medical titles and are allowed to interact with patients. As is the case in Canada, workers in specific professional fields in the USA are required to take English language proficiency tests in order to be certified to work under the designation. The Federal Aviation Administration (FAA), in particular, sets out various criteria for knowledge of technical terms and communication abilities that aviation workers must possess.

Teachers too are carefully tested for their language abilities before they can begin work in Canada. If an individual completed a teaching degree in another country, in a language other than English or French, he or she has several examination options upon arrival in Canada. Each province sets out its own criteria for teachers. The Ontario College of Teachers, for example, gives the IELTS as one such exam option; applicants must score at least 7 overall on the test, with at least 6.5 on the listening and reading components and at least 7 on the speaking and writing components. The College also sets out minimum scoring criteria for the TOEFL and Internet-based TOEFL with Test of Spoken English (TSE). Another example for teachers is the the California Basic Educational Skills Test (CBEST) (CBEST, *n.d.*), in which teachers take an English reading and writing test to assess their language competence.

Research Issues and Challenges

ESL assessment in North America is studied extensively from various perspectives ranging from the development of tests, to their administration, to innovative means of assessment delivery such as computer-adaptive testing or cognitive assessment. There are several publications that provide summaries and updates on ESL assessment and on different ESL tests (Douglas & Chapelle, 1990).

Other research has looked at the question of establishing standards in ESL assessment (Abedi, Courtney, Mirocha, Leon, & Goldberg, 2007). This is a timely topic and the International Language Testing Association (ILTA) has been addressing it more vigorously in the last few years with the publication of its code of ethics (2001) and code of practice (2007). Along with ILTA's affiliated

regional North American associations such as the Canadian Association of Language Assessment and Midwest Association of Language Testing (MwALT), or East Coast Organization of Language Testers (ECOLT), various regional and national academic societies and associations have begun addressing ESL assessment.¹⁰

More current research has shifted to focusing on the individual and on practices in ESL assessment along with the relationship between ESL assessment and educational policies and placement procedure (Teemant, 2010). Research is now focusing more on classroom ESL assessment practices in elementary and secondary education (Kauffman et al., 1995; Roessingh & Kover, 2008) and adult education (Sticht, 2010).

Issues of fairness in ESL assessment, the social and the sociolinguistic dimensions (Shohamy, 2001; McNamara & Roever, 2006), as well as the question of language variation (Davidson, 1994, 2006) have been addressed in recent and ongoing research. Another trend in ESL assessment research is cognitive assessment where the focus is on the individual.

Last, but not least, is the challenge that practitioners in the fields of ESL face on how to align ESL standards and ESL assessment. The ESL Standards and Assessment Project began officially in 1995 (Short, 2000), and the national ESL standards were developed in 1997 (TESOL, 1997). These ESL standards served as a reference to different states when addressing ESL/ELL issues, such as the Illinois ESL content standards. The work of the World-Class Instructional Design and Assessment (WIDA) consortium in trying to develop standard-based assessment and specifications is seminal in this field. WIDA published a study report (Cook, 2007) about alignment between ELP standards and the ELLs assessment. More research is being conducted in this area, and it will be leading ESL assessment research in the coming years.

Notes

- 1 In this chapter, "North America" refers to Canada and the USA only. Mexico is excluded since the context is very different, given that Spanish is dominant there.
- 2 In Quebec, French is the official language. There is a presence of French and French communities across Canada and in the province of New Brunswick, the only officially bilingual province, 45% of the population speak French. There is a presence of French in parts of Louisiana, Vermont, and Maine in the USA. There is also a strong presence of Spanish in several places in the USA, mainly in the southwest and along the borders with Mexico.
- 3 The *Standards* is a document prepared by specialists in the field of educational and psychological measurement and evaluation, and serves as a reference to varying stakeholders in the process of test development. It is endorsed by many Canadian institutions including the Canadian Psychological Association. It is also recognized worldwide as a point of reference in test development and use.

- 4 This clause is specific to those seeking potential immigration and not people who are coming to Canada as refugees.
- 5 Potential immigrants need to demonstrate their language competence in either French or English. In this section, only English is addressed.
- 6 For more in-depth analysis of this special assessment population and context, the following large testing consortiums provide information: WIDA's ACCESS for ELLs; Comprehensive English Language Learning Assessment (CELLA); State Collaborative on Assessment and Student Standards for Limited English Proficient Students (LEP-SCASS). For an excellent overview of the issues related to assessment of ELLs in the USA in the context of No Child Left Behind (NCLB), please refer to the special issue of *Language Testing* edited by Craig Deville and Micheline Chalhoub-Deville (Deville & Chalhoub-Deville, 2011).
- 7 In the field of measurement and testing (not language testing), ESL is mostly referred to as ELL, since the latter is used to describe students in academic programs and the interest in evaluation is on this category.
- 8 It is important to note that Canada receives, along with immigrants, refugees from around the world. Children of these refugees because of the conditions they were living in have not been able to pursue their schooling. ELD is designed mostly for these refugee children.
- 9 Students who have attended Anglophone schools within Quebec are exempt from these requirements.
- 10 Scholarly associations and conferences address ESL assessment: for example, Language Testing Research Colloquium (LTRC), American Association of Applied Linguistics (AAAL), Teaching English to Speakers of Other Languages (TESOL), in addition to both the American Educational Research Association (AERA), and the National Council on Measurement in Education (NCME), which have divisions exclusively for ESL assessment.

Assessing English in Mexico and Central America

Caroline Payant

University of Idaho, USA

Francisco Javier Barrón Serrano

Georgia State University, USA

Introduction

The predominance of Spanish across the Latin American expanse and its use as the language of business and travel have meant that the region in general has been slow to raise its English as a foreign language (EFL) standards (Education First, 2011). This landscape seems to be gradually changing. In Mexico and in Central America there is increasing recognition of the urgency to develop English language teaching (ELT) standards and of the need to implement a sound English curriculum beginning during the first years of education (Basurto Santos, 2010). Despite this recognition, ELT is beset by a number of factors, including a dearth of qualified human resources, outdated theoretical and methodological frameworks, ambiguous ELT curricula, and poorly defined assessment policies (Davies, 2011; Ramírez Romero, Pamplon Irigoyen, & Cota Grijalva, 2012). A general overview of current language policies and their implications for assessment in Mexico and Central America constitutes the scope of this chapter. The linguistic diversity of the region is first acknowledged, and current public education reforms are presented with particular attention to the role they reserve to ELT and assessment. Future challenges and directions for ELT are also considered.

Linguistic Landscape

The United States of Mexico, henceforth Mexico, is located in North America. Mexico is bordered by the United States of America to the north and by Guatemala and Belize to the south. According to the most recent census, Mexico has a population of approximately 112,300,000 people (INEGI, 2012). The country's official

Table 98.1 Demographic and linguistic diversity

Country	Population	Official Language	Other spoken languages
Mexico	112,300,000	Spanish	62 recognized indigenous languages: Náhuatl, Maya, Mixtec, Tzeltal, Zapotec, Tzotzil, Otomí
Belize	327,719	English	Spanish (46%), Creole; Kekchi, Maya, Garifuna
Guatemala	14,099,032	Spanish	23 recognized indigenous languages ^a : Quiche, Xinca, Kekchi, Cakchiquel, Mam, Garifuna
El Salvador	6,090,646	Spanish	Kekchi, Lenca, Pipil
Honduras	8,296,693	Spanish	Garifuna, Miskito, Pech
Costa Rica	4,636,348	Spanish	Bribri, Cabécar
Nicaragua	5,727,707	Spanish	Miskito
Panama	3,510,045	Spanish	English (14%)

^a *Ethnologue* (2012) lists 55 languages for Guatemala.

Note. Population and spoken languages are based on statistics from US CIA (2012).

language is Spanish and nearly 7,000,000 individuals aged 5 and above speak an indigenous language (INEGI, 2012).

Geographically located south of Mexico, Central America comprises seven countries: Belize, Guatemala, El Salvador, Honduras, Costa Rica, Nicaragua, and Panama. Spanish enjoys official language status across the region, with the exception of Belize. There English is the official language, although it is spoken by less than five percent of the population (US CIA, 2012). The overall population and linguistic diversity of these areas are presented in Table 98.1.

The English proficiency landscape for Mexico and Central America is not easy to establish. An attempt at this by reference to two internationally recognized assessment tools yields paradoxical results. The Education First English Proficiency Index (Education First, 2011) ranks the region at a *low to moderate proficiency* level. With a moderate proficiency level of 51.48, Mexico ranks slightly higher than its Central American neighbors, which are all placed at a low proficiency level: Costa Rica (49.15), Guatemala (47.80), El Salvador (47.65), and Panama (43.62). Scores are unavailable for Honduras, Nicaragua, and Belize. Compared to Western European nations and wealthier Asian countries, Mexico and Central America rank relatively low. The TOEFL iBT (Test of English as a Foreign Language, Internet-based test) *total score* means available from Educational Testing Service (2011) paint a different picture: Costa Rica (92), Mexico (85), El Salvador (84), Honduras (85), Nicaragua (84), Panama (82), and Guatemala (81) (the highest possible score on the iBT is 120; no data are given for Belize). These scores, which are comparable to those of wealthier Asian nations, are in line with a sampling of recommended admission scores for US colleges (77–86), thus suggesting a relatively strong command of the English language (Educational Testing Service, 2005). However, it would be a stretch to think of these scores as representative of the national mean. The TOEFL iBT is typically taken by individuals preparing to study abroad; this represents a small portion of the population. In light of the recent adoption of policies aimed at increasing the coverage of ELT by both Mexico

and Costa Rica, and of their higher proficiency scores in relation to the rest of the region, the remainder of the chapter focuses on ELT and assessment practices primarily in these two countries.

Teaching–Learning Contexts: Mexico

The Mexican education system is organized into four distinct levels: (1) preschool (K1–K3); (2) basic education, which includes primary school (*primaria*, i.e., grades 1–6) and middle school (*secundaria*, i.e., grades 7–9); (3) high school (*preparatoria*, i.e., grades 10–12); and (4) higher education; see, e.g., Organization for Economic Cooperation and Development, 2007 for a detailed description). Due to Mexico's decentralized educational system and large student population, the implementation of ELT has experienced defragmented curricula and assessment practices.

ELT was first introduced in the curriculum in 1926 (Reyes Cruz, Murrieta Loyo, & Hernández Méndez, 2011). A number of private institutions introduced ELT during preschool years; however, their coverage is negligible, since more than 87% of the student population attends public schools (Santibañez, Vernez, & Razquin, 2005). Although nationwide efforts have been made to promote the professionalization of ELT (e.g., revitalization and consolidation of professional organizations like the Asociación Mexicana de Maestros de Inglés / Mexican Association of English Teachers and the Asociación Nacional Universitaria de Profesores de Inglés / National Association of University English Teachers), three important turning points in ELT have shaped current practices. The first, in 2000, was the official recognition of the Certificate for Overseas Teachers of English by the Ministry of Education (Lengeling, 2007). This one-year ELT certificate for in-service language instructors offered through the British Council was used to set the standard for English teacher education for public schools (Lengeling, 2010). It was later succeeded by the In-Service Certificate of Overseas Teachers of English, a University of Cambridge certification, also offered through the British Council. The second turning point was marked by the publication of the results from the Program for International Student Assessment, an evaluation of 15-year-old students' academic capabilities, conducted by the Organization for Economic Cooperation and Development. Emerging recommendations included the introduction of English at the primary level of education in state schools (Organisation for Economic Co-operation and Development, 2007). During the mid-1990s five states followed this recommendation, and by the year 2009 34 additional state-wide programs had been inaugurated (Canalseb, 2009). The performance of these programs has not been systematically evaluated, yet several challenges have been identified: lack of a unified program, heavy reliance on textbooks, and limited and discontinuous number of hours of instruction (Ramírez Romero et al., 2008; Davies, 2009). Finally, in 2009–10, the Secretaría de Educación Pública (SEP) / Ministry of Public Education developed the Programa Nacional de Inglés en Educación Básica (PNIEB) / National Program of English for Basic Education.

To develop national standards that might be also amenable to international scrutiny and recognition, the SEP relied on the Common European Framework of Reference for Languages (CEFR) both for competency level descriptors and for

recommended amounts of instruction. The proposed structure is as follows: 200 hours for A1 proficiency (grades 3 and 4), 200 additional hours for A2 (grades 5 and 6), and 360 hours for B1 (grades 7–9) (Secretaría de Educación Pública, 2009). Assessment of English proficiency is vaguely referenced in the PNIEB. Primary stakeholders argue that assessment is a core element and maintain the following:

It is necessary that assessment take into account [t]he students' performance during the development of tasks or programmed activities [and t]he progress students make, related to their own starting point and the products derived from the specific competencies with the English language in different social environments. (Secretaría de Educación Pública, 2011, pp. 85–6)

It is recommended that learners be assessed periodically, after each unit, semester, year, and cycle, rather than via a final summative and isolated event. Recommended forms of assessment include mandated and teacher-developed classroom-based tests (e.g., true/false statements, matching, cloze) as well as self-assessment and peer assessment techniques and portfolios (Dirección General de Desarrollo Curricular, 2006). Although the CEFR highlights the importance of communicative competencies, measures for assessing these are not acknowledged. To date, formal evaluations of these efforts have not been reported (Davies, 2011).

The Examen Nacional de Ingreso (EXANI-I), a standardized national entrance assessment, is in place for high school applicants. The EXANI-I includes the following components: sciences, social sciences, mathematics, Spanish, and verbal reasoning. Additionally, beginning in 2002, the exam incorporated an optional English component with 16 multiple choice items, targeting reading comprehension and structural grammar (CENEVAL, 2012). Basurto Santos (2010) conducted a qualitative study with English language teachers and students and shows that examinees are often instructed not to complete the English portion of the EXANI-I on the premise that results will not be considered for admission. The inclusion of an optional English component raises some red flags and raises the question of whether ELT is in fact valued by policy makers.

During high school, ELT focuses on reading comprehension (Basurto Santos, 2010). Assessment procedures include diagnostic, formative, and summative assessment. Diagnostic assessments are implemented at the start of each semester in order to inform pedagogical decisions. Formative assessments are implemented periodically and include quizzes, participation, observations, and tests. Summative assessments are based on quantifiable participation, small assignments, and tests given at the end of each unit. Consistent with conventional approaches to assessing reading skills, tests include multiple choice and short answer items (Basurto Santos, 2010). ELT assessment practices in high school do not appear to be in line with the learning objectives stipulated by the CEFR.

A standardized national entrance assessment is also in place for higher education, namely the EXANI-II. The EXANI-II does not ordinarily include an English component; however, one is available upon request by specific institutions (CENEVAL, 2012). ELT at the college level has only recently become mandatory in most state universities. This is a much needed initiative, given recent findings

regarding students' English language proficiency. González Robles, Vivaldo Lima, and Castillo Morales (2004) evaluated the English language competencies of 5,000 first year college students from three private and six public institutions in the Mexico City area. Results indicate that the majority of students failed to meet the minimum requirement on the entrance language proficiency exams. More specifically, 76% of the test takers were around CEFR A2 level or lower, and 13% were at B1 level. Only approximately 11% of the students scored CEFR B2 level or above. To the best of our knowledge, this is the only large-scale study examining the linguistic competencies of Mexican college-age students.

Overall, in Mexico, educational reforms are often discussed both formally and informally. While proposals by the SEP suggest that the ELT and assessment standards are currently being developed, informal discussions among learners and teachers of English paint a much bleaker portrait. Assessment of ELT in the public and private sectors is indispensable to critically evaluate the plausibility and the real outcomes of the nationwide efforts.

Teaching–Learning Contexts: Costa Rica

Similar to Mexico, ELT in Costa Rica has been the focus of educational reforms. The school cycles in Costa Rica include preschool, primary school, lower secondary school, upper secondary school, and diversified education. Primary school, which lasts 6 years, includes two cycles (I Ciclo and II Ciclo). Lower secondary school includes one cycle (III Ciclo). Diversified education includes one cycle (IV Ciclo) (Freeman, 2012). Prior to 2007, students were required to complete high stakes national evaluations in order to obtain the Diploma de Conclusión de Enseñanza Primaria / Primary Education Exit Diploma (Castro, 2010). The elimination of these content-based examinations was in part due to the large amount of negative backwash experienced in the classrooms. The Ministerio de Educación Pública (MEP) / Ministry of Public Education now implements national diagnostic tests such as the Third International Mathematics and Science Study and the Program for International Student Assessment (Castro, 2010).

Today a standardized examination is only required upon completion of III Ciclo, namely Certificado de Conclusión de Estudios de Educación General Básica / Certificate of Completion of General Basic Education. The MEP determines the content of this examination, which includes mathematics, science, social studies, civic education, Spanish, and foreign language—either English or French. A minimum passing grade of 65/100 is required (Castro, 2010; Freeman, 2012).

Unlike other Central American countries, Costa Rica has a longer history of ELT. Córdoba Cubillo, Coto Keith, and Ramírez Salas (2005) trace the first English language programs back to the late 1850s. In 1954 the University of Costa Rica began offering training in ELT (Córdoba Cubillo, et al., 2005), and in 1990 its Department of Education inaugurated a four-year undergraduate program in English.

While the teaching of English has a long history in higher education, the inclusion of English in the curriculum at the primary level only took place in 1994, when a pilot program was established in 27 primary schools. In 1997 English gained

Table 98.2 English language instruction in Costa Rica (Ministerio de Educación Pública, 2007)

<i>Grade level</i>	<i>Number of institutions</i>	<i>Number of institutions with English</i>	<i>English language instruction</i>
Preschool	2,378	115	30-minute daily lessons
I and I Ciclo	3,722	1,652	5 one-hour daily lessons
III Ciclo	547	530 (regular) 17 (bilingual)	3 weekly lessons
Ciclo diversificado	547	547	3 lessons at regular colleges 5 lessons at technological colleges 10 lessons at bilingual colleges

even greater recognition when it became a mandatory subject during I and II Ciclos. One year later English was introduced in preschool. In 2004 the pilot program grew to include more than 1,500 schools, or 73.7% of the country's total number of schools (Córdoba Cubillo et al., 2005). Until 2003 Costa Rica was the only country in Central America that included ELT at the primary levels of education (Saborío Pérez & Valenzuela Arce, 2009).

Today there is even greater pressure in Costa Rica to promote ELT aggressively. In 2007 the elaboration of the Plan Nacional de Inglés, an inter-institutional initiative supported by the MEP (Ministerio de Educación Pública, 2007), was put forward. Table 98.2 specifies the grade levels, the existing number of schools per grade level, and the number of schools that offer English, including the daily or weekly amount of instruction.

Short- and long-term achievement goals were stipulated with reference to the CEFR (see the section "Teaching–Learning Contexts: Mexico" above for details about the CEFR). In the first phase (2007–9) 45,000 learners would receive ELT instruction, the targets being distributed as follows: 10,000 (C1), 15,000 (B2), and 20,000 (B1). In the second phase (2009–12), 36,000 learners would receive targeted instruction as follows: 6,000 (C1); 20,000 (B2), and 10,000 (B1). By 2017 the national goal is to ensure that 25% of high school graduates reach a C1 level, 50% reach a B2 level, and 25% a B1 level. As for college students, the target is for students majoring in English to receive a total of 2,118 hours of instruction over the course of 8 semesters. Courses focus on the teaching of specific abilities (writing, speaking, listening, and reading) and on skills integration. Language proficiency attainment in other disciplines is not specified in the Plan Nacional de Inglés (Ministerio de Educación Pública, 2007).

Despite these provisions, the current status of ELT in Costa Rica is unclear. Costa Rica Multilingüe (2008), a non-profit organization, is currently conducting a nationwide assessment of linguistic skills. However, it provides limited information regarding the type of assessment that is being conducted, and results have yet to be published.

In Costa Rica, the CERF guidelines are also employed to measure teachers' linguistic proficiency. The required language competency for teachers at all four levels of education is B2, which candidates are required to demonstrate

by completing one of the following examinations: TOEIC (Test of English for International Communication), TOEFL, and the Cambridge-based IELTS (International English Language Testing System). However, B2 proficiency for teachers is not in line with the target outcome of C1 for all students in terms of the long-term plans.

In Costa Rica there are more than 150 multinational companies, a figure that represents more than 45,000 jobs. The pressure on the job market for bilingual employees is thus of great relevance. In 2006 the Costa Rican Investment Promotion Agency assessed the English skills of their labor force (Ministerio de Educación Pública, 2007). The study revealed that managers, administrators, engineers, and technicians did not meet the target proficiency levels.

ELT in Other Central American Countries

In discussing the extraeconomic effects of the North America Free Trade Agreement signed by Canada, the United States, and Mexico in the early 1990s, Morris (2004) argues that a regional integration process was set in motion. With the United States at its geopolitical center, the Caribbean and the whole of Central America soon became pulled into its sphere of influence. Although the intended outcomes of this process were primarily economic, issues outside the scope of the agreement have emerged as a result of growing regional interdependence. These include cultural and migration issues, and also changes in language policy and use, which are of particular relevance here. The policies enacted in Mexico and Costa Rica outlined in this chapter are two cases in point. Economic motivations are driving parallel initiatives in the rest of the region. For example, in April 2012, as part of an economic stimulus package, the Guatemalan parliament issued a bill, “Inglés para todos” / “English for all,” which promotes ELT in public schools (Reyes, 2012b). Behind this initiative is the emergence and quick development of a call center industry, which has generated an ever-increasing demand for bilingual workers. According to one congressperson, call centers can in principle generate anywhere between twenty and thirty thousand jobs in Guatemala, but the country is hard pressed to meet that demand, because not enough workers are proficient in English (Reyes, 2012a). In El Salvador, private companies—mainly in the call center industry—and the public sector have joined efforts to provide specialized language instruction through the program “English training for the call center,” offered through the Salvadoran Institute for Professional Training. The program aims to bring the English competence of 400 workers with high school diplomas up to required industry standards every year (Keilhauer, 2011).

The economic promise that the call center and other offshoring ventures hold out for this region is challenged by the shortage of a qualified workforce, notably where one of the top-ranking qualifications is proficiency in English. A late 2000s report on the state of direct foreign investment in Costa Rica, for example, identifies the shortage of a qualified bilingual workforce as the single most important factor dragging the country down on the global ranking of offshoring venues for the service industry (PROCOMER, 2007). In 2010, General Electric ruled out Panama for the installation of a software development center that would have employed up to 1,500 local IT engineers because of the overall low proficiency in

English of the eligible labor pool (González Jiménez & Sandoval, 2010). In Nicaragua, where 4,500 workers (or 0.2% of the workforce) are employed by the call center industry, the pool of qualified (i.e., bilingual) labor is quickly running out. This has prompted the Nicaraguan Investment Promotion Agency ProNicaragua to partner with the industry in launching a pilot ELT instruction program with funds from the Inter-American Development Bank (Call Centers, 2012). Most of these initiatives are so recent that their outcomes are yet to be seen. In the meantime, unfortunately, foreign language instruction provided by the public education systems in many of these countries is of mediocre quality and the coverage is insufficient. According to McGuire (1996), public ELT instruction in these countries is often imparted by teachers who have not attained mastery of the language and is highly dependent on the textbook—which may be imported, and therefore bear little relation to local experience and needs. The learners' apparent generalized lack of motivation may in fact be a response to the low quality of instruction (McGuire, 1996).

Challenges

The officially sanctioned goal in Mexico and Central America is to increase the English language competencies of students and educators. In Mexico and in Costa Rica several initiatives have been undertaken recently, including the introduction of English in primary and middle school. However, one of the problems is that the demand for trained ELT professionals exceeds the supply. The minimal proficiency requirement for teachers in middle school settings is B1 on the CEFR, although B2 is allegedly preferred (see the section "Teaching–Learning Contexts: Mexico" above for details about the CEFR). Drawing on the authors' experiences in language education, even that is not enough to deliver the quality of instruction required to meet any modern-day ELT standards. In his reflections following the 2010 MEXTESOL/Central America and the Caribbean TESOL Convention in Cancun, Mexico, TESOL International President Brock Brady warned against certain official attempts, or decree-like measures on the part of governments, to implement ELT at all costs—such as appointing language instructors who have not met the required language qualifications. He also wondered about the perceived urgency to promote English as a medium of instruction in some cases, and suggested that certain skills might best be conveyed in the local language first. He further questions politicians' ability to dictate sound policy, denouncing that simplistic, unrealistic views on foreign language instruction and learning are rampant among this class (Brady, 2010). Other challenges include large classrooms, limited materials, and few facilities (Ministerio de Educación Pública, 2007).

Overall, in Central American countries and in Mexico the locus and central point of the discussions has been the integration of ELT programs during basic education. Nevertheless, the greatest challenge lies in the evaluation of these programs. Future research needs to assess the outcomes of such initiatives and the real linguistic outcomes in ELT competencies. Taking advantage of the set of established assessment norms already in place, research in a variety of educational

settings must be engaged in order to offset the dearth of studies reporting on the current gains of these programs.

Assessing English in the Middle East and North Africa

American University in Cairo, Egypt

Russanne Hozayin

American University in Cairo, Egypt

Status of English in the Middle East and North Africa (MENA)

In common with most areas of the world (Ferguson, 2006), English continues to be the most popular foreign language in the MENA countries,¹ as reflected in the large number of individuals in the region who study English for a range of purposes, in formal and informal settings. Proficiency in English continues to be essential for any person who aspires to professional or job-related success in the MENA countries. In addition, in some contexts, knowledge of English is important for social and other status reasons (Schaub, 2000).

The relationship between the English language and the MENA nations has its origins in the region's colonial past in the late 19th and early 20th century as well as in contemporary economic, social, and political realities (see Pennycook, 1998). Of particular importance in regard to the former was the British Empire's occupation of Egypt (1882–1922) (Russell, 2001) and its manipulation of the Arabian Peninsula, the Arab Gulf, Transjordan, and Palestine in the years prior to and following World War I (Al-Kahtany, 2004).

As the worldwide influence of the British Empire declined during the 1930s and the USA gradually assumed its mantle, by the post-World War II years the USA was on the road to economic, cultural, political, and military dominance (Fishman, Conrad, & Rubal-Lopez, 1996). More recently, areas which had come under French influence as the colonizing power, including the Maghreb nations of Morocco and Tunisia, as well as Lebanon, have begun to feature English prominently in a mixed national language picture (Battenberg, 1996), in light of economic and cultural pressures for an adequate supply of English language users in all nations. In the Gulf nations (Bahrain, Kuwait, Oman, Qatar, Saudi Arabia, UAE, Yemen), there is a heritage of English from the British occupation which aspired to fill the vacuum

of the post-Ottoman years in the World War I era (Al-Buainain, 2011). This influence has been superseded by the post-World-War II influence of the USA, particularly in relation to the oil industry (Baker, 2011).

Language Teaching in School, College, and Workplace

Language Teaching in Educational and Professional Settings

Almost all nations in the MENA region include English as a foreign language (EFL) in their national curriculum, at increasingly younger ages. For example, in Egypt, EFL was extended from 7th–12th grades to all 4th primary students in 1993/4. It was further extended in 2003/4 to all 1st primary students. The main stated intention of this policy shift was to help ensure that a sufficient number of learners acquire the English necessary to fill positions in science, technology, and other academic fields, as well as in banking, tourism, politics, and other essential areas.

Private sector “language schools,” whose main language of instruction is English, French, or German, have long been a feature of education in those MENA nations with early exposure to international educational systems (chiefly in Egypt and the Mashreq [the eastern part of the Arab world] of the late 19th and early 20th centuries). These schools have witnessed a resurgence over the past 30 years, with a range of English-medium school curricula available, with US, English, and Canadian models being the most popular.

In nearly all schools—whether public or private—the learning focus is on the secondary school exit exam. As Hargreaves (1997) noted in relation to the *thana-wayya amma* (the Egyptian secondary school examination),

Egypt’s education system is dominated by the secondary school leaving certificate, the *thanawiya aama* examination. From the primary years, schooling is characterised by examination orientation and ritualisation. These features, in addition to Egypt’s relatively late drive towards modernisation accompanied by centralisation and newly forged social divisions, clearly categorise Egypt as a victim of the “diploma disease”; attempts to reform the assessment system are being hampered by the continuing perception of current school qualifications as the means to success, whether in the public or private sector, within Egypt or abroad. (p. 161)

A number of colleges in public universities have English-based programs in addition to those in Arabic, including law schools (previously dominated by French in Egypt) and business schools. Medical and engineering schools have long been dominated by English across the region (except in Syria, which conducts medical schools in Arabic). Private English-medium universities have proliferated in recent decades in many MENA nations, particularly in Egypt, Kingdom of Saudi Arabia, UAE, and other Gulf countries (Romani, 2009). A large number of these institutions are branch campuses of one or more English-medium universities based in the UK, the USA, Canada, or Asia.

Throughout the region, military, foreign affairs, telecommunications, international transportation, banking, finance, and tourism sectors, among others, are all

heavily dependent on English as a common medium. The rapid growth of the Internet in the region over the past 10 years has served to emphasize this dependence on English, as the main language of the Web. Most of the institutions related to the sectors named above include an English language institute specialized in assisting workplace language development.

EFL Teaching in the MENA Countries: Realities and Problems

As mentioned above, English is currently taught in public schools starting from the elementary stage in most, if not all, the MENA countries for about four hours per week. In these countries, English is the most popular second language among students. Indeed, a number of countries in the Gulf region have the task of preparing bilingual speakers (Arabic and English) as one of their educational goals. In addition to public schools, English is taught in MENA in a wide range of private schools and also used as a language of instruction for other subjects. Most English language instructors in the MENA countries are non-native teachers with differing educational backgrounds. Some of them are graduates of teacher education programs, while others have a degree in literature or linguistics with no pedagogical preparation. In recent decades, there were a number of attempts to provide in-service training for those teachers either through short-term training or degree programs in local universities. However, the major problem encountered in relation to English language teaching in this region, in our view, is the relatively low language proficiency of many of those teachers. This problem has prompted decision makers in the rich oil-producing Gulf countries to replace English teachers from North Africa and the Levant with native teachers from either Britain or the USA. Interestingly enough, most of the international schools in MENA only hire native teachers regardless of the proficiency and academic background of non-native applicants. This practice is not uncommon in many parts of the world where negative attitudes towards non-native teachers prevail (Denving & Munro, 2005). Recruiting native speaking teachers has not proved to be a complete success since many of these teachers are not pedagogically qualified. Overall, schooling in general and English instruction in particular are not showing the expected outcomes in MENA as is indicated by a number of researchers (e.g., Al-Buainain, Hasan, & Madani, 2010).

Language Assessment: Description

Purposes of L2 Assessment: Exit, Admissions, Placement, and Hiring

EFL assessment is widespread in the MENA nations where it is being used for a number of purposes. For example, in educational programs, EFL tests are used to make a number of decisions including screening, admissions, placement, scholarship selection, and program exit. In the workplace these exams are used for hiring, promotion, and professional development purposes. More recently, EFL exams have been used to establish the English language proficiency of persons planning to immigrate to English-speaking nations.

Almost all language users in MENA have developed a high level of apparently unquestioning dependence on the English language proficiency tests and adjunct services provided by large-scale international professional organizations, specifically, the University of Cambridge Local Examinations Syndicate (UCLES) and Educational Testing Service (ETS). UCLES provides a number of English language-related services in a number of MENA countries. Chief among these is the International English Language Testing System (IELTS) test. As for ETS products, both the Test of English as a Foreign Language (TOEFL) and Test of English for International Communication (TOEIC) tests are very popular in MENA. In this region, AMIDEAST (an American nonprofit organization that is involved in educational and professional training in the Middle East and North Africa) is one of the major representatives of ETS-TOEFL, currently providing test facilities and test preparation, as well as assisting citizens of MENA nations who wish to attend university in the USA. One of the most significant areas related to English language assessment is the myriad test preparation programs, courses, tutoring, and materials, which have long been available for TOEFL, through AMIDEAST, and a host of private educational institutions. More recently, centers that provide preparation for IELTS have proliferated, with test preparation courses supplied by the British Council and a number of private agencies.

UCLES and ETS were formed in historical periods when organizations related to education were commonly “not-for-profit.” More recently, the international movement toward “for-profit” educational service providers has entered MENA markets, especially those in the Gulf and Egypt. A prominent example of commercial providers is the publisher Pearson, with its Pearson Test of English (PTE—for academic, general, and young learners). However, given the extremely strong brand recognition built up by TOEFL and, to a lesser extent, IELTS, it remains to be seen how much headway this alternative exam can make in relation to academic programs in the region. In nonacademic areas, there has been acceptance of the PTE for establishing the English language proficiency level of potential immigrants to Australia.

EFL Assessment Practices in Educational and Professional Settings

Public schools from the primary through the secondary stages in all MENA countries follow a national policy where all students have to use the same curriculum. In this centralized system, annual examinations are developed by local authorities in each country in order for students to move to the next higher grade. There are also examinations that are selective for the subsequent education phase which are used not only for selection but also for certification purposes (Hargreaves, 2001). The secondary school certificate exam is the most centralized assessment system in the region since this test is administered nationwide on the same day. The secondary school exam serves as an exit exam and also as a university admission test in most of the MENA countries.

Since a number of universities in MENA use English as a language of instruction, a wide variety of admission tests are used to measure applicants’ English proficiency. The most common tests used in MENA are the TOEFL Internet-based test (iBT) and IELTS. However, the admission requirements vary from one univer-

Mean worldwide	20.1	19.5	20	20.7	80

Note. Only these MENA countries were included in the TOEFL report.

sity to the other and also depend on the nature of the program. For example, in the American University in Cairo, a minimum TOEFL iBT score of 83 or an IELTS score of 6.5 is required for full admission. Students whose scores are below this cut-off value must take EFL classes before starting their academic classes. Other international large-scale EAP tests are less commonly used in academic institutions in MENA. As shown in both Table 99.1 and Table 99.2, the performance of MENA students on both TOEFL iBT and IELTS is generally below average—except for Egypt and Lebanon for TOEFL iBT and Egypt for the IELTS test.

Although the current trend in Middle Eastern universities promotes the use of international proficiency tests for admission purposes, some governments have established their own testing programs. For example, the Common Educational Proficiency Assessment (CEPA) was developed by the UAE Ministry of Higher Education to make placement decisions with regard to students interested in applying for federal universities in the UAE. The English test includes three sections: grammar and vocabulary, reading, and writing. Based on the score obtained on this test, students are placed in a language course that is suitable for their proficiency level.

The use of proficiency tests is not limited to those test takers who are interested in pursuing an academic degree in MENA. A substantial number of test takers take either TOEFL iBT or IELTS to apply for undergraduate or graduate programs in English-speaking countries. For example, Saudi Arabia has allocated billions of dollars on scholarships to send young Saudis to complete their studies abroad. Similar programs, albeit on a smaller scale, are provided by other oil-producing

Note. Only these MENA countries were included in the IELTS report.

countries, such as the UAE, Qatar, Kuwait, and Oman. These policies have created a huge market for test preparation centers and materials in these countries and even abroad. For example, American universities have instituted conditional admission policies for those students that allow them to travel to the USA and study in EFL programs in these institutions.

Assessment of English in workplace contexts is also a common practice in business settings in MENA, mainly in banking, tourism, and oil sectors. Most testing of business English is done either for hiring or placement purposes. For example, the BULATS test Web site shows a number of Middle East businesses using their product in a number of Middle East countries including Bahrain, Kuwait, Qatar, Saudi Arabia, Syria, and UAE. Another test of business English that has a relatively strong Middle East presence is the TOEIC test, which is developed by Educational Testing Services (ETS) and administered by AMIDEAST.

Language Assessment: Evaluation

Based on the previous discussion of EFL assessment practices in MENA, the following section provides a critical overview of the issues emerging from this analysis. The first issue addressed in this overview focuses on the status of assessment in school settings and the relationship between testing and learning. Generally, one could argue that there is a hidden tension between assessment and teaching or learning in MENA. Teachers are constantly forced to adjust their instructional activities to reflect what is being tested in final examinations. Even formative assessment places huge emphasis on preparing students for these end-of-year examinations instead of providing students with opportunities to reinforce their learning. In a study conducted on the secondary school exit examination in Jordan, Haddadin, Dweik, and Sheir (2008) found that teachers usually spend a substan-

tial amount of class time working on tested skills, such as reading, grammar, and vocabulary while they allocate much less time for listening and speaking, since these skills are not included on the test. Interestingly enough, students who participated in this study indicated that they “did not want to be taught and burdened with extra knowledge that was not tested” (p. 341). To many teachers and students in MENA, language learning has unfortunately become more about test-taking strategies rather than acquiring a new language.

The second observation based on this review has to do with the psychometric qualities of EFL assessments in MENA. Regrettably, there are hardly any data reported in the test manuals or any other publications about the psychometric qualities of these tests. Although most ministries of education in the Arab countries have established assessment centers, no published reports are available for the public. This could be due to a number of reasons. First, many of these centers do not have the technical expertise needed for test data analysis and interpretation. Second, ministry of education officials in many of these countries deal with test data as military secrets. This attitude makes it extremely difficult for researchers who are interested in analyzing test results to have access to the data. We think that these testing programs need to change their attitude for their own interest and for the sake of other stakeholders. There is an urgent need for more transparency and also for more openness when dealing with test data.

Based on our experience in this part of the world, it is apparent that test abuse is a very common practice. With the absence of locally developed tests and the lack of testing experts who can make informed decisions, international tests, like TOEFL and IELTS, are often used in inappropriate or irrelevant ways. In some MENA countries, graduate students usually complain about the TOEFL or IELTS requirement in programs where the language of instruction is Arabic not English. For example, a number of Egyptian universities require graduate students whose programs are taught in Arabic to obtain a TOEFL score for admission purposes. In other contexts, the cut-off scores for these tests are decided upon by people who have no background in language testing. So a cut-off point could move up and down according to who makes the decision, not according to the proficiency level required in such contexts.

Future Directions

As noted above, there are a number of assessment entities in MENA including international testing programs, assessment centers in the MENA ministries of education, and professional testing organizations. In spite of the assessment of literacy activities organized by these different organizations, assessment knowledge and skills are still lacking in language programs. Stakeholders who need more information on educational assessment include educators (teachers, principals, and supervisors), policy makers, learners, parents, and the society at large. As Taylor (2009) noted in her review of assessment literacy in the *Annual Review of Applied Linguistics*, “more and more people are involved in developing tests and using test score outcomes, though often without a background or training in assessment to equip them adequately for this role” (p. 21). This observation is

certainly true of most educators in MENA countries, where people making and implementing educational assessment policies are often not adequately prepared in a technical sense. There is a major need for training for educators at all levels in different areas of educational assessment, such as formative and summative assessment, the role of testing (including its limitations), and technical aspects such as validity and reliability.

While there are published critical analyses of large-scale English language assessment (e.g., Bachman, 2005; Alderson, 2009), as well as the enterprise of “corporate English” (Phillipson, 2009), there are few if any which relate it to the English language situation in MENA. Furthermore, conceptual debates which frequently occur in other parts of the world have not yet become common among English language professionals in MENA, although they could provide significant insight into the development of this field in the region. Of particular interest is the debate about “which English?”—colonial (Fishman et al., 1996), World Englishes (Kachru, 1985), English as a lingua franca (ELF) (Seidlhofer, 2009), or other (Graddol, 2006), in light of the realization that native speakers of English are increasingly in the minority when all users of English are taken into account. Other important topics that need applied research in MENA contexts are the social dimension of EFL language, washback, and assessment for learning.

SEE ALSO: Chapter 1, Fifty Years of Language Assessment; Chapter 17, International Assessments; Chapter 66, Fairness and Justice in Language Assessment

Note

- 1 Middle East and North Africa in this context refers to the 22 nations who are member states of the League of Arab Nations. The acronym “MENA” will be used throughout the chapter to refer to this region. We understand that other countries are part of MENA, but we focus here only on Arab countries given the fact that they have many linguistic and cultural characteristics in common.

Assessing English in South Asia

Rama Mathew
Delhi University, India

Introduction

South Asia consists of seven sovereign states: India, Pakistan, Bangladesh, Sri Lanka, Nepal, Bhutan, and Maldives (Kachru, 2011). While the one factor that is common to these countries is that they are all multilingual, they are also vastly different in many ways, for example, with respect to their size, population, and the role and status they accord English. Owing to the colonial past, India, Pakistan, Bangladesh, and Sri Lanka fall into Kachru's (1985) "Outer Circle" (where different varieties of English are developing in a multilingual setting), while Nepal, Bhutan, and Maldives are in the "Expanding Circle" (where English is a foreign language and is considered the most useful for international communication). More recently, however, Kachru (2011) captures the notion of *South Asianness* in South Asian Englishes—a unique identity they have acquired in the postcolonial period, which according to him is clearly a deviation from the mother tongue varieties, with hardly any input toward classroom pedagogy coming from the native speakers; English language education (ELE) in South Asia is now being debated, developed, and managed, both in theory and in practice, with a view to being made accessible to a diversified population and to being made to serve the varied needs of its members, in their own cultural contexts.

In these multilingual countries education in state-run schools is in the official regional language(s), except in Bhutan, where the medium of instruction is English. Since English is considered a means of economic progress as it ensures better job prospects and therefore upward social mobility, it is taught from the earliest years at school all the way up to higher education. Given their history over the past two centuries and their trajectories of development, these countries have responded differently to current demands, including those of globalization. The language policies put forward reflect the complex debate over English versus vernacular,

embedded as it is in issues related to the democratization of English vis-à-vis the inequality between the rich and the poor.

This chapter presents a description and evaluation of English as a second language (ESL) assessments carried out in India, Pakistan, Bangladesh, Sri Lanka, and Nepal. Other countries will be mentioned only in passing, due to the fact that published documents are not available. An examination of how these ESL assessments are carried out in different contexts provides an opportunity to look at two essentially overlapping areas: the micro-level aspects of language assessment within a curriculum-based and a construct-based framework; and the macro-level aspects of how different countries are coping with critical issues such as the hegemony of English over local languages, or the link between identity and multilingualism.

The chapter starts by presenting an overview of the status of English that affects ELE in South Asia. Next it discusses assessment practices in India, Pakistan, Bangladesh, Sri Lanka, and Nepal. We then turn to issues and challenges that need to be addressed at conceptual and systemic levels, if effective assessment practices are to be implemented in the classroom.

The Status of English in South Asia

The status of English in South Asia and the policies related to it are in a state of flux, which affects English education and assessment in significant ways.

In postcolonial India English enjoys the status of an associate official language and is used in combination with Hindi and other languages at the state level. It has been part of the education system for more than a century: all those who attend state-run schools are taught English language as a subject, and in private, fee-paying schools it is the medium of instruction. In the last decade some 18 out of the 28 states and union territories have, in principle, introduced English in classes 1 and 2 (also known as grade levels) and the remaining states in classes 3–5, with a view to making the former accessible especially to the underprivileged sections of the society; this means that about 150 million children at the primary school stage are now learning English. However, implementing this regulation has proved so far to be beyond the reach of most schools in the country, since they have neither sufficient facilities nor proficient enough teachers to cater to the demand (Meganathan, 2011). Despite this state of affairs, English continues to be associated with prestige and important jobs in the public and private sectors and higher education. Interestingly, the *dalits* (the “untouchables,” people at the bottom of India’s traditional caste system) see English not just as a means of climbing up the social and economic ladder, but also as a key to emancipation. The construction of a temple for English language in a village in a northern Hindi-speaking state of India is an example of this belief.

Both Pakistan and Bangladesh, which were part of India prior to partition in 1947, have had a somewhat similar trajectory as regards the role and policy of English. Apart from the regional-medium schools (Urdu in Pakistan and Bangla in Bangladesh) and English-medium schools, there are also madrassas—schools for traditional Islamic education—which use Arabic along with the regional

language for instruction. In the regional-medium schools English is taught as a subject from class 1, and there are a small number of elite English-medium schools that cater for the upper middle class and prepare their students mostly for the British O-level and A-level exams (see Rahman, 2007, for a comprehensive review). As in India, the English for All policy has been implemented in Pakistan without consideration for the problem whether resources for its successful implementation are available or not (Shamim, 2011). English language courses offered at the undergraduate level, and also in postgraduate programs such as business and management, are intended to help students compete for good jobs in Pakistan. In Bangladesh, proficiency in English is considered necessary for studying and working and is believed to contribute to the country's economic growth, as English is currently the language of science and technology (Begum & Farooqui, 2008).

Sri Lanka on the other hand has had a checkered history, with reversals of language policy in response to pressure and in the hope of mitigating social and economic disparities at the national and global levels. The two local languages, Sinhala and Tamil, have not been equitably adopted, as there are competing claims to nationalist identity. English is not an official language but "a working language" that links diverse ethnic groups, and also a medium for international trade and educational instruction (Saunders, 2007).

Although politically Nepal was never under British rule, it shares the Indian experience in terms of language policy. The successive governments since the 1950s have failed to produce a well-defined policy on ELE, but English is taught from primary to graduate levels. However, due to inadequate resources, under-qualified teachers, and lack of facilities in the country, the outcomes of English teaching have not been satisfactory (see Giri, 2011). In Bhutan, which is a tiny monarchy, English is the national lingua franca and occupies the most important place after Dzongkha, the national language. It is the language of instruction at all levels, since no other language is sufficiently developed to meet the demands of teaching/learning. English is the second language in the Republic of the Maldives and is taught in all the schools of the islands.

Against this backdrop, given the nonavailability of published documents in the area of ESL assessment, the present chapter will only focus on India, Pakistan, Bangladesh, Sri Lanka, and Nepal.

Assessment Practices

ESL assessments can be seen to fall into two major categories: (1) summative tests administered by national or state secondary boards of examination at the end of class 10 and class 12 or by the university; and (2) tests administered by different agencies for a variety of purposes such as admission to courses, employment, or (external) assessment of student learning. These will be discussed in turn.

School/University Exams

There are typically two points at which students take an end-of-course test, more commonly known as an exam: one at the end of class 10 and the other at the end

of class 12 (class 11 and class 13 respectively in Sri Lanka). These tests are conducted by the secondary or higher secondary boards to which the school is affiliated. They are high stakes tests, since on the basis of their results important decisions are made about the stream or courses that students will pursue—for example, at the end of class 10/11 it is decided whether they'll study sciences, humanities, or commerce, and at the end of class 12/13 a choice is made between engineering, medicine, and liberal arts or science courses. In Pakistan and Bangladesh, however, students in the English-medium stream take the British O- and A-level exams.

In India exams are largely “traditional”: they are solely paper and pencil tests where reading, writing, and grammar tasks are based on prescribed textbooks and the focus is on knowledge and the understanding of the “content” taught. As a result, students’ test scores reflect mainly their ability to memorize and to present stock responses to expected questions. Here is an example:

Class 10 (Tamil Nadu, India 2010):

Reading (based on prescribed textbooks):

What did the gun-wielding man want Sambu to do?

Who were the Pakistani bowlers Sachin faced?

Grammar: Italicized words are the answers. Frame questions for them using the clues given in brackets.

Raja has been playing here *since morning*. (How long?)

Writing: Develop the hints into a readable passage. Give it a suitable title.

A prisoner—set free—goes to a market—sees birds in cages—feels sorry for them—wants to set them free—buys them—opens the cages—all the birds fly happily—prisoner feels happy

There are boards—for example, the Central Board of Secondary Education (CBSE), a national secondary board; and the NBSE, an equivalent board in Nagaland, a northeastern state in India where English is the official language and the medium of instruction throughout school—that have moved away from a scheme based largely on content toward a not so traditional proficiency-based one. The exam scheme of CBSE is shown below:

Section→	Reading	Writing	Grammar	Literature
Marks	20	30	20	30

It should be noted that the only “unseen” part is the reading section, while writing is partly seen and partly unseen. Grammar and literature are based on prescribed texts and can be “guessed” and prepared beforehand. When it was first introduced in 1995, as an innovation within a communicative curriculum, the scheme was more skill-based—a clear regression from the point of view of a language course. From 2009 on students have been given the option to write either the board exam or the school-based exam at the end of class 10 (see <http://cbse.nic.in/> for more details). An example of a writing task is given below:

India's CBSE sample paper (2011):

While reading a magazine you came across the following article:

There is a growing lack of sensitivity and respect for our fellow creatures. There is talk about the food web and the energy cycles and ecological balance and how removal of any element disrupts the whole system, and how this can affect human beings too. What this approach lacks is the essential interaction with Nature and with other human beings. Indeed, in many environmental activities the opposite takes place.

You are an educationist and feel that Environmental Education imparted in schools, need reorientation. The stress should not be on preserving Nature for human use, but for protecting animals and plants for their own sake. Based on the information given above and ideas from the Unit Environment, write a letter to the editor of a national daily in about 120 words on the subject and give it a suitable title. (8 marks)

While this kind of communicative task may be seen to be an improvement over the "traditional" task ("Develop the hints into a readable passage"), there are some issues with it that need to be addressed. The task expects the student to take on the role of an educationist who can reorient environmental education. To the extent that the Unit on Environment from the prescribed book helps with what taking on that role entails, the task is a "seen" or a rehearsed one. For others, though, this is a new situation, and focusing on the task can be challenging and time-consuming. The difficulty is further compounded by the fact that this is a timed task of just 120 words. There is also the problem of the marking scheme, which is not clear to the test taker, and of training the person expected to mark such answers.

NBSE also tests the skills of listening and speaking (in individual as well as in group contexts), which receive 20 marks at the end of classes 9 and 10, along with guidelines and criteria for the assessment (Nagaland Board of Secondary Education, 2008); this is, however, not the case with CBSE. Although oral assessment (conversation skills) is recommended in principle as part of the formative assessment, the score on the final paper and pencil test is the sole indicator of a student's success in the language. As a result, teachers and students do not focus on developing listening and speaking skills in the classroom (see CBSE-ELT Curriculum Implementation Study, 1997; Mathew, 2004).

The Council for the Indian School Certificate Examinations (CISCE), another national board in India that offers only English-medium education, conducts the ICSE (Indian Certificate of Secondary Education) and the Indian School Certificate (ISC) exams at the end of classes 10 and 12 respectively. The exam scheme is as follows:

The language paper at class 10 level tests unseen reading comprehension of fairly long passages (about 600 words); writing—a composition of 350–400 words and a letter; and some items on grammar/structure. The paper at class 12 level is similar, except that it has longer texts and requires more complex language skills and abilities. While the number of students who take the ICSE and ISC exams (a few thousand) is much smaller than the number of those who take the CBSE's

two exams (around 2 million in 2011), the schools affiliated to CISCE are facing a further enrollment crunch, as it is believed that its syllabus and exam schemes do not support the competitive exams that different national and state agencies conduct for admission to courses in engineering and medicine.

ESL teaching and assessment in colleges and universities are similar to what is happening in schools. Students memorize ready-made answers to expected questions and pass the exam; the common features of a typical university class are extensive use of translation, emphasis on grammar, and use of study guides (Ramanathan, 2005). Exceptions to this practice exist—for example, at the University of Mumbai in India, where the course on Communicational Skills in English for the BA students is based on a completely “unseen” paper without prescribed textbooks (see University of Mumbai, 2011). According to Yasmeen Lukmani (personal communication), the nature of the exam also requires students to display their ability to handle texts involving the cognitive skills of discrimination, interpretation, analysis, and evaluation; the testing of linguistic skills is made inseparable from the testing of cognitive skills. Ready-made answers are just not possible.

The situation in Pakistan is no different. In a study of the washback of SSC (Secondary School Certificate) exams on student learning, Mumtaz (2010) found that, while no question attempted to test any language skill but only simple recall and repeatedly given essay topics, the test also contained numerous flaws. Furthermore, as a consequence of this conception, the whole emphasis of teaching was on preparing students for their exams rather than on developing in them any language skill. However, both teachers and students rate their English language courses highly in terms of meeting their future needs. According to Shamim (2011), this apparently optimistic picture could be due to limited exposure to alternative pedagogies and assessment practices, combined with the effects of a short-term goal—that of getting high scores in English. Even in tertiary contexts, the focus is on assessing content knowledge such as “major barriers to communication” or “characteristics of a good paragraph” instead of language skills. It is not surprising therefore that the majority of school and university students enter the job market with only limited literacy skills in English (Shamim, 2011).

The five regional boards in Bangladesh that administer the Secondary School Certificate (SSC) and the Higher Secondary Certificate (HSC) English tests countrywide present a similar story: while the syllabus aims to focus on the four skills of listening, speaking, reading, and writing within communicative contexts, the tests consist mainly of seen comprehension, vocabulary, grammar, and guided writing; at the HSC level, however, unseen comprehension is also tested (Khan, 2010). Rahman (1999) reports a strong resistance from exam boards, for example, to the introduction of the communicative approach to ELT and to making concomitant changes to exam schemes. Whatever changes are implemented, they are merely cosmetic, not substantial; they encourage teachers and students to spend a lot of their time preparing students for such exams, and they perpetuate a negative washback of tests on teaching and learning.

In 2007 the government of Bangladesh introduced, at junior secondary levels, a school-based assessment (SBA) scheme that aims to assess learners’ holistic

development. A study of a group of four SBA trainers and 18 secondary teachers revealed that trainers were optimistic about the assessment system, while the teachers were divided in their opinion: those who did not have training had a poor understanding of the scheme and were therefore unsure of its effectiveness. There was also a widespread apprehension that teachers will misuse the scheme by giving high grades to those who took private tuition from them (Begum & Farooqui, 2008).

Students in Sri Lanka sit the General Certificate of Education (GCE) Ordinary-level and the GCE Advanced-level exam at the end of 11 and 13 years of schooling respectively. In the junior section (classes 6–9), there is formative (SBA) and a summative evaluation, but the GCE O-level exam is a paper and pencil test. The test is largely unseen although not very communicative, as shown in the following example:

O-Level Paper I (Sri Lanka, 2006)

Complete the sentences. Select the correct word from the group of words given within brackets. There is an extra word in each group. *The first one is done for you.*

(Picture given)

Sunil is But I must finish this
 it's very

(book, eating, sleeping, interesting)

According to a World Bank (2005) report, Sri Lanka's proficiency in English is poor and has declined significantly in the last 30 years. While English is considered an important requirement for the national and global business market and a determining factor of future growth, it is the country's biggest shortfall. Although English is currently taught as a second language from class 3 to the GCE Advanced Level in all schools,

only 10 percent of children achieve a targeted level of mastery in English language skills while English writing skills are virtually non-existent with only 1 percent of children exhibiting the required skills level. Additionally, these skills are largely restricted to urban areas where 23 percent of children master English compared to only 7 percent of rural children. (World Bank, 2005, p. 57)

The SLC (School Leaving Certificate) of Nepal, a high stakes test, determines not only students' future but also teachers' careers: low scores reflect teachers' incompetence and neglect of duty and can sometimes cost them their jobs; on the other hand, those with a high success rate in the SLC are given certificates of appreciation or monetary benefits (Giri, 2011). The test is still "traditional" in that it encourages rote learning and cheating and it tests the knowledge of language without revealing a candidate's actual language proficiency. Despite its negative washback on teaching/learning and despite questions about its validity, reliability, and theoretical justification, the test continues. Khaniya (2011) is of the view that, when we ask questions from previous exam papers, notes, and guidebooks,

we are forcing the students to prepare for anticipated or predicted questions. Nepal, like NBSE in India, has a test of oral skills as part of its SLC exam. This test was introduced in the late 1990s and consists in performing tasks after listening to cassettes (10 marks), picture description (15 marks), and so on; the total is 100 marks. Rai (2011) found that students like the test, as this is the first time some of them hear or speak “real world English” (p. 216). He also reported positive washback from this reform—that is, teachers teaching listening and speaking skills in the classroom.

Descriptions of what happens in an English class across countries clearly emphasize the following elements. Most learners study English sitting in rows, in large classes. Teachers in state-run schools normally do not use English to teach English. They read out parts of a text from the prescribed reader and explain it in the regional language; examples, simpler language, easier words are devices used to make the content of the text accessible to students. Teachers are concerned about completing the syllabus, which means going through the whole textbook in order to prepare students for end-of-term tests. All the stakeholders—students, parents, and school authorities—demand that teachers rehearse answers to expected questions in class. As regards writing, the teacher gives ready-made letters, short compositions, and so on, that students copy and memorize for exam purposes. There is seldom any feedback, oral or written, on written work. In effect, English is taught as a content subject and not as a tool that they can learn to use in different situations in different ways; teaching in the classroom thus mirrors class tests, which in turn mirror final exams; and vice versa (see Mathew, 2012, for India; Shamim, 2008, for Pakistan; Khan, 2010, for Bangladesh; Karunaratne, 2008, for Sri Lanka; and Khaniya, 2011, for Nepal).

Tests Conducted by Other Agencies

This section is restricted to assessment practices that prevail in India due to non-availability of material from other countries. There are a number of English tests that are part of a bigger test and are administered by different organizations for admission and recruitment purposes. CAT (the common admission test) is a computer-adaptive test for admission to the Master of Business Administration (MBA) program in Indian institutes of management and in other prestigious institutions. The section on verbal ability consists of sentence completion, analogies, reading comprehension, and antonyms; and there are also tests in analytical and logical reasoning that are based on reading. The Railway Recruitment Board (RRB) conducts exams for different types of railway personnel and the Institute of Banking Personnel Selection (IBPS) Board for banking staff.

For Assistant Station Masters (RRB)

1. Fill the blank in the following sentence. Circle the correct answer.

She did not know the matter and . . .

- a. I did not neither
- b. neither did I
- c. neither have I
- d. either did have

2. Circle the correct word for the following.**A place where animals are kept.**

- a. Museum
- b. Zoo
- c. Sanatorium
- d. Aquarium

There are proficiency tests administered by private publishers and testing agencies such as the Trinity College ESOL (English for speakers of other languages), University of Cambridge ESOL, Educational Assessment Australia, to mention a few. These tests—for example, the Business English Certificate tests for corporate jobs—are typically taken by students in private English-medium schools or by those seeking employment. The other popular tests are IELTS and TOEFL—different versions of them—which are designed for those who seek admission to universities in English-speaking countries. While the yearly number of test takers is not available, the overall mean score of South Asian test takers for IELTS in 2010 ranged from 5.7 (Bangladesh) to 6.3 (Sri Lanka) on a 9-band scale.

Curriculum-based assessments are also carried out by organizations outside of exam boards, which determine student levels and help to chart future courses of action. ASSET (Assessment of Scholastic Skills through Educational Testing), which is designed and conducted by Educational Initiatives (EI), an Indian organization, tests students at different grade levels in five subjects, including English. The Large Scale Assessment (LSA) team at EI looks after large-scale testing and educational research projects. The benchmarking of these results against international learning levels is another significant feature of this assessment. For example, the Quality Education Study (2011) conducted by EI found that students in India's "top" schools performed lower than the Progress in Reading Literacy Study (PIRLS) at class 4 level, while they were on par at class 8 level. The improvement at class 8 level was seen to be due to students doing well on procedural questions.

Issues and Challenges

This section presents an analysis of the issues that emerge from the discussion of ESL assessment practices in South Asia. Syllabus-based tests seem to be mostly textbook-based, and therefore memory-based. Teachers and students not only spend a great deal of effort and time preparing for these high stakes tests, but they are quite content with achieving high scores on them, although such scores do not necessarily reflect competence in using the language. When large numbers of students fail a test, the political solution has been to increase the proportion of memory-based tests. When students need to take external proficiency-based tests for pursuing further studies or jobs, they unlearn much of what they have learnt earlier and start learning to read, write, and speak afresh, in order to pass these tests. It is only a very small, privileged minority that can afford the time, money, and effort necessary to achieve this goal. For the large majority, English language proficiency is only a distant dream.

South Asian countries seem to be trapped in a power syndrome where the disadvantaged (largely the regional-medium students) and the middle class (largely the English-medium students) occupy two concentric circles with members of the former occupying the outer circle and members of the latter in the inner circle; these circles never meet (Ramanathan, 2003), thus legitimizing the hegemony of English and contributing to social and economic inequality. The provision of equal access through the introduction of English from early grades is the consequence of a response to an unfulfilled longing for English, which is the language of power and as such only alienates the marginalized further. Existing curriculum-based assessments do not test students' language proficiency, let alone suggesting future courses of action; thus they maintain the status quo for the marginalized.

A major problem with assessment has been the lack of expertise in language testing: while teachers may have some familiarity with (communicative) approaches to teaching and classroom methodologies, there is no orientation to assessment literacy. Very often, teachers who are entrusted with language test-construction and marking are those with no background or training in language assessment.

It is important to note that the test items, regardless of whether they are "seen"/traditional or "unseen"/modern, are not trialed, and secondary boards or universities show no concern about their validity or reliability, let alone publishing any statistical data on the tests. This is often justified on the grounds that these are large-scale high stakes assessments that need to maintain confidentiality. Research on different aspects of the assessment—for example, on the assessment scheme, test design, test formats, test-taking strategies, or teacher/student feedback on the test—is almost impossible to carry out, since answer scripts and test results are not available for analysis. As a result, newer assessment methods are, at best, top-down prescriptions and defy any serious research-based engagement at the users' level.

Another issue that is conspicuous through its absence is the multilingual context in which a student learns English. The rich and extensive research on multilingualism in assessment has not been applied to actual, concrete situations (see Mathew, 2008). In this context, Durairajan (2003) argues for the need to visualize a developmental view of language proficiency that captures different stages of learning in multilingual settings.

Future Directions

There is an urgent need to adopt a multipronged approach to improving ESL assessment in South Asia: first by training all educators in ESL assessment and, second, by taking up curriculum reform projects that will provide for concomitant changes to assessment schemes, both formative and summative, including changes to oral assessment. Teachers need to be supported fully in order to carry out classroom-based assessments competently; up until now, the introduction of school-based assessment has been interpreted as an additional burden to teachers' busy schedule. As one teacher put it, "the titanic [*sic*] called CCE [continuous,

comprehensive evaluation] is taking its toll, and we lesser mortals are carrying the cross on not so strong shoulders. The assessment work is multiplying like India's population . . ." Macro-issues of language policies would have to be seen in terms of how they are interpreted, implemented, and reformulated in actual classroom (micro)-contexts, with teachers mediating the process (Tollefson & Tsui, 2007); assessment, in this enterprise, illuminates what learning means in actual terms .

EI abundantly demonstrates how good quality large-scale assessments can be carried out in developing countries and what all the stakeholders—teachers, parents, students, managements—can do to improve student learning. In addition we will need to adopt a "multilingual model" (Kirkpatrick, 2010) with multilingual benchmarks to measure linguistic proficiency. Blair's 1990 typology of assessment for evaluating the linguistic competence of bilinguals—namely oral proficiency testing, storytelling, comprehension tests, sentence repetition, self-assessment, and evaluation by peers (cited in Meghan, McKinnie, & Priestly, 2004)—may be a way forward.

While there is ample published scholarly work on language policy, the English–vernacular debate, and multilingual education in South Asia, research on assessment relevant to local contexts is appallingly sparse. Both academic and policy-oriented research needs to be undertaken, and it should feed into assessment practice. A research and development approach is therefore the need of the hour.

Assessing English in East Asia

Viphavee Vongpumivitch

National Tsing Hua University, Taiwan

Introduction

English is undoubtedly the most important foreign language in East Asia, which is defined here as including (1) China, (2) Hong Kong Special Administrative Region, China (HKSAR), (3) Taiwan, (4) Japan, and (5) South Korea. English is an essential tool in knowledge gathering and it is the lingua franca of international business; thus English is taught to children at school all over East Asia, even though the exact grade in which instruction starts and the contents of their lessons vary (Nunan, 2003; Butler, 2009).

Given the significance of English in their children's success in life, it is not surprising that parents throughout East Asia are concerned about their children's test scores in this language and would pay for additional lessons to make sure high scores are achieved. In fact, children across East Asia have been well socialized since elementary school to accept meritocracy—to study and do well in exams so that they can do better in life (Ross, 2008). Doing well at school and subsequently getting a well-respected job is an excellent way to express filial piety, which is considered among the greatest of virtues in Confucianism—the Chinese ethical and philosophical system, which has exercised a strong influence in East Asia for centuries. Since meritocracy gives the entire population an opportunity to climb up the social ladder regardless of one's origins, it fits well with Confucianism, as can be seen from the fact that the imperial examination system was introduced in China three thousand years ago. Even today, the general public in East Asia maintains a strong faith in tests and certificates—a reality that bodes well for national examination authorities and private testing agencies (Cheng, 2008). The popularity of the Cambridge Young Learners English Test (YLE) in HKSAR, for example, has become a social phenomenon (Chik & Besser, 2011). Chinese learners of English are among the largest test-taker groups of the Test

of English as a Foreign Language (TOEFL®) and of the International English Language Testing System (IELTS™) (Qian, 2010). South Korean and Japanese learners of English account for over 90% of the Test of English for International Communication (TOEIC®) test takers worldwide (*Korea Daily*, 2005, cited by Choi, 2008).

This chapter aims to present the English assessments used in East Asia, classified according to their intended test takers' age, from elementary school to university level and beyond. The chapter ends by discussing the role of cram schools and listing some areas for future research that are applicable to all East Asian countries or regions.

English Tests in School Settings

In the 21st century English teaching methods throughout East Asia have shifted from grammar translation to communicative language teaching. When it comes to the assessment of young learners, however, each country or region varies (Butler, 2009). In Japan, the government does not acknowledge English as an academic subject at elementary schools; thus there are no specifications for assessment and evaluation for that level. For countries or regions where English is included as part of the elementary school curriculum, such as South Korea and Taiwan, in addition to traditional paper-based tests, teachers are encouraged to use multiple and alternative methods of assessing, such as classroom observations, portfolios, interviews, self- or peer assessments.

Although positive changes are taking place at schools, it is still common for concerned parents to turn to private language institutes for additional English lessons for their children. It is usually these institutes that introduce parents and their children to commercially available English tests. Chik and Besser (2011) report the case of HKSAR, where the YLE and the Pearson Test of English Young Learners are viewed by elementary school children and their parents as more trustworthy evidence of English proficiency than school grades. Choi (2008) also reports that in South Korea, by the time the children are 11 years old, they would have become familiar with a wide range of standardized tests, the most popular one being the Practical English Level Test for Elementary English (PELT) developed by the Korea Foreign Language Evaluation Institute. International tests intended for adults such as the TOEIC and the TOEFL are also introduced to the children, due to parental demand. Choi (2008) argues that this early introduction to standardized English tests leads to negative washback: not only are young South Korean children pushed to take tests by adults, but they are also motivated to study English extrinsically rather than intrinsically. Chik and Besser (2011) also criticize the fact that the craze for international English tests in HKSAR is mainly due to the certificates they guarantee, and, since the motivation for taking tests is to obtain academic advancement rather than learning, only those who can afford these expensive tests can benefit. This situation is widely encountered throughout East Asia, where the impact of parents' socioeconomic status on students' access to high quality English instruction is a real concern (Nunan, 2003). Perhaps in East Asia more than in other parts of the world, private after-school language programs

for children as well as testing agencies are profiting a great deal from parental worries about their children's future (Chik & Besser, 2011).

Once the students reach secondary school, their most important goal would be to enter a university. In China, millions of test takers take the National Matriculation English Test (NMET) every year (Cheng & Qi, 2006). Japan and Taiwan now have multiple paths for college admission, including direct application, interviews, and teacher recommendations (Sasaki, 2008), but the nationwide university entrance exams are still extremely influential. The good news is that, due to a stronger emphasis on students' communicative ability, the national university entrance examinations in Japan, Korea, and China have recently included not only reading and grammar/vocabulary, but also English listening skills. The bad news is that, since writing is not always assessed and speaking is usually not assessed, negative washback can still be observed (Cheng & Qi, 2006; Choi, 2008). First, teachers facing limited class time could only focus on the skills being tested by the exams, ignoring those that are not; and teaching to the test is prevalent. Second, virtually all exams developed in junior and senior high schools would employ test methods that are almost identical to those of the university entrance exam. As a result, millions of students have been trained to master the multiple choice test format instead of free production. Third, often, schools' and teachers' quality would be judged on the basis of the students' scores on the university entrance exams, even though those exams are designed as a selection tool and not as an evaluation tool, to the extent that teachers in China felt that their sense of achievement depends on their students' NMET scores.

Due to its high stakes, any attempt to change university entrance examination is typically met with criticisms from the general public. In South Korea, Kwon (2010) reports a recent project to develop the National English Ability Test of Korea (NEAT) that assesses all four skills (listening, speaking, reading, writing), with the aim to improve South Korean students' English communicative competence and to promote positive washback on secondary school English education. Starting in 2012, some universities use the NEAT as supplement data for university admission, in addition to the current College Scholastic Aptitude Test (CSAT), which does not include speaking and writing sections. Kwon (2010) found that some secondary school teachers were opposed to the introduction of the NEAT and were concerned about scoring issues, practicality, schools' readiness, and cost. The teachers experienced the tests rather as a psychological burden and did not feel confident about conducting speaking and writing assessment in their own classes. They were also reluctant to participate in the NEAT speaking and writing assessments as raters.

The South Korean teachers' concerns about the NEAT are similar to those initially raised by HKSAR teachers when they were first introduced to the School-Based Assessment (SBA), a criterion-referenced assessment introduced in 2005 with the aim of influencing secondary school education positively (Cheng, Andrews, & Yu, 2010). The English SBA is a core component of the new Hong Kong Diploma of Secondary Education (HKDSE), the public examination taken by students at the end of secondary school, which replaced the Hong Kong Certificate of Education Examination (HKCEE) in 2012. The SBA requires significant teacher involvement at all stages of the assessment cycle, from planning the assessment

program to identifying and developing appropriate assessment tasks and assigning the final scores (Davison, 2007). It allows teachers to assess English oral language skills on the basis of topics, texts, and audiovisual materials chosen by students in their extensive reading program (Qian, 2008). Over the course of two years, students in Secondary 4 and 5 are assessed based on a set of criteria that addresses pronunciation and delivery, communication strategies, vocabulary and language patterns, and ideas and organization (Davison & Hamp-Lyons, 2010).

Considering that in most East Asian countries or regions, scores from classroom assessments are not used as part of college entrance examination, the SBA is both an innovation and a revolution. It is “a significant cultural and attitudinal change, not only for teachers but for the whole school community, including students and parents” (Davison, 2007, p. 49). The introduction of the SBA reflects the HKSAR government’s attempt to combine assessment *of* learning with assessment *for* learning (Cheng et al., 2010). Undoubtedly, such an innovation has its challenges. For teachers, the workload is heavy (Qian, 2008), and their limited training in the application of the criteria and standards as well as their individual attitudes and beliefs toward assessment may lead to problems (Davison & Hamp-Lyons, 2010). Also, it is difficult to equate all assessment results from different teachers and different schools fairly and accurately, especially because the SBA is highly contextualized (Davison, 2007) and students are assessed by their own teachers (Qian, 2008). Cheng et al. (2010) also report that, despite the formative nature of the SBA, students may view it as being similar to other external examinations—just another test to prepare for. Still, they found that parents can give strong support for the SBA, especially if they are well informed about it. Davison and Hamp-Lyons (2010) also report positive changes that have started to take root once teachers and parents have acquired a better understanding of the underlying assessment philosophy of the SBA, thanks to the take-home pamphlets and CD-ROMs, professional development support, school-based opportunities for discussion about students’ performances and the SBA process, and teachers’ increasing confidence as users of the SBA.

Thus, from the SBA example, it is clear that South Korean teachers will need in-service training, supporting materials, and time to adjust to the change that the NEAT will bring. The SBA case emphasizes that teacher and parental acceptance is the most crucial factor for an assessment reform to succeed.

English Tests for University Students and Beyond

The largest-scale English test for undergraduate students in East Asia (and in the world) has to be China’s College English Test (CET), which assesses whether non-English major college students have met the requirement of the National College English Teaching Syllabuses (Zheng & Cheng, 2008). The CET Bands 4 and 6 are criterion-related norm-referenced tests whose score “indicates students’ percentile position . . . in the norm group, which consists of over 10,000 college/university students from six top universities in China” (Cheng, 2008, p. 18). Although the CET-4 is no longer required by universities as a graduation requirement, university graduates typically use the certificate for help in finding jobs. The CET passing

rate is also regarded as one of the criteria by which to judge the prestige of a university. Reviewing research studies conducted in China on the CET, Cheng (2008) reports that, while the CET quality is recognized, most stakeholders are concerned about the use of students' performance on the CET to evaluate teachers. Overall, the CET has a complex social impact, and some stakeholders did not believe that the test could improve overall English teaching and learning at tertiary level in China (Han, Dai, & Yang, 2004, cited by Cheng, 2008).

In addition to the CET, China has the Test for English Majors (TEM), which assesses whether students have met the requirement of the National College Teaching Syllabus for English Majors (Jin & Fan, 2011). Chinese non-English major students wanting to enter graduate schools take the Graduate School Entrance English Examination (GSEEE) administered by the National Education Examinations Authority of the Chinese Ministry of Education (He, 2010; Q. Liu, 2010).

In other East Asian countries or regions, most college graduates are likely to take the IELTS, TOEFL, or TOEIC, depending on their future purposes. College graduates in HKSAR are encouraged to take the IELTS, especially after the HKSAR government launched the IELTS for the Common English Proficiency Assessment Scheme (CEPAS) to benchmark the English language proficiency of fresh university graduates in July 2002 (Qian, 2008, 2010). The IELTS is also popular in China, but recently the number of Chinese TOEFL iBT™ test takers has jumped dramatically and ETS now sees the largest number of Chinese test takers in history (Powell, 2012). The TOEFL has long been used for a variety of academic purposes in East Asia—especially Korea, where its tremendous popularity has sparked controversies (Choi, 2008).

The TOEIC is also used by some for academic purposes (Lee, Yoshizawa, & Shimabayashi, 2006), but it is best known in the world of work. Many major companies in Korea, Japan, and Taiwan accept the TOEIC as a proof of English proficiency for employment and promotion consideration (Honma & Takeshita, 2003). The advantage of the TOEIC is that it is an established test trusted by the general public, but despite its popularity the test has many drawbacks. First, the TOEIC only measures listening and reading in the multiple choice format, which encourages test takers to improve their test-taking strategies rather than genuine English proficiency (Shim & Baik, 2003). Although there is now another test called the TOEIC Speaking and Writing Test, that is a separate test, and test takers can still choose to take only the TOEIC Listening and Reading Test. Second, both the TOEIC and the TOEFL are seen by too many as encompassing all-purpose tests, which may compromise test validity (Choi, 2008). Many companies that use the TOEIC for decision making tend to overly rely on the test and lack the motivation to develop in-house assessment tools that may be more appropriate for their specific purposes (Chapman, 2005). Third, although the TOEIC claims to test English for international communication, Lowenberg has repeatedly pointed out that the test uses the native speaker norm, which may be unfair to test takers from other varieties of English (see, for example, Lowenberg, 2002). Even though the East Asian countries or regions belong to Kachru's "Expanding Circle" (Kachru, 1985, cited in Lowenberg, 2002), where English is used as a foreign language, in the 21st century it is no longer the case that East Asian students only learn the "Inner Circle" or traditional native speaker norm. International communication

certainly involves East Asian students communicating with speakers from the other “Expanding Circle” countries or regions as well as with speakers from the “Outer Circle” (those who speak English as a second language), and there is also more evidence of English being used *intranationally*, within each East Asian country or region. To sum up, although the TOEIC Speaking and Writing Test is a welcome addition, much research on the TOEIC validity and use in East Asia is still needed.

In addition to the tests, which can be taken at different stages of education, an East Asian person can also choose to take suites of domestic English proficiency tests designed to measure English learning throughout his or her lifespan. These tests are available to all learners, regardless of age, profession, or academic background; the levels go from junior high school English up to advanced. All four skills are assessed. The reading and listening are typically assessed through multiple choice questions, but the writing and speaking tasks vary across tests and proficiency levels. Tests that share this similar concept are the 5-level Public English Testing System (PETS) in China (J. Liu, 2010; Q. Liu, 2010), the 5-level General English Proficiency Test (GEPT) in Taiwan (Wu, 2012), and the 7-level Eiken Test in General English Proficiency or the STEP Eiken in Japan (Sasaki, 2008). These tests are supported by the authorities in their countries or regions: the PETS is developed and supported by the Chinese National Education Examinations Authority (NEEA), the GEPT is developed by the Language Testing and Training Center (LTTC) and supported by Taiwan’s Ministry of Education, and the STEP Eiken is developed by the Society for Testing English Proficiency, Inc. (STEP) and supported by the Japanese Ministry of Education, Culture, Sports, Science and Technology (MEXT). Developers of these tests do not specify how the test scores should be used. In fact, these tests are marketed as multifunctional and users can use the scores for many purposes (Q. Liu, 2010). Such freedom may make these tests sound flexible, but it actually leads to validity issues. Messick (1989, p. 13) describes validity as “an integrated evaluative judgment of the degree to which empirical evidence and theoretical rationales support the adequacy and appropriateness of inferences and actions based on test scores.” Thus there needs to be more validation research on these proficiency tests, as evidence needs to be gathered to support the inferences that are made from the scores for each specific use (American Educational Research Association, American Psychological Association, & National Council on Measurement in Education, 1999). Furthermore, developers of these proficiency tests, such as the GEPT and the STEP Eiken researchers, have started to align their tests to the Common European Framework of Reference (CEFR) (Dunlea & Matsudaira, 2009; Wu & Wu, 2010). This is definitely a new research area, not only because of the complex research methodology but also because of the unclear rationale behind the need to link tests made by East Asian test developers for East Asian test takers with the CEFR.

The Role of Cram Schools

In East Asia, test preparation institutes, or cram schools, make up a massive enterprise (Ross, 2008). They play an essential part in education, as learners of all ages line up for the different types of cram schools, which are geared toward their

specific needs. Unfortunately, due to access issues, empirical research conducted in cram schools is hard to achieve. From the language-testing perspectives, the kind of instructions provided by cram school teachers may threaten the validity of test scores. For the multiple choice questions, the right answers selected by the students may result from test-wiseness drilled at cram schools rather than reflecting their real ability. Meanwhile, model responses and formulae provided by the cram schools also undermine the validity of the scores obtained from tests designed to measure students' impromptu writing or speaking ability rather than memorization (He, 2010).

Still, despite the complications caused by cram schools, they will never disappear from East Asia as long as there are still tests. Thus it is perhaps wiser for testers to find how to maximize the benefits of their existence. For example, in a study conducted on a TOEIC preparation course at a Japanese university, Robb and Ercanbrack (1999) found that TOEIC preparation materials may help increase the students' reading component scores. Although the study as such was not conducted in cram schools, most cram schools are known to produce extensive test preparation materials. Language-testing researchers can examine those materials in order to obtain a better understanding of how the test constructs are interpreted by the preparation material writers and what test-taking skills are taught. High stakes tests can also be redesigned, so that there is less dependence on the multiple choice format and more use of complicated performance-based tasks, such as the integrated tasks in the new TOEFL iBT. Such a change may force cram schools to start teaching "English" instead of just increasing students' test-wiseness, and this in turn would facilitate test score validity rather than hinder it. Of course, only empirical research can confirm this hypothesis.

Conclusion

Living in a meritocratic system, an East Asian person has to take English tests throughout his or her life. Given the inevitable washback effects, it is up to language testers across East Asia to bring positive changes through their tests. The introduction of the SBA and the NEAT and the multiple paths to college admission shows that traditional concepts of assessment are being challenged. However, in these Confucian heritage cultures, examinations are still valued as the fairest way to make decisions (Davison & Hamp-Lyons, 2010). Convincing the general public to accept alternative assessments that are viewed as being more subjective definitely poses a challenge. For adult test takers, Qian (2010) calls for more research on the relations of the IELTS and TOEFL and academic outcomes. The same can be said about the TOEIC and job performance. The role that cram schools play in test performance is also worth further investigation (see Kwok, 2004). More work like the articles included in special journal issues such as *Language Testing*, Volume 25, Issue 1 ("Language Testing in Asia"), *Language Assessment Quarterly*, Volume 9, Issue 1 ("EFL Testing in Taiwan"), and in books such as Cheng and Curtis (2010) is needed from language testers across East Asia—who have much in common indeed.

Acknowledgments

The author would like to express her sincere gratitude to the following individuals, without whose help this chapter would not have been possible (in alphabetical order): Liying Cheng, Yo In'nami, Rie Koizumi, Antony Kunnan, Oryang Kwon, and the two anonymous reviewers of this chapter. The author also thanks Yasuyo Sawaki and Akiyo Hirai for their helpful comments.

Assessing English in Southeast Asia

Richard Watson Todd

King Mongkut's University of Technology Thonburi, Thailand

Chih-Min Shih

Nanyang Technological University, Singapore

Introduction

Southeast Asia, officially organized into the Association of Southeast Asian Nations (ASEAN), comprises 10 countries: Singapore, the Philippines, Malaysia, Brunei, Myanmar, Laos, Cambodia, Vietnam, Indonesia, and Thailand. For the first four of these countries, English is an official language or a de facto language for certain purposes and is widely used. These countries, then, fall into Kachru's (1998) Outer Circle. In the other six countries, which fall into the Expanding Circle, English is a foreign language and exposure to the language outside the education system may be limited. These differences in the role of English are reflected in English test scores by nationals of the various countries. The ETS (2009) scores for the TOEFL® iBT show Singapore (scoring 99), Malaysia (88), and the Philippines (88) all scoring higher than the Expanding Circle countries (Myanmar: 70; Laos: 60; Cambodia: 68; Vietnam: 70; Indonesia: 79; Thailand: 74; there are no TOEFL iBT scores for Brunei). These figures need to be treated with caution as they are derived from a relatively small sample of possibly unrepresentative learners from each country, namely, those planning to study abroad. Nevertheless, other figures support this distinction between Outer and Expanding Circle countries. The Education First English Proficiency Index scores (Education First, 2011) are available for four of the countries; Malaysia as a country in the Outer Circle is rated as having high English proficiency, whereas the Expanding Circle countries—Indonesia, Vietnam, and Thailand—all have very low English proficiency. It would therefore appear that the roles of and proficiency levels in English in ASEAN fall into two main groups by country. To provide an overview of English language assessment in Southeast Asia, therefore, rather than looking at assessment practices in all 10 countries, we will examine assessment practices in depth in two countries, namely, Thailand and Singapore, as exemplars of the groups of countries. Given that English is a foreign

language in Thailand but for many Singaporeans it is a first language, we should expect some differences in assessment practices. However, as both countries are members of ASEAN, there may also be some similarities. We will also provide an overview of assessment practices in a further three countries to see whether patterns identified in the two exemplar countries apply in these countries.

English Language Assessment in Thailand

Assessment and testing are major issues of concern in Thai education. Of the 75 news articles about education in the *Bangkok Post* in 2009 and 2010, 34 (45%) concerned assessment. The majority of these concern conflicts between emphasizing validity or reliability in national assessment practices and have implications for the assessment of English, since the language is a required subject in national education tests taken at grades 6, 9, and 12 and in the separate university entrance exam.

At the highest level of policy, educational assessment in Thailand is fairly progressive. The National Education Act of 1999 (Office of the National Education Commission, 1999), which guides Thai educational decision making, promotes learner-centered education and, in Section 26, addresses assessment:

Educational institutions shall assess learners' performance through observation of their development; personal conduct; learning behaviour; participation in activities and results of the tests accompanying the teaching-learning process commensurate with the different levels and types of education. Educational institutions shall use a variety of methods for providing opportunities for further education and shall also take into consideration results of the assessment of the learners' performance.

Such ideals, however, bear little relationship to educational practice. The continuous assessment practices suggested in the act are rarely used, especially in high stakes evaluation, with most assessment taking the form of multiple choice tests. This is best illustrated by the university entrance exam, the most influential assessment in the country. The importance of the entrance exam is highlighted in a survey of the problems faced by 156 secondary school English teachers (Thongsri, Charumane, & Chatupote, 2006). Problems identified included the lack of community support for learning English, students' low ability, large class size, extra work, and insufficient teaching aids. Despite the apparent potential seriousness of these problems, the problem rated as most serious by a very wide margin was the influence of the university entrance examination.

The national university entrance exam system started in 1967, using exams consisting exclusively of multiple choice items as the sole criterion for selecting candidates for university. By the late 1990s, pressure to change this system came to a head. In 1998, the exclusive reliance on exam scores stopped as marks from secondary school performance were included for the first time. Initially, secondary school scores accounted for only 10% of the overall entrance exam mark with plans to increase this to 70% eventually, prompted by a Ministry of Education desire to encourage secondary school students to pay more attention to their

studies and to reduce the influence of multiple choice testing. This was deemed important since the school English curriculum emphasizes communication, places an equal weight on each of the four skills, and also covers nonlanguage objectives such as cultural issues. Many of these goals are not clearly amenable to multiple choice testing. In the following years, the proportion of the overall mark from secondary school performance increased, albeit more slowly than originally planned, to a maximum of 30%, as the Council of University Rectors resisted its inclusion in university entrance on the basis that such scores were unreliable.

Further changes were made in 2006. Scoring on the entrance exam became norm-referenced by converting raw scores into *T* scores, and the exams included an open-ended section (a short essay for the English exam) in addition to multiple choice items. Following a marking fiasco and with most students not writing anything for the essay, the open-ended item was dropped in 2007.

With the dropping of the essay and the capping of secondary school scores at 30%, one of the supposed reasons behind the changes to the entrance system—the need to reduce the influence of multiple-choice testing in Thailand—seems unattainable. In fact, the impact of multiple choice is even larger than it appears since secondary school scores are also reliant on multiple choice. A survey of English assessment practices at 78 secondary schools throughout Thailand (Piboonkanarax, 2007) found that exams, comprising 90% multiple choice, account for 60% of overall secondary school scores on average. Other forms of assessment promoted by the National Education Act are far less important (portfolio assessment accounting for 5% on average, and classroom participation for 7%). Overall, multiple choice testing is the source of around half of all the secondary school scores and thus around 85% of all input for university entrance.

The university entrance system, and especially its heavy emphasis on multiple choice testing, has wide-ranging negative washback effects on Thai education. These effects are exacerbated since the university entrance exam is used as a model for other exam designs. This can be seen most clearly when we look at evaluations conducted in 2006, the year when the entrance exam included an essay question. The university entrance exams take place in February or March. In the following semester, many secondary schools included an essay component in their mid-term exams in July, mirroring the format of the university entrance exam. In August, the decision to drop the essay from the entrance exam was announced. In the school final exams in September, most of the schools which had previously included an essay reverted to pure multiple choice (Watson Todd, 2008).

Reported washback effects from multiple choice testing include the promotion of rote learning of simplistic, nontransferable knowledge rather than complex skills and encouraging students to be knowledge seekers, not understanding seekers. For English, an emphasis on multiple choice also means the prioritizing of reading over the productive skills. These effects are readily apparent in Thai education to the extent that students may demand that teaching be restricted to knowledge of grammar and vocabulary (Watson Todd, 2008). Such restrictions on content taught are even more apparent in the massive tutorial school system which aims to prepare students for the exam and which many parents perceive as essential if their children are to pass the exam. The high costs of these tutorial schools reinforce inequalities in access to higher education.

Given these negative impacts, why is multiple choice testing still the norm in English language assessment in Thailand? With hundreds of thousands of students taking the university entrance exam each year, practicality is clearly an issue, and multiple choice tests are very practical. Reliability is also high, and is the reason why the Council of University Rectors prefers exams over high school grades for university entrance. This argument in favor of using exams for university entrance, however, is problematic when we examine their predictive validity. For example, Patharakorn (1998) found that academic scores from secondary schools were better predictors of performance at university than the entrance exam. Recent reported scores from the exam also suggest major problems. For the 2011 entrance, students scored an average of 19.22% for English (*Bangkok Post*, 2011), an abysmal score, especially considering that all items are four-point multiple choice. With many secondary school teachers devoting time to teaching for the exam, the very low average score suggests that the target proficiency level of the exam is set unrealistically high and that the exam cannot discriminate among the majority of test takers.

For work-based assessment of English, there are few locally made exams that are widely known and accepted. Thus, most assessment outside of the mainstream education system relies on limited versions of the Test of English as a Foreign Language (TOEFL) or the Test of English for International Communication (TOEIC®), or on local exams, such as the Chulalongkorn University Test of English Proficiency (CU-TEP), which is based on the multiple choice sections of the TOEFL. The single main exception to this pattern is the Test of English for Thai Engineers and Technologists, a four-skills test using a wide range of item types (see Maneekhao, Jaturapitakkul, Watson Todd, & Tepsuriwong, 2006). Nevertheless, multiple choice tests are still the most common approach to work-based assessment of English in Thailand.

To summarize, English language education in Thailand is dominated by multiple choice testing, largely driven by the format of the university entrance exam. With the washback effects of promoting knowledge of grammar and vocabulary and with little exposure to English outside the classroom, the situation does not bode well for the future of English learning in the country.

English Language Assessment in Singapore

As in many Asian countries, Singapore has a very test-oriented education system which values meritocracy (Albright & Kramer-Dahl, 2009). Authorities, such as the director of the Planning Division at the Singapore Ministry of Education, argue that using high stakes testing as the basis for decision making promotes a meritocratic environment conducive to social mobility (Yang, 2011). In Singapore, such high stakes testing starts early with final-year primary school students taking the Primary School Leaving Examination (PSLE) for placement into six-year integrated programs and the three main streams of secondary schooling (express, normal academic, normal technical). Similarly, at the end of secondary study (the number of years in part depending on the stream selection from the PSLE), students take one of a selection of high stakes tests depending on their track and intended goal for entry to junior college or polytechnic, and again at the end of

junior college, students take the GCE Advanced-level examination for placement into university. Studying in the education system in Singapore, therefore, involves regularly taking high stakes tests that determine one's future.

Unlike Thailand where multiple choice questions are predominant, open-ended test items are widely used in high stakes tests in Singapore. For example, the GCE Advanced-level examination requires test takers to write an essay and to respond to reading passages through short answer questions and a summary, while the PSLE includes a conversation as part of the oral test. Even with open-ended assessment predominant, the high stakes tests have a deleterious impact on teaching (Koh, Gong, & Lye, 2007). Cheah (1998) argued that the examination culture in Singapore hampered the implementation of innovative teaching practices, while Albright and Kramer-Dahl (2009) point out that the high stakes tests discourage teachers in Singapore from guiding students to read critically.

Recently, however, English language assessment in Singapore has become more diverse with the introduction of holistic assessment in primary schools. In 2008, the Primary Education Review and Implementation (PERI) committee was formed to recommend initiatives to improve primary school education. One of the main recommendations was the implementation of holistic assessment in all subjects, including English. Holistic assessment is "the ongoing gathering of information on different facets of a child from various sources, with the aim of providing quantitative and qualitative feedback to support and guide the child's development" (Lee, 2010, p. 10).

A key rationale for the introduction of holistic assessment is to discourage schools from depending strongly on examinations (Ministry of Education, 2011). The introduction of holistic assessment has four key aims: to develop the whole child, to strike a balance between assessment of learning and assessment for learning, to inform teachers about their practice, and to adopt appropriate assessment approaches (Lee, 2010). Thus, in contrast to previous practices where all assessments were graded to check for mastery of learning, holistic assessment promotes the use of assessment for feedback on performance in addition to grading mastery. For English language assessment, the "bite-sized forms of assessment" used in holistic assessment (Ministry of Education, 2009, p. 35) could include dramatization, role play and show-and-tell activities to develop confidence and presentation skills with students using indicators for self- and peer assessment and receiving individualized feedback on their performance (Fu, 2010).

A further rationale for the introduction of holistic assessment is the promotion of more engaging teaching methods in primary schools, suggesting that the innovation is expected to have positive washback effects on the teaching and learning process. The Ministry of Education (2010) has published a preliminary collection of teachers' responses to the introduction of holistic assessment which includes reports that the innovation "empowered teachers and motivated students" (p. 7), and that students become more aware of their strengths and weaknesses and more willing to accept classmates' suggestions. However, it is unclear whether such reports reflect widespread washback effects from holistic assessment, since studies of other assessment practices in Asia have shown that intended washback effects are not necessarily achieved (e.g., Shih, 2007).

Although holistic assessment will play a key role in primary school education in Singapore, it should be stressed that it will be restricted to within-school

assessment and is not intended to replace the use of PSLE. While promoting more formative, continuous assessment in schools, the PERI committee acknowledged that such assessment cannot be used for high stakes placement of students at the end of their primary school education (Ministry of Education, 2009). Thus, although assessment at local primary schools will become more diverse, for high stakes purposes examinations will remain the norm.

In comparison with Thailand, there is less English language assessment outside of the education system in Singapore. Because Singaporeans are now educated in English and with many younger Singaporeans speaking English as a first language, tests of English for professional or workplace purposes are relatively rare.

English Language Assessment in Other ASEAN Countries

In the other ASEAN countries where English is a foreign language, the English language assessment system is similar to that of Thailand in many ways. For example, in Indonesia, where English is a compulsory subject at secondary schools and where it is typically taught for four hours a week, there are national level exams at the completion of both lower and upper secondary schooling and again for university entrance. All of these exams are primarily multiple choice. While school-based assessments may include elements of continuous assessment through classroom observation and homework assignments, summative final exams, again predominantly multiple choice, typically account for the majority of assessment of English.

Similarly, Vietnam is another country where exams, which often consist largely of multiple choice items, dominate English language assessment. English is typically taught from year 3 of primary school and so is included in school-based exams (typically accounting for 60–70% of school-based assessment) and in exams for finishing primary, lower secondary, and upper secondary schooling. However, English is only taken as part of the university entrance exams for those candidates applying for related subjects. At the end of undergraduate study there is a nationwide system of assessment of English for graduation, the so-called B-level exam. Again, the B-level exam is primarily multiple choice for testing listening, grammar, and reading, but it includes an essay component for testing writing. Until recently, this exam was also used by companies as a measure of English proficiency when employing university graduates, but concerns about its reliability have led to other exams, such as the TOEIC, taking over this role.

In line with the English as a foreign language ASEAN countries, high stakes exams play a central role in those ASEAN countries where English is an official or de facto language, but these exams are generally far less reliant on multiple choice testing. In Malaysia, the re-emphasis on English in the 1990s, after a period when Bahasa Malaysia was promoted in education, means that it is a compulsory subject in schools, with most students receiving 11 years of English at around 3.5 hours a week and with math and science subjects also taught through English at many schools. National level exams in English occur on completion of primary schooling, lower secondary schooling, and upper secondary schooling as well as being emphasized in university entrance. There is some flexibility and open-endedness in these exams. For instance, the assessment at the end of lower

secondary schooling allows speaking skills to be measured through continuous assessment. In addition, on the Malaysian University Entrance Test (MUET), while listening and reading are mainly tested through multiple choice items, the reading assessment also involves cloze and information transfer, the writing assessment uses essays and summary writing, and the speaking assessment requires presentations and discussions. The MUET, then, is likely to provide a better picture of all-round English proficiency than, say, the exclusively multiple choice university entrance exam in Thailand, although it has been criticized for ignoring social perspectives on literacy and for having dubious predictive validity. While the national level exams in Malaysia use British English as a model, there is some evidence that the use of Malaysian English varieties is accepted in school-based tests of English (Davies, Hamp-Lyons, & Kemp, 2003).

Conclusion

ASEAN countries (with the exception of Cambodia) place a heavy emphasis on national level examinations in their education systems, and school-based initiatives in assessment have a minor impact. There are, however, key differences in the forms the English language examinations take, which may reflect the general levels of English proficiency in the two countries. In Thailand, where overall English proficiency is rated very low, multiple choice testing dominates, leading to a focus on language knowledge at the expense of language use, a pattern also predominant in the other ASEAN countries with low general proficiency levels. In Singapore and other ASEAN countries with a high general English proficiency, the open-ended items used in the examinations primarily assess language use, a goal which we believe can also be promoted in the move toward holistic assessment. The general pattern between countries appears to be that the more English is used and the higher the general level of proficiency, the greater the reliance on open-ended assessment. In terms of English language assessment, then, Southeast Asia is a region with differences and commonalities depending on the level of English proficiency present in each country.

Assessing English in South America

Matilde Scaramucci

University of Campinas, Brazil

Adriana Boffi

University of La Plata, Argentina

Introduction

This chapter presents a brief state-of-the-art description of ESL/EFL (English as a second language / English as a foreign language) assessment in South America, placing special focus on Brazil and Argentina and taking into consideration the goals and approaches at each of the levels of the educational systems. Interest in assessment research is relatively recent, most studies being concentrated in a few Brazilian universities (Scaramucci, 1990; Belam, 2004; Barata, 2006; Araújo, 2007; Cavalari, 2009; Duboc, 2010—among others).

The first section of the chapter focuses on the status of the English language, with a view to contextualizing teaching and assessment practices. Despite some differences, there are also similarities regarding the status of the language and the culture of teaching, learning, and assessing foreign languages. The aims of ELT vary greatly across the region, and so do approaches and means of assessment. These are presented before the assessment practices are discussed in greater detail. We then proceed to challenges, and we end with a look at future directions.

Description of Language Policy

In Brazil, the Law of Directives and Bases of National Education (LDB) (9394/1996) and the National Curriculum Parameters (NCPs) state that at least one foreign language is compulsory from primary education on and throughout secondary education. There is no explicit reference to English. Starting in 2010, when Law 11.161 of August 5, 2005 came into effect, Spanish became mandatory in secondary education for public and private schools. Although an explicit policy values the possibility of choosing other languages, an implicit policy revealed by educational

practices in Brazil clearly favors English and Spanish (Ribeiro da Silva, 2011), because these are the most important foreign languages from an economic and geopolitical perspective.

In Argentina, the Law of National Education (Ministry of Education, Argentina, 2006) also prescribes that “teaching at least one foreign language will be compulsory in all primary and secondary schools” (p. 3). In practice, English is the first choice (Rivas, 2007). For the vast majority of people in the Southern cone, English is a foreign language—a school subject—and there is little interest in certification beyond the testing required by schools. Conversely, when it comes the work and study domains as defined by ALTE (Association of Language Testers in Europe), assessment choices reveal in large numbers a perception of English as a second, international, or even first language. To the largely assimilated Anglo-Argentine community, English is the home language (McArthur, 1998).

Other countries in the region show some local differences. In 2005 Colombia launched the programme “Bogotá and Cundimarca Bilingües” with the aim of setting comparable standards in Spanish and English, in order to develop teaching and assessment programmes within and beyond the school system and to provide students as well as citizens with certification for the study and work domains. In 2006 the Colombian government proposed long-term goals for the “improvement of English language skills for the whole population as a means to improve the country’s competitiveness in the global market” (Gómez Montes, Marino, & Pike, 2010).

The Uruguayan Education Law (Law 18437/2008, Art. 40: 5) states that second and foreign language teaching should aim at a plurilingual education. Portuguese has a special status, as it is the mother tongue of a significant proportion of the population, especially at the border with Brazil. English is the most widespread foreign language due to its status as an international *lingua franca*.

Such complexity in the scope and range of situations produces differences in the way in which English is taught and, consequently, assessed.

Teaching–Learning Contexts

In this section we shall concentrate on schools in the official education network in Brazil and Argentina. In Brazil, English is taught from the fifth to the ninth grade in primary education and, in secondary education, in private and public schools. In public schools English is optional from grade 1 to grade 4. Teaching is informed by the NCPs, which are recognized as a “politically avant-garde” document (Rocha, 2010), and English is considered a school subject. Despite the prestige that English enjoys as the dominant foreign language of science and technology and for its role in accessing prestigious jobs and positions in society, ELT has been generally poor, especially in public schools. As a result, the levels of proficiency attained are often very low. In this context it should be said that there is a belief, shared by many teachers as well as by students, that “it is impossible to learn English at school” (Scaramucci, 2000).

A number of unfavorable conditions in the public school system have been blamed for this situation: too many students per class, unmotivated teachers and

students, poor working conditions, low salaries. Teaching is usually dictated by ready-made materials. There is little variation or innovation. There is prevalence of a grammar-oriented approach and lack of clearly formulated learning and proficiency goals. Teachers are poorly prepared and their levels of language proficiency are often insufficient for communication or for conducting classes in English.

Whereas in primary education the focus is on teaching word lists and grammar rules, or common verbs and prepositions with “fill in the blanks” and multiple choice exercises, in secondary education reading prevails, being still treated in most cases as a decoding process. Reading is justified by the need for students to read technical literature at university, and consequently it is present in most university entrance exams. Therefore at these two levels the formative role of a foreign language—regarded as an opportunity to understand one’s own language and culture, as suggested by official documents—is not achieved.

In private schools, which have greater awareness of the importance of English for travel and study, ELT starts early on in primary education, or even before that, thus “intensifying social differences” (Rocha, 2010). Many of the youngsters instructed there take additional English classes at private language institutes, which are regarded as an ideal environment for learning English as the language for international communication in a globalized world. Teaching in private institutes is more communication-based, less grammar-centered. Some schools go as far as to outsource their English courses, by hiring the services of private language institutes.

In the past few years, with the expansion of the Brazilian economy and the consequent increase of the population’s buying power, the possibility of traveling abroad for leisure and study has increased, prompting the advent of prestigious bilingual schools. Some regular schools also offer an optional bilingual curriculum that is valued by the elites.

At universities, both public and private, English teaching is generally approached with a focus on reading comprehension. With the advent of the Internet and the recent internationalization trend in Brazilian universities, the scope of teaching has been expanded to speaking and writing skills. English is also present in corporations, as a requirement for jobs and career advancement. This is an important context for certifications, as will be discussed later in this chapter.

The training of English teachers and translators takes place in both public and private universities. In the latter, with a few exceptions, degree courses generally last three years—not enough for proper development, considering that most students enter the program with elementary levels of proficiency. These poorly prepared teachers will generally end up working in public schools, thus feeding a vicious cycle of failure.

In Argentina, the first record of EFL in the public school system dates back to 1827 (Rivas, 2007). English has been taught nationwide in secondary schools since the 1960s and in primary schools since the 1990s, starting in the third grade or earlier. The aims of English teaching across Argentina also vary. In the public school system, some provinces emphasize the usefulness of the language for international communication in a globalized world, thus showing an instrumental motivation. Others aim at opening up “windows” into other cultures. A third

perspective, which does not exclude either of the previous approaches, conceives of a second language as an alternative way of expressing one's own identity, with emphasis on an intercultural approach.

In the private sector, the English Speaking Scholastic Association of the River Plate (ESSARP) is an association of 180 private schools, most of them located in Argentina and a few in Uruguay. These are bilingual schools, defined by the Association as schools that teach subjects in English rather than (or in addition to) English as a subject, regardless of the number of subjects that are actually taught in English and of the range of exams taken by students. In practice, this means there is a wide range of scenarios, from ESL teaching to full bilingual education, as defined by García (2009). Eighteen public secondary schools in the Buenos Aires province have recently incorporated a content and language integrated learning (CLIL) approach in the last two years.

Teacher preparation courses of four to five years are offered both by public and by private universities in education programs. Although many of these institutions have a century-old tradition of quality teaching, the high demand for teachers results in many underqualified ones working in schools, and this has a negative impact on students' learning.

Assessment Practices

As expected, assessment practices in Brazilian public schools are not distinguished from the traditional teaching practices characterized earlier in this paper. Although official documents and research stress the importance of process-oriented, formative, and diagnostic assessments, what has been observed is product-oriented, summative, and classificatory assessments, conducted through discrete-point items in paper and pencil language knowledge tests; these resort to methods such as "fill in the blanks" and multiple choice, in which the students' performance is assessed through wrong and right answers (Rolim, 1998) that aim exclusively at students' promotion. The lack of more innovative and formative proposals reveals the poor training of teachers and their insufficient knowledge of assessment (Scaramucci, 2006).

One of the greatest problems observed is the lack of explicit planning, with clearly formulated learning goals that can be revisited at assessment. In contexts such as secondary education, in which written comprehension is present, approaches are often limited to assessing reading through comprehension questions based on locating information within the text. This is also true for listening comprehension: in the few contexts in which this skill is focalized, there is no effective teaching of meaning construction strategies. Assessment depends on teachers, since there are no standards or criteria established by the school or official documents. Schools only control the number of assessments during the school year, which is determined by a fixed exam calendar.

In private schools, despite a more communicative teaching approach, traditional practices are often used to assess vocabulary and content that are determined by the textbook or by materials prepared by the school. There are no explicit criteria to assess speaking performance, which makes this assessment subjective.

In private language institutes assessments are a part of teaching materials. Speaking exams and focus on writing are generally used at more advanced levels. In both public and private universities, professors are responsible for assessment practices and design their own assessment tools.

In order to associate prestigious international exams with their own English teaching (Ribeiro da Silva, 2011), upscale private schools in Brazil have been implementing international English exams like KET (Key English Test), PET (Preliminary English Test), FCE (First Certificate in English), and CAE (Certificate in Advanced English)—lately KET and FCE for Schools—a modality exclusively geared to the educational context, with topics designed for this target audience. Another exam that targets the same audience is Test of English as a Foreign Language (TOEFL) Junior, developed by the Educational Testing Service.

As there is no official national evaluation of foreign languages in either Argentina or Brazil, for most students international examinations are the first opportunity for external assessment. This is in fact as motivating as the recognition of certificates by universities in English-speaking countries, which is beyond the interests and means of most school leavers.

For teachers, there is the appeal of getting involved in the assessment process of some international exams, either by contributing with internal assessment or by becoming an international examiner and thus benefiting from professional advancement and a feeling of empowerment from submitting to an international quality control process.

Along with these impacts, which can be regarded as positive, we could not refrain from mentioning our concerns about the fact that preparatory courses for these exams are being integrated in the curriculum of some private schools without an in-depth analysis of the exams' goals and constructs vis-à-vis the teaching provided and, therefore, of implications for the training of the students involved.

In a discussion of assessment in Brazil it should be mentioned that university entrance examinations (referred to as *vestibulares*, in Portuguese), which have a long tradition in the Brazilian educational system and a hold over secondary school and society, assess general English and, more recently, also Spanish (Avelar, 2001; Souza, 2002; Bartholomeu, 2002; Correia, 2003; Retorta, 2007). Although each university decides on the nature of the exam and on its specifications and guidelines, exams are generally multiple choice, featuring either decontextualized "fill in the blanks" items of grammar or reading comprehension and prompting a typical "teaching to the test" situation. Cramming courses proliferate across the entire country, especially in public universities, which are generally high-ranking universities. Few exams, such as that of Universidade de Campinas, use open-ended items to assess reading comprehension, in this case with questions and answers written in Portuguese.

The strongest external examination board in both countries is the University of Cambridge ESOL (English for speakers of other languages) Examinations, with 23 centers in Argentina and 50 in Brazil. All of them offer tests for young learners (YLE) for children aged 7–12, and also main suite general English exams at five Common European Framework of Reference for Languages (CEFR) levels and business English certificates at three CEFR levels. Some offer specialized exams: International English Language Testing System (IELTS), International Legal

English Certificate (ILEC), International Certificate in Financial English (ICFE), and Teaching Knowledge Test (TKT).

The range of US American international examinations includes TOEFL—namely PBT (paper-based test) and iBT (Internet-based test)—Test of English for International Communication (TOEIC), Early Childhood Care and Education (ECCE), Graduate Management Admission Council (GMAT), Graduate Record Examination (GRE), and Scholastic Assessment Test (SAT). In Argentina all exams are conducted by ICANA (Instituto Cultural Argentino–Norteamericano) in Buenos Aires and by local branches in large Argentinean cities, and in Brazil by 22 different institutions in large cities and capitals.

Some exams, including TOEFL and IELTS, have also been used as a requirement for selective processes in graduate programs (master's and doctorate), as proof of academic reading in Brazil. Some of these programs therefore waive the right of assessing their candidates, leaving this responsibility to international exams or to national companies that are beginning to develop exams for this context (Lanzoni, 2004), even if these are absolutely different constructs.

The same international certificates, including TOEIC, are also used by the corporate sector for purposes of selection to jobs or career advancement, regardless of the actual communicative needs of employees or of whether they have been designed for these contexts or not (Kobayashi, 2010).

In Argentina (but not in Brazil), many universities offer EFL certification for young adults and adults. These are conceptually linked to the CEFR. The City of Buenos Aires offers certification in French, English, German, Italian, and Portuguese as a foreign language to primary and secondary school students. This certification is awarded to almost 10,000 children and adolescents annually, and over 50% of the certificates are in English.

All students from ESSARP schools in Argentina take a range of International General Certificate of Secondary Education (IGCSE) exams in English as a first, second, or foreign language. At the time of choosing an exam, there does not seem to be any conflict among these apparently conflicting approaches to teaching. Many ESSARP schools also expect their students to sit for ESOL exams, and a few (around 10%) will set the International Baccalaureate (IB) Diploma as a school-leaving target. There are 48 IB World Schools in Argentina offering one or more of the three IB programs, a number that, in Latin America, is second only to that of Mexico. Most of these schools are private, but a few are public. Although some schools offer the IB Diploma in Spanish, all of them offer the certification in English. Examination boards support schools and teachers by regularly holding academic and teacher development seminars and professional events.

In Brazil there is no long tradition of external national exams. The first of them, known as ENEM (National Survey of Secondary Education), whose initial goal was to assess the quality of secondary education at schools, dates back to 1998. It has recently been reformulated, doubling its role as an entrance examination so as to select candidates for universities, especially federal universities. Only after 2010, however, did the exam incorporate a foreign language exam, in which candidates can choose between Spanish or English.

Two other developments have characterized the context of external English language exams in Brazil in the past few years, and both are worthy of mention.

One of them is the academic discussion around the definition of a construct for the preparation of a proficiency exam for English teachers (Consolo, 2004; Martins, 2005; Quevedo-Camargo, 2011). The other is the development and validation of proficiency exams for Brazilian air traffic controllers (EPLIS or Exame de Proficiência em Língua Inglesa do Sisceab) and pilots (Santos Dumont English Assessment), as determined by the International Civil Aviation Organization (ICAO). In all three cases, exams have been regarded as mechanisms designed to increase these professionals' levels of proficiency.

In Chile the interest in assessing results in ELT in the school sector, both public and private, led to a nationwide assessment project conducted by Cambridge ESOL and to a programme initially called "English Opens Doors," now "Languages Open Doors," which aims at giving access to English and other languages to all schoolchildren and at matching learning objectives with international benchmarks.

The national assessments body (SIMCE: Sistema de Medición de la Calidad de la Educación) provides national tests and access to international tests in a range of subjects, including English. In 2010, with the support of the English Testing System, secondary school students were assessed in reading and listening comprehension. Results are published on the Web site and students who performed satisfactorily were awarded certificates. The Ministry of Education expects secondary school students to reach ALTE level 2 (CEFR B1) by 2016.

In Colombia the Ministry of Education started a certification program initiative in collaboration with Cambridge ESOL and the British Council. Today Colombia has the local capacity to cater for around 1 million students per year. The overall aim is set for 2019. It is expected that last year's high school students should reach CEFR level B1 and all teachers in basic and intermediate should reach CEFR level B2. It is also expected that the business and service sectors should significantly increase their bilingual literacy.

In 2009 the Ministry of Education designed a bilingual programme for universities in the expectation that, by 2019, most graduates will be proficient in English at level B2 and teacher trainees at level C1.

Challenges

There are great challenges for the democratization of quality English teaching, and the role of assessment is vital in this process. More democratic access to certification will ensure that English proficiency, while preserving its added value for the obtainment of job positions in international business and for job promotions, does not become a mechanism of exclusion. Access to resources for an increasingly interconnected world should be a right of all citizens—and so should certification, as an end product of education. In fact the latest reform of the Education Law in Argentina emphasizes education as a citizen's right rather than as an obligation. For García (2009, p. 6), "Language teaching programs in the twenty-first century [should] increasingly integrate language and content, therefore coming to resemble bilingual education."

In this changing scenario, language assessment will probably not stand alone. There will be a need to diversify the ways of testing content as well as language and to ensure comparability of standards across different specifications, subjects, and qualification types.

Publications in Brazil over the past few years have shown that one of the greatest handicaps to improving the quality of our English language teaching, especially in public schools, is the poor training of teachers, in terms of both their levels of proficiency and their competencies. This involves mainly a need to reassess the view of language that serves as a foundation for their teaching practices and for their knowledge and practices on assessment (Scaramucci, 2006). Teachers are also faced with the challenge of an intercultural approach to teaching vis-à-vis international standards. The impact of technology as a means of access to language exposure creates expectations of greater flexibility amongst students, which are not necessarily shared by their teachers.

Both Argentina and Brazil are norm-dependent, as assessment is invariably conducted according to native speaker norms. Understanding the notion of proficiency as a relative concept, and not necessarily as a value defined on the basis of the proficiency of native speakers (Scaramucci, 2000), is yet another challenge on the way to establishing more realistic goals.

ELT faces the challenge of a growing interest in other foreign languages (Graddol, 2006). In Argentina and Brazil, Spanish and Portuguese have gained the status of either an alternative to English or a second foreign language. It is envisaged, and even hoped, that the region will become bilingual in Spanish and Portuguese.

Future Directions

In order to overcome the challenges identified above, we believe it is essential to:

- raise teachers' awareness of the role and power of assessment in general practices, especially in teaching-learning processes and in processes that increase their assessment literacy;
- raise awareness, among local examination boards, about the importance of conducting validation processes that ensure that inferences drawn from the results of the exams under their control are valid, adequate, and reliable;
- implement measures that aim to increase the level of proficiency among teachers and the quality of their training, especially in relation to assessment literacy;
- increase research on assessment at universities, especially in connection with the validity and consequences of exams for English teaching-learning practices (washback) and for society at large (impact).

Assessing English in Europe

Gad S. Lim

University of Cambridge ESOL Examinations, England

Introduction

A number of factors have converged to make Europe a locus of developments in language teaching and assessment in our time. The continent is a compact conglomeration of states, most of which have decided upon union for political and economic reasons, but whose citizens speak many different languages, creating the need for a lingua franca. This reality required new approaches to language learning, teaching, and assessment whose goal was not formal knowledge but communication. This reality also meant that political institutions were in place to promote required developments. Finally, the reality of our historic moment made it inevitable that, desired or not, and the designation of other official languages notwithstanding, the European lingua franca would be and is English.

Teaching–Learning Contexts

A major influence on the learning, teaching, and assessment of languages in the continent at present is the Common European Framework of Reference for Languages (CEFR), produced by the Council of Europe (2001) to provide “a common basis for the elaboration of language syllabuses, curriculum guidelines, examinations, textbooks, etc. across Europe” (p. 1). The framework divides language ability into six levels—A1 and A2 for basic users, B1 and B2 for independent users, and C1 and C2 for proficient users of a language. It espouses a communicative approach to language teaching—the earliest work on which was done in Europe (e.g., Wilkins, 1976; Widdowson, 1978)—and is illustrated by descriptors of language ability that are phrased as can-do statements. While learning expectations, curricula, and textbooks across Europe are written referencing the CEFR, the

extent to which these are faithful to its principles is much debated. Also quite unfortunately, many people have reduced the CEFR to the illustrative descriptors, forgetting other aspects and features of the framework, such as approach to language learning (Jones & Saville, 2009).

Reflecting European policy, the CEFR encourages “*plurilingualism*”—that is, multilingualism as an individual rather than a societal phenomenon (Beacco & Byram, 2003). European school systems generally make provision for the learning of multiple foreign languages in compulsory education, and from an increasingly early age. The exceptions to compulsory foreign language learning are, perhaps unsurprisingly, countries where English is the primary language—the United Kingdom and Northern Ireland. In practice, English has been by far the dominant foreign language learned in almost every European country. The number of English language learners has been growing the fastest in eastern and southern Europe. In upper secondary school, approximately 90% of students learn English whether or not it is compulsory in their country (European Commission, 2006; Eurydice, 2008). In some contexts, the perceived inadequacy of English language instruction within regular school contexts has resulted in the growth of language tutors and schools offering supplementary private tuition. These include large international organizations such as the British Council, Education First, and Eurocentres, as well as smaller independent schools.

In higher education, in the interest of promoting greater exchange, the Bologna Process has created the European Higher Education area, standardizing programs largely according to the model followed in the United Kingdom. This development has also led to a rapid rise in the number of programs taught in English; one study showed that there are approximately 2,500 such programs (Wächter & Maiworm, 2008).

A strong curricular trend in Europe at all levels of education is content and language integrated learning (CLIL) (Fortanet-Gomez & Raisanen, 2008; Marsh, Mehisto, Wolff, & Martin, 2011). In a sense, CLIL is an extension of, or at least bears a family resemblance to, the communicative approach, embedding language teaching in the very disciplines that students are studying. However, it seems that CLIL is being adopted as much out of practical necessity as for pedagogical/theoretical reasons. Given the limited amount of time available in a crowded curriculum, CLIL appears to be a convenient way of claiming that both content and language have been covered. It also bears mentioning that relatively few teachers are trained in the approach, though steps are apparently being taken to address this shortcoming (Marsh et al., 2011).

In the United Kingdom, and on a smaller scale in the Republic of Ireland, the English-teaching industry is a major source of income, with people from all over the world enrolling in English language courses for varying lengths of time. Degree-level international students also often require English for academic purposes support. In addition, knowledge of the English language is also required for migration, asylum, and citizenship purposes (Shohamy & McNamara, 2009; Strik, Bocker, Luiten, & van Oers, 2010). Provision of adult ESOL programs for these people is mandatory by law, but support for them has generally been less than adequate. These learners tend to be quite diverse and quite different from traditional English as a foreign language (EFL) learners—needing English for

survival purposes, for example, but often with low literacy skills even in their first languages—but learning resources do not usually account for these differences (Cooke & Simpson, 2008; Little & Simpson, 2009).

Assessment Practices

Most European countries do not have a tradition of external examinations. Where they did exist, there was no emphasis on the use of psychometric procedures to ensure valid, reliable, and comparable outcomes. Instead, there is a tradition of localized assessment, with the individual teacher being regarded as the expert, and with validity and reliability presumed (Spolsky, 1995). This carried into the context of external assessment. For example, the Certificate of Proficiency in English offered by the University of Cambridge in 1913 was an offshoot of academic tests offered by the university. It was a combined proficiency and teaching test that included sections on translation (into German or French, and vice versa), English literature, and essay writing, among others. The test was marked by a professor in much the same way as teachers marked classroom assignments (Weir & Milanovic, 2003).

Present-day realities dictate examination outcomes that are more demonstrably valid and reliable, and the lack of a tradition that enables the production of such can be seen as one factor that led to the development of the CEFR. Many eastern and southern European countries have been reforming their school-leaving examinations (called *matura* or *maturita*), including those for English, to reflect best practices in educational assessment. Desired performance outcomes on these examinations are expressed in terms of CEFR levels; the most common level expected at the end of secondary school is B2 (Council of Europe, *n.d.*). However, cultural and political considerations have resulted in many of these reforms being thwarted or watered down (Pizorn & Nagy, 2009). Testing of the productive skills, especially speaking, is often on the verge of being excluded. Where the productive skills are tested, testing tends to be under nonstandardized conditions, or marked by the students' own teachers, making outcomes less than meaningful and trustworthy. Cut scores on tests are adjusted so low that virtually everyone passes.

Other test providers have filled the space created by state examinations' inability to provide reliable information about people's language abilities. Among these are examination bodies associated with academic institutions, for instance University of Cambridge ESOL Examinations and the University of Michigan, as well as other nonprofit and for-profit organizations, such as TELC and Pearson. These providers typically have a range of English language proficiency exams for use in various contexts and at a number of different ability levels, and operate in multiple countries. Examinations are generally structured around and usually cover the four skills—reading, writing, listening, and speaking.

No longer in the "traditional" (Spolsky, 1995) stage of language testing, these international test providers pay equal attention to psychometrics. Test items are routinely pretested or trialed, analyzed and calibrated, and then collected in item banks. Test performances are scored and equated using classical and item response theory. Where examiners are involved, for instance in writing and speaking tests,

they are generally trained, certificated, and monitored on a regular basis. Reliability information for exams and their components is generally calculated and reported. Computers have also been used in the delivery and in the scoring of tests.

Perhaps owing to their academic origins, a number of these level-based examinations are distinctive in that test takers follow a course of study in preparation for taking the tests—as opposed to cram schools that focus on test-taking strategy, or exams for which test takers simply show up on the day. Thus, these examinations are more closely tied to language teaching than others, and are to a certain extent not just proficiency measures but also achievement measures. In some countries such as Greece, preparing for and taking these exams are a rite of passage for teenagers, and certificates obtained are displayed prominently in homes (Tsagari, 2009).

On the other hand, a problem created by these exams is that their popularity and their ubiquity have made them and their associated materials very easy to use—even in contexts where they are not the most suitable or appropriate. For example, in the Republic of Ireland it was found that traditional coursebooks for EFL exams were being used with adult refugees, even though these materials did not cover the everyday, survival language these learners needed (Little & Simpson, 2009).

Fortunately, more appropriate assessments have also since been developed for nontraditional learners with different needs. One example is DIALANG, an online self-assessment available in 14 languages, including English, which learners can use to determine where they are generally on the CEFR levels (Alderson, 2005). Another example is the European Language Portfolio (ELP), of which there are multiple versions officially approved by the Council of Europe (Little & Perclova, 2001). The portfolio contains learners' language biographies, examples of their work in a language, and results of self-, teacher, and formal assessments. This has the dual function of allowing learners to report their progress in a language, and to guide further learning in the language. It is hoped that, through the ELP, learners can take more responsibility for planning their language learning according to their needs, rather than simply following some externally defined requirement.

More formal assessments for adults in the United Kingdom include officially supported Skills for Life exams, which yoke the assessment of language skills with literacy and numeracy skills. Migrants who seek naturalization as British citizens also need to take an ESOL course or a "Life in the UK" test, a test which combines English language skills with knowledge of British life and culture.

Challenges and Future Directions

Interest in and use of English language tests has been growing in Europe. This can be seen in the formation of organizations such as the Association of Language Testers in Europe (ALTE) and the European Association for Language Testing and Assessment (EALTA), as well as the existence of sections devoted to testing, evaluation, and assessment in associations of applied linguists and language teachers

(e.g., BAAL, BALEAP, and IATEFL). These groups have been at the forefront of advancing language-testing practice in the continent. For example, ALTE has been closely involved in the development of the CEFR, has devised frameworks, codes, and guidelines, and audits the practices and processes of its members. Similarly, EALTA has developed a code of testing practice that is available in 35 European languages.

However, keeping in mind that such large-scale, high stakes testing is a relatively new concept for most Europeans, it is perhaps inevitable that testing—and, along with it, comparisons and rankings, access or nonaccess to society's goods—would be controversial and contentious. For example, requiring English language proficiency as attested to by a language test has been a convenient way for the British government to reduce migration from certain demographics (Shohamy & McNamara, 2009). Commercial interests were also affected when the number of recognized test providers was reduced.

At the center of many debates, not surprisingly, is the CEFR. Among other things, the framework has been criticized for being atheoretical (e.g., Fulcher, 2004), though some critics appear to be thinking of the CEFR's illustrative scales rather than the CEFR itself. More broadly, objections to the CEFR seem to stem from its being used (or misused) as an instrument of policy. The CEFR was developed to be a reference, as its name makes clear. That is to say, language syllabi and tests would reflect certain standards, and when necessary (e.g., a student moving to another country) the CEFR could be used as a reference (e.g., to select a suitable course to take next). However, the transitivity has been reversed in many contexts, with the CEFR becoming the standard, and with language syllabi and tests having to conform to it instead (Jones & Saville, 2009). Its being used out of context is also reflected in the framework being adopted in non-European contexts as far afield as Japan, Taiwan, the Middle East, and Latin America, regions whose linguistic realities and requirements may be quite different from those in Europe (e.g., learners may be lower-level and need a framework with finer gradations of those levels).

One major area of contention has been the matter of demonstrating "alignment" to the CEFR. The Council of Europe (2009) has put together a manual with suggested procedures for this purpose. On the other hand, there are those who think the CEFR is underspecified for any sort of alignment (Weir, 2005). Many test providers claim a relationship to the CEFR. However, because the bases for these claims are not published, or, when they are, they do not seem to match with one another, some have been led to doubt the veracity of these claims (Lim, Geranpayeh, Khalifa, & Buckendahl, in press). In this the CEFR has, perhaps accidentally, proved a positive development for measurement theory. The consensus in standard-setting theory is that divergent standard-setting outcomes are acceptable, though theory has apparently developed in that direction partly as a result of the general absence of criterion measures. The current use of the CEFR has resulted in a situation where there are multiple criterion measures claiming to measure the same thing for the same contexts of use, and under such conditions it is but right that their outcomes should match.

In any event, it appears that the CEFR is here to stay. In policy settings, it generally makes sense for imperfect instruments to be improved upon instead of thrown

away. Thus, regarding the CEFR being underspecified, the levels are being fleshed out for a number of European languages; for English, this is being done by English Profile (e.g., Hawkins & Filipovic, 2012). These developments should help users to focus not just on the vertical dimension of the framework (levels) but on the horizontal dimension as well (nature of each level), both of which are in fact called for by the CEFR (Council of Europe, 2001). The CEFR is also not sufficiently defined for specific demographics (e.g., young learners) and contexts (e.g., CLIL) at this time, and will require further elaboration for those purposes.

Uses of the CEFR for its original intended purpose—comparisons across European contexts and languages—also continue apace. The European Commission, for example, has sponsored the European Survey of Language Competences, which assessed a sample of 1,500 students in each participating country on reading, writing, and listening (Jones & Saville, 2009). The aim is to provide information about foreign language learning in those countries, and the extent to which they are reaching their goals of citizens becoming plurilingual.

As those citizens become more proficient in English from ever earlier ages, the day will come (or perhaps already has come) when the number of English language learners will fall (Graddol, 2006) and, along with it, the number of English language examinations taken. On the other hand, language being the vital thing that it is, new varieties and uses of it might be found, perhaps leading to ever more specified English for specific purposes testing. If there are new uses for English in the world, it should be no surprise if Europe is once again at the vanguard, influencing English language assessment practice in the continent and beyond.

Assessing Swahili

Katrina Daly Thompson

University of California, Los Angeles, USA

Introduction—Language Teaching, Learning, and Assessment of Swahili

Swahili is a second language for the majority of its users both within East Africa and beyond, creating a great need for adequate teaching, learning, and assessment resources. Beyond the coast of East Africa, where about one million people speak it as a first language, it is used as the language of instruction in all Tanzanian primary schools, in urban Kenyan and Ugandan primary schools, and as a subject in Tanzania, Kenya, and Uganda. Outside of Africa, it is the most widely taught African language. While Swahili has been assessed through standardized tests within East Africa for decades, only recently have those involved in teaching Swahili as a foreign language begun developing standardized tests for Swahili assessment.

Description of Swahili

Swahili (*Kiswahili*) is a Bantu language, spoken as a first language (L1) along the coast and islands of Kenya and Tanzania, with about one million L1 users (*Waswahili*). In Guthrie's classification system it is considered part of the Swahili subgroup of Coastal Bantu (Guthrie, 1948, G41–43). It is spoken by between 50 and 80 million second language (L2) users in Tanzania, Kenya, Uganda, the Democratic Republic of the Congo, Rwanda, Burundi, and the East African diaspora, making it the Bantu language with the largest number of speakers (Lewis, 2009).

For centuries Swahili was used as a trade language between the coast and the interior of East Africa, and it was sufficiently widespread when German colonists

arrived in Tanganyika in the late 19th century that they chose to use it as the language of the lower levels of colonial administration; the British followed suit in 1925. In 1930 Britain's Inter-Territorial Language Committee selected Kiunguja (the main dialect on Zanzibar Island) as the basis for a Standard Swahili (Masamba, 1989). However, as the Standard dialect has been further developed by institutions such as Baraza la Kiswahili la Taifa (BAKITA; National Swahili Council) in Tanzania and Chama cha Kiswahili cha Taifa (CHAKITA; National Swahili Association) in Kenya, it has become increasingly distinct from the Zanzibar dialect. Today, Standard Swahili is the dialect taught and assessed in both East African schools and in countries, like the USA, where Swahili is taught as a foreign language.

Missionaries in both Tanganyika and Kenya helped spread Swahili beyond the coast through translations of the Bible. After Tanganyika achieved independence in 1961 and united with Zanzibar to become Tanzania in 1964, President Julius Nyerere chose Swahili as an official language (along with English). Kenya followed suit, first naming Swahili a national language in 1961 and then an official language in 1974 (Harries, 1976). In Uganda, Swahili has been a national language since 1973 but enjoys no official status, except as the language of the police and armed forces (Pawliková-Vilhanová, 1996).

There is a long history of Swahili literature, both oral and written, with the first poems still in existence having been dated to the late 17th century (Mazrui, 2007).

Swahili has at least 15 coastal dialects as well as many unnamed regional varieties that are influenced both phonologically and grammatically by the L1s of its L2 users. The best documented dialects include Kiunguja, Kiamu, and Kimvita, the dialects of Unguja (Zanzibar's largest island), Lamu, and Mombasa. A relatively new code called Sheng (G40E in the New Updated Guthrie List; Maho, 2009) has recently emerged in Kenya and has received considerable scholarly attention (Mazrui, 1995; Abdulaziz & Osinde, 1997; Githiora, 2002; Kiessling & Mous, 2004; Maho, 2009). A rapidly changing mixed code, that combines Swahili, English, and other Kenyan languages with many variations, Sheng is widely used by urban youth but not well understood by older Kenyans.

Swahili is considered a Category One language by the Foreign Service Institute (FSI) and the Defense Language Institute (DLI), and between Categories One and Two by the Interagency Language Roundtable (ILR), meaning that it is a relatively easy language for a native speaker of English to learn.

Like other Bantu languages, Swahili is considered an agglutinative language because it makes extensive use of verbal affixes. For example:

Nilimwandikia.
 ni-li-mw-andik-ia
 1SG-PST-OBJ.3SG-write-APPL
 'I wrote to her/him.'

Swahili has 18 noun classes, although Standard Swahili lacks the Bantu classes 12 and 13. Noun classes affect agreement with both verbs and adjectives, as in the following examples:

Mtoto mzuri anasoma kitabu.

m-toto m-zuri a-na-soma kitabu
CL1-child CL1-good 3SG-PRS-read book
'A good child is reading a book.'

Kitabu kizuri kinasomwa na mtoto.

kitabu ki-zuri ki-na-som-wa na mtoto
CL7.book CL7-good CL7-PRS-read-PSV by child
'A good book is being read by a child.'

Today Swahili is written in Roman script, with a standardized orthography, but prior to 1906 it was written in Arabic script (Pike, 1986). A large percentage of Swahili vocabulary is borrowed from Arabic, particularly religious terminology, reflecting both centuries of interaction between coastal first language Swahili speakers and the Arab world and the important role of Islam in Swahili culture. For example:

dini 'religion' < Ar. *di:in*

hadithi 'story' < Ar. *hadith* 'stories of the Prophet Muhammad'

hotuba 'speech' < Ar. *khutba* 'Friday sermon'

It also has borrowings from English, Portuguese, German, Persian, and Hindi, reflecting contact between the Swahili coast, European colonists, and Indian Ocean peoples (Nurse & Spear, 1985). For example:

picha 'picture' < English

meza 'table' < Portuguese

shule 'school' < German

pilau 'rice pilaf' < Persian

chapati 'flat bread' < Hindi

The prominence of Arabic vocabulary led early scholars to believe that Swahili was a pidgin or creole, but this theory has been disproved based on Swahili's Bantu grammatical structure. In fact, an anti-Arab sentiment among L2 users of Swahili has led to attempts to remove Arabic influences on Standard Swahili phonology, although many L1 users retain these Arabisms as a means of marking their sophistication within Swahili society and their religious identities as Muslims within a secular national culture (Mazrui, 1978).

Teaching, Learning, and Assessment of Swahili Within and Beyond East Africa

Teaching and Assessing Swahili in Tanzania

Tanzania uses Swahili as the medium of instruction for pre-primary and then seven years of compulsory primary school. In secondary school, the medium of instruction switches to English, but students continue studying Swahili as one

of seven subjects through form six. The first major national exam is the Primary School Leaving Examination (PSLE), a school exit examination taken in grade seven. Swahili comprises one of four sections. Performance on the PSLE, along with district quotas, determines whether a student may continue to a public secondary school. In form four, students take the Certificate of Secondary Education Examination (CSEE), an achievement exam that determines whether or not they can continue to the final two years of secondary school. Students who attend private schools must first take a qualifying test, which includes a Swahili section, in order to assess their readiness to take the CSEE. The Swahili section of the qualifying test includes four questions based on the form one and two Swahili curriculum, covering comprehension and summarizing, composition, literature, grammar, and word formation. In form six students take the Advanced Certificate of Secondary Education Examination (ACSEE), a final achievement exam that determines admission to university.

Teaching and Assessing Swahili in Kenya

Kenya's language policy requires that the medium of instruction for the first three years of schooling be the "mother tongue" of the majority of students in a given school, which means that Swahili is used in multilingual urban areas like Nairobi, as well as in Mombasa and Lamu where the majority speak Swahili as an L1 (Eisemon & Schwille, 1991). Beginning in grade four, English is the official medium of instruction but Swahili is a required subject. Kenyan students have about 66 hours of instruction in Standard Swahili per year (Arap-Maritim, 2010).

Since 1984, Swahili has been tested as one of seven subjects in the Kenya Certificate of Primary Education (KCPE) examinations, which are administered by the National Examinations Council in grade eight and determine continuation to secondary school. It is a norm-referenced, curriculum-based test (Arap-Maritim, 2010). Within the Swahili section, 40% of the score is based on a composition and 60% on multiple choice items. The composition is based on a prompt given in Swahili, such as "Write an essay about the proverb, *Haraka haraka haina baraka* [haste makes waste]. Make your essay interesting" (Mutinda, 1996). Compositions are scored by trained readers who mark for continuous prose, sequencing of ideas, correct use of tenses, punctuation, paragraphing, spelling, vocabulary, coherence, imagination, and sentence structure (Arap-Maritim, 2010). Multiple choice items include reading comprehension questions that emphasize grammar (including noun class agreement, pronoun agreement, and appropriate tense), as well as discrete items that test punctuation, abbreviations, analogies, knowledge of riddles and proverbs, vocabulary, singular and plural forms, synonyms and antonyms, paraphrase, grammatical agreement, word formation, conversion of words to numbers, telling time, appropriate salutations in a letter, road signs, and onomatopoeia (Mutinda, 1996). These items are scored mechanically using optical readers (Arap-Maritim, 2010). Outside of the Swahili section, the exam medium is English (Cleghorn, Merritt, & Abagi, 1989). In form four, students take the Kenya Certificate of Secondary Education (KCSE) examinations, of which Swahili is a compulsory section among seven. Students are tested in both Swahili literature

and language; there are no oral examinations. The languages division of the National Examinations Council Test Development Department develops both the KCPE and KCSE.

Teaching and Assessing Swahili in Uganda

In Uganda, local languages (including Swahili in some areas) are used as the medium of instruction for the first three grades, followed by English beginning in grade four. Swahili is not an examinable subject at the primary level. For the Uganda Certification of Education (UCE) O-level exam, both Swahili language and Swahili literature are examinable (but not compulsory) subjects. Each section is a 2 hour, 30 minute exam. Swahili is also an optional examinable subject for A-level exams.

Assessing Swahili in East African Private Schools

Students at private schools in East Africa have the option of taking Swahili examinations produced internationally, such as one of four International Baccalaureate (IB) exams. The *ab initio*, for beginning level learners of Swahili as a foreign language, includes short answer and multiple choice reading comprehension questions and a short writing activity (e.g., an e-mail or advertisement). B-Standard and B-High exams are for East African learners of Swahili as a second language; the latter asks students to write a short imaginative essay, such as the following:

Weve ni mwanafunzi anayesomea kilimo katika chuo kikuu na kama mwakilishi wa wanafunzi wa kilimo umeombwa na idara kuandaa kijitabu kidogo kitakachotumiwa kuwahimiza vijana wengi kuchagua somo la kilimo. Katika kijitabu eleza shughuli mbalimbali za kilimo na umuhimu wa kilimo kwa nchi yako.

'You are a student of agriculture in university and, as the representative of the agriculture students, you have been asked by the department to prepare a pamphlet that will be used to encourage more young people to study agriculture. In the pamphlet explain various agricultural activities and the importance of agriculture for your country.'

In the A1, a test of Swahili literature supposedly designed for L1 Swahili users (but more likely L2 users from mainland East Africa), students choose one essay question from a list of 12 that ask them to do comparative literary analysis on two or more Swahili novels, plays, or poetry collections. The instructions and prompts are entirely in Swahili, such as this example from a May 2010 exam:

Jadili mbinu tofauti za masimulizi kama zinavyotumiwa na waandishi wa kazi mbili ulizozi-soma na uonyeshe jinsi waandishi tofauti wanavyofaulu au kutofaulu katika mitazamo yao tofauti.

'Discuss different narrative styles as they are used by the authors of two works you read and show how different authors were successful or unsuccessful in their perspectives.'

Assessing Swahili Outside of East Africa

Students worldwide, as well as those who attend private schools in East Africa, have the option of taking Swahili examinations produced in the United Kingdom, such as the General Certificate of Education (GCE), the International General Certificate of Secondary Education (IGCSE), or the Edexcel IGCSE exams. The GCE Swahili exam, designed for intermediate learners of Swahili as a foreign language, contains four items: translation of a short passage from Swahili into English, translation of a short passage from English into Swahili, a reading passage with open-ended comprehension questions, and a short composition of about 120 words in Swahili, with some choice of topic (with prompts given in English). The Edexcel exam follows a similar format, with the addition of some translations of simple sentences from English to Swahili, a longer composition, and prompts given in both English and Swahili.

Swahili has been the most widely taught African language in the USA since the 1950s, and is currently offered at 118 US universities (CARLA, 2011), although it remains in the category of “(much) less commonly taught languages” when compared with other foreign languages taught (Thompson, Thompson, & Hiple, 1988, p. 85). In addition Swahili was regularly offered at all levels at SCALI (Summer Cooperative African Language Institute), hosted in turns by various US universities until recent cuts to federal Title VI funding led to the program’s elimination.

In 1999, the US Department of Education funded the establishment of the National African Languages Resource Center (NALRC), based at the University of Wisconsin-Madison until 2012 and now at Indiana University, and continues to fund its programs, which include workshops and institutes for teachers and coordinators in current methods of language teaching, and developing learning materials in African languages (Sanneh & Omar, 2002). For Swahili, the latter have included a reference grammar (Thompson & Schleicher, 2001), textbooks for beginning, intermediate, and advanced levels (Senkoro, 2003; Muaka, 2006; Omar & Rushubirwa, 2007), and assessments. In 2005, the NALRC began working with the Center for Applied Second Language Studies (CASLS) at the University of Oregon to create a standards-based measurement of proficiency (STAMP) examination for novice to intermediate high levels of Swahili. CASLS trained a number of US-based Swahili instructors to write items for reading, writing, and speaking exams that are conducted online. Reading items are multiple choice questions and are graded automatically, while writing and speaking are graded by reviewers, two of whom have been trained. The Swahili STAMP is now available from the NALRC (Antonia Schleicher, personal communication, April 8, 2011).

In the late 1980s, the American Council on the Teaching of Foreign Languages (ACTFL) and the Center for Applied Linguistics (CAL) began developing oral proficiency guidelines and tests for Swahili and Swahili specialists began learning how to perform ACTFL oral proficiency interviews (Dwyer & Hiple, 1988; Thompson et al., 1988; Sanneh & Omar, 2002), assessing how well a person speaks Swahili compared to the criteria outlined in the ACTFL Proficiency Guidelines for Speaking. However, Swahili-specific proficiency guidelines have never been widely accessible, except to certified testers and teachers who have participated in ACTFL familiarization workshops.

The American Councils for International Education, working with the National Security Education Program and a private company called Avant Assessment, has also developed assessments for use by its Swahili Flagship program, currently housed at Indiana University. These tests assess students at various levels using the ILR scale, and allow assessment from ILR level 0+ to 4. They are used as an admission exam for prospective participants in American Councils' overseas program in Zanzibar, Tanzania, where students must have at least level 1 proficiency for the summer program and at least level 2 for the academic year program. The test assesses the four skills, with listening, writing, and reading assessed online and speaking assessed via an oral proficiency interview (OPI). Students are tested again at the end of the program to assess increases in their proficiency (Ashford Njogu, personal communication, April 11, 2011).

Swahili Assessment Issues

Swahili Assessment Issues in East Africa

Studies of the Tanzanian education system and its exams have shown that students perform much better on Swahili assessments than they do in other areas which are tested in English. Although around 80% pass the Swahili section of the PSLE, less than 45% of students typically pass the exam as a whole (Malekela, 2006), only about 20% go on to secondary school (Nalkur, 2009), and only 5 to 10% complete secondary school (Alcock et al., 2000). Brock-Utne (2007) found that Tanzanian secondary school students perform better on tests when the tested material is taught in Swahili than when it is taught through code-switched Swahili and English (the norm) or in English only (the official policy).

National exams are produced on an ad hoc basis with no training offered to those hired to write test items—university graduates who are conversant with the Swahili curriculum and who have at least three years of teaching experience. While the National Examinations Council of Tanzania (NECTA) acknowledges that “ideally all prospective setters should be provided with some basic training in psychometrics and other essential technicalities required for the development of good test items,” this is not actually done. Instead, “setters just rely on their knowledge as teachers and on the job experience.” Many teachers appointed as setters do not respond, a problem NECTA speculates is “probably due to their incompetence in test construction techniques.” NECTA itself admits that “no comprehensive and systematic analyses and documentation on the validity and reliability” of its exams have been conducted (NECTA, 2009).

In recent years scores on the Swahili portion of the KCPE examinations have been slipping, with average scores below 52 percent in 2010. The Ministry of Education continues to blame students' use of Sheng for their poor Swahili examination results, and has suggested that Sheng be banned from schools. In late 2010, the Minister of Education ordered an investigation of the poor results in the KCPE Swahili examinations. Although the results of the investigation have not yet been released, scholars in Kenya have speculated that they are result of four factors: Swahili being taught only as a subject rather than used as the medium of

instruction, students' failure to distinguish between Sheng and (Standard) Swahili (Mundi, 2010), the exams' emphasis on vocabulary (including archaic and newly coined lexical items) over communicative competence (Njogu, 2005), and the low status of Swahili vis-à-vis English as the perceived language of upward mobility. Njogu argues that rather than attempting to ban student use of Sheng, the educational system should be revamped by insisting that only teachers who performed well in Swahili exams themselves be allowed to teach Swahili, teaching methods be developed to enable students to better understand the boundaries between Standard Swahili and Sheng, and textbooks that focus on language in context be developed.

There is some evidence that, in Kenya, L1 users of Swahili perform better on the Swahili sections of national exams than do L2 users, especially L2 users whose L1 is not a Bantu language (Arap-Maritim, 2010). "Trick questions" in which answers include L1 varieties of Swahili as distracters along with a Standard Swahili correct answer do not seem to have leveled the playing field. This finding raises questions of testing equity.

Swahili Assessment Issues in the USA

In the USA, STAMP and the ACTFL/ILR OPI are the only assessments available for Swahili at a national level. Most Swahili instructors develop their own local assessments, focused on achievement more than proficiency. For example, applicants for the Swahili Fulbright-Hayes Group Project Abroad (GPA) participate in a phone interview with Swahili instructors (the majority of whom are not certified OPI testers). On this basis, applicants are "judged on fluency, cohesion, and grammatical competency" but without any agreed-upon performance standards (Matondo, 2008, p. 147). The relatively small number of Swahili students makes it difficult to develop and pilot standardized tests, which is why the Swahili STAMP does not go beyond the Intermediate High level. The number of Swahili specialists is also relatively low and a high turnover of Swahili instructors (often East African graduate students hired as teaching assistants) has resulted in a small pool of certified OPI testers and raters (currently three for the whole USA). Tests such as the online Swahili exam used by the Swahili Flagship program are available to an extremely small number of students.

Challenges and Future Directions

Sanneh and Omar (2002) argue that the African language-teaching community in the USA needs to monitor the quality of overseas programs that include language study, through both student evaluations and external assessments; Matondo's (2008) critique of the Swahili GPA also points to a need in this area. The small number of certified OPI testers and raters for Swahili suggests there is still a need for more training and certification of testers. Moreover, the lack of trainers in Swahili means that training may need to be conducted in English as an intermediate language (Thompson et al., 1988). Challenges that Thompson et al. raised with regard to less commonly taught languages (LCTL) assessment generally in the late 1980s are still faced by Swahili. These include questions of intra-rater reliability.

Because the few certified testers are likely testing their own students, studies are needed to assess the “differences in testing one’s own students as opposed to testing someone else’s” (Thompson et al., 1988, p. 112). Among the three certified Swahili testers, one is an L1 user while two are expert L2 users, raising questions of inter-rater reliability with regard to “possible difference between native and nonnative interviewers with regard to both elicitation and rating” (Thompson et al., 1988, p. 112). Moreover, it may be difficult to maintain rating reliability over time for Swahili testers because they are “likely to have fewer opportunities to practice their elicitation and rating skills than their colleagues in the more commonly taught languages” (Thompson et al., 1988, pp. 112–13). Both in East Africa and in Swahili foreign language instructional settings, there is a need for research on the efficacy of existing Swahili assessments; and for training of testers. Within the USA, there is a need for greater collaboration among individual instructors who could share assessments with one another, perhaps through Internet sites such as the Kamusi Project (*n.d.*) and at language meetings and conferences.

Assessing Shona and Ndebele

Galen Sibanda

Michigan State University, USA

Introduction

This chapter provides an overview of first language assessment in two major African languages of Zimbabwe, isiNdebele and chiShona, starting with their description and the learning context. While the chapter touches on a number of important assessment issues, special attention is paid to the three key areas—assessment and teaching, assessment and learning, and assessment and accountability—under the two broad categories of “formative” and “summative” assessment. It considers the issue of assessment as it applies to isiNdebele and chiShona classes in primary schools, secondary schools, and universities.

Description of the Two Languages

IsiNdebele and chiShona are both members of the large family of Bantu languages. While isiNdebele belongs to the isiNguni subgroup (which also includes isiZulu, isiXhosa, and siSwati), chiShona is a subgroup made up of a number of dialects, the main ones being chiKaranga, chiZezuru, chiManyika, chiKorekore, and chiNdau. Although iKalanga and Nambya are linguistically chiShona, speakers of the dialects have been learning isiNdebele at school since colonial times, as they live in a predominantly isiNdebele-speaking region. IsiNdebele and chiShona are not mutually intelligible, but their grammars are strikingly similar and they share many lexical items, though with some sound changes in many cases. Like in many other Bantu languages, concordial agreement involving the copying of noun class features to the verb and other parts of speech is a salient feature. This may be illustrated by the following isiNdebele sentence:

Aba-fundi ba-amiaba-nengi ba-dla ama-qanda.

CL2-students CL2-my CL2-many CL2-eat CL6-eggs

“Many/Most of my students eat eggs.”

As can be seen, the noun is generally of the form: prefix + stem.

Another easily noticeable feature of these languages is the derivation of verbs from other verbs through “extensions” or derivational suffixes such as the causative *-is-/-es-*. Verbs generally have the structure: prefix(es) + root + suffix(es)—as in the following chiShona examples:

Tenga + a → *tenga* “buy”

va + no + teng + es + a → *vanotengesa* “they sell”

Prefixes may be present or absent. However, there must be at least one suffix—usually the default final vowel *-a*. The default root is of the form: consonant + vowel + consonant.

While click sounds (basic ones written as *c*, *q*, and *x*) are another salient feature of isiNdebele (Sibanda, 2010), for chiShona interesting sounds include whistled sibilants such as *sv* and *zv* and the affricates *tsv* and *dzv* (Fivaz & Ratzlaff, 1969).

Both languages have standardized orthographies, but isiNdebele has limited resources for teaching and learning. As a result, isiNdebele materials are supplemented with isiZulu ones, especially for grammar, literature, and culture.

Teaching and Learning Context

IsiNdebele (S44) and chiShona (S10)—in Guthrie’s (1967–71) classification—are Zimbabwe’s official languages together with English, although the latter is the main medium for business communication and school instruction. The 1992 census results (which were consistent with the trend in previous national counts) showed that, out of the 10.4 million people in the country, about 16% were Ndebele, whereas the vast majority of about 71% were Shona. Only about 11% percent belonged to various minority ethnic groups speaking other African languages, and the remaining 2% were speakers of non-African languages (mainly English). The 2002 census results were somewhat unlike previous ones, in that many people (especially young people from the southwestern part of the country) had left the country for economic and political reasons. However, the country’s population had increased to 11.6 million (or 14 million, if one includes those outside the country).

Instruction in Zimbabwean schools is generally in English, except for the teaching of isiNdebele and chiShona. For many decades both before and after Independence in 1980, the minorities have had to learn either isiNdebele or chiShona, depending on the region they live in, although some of their languages are taught at least for the first three years of primary school, in accordance with the requirements of the United Nations that every child must receive instruction in his/her mother tongue during the first few years of his/her education. This has resulted in isiNdebele being taught in roughly 20% of the schools and chiShona in about

80%. The curriculum is nationalized, and all schools use the same prescribed textbooks for each given subject and take the same exit exams. While ordinary level (O level) and advanced level (A level) were for many years administered externally by the University of Cambridge Local Examination Syndicate and the Associated Examination Board (AEB), examinations are now set and marked locally by the Zimbabwe School Examination Council (Zimsec), isiNdebele and chiShona being the first to make this transition, in the early 1990s. By the late 1990s all exams were set and marked locally. However, due to the country's economic collapse and to administrative problems at Zimsec, some private and trust schools turned away from Zimsec in the mid- to late 2000s and began to use the Cambridge International Examinations (CIE), which has since replaced the University of Cambridge Local Examination Syndicate (*Standard*, November 29, 2009). In 2009 the Ministry of Education announced that "Zimbabwean schools will soon be teaching the country's three main languages . . . Shona, English and Ndebele . . . [in all regions] under new reforms aimed at promoting tribal relations" (NewZimbabwe.com, November 12, 2009). The ministry added that "other languages such as Tonga, Kalanga, Nambya, Shangaan, Sotho and Venda would be taught and examined up to grade level 7" (NewZimbabwe.com, November 12, 2009). Already some schools have started teaching the three main languages (Zim-papers, October 23, 2011). Full implementation of the plans is slowed down by lack of resources, as the country is just coming out of a 10-year recession accompanied by political instability. Nor are there enough trained teachers to teach minority languages. All the students in primary schools learn either isiNdebele or chiShona up to grade 7, although these subjects have sometimes been taken less seriously in former European schools (schools for whites before independence), where the emphasis has often been on learning English. All the students also learn isiNdebele or chiShona for the first two years of secondary school education, after which some continue with the subject while others drop it. Those who do well in these subjects at O level may decide to continue up to A level. IsiNdebele and chiShona are also offered as subjects at university level and can be taken by those who would have passed the subjects at A level.

Formative Assessment

Formative Assessment and Teaching

Formative assessment in isiNdebele or chiShona has not been consistent in all schools, especially due to the different qualifications that teachers have. Soon after Independence in 1980 many new schools were built, as the government embarked on mass education; but this project was not matched by the required number of qualified teachers. This meant that older and better equipped schools attracted qualified and experienced teachers, while many new schools relied on temporary teachers with no teaching qualification or experience. Since assessment is a very important component of the teacher-training curriculum, it seems obvious that assessment and teaching in general suffered in schools with unqualified teachers, which resulted in poor exit exam results. Good formative assessment is generally

reflected in summative assessment. Mass education also meant that poorly equipped schools did not attract the best students, except in cases of zoning in cities, or when parents could not afford to send their gifted children to better schools. Unfortunately, in the past decade, at a time when this problem was almost over, many teachers left the country for political reasons or for greener pastures after the country's economy collapsed. This left the educational system in disarray. Although the government is now trying to attract qualified teachers back, the problem is far from being solved.

Where there are qualified teachers, formative assessment is more or less the same as in other parts of the world, where student are taught by qualified teachers. For qualified teachers, assessment is what determines how the next lesson(s) will be taught. Qualified teachers want to reassure themselves, through testing or other forms of assessment, that what they have taught has been understood, and then to proceed knowing which areas to revisit or emphasize. In other words, assessment is not an end in itself, but a means that facilitates teaching, feeding forward. A common complaint from headmasters about unqualified teachers has often been that they strive to cover the syllabus, in many cases with little regard for whether or not learning has taken place. For trained teachers the problem has often been assessing in preparation for examinations rather than assessing for learning. For the two languages in question, areas of assessment often include grammar, literature, composition, and culture. Paper and pencil tests are still common, but teachers also realize that things that put less pressure on students, such as class exercises, homework, and projects, provide useful feedback. Methods that promote self- and peer assessment are sometimes used, but to varying degrees in different schools. Practices that require extended time to be accomplished, like projects and observations, are sometimes used, especially at higher levels and in cities. In rural schools, especially at primary school level, there are usually no libraries, which makes it difficult to work on some projects. Many students have after-school chores, and often they have no good lighting conducive to study.

Formative Assessment and Student Learning

While teachers want to see how they are doing in terms of teaching, students too often want to know how they are performing, especially the high achievers. Assessment therefore provides the necessary feedback to both teacher and student. When students see that they are doing well in the subject, they are usually motivated to work harder and to keep their grade high. On the other hand, perpetual low achievers are often discouraged from learning by assessment especially the traditional paper and pencil tests. Although a teacher can simply comment on a student's work without giving a demoralizing grade, for the two languages grades are given most of the time, as it is traditionally the most expedient way of keeping student performance records, especially since reports are usually required at the end of each term or year.

In Zimbabwe attitudes towards certain subjects also play an important role in how assessment is viewed by students. There are many who feel that science, mathematics, and English are more prestigious subjects by comparison to isiNdebele or chiShona, and as a result they do not care much about how they perform

in the latter. However, overall students normally do better in isiNdebele and chiShona exams than in any other subject, since in other subjects they have to struggle with a second language, English, besides the content. The main skills often assessed are writing and reading comprehension. Oral reading, speaking, and listening are assessed in schools, but there are no exit exams. In fact there are no set standards for assessing them, as is done, say, by ACTFL for speaking in the US, although there has been an attempt to develop a word recognition test to measure initial reading skills in Shona (Mhundwa, 1983). Perhaps the feeling is that, since most students are native speakers of the language, they do not need, for example, to spend time listening to tapes, as second language speakers often do. Also, developing listening skills often requires the use of technology that is not readily available to many schools. Many teachers also lack the necessary technological training. More detailed studies relating to audiovisuals and computers in Zimbabwean schools are provided by, for example, Hungwe (1988) and Chitanana (2009).

Summative Assessment

Summative Assessment and Teaching

For teachers, summative assessment is a way of seeing how good or bad a job they have done throughout the year or the duration of the course. It helps them see their strengths and weaknesses in teaching and preparing students for their final assessment. It also assists them in evaluating the effectiveness of their approaches to formative assessment. This form of feedback enables them to map out better strategies for teaching and assessing the next groups of students. Summative assessment also offers teachers the opportunity to prove their teaching capabilities, as their superiors and peers see for themselves, from the final results, what these teachers can do. However, this may not be an accurate assessment of a teacher's abilities in the classroom, as a teacher may, for example, teach very well but fail to adequately drill students for the final exam. Also, the type of school, the caliber of the students taught, and other variables may contribute to the final result.

Summative Assessment and Student Learning

As has already been intimated, assessment for isiNdebele and chiShona is generally the same. In primary and secondary school, formative assessment helps the students perform better in their summative assessment, but it does not contribute directly to their final exit grade. At the end of each grade at primary school, students are given an end-of-year exam that, besides showing the actual letter or numeral grade for the subject, may show the student's position in class when ranked with others—overall and his/her rank for each subject. Most schools also have mid-term exams. The exit exam for primary school is taken at the end of grade 7, and students are tested in mathematics, English, chiShona or isiNdebele, and content (a combination of topics in sciences and social sciences). Grade 7

results generally determine the type of school the student goes to for secondary education. Those with good results in all subjects, including isiNdebele and chi-Shona, have a chance to go to the good old established schools, while those who perform badly can, in most cases, only go to the poorly equipped schools, mainly those built after Independence, where O-level results are generally poor. In urban areas, however, most students (especially those with no financial resources to go to boarding or private schools, average performers, and those who perform below average) go to schools within their zone.

At secondary school students also have mid-term and end-of-year exams for forms 1, 2, and 3 and for the lower sixth form (form 5). The form 2 exit exam, Zimbabwe Junior Certificate (ZJC), was phased out in 2001, although the curriculum remained the same (Mano, 2001). Students who continue with isiNdebele or chi-Shona after the first two years of secondary education take the O-level exit exam in form 4. The exam consists of two 2-hour papers. For the first section of Paper 1 students write a three-page composition chosen from at least five topics. The second section covers general language use, including idiomatic expressions. The last section requires students to read a passage and to answer comprehension questions, including summarizing the passage. Paper 2 has two sections covering grammar and literature (novels and poetry). Below is an example of a literature question from Shona Paper 2 (Zimbabwe School Examinations Council, 2012):

5 *Kubva muna Nhaka yeNhetembo sarudza nhetembo shanu dzerayiro dzakanyorwa nav-ananyanduri vakasiyana ugotsanangura zvinorayirwa zvacho [25]*

“Choose from Nhaka yeNhetembo five instructive poems written by different poets and describe their moral lessons.”

Note that no English translation is provided in the actual paper. Those who pass the exam (with at least four other subjects) can continue taking the same subject at lower sixth form level and take the A-level exit exam at the end of the upper sixth form. For this level students normally have two 2½-hour papers. Paper 1 has three sections, the first requiring students to write a 500–600-word composition chosen from at least five topics—such as the following, which is taken from Ndebele/Zulu (Zimbabwe School Examinations Council, 2007):

1b *Chaza ngokuqhutshwa kwesiko olizondayo utsho ukuthi ulizondelani [50]*

“Explain how a cultural tradition you hate/dislike is carried out and say why you hate/dislike it.”

This question is more complex than the O-level one above, as it requires the student not only to have knowledge of the tradition but to also come up with an opinion. The second and third sections test comprehension. While in the second section responses are short, in the third students have to summarize a passage. A pass at A level enables the student to continue studying the language at university.

For many years Zimbabwe had only one university—the University of Zimbabwe—where most exams were conducted at the end of the year. This meant that, for a BA, a student had to take and pass exams at the end of each of the three

years, so as to get a degree in addition to coursework through a number of written papers for each course. First year students also had mid-term exams, and BA Honors students were required to complete a dissertation (thesis) for their assessment. Students could proceed to do an MA in African languages and literature, which was assessed like the BA honors, except that the courses were more advanced and the dissertation longer. There was also a provision to do degrees that were assessed on research: MPhil and PhD. The university now follows a semester system; and there are more than ten universities in Zimbabwe, all with different requirements, but they do not depart much from what has just been described, although some do not offer isiNdebele and chiShona at all. The two languages are often taught and assessed in English at university level. The need to use English in teaching and assessing these African languages is debatable, but one of the main reasons often given is that most of the materials used are in English (see Chapanga & Makamani, 2006, for a detailed discussion). Outside Zimbabwe, particularly in the US, Shona is not regularly taught, but when it is offered to non-native speakers it is taught and assessed in Shona, although some instructors may use a bit of English. However, there is no standardized syllabus and there are no standards for assessment. Due to low demand, isiNdebele is hardly offered in the US and those wishing to take it are often put in isiZulu classes.

Accountability

Although accountability has not been a big issue in Zimbabwe, especially with parents, teachers often find the role they play in the educational system decided by how they perform in their work. Within the schools themselves, headmasters, headmistresses, head-teachers, or teachers-in-charge have always looked at final results such as the A level, the O level, the ZJC, and the national grade 7 finals in order to decide whether to promote or demote a teacher—perhaps subjectively at times, as there have been no strict or proper guidelines for doing this. A teacher whose students do well in external exams (exams that are neither set nor marked at the school) is often given examination classes, classes with high achievers, or higher-level classes, while a teacher whose students do badly often ends up teaching the supposedly less desirable, noncrucial, or lower-level classes.

Sometimes teachers with high-achieving students are promoted to teach at teachers' colleges, so that they can impart their skills to others. Others are elevated to the status of education officer, although headmasters too take up this position sometimes. Other teachers soon become senior teachers, deputy headmasters or deputy headmistresses, and headmasters or headmistresses within the school system. High-achieving teachers often get jobs in good schools, too. However, there are many excellent teachers who are disadvantaged by teaching at under-performing schools. In these schools the results are always bad and the teacher's great skills and efforts are hardly noticed or rewarded.

At university level student assessment does not seem to contribute much toward instructor accountability. University lecturers and professors are usually promoted mainly on the strength of their publications, although teaching evaluations by students are also considered.

Challenges and Future Directions

Perhaps the biggest challenge in Zimbabwe is attracting and retaining qualified teachers. It is clear that the assessment of isiNdebele and chiShona still faces some problems, as schools need more qualified teachers, though it must be pointed out that the situation for these languages is not as bad as it is for other subjects. For qualified teachers, the problem will be to convince them to teach and assess for learning, and not just for examinations. Schools also need to embrace technology, especially in order to improve listening skills. Although some schools now have computers, many others do not even have electricity, so they cannot start thinking about acquiring computers in the first place. Formal ways of assessing reading, speaking, and listening also need to be developed. However, the problems of assessment in Zimbabwe are not insurmountable, as the country has a well-organized educational system that just needs political stability and the support of a stronger economy.

Assessing American Sign Language

Robert J. Hoffmeister

Boston University, USA

Marlon Kuntze

Gallaudet University, USA

Sarah A. Fish

Boston University, USA

Introduction

This chapter presents a historical account of the progress in the development of measures for assessing first language abilities in American Sign Language (ASL). Historically, signed languages throughout the world have encountered negative attitudes about their use and their worth, especially in schools and in many academic communities. As a result of this and other factors, the development of adequate measures of ASL in children has taken a long time. The limitations of earlier sign language assessment were due to the efforts to use extant measures developed for English as a template to develop ASL assessment. This chapter also explores current instruments and how well they measure Deaf children's linguistic knowledge of ASL.

Historical Background

In schools for the Deaf in the USA from 1817 to 1880, the main language used for communication and instruction was ASL. By the beginning of the 20th century, however, the assumption that signing would have an adverse affect on acquiring speech and lipreading skills became widespread in the USA and throughout the world. As a result, it was deemed that ASL and other signed languages were no longer appropriate for academic instruction, and the use of sign language was banned in increasingly more schools nationally and internationally from approximately 1880 on (Lane, Hoffmeister, & Bahan, 1996).

Very little academic work was conducted on ASL until 1960, when William Stokoe published *Sign Language Structure: An Outline of the Visual Communication*

Systems of the American Deaf. However, it wasn't until the early 1970s that ASL began to gain recognition as a bona fide rule-governed language with its own grammar and syntax.

In the 1970s, research began to show that signing¹ was more effective for conveying academic information to Deaf children than oral or spoken language (Moores, 2007). The community of educators of the Deaf, however, continued to believe that ASL was neither a valid nor reliable first language and thus could not be used to support the learning of English. As a result, artificial signing systems were created to represent English morphology and word order on the hands. Paradoxically, these non-ASL manual systems borrowed many lexical items from ASL and invented signs to represent non-ASL English morphemes, which were then combined and arranged following English rules of word order. These systems failed to take advantage of the grammatically efficient use of space, movement, and location that is the foundation of a natural signed language such as ASL. Since such artificial systems were created to reflect English word order, the Deaf child needs to know English in advance in order to understand them.

In contrast, ASL has been used in residential schools for the Deaf by Deaf staff and students in communication with each other. During the years ASL was banned in the classroom (from 1880 to approximately 1980), its use continued during afterschool hours, often out of the sight of hearing educators (Lane et al., 1996). As more information became available about the validity of ASL as a natural language and the importance of ASL to Deaf culture became better understood, some of these schools that served Deaf students began to implement ASL as the language of instruction in the mid-1980s. The formal return of ASL to these schools helped to usher in the development of measures of children's ASL knowledge and these measures began to appear in research studies (Hoffmeister, 1994; Hoffmeister, de Villiers, Engen, & Topol, 1997; Schick, de Villiers, de Villiers, & Hoffmeister, 2007).

Who Uses American Sign Language?

In 2010, ASL was considered the fourth most widely used language in the USA (Lewin, 2010). Native users of American Sign Language probably number fewer than one million, with the majority of ASL users being second language learners. These figures illustrate that there are several distinct categories of ASL users: Deaf children of Deaf parents (DCDP) who acquire ASL as a first language, hearing children of Deaf parents (Codas) who also learn ASL as a first language, and Deaf children of hearing parents (DCHP) who learn ASL at schools that use ASL. This last group of ASL users, Deaf children who have hearing parents, is quite variable. They may learn ASL at a very young age, either at home or at school, or they may learn to sign much later in life. As a result the levels of fluency attained by that group vary considerably. Research on sign language acquisition has confirmed that age is a significant variable in language outcomes (Mayberry, 2002, 2007, 2010; Mayberry & Eichen, 1991; Mayberry, Lock, & Kazmi, 2002) and suggests that any measures of sign language need to consider the age of acquisition as a major background variable.

What Is American Sign Language?

American Sign Language (ASL) is a language whose form and grammar are shaped by its modality as a visually based language whose phonology is based on the use of the hands, face, and upper body. It should be emphasized that ASL is a natural language that adheres to its own unique rules of syntax, morphology, and phonology. For example, the morphemes of signed languages combine in various ways in order to create variation in lexical and phrasal meaning, similar to the morphological processes of spoken languages. However, in ASL, the specific processes are manifestations of its modality and include variations in movements such as speed, reduplication, size, and path (Klima & Bellugi, 1979). In addition, facial movements or expressions add adverbial or syntactic information. These facial or nonmanual markers provide information that includes length of time, manner, sentence type (such as declarative or interrogative), and the marking of clauses or embedded sentences (Neidle, Kegl, MacLaughlin, Bahan, & Lee, 2000).

Linguists recognize that ASL, like all languages, is a language that builds sentences and words from combinations of morphemes; and, like all signed languages, ASL uses handshapes, locations, movement, and facial expressions to deliver information in a predictable form and structure, thus making it a language that has measurable properties (Slobin et al., 2008). A variety of assessment tools that seek to measure some of these properties will be discussed later in this chapter.

Variation in Acquiring American Sign Language

One of the challenges in assessing ASL is the variation of the language acquisition process within the population of Deaf children. The language models available to them during the acquisition process can vary significantly in terms of the quality of input these models provide; for example, some children are exposed early on (even from birth) to very sophisticated, native or near-native, signers, while others are exposed to language models who themselves may just be learning ASL. In addition, as mentioned above, there is much variation in the age at which Deaf children acquire a first language, spoken or signed. Those with signing Deaf parents follow the same path of acquisition as hearing children of hearing parents (Newport & Meier, 1985), and they are native users of ASL. However, over 90% of Deaf children are born into hearing families (Mitchell & Karchmer, 2005). Those Deaf children who have hearing parents, learn to sign before age six, and go to an ASL-using school for the Deaf, are also generally considered to be learning an L1 (ASL). DCHP compare favorably in their language skills to DCDP, although there are some differences in expressive and receptive fluency (Schick et al., 2007). Deaf children of hearing parents who learn to sign between the ages of 6 and 12, have a very different acquisition profile, as do those DCHP who learn to sign after the age of 12 (Mayberry, 2010). This last group, comprising those who learn ASL after the age of 12, generally exhibits language proficiency associated with second language learners. A final group of Deaf children is composed of those who come to the USA from other countries. Within this group, some may have acquired a

spoken or signed language from their country of origin, while others may have had little exposure to any type of language. Coupled with this variation in language exposure is variation in experience with formal schooling, as some may have had very little. When designing an instrument to measure ASL that can be used across the whole population of Deaf children, one must consider the tremendous heterogeneity of the Deaf student population. This variation can create interesting issues regarding how to handle and account for the variation in language models, age of acquisition, and language exposure.

American Sign Language Versus Manually Coded English

As stated earlier, several coding systems were devised during the 1970s and 1980s that were intended to represent English grammar and vocabulary in the visual modality. Because ASL was considered inappropriate for educational purposes and was assumed to be a hindrance to learning English, it was believed that these invented artificial sign systems would visually represent the English grammar. Furthermore, it was believed to be a necessary method for Deaf children to acquire English so they might learn how to read. These systems have been generically referred to as Manually Coded English (MCE) (Nover & Andrews, 1998; Mann & Prinz, 2006). There are some inherent critical problems with using such invented systems instead of a natural language. The premise of MCE is that English can be represented manually by using ASL signs on a one-to-one correspondence with English vocabulary. Invented (i.e., non-ASL) signs are used for English words or morphemes that don't have an equivalent in ASL.

As can be imagined, there are considerable limitations in attempting to map the surface structure of one language onto a corresponding surface structure of another language without regard to underlying meaning, and these limitations are often dealt with in arbitrary, counterintuitive ways. For example, it is problematic to use the same ASL sign for an English word with a multiple set of meanings. The ASL sign for RUN² meaning *moving fast on feet* does not make sense in the following English sentences: "run to the store," "run a meeting," or "to run into someone." In another example, MCE has created a sign that uses the ASL handshape representing "S" to mark plurality by adding the "S" handshape after a sign is made. The unintended effect is that the "S" handshape ends up looking like a separate sign. In ASL plurality is indicated in completely different ways (e.g., reduplication, producing the sign on both hands, indicating arrangements of multiple objects, etc.) which are most likely in accordance to the constraints of the visual modality.

These examples demonstrate what happens when one attempts to work only with the surface forms of languages, thereby ignoring the mismatches in meaning and structure that occur, producing nonsensical and non-natural utterances. In this situation, the resulting representations are ones that are neither ASL nor English (Hoffmeister, 1996). While MCE systems are thought to accurately reflect English in an accessible modality for Deaf children, the resulting utterances are incomprehensible unless one already has a high level knowledge of English, thus defeating the purpose of such manual systems which were developed to model

English to Deaf children. Hence, Deaf students exposed to MCE spend a great deal of effort memorizing vocabulary items and many of the artificial handshapes and morphemes rather than focusing on the meaning underlying utterances. The end result is the “varying degree of sign language proficiency deaf children show as a result of their exposure to different forms of sign language input (e.g., natural sign language (ASL) vs. pedagogical sign systems (MCE))” (Mann & Prinz, 2006, p. 357).

The end result of exposing MCE to Deaf students is the pidginization of MCE. Over time, Deaf children regularize the input from this artificial system and develop ASL-like features such as handshape symmetry, classifier forms, and verb agreement that are not part of the MCE systems (Hoffmeister, 1996). These features do not have parallel surface forms in English, thus they are not components of MCE. Yet, Deaf children exposed only to MCE systems seem to develop some of these ASL-like features (Supalla, 1991). The MCE that Deaf children produce over time begins to change and incorporate properties of ASL, reflecting the fact that their signed language production becomes more efficient by capitalizing on the affordances the visual modality brings to the language. This is not to say that all Deaf children exposed to MCE become fluent ASL users; rather, their use of MCE becomes much more attuned to the grammatical requirements of the visual modality of communication (Singleton, 1989).

Language and Culture: American Sign Language and the Deaf World

As Deaf children develop, they heuristically adapt visual strategies to make sense of and affect the world around them. These strategies are different in many ways than those developed by hearing children (Bahan, 2008). Many of these strategies have become conventionalized as part of the Deaf cultural norms, though some of these strategies are in direct contrast to cultural traits found in the hearing world. For example, Deaf children develop visual attention spans at earlier ages and look at other people’s faces for extended time periods and also recognize small movements in the visual periphery as potential language components. They also use attention-getting strategies that are not dependent on sound, such as tapping the other person’s shoulder, waving hands in the other person’s visual field, or stamping the floor to create tangible vibrations the other person can feel. These strategies must be recognized as part of the Deaf child’s general language knowledge, just as hearing children are taught how to make polite requests or when interruption is appropriate. These cultural behaviors define Deaf community membership, and this cultural affinity also plays a role in language assessment.

Deaf children are members of a minority culture using a minority language that is sometimes viewed quite negatively, and so many language assessment situations can be fraught with issues that can have very real effects on both the test takers and test results. For this reason, the context surrounding any given ASL language assessment activity must be carefully documented and acknowledged (Hoffmeister, 1988). Deaf children are often familiar with and adept in making adjustments to their language in order to facilitate communication with various

people according to their level of ASL abilities. Communication options include but are not limited to ASL, MCE, and written or spoken English. Deaf students come to realize that two versions of “signing” exist: the one that is predominantly used in the classroom, that is, one of the MCE variants discussed above (especially with hearing adults who have limited ASL skills), and the one that is used in “everyday” life with Deaf adults and peers, that is, ASL. As a result, there is a subtle psychology at play in examiner–examinee interactions with regard to what signing style should be used. Factors such as the location of the assessment (e.g., home versus school) and hearing status of the examiner can and do affect the language used by the Deaf child. For example, if the examiner is hearing or the assessment is taking place in school, the student may subconsciously use more MCE-like language. If the examiner is Deaf or the assessment takes place in the home with Deaf family members, the student is more likely to use ASL (Hoffmeister & Shettle, 1984; Valli & Lucas, 2000).

Some ASL assessment tools rely on the judgments or evaluations of educational staff. But most of the adults in educational settings for the Deaf are hearing and typically second language learners, so their expressive and receptive fluency in ASL varies greatly. Most do not have the skills of native speakers, who would be able to more accurately evaluate the signing skills of students. Many of the teachers and other professional staff themselves make production errors and frequently overlook incorrect or non-standard language use in their students. As students become more proficient in ASL, it becomes increasingly important that they have language models with native fluency and are communicating with adults who are able to identify and correct their production errors and assess their receptive abilities.

Types of Sign Language Assessments

This chapter will now turn to a discussion of the sign language assessments that are currently known; at present, they are available for academic research purposes only. *Sign Language Assessment* (Haug, *n.d.*) is a comprehensive Web site which lists the 26 known sign language assessment tools from all over the world. Each assessment falls into one of four groups: *tests of sign language acquisition, diagnosis, and intervention*; *tests for educational purposes*; *tests for linguistic research*; and *tests for adult L2 learners*. The *sign language acquisition* group includes an ASL adaptation of the British Sign Language (BSL) Receptive Skills test and four assessments for ASL. There are four tests for *educational purposes*, two of which are designed for ASL. The *linguistic research* category lists four assessment batteries, two of which focus on ASL. Finally, there are two tests listed for assessing *adult L2 learners*, one of which is used to evaluate ASL. Thus, of the 26 sign language assessment instruments available internationally, 10 are created primarily for the US market, all of which are supposedly capable of assessing ASL (Haug, *n.d.*); however, none of these assessments are currently commercially available.

In addition to organizing the ASL assessment tools by testing purpose, as above, this group of 10 assessments can also be categorized by test format, of which there are four major types:

- observational checklists,
- expressive production measures,
- receptive multiple choice measures, and
- expressive and receptive measures.

A closer look at assessments from each type of format follows.

Observational Checklists

In the *tests of language acquisition* group, there are two instruments that use the observational checklist format. The first such instrument is the Language Proficiency Profile-2 (LPP-2) (Bebko & McKinnon, 1993), which uses a multiple choice rating scale that is completed by parents and teachers who are knowledgeable about the child's language behavior. The LPP-2 is designed to assess any language produced in any modality (signed or spoken, or both) by Deaf children ranging in age from 5 to 15 years. For this reason, it is envisioned to work well with the incredible linguistic variability found in the Deaf population.

As stated by Haug (2004), the LPP-2 measures five dimensions: *form* (language structure), *use* (language function), *content*, *reference* (use of nonpresent referents or information), and *cohesion* (discourse and narrative skill). Earlier versions of the LPP were tested with three populations: Deaf children who use Total Communication (a communication approach that uses sign-MCE, gesture, and speech), Deaf children who use spoken language, and hearing children who use spoken language. Bebko, Calderon, and Treder (2003) state the results of this psychometric testing indicate that the LPP possesses good construct validity, is sensitive to language change, and has high concurrent validity (as cited by Haug, 2004).

The LPP-2 has been found to strongly correlate with age but in one investigation it was found that there was greater variability in scores of the Deaf children when compared to hearing children (Bebko & MacKinnon, 1993). This result is probably due to the variability in the Deaf population as described above. Also, when comparing scores from teachers to those from (mostly hearing) parents, it was found that parents tended to score their children higher than teachers. This points to one potential issue with observational checklists in general: the scores or rankings can be highly dependent upon who is doing the scoring or ranking.

The second observational checklist measure in the *tests of language acquisition* group is the MacArthur Communicative Development Inventory for ASL (ASL-CDI) (Anderson & Reilly, 2002). The ASL-CDI measures the early ASL vocabulary development of Deaf children between the ages of 8 and 36 months, and also includes questions about home language use and fingerspelling ability. This assessment is an adaptation of the English CDI that was developed for spoken language acquisition, and uses an observational checklist that is filled in by parents, teachers, or others who are familiar with the Deaf child. The adaptation process has taken into account cultural differences and linguistic variances between the Deaf and hearing populations; for example, animal sounds are on the English CDI but not the ASL-CDI, and the ASL-CDI also includes vocabulary for such things as a TTy (originally teletypewriter),³ whereas the English CDI does not. The ASL-CDI currently lists 537 ASL vocabulary items in 20 semantic

categories. The English CDI and its multiple subscales have been developed for different age groups but, for Deaf children, the vocabulary development index of the spoken language task was the only scale adapted for ASL and covers all ages for which the original multiple measures were designed. The ASL-CDI has been found to be highly reliable (r of .91) when used by parents and has also been found to have a strong external validity (Anderson & Reilly, 2002). As with the LPP-2, the ASL-CDI only measures language production, and so additional or other assessments that measure reception should be used in order to provide as complete a picture as possible of any given Deaf child's language abilities.

Expressive Production Measures

The *tests of language acquisition* group also contains two ASL assessment measures that rely on discourse or narrative production. The first, the American Sign Language Proficiency Assessment (ASL-PA) (Maller, Singleton, Supalla, & Wix, 1999), is adapted from the oral communication proficiency interview model and is designed for use with Deaf children between the ages of 6 and 12 years old. The ASL-PA is designed to provide a measure of the sign language skills of both native and non-native users, thus attempting to capture the known variability in signing skills among Deaf children. This instrument is focused on expressive skills only, using data from three different types of language production for each child: an interview, an interaction with a peer, and a retelling of a story. All segments are videotaped and then analyzed by trained raters. The raters indicate on a checklist whether the child uses any of 23 target features across eight specific morphosyntactic structures of ASL that were identified based on a review of the ASL language acquisition literature and piloted for content validity (Maller et al., 1999). Each child is given an ASL proficiency level score based on how many of the 23 target features were produced (Level 1: fewer than 11 target structures produced, Level 2: 11–16 target structures produced, and Level 3: 16 or more target structures produced).

The ASL-PA has been found to have high validity and reliability, and this tool is able to distinguish among native signers (i.e., DCDP), DCHP who are exposed to ASL at school, and DCHP who attend schools that use MCE. For each child, the test takes approximately 30 minutes to administer and about one to two hours to score. While the ASL-PA is suited for use with a variety of groups within the Deaf population, there are a few weaknesses, the most significant one being that it focuses on the surface structures children produce during interviews, interactions, and storytelling instead of the content and meaning of such linguistic activities.

The second test in this category is the Signed Language Development Checklist (SLDC) (Mounty, 1993, 1994) and is similar to the ASL-PA in that it is also an observational rating scale of expressive sign language and uses a checklist that includes predetermined linguistic structures. The SLDC differs from the ASL-PA in that it also includes checklists for communicative competence and creative language; by doing so, it addresses the weakness of the ASL-PA mentioned above and recognizes that an assessment of ASL linguistic knowledge should evaluate more than facility with surface forms. However, the *linguistic use* section of the

checklist does focus on formational aspects of ASL such as phonology, morphology, syntactic structures, spatial reference, and perspective. The SLDC can be done live or with prerecorded video; children can be assessed while involved in a conversation, retelling a story, or producing a narrative. The SLDC can be used with people of a wide range of ages and was piloted with preschoolers through adults. However, there are no psychometric properties reported for this measure, and, as with the ASL-PA, the SLDC is heavily dependent on rater skill.

Receptive Multiple Choice Measures

The first of two multiple choice measures to be discussed in this section is the American Sign Language Receptive Skills Test (ASL-RST) (Enns & Zimmer, 2009), an assessment that falls under the *tests of language acquisition* category. The ASL-RST is adapted from the British Sign Language Receptive Skills Test (BSL-RST) (Herman, Holmes, & Woll, 1999) and targets children within the range of 4 to 13 years old. Test takers sit with an examiner and watch a signed stimulus on video, and are then requested to select the picture that best matches the stimulus from a set of four options by pointing to the selected response on the computer screen. The examiner records the child's responses as they take the test. There are 40 items in total, covering negation, number and distribution, verb morphology and noun-verb distinctions. One excellent feature of the ASL-RST is a pretest that ensures that the child's vocabulary knowledge matches the vocabulary in the task. This pretest is conducted because of the variability in ASL signing skills in Deaf children. The original version of the ASL-RST was found to be too easy for older Deaf children (above the age of 10), and a new revision of the test stimuli and responses has been completed (Haug, 2011). The revised test is in the pilot stage and is currently being implemented in the USA and Canada.

The second multiple choice measure is the Vocabulary and Passage Comprehension Test (VPCT) (Kuntze, 2004). This test was developed to investigate the relationship between ASL and English in the areas of vocabulary knowledge and passage comprehension. The VPCT assesses passage comprehension by comparing both within and between each language the knowledge of the vocabulary in the passage, the literal level of passage comprehension, and the inferential level of passage comprehension. The vocabulary component of the test contains 35 items in a multiple choice format. These items are drawn from the passage comprehension component of the test. The multiple choice format in the vocabulary component is composed of a target sign, a semantic distractor, a distractor with phonological similarity to the target sign, and a distractor with a phonological similarity to the semantic distractor. The comprehension component contains four passages followed by six questions for each passage. The questions range from literal level to the inferential level. The literal level questions are constructed mainly to assess how much of the language structure the students understood, and the inferential questions serve to assess how well the students were able to think and reason about the content.

The VPCT is designed to be administered by computer using video format, with the template of the test designed in such a way that all the video content needed for each test item is displayed together on the screen. After a response is selected,

the screen goes to the next item. Cronbach's alpha was used to determine the reliability of each measure. The coefficient is determined by calculating the level to which the performance of each item correlates with the performance of all other items. The alpha for one set of comprehension passages is 0.728 and for the other set it is 0.736. For the vocabulary, it is 0.746. The VPCT is not yet available for public use.

Expressive and Receptive Measures

The final category, tests that contain both expressive and receptive components, contains two assessment tools. The first is the Test of American Sign Language (TASL) (Prinz, Strong, & Kuntze, 1994; Strong & Prinz, 1997, 2000), which was primarily developed as a research measure to determine the relationship of ASL knowledge to English literacy skills. The TASL contains two production measures (a classifier production task and a signed narrative task), and four comprehension measures (a story comprehension task, a classifier comprehension task, a knowledge of time markers task, and a spatial representation task). It requires one hour to take the test and approximately half an hour to score, rating ASL proficiency at three levels: low, medium, and high. The TASL has undergone several revisions and is currently in its beta testing phase as a Web-based measure with psychometric data being collected. The development team of the TASL included native Deaf signers and experienced linguists. No psychometric properties of the TASL have been reported aside from inter-rater reliability.

The second assessment in this category is the American Sign Language Assessment Instrument (ASLAI) (Version 1, Hoffmeister, Bahan, Greenwald, & Cole, 1989; Version 2, Hoffmeister & Cook, 1994; Version 3, Hoffmeister, Fish, Benedict, & Henner, 2012; Hoffmeister, Fisher, & McIntyre, 2012). The ASLAI is designed for both research and educational purposes and, though it is not publicly available, it has been used in schools for the Deaf. It consists of a battery of receptive and expressive tasks, and is designed to provide both a measure of metalinguistic skills and a measure of age-related ASL knowledge. Tasks in the multiple choice format consist of either video or picture ASL prompts with four signed response options; these tasks include tests of synonyms, antonyms, classifiers, and vocabulary. The expressive tasks consist of video stimuli that require the test takers to sign responses that are captured by the computer camera; these tasks are designed to measure such things as narrative ability, classifier use, and verb agreement. At present (2012), there are 12 tasks in the battery.

Scoring for the ASLAI is done by task, by format (receptive versus expressive), and by linguistic structure. Norms on over 600 Deaf students from ages 4 to 18 have been established, with separate norms for DCDP and DCHP as well as norms for both groups combined. The ASLAI has proven to not only function as an assessment of language use and development but to also provide some diagnostic information that is otherwise difficult to ascertain. Certain score patterns have been identified as strong indicators of language delays due to impoverished input, other unspecified language problems, general learning disabilities, or neurological or spatial issues. The ASLAI is in the midst of revisions, with some of the expressive tasks being made into receptive tasks, and with the addition of new tasks and

additional data collection for further development of norms. Psychometric information will be available soon (Hoffmeister, Caldwell Harris, & Hull, 2011).

Summary

All of the ASL assessments described above were originally developed for research purposes, and nearly all have incorporated additional development so that they can eventually be used commercially.⁴ Any test of signed language requires some mechanism to present signed stimuli and to capture the signed productions of test takers. Advancements in technology have enabled the development of video-based tasks that can easily capture and digitize signed responses, and video presentation also allows for a test to be delivered fully in sign language without any need for the use of print. When taking an ASL test in this manner, the test taker is able to view and review the stimuli and responses similar to how one can view and review assessments in print. Both the ASLAI and the TASL in particular have attempted to model themselves after tests of conversational language development, language acquisition and standardized achievement tests. Additionally, in an effort to reduce memory load, the ASLAI presents still frames that are highly salient representations of each stimulus and response after the dynamic (signed) presentation, and these still frames remain on the screen to help test-taker recall.

Challenges and Future Directions

Negative attitudes toward American Sign Language have restricted advancements both in understanding the structure of the language and in developing accurate evaluation measures (Haug, 2011; Lane et al., 1996). The use of ASL was actively discouraged in educational settings for Deaf children and not viewed as a fully fledged natural language, thus developing assessment measures were seen to be of no value. In the past 30 years, however, two factors have contributed to the increase in ASL (and signed language) assessment development. First, ASL has been recognized as a language and is being used in enough educational settings to make it worthwhile to develop sign language assessment measures. Second, enhancements in technology have enabled efficient and objective assessment development and administration.

There is still continued discussion as to the best way to design measures of the linguistic knowledge of Deaf children. Adapting spoken language measures (including those in print) to sign language measures can be problematic in that they may under- or overestimate the linguistic knowledge of Deaf children. This chapter has reviewed measures of signed language based on the belief that Deaf children are bilinguals, not linguistically deficient spoken language learners in need of remediation. The issue of how one defines a bilingual and how it impacts the outcomes of educational and research questions is not restricted to Deaf children (see Bialystok, 2001, for an extensive discussion of this issue). A greater understanding of the acquisition of a language in the visual modality may impact the larger field of language acquisition by allowing us to understand the mechanisms at play for all language learning, regardless of modality. Developing

signed language assessments based on meaning will allow us to gain the clearest picture of the language knowledge and abilities of Deaf children.

We would like to acknowledge the valuable contributions of those who provided information or feedback on this chapter. We especially thank Ms. Aurora Wilber for her willingness to grapple with countless drafts.

Notes

- 1 “Signing” or terms such as “manual communication” are often used in the education arena to avoid mentioning ASL. “Signing” in education in this sense is more akin to using selected ASL vocabulary and using it to refer to English words and putting them in English word order. Using this term can lead to the mistaken impression that “signing” is just another form of “English,” which results in obscuring the fact that ASL is a distinct language.
- 2 We use the convention that ASL translations into English glosses require all capitals, while meaning translation uses just “. . .”.
- 3 TTy is a generic reference to electronic communication used by the Deaf. Technology has advanced so rapidly that the more common long distance communication is now a relay system using video access to an interpreter who “interprets” what the Deaf person and hearing person are producing. Its term now is VP (for videophone).
- 4 For more detailed information on these and other tests of ASL and other sign languages, the reader is again referred to Haug’s excellent Web site (Haug, *n.d.*).

Assessing Hawaiian

William H. Wilson

University of Hawai'i at Hilo, USA

Introduction

Hawaii is highly distinctive from the rest of the USA in its history, geography, and demographics. Uniquely among the states, it has two official languages: English and Hawaiian, a legacy of the Hawaiian kingdom. While Hawaiian is highly endangered, it has the strongest revitalization movement among the some 175 surviving Native American languages (Krauss, 1966; Grenoble & Whaley, 2006).

Annexation of Hawaii by the USA in 1898 was accompanied by the closing of Hawaiian-medium education and suppression of Hawaiian in the schools (Wilson & Kamanā, 2006). Between 1900 and 1930, Hawaiian was lost as the peer group language of locally born children in all communities but one. The replacing language was Hawaii Creole English, which includes considerable influence from Hawaiian.

In 1978, a state constitutional convention reestablished the official status of Hawaiian and required its promotion. Two years earlier the first baccalaureate degree in the language had been awarded and, five years later, there was established the nonprofit 'Aha Pūnana Leo, which has led the movement to revitalize the language through reestablishing Hawaiian-medium education. The 'Aha Pūnana Leo followed the lead of the Kōhanga Reo established in New Zealand. Like Māori and Welsh revitalization, Hawaiian revitalization is producing positive results (Wilson, 1999; Grenoble & Whaley, 2006). Between the 1990 census and 2000 census, those reporting some use of Hawaiian in the home grew from 14,315 to 27,160, an increase of almost 90%.

While progress is being made in revitalizing Hawaiian, it is still not the dominant language of any stable geographically bound community. The vast majority of Hawaiian speakers are second language learners of varying abilities under the age of 30. Most speakers come from the approximately 20% of the state population that is of Native Hawaiian ancestry. There are issues of orthography, language

variation, and contemporary vocabulary development, but on a lesser level than commonly found in language revitalization efforts (Hinton, 2001).

Description of the Language

Hawaiian is a Polynesian language with considerable mutual intelligibility with Tahitian and New Zealand Māori, and with a similar Latin-like orthography (Elbert & Pukui, 1979). Hawaiian is known for its distinctive indigenous phonemic inventory of eight consonants, five short vowels, and five long vowels. The frequent occurrence of the glottal stop (marked by a single open quote), the subtleties between short vowels and long vowels marked by a line above a vowel symbol) and the wide variety of diphthongs (written as two vowels) are areas of special attention in assessment of Hawaiian pronunciation and spelling. The example below illustrates Hawaiian words distinguished by the glottal stop, different diphthongs, and long vowels.

Words all often pronounced the same by English speakers

<i>au</i>	'current'	<i>'au</i>	'swim'	<i>a'u</i>	'swordfish'	<i>āu</i>	'your'
<i>ao</i>	'world'	<i>'ao</i>	'leaf shoot'	<i>a'o</i>	'learn'	<i>āū</i>	'Goodness gracious!'

Hawaiian grammar is distinctive in its flexible syntax and its extensive use of particles indicating emotions, direction, location, and manner. Like other Polynesian languages, Hawaiian distinguishes inclusive from exclusive first person pronouns; singular, dual, and plural number; and agentive A-possession from passive O-possession, for example, *ka'u hae* 'my flag' (personal possession) versus *ko'u hae* 'my flag' (representing my citizenship). The example below illustrates some of these grammatical features.

Opening of a letter in the newspaper Ka Nūpepa Kū'oko'a, March 26, 1864

I ke kenelala kaulana o ka na'auao nāna i 'alo nā
 To the general famous of the enlightened by-him past-tense endure the-plural

'ale o ka moana Pākīpika, e aloha pika wai 'olu
 swell of the ocean Pacific, command-particle love pitcher water refreshing

kāua: Ua koi 'ia au e ka makani Pu'ulena
 we-dual-inclusive: past-tense urge passive-particle I by the wind Pu'ulena

halihali 'ala o Pana'ewa no . . .
 transport fragrance of Pana'ewa about . . .

'To the famous general of enlightenment [the newspaper itself] who has endured the swells of the Pacific Ocean [as newspapers were delivered by ship],

refreshing pitchers of aloha between the two of us: The Pu'ulena wind that carries the sweet scent of the Pana'ewa District has encouraged me [to write] regarding . . .'

The literary traditions of Hawaiian are quite distinctive and oriented to an island environment. Pervasive are the use of metaphors, personifications, proverbs, quotations, and dialogue presented in the form of poems. Prior to the introduction of writing, information was preserved through chants, some hundreds of lines long. There is still a strong emphasis on memorization of poetry and its public performance in song. Below are the first four lines from a popular love song. It illustrates a Hawaiian poetic device called "linked assonance" in which the (double underlined) ending of one line is reflected in the (double underlined) beginning of another.

The first four lines of the song "Hi'ilawe"

<i>Kāmaka ka 'ikena iā Hi'ilawe,</i>	Highly visible is the waterfall Hi'ilawe [Cradled-in-arms],
<i>"Ka papa lohi mai a'o Mau<u>kele</u>."</i>	Known for "the sparkling flats of Maukele [Caught-in-mire]."
<i><u>Pakele</u> mai au i ka nui manu,</i>	I escape to this place from the birds [people],
<i>Hauwala'au nei puni Waipi'o.</i>	Causing a din [gossiping about us] throughout Waipi'o.

Teaching and Learning Contexts

Hawaiian has been taught as a second language in public high schools and the University of Hawai'i since the early twentieth century (Benton, 1981; Wilson & Kamanā, 2001). Until the 1980s, however, it was rare for a student to gain fluency from such classes. The change in outcomes came with teaching through the language itself, rather than through English. This methodology has spread through the educational system to the point where it is now possible to pursue a "Hawaiian immersion" education from preschool through to the doctorate.

Contemporary Hawaiian immersion sites serving students under the age of 18 are found throughout the state. They include private Pūnana Leo "language nest" preschools, standard public schools, state charter schools, and streams within schools. Hawaiian immersion differs from internationally familiar foreign language immersion in that it is a vehicle for restoring Hawaiian as a first language. It may enroll some first language speakers as well as new learners, although a "Hawaiian-medium" model is now emerging for the growing numbers of first language speakers (Wilson & Kamanā, 2011). These schools generally restrict the use of English to a one-hour daily English language arts class beginning in grade 5 (age 10) and often continue this model through to grade 12 (age 17). Statewide in 2011, enrollments were 230 in preschools and 2,144 in K-12 programs (Alohalani Housman, personal communication). The vast majority of students enrolled are Native Hawaiian, but most Native Hawaiian students still attend English-medium schools.

The state has converted the Hawaiian Studies program at the University of Hawai'i at Hilo into a Hawaiian language-administered college, Ka Haka 'Ula O Ke'elikōlani (Ka Haka 'Ula) which has partnered with the 'Aha Pūnana Leo in reestablishing Hawaiian-medium education for Hawaiian speakers. Ka Haka 'Ula offers teacher certification, master's level degrees, and doctoral study delivered through Hawaiian. Affiliated with Ka Haka 'Ula is a preschool to grade 12 model Hawaiian-medium laboratory school site, Nāwahīokalani'ōpu'u School (Nāwahī).

Master's level study and teacher certification through Hawaiian is also available at the larger Mānoa campus of the University of Hawai'i. Besides all state four-year and community college campuses, Hawaiian is taught in some private universities. The 2010 statistics from the Modern Language Association list US tertiary level Hawaiian language enrollments at 2,006, more than twice that of any other Native American language and 20th in enrollment among the 232 languages listed as offered in the USA. Hawaiian is also the only Native American language with graduate programs (Furman, Goldberg, & Lusin, 2010).

In 2009, there were 5,348 students enrolled in Hawaiian language classes in public English-medium high schools (C. Ishimaru, personal communication, 2010). Although no private schools offer Hawaiian immersion, a number of them offer Hawaiian as a second language. Nonimmersion elementary programs are poorly developed and have generally been scaled back since the 1980s. Counting students in immersion, in public and private English-medium high schools and colleges, and in college-level distance education, there were over 10,000 students studying Hawaiian in 2012.

The revitalization of Hawaiian has also resulted in a new population of children being raised as first language speakers (Kawai'ae'a, Housman, Alencaster, Māka'imoku, Ka'awa, & Lauano, 2007). The parents in these families are second language speakers. When the 'Aha Pūnana Leo was founded in 1983, there were only six such children in the entire state. The number of such first language speakers is growing with between 150 and 350 at present, most of whom are children of immersion or college program graduates. They are especially concentrated at Nāwahī, where, in 2010, approximately 33% of the enrollment had spoken Hawaiian at home since infancy (Wilson & Kamanā, 2011).

Children born into the isolated Ni'ihau community were still being raised with Hawaiian as their first language throughout the 20th century. However, movement of that population of some 200 people to residence primarily on the adjoining island of Kaua'i has negatively impacted Ni'ihauan child use of Hawaiian. A portion of the Ni'ihau community has established a P-12 Hawaiian-medium charter school to address this loss (Wilson & Kamanā, 2001; Ni'ihau Cultural Heritage Foundation, *n.d.*).

Assessment Practices

Assessments through Hawaiian are confined primarily to schools and are less developed than what is available for English, or the larger foreign languages in the USA. Yet, Hawaiian assessments are more extensive than what is generally available for indigenous languages. The Hawaiian language assessment practices

with which I am most familiar, and which are described below, are those used in Ka Haka 'Ula, the 'Aha Pūnana Leo, and the testing division of the Hawaii State Department of Education (HIDOE).

Advancement in Hawaiian Language-Focused Education

Hawaiian courses offered in secondary and tertiary educational institutions tend to measure student progress through regular written quizzes, midterm examinations, and a final examination, sometimes with transcriptions and oral interviews. At the graduate level, student master's theses and doctoral dissertations are written in Hawaiian.

A distinctive feature of Ka Haka 'Ula is expectations of student use of Hawaiian outside of class. Teachers and fellow students informally evaluate community use of Hawaiian by intermediate, third year, and advanced students. Included in campus use of the language are morning gatherings, where, on a regular schedule, individual students are expected to give teachings to the college community using Hawaiian oratorical language. Informal evaluation therefore includes both oratory and conversational use and occurs in the classroom as well as in general campus life outside the classroom. This process was adopted from similar procedures used at Nāwahī. It is this informal community evaluation that tends to drive student advancement in actual revitalization of the language.

Evaluating students entering Nāwahī involves a variety of assessments. Approximately half the kindergarten students at Nāwahī enter as speakers from Pūnana Leo preschools. These students are assessed through an oral Hawaiian interview. Other kindergarten students typically begin schooling in a summer program during which the families and school determine if they are sufficiently committed to education through Hawaiian. The school only allows entry at higher levels when applicants are transfers from immersion schools or when they and their parents have demonstrated extraordinary commitment to the program. Students who seek entry after kindergarten are evaluated through an oral interview and assessment of their reading in Hawaiian.

At the baccalaureate level, Ka Haka 'Ula administers an entrance examination for students who wish to enroll at a level other than the basic first year course. This involves an interview in Hawaiian, transcription of a tape, and a written test. The same process is used for granting credit by examination. There are no advanced placement examinations for Hawaiian as there are for foreign languages in the USA. It is possible, however, for students to take college level Hawaiian through distance education under the 'Aha Pūnana Leo's Niulohiki program with college credit available through examination from Ka Haka 'Ula.

Ka Haka 'Ula has formal entrance examinations for its graduate level Kahua-waiola Hawaiian language-medium teacher certification program (Wilson & Kawai'ae'a, 2007) and similar assessments for MA and PhD programs. The teacher certification entrance examination was developed with HIDOE-supported assistance from the Center for Applied Linguistics in Washington, DC. The examination consists of five parts: an oral interview, which the student must pass at the ACTFL Intermediate High level; a listening section consisting of a tape of an elder, which

students must transcribe before answering written questions in Hawaiian on the tape's content; a section in which candidates read an article from a 19th-century Hawaiian language newspaper, reformat it for contemporary use, and provide written responses in Hawaiian to questions on its content; a translation section, where candidates translate a contemporary English newspaper article into Hawaiian; and an essay section, where students write in Hawaiian on their selection from a list of topics.

Academic Skills Assessment Through Hawaiian

Assessment of academic skills through Hawaiian begins in the private Pūnana Leo preschools. Distinctive of the Pūnana Leo is use of a syllabic approach to literacy that characterized 19th-century public Hawaiian-medium schools. The teaching of reading through syllables aligns well with the structure of Hawaiian. It is also consistent with the progression of metalinguistic cognitive development in children, where the ability to divide words syllabically appears considerably earlier than the ability to divide words into phonemes, the skill used in teaching beginning reading in English (Treiman & Zukowski, 1991).

The Pūnana Leo assesses syllabic reading skills of preschool children up to the level of short paragraphs. Beginning in kindergarten, Nāwahī assesses syllabic reading among students, expanding that to two writing systems in first grade. Using "kanji," Chinese characters, to read Hawaiian serves as a bridge to the school's program in Japanese that begins in first grade. The first two lines of the Hawaiian hakalama syllabary are illustrated below.

The first two lines of the Hakalama in roman letters and kanji

ha	ka	la	ma	na	pa	wa	'a
hā	kā	lā	mā	nā	pā	wā	'ā
作 _°	人 _°	天 _°	目 _°	森 _°	刀 _°	口 _°	食 _°
作	人	天	目	森	刀	口	食

Assessment of academic skills through Hawaiian began in a protest kindergarten opened by the 'Aha Pūnana Leo in 1986. Since then, legislation establishing Ka Haka 'Ula has provided a government-supported entity and Nāwahī laboratory school for developing further assessments. Among the assessments developed are: assessments of literacy and mathematics from preschool to grade 8 (Curriculum Based Measures); assessments of reading comprehension from kindergarten to grade 12 (He Lawai'a No Ke Kai Hohonu); assessments of reading from grade 1 through 3 (He Aupuni Palapala); and assessments of oral Hawaiian from grade 1 through grade 3 (Hawaiian Oral Language Assessments).

The history of education through Hawaiian has been highly political. Pūnana Leo parents had to lobby the legislature and the state Board of Education to legalize and provide education through Hawaiian for their children (Wilson, 1999; Wilson & Kamanā, 2001). Lack of official state testing through Hawaiian was long a simmering issue; it became more serious with US Congress passage of the No

Child Left Behind Act of 2001 (NCLB). NCLB requires state assessments of all children in public schools beginning in grade 3 and punitive actions against the schools based on student scores.

The HIDOE has actively sought relief for Hawaiian immersion, reaching an agreement with the United States Department of Education (USDE) to use Hawaiian to test Hawaiian immersion students through to grade 4 using HIDOE-contracted instruments. This agreement—unique for a Native American language—meets provisions of Section 1111 (b)(3)(C)(ix)(III) and (x) of NCLB for recent non-English-speaking immigrants. After grade 4, however, Hawaiian immersion students are required to be tested through the English-medium Hawaii State Assessment (HSA).

Nāwahī parents have pointed out that testing through English and treating Hawaiian-speaking students under provisions for assimilating immigrants is contrary to the Native American Languages Act of 1990 (NALA). The restrictions on use of Hawaiian for NCLB testing have resulted in a long series of boycotts of state testing at Nāwahī (Wilson, 2012).

The Hawaiian translation of the HSA initially developed under the agreement between the USDE and HIDOE proved highly unacceptable. Subsequently the HIDOE contracted Pacific Resources for Education and Learning to develop an original examination of literacy and mathematics for grades 3 and 4 entitled the Hawaiian Aligned Portfolio Assessment (HAPA). The HAPA literacy measure includes a passage originally written in Hawaiian. The results of the HAPA have been very positive for tested students. At Nāwahī, for example, in the 2008 HAPA assessment when most parents relaxed their boycott, the results for reading were 100% of grades 3 and 4 students reaching “adequate yearly progress” (AYP) and also quite high for mathematics with 88% reaching AYP in grade 4, and 96% in grade 3 (Nāwahī teacher K. Kala’i, personal communication, 2011). The state average for all students that year was 62% meeting AYP in reading and 43% in mathematics (HIDOE Systems Accountability Office, 2011.)

When NCLB passed, the administration of the ‘Aha Pūnana Leo and Ka Haka ‘Ula sought out a proactive means to demonstrate academic progress. It contacted Dr. William Demmert to work with it to develop testing which could be used as an alternative to HSA testing to demonstrate proficiency in reading and mathematics (Demmert & Towner, 2003; Rawlins, Wilson, & Kawai’ae’a, 2011). Piloted at Nāwahī in the 2003/4 school year, these Hawaiian-medium reading and mathematics assessments are called Curriculum Based Measures (CBM). After the validity and reliability of the CBM assessments were determined independently by the Northwest Regional Educational Laboratory, the project expanded to national school partners teaching through Navajo, Ojibwe, Blackfeet, and Central Alaskan Yup’ik.

Use of CBM instruments at Nāwahī and other Native American language-medium or immersion schools has not been accepted by the USDE for official purposes, but it serves as an internal means of demonstrating the academic quality in these schools as they struggle with discriminatory assessment policies of the USDE. Also demonstrative of academic quality at Nāwahī is the school’s record of 100% high school graduation and 80% college attendance rate since the graduation of its first senior class in 1999. At Hawaiian immersion schools where parents have not boycotted the English-medium HSA, student scores drop sharply from

the HAPA on the English HSA, but, not dramatically lower than the scores of Native Hawaiian peers educated in English-medium schools (HIDOE Deputy Superintendent R. Nozoe, personal communication, 2011). Still these lower scores subject schools to punitive action under NCLB. Internal CBM assessments at Nāwahī show Hawaiian-medium testing results higher than those obtained through English, but a steeper rise in English-medium scores than in Hawaiian scores as students move into higher grades (K. Kala'i, personal communication, 2011). These results and the ability of Nāwahī students to perform well in English-medium universities supports theories of an academic and second language learning advantage in a program such as Nāwahī's for first language Hawaiian and Hawaii Creole English speaking students (Wilson and Kamanā, 2006, pp. 169-71).

Challenges

The USDE has pressured the HIDOE to abandon the HAPA and translate the grades 3 and 4 HSA into Hawaiian. Research in Canada has shown that translating between the two official languages there—French and English—produces instruments that are not equivalent (Ercikan, Gierl, McCreith, Puhan, & Koh, 2004). Hawaiian is more different from English than French is from English and consequently translating English assessments into Hawaiian has proven highly problematic. The example below illustrates some of the complications in translating words for reading and mathematical word problems between English and Hawaiian.

Inappropriateness of translation for assessing through Hawaiian

Original easy

Translation difficult

Reading words

Eng: bat

Haw: 'ōpe'ape'a

Eng: foot

Haw: kapua'i wāwae

Haw: kala

Eng: unicorn tang

Haw: na'o

Eng: phlegm

Mathematical word problems

Eng:

Haw:

Mary is as old as Tom weighs, less 65 pounds. If she is 10, how much does he weigh?

Like nā makahiki o Mary me ko Tom mau paona ke lawe 'ia he kanaonokūmālima. He 'umi makahiki o Mary. 'Ehia paona o Tom?

Haw:

Eng:

He 'umikūmāhā 'īmiha o kā Pua lei. Pāhā nā kenimika o ko Nani. 'Ehia ka lō'ihī o ko Nani?

Pua has made a lei that is 14 inches long. The lei that Nani is wearing is four times as long, in centimeters, as is the lei that Pua has made, in inches. How long is the lei that Nani is wearing?

As easily seen in the examples above, translation problems include simple spelling words in one language, for example, “bat,” being translated with difficult ones in the other, “ōpe’ape’a”. Differences in length pose another problem. Less obvious, but equally important, are grammatical, semantic, and cultural familiarity challenges.

Future Directions

Calls for assessment through Hawaiian are part of the larger movement to revitalize Hawaiian and use it in Hawaii as an official language equal to English. Under US policy statements such as NALA and the recent US adoption of the United Nations Declaration on the Rights of Indigenous Peoples, Hawaiian is legally equal to English. Efforts will continue to push for US policy to be reflected in actual practice by government agencies. Government compliance with its own policies is likely to improve as language revitalization spreads among other Native American groups. The sophistication of measurement of Hawaiian proficiency and content taught through Hawaiian will continue to grow with the revitalization movement.

Assessing North American Indigenous Languages

J. Dean Mellow

Simon Fraser University, Canada

Kaitlyn Begg

McGill University, Canada

Introduction and Challenges

The languages of the indigenous people of North America are remarkably diverse. Some of the languages are as distinct from each other as English is from Chinese and Swahili. Mithun (1999, p. 300) explained that a language family refers to all of the languages that are related to each other because they have historically “evolved from a common ancestral language,” and observed that all of the European languages have been classified into just three families (p. 1). In contrast, the various taxonomic classifications proposed by linguists indicate that about 35 distinct language families and about another 30 language isolates (not related to each other or other families) were spoken in the areas now known as Canada, the USA, and Mexico. Some of the families, such as Athabaskan–Eyak–Tlingit, include as many as 40 languages, and therefore 300 or more mutually unintelligible languages were indigenous to North America before European colonization (Mithun, 1999, pp. 1, 346).

As a result of European colonization and subsequent political and educational policies, the use of these languages has been substantially reduced. At present, some of these languages are widely spoken, including more than 100,000 speakers of Navajo (Mithun, 1999, p. 2), and, in Canada, about 97,000 speakers of Cree; 33,000 speakers of Inuktitut; 31,000 speakers of Ojibway; and 10,000 speakers each of Anihshiniimowin (or Oji-Cree), Dene, Micmac, and Montagnais-Naskapi (Norris, 2007, p. 21). However, many languages are endangered and are used by a relatively small number of speakers. For example, Haida, Kutenai, and Tlingit (in Canada) and Seneca (in New York) each have fewer than 300 speakers (Norris, 2007, p. 21; Borgia, 2009). Tragically, as many as 100 of the languages are now extinct, including Apalachee (spoken in present Florida and Georgia), Beothuk (spoken in present Newfoundland), Cochimí (spoken in present Baja California), Miami-Illinois

(spoken in present Indiana, Illinois, and Oklahoma), and Pentlatch (spoken on present Vancouver Island) (Mithun, 1999, pp. 297, 334, 368, 461, 487, 577).

Only a few languages, such as Inuktitut, are being learned as a first language by a substantial number of children. On the basis of 2006 census data, Statistics Canada (2008, p. 28) reported that "Inuktitut was spoken equally by Inuit in all age groups. About seven in 10 young, middle-aged and older Inuit could converse in Inuktitut." Many other languages are not being widely acquired as a first language by children and therefore a large proportion of the speakers is relatively older (e.g., Norris, 2007, p. 20). With respect to 60 different indigenous languages spoken by First Nations people, Statistics Canada (2008, p. 49) reported that 21% between the ages of 0 and 14 years had knowledge of an Aboriginal language. The percentage was 50% between the ages of 65 and 74 years (including 79% of individuals of that age living on reserve). In addition, many of the languages are being acquired as a second language (L2) by children and adults, often due to revitalization programs (see the section on teaching-learning contexts) (e.g., Norris, 2007; Statistics Canada, 2008, p. 50). Almost all of the speakers of these indigenous languages are multilingual and can also use some or one of English, French, and Spanish. For example, one percent of Canadian First Nations people speak only an indigenous language, and most of these individuals are aged 65 and older (Statistics Canada, 2008, p. 48)

These historical and social contexts have resulted in a wide array of discourse and content domains in which the languages are used. Navajo is used for automobile commercials on radio stations in Chinle, Arizona. Secwepemc includes a storehouse of information about biodiversity, such as tree species, in the southern interior of British Columbia (e.g., Turner, Ignace, & Compton, 1997). Upriver Halkomelem is used for personal and cultural topics by speakers who live near the Fraser River in British Columbia (Russell, 2009). Each language is therefore a unique and essential aspect of personal identity and an irreplaceable repository of cultural knowledge and wisdom.

Assessment of proficiency in these diverse languages is varied in local implementations and presents significant challenges for those who develop and interpret the assessment instruments. The practical development of tests is challenged by the limited financial and personnel resources that are available within schools and communities. The validation of tests is challenged by the small number of preexisting tests that are used in other contexts or for similar languages, by the small number of preexisting published descriptions of the languages, and by the even smaller number of empirical reports of either first or second language acquisition that could provide benchmarks for typical patterns and stages of development. The creation of tests is challenged by the difficulty of developing instruments that are perceived as authentic by the diverse stakeholders within communities, schools, and governments. Crucially, the stakes are very high. Many of these educational programs do not just seek learning outcomes by students. The programs must justify funding decisions in social and political contexts that are dominated by the governments of the colonizing cultures and that sometimes include English-only political movements. And if the programs do not succeed, the outcome may not just be limited student proficiency. The outcome may be the end of the language itself.

Description of the Languages

Properties of the Languages

Bachman and Palmer (1996, pp. 66–70) argued that assessment requires a comprehensive model of language ability that includes grammatical, textual, functional, and sociolinguistic knowledge. The diverse properties of these indigenous languages present challenges for L2 learners and for test developers who have learned about linguistics in an Indo-European language. With respect to pronunciation, the number of distinctive consonants ranges from 9 in Mohawk to 45 in Tlingit (Mithun, 1999, p. 15; varieties of English have about 25). Haida is especially challenging from an English perspective. It utilizes stops and fricatives at both velar and uvular places of articulation, including an ejective uvular stop [qʼ], produced with simultaneous closures of the tongue and glottis, causing an increase in air pressure that results in a burst of air and sound (Mithun, 1999, pp. 17–19, 415). Achieving a native speaker accent with sounds like these may be very difficult. Consequently, L2 test developers may focus on intelligibility rather than accent.

With respect to grammar, the word and sentence patterns in these languages are often very different from each other and from Indo-European languages. For example, Algonquian languages have complex words with many meaningful units (or morphemes) (cf. English *re-act-iv-at-ion*). Therefore, a complete sentence may have only one word, as illustrated in the Plains Cree verb *pawaapiskahowiiw* in (1).

- (1) *paw-aapisk-ahow-iiw*
brush-metal-by tool-he-it
'He brushes the metal object (such as a stove with a feather).'

Source: Yvonne Carifelle

In addition, Algonquian languages do not always use a verb equivalent to the English copula *be*. Therefore, many sentences do not have a verb, as illustrated in the Anihshiniimowin sentence *picikapat kaye acic* in (2), describing a young child at play.

- (2) *pici-kapat* *kaye acic*
inside-cupboard also baby
'The baby is in the cupboard too.'

Source: Modina McKay, reported in Mellow (2010)

Much of the published information about the grammatical patterns in these languages has been informed by theories that presuppose abstract universals, especially the Universal Grammar theory proposed by Noam Chomsky. However, these hypothetical universals have been widely criticized as Eurocentric (a review is provided in Mellow, 2010). In addition, linguistic abstractions may provide historical generalizations and central tendencies that are difficult to apply to language teaching and testing. For example, Athabaskan languages are said to have nearly 20 prefix positions that could precede a verb stem (Mithun, 1999, p. 363).

In authentic usage, these prefixes may be difficult to identify and may only be interpreted in relation to abstract or historical phonological changes. As a result, the identification of the morphemes in Athabaskan words is affected by different theoretical constructs. In contrast to abstract theories that propose the existence of a sequence of underlying morphemes, concrete analyses of the pronounced word might suggest fusional or portmanteau morphemes that express a combination of meanings (similar to English suppletive forms of *be*: *I walk-ed* vs. *I was* [not *be-ed*]). For example, the two Tsilhqut'in words in (3) relate to a cautionary story, "The Owl Story," that urges children to not wander too far from home.

- (3) (a) *yaghetal-chelh* 'He (the owl) will grab/take her (the child).'
 (b) *xetilh-chud* 'He grabbed/took her.'

Source: Maria Myers

In these examples, it is difficult to isolate individual prefixes that express the subject, the object, and tense/aspect. In addition, the verb stem also varies (*chelh* vs. *chud*).

The properties of these languages and the choice of constructs for describing grammar have implications for assessment. For example, complexity in English writing, especially for young writers, is often assessed by determining the average number of words per T-unit (i.e., per sentence that includes an independent or main clause and any dependent or subordinate clauses). However, this measure will not be valid for a language in which a single multimorphemic word is an entire sentence, as in (1). Similarly, complexity in English speech, especially for first language acquisition, is often measured by determining the average number of morphemes per utterance (e.g., the mean length of utterance, MLU). However, the MLU measure will not provide a valid assessment of complexity in languages in which many morphemes are fusional and cannot easily be divided into units that each have a single meaning, as in (3).

Although a moderate amount of information exists about the pronunciation and grammar of some indigenous languages, very little information has been published about the pragmatic and discourse patterns of these languages. Wolfart (1997) provided some information about how utterances and sentences are organized within Cree spoken narratives. In particular, Wolfart discussed the way in which variations in verb stems create a dense literary texture and the way in which parallelism in clause structure adds force to the homiletic tone of a spoken monologue. Russell (2009) examined the interactional patterns of turntaking and repair in classrooms in which adults were learning Halkomelem as an L2. Hack and Mellow (2007) reported the distribution of different types of speech act functions in mother–daughter Anihshiniimowin conversations between the ages of 11 and 40 months. Further reports about topics such as these would be very valuable.

Patterns of Language Use

The development of assessment materials must also consider the patterns and contexts of language use. Many of these languages are primarily oral, especially among elders, and therefore written measures may not be relevant. Even when

writing is being learned, it is not within an extensive literate context, as exists for languages such as French, Spanish, and English. In addition, many languages have regional varieties that may be mutually intelligible, but still differ considerably in terms of morphological patterns and lexical items. Basic vocabulary for family members, body parts, and animals are often used in early word recognition or naming tasks. However, these words could vary regionally, making it difficult to create widely applicable or “standard” assessment materials. In addition to regional variation, historical language change may be very rapid in these conditions, potentially resulting in younger speakers using a different variety of the language than the elders. These changes can occur throughout a language system, affecting pronunciation, word patterns, and discourse patterns.

Most speakers of indigenous languages are now likely to be bilingual or multilingual, leading to different domains of use for each language. The range of topics or functions for which a language is used may vary (e.g., not including some types of work, transportation, recreation, and government issues). In some cases, the range of use for an indigenous language could be limited to what happens in a classroom as part of a revitalization effort. Furthermore, code switching between languages within individual utterances and across conversational turns is normal in multilingual situations such as these. The diversity of language use is recognized by indigenous education programs such as the Kwayaciiwin Education Resource Centre (KERC), who provided the following statement of their goals:

We all have our own dialects, accents, colloquialisms, and levels of proficiency in English and Anihshiniimowin. It is necessary to adopt language expectations to meet the individual needs of each community. Our children will become bilingual/bicultural and will be able to live in both native and non-native settings. (KERC, 2007, p. 5)

Teaching–Learning Contexts

Examples of the teaching and learning contexts of these many languages are provided in the nine Teaching Indigenous Languages books that have been coordinated by Jon Reyhner and are available online at Northern Arizona University (*n.d.*). Many communities have created language “nests” in which preschool children (and some members of the family) interact with fluent elders. Many grade school programs exist. Some of these provide a few hours per week of language and culture instruction and exposure. Other programs are immersion programs that provide instruction in the indigenous language for at least several hours per day and in which content areas such as social studies and science are learned in the indigenous language.

Many adults are learning indigenous languages in an instructed, second language education context. Noncredit classes and drop-in learning opportunities are provided through community centers, school boards, and colleges and universities. Postsecondary credit courses are provided at many colleges and universities.

Some of these courses have classroom and learning structures similar to modern/foreign language courses. Other credit (and noncredit) courses follow a “master–apprentice” format with intensive one-on-one learning between a fluent speaker and a learner, often in natural contexts rather than classrooms.

Assessment Practices

Local Decision Making

Local input regarding language education and policy is always important. For indigenous languages, local decision making about the assessment of the language abilities that are valued and viable to achieve is necessitated by the limitations of published information about these languages, by the dynamic and variable patterns of language use, and by the diverse types of teaching and learning contexts. Local educators, test developers, fluent speakers, and elders work collaboratively to assess the desired types of language use, especially because language is so closely intertwined with identity and culture.

In most cases, empirical evidence for the construct validity of assessment instruments (correlations or comparisons to preexisting tests that have been deemed valid) is not possible because such tests do not exist for most of these languages. Because of the limitations of published descriptions of the languages, content-related or logical evidence for construct validity primarily depends on the expertise of local speakers and educators. Therefore, the contexts of indigenous languages place a substantial workload and responsibility on local agencies that often have limited financial and personnel resources. The following sections discuss four examples of systematic assessment procedures that were developed for particular languages, focusing on some of the ways in which assessment was implemented locally. These four examples provide an overview of languages from different language families and from different regions of North America. The examples also include languages that have varying numbers of speakers (from 97,000 speakers, Cree, to fewer than 50 speakers, Seneca).

Anihshiniimowin

Anihshiniimowin is being learned in immersion schools across northern Ontario. The KERC has developed a detailed curriculum for kindergarten to grade 8, with the students learning aspects of social studies, science, mathematics, and health in Anihshiniimowin (e.g., KERC, 2008a). KERC has also developed language assessment materials and procedures. The curriculum materials include formative evaluation expectations that guide the student and teacher through a series of thematic units. KERC has also developed summative evaluation materials that can be used at the end of a school year. For example, the summative instruments for pre-grade 1 include vocabulary assessment through visual prompts (flashcards), counting, listening comprehension, recognition of syllabics (writing symbols), as well as shape and color identification (KERC, 2008b).

One aspect of local implementation is that the content relates to relevant cultural activities. For example, the grade 1 curriculum (KERC, 2008a) includes a

series of activities that build to the comprehension of a story about moose hunting. One of the formative expectations for this lesson asks the students to retell the hunting story to the instructor. Throughout the grade 1 curriculum, elders and other community members are encouraged to come to the class and provide cultural information and language models for the children.

Another aspect of local implementation is that KERC has considered regional language variation. They have created the summative materials in both Anihshiniimowin and Anihshinabemowin, a related Algonquian language that is spoken in some of the communities in northern Ontario. In addition, the curriculum materials allow for variations according to region, such as activities about different types of ducks that are familiar in and hunted in different regions.

Inuttitut

Mithun (1999, p. 404) explained that Inuktitut-Iñupiaq is a chain of dialects spoken from Greenland in the east to the Bering Strait in the west. The language spoken in the Nunavik region of northern Quebec is called Inuttitut. The Katavik School Board has developed many curricular resources that facilitate the teaching and learning of Inuttitut in the schools in this region. The Katavik School Board has also worked with university-based researchers to develop an extensive set of language assessment materials from kindergarten to grade 7 (e.g., Wright, Taylor, & Macarthur, 2000). For example, the kindergarten assessment materials involve 16 tasks that include sentence comprehension, writing symbol (syllabic) identification, picture description, general comprehension, as well as naming of items such as colors, shapes, body parts, and animals. The complexity of the tasks increases with grade level. The grade 6 tasks include inferential thinking, writing (picture description), as well as paragraph reading and comprehension.

Wright et al. (2000, p. 68) explained that “the content and style of most standard [English] tests make them culturally inappropriate for children living in Nunavik.” Instead, a panel of researchers, teachers, and educators worked together to generate, critique, and refine the testing items. As a result, the materials that they created were “uniquely tailored” for those children (p. 69). For example, Task 13 for grade 2 children generates speech from the students using pictures of homes, settlements, and outdoor camps that are comparable to those that the children know.

Seneca (or Onön:dowaga:)

Borgia (2009) reported that Seneca is being learned in Ganöhsesge:kha? Hë:nödeyë:stha, or the Faithkeeper’s School, in New York State. It is a multi-age school that has about 10 elementary and middle school-aged students, as well as about 10 adult community members. Borgia explained that the staff at the school created their own assessment materials by modifying scales and rubrics from general foreign language oral skills evaluation and from New York State guidelines. The school staff worked through stages of research, evaluation, discussion, adoption, and implementation. Ultimately, they developed criteria for four proficiency levels (pre-production, beginning production, intermediate production,

and advanced production) for listening/comprehension, vocabulary, pronunciation/fluency, task completion, grammar, and sequencing.

Borgia also explained that one component of the locally relevant curriculum is the daily recitation of Gano:nyök (the thanksgiving address), which is a spiritual lesson that thanks the creator for all of the splendors of the earth. The importance of the discourse structure or sequencing in this type of ceremonial language was incorporated into the assessment tools.

Cree

Plains Cree is a variety of Cree and is being learned across the prairies in Canada (i.e., Alberta, Saskatchewan, and Manitoba). Alberta Education, a ministry within the Government of Alberta, has produced curriculum materials for both 9-year (grades 4 to 12) and 12-year Cree language-learning programs. In addition to suggested lesson plans and resource materials, Alberta Education has produced detailed assessment materials and procedures (e.g., Alberta Education, 2008).

In contrast to the three previous examples, the Alberta Education assessment instruments were not developed by an individual school or school board. However, these materials have a number of characteristics that can result in effective local implementation. First, Alberta Education consulted with a large number of Cree elders and teachers throughout the stages of curriculum development (Alberta Education, 2005, p. 1). Second, Alberta Education (2005, p. 4) acknowledged the importance of local control, stating that “[l]ocal communities must be the ones to create and control language and culture programs to suit their particular needs.” Third, Alberta Education (2009, p. 1) acknowledged the regional differences in Cree pronunciation, vocabulary, and grammar, and therefore advised that the published materials may need to be adapted in local communities. Fourth, the categories of language within the assessment materials (Alberta Education, 2008) often refer to general functional categories such as: share factual information, ideas, thoughts, preferences, emotions, and feelings; manage personal relationships; guide actions of others; and solve problems. Educators can determine how these functions are expressed in the local language and culture. Fifth, Alberta Education (2008, p. 2) explained that a large number of assessment tasks were included within the government document so that teachers could choose among those evaluation tools according to the abilities, needs, and interests of their students.

Future Directions

As communities and schools continue to develop assessment procedures, they may benefit from the shared experiences of other communities that have followed bottom-up procedures to create and adapt culturally appropriate materials. Because indigenous education is profoundly affected by historical and political contexts, educators will also benefit from an understanding of how governmental policies have impacted assessment within revitalization efforts (for detailed discussions, see Chapter 108, *Assessing Hawaiian* and Chapter 128, *Assessing Māori*

Indigenous Language Learners). Several key challenges lie ahead. For languages that have many speakers, bilingual language use will continue. Educators and policy makers will contemplate the types of contexts of language use that they can facilitate with programs and with the “washback” effect of learning toward testing procedures. For languages that are very endangered, educators and policy makers will also contemplate contexts of language use. For example, with effectively archived multimedia resources, future learners will be able to study and use culturally embedded language. Learners will be able to discover the stories, philosophies, and worldviews that link the past to the future.

Assessing North American Spanish

M. Rafael Salaberry
University of Texas, Austin, USA

The Role of Spanish in the World and in the USA

Spanish is a Romance language that is spoken by approximately 438 million people in the world. The majority (about 424 million) are native speakers, whereas approximately 14 million are second language users of Spanish (see Moreno Fernández & Otero Roth, 2007). English, the undisputed world's lingua franca, has about 375 million native speakers. Thus, in terms of native speakers, Mandarin Chinese is the first language, Spanish is the second, and English is the third.

Relatively speaking, Spanish is a fairly homogeneous language. That is, compared to other languages such as Chinese or Arabic, Spanish does not show a significant degree of variation across regional dialects, nor does it display radical contrasts between spoken and written registers (e.g., Lipski, 1994, 2008; Moreno Fernández, 2010). Nevertheless, Spanish has enough variation in the spoken register (principally in terms of pronunciation and vocabulary) and in informal registers in general to warrant the constant oversight of prescriptive norms. The Real Academia Española, along with the Association of Spanish Academies, provides directives and guidelines about the norms of the language.

In the USA Spanish is the dominant minority language, although it is not used nearly as much as the majority language that is English. The prevalence of Spanish is mostly due to the constant influx of Spanish-speaking immigrants from neighboring regions, principally Mexico, and to a lesser extent El Salvador and other Central American countries (note that Puerto Rico is part of the territories of the USA). Contrary to popular myth, the immigrant language is typically lost or suffers severe attrition after only two generations, by the time of the immigrants' grandchildren (see, e.g., Silva-Corvalán, 2001). This trend has important consequences in terms of the demographics of the population of Spanish students in

the USA—that is, among heritage learners as a subgroup of the overall group of Spanish learners.

Data from the last two censuses indicate that the Hispanic population in the US grew from 35.3 million in 2000 to 50.4 million in 2010 (Ennis, Ríos-Vargas, & Albert, 2011). In percentages, the growth went from 12.6% to 16.3%. Comparatively speaking, Hispanics grew 10 times faster than non-Hispanics in general (43% increase versus a 4.9%). About 63% of Hispanics are of Mexican origin, whereas about 10% are Puerto Ricans. Furthermore, Hispanics tend to concentrate in some specific regions of the USA: over half of the Hispanic population lives in the states of California, Texas, and Florida (in that order). In terms of language use, the US Census reports that in 2007 there were about 35 million speakers of Spanish, who represented about 60% of all speakers of languages other than English in the US population (Shin & Kominski, 2010). The majority of these Spanish speakers (71% of the total) were bilinguals, given that 53% spoke English very well and 18% spoke it well.

Over the last 50 years, Spanish has become the predominant second language of choice in the academic context. Currently the three most studied languages at the college level in the USA are Spanish, French, and German (in this order). According to the Modern Language Association (MLA) language enrollment database of postsecondary institutions (Modern Language Association, 2009), the number of students enrolled in Spanish courses per annum has increased from 746,267 in 2002 to 822,985 in 2006 to 864,986 in 2009. Given that the overall number of student enrollments in courses other than English is almost 1.7 million, enrollment in Spanish represents about 50% of all enrollments in languages other than English. In contrast, in 2009 French and German accounted for about 300,000 registered students, constituting together roughly one third of the students in Spanish. Furthermore, whereas enrollments in French and German have barely kept pace with demographic increases, the interest in studying Spanish at the college level has continued to increase steadily for many decades. As the figures above show, the changes in enrollment in Spanish from 2002 to 2009 represent an increase of almost 120,000 students in the relatively short time span of seven years. This increase is equivalent to almost a 16% increase in enrollments. In turn, the other two largest languages of the US curriculum have seen increases in their numbers of registered students of 7% for French and 5% for German over the same time span.

Assessment Practices in Academic Contexts in the USA

Although Spanish is taught at all levels of the US curriculum (from elementary to college level), it is mostly at the college level that there has been a variety of standardized tests that are used at the national level to assess language competence in Spanish. The American Council on the Teaching of Foreign Languages (ACTFL) has become the most important reference point for any type of assessment procedure at the college level, and in some cases its influence has been extended to the K-12 level (Swender, Breiner-Sanders, Mujica-Laughlin, Lowe, & Miles, 1999). The European counterpart, the Common European

Framework of Reference (CEFR), targets the same objectives as ACTFL (i.e., proficiency as performance in the social setting). Given that CEFR is focused on the European context, it has had a limited influence in the US setting. ACTFL has developed well-known guidelines for testing, especially for oral testing—the Oral Proficiency Interview (OPI). It has also developed standards for the achievement of pedagogical goals. Before describing the assessment procedures in place for Spanish, I will present a brief description and analysis of the *Standards for Foreign Language Learning* (National Standards in Foreign Language Education, 1996).

Standards

The *Standards for Foreign Language Learning: Preparing for the 21st Century* is a document first published in 1996 (ten years after the ACTFL Guidelines were published for the first time). The *Standards* describe in detail the theoretical construct of language competence that has been adopted by the majority of the standardized tests currently in use in most schools, from elementary to college level education. More specifically, the document presents a definition of the goals to be assessed, and thus it provides a road map toward pedagogical objectives. They promote the achievement of five inter-related goals: communication, culture, connections, comparisons, and communities. The *Standards* also describe three communicative modes for the assessment of language proficiency: interpersonal, interpretive, and presentational. The interpersonal mode involves two-way, interactive communication, such as in face-to-face conversations or through interactive written electronic messages (e.g., bulletin boards). This mode requires the active negotiation of meaning: observing, monitoring, providing clarifications, and adjusting the message dynamically, as communication occurs in real time. The interpretive and presentational modes are based on one-way communication: understanding spoken or written language (e.g., listening to a news piece or reading a newspaper), or expressing oneself in written or spoken mode (e.g., giving a speech or writing an e-mail).

The revolutionary aspect of the *Standards* is that it provides a clear endorsement of an expanded definition of language by comparison to the traditional socially decontextualized construct. The definition offered by the *Standards* goes beyond simply exercising the vocabulary and rules of language in a social vacuum to viewing rules and structures as socially embedded: “Students *must be able* to participate appropriately in a range of social relationships and in a variety of contexts” (National Standards in Foreign Language Education, 1996, p. 439; emphasis added). Moreover, the *Standards* is unapologetic about the achievement of objectives that go beyond the traditional communicative goal: “The capacity to communicate *requires not only* an awareness of the linguistic code to be used, *but also* an understanding of the cultural context within which meaning is encoded and decoded” (p. 439; emphasis added). For instance, Standard 4.1 proposes that “students demonstrate understanding of the nature of language through comparisons of the language studied and their own.” The *Standards* goes a long way toward addressing the major shortcoming of previous definitions of language competence. Previous descriptions of communicative competence focused on a concept

of language that incorporated limited information about the rich social contextual traits that are an inherent part of language use.

Obviously the *Standards* document only describes the type of competence that learners need in order to acquire the target language, in this case Spanish. Apart from identifying the theoretical construct, however, we need to specify the type of procedure to be adopted in order to measure the level of competence of the learners. In the following sections I will describe some of the standardized tests that have been used to assess knowledge of Spanish.

K-12 Standardized Exams

The National Spanish Examination (NSE) is a popular standardized test designed to measure proficiency in grades 6 to 12. For instance, in 2011 approximately 140,000 students took the test. Oftentimes this test is used to prepare students to take other standardized tests such as the AP (Advanced Placement), IB (International Baccalaureate) and SAT (Standardized Admission Test) (see below). There is no other national standardized test of Spanish for K-12 education, except for the short-lived project associated with the National Assessment of Educational Progress (NAEP). Funded by Congress in 1969 under the guidance of the National Assessment Governing Board (NAGB), NAEP is a measure of achievement in core subjects that can be described as nationally representative at grades 4, 8, and 12 (National Assessment Governing Board, 2013). In 1999 NAGB delegated to the Center for Applied Linguistics (CAL), the ACTFL, and the American Institutes for Research (AIR) the task of developing recommendations on the framework and specifications for the Foreign Language NAEP. Spanish was the most important language targeted by NAEP. The specific purpose of the NAEP was to gather information on the attainment of communicative abilities of US students in grades K-12: "How long does it take students to reach meaningful levels of achievement in a foreign language?" (National Assessment Governing Board, 2000, p. 5).

The NAEP committee adopted the framework of the *Standards for Foreign Language Learning* and specifically targeted the achievement of abilities in the areas of communication, culture, connections, comparisons, and communities. The NAEP test identified three levels of competence in the language and was composed of three different tasks—listening, reading, and writing—that targeted the three communication modes identified by the National Standards: interpretational, presentational, and interpersonal. Unfortunately, the Foreign Language NAEP was discontinued and tabled until at least the year 2020 (Mary Crovo, NAGB, personal communication, August 16, 2011). The apparent problem with the exam was the difficulty of administering the interpersonal component of the test (see below).

Pre-College Level Exams

The College Board administers the three most important exams that allow secondary school students to obtain admission and course credit in tertiary education: the Spanish SAT, the Spanish CLEP (College Level Examination Program), and

the Spanish AP. Another standardized test is the IB exam, which also grants credit for previous knowledge in Spanish (and a variety of other languages). Both the IB and the AP exams are linked to the content of coursework that precedes those tests. I will discuss the latter two tests in more detail.

Both the SAT subject test in Spanish and the CLEP are developed and administered by the College Board. The SAT test can be taken with or without a listening component. The longer version is a 60-minute test that contains 85 multiple choice questions that test both listening and reading abilities. The Spanish SAT is used to enhance a college application, or in some cases to test out of a language requirement. The CLEP test, in turn, is mainly geared toward students entering college who may have finished secondary education before, or who are already in college and would like to receive credit for their knowledge of Spanish. Students can earn from 3 up to 12 college credits by passing the CLEP Spanish Language exam. The exam is composed of 120 questions that students need to answer in a maximum time of 90 minutes. The test contains two listening sections (30 minutes each) and one reading section (60 minutes).

The AP exam is different from the other exams in that there are Spanish AP courses offered in secondary schools to help students prepare for the AP exam. Essentially, the Spanish AP exam assesses the achievement of objectives of the advanced placement course. There are two AP tests: one focused on general language knowledge and another one focused on literature. The basic AP test is comprised of two main sections. The first one contains reading and listening passages with follow-up multiple choice answers. The second section contains a variety of procedures designed to assess interpersonal and presentational skills in both writing and speaking. The scoring criteria of the AP exam are based on the objectives outlined in the *Standards for Foreign Language Learning for the 21st Century* (National Standards, 1996). The AP test measures competence in Spanish up to the fifth or sixth semester of most colleges and universities. The exam uses a five-point scale, and colleges typically give credit for scores of 3 or higher. As a point of reference, approximately 12.5% of the nonheritage students who take the AP test obtain the highest score of 5, whereas roughly 50% of the students taking the test score below the cutoff point of 3 that is typically necessary in order to have any credit recognized (on the basis of data from the student grade distribution for the years 2009 and 2010 provided by the College Board). When we also include heritage students in the overall group of test takers, the percentage of students who obtain a score of 5 increases to about 26%, whereas students who score 1 and 2 decreases to about 27%.

Finally, the IB Diploma exam is the exam most inherently connected to the actual courses that precede the test. The IB exam is composed of both internal and external tests. That is, the internal tests are part of the regular courses that give students the opportunity to move from formative to summative evaluation. For instance, for the internal assessment, teachers may help learners draft and revise a written paper. Furthermore, the IB test is mostly based on the assessment of performance that demonstrates the achievement of higher order thinking skills, as described in Bloom's (1956) taxonomy: analysis, synthesis, evaluation. The IB Diploma measures competence on a 1 to 7 scale, and most schools grant some level of credit starting with a score of 2.

College Level Exams

At the college level there are a variety of assessment instruments developed by several universities. Two of the most well known are the MLPA (Modern Language Proficiency Assessment), developed by the University of Minnesota, and the STAMP (Standards-Based Measurement of Proficiency), developed by the University of Oregon. College level tests like the STAMP or MLPA include sections that test students' reading and listening abilities. These sections are typically composed of short written or audio segments, followed by multiple choice questions that students need to answer within a prescribed time. These tests also include some performance-based measurements of the spoken and written language produced by test takers. Overall, these tests tend to be similar to each other because, almost without exception, they are based on the criteria described by the ACTFL Guidelines. There are, however, some noticeable differences between these tests and the traditional ACTFL proficiency tests (especially the OPI). These differences are, nevertheless, mostly logistical, to the extent that the standardized university tests are adapted to administering the test to a large number of students at a low cost. As an example, the MLPA Contextualized Speaking Assessment is a test based on recorded prompts (as opposed to a face-to-face interview like the traditional ACTFL-OPI). In this type of guided test students record short narrations and brief descriptions and ask and answer questions during guided "dialogues," after listening to the videorecorded or audiorecorded prompts. There are also distinctions with regards to the scoring procedures. For example, in the case of the MLPA test, the scoring criteria focus on four dimensions of analysis: task fulfillment, vocabulary, discourse, and accuracy.

Challenges

There are two main challenges for the assessment of Spanish language competence in the US setting: (1) the clear description of the theoretical construct that represents Spanish competence; and, concomitantly, (2) the identification of efficient procedures for measuring the target construct to be identified in (1) above. I will contextualize these intertwined challenges with regard to the US situation through the analysis of three different assessment cases: the use of the ACTFL framework to develop tests of language competence, its adaptation to the NAEP exam, and finally the use of exit exams to assess proficiency above and beyond course completion.

As described in previous sections, the prevalent influence of the overarching framework of the ACTFL movement on the assessment landscape of Spanish (and other second languages, for that matter) highlights both the positive and the negative aspects of the ACTFL conceptual model (and, by extension, of the CEFR model). As acknowledged in the document that describes the ACTFL Guidelines, the latter were developed by a committee, and all subsequent developments of the original framework (e.g., the Standards) were also drafted by committees. It is precisely the fact that decisions were made by a committee

that brings about both the positive and the negative aspects of the process (e.g., Fulcher, 1996). By and large, committees can make quick and proactive decisions while putting on hold concerns about incomplete theoretical models for the benefit of advancing a progressive agenda. By the same token, however, committee-based decisions can be inadequate for developing, over the long term, a research-based, stage-wise, open system of evaluation of the implementation of assessment procedures.

In other words, the committee-based system adopted by ACTFL to make decisions about assessment procedures has both succeeded and failed. It has succeeded in developing a strategic and progressive agenda that should be both recognized and lauded. This is one reason why the ACTFL movement has drawn such a massive level of support from the majority of second language teachers and testers. On the other hand, it is hardly controversial to say that, after substantive and extensive criticism over more than 25 years, the ACTFL Guidelines have changed only minimally, despite the fact that critiques of the ACTFL Guidelines, starting in the early 1980s, have been followed by concrete suggestions. For instance, Salaberry (2000) provided a list of possible modifications that the Spanish version of the ACTFL-OPI test would require to improve the construct validity of the test. Similarly, Chalhoub-Deville and Fulcher (2003) outlined a general agenda of future research, to improve on the current assessment procedures of the ACTFL-OPI.

The challenge of implementing an assessment procedure to measure the construct of language competence can be as important as the one of defining the given construct. For instance, the FL (foreign language) NAEP test became nonviable due to an implementation constraint. It was assumed that newer technological tools (e.g., video conferencing) would eventually improve the process of assessing interpersonal competence, making the test more efficient and thus viable. Alternatively, the assessment of the construct of language competence could have been operationalized alongside multiple layers or tracks of information that would allow for greater flexibility with regard to the implementation phase. More importantly, the implementation of testing procedures to assess the construct of language proficiency does not have to be in the form of a high stakes external exam administered after students have completed a series of courses intended to achieve a minimum level of proficiency. For instance, one of the reasons that prompted the use of a standardized measure of proficiency of Spanish at the University of Minnesota was the claim that seat-time requirements (i.e., the establishment of a required number of credit hours through course completion) were not adequate to achieve high levels of competence in Spanish. The argument was that a course-external testing instrument was necessary to ascertain that the objectives of the course were actually achieved. While there is nothing intrinsically wrong with the use of additional external testing procedures to measure achievement of course objectives (see the previous discussion of the internal and external test of the IB exam), it is also possible to argue that such external tests may simply shift the shortcomings of a course-internal testing system to one used outside of the course. What matters most is that the construct of language competence be properly defined, circumscribed, and implemented through clear assessment procedures. In fact, in some cases the objective of

external assessment can be accomplished in a more efficient way through the use of internal testing procedures easily implemented with the adaptation of final exams. For instance, the results of a final exam can be taken into account to compute a final grade for a course, but they can also be regarded as a test of minimal competence, which must be approved in order to complete a second language requirement.

Future Directions

Arguably there has been some limited progress in the assessment of language competence in Spanish. Nevertheless, the two biggest challenges continue to be the identification of the construct of communicative ability (a concept advanced in part by the communicative movement of the 1980s) and the search for guidelines and procedures for measuring such competence accurately (a goal brought up by the ACTFL movement in the 1980s). The responsibility for addressing these challenges should be shared by testing agencies as well as by academic institutions.

In this respect, there are a number of promising options that the profession should continue developing. These possibilities are inherently defined by the challenges identified in the previous sections. For instance, of the three College Board Spanish exams (the AP, the CLEP, and the SAT) the AP is the most promising one, mostly because it incorporates an educational component—the AP course—that precedes the actual assessment—the AP exam. The AP course preparation is progressive in its outlook (e.g., focus on sociolinguistic appropriateness to measure grammatical competence) where learning processes are concerned, and thus it paves the way for the development of a test that can match the objectives of a forward-looking curriculum. More importantly, the AP exam, by virtue of being connected to the pedagogical structure that precedes it, is most likely to incorporate the changes in our definition of the construct of language competence, which is already fairly sophisticated.

There are also opportunities to continue developing the theoretical framework advanced by the *Standards for Foreign Language Learning*, a document that already proposed an ambitious agenda. That is, both demographic trends (e.g., Crawford, 2000; del Valle, 2003) and new theoretical outlooks (e.g., Swain, Kinnear, & Steinman, 2011) promote the expansion of the definition of a second language learner as someone who can compare and assess the sociolinguistic context of a particular interaction so as to incorporate a notion of a bilingual speaker in a broad manner, as someone who can manage more than one linguistic code in diverse social contexts. This expanded view of language competence, which moves from a sociolinguistically sensitive second language learner to a sociolinguistically aware bilingual speaker, incorporates an even more sophisticated definition of language. This new definition, so broad and complex, will pose even more challenges with regard to the testing procedures necessary to assess it.

Arabic Language: Current Status and Policy

Arabic is spoken as a native language by over 300 million people on two different continents: Africa and Asia. In addition, Arabic is the official language in 26 countries around the world. Given the enormous number of native speakers and the large number of countries where it is spoken as a native language, Arabic was selected as one of the six official languages in the United Nations. Another point of pride for the Arabic language is its historical connection to Islam, since it is the language of the Qur'an. This makes it the religious language of over a billion Muslims around the world. In Muslim countries, learners of Arabic are revered and enjoy several privileges because of this prestigious status of Arabic in Islam (Suleiman, 2003). Recently, there has been a substantial increase in the number of Arabic learners in Western countries. For example, in the USA, numbers of Arabic learners increased from 5,505 in 1998 to 35,083 students in 2009, according to a survey conducted by the Modern Language Association (Furman, Goldberg, & Lusin, 2010). Because of this growing interest, Arabic has become the eighth most studied language in US universities. The renewed interest could be interpreted within a wider context of Westerners attempting to better understand Islam and Muslims. Also, it is clear that there is a growing political and economic interest in the Middle East. More importantly, many Western governments now have a firm belief that learning strategic languages, such as Arabic, is part of their national security strategy, particularly after the events of 9/11 (National Research Council, 2007).

After reclaiming their independence in the second half of the 20th century, the Arab countries espoused educational policies that promoted the teaching and learning of Arabic in schools and the use of the language in the wider society. Arabic was also stated in all Arab constitutions as the national and official

language of these countries. One of the main goals of any educational system in the Arab world has apparently become the training of citizens who can use Standard Arabic accurately and fluently. The purpose of this policy was to revitalize the status of Arabic which was negatively affected by colonial policies that promoted native languages of the imperial powers (see Daoud, 1991, for a comprehensive discussion of the Arabization policies). Modern Standard Arabic, which is a simplified version of Arabic, replaced Classical Arabic in schools and media. Also, Arab governments have provided substantial funding for developing new Arabic curricula and also establishing teacher-training programs. Arabic is currently taught in schools as a core subject from kindergarten to secondary level for around six to eight hours per week. In addition, university students are required to take Arabic as part of their academic programs.

Description of the Arabic Language

Linguistic Features of Arabic

Arabic is a Semitic language that consists of 28 letters written from right to left. Modern Standard Arabic (MSA) is the media language and what is used in the formal public domain. MSA is understood by anyone who has a basic level of education across the Arab world (Taha-Thomure, 2008). It coexists with tens of national and local dialects or vernaculars such as Egyptian, Lebanese, Syrian, Yemeni, Tunisian, and many others that were distributed and redistributed mainly due to large-scale migrations (Owens, 2003). This could be seen as a continuum: MSA resides on one side, and the various vernaculars are dotted all over it. Following Blanc's (1960) approach, one could see the plausibility of this continuum, which includes five levels of speech ranging from plain colloquial to standard classical. Each of those levels has its own linguistic characteristics and features.

Diglossia in Arabic

Charles Ferguson was the first to coin the term "diglossia" in 1959. Ferguson defined diglossia as a language environment in which, in addition to several primary dialects, there is a highly codified variety reserved for written literature and learned largely through formal education. That is the variety of choice for most written and formal spoken purposes; however, it is not usually used by the community for everyday conversation (Ferguson, 1959).

Every native speaker of Arabic acquires his or her own regional/local dialect, which is considered less prestigious (L) within this diglossic context. MSA, or the more prestigious high (H) variety of the language, is taught in schools to all students as of grade 1 across the Arab world. MSA is considered to be a "superposed" variety, in Ferguson's words, and is considered to be the only true form of Arabic (Ferguson, 1959). All written communication is done in MSA, including newspapers, magazines, official letters, formal speeches, bills (both utility bills and government resolutions), and so forth, although recently and with the advent of various Internet tools such as Facebook, Yahoo! groups, Google Chat, and Skype, many have started using dialects as a writing genre at this informal level.

Teaching and Learning of Arabic in Schools, Colleges, and the Workplace

Teaching Arabic as a First Language in the Middle East: Realities and Problems

In most public schools in the Arab world, and in many of its private schools, Arabic language skills are taught through textbooks provided by the ministries of education (Taha-Thomure, 2011). Arabic language textbooks are made up of texts written or edited by Ministry of Education curriculum specialists. These texts often range from those composed of a few words and sentences, to relatively higher-level texts composed of paragraphs, to extended texts that may be one to three pages long at most. Examples of topics include family, school, environment, animals, folk stories, poetry, and myths, which are often edited by authors as needed.

The learning and teaching of Arabic language in most schools have been closely synonymous with textbooks. Many unknowingly believe that the textbook is the school “curriculum” while, in fact, any curriculum must include: standards for teaching, benchmarks and performance indicators, teaching techniques, and assessment tools. The absence of those and of print-rich classrooms has led schools to having a teacher- or textbook-centered curriculum that tests rote learning and knowledge level skills rather than actual achievement and growth (Taha-Thomure, 2008).

Teaching Arabic as a Foreign Language in Different Parts of the World: Realities and Problems

Foreign languages such as Arabic have experienced unprecedented growth in student enrollment—126.5% between 2002 and 2006 (Furman et al., 2010). Such growth has led to the mushrooming of hundreds of Arabic language programs around the USA, where the language is taught primarily by native speakers who do not necessarily have the training needed in pedagogy to effectively teach and assess students’ language proficiency. Many experts in the field of Arabic language teaching complain of the scarcity of Arabic language teachers who are able to combine a solid foundation in pedagogy, teaching methodologies, reflective techniques, and instructional technology (McCarus, 1992). Many initiatives have been launched to help ease those issues including the StarTalk program, which trains thousands of teachers of critical languages including Arabic every summer across the USA (StarTalk, 2011).

Assessment of L1/L2 Arabic

Assessment of Arabic as a Foreign Language (AFL)

This section addresses the AFL assessment practices with specific focus on the US context. One of the most commonly used assessment frameworks in a number of

AFL contexts is the Interagency Language Roundtable (ILR) scale. For example, the ILR Oral Proficiency Interview (OPI) is used by different governmental agencies to make hiring and promotion decisions (Swender, 2003). Also, it is used in intensive AFL programs to make various decisions including ones regarding placement, exit, and admission. A widely used test that was developed based on the ILR platform is the Defense Language Proficiency Test 5 (DLPT 5). The DLPT 5 is the latest version of this test originally developed in the 1950s (Defense Language Institute [DLI], 2012). The test measures three areas: listening comprehension, reading comprehension, and speaking proficiency (using an OPI protocol). It uses a multiple choice format for both the reading and the listening sections, and an interview procedure for the speaking part. The DLPT 5 was mainly developed as a computer-based test (CBT), but it is also available in a paper and pencil format, and the scores are reported according to the ILR scale levels (e.g., 0+, 1, 1+, 2, etc.). Scores obtained from this test are used to assess the language proficiency of military personnel, and decisions regarding promotion or extra pay are made accordingly (DLI, 2012).

In academic circles, most Arabic language tests are developed based on the ACTFL guidelines, which were developed in the 1980s by the American Council on Teaching Foreign Languages (ACTFL) and the Educational Testing Service (ETS). One of the most commonly used exams in this context is the ACTFL Oral Proficiency Interview (OPI), which is an adaptive test between an ACTFL-certified interviewer and an interviewee lasting between 10 and 30 minutes (Swender, 2003). The interviewer asks a number of questions that target different language functions in order to establish the ceiling and floor of the examinee's proficiency. Once she or he decides on a level (out of 11 ACTFL levels), the interview comes to an end. The speech sample is second-rated by another examiner and in case of disagreement a third rater is employed (see Swender, 2003, for more information). The ACTFL OPI is used for a number of purposes, such as placement, diagnosis, and certification of teachers (Gebriel, 2009a). A new version of ACTFL OPI that was recently developed is called ACTFL[®] Oral Proficiency Interview-computer (OPIC). This computer-based interview is conducted between the examinee and a virtual avatar. The responses are digitally recorded and simultaneously stored on a secure electronic system.

The Center for Applied Linguistics (CAL) has a suite of Arabic language tests that are used for a number of purposes in different contexts (Center for Applied Linguistics, 2007):

- *Arabic Proficiency Test (APT)*: This is a paper and pencil test that measures both reading and listening based on the ACTFL levels. APT is used in different contexts including high school, university, and nondegree programs.
- *Arabic Speaking Test (AST)*: This test includes a simulated OPI that measures speaking proficiency in Arabic. AST is tape-mediated since students listen to prompts from a tape and then their responses are simultaneously audiorecorded.
- *Online Arabic Proficiency Test (O-APT)*: O-APT is a paper and pencil test that includes three sections: listening, reading, and writing. The O-APT is used by students who are interested in college credit for the Arabic language.

Mahdi Alish, while working at Ohio State University, developed Arabic Course Achievement Tests that are used as quizzes, midterms, and finals at different levels including beginners, intermediate, and advanced. Also, he developed the Arabic Reading Proficiency Test, which is used with high school, college, and nondegree programs to assess reading proficiency based on ACTFL levels (Center for Applied Linguistics, 2007).

Assessment of Arabic as a First Language

The educational system in Arab countries is very centralized: Schools use the same textbook and follow the same syllabus. This centralized system has affected assessment practices in schools. Final exams are developed by educational directorates in each governorate and administered on the same day for all students in this region. The centralized system reaches its peak in the high school leaving exam which is a nationwide test. This exam is used in most Arab countries as both an exit and a university admission test, which makes it a very high stakes test. Hargreaves (1997) accurately refers to the stress and pressure students, parents, and teachers go through when preparing for the high school leaving exam in Egypt, and by default in many other Arab countries. Almost 15 years after Hargreaves wrote her description, the situation in Egypt and in most Arab countries is still the same. Assessment in this region has a huge impact on curricula and other school activities. In a study conducted in Jordan, Al-Jamal and Ghadi (2008) showed that the high school leaving exam affected teachers' selection of teaching materials and techniques. Accordingly, those teachers adapted their teaching and focused mainly on preparing their students for this exam.

Arabic exams follow a traditional paper and pencil format with a specific focus on reading, writing, vocabulary, and grammar. Grammar is given special attention because of the grammar-centered teaching methods and also the complex nature of Arabic grammar. Interestingly, in most Arabic tests, there is a separate section assigned for poetry. This is not surprising given the historical connection between Arabs and poetry. Most of these exams usually use a combination of multiple choice and gap-filling formats, in addition to a writing section where students are asked to compose an essay or a paragraph depending on their grade level. Traditional test formats are preferred over alternative assessment because of their practicality. In most Arab countries, large classes are very common in schools, and consequently teachers attempt to use tests that are suitable for this context. Hence, it is very rare to find any testing of both speaking and listening skills. Before exams, teachers spend a considerable amount of time preparing their students using various materials and strategies. The preparation time increases substantially before final exams.

Until very recently, there were almost no standardized proficiency tests of Arabic as a native language. A very promising project for developing a proficiency test for native speakers of Arabic started recently at the United Arab Emirates (UAE) University (2010). The new test, which is called the Alain Test of Arabic Proficiency (ATAP), moves away from the grammar-oriented paradigm that is very common in academic circles in Arab countries and follows a communicative approach to language assessment. ATAP has four sections: reading, listening,

speaking, and writing. For both reading and listening a multiple choice format is used, while for writing and speaking test takers have to produce written and oral texts. The test is computer-based and it is scored automatically except for the writing and speaking sections. Since it is designed as a proficiency test, ATAP is not linked to any teaching context or specific curriculum. That is why it can be used in different contexts to assess the proficiency of native speakers in MSA. For example, the UAE Ministry of Education started using ATAP to assess the Arabic proficiency of their current teachers. Also, the UAE Ministry of Defense is planning to use ATAP with military personnel (Ali, personal communication, July 24, 2011). The UAE University aims also to promote the test in other Arab countries since there is no other competitor in the market to date.

Evaluation

The review of the different Arabic language tests has shown a wide range of assessments used for different purposes in academic settings such as admission, placement, and exit decisions. In nonacademic contexts, these tests are mainly used for either hiring or promotion purposes, especially in AFL settings. Current trends in language assessment, which espouse new functions of assessment beyond gatekeeping, should be considered in Arabic language test development. For example, Chalhoub-Deville (2001) argues that the need for diagnostic testing is on the rise and consequently new diagnostic tests should be developed to address this issue. Another observation from this review is the very few tests in the first language context that measure general proficiency of Arabic. Adding to this, there is an urgent need for tests that target Arabic for specific purposes.

A unique problem associated with assessment of Arabic has to do with authenticity (i.e., the similarity between the test tasks and the target language use [TLU] domain). First of all, the diglossic situation in Arabic makes it extremely difficult to reach a definition of the native speaker. MSA is a variety which is only taught in schools and rarely used in everyday activities—except for formal contexts, such as journalism and news reporting. Accordingly, it is not easy to develop authentic assessment tasks that are reflective of the TLU domain. Elgibali and Taha (1995) analyzed the different tasks described in the ACTFL Arabic Proficiency Guidelines and concluded that listening and speaking tasks at both the advanced and intermediate levels require dialectal use, not MSA. For this reason and others, testing programs have recently developed new assessments for different dialects of Arabic (ACTFL, www.languageTesting.com).

The final remark in this discussion focuses on the psychometric qualities of the different L1/L2 Arabic tests. Testing programs involved in developing Arabic assessments need to provide more information about the reliability and validity of their test scores. Most of the testing programs do not offer sufficient data about the validation process in their test manuals. In addition, the field testing of AFL tests is problematic, since it is hard to find candidates with advanced Arabic proficiency as indicated by Winke and Aquil (2006). Furthermore, the investigation of score reliability in the OPI context does not go beyond checking inter-rater reliability. Although inter-rater reliability is a required procedure in this context, it is not sufficient. There is a clear need for using more sophisticated techniques, such

as generalizability theory and IRT, to look into the relative effects of different test facets on test scores (Gebriel, 2009b, 2012). Finally, a number of Arabic tests reviewed in this chapter are used for making various decisions. However, little evidence is provided about the suitability of using test scores in making such decisions.

Challenges and Future Directions

According to Al-Rajhi (2006), one of the biggest challenges facing Arabic language teaching is the absence of an academic body in charge of setting educational guidelines and standards. Schools independently develop their own set of acceptable standards guidelines and skills to be taught, which vary considerably from one institution to another. Many schools do not have a comprehensive articulation of standards, benchmarks, performance indicators, and instructional and assessment methods to be used. Classroom instruction around the Arab world remains largely textbook-based and teacher-centered, and standards have not found their way yet into classrooms, especially in public schools (Taha-Thomure, 2008). Arab countries taking the 2006 PIRLS test (Progress in International Reading Literacy) ranked 42, 43 and 44 out of 45 (PIRLS, 2006).

For Arabic as a foreign language, the same concerns prevail, except that ACTFL has developed standards for teaching Arabic as a foreign language. The standards are referred to as the 5Cs and include: cultures, communication, communities, connections, and comparisons. The difficulty, however, lies in regulating what the various Arabic language programs offer and moving to a more standards-based approach that aligns all aspects of the curriculum (Taha-Thomure & Lyman-Hager, 2009).

Standardized tests for Arabic as a foreign language have blossomed since the year 2000, and the field now has several high and low stakes tests to use including many that were outlined earlier in this chapter. However, for Arabic as a first language those tests remain scarce and unrelated to any national Arabic language arts standards and benchmarks (Sakr, 2008). Stakeholders will very soon need to call on assessment experts to help them define their purpose for having national Arabic literacy assessment and develop the performance and content standards it is based on.

Based on the previous discussion, it is clear that more attention should be paid to test fairness and ethics issues. These concepts should be regularly discussed among school administrators, test developers, teachers, and, more importantly students—particularly in the Middle East where there is little awareness about test fairness. There is also an urgent need for more transparency in test development and validation. Since Arabic tests are increasingly used in a number of contexts to make various decisions, validation studies are needed to check the appropriateness of these decisions. In addition, students should be provided with more information about their rights and responsibilities. Furthermore, the public should have access to different sources of information about how Arabic tests are validated, for what purposes they should be used, and what procedures are employed to ensure the accuracy of test scores. Such a course of action will help achieve the professionalization of the field of Arabic language assessment.

Assessing Farsi

Hossein Farhady

Iran University of Science and Technology, Iran

Kobra Tavassoli

Karaj Branch, Islamic Azad University, Iran

Introduction

The Persian language, also known as Farsi, is the most widely spoken member of the Iranian branch of the Indo-Iranian languages, itself a subfamily of the Indo-European languages. It was the language of the Persian Empire (550–330 BC) and was spoken in ancient times ranging from the borders of India in the east, Russia in the north, the shores of the Persian Gulf in the south, to Egypt and the eastern Mediterranean in the west (Rahnamoon, 2011). In fact, Persia or Pars was the land, and Persian or Parsi referred to both the language and the inhabitants of the land (Yarshater, 1989; Akbarzadeh, 2003). The change from Persia to Iran and Persian to Farsi occurred in 1935 when the ruling government of the time requested those countries with which it had diplomatic relations to call the country Iran rather than Persia. The suggestion for the change is said to have come from the Iranian ambassador to Germany who, under the influence of the German government, wanted to develop good relations with nations of “Aryan” blood. That is how Persia changed into Iran and Persian or Parsi changed into Farsi, though some scholars still prefer the word Persian (Yarshater, 1989).

Scholars recognize three major dialects of Persian spoken in Iran, Afghanistan, and Tajikistan, called Farsi, Dari, and Tajiki, respectively. According to *The World Factbook* (CIA, *n.d.*) and UCLA Language Materials Projects (2011), the distribution of Farsi speakers includes over 40 million in Iran (about 55% of the population), over 14 million in Afghanistan (50% of the population), and over 4 million in Tajikistan (65% of the population). It should be mentioned that, although Farsi is the official language of Iran, other languages are used as the first language of many Iranians, including 18% Azari, 10% Kurdish, 7% Guilaki and Mazandarani, 6% Lori, and 5% Balouchi, Arabic, and other languages (CIA, *n.d.*). Further, despite the fact that versions of Farsi are spoken in different countries, except for Iran,

there is not much documented information on either teaching or assessing it in these countries. Therefore, information in this article is mostly based on documentation from Iran.

Description of the Language

Farsi is written in a variety of the Arabic script called Perso-Arabic, with some variations due to the phonological differences between Farsi and Arabic. This variety came into use in Iran after the Islamic conquest in the seventh century (UCLA Language Materials Projects, 2011). After the Arab conquest, knowledge of Arabic became necessary for Iranians because it was the language of both the new rulers and their religion. Consequently, Arabic greatly influenced Farsi, especially by inclusion of a large number of Arabic words into Farsi (Iran Chamber Society, 2011a).

Persian script is composed of Arabic letters written from right to left. The alphabet consists of 32 letters, most of which are capable of being linked to each other from left and right just as in English cursive writing. Therefore, letters often change shape depending on their location within a word. Except for eight letters that have single forms, the rest have both a full form and a short form. Further, eight letters are exclusively Arabic, and appear only in the Arabic words, and four letters are exclusively Farsi, and do not appear in Arabic words. Persian syllables appear in three types: consonant vowel (CV), CVC, and CVCC. Farsi is usually written using only consonants and long vowels. Short vowels are not used in writing but they are pronounced. Some diacritics are used above or below letters to indicate short vowels, but these diacritics are normally used only by children or by people learning Farsi as a foreign language (Iran Chamber Society, 2011b).

Farsi grammar is relatively simple. It has no grammatical gender or articles, but has person and number distinctions. Farsi nouns are marked for specificity with one marker in the singular and two in the plural. Farsi adjectives usually follow the nouns they modify, although there are special constructions in which they may appear before the nouns. Verbs are formed using one of two basic stems, conjugated by adding prefixes and suffixes to indicate tense, mood, and person, and they agree with the subject in person and number. The most common word order is subject–object–verb, though other orders are possible but not common (UCLA Language Materials Projects, 2011).

Teaching–Learning Contexts in Iran

Despite Iran's long history, the first modern school and university in Iran are not more than 150 and 75 years old, respectively. However, the previous regime speeded modernization in education at all levels, and developed a systematic educational program from primary to high school and some higher education centers. After the Islamic Revolution in 1979, significant reforms were planned at all levels of education and some of the Islamic values were applied to the

educational system, most important of which was Islamizing the textbooks and instructional materials (Farhady & Hedayati, 2009).

Iran has a unified public educational system that includes five years of primary school, three years of junior high school, three years of high school, and one year of pre-university, which is available for those who intend to continue their studies at university. All planning and policies are designed, implemented, and evaluated by the Ministry of Education (Secretariat of the Higher Council of Education, SHCE, 2006). At school, Farsi is taught as a subject similar to other courses such as mathematics and science, even though it is the language of instruction. The time allocated to teaching Farsi at primary school is 12 hours a week at grade 1, 8 hours at grades 2 and 3, 7 hours at grades 4 and 5, 5 hours a week at junior high school, and 4 hours a week at high school (SHCE, 2006, pp. 155, 170, 632). Unfortunately, there is no accommodation for students with a first language other than Farsi when they start their education at primary school. At primary school, one teacher teaches all the subject courses, but at junior high and high school Farsi is taught by teachers who have university degrees in either Persian literature or teaching Persian.

All textbooks are prepared and distributed by the Ministry of Education and used at all schools across the country following the same procedures mandated by the ministry. Despite the uniformity implemented by the Ministry of Education in teaching Farsi, assessing Farsi is localized at the school level. Teachers prepare, administer, and score the exams based on the instructions provided by the ministry (SHCE, 2006). However, to observe certain standards of achievement, at the last grade of every educational cycle, the tests are prepared by selected teachers, administered in specific locations at the national level, and scored blindly under the supervision of the ministry (SHCE, 2006; Farhady & Hedayati, 2009).

The Ministry of Science, Research, and Technology (MSRT) coordinates teaching Farsi at the higher education level. All university students, regardless of their field of study, are required to take a three-unit credit course called General Persian (Hatami, 2006). There are no documented objectives or guidelines for teaching this course. However, comments provided by a number of professors indicate that the unwritten objectives of this course are to provide information about Farsi language and literature, introduce some prominent authors and poets of the Farsi language, teach some literary prose and poems, talk about literary schools, and teach Farsi grammar. Although the textbook for this general course is prepared by a group of specialists in Farsi language and literature and published by MSRT, there does not seem to be a uniform set of strategies to teaching the textbook across the universities. Each university has its own procedures, mostly initiated by the preferences of the professors teaching the course. For example, one of the preferred objectives of teaching Farsi in one of the universities, as stated by the professors, is to prepare students to write well-organized academic papers in their field of study in Farsi.

Of course, both ministries emphasize the importance of the Farsi language and many documents exist on planning the objectives of teaching Farsi at all levels of education. Table 112.1 is a summary of the objectives of teaching Farsi at different levels of schools published by SCHE (2006).

Table 112.1 Objectives of teaching Farsi at schools in Iran (SHCE, 2006)

General goals	Establishing the Persian language as the formal common spoken and written language of Iranians (p. 26) Valuing Persian literature as an art and considering it a symbol of the national and social integrity of the country (p. 27)
Objectives at primary school	Students should be able to read and understand books and newspapers (p. 31)
Objectives at junior high school	Students should be able to use language skills fluently (p. 37) Students should develop an interest in reading literary and cultural texts (p. 38)
Objectives at high school	Students should be able to read books written in Persian and speak fluently (p. 42) Students should be able to write letters, reports, and essays (p. 42) Students should be able to understand the important role of the Persian language in communication among Iranians and be familiar with important literary works in Persian (p. 43)

Assessment Practices

With new developments in educational psychology and with the recent shift from traditional testing to assessment culture, the Ministry of Education has made every attempt to direct the educational system in a way to conform to new developments (Farhady & Hedayati, 2009). Short in-service teacher-training courses have been offered to familiarize teachers and administrators with the new philosophy of assessment and the relationship between teaching, learning, and assessment (World Data on Education, 2011). As a result of this philosophy, assessment policies were designed and sent to all school districts for implementation (SHCE, 2006). Below is a list of 15 general assessment principles at school level that are approved by the ministry (SHCE, 2006, pp. 260–2).

Principles of assessing Farsi in schools in Iran

1. Paying attention to the inseparability of assessment and learning
2. Using assessment results to improve teaching, learning, and methods of teaching
3. Observing coordination between objectives, materials, teaching methods, learning strategies, and assessment processes
4. Paying attention to students' readiness
5. Paying attention to all aspects of students' growth
6. Paying attention to different aspects of knowledge and skills
7. Paying attention to students' self-assessment
8. Using assessment for group work projects
9. Paying attention to processes that help students to be critical readers
10. Emphasizing creativity
11. Using different instruments and methods in assessing students' achievement

12. Paying attention to schools' and teachers' autonomy in assessment processes
13. Observing ethical issues in assessment
14. Paying attention to individual differences
15. Applying uniformity in assessment procedures

The principles above seem quite progressive and in accordance with recent developments in educational assessment. However, another reality lies behind the documented principles. Both teaching and assessment are carried out using traditional methods with the belief that knowledge of language is the knowledge of its rules and the main emphasis is on learning language components (vocabulary, spelling, and grammar) rather than using language in actual communication (Farhady & Hedayati, 2009). In addition, knowledge of the literature rather than language becomes important at junior high and high school levels. Further, despite such elaborate strategic principles at the public education level regarding both teaching and assessment, there are no documented goals or guidelines either for assessing Farsi in the University Entrance Examination (UEE) or for teaching and assessing Farsi at the university level.

According to the instructions given by the Ministry of Education (SHCE, 2006), the assessment of Farsi at primary and junior high school should focus on three skills of "dictation or spelling," "reading comprehension," and "writing." Although no such instructions are given for assessing Farsi at the high school level, teachers claim that tests consist of four major sections of "grammar," "linguistics," "dictation," and "writing rules" in written form. Most of the items at the high school level are related to knowledge about language and literature rather than to language use. Teachers also claim that most of the items focus on memorizing rules of language rather than on either the use of language in actual communication or students' ability in producing appropriate language.

Assessing Farsi is also unsystematic at post-high school levels. In the nationwide UEE, for example, only 25 multiple choice items are allocated to assessing applicants' command of Farsi (National Organization of Educational Testing, NOET, 2010). The general section of the UEE is designed to measure the applicants' general knowledge of Islamic studies, Farsi language, Arabic language, and a foreign language (English, French, German, Italian, or Russian). The UEE is developed each year under strict security in the NOET headquarters by experienced teachers, who write parallel tests for each subject area. The items are never pretested because each test is published for public use with keys to the items a few days after the exam and, unfortunately, no written report on the psychometric characteristics of the UEE is available to independent researchers (Farhady & Hedayati, 2009). However, the content of items is based on the content of the textbooks studied at high school and the Farsi items are mostly intended to measure knowledge of literature and rules of grammar. At the university level, too, in addition to the lack of uniformity across universities, most of the tests of Farsi are directed towards measuring "word meaning," "meaning of literary sentences and poems," "biography of authors," "literary devices," "literary schools," and "grammar."

To see how the instructions by the Ministry of Education are translated into real testing contexts, several tests from different levels of education were examined.

Three types of items emerged from analyzing the tests: selected response, including true or false and multiple choice; constructed response, which includes completing a word, a sentence, or a paragraph; and free response, which includes writing a composition for which no rubric is provided. Analysis of different tests at each level and counting the frequency of each item type revealed that, with varying degrees, more than 40% of the items measure vocabulary with different purposes such as finding synonyms, antonyms, or plain meaning, and about 50% of the items deal with measuring knowledge of grammatical rules. The rest of the items are intended to measure knowledge of literature. Some examples are given below to demonstrate what the items focus on.

Selected response

Underline the (bound or free) morphemes in the following words.

Underline the subject and the predicate in the following sentence.

Underline the words with wrong spelling in the following paragraph.

Underline the literary devices in the following poem.

Underline the name of the author of the following piece.

Constructed response

Fill in the blanks to complete the following words.

Fill in the blanks to complete the following sentences.

Write answers to the questions following the passage.

What points should be taken into consideration in writing a letter?

Write the synonyms or antonyms of the following words.

Write a sentence using the following three words.

Name the literary device used in the following poem.

Name the authors of the following books.

Write the meaning of the following sentences or poems in plain Persian.

Free response

Choose one of the following topics and write a composition on it.

The form of some of the items seems to be in line with the principles outlined by the Ministry of Education. Nevertheless, only a few, if any, of the general assessment principles mentioned are used. Most of the items focus on word and sentence meaning that require no engagement on the part of test takers. Further, a majority of the items seek information about the language and literature that can be answered by memorizing details from the textbooks. There is no or little sign of attempt to measure test takers' ability in using language appropriately, which is one of the purposes of language tests for native speakers (Mumford, 2009).

Challenges and Future Directions

In an informal survey, primary school teachers claimed overall satisfaction with teaching and assessing procedures of Farsi because they believed that textbooks and the assessment practice were in line with the instructions from the Ministry

of Education. However, teachers at junior high and high school showed concerns about three issues. First, they believed that the time allocated to teaching Farsi is not sufficient to cover the content of the textbooks, let alone to perform activities such as group work, self-assessment, project completion, etc. Second, students do not take Farsi instruction seriously because they believe that it is their native language and they already know it. Therefore, they are not motivated to improve their language ability. Their only concern is passing the course, which is not very difficult with a 50% achievement criterion. Third, the textbooks change frequently. This makes assessment more difficult for teachers because they have to change their testing strategies and techniques without preparation. Further, many test preparation materials exist in the market that are based on previously administered tests. These materials are designed to boost students' scores on the test rather than help them learn using language in context. Similar comments were made by university instructors about the lack of systematicity in teaching as well as assessing Farsi. They believe that although the purpose of teaching Farsi at the university level should be writing academic essays and performing academic language, no such skills are taught or assessed because the course content is directed towards Persian literature and literary devices.

Although the Ministry of Education has made reasonable efforts to alleviate the shortcomings of teaching and assessing Farsi, there do not seem to be ready-made and short-term solutions to make the transformation easy, since implementing the principles of a new philosophy of education requires long-term plans. However, the following suggestions may help facilitate the process.

First, most of the assessment of Farsi in Iran, as the sample items revealed, focuses on measuring detailed pieces of language and grammatical rules rather than on comprehending and using language in real contexts. According to the teachers and instructors, comprehension of texts, using appropriate utterances in communicative contexts, and skills in writing are not included in the tests. To address this issue, it seems necessary to provide teachers with appropriate in-service training courses and encourage them to move from traditional teacher-dominant classroom procedures to more democratic and student-centered strategies. This will enable teachers to follow assessment procedures and processes outlined by the Ministry.

Second, there seems to be no attention paid to psychometric characteristics, especially reliability and validity, of the assessment devices. There is no report on validity or reliability of the tests used at different levels of education. Except for content validity, which can be subjectively verified by comparing the content of the tests with the content of the materials to be tested, there is no evidence of statistical desirability of the items, empirical validity, or reliability. Of course, most of the teachers have university degrees and training on the fundamentals of assessment at the university. However, they may not have an opportunity to use their knowledge in the assessment process. It could help if committees were established to oversee the tests used in public schools. Of course, there is an office of testing and assessment in the Ministry of Education to oversee all assessment activities for all subject areas including Farsi. However, this office seems to be more involved in policy making rather than helping teachers and administrators in schools.

Third, it seems essential that ministry officials think about a general language proficiency test of Farsi both as a first language and as a second language at different levels of education. As far as documented literature indicates, there is no such test. Of course, organizations outside the country such as the US Defense Language Institute (DLI), Foreign Service Institute (FSI), American Council of Teaching Foreign Languages (ACTFL), and other private organizations have developed good language proficiency tests of Farsi as a second language. These tests, however, are designed for particular uses and are not available for public purposes. It is time that the Ministry of Education, experts in Farsi language, and experts in language assessment started a joint attempt to design a proficiency test that would serve as a criterion of language ability in various academic contexts in Iran. Such a test would also be useful in recruiting people for jobs that require advanced proficiency in Farsi.

Finally, there is a great need to improve the assessment literacy of the stakeholders, including authorities, teachers, professors, students, parents, and community members. A shared knowledge and a common understanding of the importance of assessment and its influence on the meaningful learning of the materials will certainly facilitate the transition from traditional approaches of teaching and testing to modern learning and assessment procedures.

Assessing Hebrew

Ofra Inbar-Lourie

Tel Aviv University, Israel

Introduction

Hebrew is spoken today as a first, second, or additional language by about nine million speakers, the majority of whom reside in Israel. These include native Hebrew speakers and second language speakers, immigrants and ethnic minorities, in particular Muslim and Christian Arabs, as well as foreign workers who live in the country on a temporary basis. Hebrew is studied as an additional language in various settings outside Israel, most prominently at Jewish schools, and used for religious purposes by Jews the world over. It is also spoken as a heritage language by former Israelis living abroad. Last but not least it is studied for academic and vocational motives.

Hence the assessment of Hebrew is targeted at various audiences in diverse frameworks, as a first, second, foreign, heritage, or additional language. Due to its religious historical standing, considerations for using Hebrew extend beyond the educational or linguistic realm, with Hebrew serving as symbolic means for gaining and retaining self- and group identity among Jews living in or outside Israel.

This chapter begins by providing some information on the background and characterizing features of the Hebrew language. It proceeds to describe the manner in which knowledge in Hebrew is evaluated in Israel and elsewhere, culminating with challenges and future orientations.

Description of the Hebrew Language

Hebrew belongs to the Canaanite group of languages, a branch of the Semitic languages. Hebrew is the language of the Bible, with the written language going back some 3,000 years. Following the destruction of the Second Temple and Jewish

exile (AD 70), the language was employed mostly for liturgical purposes (Haramati, 2000). Sáenz-Badillos (1993) divides the Hebrew corpus into four parts: Biblical Hebrew, Rabbinic Hebrew, Mediaeval Hebrew and Modern or Israeli Hebrew. Throughout the years Hebrew has retained its essential morphological, phonological, and even syntactical features with the biblical lexicon forming the basis for present-day Hebrew. The language is written from right to left, and has an abjad writing system (a consonant alphabet with vowel sounds indicated by diacritics) with 22 consonants and 5 final letters. The consonantal alphabet appears with vowel signs in the form of diacritics or points, currently used mostly for beginning readers and in sacred texts (Shimron, 2008).

The revival of Hebrew as a vernacular occurred toward the end of the 19th century along with the rise of the Zionist movement. Eliezer Ben-Yehuda is documented as having led what is often referred to as the “miraculous” revival of the language as a modern medium of communication (Fishman, 1991). Hebrew became the symbol of the national ideological aspirations and identity of the Jewish people and a common unifying factor in establishing the Jewish state. Accordingly immigrants to Israel were required to forgo their home languages and make the transition toward becoming Hebrew speakers (Ben-Rafael, 1994).

Hebrew was decreed as one of the languages of Palestine during the British Mandate (1922) along with Arabic and English. It retained its official status (with Arabic) once the state of Israel was created in 1948. An important milestone in the institutionalization and development of the language was the establishment of the Academy of the Hebrew Language (in 1953) which “prescribes standards for modern Hebrew grammar, orthography, transliteration, and punctuation based on the study of Hebrew’s historical development” (Academy of the Hebrew Language, *n.d.*).

Currently Hebrew is Israel’s dominant language, the language of government, commerce, culture, and instruction in Jewish schools, and the main language of academic institutions, with Arabic trailing far behind (Saban & Amara, 2002). The teaching of Hebrew is still strongly anchored in ideological beliefs of “the national language.” The last two decades have, however, witnessed some change towards recognition of multilingual legitimacy, especially following the large wave of immigration from the former USSR and on a smaller scale from Ethiopia. A multilingual educational language policy document published in 1996 advocates the teaching of the two official languages, Hebrew and Arabic, as the first and second languages of all Israeli school children, English as the first foreign language, and an additional world language. Though received with great enthusiasm the actual implementation of this policy is, at best, limited.

Teaching and Learning Contexts and Assessment Practices

Assessing Hebrew as a First Language

Assessing Hebrew in the Israeli School System The Israeli educational system is divided into primary school (grades 1 to 6), three years of junior high or middle school and three years of high school. The Jewish and Arab sectors are separated

with Hebrew as the language of instruction in the Jewish sector and as a second language in the Arab sector. The system is centralized and heavily monitored by national examinations at all age levels (Zuzovsky & Olshtain, 2006), from a reading test in grade 2 (the age of seven), to the high school graduation exams (the matriculations). Some of the tests bear high stakes consequences for the individual student, while others serve to provide feedback to the system on the local, national, or international levels. Formative internal assessment is strongly encouraged and teachers receive training in performance assessment and test construction as part of their pre- and in-service professional development. However the use of tests and quizzes still dominates teacher-based assessment, with tests all too often replicating in format and content the external test (Shohamy, 1998).

All the external and some of the internal assessments are regulated by the national authority for measurement and evaluation in education (Hebrew acronym, RAMA, established in 2005), an independent governmental body whose responsibilities and jurisdictions are defined by law. The assessment policy advocated by RAMA integrates external and internal assessment and promotes

a culture of “measurement for learning”, through the alignment of learning goals with the school’s vision, based on the understanding that tests are not a goal in and of themselves but rather an instrument for learning. (Beller, 2010, p. 1)

The gap between the declarative goals and the procedural top-down test-focused reality is a source of confusion and frustration, particularly among classroom teachers in the upper grades (Inbar-Lourie & Donitsa-Schmidt, 2009).

Hebrew as a school subject in primary Jewish schools is referred to as “language education” and aims to foster active critical readers and writers (Ministry of Education, 2003a). In the upper grades the current curriculum (Ministry of Education, 2003b) is text based with a focus on reading comprehension skills and discursive features, and recently on the teaching of oral skills in addition to grammar components. All these aspects, except speaking, are assessed by external standardized tests at different stages.

The external tests for assessing Hebrew in the school system can be described as falling into three categories:

1. Exams which form part of a national evaluation battery, the MEITZAV, the Hebrew acronym for “growth and efficiency measures of schools” (henceforth GEMS), produced by RAMA. External administration is rotated with each school participating in the tested sample once in four years, but expected to administer the tests internally annually. The external grades are not recorded per student but as class and school scores. The tests are administered in grades 2, 5, and 8. The grade 2 test focuses on reading ability, while the grade 5 and 8 tests assess reading comprehension of different genres (narrative, informative, and instructions), writing ability, grammar, and metalinguistic awareness. Analysis of the results of the GEMS tests in grades 5 and 8 demonstrates the relevance of socioeconomic status to students’ scores, in particular the level of parental education (Gilboa, 2010). Shilton (2010) found that the GEMS tests have a differential impact in the schools depending on

- local organizational culture. Negative impact was apparent in schools with low organizational culture, while, conversely, in schools with a high organizational level, the teaching and administrative staff made effective use of the information gained via the tests to improve teaching and learning.
2. The matriculation exams are high stakes exams administered toward the end of high school in different subject areas that have meaningful washback on the system, for they affect eligibility for academic studies. The Hebrew matriculation exam is administered in grades 10–12 (school choice), and assesses grammar, vocabulary, syntax, and reading comprehension with textual emphasis and writing ability. About 60,000 students take the exam annually. Accommodations such as oral readings and time extensions are available for students with learning disabilities. The mean score for the 2009 exam was 75, with about half of the examinees failing on items requiring high order thinking skills, like analysis and drawing conclusions (Kashti, 2009). This reaffirms findings from other test batteries, national and international, regarding the difficulties Israeli students encounter in literacy-related tasks, and is attributed, among other things, to the overemphasis placed on test preparation, which leaves little time for teaching (Olshtain in Kashti, 2009).
 3. International exams in the area of literacy: (a) Program for International Student Assessment (PISA) on reading literacy, administered by the Organization for Economic Co-operation and Development (OECD) internationally. Though only a sample of the student body (grade 10, aged 15) takes the test, the impact on the whole grade 10 cohort, and the previous grades as well, is enormous. In the PISA reading literacy 2009 administration Israeli students scored below the OECD mean (mean score = 474; OECD mean = 493) (OECD, 2009), placing the country in 36th place (out of 64 countries). Though performance has improved since the 2006 test (by 36 points), the results are still deemed unsatisfactory, and are constantly referred to in the media and by the public as reflecting the low quality of Israeli education (Detal, 2010). Financial resources have been allocated to schools in the form of teaching hours and materials in a national effort to gain a better standing in the next exam cycle. (b) The Progress in International Reading Literacy Study (PIRLS) test, created by the International Association for the Evaluation of Educational Achievement (IEA), checks mother tongue reading literacy (Hebrew and Arabic) in grade 4. Here the level of achievement was found to be mediocre, as Israel in 2006 barely made the mean grade (score of 512; mean score for all participating countries 500). Overall students scored significantly higher on narrative texts than on informative expository ones (Zuzovsky & Olshtain, 2006).

Thus it is evident that Hebrew first language (L1) assessment in the educational system is frequent and heavily monitored, with tests all too often becoming the end rather than the means of the educational program (Brosh-Vaitz, 2005). In an attempt to balance the test-oriented culture and in line with the stated ministry policy (via RAMA) which encourages internal class- and school-based assessments, formative assessment tools, such as performance tasks (Ministry of Education, Sport, and Culture, 2002) are offered. However, the potential of utilizing these tools is not fully realized, perhaps due to lack of literacy assessment knowledge

on the part of the teachers as to how to use the tasks and integrate them with their teaching.

Special emphasis has been placed in recent years on promoting early literacy assessment in Hebrew via a diagnostic reading and writing battery aligned with the curriculum, to be administered by the home room teacher in grade 1. The eight tasks included range from letter recognition to reading comprehension, all aimed at detecting reading problems as early as possible. Findings for the second year of administration (2006/7) show that most of the students (78%) performed according to the standards on all tasks, and that the results of the assessment tool were used by 57% of the teacher sample to plan individualized instruction (Kaise-Sugerman & Raz, 2007).

Another diagnostic Hebrew language assessment tool offered is the “student mapping kit” (Hebrew acronym, AMIT) test administered at the entrance point to junior high school (grade 7). Designed in accordance with features typifying literate knowledge (Berman & Ravid, 2009) the AMIT test allows for the identification and mapping of mother tongue Hebrew literacy skills (reading comprehension and writing), focusing on rhetorical structures, discourse, and vocabulary. The tool provides feedback which is then utilized to plan individual and group instruction in line with the “assessment for learning” approach. In order to promote the internal assessment of speaking a Web-based assessment kit was recently introduced, comprising three modules: reading aloud, reporting, and participating in a discussion.

Assessing Hebrew as L1 in the Academic Context Eligibility for academic studies in Israel is contingent upon the combined score of two measurements: the matriculation exams and a psychometric entrance test (PET) so as to ensure high predictive validity of academic success. The psychometric exam is written and administered by the National Institute for Testing and Evaluation (NITE), established by the Israeli universities in 1981. Based on test scores candidates are placed on a scale from 1 to 800, and the score is then combined with the matriculation scores. PET scores are valid for 10 years, with a high number of test takers (e.g., 89,041 in 2006), some of whom are second timers. The test includes three sections: a language section called “verbal reasoning” requiring lexical knowledge (tested through analogies and multiple choice sentence completions), and academic reading comprehension; a section on quantitative reasoning; and English academic reading comprehension (NITE, *n.d.a*).

The test has been a source of intense public and political debate, and was even abolished at one point due to what was deemed a lack of equity in test preparation, and then reinstated (for a detailed review on the educational and political issues associated with the test see Yogev & Ayalon, 2000). Language-wise the administration of the test in Hebrew is viewed as biased against speakers of other languages, especially Arabic, but also of immigrant languages. At present the test is available in five languages with an integrated Hebrew/English version and accommodations for learning disabled candidates. Students in academic institutions who take the translated test versions are obliged to take an exam in Hebrew, the Yael test (also prepared by NITE, *n.d.b*), which examines basic reading and writing ability (sentence completion, rephrasing, and an essay).

Assessing Hebrew as a Second Language

Assessing Immigrants Since the establishment of the State of Israel, more than three million immigrants have arrived in the country from 130 countries, about 40% of them since 1990. Over 160,000 new immigrant students have enrolled in Israeli schools since 1989, mostly from the former Soviet Union and Ethiopia. The teaching and assessment of Hebrew for the new and veteran arrivals is regarded as vital in the acculturation and absorption process, and falls under the jurisdiction of the Ministry of Education for both students in the school framework and adults in Ulpan (Hebrew) classes. The evaluation of the Hebrew proficiency of new immigrants varies greatly depending on the context, the program, and its goals.

Immigrant students are usually placed in regular mainstream classes upon arrival, with some support in the form of individual or group tutoring, or in the case of schools with a large immigrant population, in special classes for a short acculturation and language acquisition period. The standards for immigrant students (Ministry of Education, 2005) specify the need to formulate a personal study program for each student based on rigorous ongoing assessment in Hebrew and in the various subject areas. Shohamy (1996) reports on a project to assess Hebrew as a second language among new immigrant students using a battery of instruments (a test, self-assessment, observations by two teachers, and a portfolio), each contributing additional insight into the learners' language abilities and culminating in a final student profile. The comprehensive information obtained is then discussed in a conference shared by the learner, the Hebrew teacher, and subject area teachers, to allow for multiple perspectives and to maximize instructional effectiveness. Results pointed at different evaluations among different subject teachers, especially humanity subject areas versus the sciences, and at the fact that teachers seemed to prioritize the test as the most significant evaluation instrument. In addition, it was found that teachers found it difficult to translate the findings into instructional plans and activities, and it is therefore recommended that the utilization of the different instruments be accompanied with teacher training to allow for effective implementation (Shohamy, 1996).

A comprehensive study on the academic achievements of immigrant students from the former USSR and Ethiopia by Levine, Shohamy, and Spolsky (2003), contributed meaningfully to understanding different facets of the Hebrew acquisition process of these learners. Immigrant students' achievements at different class levels (grades 5, 8, and 11) were compared to the achievements of Israeli-born students. Data were gathered via tests anchored in school subjects, with reading tasks divided into three textual processing levels: verbal, local, and global and interpretive. The writing tasks comprised different school genres: functional, academic, and formal writing, and answers to open-ended questions. Differences were found among the students for school subjects (the more language-laden subjects were more difficult), for grade levels (the 9th graders performing the best and 11th graders the worst), and length of stay in the country (the longer the duration the higher the scores). Results showed that it takes five to nine years or even longer for immigrant children from the former USSR and Ethiopia to master adequate academic language skills. Hebrew language proficiency was found to be a major predictor of success in math, but the use of bilingual tests (Hebrew/

Russian) facilitated higher achievements, as well as the integration of familiar and relevant topics in the Hebrew tests. Findings point at lack of expertise among the teachers in teaching Hebrew as a second or additional language, as well as lack of awareness of the language needs of new immigrant students (Levine, Shohamy, & Inbar, 2007).

Recommendations following the research led to policy changes in particular with regard to examination procedures, as non-Israeli-born students are now eligible for testing accommodations for 10 years following their arrival in the country (Ministry of Education, 2008). In terms of the matriculation exams, a choice of accommodations is available for new and veteran immigrant students for both Hebrew language tests and tests in subject areas in Hebrew as the test language. In the Lashon (Hebrew) exam students can choose between taking the regular exam with a 10-point bonus, or alternatively the exam intended for new immigrants. In the other subject areas there is a choice between translated questionnaires, taking the original exam plus a bonus, being examined orally, or taking an exam in Hebrew with mother tongue responses.

Hebrew tests are available for young immigrant students aligned with a new curriculum for this population which focuses on discourse worlds (Ministry of Education, 2009). The tests, developed by RAMA, include a section on discourse, a reading aloud task, listening comprehension, reading comprehension, and a writing proficiency section, all aimed at diagnosing individual language difficulties so as to provide the assistance needed for successful integration into mainstream classes (RAMA, 2010).

Adults who immigrate to Israel are entitled to Hebrew studies through a language acquisition program called the Ulpan, aimed at facilitating the acquisition of communicative functional language abilities (Spolsky & Shohamy, 1999). There is no official measure for assessing adult proficiency and achievements are assessed by periodical low stakes tests for different levels (tests from 2001–9 are available, Ministry of Education, Division for Adult Education, 2009). The tests comprise a reading comprehension section, grammar (tenses, connectors, singular and plural, passive active forms), writing for functional, academic, and creative purposes (e.g., a complaint letter, an essay, and a story). In addition, special Hebrew courses are offered in colleges and universities as preparatory programs.

In terms of vocational needs, there are some classes for professionals (engineers, physicians, paramedical professionals, construction workers, etc.), with emphasis on their particular linguistic context. Shohamy and Donitsa-Schmidt (2004) investigated the Hebrew language abilities of immigrants from the former USSR, all mother tongue Russian speakers, who had been in the country between one and six years: doctors, teachers, and technicians. The research test included authentic tasks or activities that the immigrants require professionally, self-report questionnaires, and semistructured interviews. Findings showed that all the respondents experienced difficulty in using professionally related language as well as in acculturating to local norms. Speaking and listening were found to cause the most difficulty, affected by length of duration in the country and educational level. Following these results the researchers recommend the incorporation of professionally related language content and lexis in the Ulpan study program. An interesting finding which arose from the research is the need to study English as well, for the

language plays a major role in the professional lives of the respondents in this study.

Assessing Hebrew as a Second Language Among Arab Students Speakers of Arabic study in Arabic-medium schools and learn Hebrew as a second language (L2), generally from grade 3 until graduation in grade 12. The learners are instrumentally motivated to study Hebrew as knowledge of the language is a prerequisite for academic and vocational purposes, since all academic studies, except teacher certification programs, are conducted in Hebrew. Therefore one of the goals of a recently instated curriculum for Hebrew as a second language for speakers of Arabic is preparation for academic Hebrew use (Wated, 2007).

Hebrew is assessed internally via teacher-made instruments, mostly tests. The only external exam is at the end of high school studies: the matriculation examination in Hebrew as a second language for speakers of Arabic. The test is aligned with the communicative-oriented curriculum (published in 2008), and includes reading comprehension, writing (informative, argumentative, descriptive, or functional) and grammar, and a speaking component (an interview and presentation). A more extensive format also includes Hebrew literature and Jewish canonical literary writings and historical sources. Close to 25,000 students participate in the tests annually with a high success rate (Ministry of Education, Inspectorate for Teaching Hebrew to Speakers of Arabic, 2011).

It was found that achievement in reading comprehension in Hebrew among Israeli Druze students, one of the Arabic-speaking minorities, is related to the cultural content of the passages read. Research by Abu-Rabia (1996) showed that cultural familiarity with the texts made a difference with regard to achievements: the Druze students scored higher on items on Arab culture than on Jewish culture. A small-scale research project (Talal, 2011) on Hebrew narrative writing among Arab students towards the end of their high school studies shows that focused feedback and intervention improve students' writing performance. Differences were found in terms of text organization and length, richness of vocabulary, more frequent use of adjectives and of abstract nouns, and metalinguistic awareness. Hebrew grammatical accuracy was not improved, showing strong influence of the students' L1.

Hebrew Outside of Israel

Assessing Hebrew as a Foreign Language in Jewish Schools The status of the Hebrew language outside Israel in Jewish communities is undergoing meaningful change. Knowledge of Hebrew it is no longer perceived as an essential component of Jewish existence or as a marker of Jewish identity. Hebrew teaching is declining and plagued with a number of problems: lack of clear learning objectives and of teacher professionalization, reduced teaching hours, unsuitable teaching materials, and the lack of professionally produced assessment measures. All of these result in unsatisfactory achievement, particularly poor Hebrew communication skills (Nevo, 2011). This is further complicated by the great variability among schools in terms of geographical location and denominational affiliation. The situation regarding Hebrew-teaching programs at the college level is also regressing,

typified by low registration as a function of low motivation, inadequate teacher training, and not enough exposure to comprehensible input (Feuer, Armon-Lotem, & Cooperman, 2009).

One of the major issues that Hebrew language educators outside Israel are battling with is language norms, particularly what constitutes Hebrew speech in this day and age, considering immigration and language variability (Spolsky, 2009). This of course constitutes a vital concern with respect to determining assessment criteria and uniformity. Additionally the debate centers on the role of Hebrew studies vis-à-vis Jewish culture: "What is 'real' Hebrew and which Hebrew should we teach? Is Hebrew pedagogy a subject that ought to be embedded within the fields of Jewish Education, Linguistics, or Israel Studies?" (Feuer et al., 2009, pp. 1-2).

According to a recent census (Schick, 2009) there are about 230,000 students in Jewish elementary and secondary schools in the USA, the largest Jewish diaspora. Hebrew is usually taught from kindergarten or grade 2 via numerous programs, many of which do not have accompanying assessment tools (Nevo, 2011). In Jewish day schools knowledge of Hebrew is instrumental since it is also used as a language of instruction for part or all of the Judaic studies. The acquisition of beginning reading presents a special problem as in some cases learners can only mechanically decode, due to similarity among the letters and the need to employ contextual clues (especially in the unpointed version), knowledge which learners may lack due to a poor oral base (Schachter, 2010). Since there are no monitoring mechanisms this can go undetected, a crucial factor for the 100,000 learners in 3rd grade or below struggling with the acquisition of Hebrew reading skills (Schick, 2009). According to Goldberg, Weinberger, Goodman, and Ross (2010) the existing reading assessment tools for this population lack standardized validity and reliability indices. They therefore offer a "Hebrew dynamic oral reading fluency measure" conducted individually to track foundational reading skills.

Shohamy (1992) describes a collaborative model for assessing Hebrew and Jewish studies administered in 10 Jewish schools in the USA and Canada. Results were diagnostically interpreted within the school context with the management and teaching staff. Shohamy reports on variability in terms of the manner in which the schools participating in the project utilized the information that was gleaned from the assessment procedures. Furthermore she notes the potentially influential role of a local school coordinator with basic assessment knowledge who can contribute meaningfully to the success of such an initiative.

High school graduates outside Israel can take the "Jerusalem test," an advanced test of Hebrew and Jewish knowledge prepared by the Jewish Agency and the Hebrew University. The Jerusalem test incorporates Jewish culture in the form of texts from various historical periods with Hebrew proficiency, and is intended for providing graduates of Jewish high schools and other students of Hebrew with an official record of their studies (Jewish Agency for Israel, *n.d.*). About 400 students a year take the test, most of them in the USA, some in South America and in Europe. The test contains an essay, a reading comprehension passage, and grammar and syntax exercises. In some cases speaking is tested as well. The success rate is high (91%), with an option for repeated test administration in case of failure (Mr. Rafi Bannai, personal communication).

Modern Hebrew is one of the subjects that students can choose from as an exam topic in the United Kingdom as part of their General Certificate of Education (GCE). The "Modern Hebrew" exam is usually taken in Jewish schools and by Hebrew speakers in British or international schools outside the UK, with a total of about 400 students participating in the exam in 2011. The exam is divided into two parts, AS level in year 12, A2 level in year 13, which together comprise the A-level requirements. The first paper includes reading comprehension, translation into English, and writing in Hebrew; the second paper also includes two essays (on day-to-day issues, contemporary society, and environment and citizenship) and literary topics. Students can choose to take Modern Hebrew as one of their choice options for their GCSE (General Certificate of Secondary Education) exam at the end of year 11 (15 to 16 years old) in England, Wales, and Northern Ireland. The exams are produced in the UK by Hebrew teachers in secondary schools and follow guidelines from the Assessment and Qualifications Alliance (AQA) exam board. The exam is divided according to the four skills (AQA, *n.d.a*).

Assessing Hebrew as a Foreign Language in Academic Institutions Hebrew tests at the academic level are required in different programs such as Jewish, religious, historical, archaeological, or Middle Eastern studies. Proficiency in Hebrew also counts as part of the language requirements for graduation in undergraduate and graduate programs. In-house placement or proficiency tests are available per institution usually comprising what is referred to as a Modern Hebrew grammar section, reading comprehension, and writing (e.g., Carleton College, *n.d.*). In addition to Modern Hebrew, Biblical Hebrew tests are in use for advanced or specialized study programs. The Rabbinical School in the Jewish Theological Seminary in New York, for example, requires a placement test in both Modern and Biblical Hebrew, and "[s]tudents are expected to demonstrate the ability to recognize the significance of verb tense and aspect, word order, and vocalization in Biblical Hebrew" (Jewish Theological Seminary, *n.d.*). As with the in-house tests in primary and secondary school, there is no research available on the validity and psychometric properties of the tests or on their criterion or predictive validity.

Speaking ability at the college or university level can be assessed using a semidirect test: the Simulated Oral Proficiency Interview (SOPI). The test contains audiotaped instructions directed at eliciting language utterances following the American Council on the Teaching of Foreign Languages (ACTFL) guidelines (intermediate, advanced, and superior levels), and is recognized by the American Council on Education (ACE) for college credit. The test follows the structure of the four phases of the Oral Proficiency Interview (OPI) (Malone, 2000). Results of a research study showed that the Hebrew SOPI version correlated highly with the direct OPI version administered to both immigrant L2 Hebrew speakers in Israel and to university students in the USA. All the participants took both the SOPI and OPI versions of the test. The correlation between the OPI and the SOPI versions in Israel was .89 and .94 for the US version (Shohamy, Gordon, Kenyon, & Stansfield, 1989).

Assessment on the academic level is usually test focused, with some performance-based assessment of authentic Hebrew use. Feuer (2011) reports on a study conducted among advanced Hebrew college students asked to create a fictional Israeli

American town in the USA. In addition to its social and cultural benefits the author notes that the project improved the students' language proficiency, in particular Hebrew writing skills.

Hebrew outside of Israel is also assessed for vocational purposes, especially for teaching certification. The foreign language content area test in Hebrew in Illinois, for example, is part of the Illinois Certification Testing system. The test contains Hebrew language skills: listening, reading, and vocabulary, and written and oral expression. In addition language structures and language acquisition are assessed where candidates need to "[d]emonstrate the ability to organize, analyze, and explain to students the structure of the Hebrew language" and to "[u]nderstand processes involved in second-language acquisition" (Illinois State Board of Education, 2006, pp. 3–4). Israeli-embedded cultural practices, as well as "an understanding of the history, government, geography, and economy" of the country are also required (p. 5). The items are mostly closed except for the oral and written expression, and results are reported on a scale from 100 to 300, with a score of 240 or above required to pass the test. The New York State teacher certification examination in Hebrew is part of the bilingual education system. The test requires bilingual knowledge with sections in English and in the target language Hebrew. In addition it also assesses the candidates' knowledge of the foundations of bilingual education. The oral section is a semidirect test in which candidates react to a recorded text describing a situation. Here too, as in the Illinois test, detailed scoring guides are provided (New York State Education Department, 2005).

Challenges and Future Directions

This chapter has demonstrated that despite the rather small number of Hebrew speakers and learners the assessment needs are extremely diverse, partially due to the unique historical, national, and religious status of the language. Clearly the goals for assessment will vary depending on the purpose for learning, whether for daily use, for developing language identity, for prayer, or for academic purposes. But even though the context-embedded considerations are very prominent, a number of general trends and challenges that transcend localized needs can be identified.

Assessment School Culture

Within the school framework, in Israel and abroad, the challenge is to create a better balanced school culture in terms of combined external and internal assessment procedures. While in Israel there is an overuse of external vigilance via standardized tests for Hebrew as L1, Hebrew assessment outside of Israel in the educational teaching milieu seems to lack an outsider's perspective in the form of agreed-upon assessment criteria and valid assessment instruments. The Hebrew assessment scene in the Arab sector is also clearly imbalanced, as no internal or external measures (except the final exam) are offered. Though this is clearly reflective of the context, a national policy on one hand, versus policy set by separate

autonomous entities on the other, it is still clear that there is room for moderation in each of the settings.

Setting Teaching and Assessment Objectives

An initial preliminary challenge has to do with the clarification of the teaching objectives to be followed by an assessment agenda, particularly in the context of teaching Hebrew outside Israel where the goals for Hebrew instruction are nebulous, but also with regard to Hebrew L2 speakers, both immigrants (children and adults) and Arab students. There are no performance or diagnostic tasks offered for example for the Arab Hebrew L2 learners. As to the teaching of vocational Hebrew to adults, if expanded, compatible assessment procedures will be required, most probably in the form of performance tasks.

Teacher Professionalization

Even in cases where Hebrew assessment measures are available and agreed upon their implementation depends to a great extent on the professionalization of the teaching and administrative staff. As can be seen from the studies cited both in Israel and abroad (Shohamy, 1992, 1998; Levine, Shohamy, & Spolsky, 2003), assessment literacy on the part of the parties engaged in carrying out the assessment projects is crucial, as is the collaboration between internal and external experts. The resources available on the Internet are impressive. The question is whether the teachers know how to make sense of this information for the benefit of improved instruction.

Research

The paucity of updated research on various aspects of Hebrew assessment on the numerous teaching fronts seriously impedes the decision-making process and the subsequent implementation. Even the large-scale tests are not accompanied by sufficient research by independent bodies. Data are lacking as to whether and how internal and external instruments complement one another, on the predictive validity of the tests, and on the test takers' reaction to the tests, as with Abu Rabia's (1996) study on the effect of ethnically familiar text topics on performance. The lack of research is particularly striking in the Hebrew as a foreign language context for all levels. Hence a major challenge would be the creation of a researched and validated test battery which could have general proficiency components as well as localized school-based ones, with discussion among educators as to the results and how to feed them back into the system.

Accommodations

With regard to immigrant populations there needs to be follow-up on the proposed accommodations to see the extent to which they are actually employed on a day-to-day basis, and also an accelerated move towards utilizing the learners' L1 in Hebrew L2 assessments (e.g., bilingual tests).

Future directions would thus need to focus on professionalized assessment initiatives conducted with the relevant parties: schools, teachers, student and parent communities, and policy makers. The process will commence by discussing and defining the knowledge to be assessed—whether linguistic, cultural or both—followed by ongoing evaluative research. In working with teachers and local stakeholders prototypes of assessment tools for internal use need to be introduced as part of, and alongside, the development of criteria for assessing the different populations, with technology facilitating such initiatives and overcoming geographical distances. Future initiatives can follow models similar to the one described in Shohamy (1996) where an array of assessment tools were used to allow for multiple assessment measures. Future directions also need to promote collaboration among academic institutions which assess Hebrew knowledge outside Israel to ensure the content and construct validity of the tests produced. And, last but not least, future directions should prioritize research on all fronts of both formal and informal assessment practices of the Hebrew language.

Assessing Hindi

Pritha Chandra

Indian Institute of Technology Delhi, India

Introduction

This chapter explores the evaluation methods adopted for Hindi, an Indo-Aryan language spoken in India. The chapter examines the goals of learning Hindi as a first language (L1) and second language (L2) at primary and advanced school levels, and then moves on to analyze some materials prepared for these purposes. Next, some classroom practices are used to illustrate the actual methods adopted for teaching Hindi and developing the basic skills of reading, writing, listening, and speaking, especially at primary level. This is followed by a detailed examination of the methods adopted to assess the knowledge of the learner, first at the classroom/school level and then at the national level. Question papers at grades 5, 10, and 12 are looked at carefully with the aim of understanding how learners and their linguistic proficiency in the language are evaluated. The final section summarizes observations made in the paper and makes some suggestions to fill the gaps that may exist between actual Hindi teaching and evaluation practices, and the recommendations of the National Curriculum Framework (NCF) (National Council of Educational Research and Training, 2005). First, however, a few details are given about the language itself—the states where it is spoken, the total number of its speakers, and also its status in the Union.

According to the 2001 Indian census, Hindi has around 258 million native speakers, including those who speak one of its copious dialects. The language is mutually intelligible with Urdu; variations between the two are restricted to their respective literary styles, with Hindi drawing its vocabulary primarily from Sanskrit, and Urdu from Persian. Hindi also uses the Devanagari script while Urdu uses the Nastaliq script.

The Linguistic Survey of India carried out by Sir G. A. Grierson between 1866 and 1927 identified 179 languages and 544 dialects. These numbers have changed

since then, with the 1991 census suggesting 10,400 raw returns, including 1,576 rationalized mother tongues. These in turn are regrouped under 114 languages out of which only 22 languages are included in the VIIIth Schedule of the Constitution of India (see Sharma, 2001, for a comprehensive survey of multilingualism in India). The VIIIth Schedule, along with Articles 343–51 of Part XVII also state that “The official language of the Union shall be Hindi in Devanagari script.” Clear directives are laid out for the promotion of Hindi “so that it may serve as a medium of expression for all elements of the composite culture of India” (Article 351). Other than this, Hindi is also listed as the official state language of Bihar, Chhattishgarh, Haryana, Himachal Pradesh, Jharkhand, Madhya Pradesh, Rajasthan, Uttarakhand, Uttar Pradesh, and the national capital territory of Delhi, and as a “co-official language” in some other states.

Following the increasing awareness of the need for proper representation of minority languages and the promotion of multilingualism in education, the Indian Union Ministry in consultation with the states articulated a Three Language Formula (1961) that was later enunciated in the National Policy Resolution (1968) and reiterated in the National Policy on Education (1986). The formula provides that, in Hindi-speaking states, Hindi should be taught to children alongside two other languages: English and a Dravidian language. In non-Hindi speaking states, it should be introduced (alongside already studied regional/state languages and English) at or after grade 5. However, as has been observed,

The Hindi-speaking states operate largely with Hindi, English and Sanskrit, whereas the non-Hindi-speaking states, particularly Tamil Nadu, operate through a two-language formula that is Tamil and English. Still, many states such as Orissa, West Bengal, and Maharashtra among others have implemented the formula. (National Council of Educational Research and Training, 2008)

Objectives of Hindi Teaching

The NCF (National Council of Educational Research and Training, 2005), while emphasizing the importance of the three-language formula, recognizes children’s mother tongues, including tribal and minority languages, as the best mediums of instruction in education. Mother tongue instruction is also taken to positively impact children’s overall cognitive development. The framework also encourages a holistic approach to language learning while simultaneously fostering individual skills like reading and writing, listening and speaking. Noteworthy is the special emphasis it puts on reading, especially in the primary classes, as necessary for laying a solid foundation for school learning.

For first languages, such as Hindi in Hindi-speaking states, the framework states:

[C]hildren come to school with full-blown communicative competence in their language, or in many cases, languages. They enter school not only with thousands of words but also with a full control of the rules that govern the complex and rich structure of language at the level of sounds, words, sentences and discourse . . . [They] obviously have the cognitive abilities to abstract extremely complex systems

of language from the flux of sounds. Honing these skills by progressively fostering advanced-level communicative and cognitive abilities in the classroom is the goal of first-language(s) education. (p. 37)

Oracy and literacy become important tools for learning and fostering higher order communicative skills and critical thinking. With increasing exposure to rich literature, children also eventually learn more standard varieties, both in speech and in writing.

In some non-Hindi-speaking states, Hindi is taught as a second language to children already well equipped with one or more languages including their mother tongues/regional languages. As is obvious, these learners too possess a certain level of conceptual understanding, are capable of abstract thought and can relate to their surroundings. There are two stated goals of second language learning at this stage that NCF recognizes, and though these goals are not explicitly mentioned for Hindi, they apply to its teaching as well. The first objective is to master the fundamentals of the language, and gain proficiency over it so as to be able to use it for communicative purposes. The second is to use it for further knowledge enhancement through abstract thinking and literary appreciation.

Materials and Instructions to Teachers

The NCF objectives for language learning are reiterated in the beginning of and built into the designs of all textbooks prepared for Hindi L1 and L2 learners by the National Council of Educational Research and Training (NCERT). For L1 learners, there are four textbooks that are sequenced thus: *Rimjhim* textbooks cover grades 1 to 5, *Vasant* 6 to 8, *Kshitij* 9 to 10, and *Aaroh* 11 to 12.

The beginners' textbooks take reading and writing to be integrated activities. Language pedagogy at this level is geared not simply toward improving learners' communicative abilities, but also toward enabling them to use language effectively to debate, summarize, infer, and think creatively. To achieve these goals, the textbooks consist of a number of stories, poems, and folktales that allow learners to transcend their own little worlds and enter into unknown and imaginary ones. Pictures are strewn all over the books with the intention that learners use them to create stories of their own accord. A lot of attention is also paid to improving their vocabulary skills. At more advanced levels (especially in the fourth and fifth years), *Rimjhim* textbooks also aim at dispersing the knowledge of the nation's varied cultures, customs, lifestyles, occupations, and languages to learners. Another major objective of the series is to teach them to communicate efficiently in different sociocultural contexts.

Textbooks at the next level—in the *Vasant* series—carry these same objectives forward by introducing learners to more themes and stories from their national and regional cultures. Keeping in mind NCF's directive that language learning is also a means to overall cognitive development, these books connect language to different disciplines and topics. Without undermining the necessity of improving the linguistic proficiency of learners, the chosen texts touch on issues of nature, society, science, and history, thus forcing them to think more creatively and become

more socially conscious. Similarly, in the *Kshitij* and the *Aaroh* series meant for advanced learners, the emphasis is once again on developing the learners' personalities by integrating language teaching with other aspects of learning. Chapters include literary texts, poems, historical essays, and biographies, among others.

The materials for Hindi as L2 up to grade 10 are divided into two levels. The first—*Durva*—mainly concentrates on building the communicative abilities of learners in the target language. There are three parts to it and each is devoted to one of the first three years of learning Hindi (i.e., from grades 6 to 8). Once learners have control over the structure of the language and have gained a basic understanding of its rich literary heritage, they are exposed to the second level—covered by the series entitled *Sparsh*. This is where language proficiency—in terms of the basic skills—though not completely undermined, takes a backseat. Literary appreciation and high order linguistic skills such as the usage of idioms and metaphors are encouraged at this level.

In view of the overall emphasis of the NCF on multilingualism, teachers are specifically instructed to use the textbook materials to build up learners' confidence in their own languages and dialects. Exercises given at the end of chapters provide ample opportunities for both teachers and learners to discuss the morphological and syntactic differences that may exist between the latter's regional varieties/mother tongues and Standard Hindi. Teachers are also expected to focus on improving the communicative skills of students by following an integrated approach to reading, writing, speaking, and listening, with special emphasis laid on reading. At the primary levels, learners must be appreciated for the linguistic proficiency they have already gained, and more emphasis should be placed on enhancing their skills via pictures and stories. Learners at the more advanced levels should be given more integrated knowledge of language via different kinds of subject matter. Teachers for the advanced grades are therefore expected to keep upgrading their knowledge of varied issues—whether cultural, social, political, or scientific—so that they can engage in higher-level discussions with learners.

Classroom Activities and Evaluation

Schools run in two semesters—the first lasts from April to September and the second from October to March. Lessons in Hindi language classrooms, especially at the primary level, mainly revolve around developing the four skills—reading, listening, speaking, and writing.¹ This section illustrates some L1-learning activities carried out in grade 5 in Central School (NCERT campus, New Delhi).²

For reading purposes, learners have access to textbook chapters as well as unseen passages. This improves their ability to read and comprehend. Reading aloud and speaking are, however, mostly practiced as part of cocurricular activities, with students reciting their poems, presenting write-ups, or even enacting plays during these hours.

For writing assignments, learners are given different themes by the teachers, which could be as varied as “a picnic trip” or “activities on the beach.” Learners are asked to submit one-page write-ups on these topics, which are then judged on spelling, grammar, creativity, and vocabulary.

Each semester, there are three exams at the school level—two formatives and one summative. The formatives are mainly activity-based or revolve around projects assigned by the teacher. Learners are also assessed in terms of picture stories (i.e., how well they write a story based on a picture provided to them), relay stories, and poems.

As for the summative,³ the exam paper is divided into two parts: reading/comprehension and writing. In the first part, learners are given extracts from two essays—one from the textbook and one unseen passage. Each essay is followed by questions, which the learners are expected to answer based on information they draw from the given text. This section is meant to assess how well they comprehend written passages. They are also expected to identify the correct grammatical categories and provide synonyms and so on for terms from the texts.

The writing part is divided into the following subparts: prose and poetry, grammar, creative writing, spelling, and handwriting. For prose, learners get extracts from the prescribed textbooks and must answer some questions on them. For poetry, they are asked to complete a poem that they have already read (thus also enabling teachers to assess their memory power) and answer a few related questions. In grammar, learners are judged on their knowledge of different grammatical concepts, such as pronominal forms in the language (including person, number, gender, and possessive differences), parts of speech (verbs, adjectives), tense changes, idiomatic expressions, sentential types (matrix versus adjunct sentences), synonyms and antonyms, and so forth. As part of creative writing, they are provided with topics like “water crisis in the city” or “the hazards of traveling in the mountains.” Letter writing is also included in this subsection. Learners are then judged on their spelling, where they are asked to identify between pairs of correct and incorrect spellings. Finally, they are also given points for good handwriting. For this, they are instructed to copy in their own hand a small paragraph given in the question paper.

Summative question papers are designed to assess learners on some of the major skills of language learning. The points allotted for each category are thus: reading/comprehension: 20; writing/prose: 5; writing/poetry: 5; grammar: 10; creative writing: 10; spelling: 5; handwriting: 5; with the total amounting to 60 points.

National Level Examinations for School Learners

The NCF (National Council of Educational Research and Training, 2005) recognizes the importance of examination reforms to alleviate the growing psychological pressures faced by school students and their parents, especially during the national level grade 10 and grade 12 exams. These reforms also pave the way for an effective curricular renewal. Specific measures suggested include modifying the typology of question papers so as to prioritize reasoning and creative abilities over rote memorization. The other recommendation is to integrate these exams with classroom life by encouraging transparency and internal assessment. Below, some detail is given on some question papers from these national level exams held by the Central Board of Secondary Education (CBSE).

The exam paper for Hindi as L1 for grade 10 is termed Hindi-course A and amounts to a total of 100 points.⁴ The paper is divided into two parts: reading/comprehension and writing. The reading/comprehension part has prose and poetry extracts, followed by questions based on the given texts. The second part involves essay writing, where some themes are provided for the learners to choose from (such as “a cricket match you have watched recently” or “commuting woes and petrol price hike”). Also in this part is letter writing, again on a predetermined theme (e.g., “inviting the regional police chief to an event in your locality”). The third part is on grammar, where questions involve identifying predicates, adverbial phrases, and parts of speech in given sentences, creating complex or conjunct sentences out of simple ones, changing the voice of sentences, and explaining metaphors. The last part has questions from seen and unseen passages and poems. It also includes many questions from the chapters of the textbooks. The total points are distributed thus: reading/comprehension: 20; essay and letter writing: 15; grammar: 15; and questions from texts: 50.

For L1 speakers taking the Hindi(-core) exam in year 12, the distribution of marks changes slightly. Comprehension gets 20 points and essay and letter writing another 20. However, for the latter section, there is a third type of question: Students are asked to critically review a film or an article they have read recently on a socially relevant topic such as “the increasing number of vehicles” or “rising prices and the impact on a worker’s life.” The rest (60 points) is for questions from seen and unseen passages and poems. Grammar, which is evaluated separately in the examination at grade 10, does not find a place here.

For Hindi as L2 at grade 10 (Hindi-course B), there are, once again, four sections. The first is comprehension (prose and poetry), to which are allocated 20 points. The second section is on paragraph writing. Some phrases are provided as cues—such as “Himalaya: the crown of India,” “the reasons why it is called crown,” “beauty,” “utilities”—for the learner to use while constructing the paragraph. Letter writing is also included in this section, on themes like “letter to the post office complaining about postal irregularities.” This section has a total of 10 points. The third section covers grammatical concepts. Learners are asked to complete morphological analysis of words, construct sentences with idioms and metaphors, and correct incorrect sentences. Questions on grammar add up to 20 points. The remaining 50 points are distributed over questions from the textbooks and unseen passages and poetry.

Future Directions and Challenges

To summarize, since Hindi is the official language of India, there are very clear directives to use it in building a composite culture in an otherwise culturally diverse and multilingual country. One way to ensure Hindi’s promotion in the entire nation was to propose the three-language formula that, along with fostering multilingualism, also forces the education system to treat Hindi either as an L1 or as an L2 for all school students. However, the objectives of Hindi as L1 and as L2 are quite different; while L1 learners are expected to use their language to explore higher fields of knowledge and use it for their overall cognitive and personality development, L2 learners are mainly expected to gain proficiency over

the language and use it for communicative purposes. To this effect, we have also seen that Hindi is introduced as a subject very early on (from grade 1 onwards) for L1 learners but only from grade 6 onwards for L2 learners. Moreover, the materials prepared for each are also different, with those for L2 geared more toward improving the communicative and other linguistic skills of respective learners. Naturally, the assessment methods for Hindi as L1 and as L2 are also different. There are separate question papers for each set of students, and, while the questions for L1 learners mostly cover the same aspects—comprehension, writing, grammar, and so on—as the questions for L2 learners, the topics for the former are more complex and demand advanced levels of thought and linguistic skills. The latter, on the other hand, are evaluated more on their command over the language and their ability to comprehend, read, and write it.

The NCF (National Council of Educational Research and Training, 2005), as has already been discussed, recommends a holistic approach to language learning, but also emphasizes developing individual linguistic skills, most notably reading. Through classroom activities, assignments, and exams, most basic skills are taken care of. Learners, from very early on, are encouraged to read and comprehend seen and unseen passages and poems and to answer related questions accordingly. Moreover, they are also encouraged to write creative pieces on varied topics—directly or indirectly related to their daily lives. Read-aloud and speaking activities are not highlighted enough, however, for both classroom practice and evaluation. This may be a problem specifically for L2 learners who are introduced to Hindi quite late and need to be evaluated constantly on their ability to communicate properly in the language. Even for L1 learners, who speak one of the dialects of standard Hindi, it is pertinent that we have appropriate measures to evaluate their linguistic proficiency—in terms of speech—in the standard variety.

Finally, the thorny issue of multilingualism in the Indian context, especially in its educational system, is far from being resolved (see Agnihotri, 2007). Though there is consensus on fostering multilingualism in the classroom and building up the confidence of learners in their own dialects and languages, no serious effort in that direction seems apparent. The assessment methods adopted for Hindi as both L1 and L2 focus on the standard language; there is no space and encouragement provided for dialectal variations, whether that be through classroom assignments, school formative and summative assessments, or even national level examinations. As a result, learners, especially those with a Hindi dialect as a mother tongue, often tend to cross over entirely to the standard variety, relegating the nonstandard variety to some chosen informal contexts. This creates a conflict: While the NCF proposes promotion of multilingualism and hence linguistic heterogeneity, in the process inculcating respect for one's mother tongue among learners, actual classroom practice and evaluation measures inadvertently promote linguistic homogeneity. The situation therefore calls for urgent attention, and attempts need to be made to get all NCF recommendations in place in actual classroom practice and evaluation.

Assessing Malayalam

Suchitra Sadanandan

California State University, Los Angeles, USA

Introduction

Malayalam is one of the 22 dominant regional languages recognized by the government of India in the Eighth Schedule of the Indian Constitution. It is the primary language spoken in the state of Kerala in India. The state was formed in 1956 as part of the dissolution of princedoms and re-formation of states in India on linguistic lines. It includes the former princely states of Travancore and Cochin in the south and part of the Madras presidency in the north. Currently, Malayalam is the primary language of communication, business, and government in the state. However, in areas that adjoin neighboring states, languages like Kannada and Tamil are the first languages of minority populations. As of the 2001 census,¹ there are about 33 million speakers of Malayalam, nearly 31 million of them in Kerala.

Description

Malayalam belongs to the Dravidian language family and is closely related to Tamil and Kannada, which are spoken in the states to the east and north respectively. These three languages, along with Telugu, another Dravidian language which is spoken in a noncontiguous state, comprise the majority of the speakers in southern India. While the four languages are closely related, they are not mutually intelligible. This last statement has to be modified a little when it comes to Tamil, Malayalam's closest linguistic and geographical relative. Access to and popularity of Tamil entertainment has led to it being perceived as intelligible by Malayalam speakers but not vice versa.

Orthography

Modern Malayalam has its own unique orthographic system which evolved from the Grantha script, a non-Dravidian script which was initially used to write the heavily Sanskritized literary Malayalam in vogue in the 17th century. In the late 20th century, it underwent a series of reforms, primarily to reduce the number of characters. These reforms produced an orthography which can be construed as an alphabet where each symbol represents a single segment. Where earlier there was a single (conjunct) character for many consonant–vowel combinations and consonant clusters, the current orthography has, with the exception of short [a], a unique set of consonant and vowel symbols and diacritics replacing the old conjunct characters. However, there is variation in the adoption of these reforms and one still finds idiosyncratic retention of elements of the old syllabary in modern publications. Malayalam is written from left to right and uses Western (English) punctuation like the period, comma, and colon. Unlike English, however, when words are linked by phonological rules or are part of a phonological phrase they are not always separated by spaces. This would be the equivalent of writing the English words “in pain” as a single word (*inpain) because of assimilation.

Syntax and Morphology

Like other Dravidian languages, Malayalam is a head final language with a subject–object–verb word order, adjectival or relative clauses preceding the head noun and post-positions. There is, however, quite a lot of flexibility with word order especially in main clauses (Asher & Kumari, 1997). Subjects can be deleted rather freely, and elements (noun phrases as well as adverbs and adverbial phrases) can be topicalized by fronting or affixation (Comrie, 1995). What makes Malayalam distinct from other Dravidian languages is the lack of agreement in the verbal system on the basis of person, number and gender. The inflectional morphology is rich with a plethora of post-positional affixes that represent case, tense, and aspect, valency, mood, degree, etc. So a verbal phrase like “must have got the dishes washed” would be:

paatranṅaḷ kaṭuk-ippicc-itttuṅḍ-aayiruṅṅu.
dish pl wash + causative + perfective + past

Phonology

Malayalam phonology has many of the elements found in other Dravidian languages. The vowel system is the basic five vowel system with short and long counterparts. With the exception of nasals and liquids, open syllables are preferred word-finally. Like other Dravidian languages, it has geminate consonants and the ubiquitous intervocalic and postnasal voicing. However, Malayalam exhibits a four-way contrast among the stops—it has unaspirated, aspirated, voiced, and breathy voiced obstruents at labial, dental, retroflex, palatal, and velar places of articulation. This complexity can readily be traced to the influence and place of Sanskrit, an Indo-Aryan language, in Malayalam literature. The literature of the

13th–17th century, the *manipravala* period, was marked by works which show heavy incorporation not only of the Sanskrit verse style but also of Sanskrit vocabulary and morphology. The influence of this massive borrowing has left its mark on Malayalam phonology and vocabulary and consequently its orthography, which has symbols for these non-Dravidian sounds. This hybrid phonology, which incorporates Indo-Aryan and Dravidian systems, has led to a mild diglossic situation where the spoken variety is at odds with the written variety with its preservation of the Indo-Aryan contrasts of voiced, aspirated, and breathy voiced sounds in words of Sanskrit origin. Currently, voiced consonants and to some extent aspirated and breathy voiced sounds, are a part of the phonology of standard Malayalam (Mohanani & Mohanani, 1984).

Varieties

Dialectal differences (in Malayalam) are based both on regional and communal lines. Dialectal variations are mainly demarcated on a north–south basis with pockets of variation within insular regions in the Western Ghats. The most distinct communal variety is the dialect spoken by Malayali Muslims in northern Kerala, with its Arabic loanwords, absence of consonant clusters, and the absence of retroflex central approximant. Dialects spoken by certain tribes in the Western Ghats show the maximum difference from the standard language. Besides the usual differences in vocabulary, dialects vary from each other in the amount of Sanskrit borrowings and the level to which these borrowings have been changed to fit in with the phonology of the Dravidian substrata. Other differences include the type and amount of consonant lenition and elision, differences in the quality of the epenthetic vowel, and differences in the use of completive markers like “kala” in the northern dialects. Overall, the language used by the educated in central Kerala is considered the closest to standard Malayalam (Asher & Kumari, 1997).

Teaching–Learning Contexts

The current teaching and learning of Malayalam can be best understood in the light of the three-language formula articulated by the Kothari Commission in 1964–6, keeping in mind the multilingual complexity of India. Recognition of the right of ethnic minorities to be educated in their mother tongue, promotion of the state language to bring about regional unity, and the development of a pan-Indian national language for national polity are the three main underlying principles that inform the recommendations of the Kothari Commission. These recommendations were in the national curriculum framework in 2005, which in turn played a pivotal role in the framing of the educational curriculum in Kerala. The description of language education that follows is based on the latest Kerala Curriculum Framework (2007; henceforth KCF) prepared by the State Council of Educational Research and Training (SCERT, 2007).

Education is divided into primary, secondary, and upper secondary schools. Grades 1–7 (commonly known as standards) are considered primary school, grades 8–10 secondary school, and grades 11 and 12 upper secondary or, in

common parlance, +2 (for two years beyond grade 10). Entry into primary school is at age five. The KCF also recognizes two pre-primary levels, though there is strong encouragement to make these years more exploratory and less academic than they are now. The medium of instruction is Malayalam in the primary and secondary grades, though in principle the curriculum allows for the mother tongue (if different from Malayalam) and nonstandard dialects to be the medium of instruction for the first two years of primary school. Malayalam language and literature is taught as a subject starting from grade 1 continuing through grade 10. English is introduced at grade 1 and continues to be taught through grade 12 and beyond. A third language is introduced at grade 3 and continues to be taught till grade 10. At the upper secondary level, the medium of instruction is English. The number of languages needed at the upper secondary level drops to two with English as a required language and a choice of a second language from among the following: Hindi, Malayalam, Urdu, Arabic, or European languages like French, German, etc. From the above description it is clear that, apart from the first two years of primary school, Malayalam is taught as if it were the first language of the students (which is indeed true of the majority of students). Even where the curriculum leaves open the possibility of teaching Malayalam as a second language in the early grades, actual practice seems to indicate that this is not implemented, even in areas where students come from a different background (SCERT, 2007, pp. 44, 79).

While the above description of language learning and teaching is true of most of the public schools in Kerala, there is a sizable number of private schools in Kerala that differ from the above curriculum. For example, many of the private schools that receive financial aid from the government to run the schools offer English as the medium of instruction while conforming to the language requirements of the Kerala Curriculum in all other respects. Other unaided private schools follow the curriculum of the Central Board of Secondary Education (CBSE) or the Indian Council for Secondary Examinations (ICSE). In the CBSE schools, the medium of instruction is English and a slightly different three-language formula is followed: Malayalam is learned as a third language until grade 8 while English and Hindi continue and are required of all students in grades 9 and 10.

The above survey of the place of languages in the school curriculum in Kerala shows that while terms like second and third language are used they do not readily translate into established notions of teaching and learning a second or third language. For most students, Malayalam is the home language, but is designated as a first, second, or third language depending on the schools they attend. To see if there is any variation in the way language is tested depending on its designation we will look at the assessment practices followed by the Kerala Curriculum and the CBSE board.

Assessment Practices

Assessment of Malayalam in the Kerala Curriculum Schools

In schools that follow the guidelines set by the Kerala Curriculum, assessment is both formative and summative. Students are assessed on an ongoing basis

through the school year as well as through two summative exams—one midway through the term and the other at the end of the year. At the end of the 10th grade all students take an exam titled the Secondary School Leaving Certificate (SSLC), which they must pass in order to go on to the upper secondary schools. An examination of this terminal exam is used as a way of understanding the general approach to assessment of Malayalam in this curriculum, and, since the guidelines and model question papers from earlier years are readily available, discussion of the assessment of Malayalam will focus on them.

The grade 10 summative assessment is made up of two exams (Malayalam I and Malayalam II), each an hour and a half long. Malayalam I is based on the units covered in the prescribed text and includes responses to Malayalam essays, poems, and literary history. These responses are on the whole open-ended questions that test students' ability to critically analyze, interpret, discuss, and explain excerpts from Malayalam literature. While most of the questions deal with social, political, and aesthetic aspects of literature, about 10% of the questions deal directly with poetic meter and language use. The guidelines for the questions clearly eschew purely memory-based questions and emphasize questions that call for critical analysis. The model question paper for 2012, for example, calls for a synopsis of a story, analysis of an excerpt based on a quote, interpreting a poem from a social perspective, identifying the poetic meter used, and determining the criteria used to select entries for a school magazine. Responses call for short and long essays, lists, bulleted lists, and a couple of one-word answers. The questions also ask the students to direct their responses to different audiences and write for different modes: an academic audience, readers of school newspapers, addressing a celebratory gathering, notes for a play, etc.

Malayalam II is partly based on the nondetailed text prescribed and the rest on general writing tasks. In the model question paper for 2012, tasks include responses to ideas and incidents from the prescribed text, a report on government involvement in health care based on two statistical charts, and a long essay on the topic "Malayalee children must learn Malayalam."

Aside from the summative exams Malayalam I and II, which carry most of the grade (50% and 40% respectively), assessment also includes a formative part. The formative grade is based on work done during the school year, which could include putting together a magazine as a group project, writing a biography of a literary personality, creative outputs in the form of short stories or poems, etc.

The above summary of assessment in the SSLC exam shows that the assessment of Malayalam achieves to a large extent the goals of teaching and studying Malayalam that are spelled out in the Kerala Curriculum. The focus is on the use of language to perform multiple functions, from literary analysis to summarizing environmental data presented in charts. Even when the questions deal with grammatical form, the activities call for language production and not metalanguage. The aim of the assessment, as the preamble to the model question puts it, is: "to evaluate what a student knows rather than what he lacks" (SCERT 2012; author's translation). The mandatory 15-minute "cool off" time in the actual exam where students get extra time to plan their responses is yet another innovation that reflects this student-centered assessment.

Assessment of Malayalam in the CBSE Curriculum Schools

As described in the section on teaching–learning contexts, Malayalam is studied as a third language in schools that follow the CBSE curriculum. A passing grade in the third language for two terms (semesters) is a prerequisite for completing the school requirements and may be taken in either grades 9 or 10. While the assessment of Malayalam is both formative and summative in nature, the assessment clearly favors the summative end of the assessment. Each term is marked for 110 points with 90 points for the term-end summative assessment. While a few changes can be noted between 2011 and 2012, the breakdown of the summative paper on the whole follows this pattern: most of the questions deal with lessons from the prescribed textbook and take the form of short answer responses to literary-type questions (48 points); the rest of the exam includes reading comprehension of an unseen passage (10 points); a writing segment that requires an essay on social issues and a formal letter (14 points); and a section on grammar which has questions on transforming sentences, vocabulary, and *sandhi* and *samasam* (formal rules dealing with compounding and assimilation) (18 points).

A review of the model question papers for 2011 shows that, unlike the SSLC exam questions, these questions are based on the textbook and test for content of the lessons studied. Questions typically deal with who said what, to whom, and why. The section on structure is mainly made up of discrete-type questions that deal with antonyms, synonyms, transforming sentences (passive–active; affirmative–negative), identifying clauses and phrases, all couched in metalinguistic terminology. The two free writing activities have prompts that are general and not contextualized, for example, the importance of reading or problems of deforestation. The prompts for letter writing are less abstract: a formal letter inviting a literary figure to the inauguration of a literary club and a letter to a state representative on the condition of the roads. Thus, it is only the reading passage task that targets reading and writing skills independent of memory and general knowledge.

The formative assessment covers the skills of reading, writing, and speaking. The students are assessed on their participation in activities like essay writing, story writing, storytelling, acting, drama, *akshara slokam* (a recitation competition based on memory and diction), creating albums of famous writers, etc. A total of 20 points is allotted to each school term.

A comparison of the two school examination systems described above shows clearly that, while the CBSE exam is primarily focused on assessing metalinguistic knowledge, the SSLC exam has embraced the idea of testing language use. The questions in the SSLC exam are contextualized and the writing calls for the students to demonstrate their ability in language use. Even when the questions are based on the texts studied, the focus is on students' language and analytical abilities and not on rote recall. Students are provided with enough scaffolding either through models or helpful hints.

Assessment Outside the School Curriculum

Large-scale testing of Malayalam also takes place in exams that lead to employment in the Kerala Public Service Commission (KPSC). For example, for the lower

division clerk (LDC) exam, Malayalam is one component (10%), the rest of which is taken up by current affairs, general knowledge, mathematics, logical analysis, and English. A survey of the sample question papers on the KPSC website for the LDC exam in 2011 shows that the Malayalam section is a mixed bag of questions including knowledge of literary figures and literary works interspersed with a few language questions, all in a multiple choice format. The language questions include identifying grammatical metalanguage (type of assimilation, type of compounding), identifying the right orthographic representation, and questions that call for the right meaning of an English phrase or idiom.

Another prestigious exam, the Indian Administrative Services (IAS) exam requires candidates to take an exam in one of the scheduled regional languages, Malayalam being one. Unlike the LDC exam, the focus here is on language and language use. Test items include reading passages with comprehension questions, understanding idiomatic phrases, identifying ungrammatical sentences and orthographic mistakes, short and long writing tasks on current topics, idioms, and proverbs, and translation tasks from and into English.

Challenges

One of the striking features of all the tests surveyed is the singular lack of focus on listening and speaking. The closest the tests come to testing speaking are questions that require composing a speech for a specific audience. Presumably, this task would reflect features of a spoken model. Apart from this, all questions test only writing and reading skills. While it could be argued that the majority of test takers in these exams are first language speakers of Malayalam and possess speaking and listening skills, one should not lose sight of general variation among first language speakers in these skills and the diversity of dialects in the language. As students come from backgrounds with markedly different phonologies they are likely to use their dialect when speaking. Saidalavi (2012) points out in his examination of the writing of 6th grade students that their writing clearly reflects their speaking. Presumably, test writers have these speakers in mind when they test orthography that reflect sounds that are absent in their speech, like aspirated and breathy voiced sounds. Given the washback effect of tests on teaching, the lack of speaking and listening components will decidedly deemphasize any effort to get the students to speak standard Malayalam.

The quality of test questions in the CBSC and the LDC exam also need to be reexamined. The predominance of memory-based content questions in the CBSC exam needs to give way to questions that will assess language skills. Even when the questions are directly linked to structure and vocabulary, they are more often than not questions that require metalinguistic knowledge. Besides these obvious drawbacks, there are other questions of doubtful value. Prime among them are items that require translation from English into Malayalam. These translation tasks are ubiquitous in all the tests examined and except for the IAS exam, where one would expect candidates to be highly proficient in both Malayalam and English and translation skills to be a necessity, the relevance of such tasks is questionable. Further, even if a case is made for translation, how would

a translation task of the phrase (from the LDC exam, 2011) “a sound mind in a sound body,” with the focus on the word “sound,” be a test of Malayalam and not of English?

A search for information on assessing Malayalam revealed that the only documents readily available are on language policy and test descriptions. There are no research reports that provide documentation on the validity, reliability, and fairness of the assessments. It is critical that such reports are made available to the public as the tests surveyed are high stakes tests that serve as gatekeepers to higher education or stepping stones to desired jobs.

Finally, there seem to be no tests that assess Malayalam as a second language. Given the homogeneous nature of Kerala (99.5% gave Malayalam as their first language according to the 2001 census), it is perhaps not necessary for a centralized exam to address this need. However, as the 2007 Kerala Curriculum Framework has rightly pointed out, there is definitely a need for teaching and testing Malayalam as a second language at the lower grades in those areas in the state where the home language is different from Malayalam. If the aim is to use the first language in the primary school levels for intellectual development, then there should be active effort from educators to provide for the transition from the home language to standard Malayalam. This would require teaching and testing Malayalam as a second language. As it stands, minority language learners are all in mainstream classes with mainstream texts and exams and mainstream pedagogical practices.

Conclusion

This survey of Malayalam assessment shows that current approaches range from assessing Malayalam as a skill to a more traditional approach of equating language proficiency with literature. In curricula that combine literature and language the thoughtful innovations incorporated in the SSLC exam should be considered a model launching point for future reform in assessing Malayalam. Minimization of the role of rote learning and knowledge-based questions is necessary to keep language ability distinct from other cognitive abilities. Where the main purpose of the assessment is general language proficiency, the IAS language exam has the right approach, with its focus on reading comprehension and writing skills. All the exams surveyed would definitely benefit by including speaking and listening skills.

Assessing Nepali

Madhav P. Pokharel

Tribhuvan University, Nepal

Introduction

Nepali is an Indo-Aryan language primarily spoken in Nepal. The language has been spoken for a few centuries in southern Bhutan and several states of northeast India. Relatives of many retired British army officials speak it in Britain and Hong Kong. Recently, many Nepalese speakers have moved to the USA, Canada, Australia, several European countries, a couple of southeast Asian, and many west Asian, countries for education and jobs. They all speak Nepali as a lingua franca. Nepali is also the official language of Nepal, the Indian state of Sikkim and the Darjeeling Hill Council of West Bengal. It is also one of the 22 constitutional languages of India.

Other Names for Nepali

Traditionally, the Magars of western Nepal call Nepali “Khas bhasa” (Hodgson, 1874) or “Khas kura” (Grierson, 1916), originally to identify it as the language of the Khasa people. The Newar of the Kathmandu valley and some others call it “Parbate,” which is often Sanskritized as “Parbatiya” (Beams, 1872) or “Parbati” (Kirkpatrick, 1811). Nepali is one of the “Pahadi” or “Pahari” (Grierson, 1916) languages which denote the languages of the hillmen. Hoernle (1880) has classified it as “northern Gaudian.” It is often called “Gorkhali” or “Gurkhali” (Money, 1919) or “Gorkha bhasa” (Pandit, 1912), because Nepal was unified by Prithvi Narayan Shah, a king of Gorkha in western Nepal. Arjyal (1900–5) and Singha (1912) have called the language “Prakrit bhasa,” to mean the language of the common people, and some writers, like Chakrapani Chalise, prefer to call it simply *Bhasa* “language”. The name “Nepali” for the language cannot be earlier than the date of unification (1769) of Nepal.

Nepali: A Language of the Khasa

Sankrityayan (1956) says that the Khasa people were the original inhabitants of the Taklamakan valley during the Bronze Age. Grierson (1916) has noted that Nepali is a language of the Khasa who lived in the mountains between Kashgar and Hindukush on the west of the Taklamakan valley in Central Asia. Later they occupied Balkh (Bactria), in modern Afghanistan, until around the sixth century, when they were pushed eastward along the sub-Himalayan region as far as Nepal by the Gurjara people, who were closely related to them ethnically and linguistically. Grierson estimates that the Khasa spoke an Aryan language not very different from Avestan (Old Persian).

Modern representatives of the original language of the Khasa are spoken in the sub-Himalayan mountainous region from Chamba (India) to Nepal. According to Grierson (1916) the region was called Sapādalaksa. Sapādalaksa has been mentioned in two historical inscriptions (Aksāya Malla's and Shakti Brahma's) (Chalise, 2006) in Nepal. Modern Pahadi or Pahari languages are primarily spoken in the Sapādalaksa region: Nepali is the eastern Pahadi, Kumaoni and Garhwali are central Pahadi, and there are several languages spoken around Chamba, categorized as western Pahadi by Grierson. Chatterji (1926) has named "Khasa Prakrit" and "Khasa Apabhramsa" as the varieties of Middle Indo-Aryan presumably spoken in different historical periods in the Sapādalaksa region.

The Gurjara and the Pisaca (Grierson, 1906) also spoke closely related neighboring languages. Later on the Gurjara developed the Rajasthani dialects and the Pisaca developed Kashmiri, Shina, and related dialects of New Indo-Aryan. Grierson (1916) thinks Nepali and Rajasthani are similar.

Typological Similarity with Northwestern Indo-Aryan

The prehistoric picture drawn above helps us to explain why Nepali is typologically closer to the northern (Kashmiri) and western (Rajasthani, Gujarati, and Sindhi) than the neighboring Indo-Aryan languages (Awadhi, Bhojpuri, Maithili, Rajbamshi, and Bangla) of the east.

In support of his speculation Grierson (1916) says that Khasa, Gurjara and Pisaca languages share the existential verb $t^{sh}\lambda\ddot{u}$ "we are" and the probabilitive verbal suffix *-lo*. Beams (1872, p. 162) has given the distribution of the *-lo/-la/-l* suffix in Nepali, Kumaoni, Garhwali, and Rajasthani. Masica (1991, p. 290) has supplied this *-l* even for Marathi and Konkani. All of the languages which share this feature belong either to the northwestern or to the western group of the Indo-Aryan.

Turner (1931) has noted the following linguistic features of Nepali shared by the languages of the northwestern and western groups in sharp contrast with the eastern and the central Indo-Aryan.

- A voiceless stop is voiced after a nasal. According to Turner this feature is shared even by the Gypsy dialects. Masica (1991, p. 459) has surveyed this feature in Kashmiri, Lahanda, Sindhi, Panjabi, and other Pahadi languages.
- The cluster k_s changes into t^{sh} in the northwest and is shared by Nepali, while in most of the languages of the western, central, and eastern groups it is

realized as k^h . All the words in Nepali which have k^h corresponding to $kṣ$ in Sanskrit are borrowings from neighboring sister languages.

Masica (1991) notes:

- The Sanskrit passive suffix *-ya-* (p. 330), which has been developed as *-i-* in the New Indo-Aryan, has been preserved only in the northern and western groups (Kashmiri, Lahanda, Sindhi, Western Rajasthani, apart from Kumaoni and Nepali).
- O-ending direct case nominals (nouns, adjectives, and adjectival participles) are found in Kashmiri, Sindhi, Rajasthani, Kumaoni, and Nepali. Pokharel (2002) has traced the high frequency of o-ending suffixes shared by the languages of the Khasa of the Himalayas and the Gurjara of the Aravalli range in western India against the rest of the a-ending suffix shared by the languages of the Ganges basin.

These points support the theory of inner and outer groups of Indo-Aryan proposed by Hoernle (1880), following which Nepali belongs to the outer group of Indo-Aryan against the languages of the plains.

Inscriptional Nepali

The Nepali language is older than Nepal, which was unified in 1768–9. Tucci (1962, p. 84) who discovered a 14th-century inscription in Nepali, has estimated that the Malla, who used the language in the Devanagari script first at Semja in midwestern Nepal, founded a “great empire” which ruled both western Tibet and western Nepal during the 10th to 13th centuries. There is a debate over the earliest document in the language. Yatri (1982) has claimed that the inscription he has published is to be dated as 10th century and Khanal (2012) has published another inscription dated to the 11th century and claimed it to be the first inscription. In any case, it is likely that Nepali may have taken shape around the 10th century, comparable to other New Indo-Aryan sister languages like Marathi (Sircar, 1965). Nepali has been used by the royal courts as the inscriptional language in the Karnali catchment area for the last millennium. This practice became widespread after the unification of Nepal.

Historical Dialects

Pokharel (1964) has classified inscriptional Nepali into Old Nepali (beginning–15th century), Middle Nepali (15th–18th century) and New Nepali (since the 18th century). The beginning of Old Nepali coincides with the first inscription, Middle Nepali coincides with the borrowings of Perso-Arabic vocabularies, and New Nepali begins with the unification of Nepal. The formation of Middle Nepali also connects with the disintegration of the original Khasa kingdom and the beginning of its geographical dialects, presumably due to contact with Tibeto-Burman speaking peoples.

Geographical Dialects

Niraula (1993) has discovered 12 geographical dialects of Nepali. Most of the varieties unintelligible to the average speakers of standard Nepali are spoken in the Karnali river catchment areas of midwestern and far western regions. The eastern dialect of Nepali is primarily chosen for standardization.

Grammatical Sketch

Nepali follows the subject–object–verb order of the majority of the South Asian languages. Passivization and causativization are represented both morphologically and syntactically. Both transitive and intransitive sentences can be passivized. Evidential mood distinguishes Nepali from other Indo-Aryan languages. There are 11 patterns of nominative verb agreement triggered by countability, animacy, human–nonhuman distinction, honorificity, gender, size, number, person, and passivization. There are at least four grades of morphological honorific. Nepali is a classifier language using about 500 classifiers. Case distinction is controlled by post-positions, morphology, and agreement. Onomatopoeia is a productive area of the vocabulary.

Nepali in the Multilingual Setting

Nepal being a multilingual country, Nepali is spoken in a multilingual setting. According to the 2001 census (Yadava, 2003) there are 92 mother tongues spoken in Nepal. There are about 60 Tibeto-Burman languages. The Bodish/Tibetic group of Tibeto-Burman, which is spoken mainly along the northern Nepal–Tibet border amounts to 15 while the Himalayish group, which is mainly spoken east–west in the mountainous midland amounts to about 45. There are about 25 Indo-Aryan languages, 17 of which belong to the eastern Indo-Aryan of the Magadhi group. Most of the Nepalese Indo-Aryan languages are spoken along the Indo-Nepal border of the south, except Nepali, which links all the languages spoken in the country, being patronized by rulers, constitutions, and institutions. This prominent role of Nepali inside the country influences other languages and is in turn influenced by them. The phenomenon of diffusion of Nepali linguistic features into other Nepalese languages can be clearly seen in the “Nayā Nepal” (New Nepal) column of the *Gorkhapatra* daily paper. On the other hand, the gender system in Nepali is almost lost in the nonstandard colloquial varieties of some of its native speakers, whose ancestral language was Tibeto-Burman and not Nepali. The degree of crosslinguistic diffusion of the vocabulary items in Nepali is less than the grammatical features, compared to the other way round. Thus the Indo-Aryan native features in Nepali are more prominent in the western and far western dialects compared to the eastern, although the eastern dialect is basically chosen in standardization for educational, national, and international functions.

Nepali in the Workplace

In government, private offices, and other social institutions Nepali is used except when a situation permits workers to communicate in their mother tongues.

Spoken Varieties of Nepali Monolinguals and Nepali in Education

Spoken Nepali has kaleidoscopic divergences. It can be broadly divided into two types: the variety used by the descendants of Nepali speakers and the variety used by the descendants of non-Nepali speakers. The varieties of Nepali spoken by the speakers of Nepali geographical dialects, and specifically those whose ancestors spoke only Nepali for generations, is characterized by the presence of gender, number, and person contrasts while the varieties of Nepali spoken by those whose ancestors were not native speakers of Nepali for generations is characterized by attenuated contrasts in gender, number, and person agreements. The second group of speakers is mainly comprised of the descendants of bilingual and monolingual Tibeto-Burman speakers.

There is a mosaic of varieties of Nepali spoken by the second group. The formation of the second varieties seems to be the result of the use of Nepali vocabulary and the substratum grammar (Bickerton, 1983). One can speculate that when the predecessors of the modern Nepali speakers first came in contact with the speakers of each of the Tibeto-Burman languages, they may have started with the pidgin form of the languages. In the succeeding generations different varieties of Nepali creoles developed. Standard Nepali is the common code developed from those different spoken creoles and the colloquial varieties of the language of the first group. This may be the reason why the eastern dialect of Nepali is closer to the standard variety rather than the purer forms of Nepali dialects used in the west. Nepali language, in its gradual historical and geographical movement from the west to the east, has been more and more polluted by the grammars of the neighboring languages. In this way, the eastern dialect is most polluted and, therefore, is the one to be chosen as the lingua franca of speakers of all the varieties of all the languages spoken in Nepal.

There is a fine-grained continuum of spoken varieties of Nepali, starting from the first generation creoles of each of the 100 mother tongues and standard Nepali, an ideal status to be gained by creole speakers of Nepali by schooling and other means of communication. Therefore it is not surprising to find even educated first language Nepali speakers born of Tibeto-Burman-speaking predecessors not consistently distinguishing gender, number, and even person, although they have studied Nepali as a compulsory subject for at least 10 years. This implies that the teaching of compulsory Nepali in the schools has not been effective.

Nepali as a Link Language

Nepalese languages belong to four major families (Indo-Aryan, Tibeto-Burman, Austroasiatic, and Dravidian) and Kusunda, a language isolate. By centuries of privileged position in politics, administration, historical inscriptions, and interpersonal communication, Nepali has become the link language of wider communication. It is therefore interesting to witness that when bilingual and monolingual Nepali-speaking language activists whose ancestral language is other than Nepali

gather together to speak against Nepali, the medium of interaction has to be Nepali. Not only that; when Magars and Rais speaking different languages conduct meetings among themselves, they cannot communicate with each other without using Nepali.

Standardization

Standardization of Writing

The Devanagari script is the result of the gradual process of evolution of the Brāhmi script in order to capture Sanskrit phonology. However, Nepali does not have the following phonological characteristics of Sanskrit: (a) syllabic consonants, (b) phonemic contrast of length in vowels, (c) constraints on vowel sequence, (d) palatal and retroflex stops, (e) labiodental glide, (f) absence of phonemic contrast between dental and alveolar places, (g) the three-place phonemic contrasts in sibilants, (h) neutralization of liquids after /t/ as /r/, (i) neutralization of three-place contrast in sibilants as the retroflex /ʂ/ after /k/, (j) neutralization of different place phonemic contrast in nasals as the palatal /ɲ/ after /j/, and (k) the lack of phonemic nasalization. The velar nasal and bilabial approximant are the innovative phonemes in Nepali and not significant in Sanskrit. In spite of these structural differences between Sanskrit and Nepali, the orthodox Nepali pundits have a tendency to maintain the original Sanskrit spellings in Nepali borrowings even if they have no phonemic status in Nepali. Although university teachers of Nepali have simplified consonants in borrowings other than Sanskrit sources (Dahal, Tripathi, Parajuli, Sharma, & Adhikari, 1976) and the Royal Nepal Academy (Pokharel, 1982) has incorporated these changes, length in high vowels is still maintained in borrowings although there is no phonemic contrast in vowel length.

Standardization of Vocabulary

Nepali has borrowed some words denoting cultural items from the neighboring languages. There are many Perso-Arabic borrowings commonly used in the legal and administrative domains. Many English (and indirectly Greek and Latin) borrowings are increasingly being used in media and textbooks on technical domains. The majority of scientific and technical terms are calqued and coined by using the Sanskrit grammar and lexicon. The majority of the vocabularies used in High Nepali are served by replacing native Nepali words with literary Sanskrit.

Myth of Homogeneity in Standard Nepali

Although the standard dialect of Nepali is supposed to be the homogeneous variety, in reality it is not. The so-called standard variety used in India, specifically in Darjeeling and the Brahmaputra valley, slightly differs from the variety used in Kathmandu and major centers of Nepali inside Nepal. The myth of homogeneity in a standard language applies not only in the spoken but also in the written varieties of Nepali.

Teaching, Learning, and Assessing Nepali in Schools

Nepali was introduced as the medium of formal school education in 1854 when Durbar High School was established. The school was opened to the general public only in 1883. The language was introduced in higher education only after the establishment of Trichandra College in 1918. At the university level it was first used in Calcutta University (India) before Tribhuvan University (Nepal) was established in 1959. Since then Nepali has been a compulsory subject in education.

Levels of Teaching Compulsory Nepali

Up to grade 10 Nepali is a compulsory subject. After grade 10 Nepali remains a compulsory subject for one more year at the higher secondary level. Compulsory Nepali is taught for one more year at bachelor level in the humanities but stopped after the higher secondary level in the faculties of science and technology.

Assessment Practices

Objective tests have not been practicable in Nepal due to the volatile political situation, therefore long and short answer subjective questions have been the general assessment practice. There are mainly annual examinations for testing Nepali. Internal assessments, ongoing evaluation practices, and even objective tests, which were introduced in the 1970s, have become things of the past.

Classroom Teaching–Learning Situations

Classrooms are less interactive than current ideal teaching–learning practices. There are no special courses for those who are learning Nepali as a second language. Students who speak Nepali as their mother tongue, as bilingual speakers, and second language speakers are given the same course in the same classroom and are assessed with the same question papers to be solved within the same amount of time in the final examinations.

Nepali as Literary Major

Besides compulsory Nepali, there is a Nepali major in humanities and education as an optional subject. The general focus is teaching Nepali literature, in contrast with compulsory Nepali, where the focus is more on teaching language structure than on literature.

Manipulation of the Census Data

Population censuses in Nepal started in 1952–4. Since then the population of those who speak Nepali as a mother tongue has been gradually increasing, up to almost

58%, with a corresponding gradual decrease in the population of other languages like Maithili, Tharu, Newar, Magar, and Limbu, until 1981. The political change of 1990 has brought a U-turn in the apparent percentage of Nepali, which has now gradually dropped to almost 48%, vis-à-vis that of the other languages, which have been gradually increasing since the 1991 census. The percentage of speakers of Nepali as a second language is almost 25% in 2001. The figures show that almost three quarters of the total population of Nepal communicates in Nepali, therefore Nepali is the language of widest communication in Nepal.

Future Directions

The present situation indicates that in future more and more speakers of other languages may leave their mother tongues for Nepali, but political manipulation of census data will continue to reduce the percentage of actual Nepali speakers. More and more newcomers as Nepali first language speakers will work for the loss of passivization, loss of gender distinction, and the gradual loss of inflections and increase in agglutination and periphrastic structures.

University of Colombo, Sri Lanka

Introduction

Sri Lanka, a multilingual, multiethnic, and multireligious country has a history and culture more than 2,000 years old. Sinhala, an Indo-European language, is spoken by about 13 million people in Sri Lanka. It is the mother tongue of the largest ethnic group, the Sinhalese (82%; Department of Census and Statistics, Sri Lanka, 2001), who are predominantly Buddhist. Because of Sri Lanka's close proximity to India, there has been much influence from that country, principally from the ethnic community of Tamils who first came to Sri Lanka as traders from southern India. They speak Tamil, a Dravidian language, and are mainly Hindus. Today, this ethnic group makes up about 9% of the population (Department of Census and Statistics, Sri Lanka, 2001). Another large minority is the Muslims (8%) whose ancestors came to Sri Lanka as Arab traders. They mainly speak Tamil, though communities living in Sinhala areas also speak Sinhala. The Malays (.03%) who came from Indonesia and Malaysia (during Dutch and British rule) speak Sri Lankan Malay and either Sinhala or Tamil, or both. The Burghers (.02%), the smallest ethnic group of Portuguese or Dutch descent began speaking English when the British took over the country. Though dominant in English, today some also speak Sinhala.

During the 16th century, European languages had an impact on Sri Lanka. The Portuguese colonized the country in 1505, and were displaced by the Dutch in 1656. While Portuguese and Dutch were used for colonial administration, Sinhala continued to be used in religious and literary arenas. As a result of these languages being used side by side, many Portuguese words, for example, *sapattu* (sapato "shoes"), *mesaya* (mesa "table"), and Dutch words such as *bonci* (boontje "beans"), and *kantoruva* (kantoor "office") have come into Sinhala. But it was the British who had the most impact when they took control of the country

from 1815 to 1948, with English becoming the official language from 1815 to 1956. Although Sri Lanka (known then as Ceylon) gained independence from the British in 1948, English continued to be the de facto official language of the country and, not surprisingly, even today it is still used widely in government, commerce, and higher education. Eight years after independence, the Official Language Act No. 33 (commonly known as the “Sinhala-only” Act of 1956) replaced English with Sinhala, making it the sole official language of the country (Government of Sri Lanka [Ceylon], 1956). This change had lasting repercussions, one of which was to exacerbate the communal rivalry between the Sinhalese and the Tamils, which until recently resulted in a civil war between the two groups. During the escalation of the civil war, in 1987, as a part of the 13th Amendment to the Constitution, Tamil was made an official language, and English was given the position of a link language (Government of Sri Lanka, 1978). Today Sinhala and Tamil are both national and official languages in Sri Lanka, while English is a link language.

Description of Sinhala

The origin of Sinhala (some scholars also use the term Sinhalese) is thought to be an ancient north Indian language, and there are two main theories as to where its speakers originally came from: one which supports northeastern India around the Bengal area, and the other northwestern India. However, since there are no written records from this era (about 2,500 years ago) there is no conclusive reason to select one theory over the other (de Silva, 1970; Disanayaka, 2006). Today Sinhala is the southernmost Indo-European language in Asia, and, for over two millennia, as noted by Gair (1998), it has been isolated from its sister languages to the north (e.g., Hindi, Bengali, Gujarati, etc.) both by its island location and by the intervening Dravidian languages of south India. However, due to its close contact with Sri Lankan Tamil, the vocabulary and phonology of modern Sinhala does show some Dravidian influence.

Four periods of historical development are usually identified for Sinhala, as follows (Geiger 1938):

- Sinhalese Prakrit—until the 3rd century
- Proto-Sinhalese—circa 4th to the 8th century
- Medieval Sinhalese—8th to the 13th century
- Modern Sinhalese—13th century to the present

As Modern Sinhala is a diglossic language, differences between written (literary Sinhala) and spoken (colloquial Sinhala) varieties are visible in terms of *orthography*. Modern Sinhala has two alphabets: one known as the Suddha Sinhala (pure Sinhala) or Elu alphabet and the other as the Misra Sinhala (mixed Sinhala) alphabet. Suddha Sinhala has 21 consonants¹ and 12 vowels, and all the phonemes of colloquial Sinhala as well as the wordstock of one of the earliest varieties of the language—Elu—can be represented orthographically by this alphabet. However, to represent words borrowed from Sanskrit, Pali, or English, which have more

extensive phonological systems than colloquial Sinhala, the larger Misra Sinhala alphabet, with 18 vowels and 36 consonants, is required.

The Sinhala script is semisyllabic, as a basic character (letter) represents a syllable with a default vowel (Daniels, 1996). Vowels in Sinhala are represented in two forms: as independent characters, and as diacritics. The independent character is used when a vowel does not follow a consonant, for instance, at word-initial position. The diacritic occurs when a vowel immediately follows a consonant. When written, diacritics can precede or follow a character, or can be attached above or below a character. Sinhala has a strong sound–symbol correspondence, that is, each character or grapheme can be pronounced in only one way. This means that the actual pronunciation of a word is always clear from its orthographic form.

Gair (1998) observes that the *phonological system* of Sinhala closely resembles the Middle Indo-European system except for the lack of a voiced and voiceless aspirated stop series contrasting with the unaspirated ones in colloquial Sinhala. Colloquial Sinhala has also lost the feature of retroflexion except in rare, highly formal contexts. Literary Sinhala, however, maintains these distinctions as represented in orthography, and this is one aspect of the language that is assessed in primary school education. A unique feature of Sinhala is the existence of prenasalized stops, found in both colloquial Sinhala and literary Sinhala, as the lexicon of both varieties have minimal pairs in which the sole distinction is a prenasalized stop consonant.

The *vocabulary* of Sinhala remains fundamentally Indo-European, with many terms that apparently come from an indigenous source, but there is a large component of borrowings from Tamil, Portuguese, and Dutch (Gair, 1998), and, more recently, from English. Sanskrit borrowings are common, and technical and academic registers of literary Sinhala tend to draw heavily on forms or coinages based on Sanskrit words (Gair, 1998).

Sinhala is a left-branching subject–object–verb (SOV) language which, according to Gunesekara (1986), has only four parts of speech: nouns, verbs, and two types of indeclinable particles. The category of nouns includes proper nouns, common nouns, pronouns, and also adjectives; the indeclinable particles include adverbs, prepositions, conjunctions, interjections, prefixes, and suffixes. Nouns inflect for (natural) gender, number, person, and case, and there are nine cases in Sinhala: nominative, accusative, instrumental, auxiliary, dative, ablative, genitive, locative, and vocative (Gunesekara, 1986).

Verbs in literary Sinhala are inflected for tense, person, number, and gender, but verbs in colloquial Sinhala require no such inflection. In other words, there is subject–verb agreement in literary Sinhala but not in colloquial Sinhala.

Teaching, Learning, and Assessment of Sinhala in Schools, Universities, and the Workplace

The Ministry of Education directs the formulation and implementation of policies related to primary (kindergarten to grade 5) and secondary education (grades 6 to 13) while the Ministry of Higher Education focuses on tertiary or university education in Sri Lanka.

In recent years, classroom-based assessment practices that are more informal have become widespread in the educational philosophy of the country, as evidenced in syllabi and teacher instruction manuals. So while summative assessments are used in the evaluation of learning in the higher grades, formative assessments are now commonly used to give students feedback on learning in the lower grades. In both primary and secondary education, all subjects are taught in Sinhala or Tamil and some schools with teachers proficient in English have English-medium instruction. The National Institute of Education (NIE), which advises the Ministry of Education on the development of curricula in Sri Lankan schools, identifies general competencies as well as specific competencies for each grade. For grades 1 and 2 these competencies primarily involve whole language development (Edelsky, 1993) and young learners' cognitive development. Assessment of learning in these grades is done through observations, discussions, question and answer during activities, and the textbook or workbook, rather than through written tests (NIE, *n.d.a*). In grades 3 and 4, subjects taught are first language: Sinhala or Tamil, and others (natural and social environment, English). Similarly assessments are done through observations, discussions, question and answer during activities, and using the textbook or workbook. For each subject a rubric is provided for making an evaluation. A teacher places a check (✓) if the student displays the ability or a dot (·) if the student has difficulty or needs further development in that area. In grade 5, the final phase of primary education, Sinhala is taught for an hour each day. As with the lower grades, assessing student achievement is done primarily through observations and interactions, but specific suggestions in the grade 5 syllabus and teacher instruction manuals (TIMs) (NIE, *n.d.b*) are made for using group work, a portfolio of written work, student notebooks, homework, written tests, and end of semester tests for summative assessment purposes. As with the previous grades, a rubric is provided for the purpose of assessing Sinhala and for the assessment of student learning in general.

Grades 6–10 form the middle school phase in the Sri Lankan education system. In these grades the syllabi and TIMs clearly outline teaching and assessing of both language and literature. Because of its rich literary history, Sinhala poetry, plays, and novels are central in Sri Lankan education. While no guidance is given for constructing tests, the TIMs suggest that both summative and formative types of assessment be done. Unlike in the primary grades, these manuals have a separate section on assessment and evaluation—they state that teachers can use typical test item types such as multiple choice questions, filling in the blanks, short answers, etc. The TIMs also suggest that teachers should take the initiative in creating tests for their classes in recognition of the fact that there can be differences in ability of student populations across the country. The manual further states that for the purpose of creating tests, teachers should have the requisite knowledge, concepts, and have done the training. This suggests that teachers receive such knowledge in pre-service or in-service teacher-training programs. However, the common practice is to look at past test papers and use them as templates for creating tests for the classroom.

The culmination of middle school education is passing the General Certificate of Education Ordinary Level (GCE O-level) Examination, which consists of written tests of the first language (Sinhala or Tamil), mathematics, science, English, history,

religion, and three elective subjects (e.g., music, art, dance, foreign language, etc.) Passing this national examination allows students to continue onto grades 11–13 (also referred to as upper secondary level), that is, based on their performance students are channeled into General Certificate of Education Advanced Level Examination (GCE A-level) streams. For example, a student receiving excellent grades for mathematics and science can enter the science stream (pure mathematics, applied mathematics, physics, chemistry, biology) or any other stream, whereas a student receiving satisfactory grades can only study arts or commerce subjects (geography; history; Sinhala, Tamil, or English; French, German, or Japanese; dance; music; etc.).

Grades 11–13 in Sri Lanka are geared toward pre-university instruction and, as students have already chosen their streams (mathematics, science, commerce, arts), the goal of teaching is to prepare students for the GCE A level. The syllabi and TIMs describe the content for teaching, as well as methods of assessment. For example, the Sinhala syllabus for grade 13 outlines 26 types of formative assessments: structured essays, concept maps, observations, discussions, impromptu speeches, projects, presentations, quizzes, open book assessments, and double entry journals (NIE, *n.d.a*) and sample assessments are given. The assessments include a rubric for teachers to use or adapt. As with other syllabi and TIMs, there is no guidance on how to construct these assessments. For summative assessments, teachers refer to past A-level examination papers for structure and content.

University instruction takes place in English for medicine, dentistry, veterinary science, science, engineering, and law. Though social sciences and humanities offer English-medium instruction, because of low levels of academic English proficiency, students have the option of Sinhala- or Tamil-medium instruction. The purpose of testing is for achievement and the most common test type is written essay-type questions.

In terms of employment, competency in both Sinhala and Tamil is required for government jobs. According to a government public administration circular, competency can be shown either by passing Sinhala and Tamil at the GCE O-level examination or by passing the Department of Official Languages' competence examinations. The Level 3 competency test is for any employee, Level 2 is for middle management, and Level 1 is for executives. Assessment is summative, except when language training is provided, and then formative assessments make up a small percentage of the overall grade. Assessment at each level is through written papers and an oral test covers work-related speech and conversation. To show competency, a test taker must score a total of 40% on all parts of the assessment.

Issues Related to the Assessment of Sinhala

As discussed above, Sinhala is assessed mainly through written paper and pencil tests. While primary education may use informal tests for formative purposes, the majority of significant tests such as the GCE O level and A level (i.e., ones used for making decisions about secondary education and university entrance) are formal and summative.

The GCE O-level test of Sinhala consists of three papers. Paper 1, lasting one hour and assigned 40 points, consists of 40 multiple choice questions assessing knowledge of grammar. Paper 2 is two hours and has four questions worth 80 points, testing composition, summarizing short paragraphs, comprehension of a short poem through short answers, and writing a formal letter. Paper 3 is two hours, worth 80 points, and is focused on literature, assessing comprehension and implied and literal meanings of poems and short stories, and requires responses that are short to moderate length paragraphs utilizing quotes from the literary texts.

Similarly, the GCE A-level examination of Sinhala consists of two papers, each of three hours, and worth 100 points. Paper 1 tests Sinhala literature with five essay-type questions. Paper 2 tests Sinhala language. Part 1 is compulsory multiple choice grammar questions and Part 2 tests reading comprehension, summarizing, composition, and short answer responses related to vocabulary, grammar, and punctuation.

According to Ananda Tissa Kumara, Professor of Sinhala, University of Colombo, at the university level, too, Sinhala is assessed through traditional paper and pencil tests, but, rather than multiple choice questions that use structured responses, test questions are essay-type, eliciting longer samples of language (personal communication, January 20, 2010). In primary or secondary school or at the university level the ability to speak and understand (through listening) Sinhala, two of the major skills of language ability, is not measured.

For employment, the Department of Official Languages' Level 3 (minimum competency) test has two papers. One has "fill in the blanks" grammar and vocabulary questions, and the other requires test takers to construct dialogues for typical situations encountered in government offices. Level 2 and Level 1 each have three papers of one hour's duration. Paper 1 consists of writing an essay, an official report or letter, and summarizing short texts. Paper 2 assesses grammar and vocabulary knowledge, with multiple choice and fill-in items and reading comprehension with short answer questions. It also includes translation from Sinhala to English and Tamil and vice versa. Paper 3 tests other work-related genres of writing that require longer responses such as memos, newspaper advertisements, and notices.

The methods of testing in each of these areas (primary and secondary education, university, and employment) are traditional in that "they are typically used for the assessment either of separate components of language knowledge (grammar, vocabulary etc.) or of receptive understanding (listening and reading comprehension)" (McNamara, 2000, p. 5). The items in such tests often use multiple choice, which is a fixed test response. Having said that, the assessment of Sinhala for employment is more aligned with second language assessment practices, as the purpose is to evaluate proficiency in language use. While some questions measure discrete aspects of language such as grammar and vocabulary which "may be self enclosed in the sense that it may not bear any direct relationship to language use in the world outside the classroom" (McNamara, 2000, p. 7), some of the test questions include performance features in their design. For example, writing an office memo or writing an official report or translating documents into or from Sinhala are some common tasks an employee will need to be able to do. In addition, as test

takers' speaking ability is also measured, from an assessment perspective, the Department of Official Languages demonstrates some understanding of performance (i.e., real-life language use) being an important part of language proficiency.

When designing and developing language tests the most important consideration is the usefulness of the test (Bachman & Palmer, 1996). While tests serve the pedagogical purposes of promoting learning, their primary function in Sri Lanka is to make important and sometimes high stakes decisions such as qualifying for advanced levels of study, university entrance, or job promotions, and therefore the qualities of reliability and validity are critical. In the context of schools many of the syllabi and TIMs allude to teachers having knowledge of testing concepts, and while assessment (for the purpose of promotion) in school is low stakes, the GCE O level and A level are high stakes examinations. For these national examinations the Department of Examinations' National Evaluation and Testing Service (DOENETS) recruits teachers to develop test items from grades 11–13 for the GCE O level, and university academics for the GCE A level. The common practice in developing test questions is to look at previous test papers for structure and content. While no formal test development training occurs at these "paper setting" meetings, a panel of examiners (DOENETS officials and university academics) oversees the test development process. At the time these test papers are created, answer keys and scoring rubrics are also developed. Before tests are graded, a rater training takes place to norm raters before they begin to rate the tests (Ananda Tissa Kumara, personal communication, February 19, 2010). Clearly testing practices do not seem rigorous but there is some indication that DOENETS understands that reliability is an essential quality of testing and tries to minimize the effects of potential sources of inconsistency. In terms of providing validity for these examinations, several types of evidence such as the relevance of the content and coverage can be used to demonstrate and justify the intended interpretations of the test scores. While DOENETS claims that the department "provides guidance toward excellence in educational achievement and certification activities using evaluation instrument and methodologies ensuring reliability and validity to suit national needs" (Department of Examinations, Sri Lanka, *n.d.*), other than anecdotal evidence no documentation or statistical data is made public about the reliability and validity of these examinations.

The two qualities that seem to have the greatest bearing on the assessment of Sinhala (and assessment practices in general) in Sri Lanka are impact and practicality. Because the O-level and A-level examinations are high stakes, failing or passing them has serious consequences: passing the O level is a basic requirement for employment as well as continuing on to grades 11–13, passing the A level is the only way to enter university or to be eligible for entry level managerial positions. Because these exams are high stakes, naturally "the effect of testing on teaching and learning" (Hughes, 2003, p. 1) can be seen on educational practices and beliefs. For example, many students incur extra costs for private classes or tutors to help them pass these examinations. Or, as Ransirini (2004, p. 21) says, "if our decisions in class rooms are restricted by test formats or test items, we would invariably neglect certain [language] tasks and skills that students need to master." Such practices train students in the skill of answering tests but not in the necessary skills that would ultimately make them proficient users of the language.

In terms of employment, while the stakes are not as high as O level and A level, the Department of Official Languages' competency tests are still significant gatekeepers because promotions and salary increases are based on passing them.

As the GCE O level and GCE A level are national exams, they are administered to large numbers of test takers every year. In terms of practicality these tests need to be developed, administered, and rated in a timely manner with the available human and material resources. Therefore it is not surprising that test types such as multiple choice and short answer are often used and that oral language ability is not assessed. In contrast, competency tests for employment may not require the same type or amount of resources as the number of test takers is fewer. The Department of Official Languages uses some multiple choice test types but most of the test questions are task based and the inclusion of an oral component indicates that the Department allocates resources to all aspects of language ability.

Challenges and Future Directions

Sinhala is spoken only in Sri Lanka, and much of the research about the language is in Sinhala. As this chapter shows, the small number of studies in English is mainly linguistic in nature and research regarding the assessment of Sinhala (in Sinhala or English) is sparse. Considering what we know about language testing (Bachman, 2000), assessing Sinhala still follows a very traditional path. Tests are mainly summative and test-type questions such as multiple choice questions and written responses are favored over more task-based, performance-type questions. Oral tests are rare, thus ignoring assessing language proficiency in speaking and listening. Moreover, given the fact that spoken (colloquial) Sinhala has significant linguistic differences from written Sinhala due to the diglossic nature of the language, one could argue that colloquial Sinhala warrants assessment. Finally, tests are used to make very high stakes decisions and therefore the "washback" or impact from these tests on education (learning and teaching) and employment and thereby on society is significant.

Also, the test development process, especially the high stakes GCE O-level and A-level examinations, lacks a level of quality accepted as the norm in the assessment field. Though DOENETS states that it ensures the reliability and validity of the national exams, there is no evidence of trained professionals (testing in general and language testing specifically) or employment of professional practices.

While there are many challenges to assessment practices in Sri Lanka, there is evidence of some understanding of the shortcomings and the push to make changes, especially in the educational arena. More formative assessment practices are being encouraged, as evidenced by revisions to primary and secondary school syllabi and teaching manuals. Also more pre-service teacher-training programs include courses in assessment and prepare or guide teachers in assessment practices, and in-service assessment workshops are offered through the National Institute of Education. Looking towards the future, one of the greatest needs is ensuring transparency about the assessment process of GCE O level and A level, the two national examinations. The need for expert professionals who can guide item writers and train raters on a consistent basis is desirable and more transparency

of test reliability and validity of score interpretations is needed. In terms of tests, an area in need of development is the inclusion of performance-based test tasks, including the assessment of spoken Sinhala. Whether it is the more formal variety or colloquial Sinhala that is tested, given the large numbers taking O- and A-level examinations, relatively authentic but practical test tasks need to be considered.

Examining the assessment of Sinhala as a first language in Sri Lanka has led this chapter to point to a number of issues that need to be addressed. Without a doubt, any contribution towards the development of assessing Sinhala will be noteworthy in terms of language testing and testing practices in general.

Assessing Tamil

Vyjayanthi Sankar

Educational Initiatives, India

Introduction

Tamil is one of the widely spoken Dravidian languages and occupies a distinct place among them owing to its geographical spread beyond the boundaries of India. Apart from being the first language of nearly 48 million people in the Indian state of Tamil Nadu, it is the spoken and the written language of several million people across the globe, specifically Tamilians living in Sri Lanka, Burma, Singapore, Malaysia, Indonesia, South Africa, and Mauritius. The wide geographical spread and the number of people who speak Tamil, either as a first language (L1) or as a second language (L2), have created a need for adequate systems of teaching, learning, and assessing Tamil. However, the robust diglossia it exhibits, the existence of several dialects, and the ongoing anglicization (among other things) pose several challenges, especially for assessment. The present chapter discusses these challenges and takes a look at the assessment of Tamil for educational purposes, specifically at the school level.

A Description of Tamil

Tamil is one of the oldest languages of the world; it developed from around 100 BC in the Indian subcontinent, and it prospered as an independent language with a great literary tradition. The rock inscriptions of the 2nd century BC and the several thousand inscriptions in Tamil discovered in India stand testimony to the greatness of this ancient living language.

At present, Tamil is one of the 22 languages recognized in the Eighth Schedule of the Constitution of India and the official language of the state of Tamil Nadu.

It is the first Indian language to be declared a classical language by the government of India; this happened in 2004 and was based on the following criteria:

high antiquity of its early texts/recorded history over a period of 1500–2000 years; a body of ancient literature/texts, which is considered a valuable heritage by generations of speakers; the literary tradition be[ing] original and not borrowed from another speech community; the classical language and literature being distinct from the modern. (The criteria shared by the Minister of Tourism and Culture Ambika Soni in a 2006 press release in Rajya Sabha)

In Sri Lanka, Tamil shares the status of official language with Sinhalese. In Singapore, Tamil enjoys the status of “official” mother tongue and symbol of identity and culture, along with English, Chinese, and Malay. Many of Tamil origin live in countries like Fiji, Trinidad and Tobago, Guyana, Surinam, and so on; but only a small proportion of them speak Tamil. Migrants from India and Sri Lanka also live in countries like USA, Canada, Australia, European countries, and the Middle East.

The Script

The Tamil script consists of 12 vowels, 18 consonants, and one special character called *Āytam*, which is used to represent foreign sounds. The vowels and consonants combine to form 216 compound characters, thus giving a total of 247 characters to the script. The following are some of the notable features of the Tamil script:

- type of writing system: syllabic alphabet;
- direction of writing: left to right, in horizontal lines;
- vowels are generally written as diacritics or smaller symbols appearing adjacent to the consonant on either side; when vowels appear at the beginning of a syllable, they are written as independent letters;
- the script is transparent with respect to pronunciation.

Word and Sentence Structure

Tamil is a consistently head-final language. The verb comes at the end of the clause, and the typical word order is subject object verb (SOV). Tamil has postpositions rather than prepositions. Demonstratives and modifiers precede the noun within the noun phrase. Subordinate clauses precede the verb of the matrix clause.

Tamil shows rich agreement between subject and predicate and therefore allows different word orders. It shows agreement in person, number, and gender; and also the inflection is different when the person addressed is honored. Some examples of agreement are provided below. These sentences also show the canonical word order.

- (1) *avan sorru saappittaaan*
 he rice ate-3sg.masc.
 “He ate rice.”

(2) *aval sorru saappittaaal*
 she rice ate-3sg.fem.
 “She ate rice.”

(3) *avar sorru saappittaaar*
 they / he (honorific) rice ate-3pl./3sg.masc.hon.
 “They ate rice” / “He [honorific] ate rice”

Dialects

The wide geographical spread of the language has led to widespread variation in how the language is spoken. Even within the confines of India, Tamil shows large variation in the form of dialects; this variation is determined by regional as well as social factors. The various dialects of Tamil can be classified as follows:

- 1 dialects of different regions like Kovai, Madurai, Chettinadu, Chennai, Tanjavur, Tirunelveli, Jaffna, and so on;
- 2 dialects of various caste groups like Brahmin, Pillai, Chettiar, Goundar, Dalit, and so on (these could come under a single regional dialect, but each one is distinct and has its own flavor);
- 3 dialects of immigrants to Tamil Nadu such as Telugu Naikars, Naidus, Chettiars, Palgat, Brahmins, Kannada immigrants, and so on;
- 4 dialects of diaspora Tamils such as in Singapore, Malaysia, Europe, Canada, Australia, South Africa, Mauritius, and so on.

For example, let us look at a few kinship words as used in two colloquial varieties of Indian Tamil—Iyengar and Mudaliyar dialects (see Table 118.1). The former is a Brahmin dialect and the latter is a non-Brahmin but upper-caste dialect. Both are spoken in all the Tamil-speaking regions; so regional variants can be separated from caste variants.

Diglossia

One of the most important features of Tamil is its severe diglossia. A language is considered diglossic if

it has two codes which are complementary in their functions with the “superposed” or the “higher” code being utilized in situations that can easily be characterized as

Table 118.1 Examples of lexical elements that are different in two dialects. Adapted from Ramanujan (1968)

<i>English word</i>	<i>Equivalent in Mudaliyar dialect</i>	<i>Equivalent in Iyengar dialect</i>
son-in-law	<i>marumahā</i>	<i>maap̄le</i>
younger sister’s husband	<i>maccāā</i>	<i>maap̄le</i>
wife’s brother	<i>maccāā</i>	<i>maccina</i>
elder sister’s husband	<i>maccāā</i>	<i>attimbeer</i>

formal while the “underposed” or the “lower” code is used in informal contexts. In terms of acquisition, the higher code is learned through formal means of instruction while the lower code is acquired naturally as an L1; the higher code does not have native speakers while the lower one has. (Matiki, 2010, p. 25)

Tamil exhibits this functional and acquisitional complementarity of codes. In fact, instead of two codes, it has many varieties that contribute to two systems, each of which is basically a continuum of related varieties. Varieties that are acquisitionally and functionally superposed constitute the higher diasystem, while the other varieties form the lower diasystem. In other words, the lower varieties are used in all day-to-day situations, while the higher varieties are used in more formal situations.

The degree of formality of a situation determines the variety in the higher diasystem which will be used in that situation. For instance, *Cen Tamil*, which is on the higher rungs of the higher diasystem, is the preferred variety in the more formal situations such as religion and education. The other higher varieties of Tamil such as *Popular Tamil*, which are less rigid than *Cen Tamil* or *Literary Tamil* and are accessible to more people, are used in less formal contexts such as newspapers, the radio, television, prose fiction and so on. (Matiki, 2010, p. 25)

The higher varieties are learnt through formal means of instruction whereas the lower varieties are acquired naturally. Moreover, the higher varieties are held in higher esteem and speakers even deny using the lower varieties because of the stigma they carry.

Research has established that the higher varieties of Tamil are distinguishable from the lower varieties at both phonological and morphological levels. All Tamil words are pronounced differently in the higher and lower diasystems, with very few exceptions. The differences are caused by a number of phonological processes in the language and include nasalization, monophthongization, vowel lowering, assimilation, and lateral deletion (Schiffman, 1978). At the morphological level, a number of morphemes such as quotative particles, conditional clause markers, and perfective aspect suffixes appear as bound forms in the lower variety and as free forms in the higher variety (Matiki, 2010).

The distinctions between the higher and the lower varieties mostly coincide with the disparities that exist between written and spoken Tamil. The written form exhibits the traits of a classical language and is widely used in literary writings, print media, radio and television broadcasts, government records, speeches, and so on. In contrast, the spoken form of the language is widely used in everyday conversations, films, fictional writings, and so on.

The Teaching and the Learning of Tamil

The teaching–learning scenarios of Tamil fall into two broad categories: teaching–learning of Tamil as L1 and teaching–learning of Tamil as L2.

India is representative of a situation where Tamil is the main language spoken within a region, and hence learnt as a first language. Tamil is the language of the

majority in the region of Tamil Nadu, though not the language of the majority nationally. Singapore, on the other hand, is a typical example of Tamil co-existing with other languages within the same region of the country, and hence being learnt as a second language.

Tamil Nadu, India

Tamil is the main language as well as the main medium of instruction in the state of Tamil Nadu. Instruction in Tamil is quite common up to the higher secondary level of schooling, but not at the college level, especially in technical courses.

Tamil, as has been noted above, is a highly diglossic language that uses the high variety for all formal activities, including education. This leads to a situation where the language spoken at the student's home and acquired by the student is very different from the language taught in the classroom. In fact the divergence is so great in phonological, morphological, lexical, and syntactical respects that the child has to learn the higher variety as a new language. An additional factor that exacerbates this effect is that most of the material used to teach the language is not contemporary.

In recent times this phenomenon has been recognized, and a more child-centered approach has been introduced in schools run by the state government of Tamil Nadu. The activity-based learning approach has been implemented from 2007/8 at the primary level, and the government is planning to take it forward and implement it at the middle school level (grades 6–8). The change in approach shifts the focus from the teacher to the learner and from rote learning to learning with understanding.

Singapore

Singapore is a multiracial country where various languages are spoken, including Tamil. Singapore takes a bilingual approach, in which the common linking language—English—is L1 and the other mother tongues—Chinese, Malay, and Tamil—serve as L2. This has led to a situation where English has gained primacy over the other languages (Pakir, 1993). Saravanan (1994) suggests that the shift away from Tamil, in particular, was significant. In general, the use of Tamil seems to be on the decline (Department of Statistics, 1990); even people of Tamil origin are using English at home. Hence students who are mostly exposed to the higher variety of Tamil at school are left ill-equipped to communicate in Tamil effectively in everyday situations, where the low varieties, to which they have limited exposure, are used.

In a research report released by the Centre for Research in Pedagogy and Practice, Chitra Shegar and Ridzuan Bin Abdul Rahim make a number of valid observations on the pedagogical issues related to Tamil in Singapore (Shegar & Rahim, 2005). Some of these issues are discussed below.

The social context in which Tamil is declining in importance does not provide sufficient motivation for students to take up study of the language. The only reason for studying the language that is apparent to students is that this is a part of their curriculum. Since English is regarded as the more important language,

there is rampant code switching both within and outside the classrooms. Teachers compound this issue by restricting their teaching goals to the curriculum and the classroom context. As a result, Tamil is treated as a subject and not learnt as a means of communication, and there is an over-reliance on textbooks and worksheets, which are used instead of material relevant to the context of the students. Rather than developing and enhancing their linguistic as well as higher order thinking skills, students learn the language by rote and do not see any use for it beyond clearing the examinations.

Assessment of Tamil: Current Practices in Tamil Nadu and Singapore

In Tamil Nadu, assessment in Tamil usually happens within the classroom at most levels. Common exams are conducted by the Department of Education at two levels: grade 10 (Secondary School Leaving Certificate) and grade 12. However, these are high stakes assessments that determine the students' eligibility to pursue higher studies and do not provide diagnostic information on the learning of Tamil at the student, school, or system level. The grade 10 State Board Exam has two papers in Tamil: (1) paper 1 is mostly based on the literature in the textbooks and has a few questions on grammar and vocabulary; (2) paper 2 is mostly based on grammar and includes a few questions that assess writing skills and comprehension of an unseen text. Both papers comprise mostly free response items, along with a few multiple choice items. The items, as well as the evaluation rubrics, are not built with a clear intention to identify patterns and common errors in student responses. The evaluation rubric usually assigns marks for each item on the basis of an expected correct answer and ignores all the answers that are not correct. The diagnostic information on what students know and are able to do is usually lost in these assessments.

There have been few attempts to conduct large-scale, low stakes assessments to benchmark learning levels and to diagnose teaching-learning issues at the system level. One significant attempt was the Student Learning Study (SLS) conducted by Educational Initiatives in 2008–9 (Educational Initiatives Private Ltd., 2009) across 19 states of India. This study assessed representative samples of students in each state, including Tamil Nadu, for grades 4, 6 and 8. It assessed students on the complete range of grade-appropriate skills that comprise language and mathematics, through the main medium of instruction of the state. The study in general found that students did well in mechanical or procedural questions but poorly in questions requiring higher order skills.

Another assessment that tries to provide diagnostic information at the systemic level is the Annual Status of Education Report, which is conducted across various states annually by the education advocacy group Pratham (Pratham, 2010) and focuses on basic skills in math and language such as arithmetic and decoding, respectively.

The scenario in Singapore was not very different and revolved around conventional high stakes assessments. However, there is a recent inclination toward alternative assessment methods that do away with the practice of "teaching to the

test” and focus on teacher-designed classroom assignments that require students to demonstrate authentic intellectual capacities (Koh & Luke, 2009).

Challenges in the Assessment of Tamil

This section focuses on the issues encountered in assessing Tamil in Tamil Nadu, India, but most of them are relevant in other Tamil-speaking contexts as well.

Diglossia

Tamil being a diglossic language results in its students learning the high variety in school as though it were a second language. Also, high stakes assessments provide very little scope for assessing students on their competency in the spoken language or the low varieties.

Let us look at two sample test items that demonstrate the issues due to diglossia with respect to (1) grammar (mostly morphology) and vocabulary; and (2) appropriateness of the language to be used. (Both items were used to assess class 4 students on Tamil, as part of a research study conducted by Educational Initiatives Private Ltd. in Tamil Nadu for the organization AID India.)

Sample item 1

Passage excerpt in English: One day the King became upset with Tenali Raman and angrily ordered him to go out of his country.

Passage excerpt in Tamil: *ஒரு நாள் தெனாலிராமனால் அமைதியை இழந்த அரசர்கோபத்துடன் அவரை நாட்டைவிட்டு வெளியேறும்படி உத்தரவிட்டார்.*

Transliteration: *oru nall tenali ramanal amaidiyai izhandha arasar, kobatthudan avarai nattai vittu veyliyerumaaru uttaravittar.*

Question: Who ordered Tenali Raman out of the country?

The students are expected to answer “the king” (*arasar*). However, the word that is commonly used at home and outside the print environment to refer to a “king” is *raja*—and not *arasar*, which is used in the given excerpt. While a child reading or listening to this passage may understand what the word “king” stands for, he/she may not necessarily know that the word *arasar* in the passage refers to a king. A child exposed to the term *arasar* at an earlier stage may possibly require a mental translation into the more familiar synonym *raja* in order to be able to answer the question. To account for these diglossic issues, the answer key provided for the question should accept both the high and the low variety of the word for the king, as the item only assesses students’ comprehension of explicitly stated information.

Sample item 2

Passage excerpt in English: . . . Balu came to Kashiram and asked him, “Master, did you drink your tea?” . . .

Passage excerpt in Tamil: . . . பாலு காசிராமிடம் வந்து, “முதலாளி, நீங்கள் தேநீர் பருகினீர்களா?” என்று கேட்டான்.

Transliteration: . . . *Balu Kashiramidam vandhu, “Mudhalali, neengal theyneer parugineergalaa?” yendru kettaan.*

The sequence *theyneer parugineergalaa?* (“did you drink your tea?”) in the given excerpt belongs to the high variety and is not used in everyday conversations. The low variety equivalent for *theyneer* is the English word tea and for *parugineergalaa* it is *kudhicheengala*, and students would be familiar with the question *tea kudhicheengala?* of the lower variety. However, the textbooks, and hence the assessments, too, use the high variety, which normally comes across as an alien language to the child, thereby interfering with his/her comprehension of the information.

In a diglossic situation, literacy usually consists in the acquisition of the higher variety. However, the diglossic issues mentioned above need to be accounted for when creating assessment tools, especially for the lower grades (up to grade 4)—that is, until students gain enough exposure to the higher variety to cease to perceive it as an alien language. More classroom tests and oral assessments should be encouraged, as they allow for a greater degree of freedom in accepting lower varieties when assessing a child’s language ability. Written assessments should include detailed rubrics that accept lower varieties in the lower grades and recognize them in the higher grades. Such rubrics would provide diagnostic information to the teachers, who would thus be in a better position to facilitate acquisition. Periodic low stakes assessments that test the students’ language skills through unseen texts, doing away with rote learning and guides, will also help them meet this objective.

Dialectic Issues

Tamil, as has been noted, shows wide variation in the form of dialects; this situation is determined by various geographical and social factors. While developing assessments, it is crucial to account for student responses that may be correct in a different dialect. For example, consider the item below.

Complete the sentence below correctly and meaningfully:

Aarthis mother and her uncle went to visit their mother, Seema. Seema is Aarthis _____.

Here, the word tested is “grandmother.” The scoring rubric for this particular question should accept all the well-known words for “grandmother” in the different Tamil dialects—such as *patti*, *aachi*, *periatha*—to ensure the item’s validity across the different dialects.

Anglicization

Most Indian languages tend to borrow words from English, mostly to denote newer concepts in the fields of science and technology (see Table 118.2). But

Table 118.2 Example of English words used in the low variety and their equivalents in the high variety

<i>English word</i>	<i>Tamil high variety (Transliteration)</i>	<i>Tamil low variety (Transliteration)</i>
Road	சாலை (<i>salai</i>)	ரோடு (road)
Telephone	தொலைப்பேசி (<i>tholaipesti</i>)	போன் (phone)
Television	தொலைக்காட்சி (<i>tholaiatchi</i>)	டி .வி (TV) / டி .வி பெட்டி (TV Potti)
Teacher	ஆசிரியர் (<i>aasiriyar</i>)	டீச்சர் (teacher)

Tamil is unusual in that the native speakers try to create new words as a need arises. More often than not, students are taught these new words in schools, as the high variety; but their English equivalents are used in the lower varieties outside school. This usage of English words is more common in urban than in rural areas.

When vocabulary is assessed, the higher variety words are tested as usual, but it is often difficult to account for the frequency of occurrence of the newly coined Tamil words. One way to look at it is to say that the assessment is checking for the students' extent of vocabulary; therefore it is sufficient if the word is present in the student's vocabulary in either the high variety or the low variety form.

Disproportionate Attention to Literary Appreciation and Insufficient Attention to Contemporary Use of Language

The importance of assessing students' comprehension of historically important texts cannot be overstated. However, this leads to a situation where functional aspects or uses of the language are not assessed adequately. For instance, the students' comprehension and interpretation of authentic materials such as notices, posters, advertisements, and the like is rarely considered worthy of assessment and the examples provided in Figure 118.1 hardly find place in formal assessments.

Lack of Periodic, Low Stakes Diagnostic Assessments

Like most Indian languages, Tamil suffers from the lack of periodic, large-scale, low stakes diagnostic assessments to give educators insights into the acquisition and learning of Tamil. Such assessments would enable educators to devise ways in which the present challenges in teaching, learning, and assessing Tamil can be overcome.

Multilingual Testing: Difference in Language Families

Tamil is a Dravidian language, whereas most of the languages spoken in India belong to the Indo-European family. This leads to various challenges when children across the country are assessed on their linguistic skills, particularly to

The item in English:

<ul style="list-style-type: none">• Ingredients: mango slices, red chillies, garlic, edible oil, mustard, asofoetida, fenugreek, turmeric powder, green chillies, tamarind, salt and oil.• Use a dry spoon• Please keep in a cool and dry place.• Net weight 150 g.• Max Retail price: Rs 19.00		<ul style="list-style-type: none">• Date of packing Aug 2008• Date of Expiry: Aug 2009 <p>Manufactured by Star Trading Regd. Office, Shivaji Nagar Bangalore</p>
--	---	--

Q1. Which of these is not used to make the pickle?

- A. salt
- B. sugar
- C. oil
- D. chilly

Q2. The cost of the pickle is rupees _____.

The item in Tamil:

<p>கலவைப் பொருட்கள்: மாங்காய் துண்டுகள், சிவப்பு மிளகாய், பூண்டு, சமையல் எண்ணெய், கடுகு, பெருங்காயம், வெந்தயம், மஞ்சள் தூள், பச்சை மிளகாய், புளி, உப்பு, எண்ணெய்.</p> <ul style="list-style-type: none">• உலர்ந்த கரண்டியைப் பயன்படுத்தவும்• குளிர்ச்சியான, ஈரப்பதமில்லாத இடத்தில் வைக்கவும்.		<ul style="list-style-type: none">• நிகர எடை 150 கிராம்• அதிகபட்ச சில்லறை விலை ரூ.19.00 <p>தயாரிப்புத் தேதி ஆகஸ்ட் 2008 முடிவுக்காலம் ஆகஸ்ட் 2009</p> <p>தயாரிப்பு: ஸ்டார் டிரேடிங் பதிவு செய்யப்பட்ட அலுவலகம்,</p>

Q1. இவற்றுள் ஊறுகாய் தயாரிக்கப் பயன்படுத்தப்படாத பொருள் எது?

- அ. உப்பு
- ஆ. சர்க்கரை
- இ. எண்ணெய்
- ஈ. மிளகாய்

Q2. ஊறுகாயின் விலை _____ ரூபாய்கள்.

Figure 118.1 Example of a graphical text used for assessing class 6 students on Tamil in the Student Learning Study conducted by Educational Initiatives Pvt. Ltd. © Educational Initiatives Pvt. Ltd., India. Reprinted with permission

Table 118.3 Example of an item used to test vocabulary across multiple languages

	<i>English</i>	<i>Hindi</i>	<i>Tamil</i>
Answer	mango	<aam>	<maampazham>
Word length	5 letters	2 letters	3 letters
Level of difficulty	Medium	Easy (one syllable, one diacritic, no consonant clusters)	Medium (three syllables, two diacritics, one consonant cluster)

benchmark learning levels nationally. The different characteristics of a Dravidian family need to be kept in mind while adapting the common tests to Tamil, especially for the lower grades. For example, the scripts of most Indo-European languages contain letters of three levels of difficulty: simple letters, letters with diacritics, and conjoined letters. Therefore, when children of lower grades are tested on their knowledge of letters or reading skills, it is difficult to assume the same degree of difficulty for the same items in different languages. For example, see the question for grade 2 below:

Question description: Write the name of the fruit in the picture:

Future Directions

The diglossic nature of Tamil, the several dialects, and the widespread usage of English vocabulary in urban and semiurban regions need to be taken into account while developing assessments in Tamil. In addition, initiatives must be taken to conduct periodic, low stakes, large-scale diagnostic assessments to monitor the teaching and learning of Tamil, which will in turn lead to newer arenas of improvement.

The author would like to acknowledge Mr. Ashtamurthy Killimangalam, Ms. Sailaja N. Ravi, and Ms. Neethu S. Kumar for their contributions to this chapter.

Assessing Telugu

K. V. V. L. Narasimha Rao

Central Institute of Indian Languages, India

Introduction

Telugu, a major South Dravidian language, is spoken mainly in the state of Andhra Pradesh in India, where it is the local language of education, administration, and mass communication. According to the census of India (Office of the Registrar General, 2001), Andhra Pradesh had a population of 74,002,856 in 2001—a figure that is likely to have increased to about 100,000,000 by 2012. There are substantial pockets of Telugu speakers in Karnataka, Tamil Nadu, Maharashtra, Odisha, and several other states, besides metropolitan cities like Delhi, Mumbai, Kolkata, Chennai, and Bangalore. Telugu speakers are also found in various countries all over the globe, such as the USA, the UK, Australia, Mauritius, South Africa, Fiji, Canada, and Malaysia.

According to Krishnamurti (1978), the history of the Telugu language can be divided into four stages: (a) 2000 BC to AD 500, (b) AD 500 to 1100, (c) 1100 to 1400, and (d) 1400 to 1900. During the first stage, only place-names and names of persons are found, in Prakrit and Sanskrit inscriptions. During the second stage, the literary language was developed by poets and important literary figures, while the spoken language evolved alongside. During the third stage, the literary language became standardized, while the spoken language continued to undergo several phonetic and grammatical changes, resulting in Modern Telugu. The spoken language was primarily used in poetry, inscriptions, folk literature, and common speech until the mid-19th century, after which prose style started to be developed. After 1940, the spoken form became popular due to the emergence of mass media and took the shape of Modern Telugu. Telugu has also become the language of textbooks and school education. It became the official language in 1966 and has been the language of education at higher levels since 1969. Telugu was declared a classical language in 2004.

The Telugu Script

The Telugu script is said to have emerged from the Brahmi script. The script of Modern Telugu is a syllabic script, and consists of 14 vowel symbols and 35 consonant symbols. Each vowel and each consonant has a secondary symbol associated with it, which is used in combination with the consonants in the course of writing. Such combinations are of two types: (a) geminates (consonants + corresponding secondary symbols) and (b) clusters (consonants + secondary symbols of other consonants or vowels). Telugu is written from left to right and top to bottom. All the letter formations are round in shape and each one can be inscribed in a circle.

The Structure of the Telugu Language

Phonology

Modern Telugu has 14 vowel and 35 consonant sounds. Consonants occur at the following places of articulation: bilabial, labiodental, dental, palatal, retroflex, alveolar, and velar. There is a four-way distinction among stops: They may be voiced, assimilated, breathy voiced, or voiceless. Telugu exhibits vowel harmony, which is discussed in the section on morphology.

Morphology

Telugu has an agglutinative morphological structure. Umamaheswararao maintains that the morphology of Telugu is agglutinating, which means that words are built from component morphemes that retain their form and meaning in the process of combining (cited in Venkataramana Rao, 2011). Suffixes are frequently attached to a form of the noun which is called the “oblique stem.” Telugu is both single and poly-agglutinative. Examples relating to inflection, location, motion, and relation are plenty in Telugu, besides morphosyntactic alignment. Examples include:

రాముడు + తో <i>/ra:muDu + to:/</i>	రాముడితో <i>/ra:muDito:/</i>
Rama + connotative case marker	‘along with Rama’
రాముడు + ని <i>/ra:muDu + ni/</i>	రాముడిని <i>/ra:muDini/</i>
Rama + accusative case marker	‘Rama (him)’

Telugu consists of several borrowings from Sanskrit and a small number of borrowings from Persio-Arabic sources, as well as a host of native vocabulary. Vowel harmony is Telugu’s unique feature. This is a type of assimilation which takes place when vowels come to share certain features with contrastive vowels elsewhere in a word or phrase. Subbarao (1971) states that addition of the imperative suffix */-u/*, the absolute suffix */-i/*, and the negative suffix */-aka/* triggers full assimilation and provides the following examples:

చదువు + ఇ /tsadu ^v u + i/ read + absolute suffix	చదివి /tsadivi/ 'having read'
చదువు + ఆక /tsadu ^v u + aka/ read + neg. past participle	చదవక /tsadavaka/ 'not having read'
పిల్లి + లు /pilli + lu/ cat + plural marker	పిల్లలు /pillulu/ 'cats'
ఊరు + కి /u:ru + ki/ town or village + dative suffix	ఊరికి /u:riki/ 'to the town or village'

Telugu has a number of different types of compounds called *samasams* in traditional grammar. Compounds are classified according to (a) word origins and (b) word meanings. Based on word meanings, compounds are classified as *sanskritika* (combination of Sanskrit words), *aacchika* (combination of pure native Telugu words), or *misrama* (combination of Sanskrit and Telugu words). Based on meaning, compounds are further divided into exophoric (*tatpuru^{sha}*) and endophoric (*bahuvrihi*) compounds.

Cases in Telugu

The seven important cases in Telugu are as follows, listed by case marker: (a) accusative: ను /nu/, ని /ni/; (b) connotative: తో /to:/; (c) dative: కు /ku/, కి /ki/; (d) purposive: కొరకు /koraku/, కై /kai/, కోసం /ko:sam/; (e) locative: లో /lo:/, లోపల /lo:pala/, పైన /paina/, మీద /mi:da/, కింద /kinda/; (f) ablative: నుంచి /nunci/, నించి /ninci/; and (g) comparative: కంటే /kanTe/, కన్న /kanna/.

Syntax

The sentence structure is of subject–object–verb (SOV) type. The unique feature of Telugu is that it has a typical sentence type called equational sentences. Such sentences *do not* contain any verb/copula. For example:

అది పుస్తకం /adi pustakam/ that book	'That is a book.'
వాడు రాముడు /wa:Du ra:muDu/ he Rama	'He is Rama.'
నా పేరు గోవిందు /na: pe:ru go:vindu/ my name Govind	'My name is Govind.'

The other sentence types in Telugu include minor sentences (interjectives and vocatives), simple sentences (noun phrase, nominal, and numeral predication), subordinate sentences (indirect sentences, coordinative clauses, conjunctive clauses, relative clauses, participial constructions), coordinative sentences (compound sentences), exclamatory sentences, verificative sentences (tag question sentences or interrogative sentences), and negative sentences.

The use of the reduced relative clause instead of the full length relative clause is another unique feature of several Dravidian languages including Telugu. For example:

నేను ఏ పుస్తకం చదివానో, ఆ పుస్తకం /ne:nu e: pustakam cadiwaeno:, a: pustakam/
I which book read that book

is condensed and reduced as

నేను చదివిన పుస్తకం /ne:nu cadiwina pustakam/

meaning 'the book I read'.

Telugu Dialects and Registers

There are two types of dialect in Telugu: (a) region-based and (b) caste-based. Syntactically there is no difference, but there exists a marked difference in terms of vocabulary in at least two ways: (a) different vocabulary items with the same meaning and (b) same vocabulary item with different meanings. There are four regional dialects of Telugu: (a) eastern (Kalinga), (b) southern (Rayalaseema), (c) northern (Telangana), and (d) central (other coastal). A few examples illustrative of this regional difference are as follows:

<i>Kalinga</i>	<i>Rayalaseema</i>	<i>Telangana</i>	<i>Coastal</i>	<i>Meaning in English</i>
పూజు/పూడు /pu:ju/pu:Du/	కాడిమాను /ka:Di:ma:nu/	కాండి / కాణి /ka:nDi/ka:Ni/	కాడి /ka:Di/	yoke
పేడ /pe:Da/	పేడ /pe:Da/	పెండ /peNDa/	పేడ /pe:Da/	cow dung
ఆనపకాయ /a:napaka:ya/	సొరకాయ /soraka:ya/	ఆనింగెకాయ /a:ningeka:ya/	సొరకాయ /soraka:ya/	bottle gourd

Below are some examples of the second type of expression—those with different meanings in different regions:

<i>Rayalaseema</i>	<i>Coastal</i>
గమ్మునుండు /gammununDu/ (keep silent)	నేరు మూసుకో /no:ru mu:suko:/ (shut up)
ఎత్తి పెట్టు /etti peTTu/ (pick it up and keep)	కొని పెట్టు /koni peTTu/ (buy and keep it for me)

Register

Register refers to the kind of language used in different areas of communication, such as the language of law, science, technology, and so on. In Telugu, for instance, passive constructions are mostly used in texts dealing with science and technology, and specific vocabulary items like */mudda:yi/* (person complained against) and */tsaTTam/* (law) are unique to law.

Teaching and Assessing Telugu in Andhra Pradesh

Telugu is taught as a subject and used as a medium of instruction up to high school level, with the exception of a few English-medium schools, where Telugu is taught only as a subject. It remains both a subject and a medium of instruction at collegiate (+2 level) and other higher levels of education in Telugu-medium institutions, and an optional subject in English-medium institutions. Telugu is taught as a second language in Andhra Pradesh from primary to collegiate (+2) level for those whose mother tongue is not Telugu.

The teaching of Telugu as a subject up to high school in Telugu-medium schools and English-medium schools is compulsory in Andhra Pradesh and, to obtain a pass in the school examination, students are required to score a minimum of 35% marks. The examination contains two exams, of about three hours each; the question types are mostly open ended, consisting of paragraph and essay questions. Questions are primarily focused on content and grammar, not on skills. At collegiate level, those who opt for Telugu as a second language are required to secure minimum marks of 35% in the two exams and, again, teaching and assessment are focused on content and grammar. The same situation continues until graduate (bachelor's) level. At postgraduate level, specialization in Telugu takes place and there are eight exams: one on the history of the language, one on the history of the literature, and the rest pertaining to different kinds of literature (e.g., old poetry, prose, drama, novel, etc.). Assessment pertaining to these is mostly subjective, although the oral examination is objective to some extent.

Normally, exams are conducted three times a year—quarterly, half-yearly and annually. However, the scores obtained in the annual examination alone are considered for assessment and evaluation. At bachelor's level, Telugu is taught both as a language (optional) and as a specialization (compulsory) for those who opt for it. Teaching methodology and evaluation are different in both cases. Taken as an option, the course is less intensive; the compulsory course contains much more literature and history of language and literature. At master's level, more emphasis is given to literature, history of Telugu language and literature, and literary criticism, as well as to specialization (on a chosen poet, period, etc.).

Subjects other than Telugu do not exist at master's level or above. As far as optional Telugu is concerned, all students majoring in different disciplines take the same exams. As a result of research around the objectives of language teaching, there has been a trend to change the system of teaching and assessment. This change is toward emphasizing language skills and communicative skills in

teaching, and assessment procedures have therefore also started to undergo changes, such as the introduction of tasks like comprehension, summary writing, critical appreciation, and so on, mostly through objective type questions. These include multiple choice questions, yes/no or true/false questions, fill-in-the-blanks, matching type, short answer questions, transformation of sentences (affirmative to negative, interrogative, etc.), one word answer questions, cloze test (n-th word deletion and random deletion depending on the level of attachment), and so forth. The level of difficulty depends on the level of instruction. Such changes are applied to language teaching and evaluation in all major languages up to high school level. Below are some examples of objective test items (selected from some question papers):

Multiple Choice

“మూడు పువ్వులూ—ఆరు కాయలు” అంటే /mu:Du puvvulu—a:ru ka:yalu’ ante/
(three flowers—six raw fruits means?)

- (i) అభివృద్ధికరం /abhi-vruddhikaram/ (prosperous)
- (ii) గందరగోళం /gandarago:Lam/ (disturbance)
- (iii) అయోమయం /ayomayam/ (confusion)
- (iv) అసందర్భం /asandarbhham/ (out of context)

The correct answer is (i) above.

This type of item tests knowledge of idioms, phrases, and their meanings.

Rearrangement of words

Rearrange the words below to make a grammatically accurate sentence:

పుస్తకం	మంచి	కొన్నాను	నేను	బజారులో
/pustakam/	/manici/	/konna:nu/	/ne:nu/	/baza:rulo:/
book	good	bought	I	in the market

The correct response is: నేను బజారులో మంచి పుస్తకం కొన్నాను /ne:nu baza:rlo: manici pustakam konna:anu/.

This type of item tests knowledge of linguistic structures.

Fill-in-the-blanks

Fill in the blanks with appropriate words:

రాముడు రోజూ కాఫీ /ra:muDu ro:ju: ka:fi: / (drinks)
Rama every day coffee

The correct word that fits into the blanks is: తాగుతాడు /ta:guta:Du/ (drinks).

This type of item tests knowledge of vocabulary and morphological structure of the language.

The Government of India through its National Curriculum Framework (NCF) (National Council of Educational Research and Training, 2005) recommended certain guidelines. In accordance with this policy, it was recommended that reasoning and creative abilities replace memorization as the basis for both teaching and assessment. It was further recommended that the examinations be integrated with classroom performance so as to ensure a highly reliable overall assessment.

Consequent to the recommendations made in the NCF, the state governments have embarked on the task of preparing language-teaching materials (textbooks) in line with the suggested reforms, and most of the states, including Andhra Pradesh, are actively engaged in introducing new teaching material focused on the objectives at school level.

It is mandatory for all state governments to implement these recommendations in language-teaching materials/textbooks and, consequently, in the process of evaluation. Several state governments have been in the process of implementing them while revising the textbooks and examination patterns. The study skills that are recommended for inclusion along with the language skills—both basic (listening, speaking, reading, and writing, referred to as LSRW) and advanced (representation, argumentation, refutation, and establishment of one's own point of view, referred to as RARE)—and the corresponding tools for assessment are as follows:

1. listening and reading comprehension—multiple choice, short answer questions, and epitomization;
2. listening, reading, and note taking—fill-in-the-blanks, synonyms and antonyms, word association;
3. comprehension and composition—unfamiliar and familiar texts (presented orally for listening and on the printed page for writing), followed by a set of objective questions given in such a way that the answers put together in the same order become a gist/summary of the original text;
4. guided composition—(a) cues consisting of systematically and logically arranged content words which, when assembled in sentences, become a grammatically accurate, coherent, and cogent text; and (b) cue words given in a disorderly manner, requiring learners to arrange sentences sequentially, as well as make a grammatically accurate, coherent, and cogent text;
5. free composition—(a) familiar topics and (b) unfamiliar topics (imagination and creative abilities expected of learners in suitably developing coherent and cogent discourses while maintaining grammatical accuracy);
6. critical analysis and synthesis (primarily written mode at secondary level)—expressing possible interpretations with suitable and appropriate reasoning for and against the ideas contained in the given text and arriving at appropriate conclusions;
7. creative expression (spoken and written)—development of coherent and cogent paragraphs/short discourses ensuring grammatical accuracy;
8. mixed skills—classroom observation (checklists and observation schedules), overall performance (learners' profiles, anecdotal records, etc.), group or project work, identification of figures of speech and prosodic features, and so on.

While first language instructional material could consist of aspects of literature and topics/themes from as many disciplines/subjects as possible and feasible, in the case of second language material, it is recommended that the topics and themes of lessons be in conceptual prose and selected from a variety of disciplines, such as art, science, social science, history, geography, civics, engineering,

medicine, and so on, in order to enable language learners to understand language use in different fields of knowledge as well as understand the content. Drills and exercises are more important in L2 instruction than in L1 instruction. Instructions for carrying out the drills and exercises must be in Telugu, and they must be brief, precise, clear, and unambiguous. Further, each type of exercise should be provided with an example.

Telugu Teaching and Assessment in the USA

Telugu is currently taught in five or six universities in the USA as a third language under the foreign language requirement for postgraduate students. It is taught at basic, intermediate, and advanced levels. The basic level teaches the script and some elements of Telugu language, as well as simple texts; the intermediate level goes on to introduce simple pieces of literature, and the advanced level deals with a little more of modern literature, along with texts from different disciplines. The instructional material is prepared by the relevant faculty without any prescribed textbook. Assessment is mostly objective, and a few open-ended questions like paragraph questions, comprehension, and summary writing are adopted. Grades are assigned to students in lieu of marks. Evaluation is primarily focused on spoken skills at the basic level; written skills are included to a certain extent at intermediate level, and they are assessed in the same way as spoken skills at advanced level.

Challenges

A lot needs to be done to improve the teaching and assessment of Telugu within and outside Andhra Pradesh. A few recommendations proposed by expert committees are as follows: preparation of new instructional material for teaching Telugu as a first, second, and third language at different levels; preparation of separate question banks at different levels for first, second, and third language teaching situations; development of standardized tests, including diagnostic, achievement, and proficiency tests at different levels and development of a battery of tests; revisiting the existing teaching and assessment procedures and devising improvised methods, materials, and media for language instruction; active use of anecdotal records, checklists, questionnaires, and rating scales; interviews of learners; use of individual portfolios during continuous/ongoing evaluation throughout the learning program to ensure more valid and reliable assessment; and inclusion of translation as one of the strategies to assess learners' abilities.

Assessing Bahasa Melayu and Bahasa Indonesia

May Tan

McGill University, Canada

Introduction

Bahasa Melayu (BM) is the sole national language of Indonesia, Malaysia, and Brunei. It is one of the four national languages of the island state of Singapore, along with Mandarin, English, and Tamil. It is also present in the southernmost provinces of Thailand, adjacent to Malaysia, although it has no official status there.

This language is the medium of instruction for all public schools in Indonesia (Departemen Pendidikan Nasional Republik Indonesia [MONE = Indonesian Ministry of Education], 2006) and Malaysia (Malaysian Ministry of Education [MMOE], 2010). All students in these educational systems are required to take the language as a core subject of the curriculum in primary and secondary school. Students are assessed on BM in school exams and also, at specific levels, in nationwide standardized exams. At higher levels of schooling, students are required to pass a standardized exam in order to obtain school-leaving certification. In Brunei, BM is the medium of instruction for students up to the third year of elementary schooling. English is added as an additional medium of instruction from year four onwards. BM is also taken as a mother tongue or second language subject by students in Singapore (Singapore Ministry of Education, 2011). However, this chapter will focus specifically on the assessment of BM in the educational systems of Malaysia and Indonesia. For these two countries, BM is the first language of the majority of the population. It is also the official first language and the principal language of instruction from elementary to secondary levels of schooling. In total, Malaysia and Indonesia account for approximately 265 million BM speakers in the world.

In both countries, BM is primarily assessed during elementary and secondary school levels within the educational system. By the end of secondary schooling, students are expected to have acquired all the linguistic skills necessary for them

to function in formal and informal social and professional contexts. They are required to take the national language as a mandatory subject until the end of secondary five (which is equivalent to grade 11). The assessment closely follows curriculum guidelines for the learning of BM in Malaysia and BI in Indonesia (on which see further down). This being the case, the language curriculum prescribed by the Ministry of Education (respectively, MMOE in Malaysia and MONE in Indonesia) in each country will be described here first, and the ways used to assess students in the language in Malaysia and Indonesia will be presented afterwards.

This chapter concentrates on the assessment of BM through high stakes exams for certification purposes. In the heavily exam-oriented Malaysian and Indonesian systems, for each level, these assessments usually happen at the end of students' schooling. The assessments usually take the form of standardized exams prepared by a national examination board. They are administered nationwide to all eligible students at the same time.

Before describing the exams, some linguistic descriptions of the language itself are in order, since these are elements that students are taught in the curriculum. These same linguistic elements are the features also assessed in the high stakes exams.

Description of BM

Origins and History

Bahasa Melayu belongs to the Austronesian family of languages. Other languages in this family are the aboriginal languages of Taiwan and the indigenous languages spoken in the Philippines, Borneo, and the Polynesian islands (Bellwood, 1997).

Historically, this language was widely used as a lingua franca among Chinese, Indian, Persian, and Arab merchants when they were trading with the local population in the Southeast Asian region (Liang, 1994). This started when Indo-Malayan empires such as Melayu and Srivijaya (7th–13th century AD) began expanding their trade and political control in Southeast Asia, and it was especially true of the period of the Malacca sultanate (15th–16th century). At the height of the Malaccan empire Malay literature flourished at court. Malay also spread and became the language of courts and literature in other, nontraditionally Malay-speaking areas such as Aceh, Makassar, and Mindanao in the southern Philippines (Sneddon, 2003). This literate and prestigious form of Malay, which later came to be known as classical Malay or classical Riau Malay, would serve as the basis for the development of the language into its standardized modern form.

In Indonesia, standard Malay is called Bahasa Indonesia (language of Indonesia). This is usually abbreviated to BI. In Malaysia, it has been called both Bahasa Malaysia (language of Malaysia) and Bahasa Melayu (language of the Malays). Both these names are often referred to by the same acronym, BM. In Brunei and Singapore, the language is called Bahasa Melayu. At present there are many oral variants of Bahasa Melayu in the areas in which it is used. In Indonesia, for example, Minangkabau is one of these variants, while in Malaysia, there is *loghat Kelantan* or *loghat Kedah* (Kelantanese or Kedahan dialect). However, these forms

are usually employed in the home environment or in informal contexts. Only the standardized version of the language is used in official oral and print communications by the Indonesian, Malaysian, Bruneian, and Singaporean governments. It is also standard BM that is taught and assessed in schools. Students are penalized if they employ dialectal or colloquial forms in their oral or written productions during assessment.

Differences Between Standard BM and Standard BI

As Sneddon (2003) has observed, the differences between the standard forms of Malay used in Indonesia, in Malaysia, in Singapore, and in Brunei are slight. These differences are due to the fact that the Malay empire was divided between two colonizing nations, the Dutch and the English.

The most apparent variation is in the domain of vocabulary. In many cases, BM adopted a word from English where BI borrowed one from Dutch.

BM	BI
Mac (from English <i>March</i>)	Maret (from Dutch <i>Maart</i>)
universiti (from English <i>university</i>)	universitas (from Dutch <i>universiteit</i>)

In the past, before efforts at standardization were made by Malay-speaking countries, BM and BI differed in spelling along similar lines. In Malaysia, BM conformed to English-influenced spelling conventions while in Indonesia BI followed the Dutch spelling system. Recent electronic and print publications use a more streamlined spelling system for both BM and BI.

Moreover, the linguistic diversity of local populations also contributes to this situation. In Malaysia, BM contains loanwords from the local Chinese and Indian linguistic communities, while in Indonesia words from Javanese and Jakarta Malay have been adopted into standard BI. However, since standard Malay is actually based on the literary traditions of classical Riau Malay, these standard varieties are still mutually intelligible despite their minor differences. The governments of these countries, in fact, actively encourage cooperation among their language agencies to harmonize the use of standard BM.

Standard Compared to Dialectal Varieties

The standard variety of any language is usually associated with uniformity in pronunciation and in its written form and function. In addition, the standard variety also carries with it a certain prestige, due to its association with access to social, economic, and intellectual resources (Haji Omar, 1971). For BM, the standard variety, which is used in official and academic contexts, is called *bahasa baku*. It is sometimes known as *bahasa halus* ("fine language") because of its refinement and sophistication, while the colloquial variety is called *bahasa kasar* ("rough language").

There are also dialectal varieties, which may differ from the standard variety in vocabulary, syntax, and grammar. In vocabulary, for example, the verb *habak* is used instead of *kata* ("to say") in the Kedah dialect in Malaysia. In Indonesia,

although BI is the main official language, many Indonesians in fact come from ethnic groups such as Javanese, Sundanese, or Betawi, and these groups use languages that have some kind of Malayic or proto-Malayic affiliation. However, they can be quite different from the standardized form of Malay which is BI. The example below illustrates such differences:

BI: *Saya suka sekali tulisan itu.*

I like really writing that.

Betawi: *Ane resep dah ma tulisan tu.*

I like really writing that.

Sundanese: *Urang mah resep pisan kana tulisan eta te.*

I really like [verb intensifier] [dative marker] writing that [object referent].

English: "I really like that writing."

As can be seen from these sentences, even though the syntactic structure of subject–verb–object remains the same and the word *tulisan* is retained in all three versions, the other vocabulary and grammatical markers are dissimilar to such an extent that any of these sentences could be incomprehensible to speakers of the other two dialects or languages.

Syntax

The syntax of BM/BI follows the subject–verb–object (SVO) word order, particularly in standard Malay. Informal and dialectal varieties may, however, show some variation, elision of the subject being quite acceptable in spoken, informal situations or in colloquial Malay. The following example illustrates this difference:

Standard BM: *Kamu pergi ke mana?*

You going to where?

Dialect: [] *Pi mana?*

[elided subject] Going where?

English: "Where are you going?"

Spelling and Pronunciation

BM is usually written in Roman script, although Arabic script, called Jawi, has also been used in the past and continues to be used by a small part of the population in Malaysia. Spelling is very regular in BM, all letters in a word being pronounced. Consonants and vowels are consistently pronounced in the same manner. The consonant *k*, for example, represents the same sound, whether it is in word-initial, middle, or end position. Thus the words *kawan* /**k**awan/, *tekan* /t**k**an/, and *habuk* /hab**u**k/ are all pronounced with a hard *k* sound. The same goes for vowels: the *a* in *kapan* /k**a**pan/, *singkat* /s**i**ngkat/, and *kepada* /k**e**pada/ are all pronounced as the open *a* in *bahasa baku* (standard BM).

Plural Formation

Plurals in BM are usually formed through a process of repetition of the singular form. For example:

BM: *buku / buku-buku*
 English: *a book / some books*

However, the repetition is not always an exact replication of the singular form. For example:

BM: *kuih / kuih-muih*
 English: *a cake / some cakes*

Tense and Verb Aspect

In terms of verb tense, temporal markers are often time adverbials (that is, temporal adverbs) such as *semalam* (“yesterday”) or *tahun depan* (“next year”). Tense is not marked on the verb itself, as happens in languages such as English. Here is an example:

Present
 BM: *Mereka pergi ke pasar malam setiap minggu.*
 English: “They **go** to the night market every week.”

Past
 BM: *Minggu yang lalu, mereka pergi ke pasar malam.*
 English: “Last week they **went** to the night market.”

In the example above, while the English verb changes from “go” (present) to “went” (past), the equivalent verb in BM is invariable, the only indicator of time being the adverbial time clause *Minggu yang lalu*.

Similarly, the verbal aspect is not indicated through changes in the verb form in BM. It is indicated instead by specific words or particles, as in Mandarin. An example is given below:

BM: *Halim sedang makan bersama kawan-kawannya.*
 Halim [continuous action] eat with friends [possessive particle].
 English: “Halim is eating with his friends.”

In this case, the word *sedang* is used to indicate that the action is continuing.

Verbs: Agency/Voice Markers

In BM, agency or voice is rendered through the addition of prefixes or suffixes to verbal stems. Prefixes and suffixes can indicate intentionality or nonintentionality, passive or active voice. Basic prefixes include *me-*, *ter-*, *di-*, *ber-*; and suffixes

include *-kan* and *-i*. For example, in the following sentence, the prefix *me-* shows that the verb is in the active voice. The action is planned or intended:

BM: *Saleha memilih sepasang kasut yang berwarna biru.*
 Saleha chose a pair [of] shoes that [are] of the color blue.
 English: "Saleha chose a pair of blue shoes."

In the next sentence the prefix *ter-* indicates that the action is accidental, while still in active voice:

BM: *Kakinya tersepak batu semasa bermain bola sepak.*
 Foot [possessive particle] [accidentally] kicked a rock while playing soccer.
 English: "He (accidentally) kicked a rock while playing soccer."

These prefixes and suffixes can also take compound, complex forms (i.e., more than one prefix or suffix can be used to form a verb). For example, for the verb *kembang* ("develop," "bloom"), compound prefixes (*mem + per*) are added along with the suffix *-kan* to form *memperkembangkan*.

Rules for prefixing and suffixing are in fact quite difficult to learn, even for native speakers of BM. This could be due to the fact that colloquial or informal speech often drops these prefixes and suffixes, employing the more basic verbal forms.

This section has presented some of the more salient linguistic features of BM. Although standard BM and dialectal varieties have been discussed here, the only acceptable forms of vocabulary, spelling, syntax, and grammar used in formal assessments of the language are those of standard BM. Knowledge and application of the syntactic and grammatical features described above are obligatory in the assessments of BM in Malaysia and BI in Indonesia.

The next section focuses on the assessment of BM in Malaysia. It first provides a historical overview of how BM came to be adopted as the official language of instruction, then it goes on to describe the curriculum and the high stakes assessment of BM at the exit levels of elementary and secondary schooling.

Nation Building and Standard Bahasa Melayu in Malaysia

In Malaysia, the adoption of Malay as the national language was based on the need to forge a nation from the ethnically and linguistically diverse population that resulted from large-scale immigration under British colonial rule. Under the colonial system, each of the major ethnic groups—Malay, Chinese, and Indian—conducted education using its own language, which resulted in a fragmented, unequal education system. In contrast, the leaders who guided the country towards its independence believed that the educational system needed to work toward creating a sense of nationhood in youth from different cultural and linguistic backgrounds (Puteh, 2006). The Education Review Committee of 1956, which produced the 1956 Razak Report, recommended a school system

that, while supporting many languages, would have one main language, thereby promoting unity among the various ethnic groups (Pandian, 2003). The language chosen for this function was Bahasa Melayu, the language of the Malays, the main ethnic group in the country. The language was eventually named Bahasa Malaysia (language of Malaysia) so that it would no longer be associated exclusively with one group but would come to be perceived as the language of the nation. The use of BM as the language of government, official media broadcasts, and education was enshrined in Article 152 of the constitution of Malaysia.

Within the educational system, the use of BM as the sole language of instruction in all subjects (except English), at all levels, in all national public elementary and secondary schools was implemented for thirty years; by 1970 all elementary schools were using BM as the medium of instruction, and by 1982 all secondary schools were doing the same. This state of things has only recently undergone a modification, with the 2003 directive of the Ministry of Education that mathematics and science subjects be taught in English from 2004 on. However, BM remains a mandatory subject that all students must take and pass during national standardized exams. These high stakes assessments have exit and gatekeeping functions in terms of determining who can access subsequent levels of higher education.

Sekolah Rendah (Elementary Level): The Ujian Pencapaian Sekolah Rendah (UPSR—Primary School Achievement Test)

In Malaysia students complete six years of elementary schooling in order to advance to the secondary level. During elementary schooling, all students in national schools must study five basic subjects: BM, English, morals, science, and mathematics. The last two subjects are currently taught in English. Students in national-type schools, where one other vernacular language such as Tamil or Mandarin is taught, take six or seven subjects.

The BM curriculum documents for the elementary school standard curriculum (Malaysian Ministry of Education, 2010) state that the content and learning standards are based on the students' mastery of essential language skills and of the language system. The four language skills that the students are expected to develop are listening, speaking, reading, and writing. Students are also expected to develop an appreciation for the aesthetic value of language in its various artistic forms—poems, proverbs, similes, and so on. Students must acquire a sound grounding in the syntax, morphology, grammar, spelling, vocabulary, and punctuation of the language as well. At this stage, the goal is to give students a broad general base in terms of the phonetic system, rules of spelling and writing, and basic sociolinguistic knowledge concerning different forms of oral and written discourse and their appropriate use.

All students take their exit exams at the end of their sixth year of schooling. This exit exam, called Ujian Pencapaian Sekolah Rendah (UPSR; Primary School Achievement Test), comprises five mandatory subjects for national schools and six for national-type schools. BM is one of these compulsory subjects. Passing or failing all these subjects does not truly have a great impact on the academic path

of students in terms of their continuing to secondary school, because they are automatically promoted (Ong, 2011). However, these results are used as a selection or gatekeeping mechanism for entry to key schools, premium schools, or boarding schools. In this sense, obtaining good grades in the UPSR does have an impact on students' academic future and the UPSR itself can be a high stakes exam, since doing well can mean access to better educational opportunities at the secondary level.

The UPSR BM exam is divided into two papers that students have to sit for. Paper 1 consists of 40 multiple choice questions. Students have 50 minutes to complete the exam. The first 30 questions test students' knowledge of vocabulary, grammatical aspects such as suffixes and plural construction, and also their knowledge of correct syntax. An example of a question on the use of suffixes, taken from a trial exam from the Perak State Education Ministry (Jabatan Pelajaran Perak, 2009), a northern Malaysian state, is provided here:

6. Semua murid perlu _____ budaya lepak dan merosakkan harta awam. "All students need to _____ the culture of idleness and vandalism."

A menjauh (*keeping away*)

B menjauhi (*stay away from*)

C berjauhan (*be at a distance*)

D menjauhkan (*keep away*)

Kunci: B

Answer key: B

The last 10 questions relate to comprehension of various passages. These can be in the form of prose or poetry. All answers are assessed as correct or incorrect on the basis of the official answer key provided.

The UPSR Paper 2 is divided into three parts. Students are given an hour and 15 minutes to do the exam. In the first part (part A: 10 points), they are required to transfer information from visual prompts such as charts, graphs, schedules, and so forth into words (five complete sentences). The second part of the exam (part B: 30 points) asks students to write a short story based on a textual prompt. Three topic choices are given, and students must write an essay of a minimum of 80 words about one of them. The final section (part C: 20 points) asks students to provide a commentary based on a text they are given to read. This commentary must be at least 50 words in length.

For part A, students are evaluated on three criteria: the accuracy or appropriateness of the content; the quality and variety of the vocabulary and sentence structures used; and spelling and punctuation. In evaluating part B, another set of three criteria are followed: the quality of delivery (how engaging it is) and the coherence of the ideas presented; the appropriateness of the vocabulary and sentence structures used; and, as in part A, spelling and punctuation. And finally, there are three new criteria for evaluating part C: the clarity and accuracy of the commentary; the appropriateness of vocabulary and sentence structures in relation to the source text; and, again, spelling and punctuation.

Secondary Level: The Sijil Pelajaran Menengah (SPM: Secondary Education Certificate)

Malaysian students complete five years of secondary schooling before going on to college or pre-university education. At the end of their fifth year, students are required to sit for a secondary school exit exam, called the Sijil Pelajaran Menengah (SPM: Secondary Education Certificate). At this level the stakes are higher, because results from the SPM are used to obtain entry into specific college and pre-university programs. A passing grade in BM (and higher) is an entrance requirement for all programs at public universities. However, this condition may be relaxed at private institutions.

At the secondary level the curriculum is more demanding and expectations are higher. The curriculum aims to ensure that students have the linguistic and communicative skills needed to function in education, at work, and in daily social interactions. The students are still developing their listening, speaking, reading, and writing skills, but they do so at a more advanced level. Moreover, their knowledge of the syntactic, morphological, and grammatical elements becomes more specialized. By the end of secondary five, when the SPM is administered, students should be able to parse sentences and to recognize and correct errors in language usage. Components of literary study and analysis of both modern and classical Malay works also become part of the upper secondary curriculum. In addition, students are expected to develop the ability to be critical when engaging with audio, visual, and print media.

During the SPM students must sit for two BM exam papers: paper 1 and paper 2. They are also allowed to write their responses in standard Roman script, or they may choose to respond using the Arabic script of Jawi. Paper 1 has a time limit of two hours and 15 minutes. It is divided into two parts: part A and part B.

In part A (30 points) students are presented with a visual prompt such as a cartoon or photographs, and a textual prompt on a social issue; and they are required to write a text of about 200 to 250 words in response to the prompts. For example, in the trial exam of Perlis state, sponsored by the Council of Secondary School Principals, Perlis (Persidangan Kebangsaan Pengetua-Pengetua Sekolah Menengah, Cawangan Negeri Perlis, 2009), the candidates are given a cartoon where students in uniform are eating at a food stall when they clearly should be in school. This is remarked upon by the stall owner. The candidates are then asked to write about ways to overcome absenteeism among students. The text is scored on the basis of the relevance of the content in relation to the prompts provided; the clarity and maturity of the explanation or discussion; the correct use of grammatical and syntactic elements; and the use of varied and engaging language.

In part B (100 points) students are given a choice among five topics, which can range from social issues to traditional proverbs. They must write an opinion or an expository text of at least 350 words. The texts are assessed according to several criteria. The first of these is how well the content fits the demands of the question; the clarity of the discussion and the suitability of examples are important elements here. The second criterion is the quality of the language, which ideally should be flowing, display a wide range of sentence structures, and demonstrate accurate

use of vocabulary. Finally the presentation and format of the text are taken into account, along with punctuation and spelling.

In addition, students are also expected to demonstrate oral proficiency in the language. Oral examinations used to be administered by external examiners trained by the examinations board. However, these examinations have been school-based since 2003. Currently students are expected to complete the oral examination in three stages, two during secondary four and one in secondary five. For these exams they can choose the topic and the task they would like to perform—from a list of 24 tasks ranging from interviews to speeches. The assessments can be conducted using various formats. The student may choose, for example, to have another student as a speaking partner or to perform the task alone. The teacher may also play an active role in the oral exam or simply be the audience.

The next section describes the way BM is assessed in Indonesia. While the Indonesian system has many similarities with the Malaysian system, it also has its own particularities. The section begins by explaining the adoption of BI as the national language and as the language of instruction in Indonesia; then it describes the curriculum and how BI is assessed at the end of elementary six and secondary three (grades 6 and 9 respectively). The assessment conducted at these two key points in the students' educational career impacts their ability to continue their academic development or to gain access to quality education.

Indonesia: Sumpah Pemuda, Decolonization and National Unity

The idea of one common language for all Indonesians was first proposed by young nationalists eager for independence from their Dutch colonizers. The Sumpah Pemuda (Youth's Declaration) was made in Jakarta, 1928, during a congress of nationalist youth organizations. The declaration expresses the unity of the Indonesian nation: with one homeland, one nation, and one language (Foulcher, 2000). Part of the 1928 declaration is given below, followed by its translation:

*Kami poetera dan poeteri Indonesia mengakoe bertoempah-darah jang satoe, tanah Indonesia.
Kami poetera dan poeteri Indonesia mengakoe berbangsa jang satoe, bangsa Indonesia.
Kami poetera dan poeteri Indonesia mendjoendjoeng bahasa persatoean, bahasa Indonesia.*

We sons and daughters of Indonesia declare that we have one birthplace, the land of Indonesia.

We sons and daughters of Indonesia declare that we are one nation, the Indonesian nation.

We sons and daughters of Indonesia uphold (revere) the language of unity, the Indonesian language. (Foulcher, 2000. p. 380)

This declaration planted the seed of the idea of nationhood in the diverse groups that populated the many islands forming Indonesia and that had different local languages, cultures, and traditions; it drew together a population which at that time still regarded itself in regional terms. Just as in Malaysia, here too the

adoption of Bahasa Indonesia as the national language had the objective of creating a stronger sense of national identity among its citizens. This concept is also expressed in the Indonesian national motto, *Bhineka Tunggal Ika* (“Unity in diversity”).

Sekolah Dasar (Elementary School): Ujian Nasional Sekolah Dasar (UNSD: Elementary School National Exams)

In Indonesia as in Malaysia, students are expected to complete six years of elementary schooling. Again as in Malaysia, BI, as the national language, is a mandatory part of the school curriculum, along with six other subjects. However, students are only required to sit for three mandatory subjects at the elementary level UNSD: BI, mathematics, and geography. The Sekolah Dasar (SD; elementary school) curriculum for BI specifies the learning of the four language skills: listening, speaking, reading, and writing. Competency standards for all subjects are issued by the Departemen Pendidikan Nasional (2005). Learning outcomes are stated for every skill at the SD level:

1. listening: students must be able to understand commands, explanations, advice, announcements, news, descriptions of events and things, as well as literary works for children such as fairy tales, poems, stories, drama, *pantun* (a traditional Malay poem arranged in quatrains) and folk tales;
2. speaking: students must be able to express their thoughts and feelings and to give information in various conversational situations such as introductions, greetings, interviews, phone calls, speeches, and so forth. They should also be able to give directions, tell stories, and report on their observations and reading of various literary forms;
3. reading: students must be able to read and understand various texts such as instructions, lengthy texts, and works of children’s literature;
4. writing: students must be able to express thoughts, feelings, and information in writing. This can take various forms such as essays, instructions, letters, announcements, dialogues, reports, summaries, and literary forms suitable for children.

At the end of the sixth year of elementary schooling, students are eligible to sit for the Ujian Nasional (national exam). This nationwide exam is prepared by the Pusat Penilaian Pendidikan (PPP; educational evaluation center) and is based on the competence standards issued by the MONE. It accounts for 60% of students’ grades; the remaining 40% are obtained through school-based assessment. The Badan Standar Nasional Pendidikan (BSNP; national evaluation board) furnishes 25% of the exam content; the remaining 75% is provided by provincial examination boards. Students’ results on this exam determine which secondary school they will be admitted into (Departemen Pendidikan Nasional, 2011).

This exam takes 120 minutes and is made up of 50 questions. It is not divided into any sections. All questions are multiple choice, each with four answer options. The exam tests students’ comprehension of texts of various genres and their ability to extract the main idea. There can be more than one question per text for this

type of item. The following question is an example of what students could be asked on the exam:

Pulang dari lomba bulu tangkis, *hati Arman berbunga-bunga*. Ia tak menyangka berhasil **menaklukkan** Rizal sang juara bulu tangkis tahun lalu. Setiba di rumah, Arman segera mengabarkan kabar gembira tersebut. Ibu bangga dengan keberhasilannya Arman. Ibu berpesan kepada Arman supaya jangan sombong atas keberhasilannya.

*Returning from the badminton competition, Arman's heart leapt with joy. He didn't think he would succeed in **conquering** Rizal, the reigning champion from last year. As soon as he arrived home, Arman immediately announced the good news. Mother was proud of his achievement. [But] Mother advised Arman not to be arrogant because of his success.*

Arti kata **menaklukkan** pada paragraf di atas adalah . . .

The meaning of *conquering* in the paragraph above is . . .

- A. meremehkan
complicating
- B. mengalahkan
defeating
- C. mengecewakan
disappointing
- D. mempermainkan
tricking

Kunci: B

Answer key: B

Students can also be asked to complete texts or poems, to choose the correct caption or title for a text, to rearrange instructions according to a logical order, or to rearrange visual elements into a coherent story. They are also tested on the correct use of various linguistic elements such as vocabulary, conjunctions, prefixes, and suffixes. An example of one such task is provided below:

Rosa anak yang rajin.

Rosa is a hardworking child.

Rosa anak yang pintar.

Rosa is an intelligent child.

Penggabungan dua kalimat di atas yang benar adalah . . .

The right way of connecting the two sentences above is . . .

- A. Rosa anak yang rajin tetapi pintar
Rosa is a hardworking but intelligent child
- B. Rosa anak yang rajin sedangkan pintar
Rosa is a hardworking while intelligent child

- C. Rosa anak yang rajin padahal pintar
Rosa is a hardworking child, even though [she is] intelligent
- D. Rosa anak yang rajin dan pintar
Rosa is a hardworking and intelligent child

Kunci: D
Answer key: D

Sekolah Menengah Pertengahan (Lower Secondary Level): Ujian Nasional Sekolah Menengah Pertengahan

At the secondary level school-based exams are still administered, but these are not taken into account for admission purposes. In the description of the secondary curriculum and assessment provided here, the level selected is the Sekolah Menengah Pertengahan (SMP or lower secondary level), because this is a high stakes exam. The results determine admission into state upper secondary schools, which means access to better teachers and resources for those students who succeed. This increases their chances of gaining admission into prestigious universities later on, because of the better academic preparation and higher standards in these schools. In contrast, the results of the upper secondary level ministerial exam are not used by Indonesian universities, which prefer to use their own entrance exams, although this exam certifies completion of secondary school.

The secondary school BI curriculum is similar to the one for the elementary school in that it, too, focuses on the four skills. Of course, the competence demands for each of these skills are at a more advanced level. In terms of listening, students are expected to understand content presented in oral formats such as speeches, lectures, interactive dialogues, interviews, discussions, TV/radio news presentations, and other kinds of reports. They must also understand oral forms of poetry, drama, youth novels, folktales, and the like. In the area of speaking, students need to be able to express their thoughts, experiences, opinions, and comments and to present information in formats such as oral reports, storytelling, interviews, discussions, seminars, debates, and public speaking. In the reading component, they are expected to be able to understand the content of texts such as poems, short stories, drama, youth novels and novels of other kinds. In terms of writing, they have to be able present their thoughts and information in various written genres such as journals, personal letters, short notes, instructions, slogans, posters, and advertisements, as well as in poems, folktales, dramas, and short stories.

For the assessment of BI at SMP level, the exam is based on the lower secondary curriculum; and it is prepared by the PPP as well. It is made up of 60 multiple choice questions. Students are given two hours to complete the exam. What is tested is their ability to understand texts, tables, and visuals; proper use of terminology; use of affixes; correct sentence structure and paragraphing; use of similes and idioms; use of formal and informal letters; use of literary elements; and literary appreciation. An example of the kind of multiple choice question used is given below:

6. Untuk meningkatkan prestasi belajar, alangkah baiknya jika mulai sekarang kita membentuk kelompok belajar.

"To raise academic performance, what a good thing it would be if we start forming study groups right now."

Tanggapan yang tepat terhadap pernyataan tersebut adalah . . .

"The right conclusion to be drawn from this statement is . . ."

a. Belajar kelompok dapat meningkatkan prestasi belajar.

"Studying in groups can increase academic performance."

b. Meningkatkan belajar sungguh baik sekali.

"Increasing our studies is a really good thing."

c. Dengan membentuk kelompok belajar dapat meningkatkan prestasi.

"By forming study groups, performance can be increased."

d. Belajar dapat meningkatkan prestasi belajar, sebaiknya dengan kerja kelompok.

"Studying can raise academic performance, the best being through group work."

Kunci: A

Answer key: A

There is no direct writing component for the BI national exams. This is probably because several million students sit for these national exams every year. The logistics and costs involved in assessing student writing could be prohibitive in relation to the resources available in the Indonesian education system.

BM in Other Contexts

Apart from Malaysia, Indonesia, Brunei, and Singapore, there are continuous efforts to promote the use of BM in the Southeast Asian and Asia-Pacific regions and elsewhere in the world as well. Indeed BM is taught in some colleges or institutions of higher learning outside Malaysia, Indonesia, Brunei, and Singapore. For example, a centre for the study of BM has existed in Leiden since 1876. The Malaysian government established a Chair for Malay Studies in the University of Leiden in 1992, another in the University of Wellington New Zealand in 1995. There are also programs available in some universities of countries such as the US, Russia, and China. However, students who take such programs constitute a small number of learners. Sneddon (2003) pointed out that BI was a popular foreign language in Australia and remains an important language other than English in that educational system. However, the economic crisis of the 1990s and violence in parts of the country such as Timor Leste have negatively affected interest in learning BI.

In contexts where it is not one of the languages spoken by a majority local community, BM is taught and evaluated as a foreign language. In this case, the learners may be expected to learn the grammatical rules or syntactic structures governing BM, but they may not be expected to have as high a level of functionality or

sociolinguistic competence in the language as students in Indonesia or Malaysia. Assessments used for these students are usually developed locally, on the basis of the course syllabi used.

Challenges for the Growth and Assessment of BM

One of the main challenges for the continued growth, use, and assessment of BM is the pressure exerted by the rapid pace of globalization. This process favors the expanding role of English both as the language of science and technology and as the major global lingua franca. The continuous production of new knowledge and vocabulary in English means that BM language experts need to keep abreast of these developments. There is an ongoing need to increase the number of specialized terms related to multiple domains and to control their integration into standard usage, and there is also a need to translate the latest scientific or technological works into BM. These efforts require a great deal of resources and have led to increasing cooperation and measures of standardization among the various bodies that safeguard and promote the use of BM in Malaysia, Indonesia, Brunei, and Singapore. Such developments do have an impact on the assessment of the language, because examinations need to be updated to reflect changes in vocabulary—that is, the current usage of terms.

Concerning standard BM, there is an organization in charge of promoting the national language in Malaysia, Indonesia, and Brunei. In Malaysia this body is called Dewan Bahasa dan Pustaka Malaysia (DBP); in Indonesia it is called Badan Pengembangan dan Pembinaan Bahasa (BPPB), while in Brunei it is also called Dewan Bahasa dan Pustaka. These organizations are the equivalent of what the Académie Française is for French: they oversee the correct spelling and use of the language, especially in official domains, and they are usually the authority on vocabulary. They also decide what new words or terms are accepted, and they may coin new terms to meet the demands of the changing contexts of language use.

Through the publication of dictionaries, terminology lists, and suchlike, these organizations have made many efforts to regulate the use of terminology in specific fields across the countries, as well as to modernize current vocabulary, spelling, and pronunciation. In order to coordinate these endeavors, a language council was created by the three countries, with Singapore as an observer: Majlis Bahasa Brunei Darussalam–Indonesia–Malaysia (MABBIM). MABBIM has several specific goals, such as to promote the role of the national language as a wider medium of communication, to build and develop BM so that it is on par with other modern languages, and to standardize the use of language in creative and knowledge domains through guidelines and instructions (MABBIM, 2012).

In assessment, the usage specified by DBP in Malaysia and by BPPB in Indonesia is the standard. In Malaysia, the DBP Malay dictionary (*Kamus Dewan Bahasa dan Pustaka*) is *the* standard reference work for verifying the spelling, meaning, or usage of a word. Its Indonesian equivalent (*Kamus Besar Bahasa Indonesia*), published by BPPB, serves the same function. In order to promote the language, BPPB has also made this dictionary available online via the Ministry of Education

Web site. Students may be penalized for using slang or nonstandard terms in their oral or written exams.

Conclusion

This chapter has presented how the social and demographic changes, brought about as a result of colonization in the Malay-speaking regions of Southeast Asia, have led to the adoption of classical Riau Malay as the basis for developing a standard BM. The association of this classical form with the refinement, prestige, and power of former Malay empires explains why classical Riau Malay came to be considered a necessary tool in the process of unifying the various communities that lived in these postcolonial countries.

The adoption of this “high” variety of the language as the standard and the sole national language in Malaysia, Indonesia, and Brunei (and as one of the national languages in Singapore) resulted in the need to teach, and consequently to assess, standard BM in the newly created national school systems. The most widespread forms of assessment for BM are therefore based on school curricula and ministry of education standards in each of these countries. In Malaysia and Indonesia especially, doing well in these ministry BM exams can have an important impact on the educational and life prospects of the students.

Acknowledgments

Many thanks to Dr. Didin Syafruddin, lecturer at the Faculty of Education Syarif Hidayatullah State Islamic University, Jakarta for being my resource person for Sundanese and Betawi and for several aspects related to the assessment of Bahasa Indonesia and the Indonesian educational system.

Assessing Cantonese

Wing Sat Chan

Hong Kong Polytechnic University, Hong Kong

Introduction

Cantonese is the most widely spoken dialect among the southern Chinese dialect families of Yuè over wide areas of Guangdong and Guangxi provinces (Bauer, 1988). Within this vast area, Hong Kong represents one way Cantonese is used in society and in the education system. This situation is due to three sociocultural reasons:

1. At the beginning of the 20th century, the early government of the People's Republic of China launched a movement to promote Modern Standard Chinese (MSC) and Putonghua (PTH) for official and educational uses on a national basis. Under this movement, Cantonese in all cities of southern China became a regional dialect confined to nongovernmental contact, a people-to-people exchange of daily communication. Since then, Cantonese has not played a role in education in mainland China. In contrast, Hong Kong, as a British colony, was free from the PTH standardization of the mainland and, as a result, Cantonese is used in various social sectors including education.
2. About 98% of the Hong Kong population are ethnic Chinese, of whom more than 90% are Cantonese native speakers. When Hong Kong was a British colony, English was the only official language for communication in higher levels of government, courts of law, commerce, and education.
3. In the early 1970s, there was an anti-English movement which led to two important results: (a) the Chinese language became one of the official languages from 1974; (b) in addition to English, Cantonese was officially permitted to be used as the medium of instruction for primary, secondary, and tertiary education. Since then, Cantonese has gained its L1 position for formal education in Hong Kong, which helped it to develop into a predominately Cantonese-speaking community.

Description

Cantonese is a tone language in which the pitch or pitch pattern contributes to the meaning of the word or syllable (Matthews & Yip, 1994, p. 13). According to the Yale system (the romanization system for representing Cantonese in alphabetic form), there are 16 initial consonants that may occur at the beginning of a Cantonese word (Matthews & Yip, 1994, p. 13) (Table 121.1).

There are two “semivowels” which occur as initials: “y” as in *yàhn* (person), and “w” as in *wái* (place, position) (Matthews and Yip, 1994, p. 15). There are also eight vowels, see Table 121.2.

The tonal system of Cantonese has traditionally been identified as having nine distinct tones. However, if you leave aside syllables with final unreleased consonants such as *p*, *t*, *k*, there are only six tones that are clearly distinctive in Hong Kong Cantonese. For example, the different tones of the syllable *yau* refer to different characters with different meanings (Table 121.3) (Cheung, 1986; Matthews & Yip, 1994, pp. 20–1).

Table 121.1 Initial consonants of Cantonese

	<i>Unaspirated</i>	<i>Aspirated</i>	<i>Fricative</i>	<i>Nasal/liquid</i>
Bilabial	b	p	f	m
Dental/alveolar	d	t	s	n/l
Velar/glottal	g	k	h	ng
Labiovelar	gw	kw	-	-
Affricates	j	ch	-	-

Table 121.2 Vowels of Cantonese

	<i>Front</i>	<i>Central</i>	<i>Back</i>
High	i	yu	u
Mid	e	eu	o
Low	-	a, aa	-

Table 121.3 The tonal system of Cantonese

<i>Tone</i>	<i>Voice pitch*</i>	<i>Syllable</i>	<i>Character</i>	<i>Meaning</i>
High level	55/35	<i>yāu</i>	休/憂	“rest”; “worry” (in compounds)
High rising	35	<i>yǎu</i>	髹	“paint” (noun)
Mid level	33	<i>yau</i>	幼	“thin”
Low falling	21	<i>yàuh</i>	油/游	“oil”; “swim” (verb)
Low rising	23	<i>yáuh</i>	有/友	“have”; “friend”
Low level	22	<i>yauh</i>	又/右	“again”; “right” (hand)

*The numbers refer to the variations in voice pitch at which a syllable is pronounced as a word distinguishable from another.

Like other languages, Cantonese has homophones: words which have the same tone have multiple meanings. These homophones can be distinguished by the context in which they appear (Matthews & Yip, 1994, pp. 20–1).

Intonation

The intonation of Cantonese cannot be described at the level of sentence intonation pattern, but can be observed from the variation of the tone of a word or syllable in an utterance (Matthews & Yip, 1994). As a tonal language, a word in Cantonese has its own tone value and pitch that distinguishes it from other words in meaning and grammatical function. When a word is uttered with other words in a phrase or utterance, the word may be lengthened or undergo pitch change in contrast to the word uttered before or after it. Such variations result in patterns of intonation in Cantonese in two ways (Chang, 2003). First, change of syllable length is one of the aspects in intonation. For example, when two adjacent syllables are in pairs such as *hów hów* “very good”, the first syllable may become longer and the second one shorter “_____” in order to emphasize how good it is (Chang, 2003, p. 74). Vice versa, as observed by Matthews and Yip (1994, p. 27), in an adverb phrase *sī-sī-màhn-màhn* “gentlemanly” (the hyphen “-” links the elements within the phrase), the first two syllables both have high tones but the second *sī* may tend to drop off (shortened, in Chang’s terms) during the vowel in anticipation of the low falling tone of *màhn* immediately following it.

Second, declination is another phenomenon in Cantonese intonation, which refers to the fundamental frequency having a tendency to decline gradually during the course of utterance (Ladd, 1984, p. 53). For example, in *wù sēng jēun jòng* “mutual respect”, the first syllable and the fourth are both low falling tones (LF), but the fourth is lower than the first; both the second and third ones are high level (HL), but the first is higher than the third. The pattern is something like:

—		—
<i>sēng</i> (1st HL)		<i>jēun</i> (2nd HL)
—		—
<i>wù</i> (1st LF)		<i>jòng</i> (2nd LF)

In this phrase, the pitch value of the second HL tone is lower than that of the first HL, and the same occurs among the two LF tones (Chang, 2003, p. 85).

Tone Change

The phenomenon of tone change in Cantonese can be categorized into regular changes, which are rule governed, and irregular changes, which are not predictable (Hashimoto, 1972; Wong, 1993). An example of regular change is using alternative ways of saying the same thing: *hàng 21 jat hàng 21* “to take a walk” can be expressed as *hǎng 35 hàng 21* with the same meaning (Wong, 1993, p. 17).

An example of irregular change is as follows: the tone *nìn 21* “year” may remain the same in *kām 55 nìn 21* “this year” or change into the phrase *kām 55 nìn 35*, also

“this year”. However, it is pronounced with the rising tone (35) only in the phrase *kau 22 n̄n 35* “last year” (Wong, 1993, p. 44).

The Grammar

As a tone language with little grammatical morphology, the grammatical relations, such as subject and verb, subject and object, of Chinese are mainly presented through word order. The basic word order of Chinese languages is subject (S), verb (V), object (O), and this SVO order is common to almost all dialects of China including Cantonese (Norman, 1988, p. 11). However, what identifies Cantonese grammar in its own right are four features which deviate from the basic SVO order.

1. Subject–object–verb (SOV) order usually appears in simple sentences. For example:

Ngóh	daaih bá	yéh	jouh
I	many	things	to do
S (I)		O (things)	V (to do)

“I have many things to do.”

2. Verb–subject inversion occurs in the use of intransitive verbs (Matthews & Yip, 1993, p. 69), for example:

Sihk	lěih	mh	séi
Eat	you	not	dead
V (intransitive)	S		

“Your eating does not harm you.”

3. “Right dislocation” occurs in colloquial speech where the subject of a clause is placed at the end of an utterance. For example (Matthews & Yip, 1993, p. 71):

Hǒu	lěk	wo	lěih!
very	smart	PRT (particle)	you
			S (subject)

“You’re so smart!”

4. “Topicalization” has been identified as a central feature in the status of subject and topics in Chinese grammar (Chao, 1968; Li & Thompson, 1981). It refers to the placement of a word or a phrase at the beginning of a sentence or utterance, making it the sentence topic, or the first thing to be conveyed of a message, for example (Matthews & Yip, 1993, p. 73):

Nī	dī	yěh	mǒuh	yànn	sīk	ge
This	CL	stuff	no	person	know	PRT (topicalization)

“No one knows this stuff.”

Teaching, Learning, and Assessment

Three types of Cantonese tests on articulation and pronunciation, oral ability, and vocabulary are described below. The relationship between Cantonese and Modern Standard Chinese, and how Cantonese is learned in Hong Kong, is as follows.

Two major varieties of Cantonese exist in Hong Kong. One is the standardized Cantonese termed as “high” Cantonese, and the other is the colloquial variety, “low” Cantonese. The high variety in both spoken and written forms is similar to Modern Standard Chinese (MSC). Most of the grammatical features of the “high” variety are incorporated into Modern Standard Chinese (MSC), with deviations in vocabulary, and in some sentence structure such as comparative expression, and the position of adverb in the sentence. The “low” variety is colloquial Cantonese for casual conversation in daily life, among family members and friends. Expressions of this variety are generally not included in dictionaries, and it is considered as vulgar and of low educational value.

The following taxonomy can be seen as a summary of Cantonese varieties in terms of their applications:

1. written Modern Standard Chinese (MSC), that is, Pǎi-huà
2. spoken Modern Standard Chinese, that is, Putonghua
3. “high” written Cantonese for official, editorial, and legal functions, which is incorporated in written MSC (Shi, 2000)
4. “low” written Cantonese for entertainment, leisure, and general communications which is mingled with vernacular Cantonese
5. “high” spoken Cantonese which is close to (3)
6. “low” spoken Cantonese which is close to (4) (Chan, 1995; Sun, 2002).

Both “low” and “high” Cantonese are acquired in Hong Kong from kindergarten to graduate studies.

Assessing Cantonese Articulation and Pronunciation

There are two assessments that focus on the accuracy of articulation and pronunciation of Cantonese: the Hong Kong Cantonese Articulation Test (HKCAT, 香港粵語發音測試) and the “Reading aloud of written text” in the Chinese section of the Hong Kong Diploma of Secondary Education (HKDSE) (Hong Kong Examination and Assessment Authority, 2011).

The former is a standardized assessment aiming to provide a linguistic description of the development process in mastering Cantonese articulation. The test has 41 words as test items which cover all phonemes in Cantonese. Each item is matched with a picture to guide test takers to pronounce the target words or characters. About 80% of these items ask test takers to pronounce only one target word or character, for example, Item 1, “車” /tse1/, the rest will ask test takers to pronounce two semantically related words or characters, for example, Item 41: “5” /mh5/, “唔” /mh4/. When test takers say a word or character, their pronunciation will then be analyzed and marked in terms of initial consonant, vowel, diphthong, final consonant, and tone, in a format as in Table 121.4.

Table 121.4 Test item and its analytical components

Item	Pinyin	Initial consonant	Vowel/ diphthong	Final consonant	Tone	
1	車	tse1	ts ✓	e ✓	–	1 ✓

Each “✓” indicates that the articulation is correct; incorrect articulations are recorded for analysis. This test has been used by qualified speech therapists in diagnosing articulation problems of Hong Kong Cantonese speakers, ranging from children two and a half years of age to adults, by referring to developmental norms.

“Reading aloud of written text” in the Hong Kong Diploma of Secondary Education (HKDSE) (Hong Kong Examination and Assessment Authority, 2011) is a graduation examination that is taken by secondary school leavers in Hong Kong. It requires test takers to read aloud in Cantonese a written modern Chinese text of 150–70 characters. They are then assessed in terms of: (a) pronunciation: correct pronunciation of each character, for example, in the text for reading aloud, the character 贅 /ju3/ of the word 累贅 /lu3ju3/ may be mispronounced as 累 “然 /yin1”; (b) tone of a character: correct tone of a character which is easily mixed up with another, for example, the character 聊 /liu1/ of the word 聊賴 may be wrongly pronounced as 了 /liu2/; (c) reading speed: normal speed of reading fluency, evenness, and pausing based on punctuation marks; (d) intonation: six pieces of texts of different contents; the intonation while reading aloud should reflect the mood of the content in each text.

Assessing Cantonese Vocabulary

The Hong Kong Cantonese Receptive Vocabulary Test (CRVT; Cheung, Lee, & Lee, 1997) aims to understand how far 2–6-year-old Hong Kong children can learn, and what problems they may have in acquiring Cantonese vocabulary for both colloquial expressions (e.g., 喊 /ham3/ “cry”) and literal uses (哭泣 /hok4 yap4/, also “cry”). The CRVT consists of 100 test items covering a variety of noun, verb, adjective, adverb, and classifier from easy to difficult. The test uses multiple choice questions as its response format and each item has four options, with distractors in the categories of phonological and semantic relatedness. In Table 121.5, four words are provided as possible options in response to a stimulus picture: (a) the target word, 飽 /pāou1/ “a bun”, (b) a phonological distractor 貓 /māou1/ “a cat”, (c) a semantic distractor 蛋糕 /dan4 gao1/ “a cake”, and (d) an unrelated word 筆 /bèp4/ “a pen”.

Table 121.5 Options in response to a stimulus

Picture sequence	Correct answer	Target word	Phonological distractor	Semantic distractor	Unrelated distractor
2	_____	飽	貓	蛋糕	筆

Assessing Oral Cantonese Ability

The Hong Kong Cantonese Oral Language Assessment Scale (HKCOLAS) (Child Assessment Service, Department of Health, HKSAR, 2006) evaluates the native oral Cantonese proficiency of Hong Kong children from kindergarten to Primary 6. It includes seven composite tests: Cantonese grammar, textual comprehension, word definition, lexical semantic relations, narrative skills, expressive nominal vocabulary, and nonword repetition, as follows:

1. Cantonese grammar: for example, test takers see three simple pictures, a walking girl, a boy sitting on a chair, and a boy playing football, and hear the sentence 小朋友踢波 in Cantonese; they have to match the picture with the utterance.
2. Textual comprehension: for example, test takers listen to two short stories of daily events in Cantonese. For each story, they are asked to answer six questions, covering literal questions assessing factual contents in the stories, inference questions about reasons or consequences of some actions in the stories, and questions about lexical meaning in the stories.
3. Word definition: for example, test takers are asked to give definitions of six nouns of common objects such as 蘋果 /pehng3 gwúo2/ 狗 /gwáu2/.
4. Lexical semantic relations: for example, test takers are asked to provide answers regarding lexical semantic relations such as synonym, antonym, polysemic word, superordinate, and hyponym: 琪琪很“懶惰”，相反冰冰很_____。 “Kei Kei is very lazy, on the contrary, Bing Bing is _____.” The expected answer is 勤力 /keng1 lèk4/ “diligent”.
5. Narrative skills: for example, test takers are given a series of pictures about a story, then they listen to a recorded story in the order of the pictures. Then, they are asked to review the pictures from beginning and retell the story as far as they can. The story has a macrostructure that includes setting, initiating events, response or goal, plan, attempt, consequence, and reaction. The test takers’ retelling will be analyzed and compared against this structure for assessment.
6. Expressive nominal vocabulary: for example, there are 100 nouns or noun phrases with pictures, equally divided into 10 groups for different age groups. Group 1 for 4 years 10 months to 5 years, Group 2 for those 5 to 5 years 3 months, and so on. Test takers are asked to name the object or person in the picture, moving from Group 1 to Group 10.
7. Nonword repetition: for example, test takers listen to the sounds of some words with no semantic relation. The number of words to be heard increases from 1 to 9, and the test takers are asked to repeat the sound of the word(s). For example, the first sound is one word /ten1/ (敦); the second two words, /kin1/ (堅), /set4/ (述); and the third three words, /ley5/ (理), /diŋ1/ (叮), /pai3/ (派), and so on. The reason for asking test takers to repeat nonwords is to assess how far test takers can apply the implicit knowledge of Cantonese phonological rules from their mental lexicon to remember a randomly given character or word.

The assessment describes students' Cantonese proficiency as well as their cognitive development. Another function of the tool is to identify students' diverse language difficulties such as articulation problems, inadequate vocabulary, grammatical errors, and communication difficulties for remedial treatment.

The types of tests above reflect the most widely used methods for assessing test takers' linguistic competence of Cantonese as a first language. Other Cantonese tests may vary in: (a) the use of technology, such as the Computerized Oral Proficiency Assessment (Cantonese) at the Chinese University of Hong Kong; (b) the use of modern standard Chinese, that is, high Cantonese for assessing speaking and listening, such as the Assessment of Cantonese in the Scottish Qualification Authority (SQA).

Challenges and Future Directions

There are two major challenges for Cantonese in the Hong Kong context: (a) the replacement of Cantonese by Putonghua after 1997, when the sovereignty of the colony was returned to China as a special administrative region of China, and (b) the influence of English on Cantonese in daily and professional communications.

There are two different views on the future of Cantonese: first, that it is "heading north" and flourishing (Zhan, 1993) as the use of Cantonese in the Chinese mainland is increasing due to increasing business activities between mainland provinces and Hong Kong. Second, Bauer (2000) predicts that the status of Cantonese as an official language, as medium of instruction for education, and as medium of communication in the commercial sector, will gradually be replaced by Putonghua, the national language of China. The key to where Cantonese will go lies mainly with the question of how Hong Kong's economy grows in future.

Scholars in Hong Kong realize the impact of English on Cantonese, and are reacting against its influence by working on the linguistic description of Cantonese, as in the standardization of the linguistic system of Cantonese grammar by Cheung (1972), a romanization scheme (Linguistic Society of Hong Kong symbols) for describing Cantonese phonology (Matthews & Yip, 1994), and a useful reference on the Cantonese characters by Cheung and Bauer (2002).

Assessing Japanese

Yoshinori Watanabe

Sophia University, Japan

Kaoru Koyanagi

Sophia University, Japan

Introduction

This chapter presents and discusses the issue of assessing Japanese. Focus is placed on Japanese as a foreign (JFL) or second language (JSL), but assessing first language (L1) Japanese will also be briefly addressed. The entire chapter is divided into four sections. First, the characteristics of Japanese language are briefly described with a focus on its unique features. Second, different types of learner needs are illustrated for the process of learning JSL or JFL, as they are related to the issue of developing an instrument for assessing Japanese. Third, amongst large-scale tests, four major tests and one framework for assessment will be presented with their purposes and uniquely distinguishing features. Fourth, prominent issues of assessing Japanese as an L1 will be presented and discussed with illustrations. In the final section, several problems with assessing Japanese in general and assessing JSL and JFL in particular will be presented and discussed in the hope that they will be solved in the future.

Description of Japanese

Japanese is spoken by more than 120 million people as a first language. Most of the speakers live on the four main islands of Japan. Contrary to the widespread claim that Japanese is unique, the language is a rather ordinary subject-object-verb (SOV) order human language (e.g., Shibatani, 1990). Its basic word order is verb-final, modifiers (e.g., adjectives and clausal modifiers) precede modified expressions, and particles are post-positioned to the element whose relation is defined. Its phonological system also has very little that is uncommon. There are 5 vowels and approximately 20 consonants. Different combinations of these

produce a total of approximately 100 different types of *mora*, the minimum unit of sounds in Japanese.

Two features which make Japanese unique and thus particularly challenging for learners of Japanese, as L1 and L2 alike, are politeness expressions and orthography. There are three broad categories in the politeness principle of Japanese, and the use of each category is dictated in an intricate manner depending upon many factors, including the speaker's and the addressee's social status, age, gender, the degree of task demand, and so forth. Japanese orthography consists of three layers: *hiragana* (syllabic symbols created as part of Chinese characters in the 10th century), *katakana* (a version of hiragana used mainly to write Western loanwords), and *kanji* (the ideographic writing system consisting of Chinese characters imported from China more than 1,500 years ago). Hiragana and katakana are not difficult to use, because these are syllabic systems in which each foreign letter corresponds to the syllabaries. The major challenge to learners is the fact that each kanji character can be pronounced two or more ways. Because of the difficulty, language teachers often claim that written language ability and oral language ability differentially favor students from different language backgrounds.

Teaching, Learning, and Assessing Japanese

The Teaching and Learning of Japanese as a Foreign and Second Language

According to a report issued by the Ministry of Justice, in 2009, there were 2,180,000 residents holding foreign registration cards living in Japan (1.7% of the total population), from 189 countries. Besides these potential learners, there were approximately 3,650,000 people learning Japanese in 133 countries. The reasons for learning Japanese today thus vary widely, including even those learning for entertainment purposes, for example pop culture, such as animated films (*animé*), comics (*manga*), and Japanese pop music. The following description focuses on the needs of learners who are learning Japanese as a second language in Japan.

One group learns Japanese for academic purposes. One third of this comprises students in higher education, the rest are learning Japanese with an ultimate goal of matriculating to higher education. Another group is learning Japanese for business purposes. In this group, there are not only those who use Japanese in authentic business situations, but also those who have to communicate with others using formal Japanese. There is also a third group, including employees of Japanese descent and technical trainees from developing countries. It is relatively easy for them to obtain working visas, yet not all of them are proficient enough in the language to accomplish a task in a specialized field, though they are able to use the language to maintain a minimum level of quality in daily life. The latest addition to this group involves clinical nurses and welfare caregivers. Though they hold a certificate issued in their own country that guarantees their professional skills, it is extremely difficult for them to obtain the equivalent certificate in Japan, because there is a gap between the type of Japanese they learn through a training course, the one that is required in the examination, and the

one that must be used in real-life settings. Besides these adult learners, there are young learners who need to learn JSL while maintaining their first language. Since 2008, when a total of 75,000 students were enrolled in primary and secondary public schools, the number has been increasing. Textbooks and materials for teaching basic Japanese are needed to help them acquire the knowledge in school subjects, which covers a different level of Japanese from that targeted at students of higher education.

Assessing Japanese in Practice

In this section, the four major Japanese tests are presented. They are used to measure the language ability of non-native speakers of Japanese, the scores of which are used to make high stakes decisions. Besides these four major tests, a system of evaluation called JF-Standard will also briefly be introduced as a new trend in the approach to assessing Japanese (JF-Standard, *n.d.*).

The Japanese-Language Proficiency Test (JLPT) The Japanese-Language Proficiency Test (JLPT, *n.d.*) is the largest examination that is designed to measure proficiency in Japanese, with a total number of test takers of more than 770,000 in 2009 alone. The JLPT is used for a wide variety of purposes, including making decisions about admission to academic programs, the awarding of scholarships, qualifying the level of Japanese of a candidate for an employment, and so forth. Though the Examination for Japanese University Admission for International Students (EJU) (see below) is now available as an instrument for making admission decisions, the JLPT is still widely used in parallel for that purpose by many institutions. The new version was implemented in 2010, and aims to measure the integrated and functional skills of Japanese required to accomplish a given task. It is provided in five different forms, each of which measures different levels of proficiency from N1, the least proficient, to N5, the most proficient. The test of each level includes the knowledge of language (vocabulary and grammar), reading, and listening comprehension. All items in all versions are multiple choice type. The new version is being offered twice a year.

The test is evaluated annually by external evaluators consisting of experts in Japanese education and educational measurement and in-service teachers. The analysis of test data is conducted by various methods including item response theory (IRT). The results of calibration are employed in the new version of the test. The results of evaluation for the previous version of the JLPT used to be released in the annual report. However, the new version is evaluated by the Japan Foundation, the body in charge of developing and administering the test, and the test items and tasks are no longer made public, nor is the report released.

The Examination for Japanese University Admission for International Students (EJU) The Examination for Japanese University Admission for International Students is the test specifically designed to be used for the purposes of university admission. The test is commissioned by the Japan Student Services Organization and is run twice a year in more than 10 countries to measure the basic functional skills and knowledge of JFL.

The test battery consists of reading and listening comprehension, integrated reading and listening, and writing. The comprehension section consists of items consisting of written language and nonlinguistic visual information, including graphs and charts. The aural section consists of items made up of sounds and nonlinguistic visual information. In the integrated component, written, spoken, and nonlinguistic information are combined, which requires test takers to deal with all these areas. All test items are multiple choice. The construct that the test is intended to measure involves the ability to understand information in written or spoken text, to comprehend relationships between pieces of information, and to infer a logically valid interpretation. The writing component purports to specifically assess the ability of the student to follow the instructions and to write his or her own ideas along with convincing reasons. The assessment criteria are made public.

Business Japanese Proficiency Test (BJT) The Business Japanese Proficiency Test is a test for business purposes. As has been stated above, an increasing number of learners wish to get involved in businesses that require Japanese. The test has been developed to meet the needs of such learners. It is administered twice a year in 10 cities in China, in Hawaii, and in Bangkok, with the total number of test takers being 6,592 in 2009.

The BJT consists of reading and listening comprehension, and integrated listening and reading. The entire test battery is intended to measure the ability to understand and use Japanese in a context where business issues are dealt with. All items are multiple choice. With a maximum score of 800, 6 different levels are identified according to the test score. The highest grade is awarded to the test taker whose score is 600 and above. At this level, the test taker is considered to possess sufficient ability to communicate and deal with a range of problems using the language in virtually any setting. Comparable scores to the JLPT are released regularly, which in turn may underscore the validity of the tests, an issue we will come back to in the next section. The results of the BJT are analyzed from multiple perspectives, including IRT, and the results are incorporated in the subsequent revision processes. The results of external evaluation of the test are released on the Internet.

Test of Practical Japanese (J.TEST) Another major examination is the Test of Practical Japanese. The J.TEST has been administered six times a year since 1991, with the number of test takers amounting to approximately 70,000 a year (J.TEST, *n.d.*). The test consists of two components, reading (comprising grammar and vocabulary as well as reading comprehension) and listening comprehension. Different versions are prepared for different levels of learners ranging from advanced to beginners. Within each level, sublevels are further assigned according to the test scores. For example, in the case of the A–D level test, a test taker who scores 930 and above will be ranked at the super A level; 900 to 929, A; 850 to 899, pre-A level; and so forth. As is the case for the BJT, the J.TEST purports to measure ability that is considered higher than that which is measured by N1 of the JLPT. Perhaps because the test is relatively new to the field, not much information is available, particularly for the one which is specifically addressed to researchers. A new

version of the J.TEST is now being prepared, with a test for business purposes called the Business J.TEST.

JF-Standard JF-Standard for Japanese-Language Education (JF-Standard) is the framework for assessing JSL or JFL developed on the model of the Common European Framework of Reference (CEFR) by the Japan Foundation in order to meet the demand of diversifying learner needs and methods in different contexts around the world. The standard is based on the belief that to achieve mutual understanding through Japanese around the world two types of competencies are required:

competence in accomplishing tasks, which involves what a person can do by using Japanese, and competence in intercultural understanding, which involves understanding and respecting other cultures by expanding one's horizon through encounters with various cultures. (JF-Standard, 2010, p. 1)

JF-Standard illustrates the proficiency in Japanese by using a set of descriptors that are aligned with those of CEFR. By providing the same framework, an attempt is made to help learners and teachers of JFL and JSL assess the level of Japanese proficiency in any context around the world. One of the unique features of the JF-Standard is that the assessment system is provided in combination with a study guide that is prepared to help learners improve language skills based on the assessment offered by the standard.

Assessing Japanese as a First Language

In teaching Japanese as an L1, a greater emphasis has traditionally been placed on orthography and the interpretation of literary works than on the ability to use Japanese in an actual language use setting. It is common to include Modern Japanese and Classical Japanese and Classical Chinese literature (rendered in special Japanese readings) in high stakes tests, such as university entrance examinations. However, the past decade has witnessed a shift in emphasis in assessment, as well as in teaching, to authentic reading skills (Ministry of Education, Culture, Sports, Science and Technology, MEXT, 2011), partly due to the Programme for International Student Assessment (PISA) report issued by the Organisation for Economic Co-operation and Development (OECD, 2004), where Japanese students scored high on mathematics and science, but low in reading comprehension skills. The result was interpreted to indicate that the construct defined in the national curriculum may not be congruent with the standard of the OECD; that is, "the ability of students to use written information in situations which they encounter in their life" (OECD, 2004, p. 272).

Meanwhile, with the advancement of new technology, the difficulty of producing Japanese in written mode has greatly been alleviated. Ironically, however, an increasing number of nationals seem to have become interested in assessing their own L1 competence by taking various tests developed and administered by the private sector, ranging from such specific areas as the knowledge of kanji characters (Japan Kanji Aptitude Testing Foundation, *n.d.*) to more general

Japanese competence (Japanese Language Examination Committee, *n.d.*). All these data seem to indicate the Japanese fixation with great expectations of the power of testing.

Challenges

In the process of constructing and revising the tests that were introduced in the previous section, many empirical studies have been conducted and referred to. For example, prior to developing the new version of JLPT, a series of studies had been conducted (e.g., Shoji et al., 2004; Noguchi, Kumagai, & Oosumi, 2007), and the process of revision was informed by these findings. Such reports include the research that was administered outside Japan, though this is still limited (e.g. Li, 2006; Miyafuku, 2006).

Despite the availability of information for professionals, however, surprisingly little research has been conducted on the consequences of the test of JSL or JFL, in the sense defined in the framework of Messick (1988) and other studies relating to washback in the field of language assessment. Indeed, there is a notable lack of empirical studies on validity in general, be it consequential validity, construct validity, or that based on an argument-based approach (Kane, 1992), which the test takers or test users may refer to as a source of deciding which test to take or how to use test scores for making accurate decisions. A lack of information for test takers and users is one of the issues that need to be addressed in future research.

Besides these issues, there are other areas which await further research, though several attempts have already been made. These attempts are summarized below.

First, virtually no instrument exists to date to assess the productive ability of JSL or JFL for high stakes purposes, though several studies have recently been conducted to that end. A Japanese version of the American Council on the Teaching of Foreign Languages Oral Proficiency Interview (ACTFL OPI) is an example. However, Okumura (2011) observes that the test is suitable only for a large-scale assessment due to the constraint of cost-effectiveness. Another test of productive ability is the Japanese Standard Speaking Test (JSST), which has been developed by ALC Inc. The test is carried out by choosing from a number of question prompts saved in the past, the test taker being asked to record his or her responses on tape. The feasibility of using this type of test on a larger scale is yet to be fully determined.

Second, there are many temporary residents in Japan who would like an extension of their stay in the country, which could be made with the proviso that they possess a certain level of proficiency in Japanese. The type of ability that is required of them includes getting involved in social gatherings in the community, communicating with teachers at school regarding their children, and the like. Though criteria are yet to be established for certifying this type of Japanese ability, there has recently been a hint of development. One example is the Japanese Language Learning Support System (*n.d.*), which has been developed by a research team at Nagoya University commissioned by Toyota City. In the system, test takers are first asked to assess their own level of ability by “can-do”

statements, and then take an interview and written test to determine their proficiency objectively.

Third, there are a number of international students at elementary and junior high schools, who are not proficient enough to learn school subjects in Japanese. What is needed for such learners is a diagnostic system leading to instruction. One promising approach has been the Oral Proficiency Assessment for Bilingual Children developed by the Canadian Association for Japanese Language Education (2000). Another approach is reported in Kawakami (2006), where a series of attempts are demonstrated to develop a diagnostic evaluation system called the JSL bandscales. The system has been developed on the basis of a large amount of observation data gathered from primary school students. It is currently limited in use to certain areas in Japan, though it seems to be generalizable to other areas.

Finally, computer-adaptive testing (CAT) is an area which needs further development. CAT is slow to be available for several reasons. The most obvious one is attributed to the widespread ethos that public examinations should be released to the public after the administration. This means that in order to guarantee fairness to all test takers test questions that have been used once should not be used again or “recycled.” Still another practical problem to overcome is that of using the complex Japanese orthography system. Despite these factors, however, several useful attempts have already been made, for instance the Japanese Computerized Adaptive Test (J-CAT) (Imai et al., 2009). J-CAT consists of four components, including listening comprehension, vocabulary, grammar, and reading comprehension. It has been developed and run on a pilot basis on the Internet (J-CAT, *n.d.*).

Assessing Hakka, Southern Min, and Taiwanese Indigenous Languages

Jessica R. W. Wu

Language Training and Testing Center, Taiwan

Introduction

Taiwan is a multilingual and multiethnic country composed of four major ethnic groups. According to Huang (1993), they are: the Taiwanese, who speak Southern Min, comprising 73.3% of the population, mainlanders (13%), Hakka (12%), and the indigenous peoples (speakers of Austronesian languages; 1.7%). Southern Min and Hakka are Han dialects, mainly spoken by those whose ancestors immigrated from China's Fujian and Guangdong Provinces four centuries ago. At present, there are 17 languages and dialects used in Taiwan. However, due to the compulsory "national language policy" implemented in Taiwan in the 1950s, Mandarin Chinese is the official language. As a result, mother tongues or first languages (L1s) were quickly diluted, and some have nearly vanished. Not until the dramatic political and socioeconomic changes of the late 1980s did these L1s experience a revival. Since then, L1 education has received increasing attention from the government as well as from society at large (Tsao, 1997a). To effectively preserve and promote these languages and their cultures, and to meet the need for qualified L1 teachers, the Taiwan government has implemented public testing and assessment procedures to measure proficiency in the three major types of L1, namely indigenous languages, Hakka, and Taiwanese (Southern Min). Now, public tests of Taiwan's three major L1s are administered regularly and are gradually gaining in importance. This chapter starts with a historical overview of the status of L1s in Taiwan, then describes current teaching and testing practices of these languages. Anticipating that these new L1 tests are valid assessment instruments, the chapter addresses some pressing issues emerging from the new context.

Historical Review

Due to its long history, Taiwan's society is a rich mixture of diverse cultures. As claimed by several academics, Taiwan is one of the original places of the Austronesian tribes. Today, the government officially recognizes at least 14 different groups of indigenous people that inhabit the island. In the 18th century, an ever increasing number of Chinese migrants settled in Taiwan, thus transforming its demographic structure. Eventually, the Han Chinese constituted a majority of the island's population, making the Han Chinese culture dominant in Taiwan. Then, in 1895, after its defeat in the Sino-Japanese war, the Ching government ceded Taiwan to Japan and the island was ruled as a Japanese colony until the end of World War II. In 1945, Japan surrendered to the Allies and sovereignty over Taiwan passed to the KMT-led government of the Republic of China.

To eradicate the Japanese influences shaped during the Japanese occupation, the KMT government immediately implemented the Guoyu policy on Taiwan, promoting a Chinese-only education program. The use of Japanese was forbidden in schools and governmental agencies. Instead, Mandarin, a Beijing dialect, was designated as the sole official national language (pronounced "Guoyu" in Mandarin), and was to be used on all occasions. Furthermore, in the process of ensuring that everyone mastered the common national language, the importance of other dialects and languages was sacrificed, resulting in a serious language shift among minority groups.

Not until the dramatic political and socioeconomic changes of the late 1980s, particularly the lifting of martial law in 1988, did L1s like Taiwanese (Southern Min), Hakka, and the indigenous languages experience a revival (the 14 indigenous languages are considered as an L1 in this chapter). Over the next decade, a grassroots movement seeking self-identity emerged in Taiwan, leading the KMT government to change its China-centered education policies. In order to preserve and promote these local languages and cultures effectively, the "mother tongue education" policy has been implemented by the Ministry of Education since 1996.

Mother Tongue Education

To provide a bylaw for the implementation of mother tongue education in Taiwan, the Ministry of Education approved the Curriculum Framework for Local Languages and Culture in Elementary School Education in 1996. Since then, the teaching of mother tongues has officially been included in the elementary education curriculum. The curriculum aims to foster students' interest in the natural and humanistic aspects of their immediate environment, and to increase their knowledge of Taiwan's history and natural resources. Since 2001, all elementary school classes have been required to hold one 50-minute "local language" class weekly. The schools may choose which local language to teach depending on student interest. Besides encouraging the teaching and learning of mother languages, research on mother languages is also sponsored by the government through various types of financial support (Chiang, 1994; Tsao, 1997b).

However, despite the growing importance of mother tongue education, mother language teachers (L1 teachers) were in short supply since only one university provided programs for teachers of mother languages when mother tongue education was first implemented in schools. To solve the problem, school teachers who taught other subjects were requested to attend workshops and training programs on teaching mother tongues and were then assigned to teach mother languages at schools. While this eased the shortage of teachers to some degree, the government recognized there was an immediate need for qualified L1 teachers. The recruitment of qualified L1 teachers also led to the development of L1 assessment (see below).

Mother tongue education is generally appreciated by learners and their parents; however, it is not without problems (Chiang, 1994). One obstacle is the belief many parents hold that the instructional time spent cultivating competence in a mother language might negatively affect a student's ability in Mandarin Chinese, the official language in Taiwan and the language used in the high school and college entrance examinations. Other parents find little value in allocating time at school for the mother tongue program, suggesting that English or mathematics, subjects on entrance examinations, are more useful. This attitude is more commonly found among families that are less well off, due to their concern for economic and social advancement; they may see bilingual education as an unaffordable luxury.

Another obstacle is the absence of a common written language for each of the L1s in Taiwan. For example, in the case of Southern Min, there are different phonetic systems in use. It has long been debated whether to adopt romanization systems or to create new writing systems for the Southern Min language. Romanization systems, supporters claim, are flexible, precise, and well suited for use as the primary writing system for local languages (Huang, 2003); on the other hand, opponents of romanization maintain that the use of these systems is too difficult for local people who are not familiar with romanization alphabets (Tsao, 1997b). As a result, disagreements over the standard written forms for L1s have affected the development of textbooks and other materials for Taiwan's mother language education.

This situation has improved since the National Languages Committee (NLC) acted to standardize the written forms of the local languages and promote local language education (Ministry of Education, 2011), including the announcement of Southern Min's romanization to unify the language's pronunciation and to facilitate the teaching of pronunciation, the announcement of characters recommended for use in Southern Min in order to set up a common writing system for the language, and the publication of online dictionaries of frequently used words in Hakka, Southern Min, and indigenous languages. To further promote the use of L1s, the NLC also periodically holds a variety of activities, including national language contests, Mother Tongue Day events, L1 teaching and award programs, and so on.

Assessment of L1s

As mentioned earlier, the development of L1 assessment in Taiwan originated from the need for qualified L1 teachers. The Taiwan government has implemented new testing and assessment procedures to measure L1 proficiency. School teachers

seeking certification as qualified L1 teachers are encouraged to take an official test of the L1 they want to teach. The general public is also encouraged to take an L1 test in order to assess their L1 proficiency. Official tests of the three major L1s are administered regularly in Taiwan and are gradually gaining in importance:

- Indigenous Peoples Language Skill Certification, implemented by the Council of Indigenous Peoples (CIP) in 2001;
- Hakka Language Certification, implemented by the Council for Hakka Affairs (CHA), in 2005;
- Taiwanese Southern Min Language Certification, implemented by the National Languages Committee (NLC) in 2010.

Indigenous Peoples Language Skill Certification

The Indigenous Peoples Language Skill Certification is promulgated pursuant to the Education Act for Indigenous Peoples (CIP, 1998). Certification is conducted annually and covers a total of 14 tribal languages, and each of the tests follows a standardized structure and format (CIP, 2010). When test takers register for the test, they must specify which version of the test they will take. There are two application methods for certification. One is a written and oral test; the other is a testimonial evaluation. The application is also open to nonindigenous people. A person who obtains an indigenous language certificate is considered a qualified teacher of that indigenous language.

There are no level distinctions in indigenous language certification. To pass the written and oral language tests, one must achieve 140 points out of a total score of 200 points (80 for written and 120 for oral). As for the test format, the written test is 70 minutes in length and consists of four sections: vocabulary, usage, reading, and dictation. The question types include true/false and multiple choice. The oral test is about 10 minutes in length and consists of two sections: read aloud and answering questions. The number of test takers averages 2,000 annually, with pass rates between 52% and 73% (Wang & Lee, 2006; Ho, 2010).

Alternatively, applicants who apply for indigenous language certification may choose to undertake the testimonial evaluation procedure, which requires recommendation letters issued by indigenous organizations, religious organizations, schools, local administration offices, or rural (community) offices, as well as related documentary information. The CIP issues an indigenous language certificate to applicants who pass the language test or successfully complete the testimonial evaluation procedure.

Hakka Language Certification

The results of a 2004 CHA survey show that one in every 3.7 Taiwanese is of Hakka origin. This indicates that there is a pressing need to certify qualified teachers of the Hakka language. Moreover, individuals working in organizations related to the Hakka language, such as CHA, the Hakka affairs bureaus of various counties and cities, schools promoting Hakka language teaching, and Hakka culture research centers, as well as those studying the Hakka language in institutes of Hakka

language and culture, are all required to be able to speak, read, and write the Hakka language. Only certified personnel are qualified to work at organizations engaging in Hakka studies or services. Therefore, certification of Hakka language proficiency has become indispensable for promoting the Hakka language.

Hakka Language Certification is administered in basic, mid-, and high-intermediate levels. Each level of the test includes a written and oral part, with the oral part conducted in a tape-mediated format. Each level of the test is provided in five different versions, corresponding to the five dialects of the Hakka language used in Taiwan. Test takers must indicate which version of the test they prefer to take. The basic test concentrates on testing examinees' communication skills, while the mid- and high-intermediate certifications additionally include cultural studies and writing ability. As with the indigenous language certification test, the oral part is given more weight than the written part (2:1).

Although there are three levels in the certification testing system, only the basic level is administered as an independent test; the two higher levels are tested in one paper. To pass the basic level, one needs to get 70 out of the total score of 100. As the two higher levels are tested in one paper with a total score of 300 points, a test taker who scores between 150 and 215 is considered as passing the mid-intermediate level, and one with a score greater than 215 is considered as passing the high-intermediate level certification. Only those who attain the high-intermediate level are considered qualified teachers of the Hakka language.

The CHA enthusiastically promotes the Hakka language test, leading to steady growth of the test population. The CHA's promotional efforts include developing an online Hakka language school (<http://elearning.hakka.gov.tw>) and providing everyone who completes the application process with free practice materials (CD included) to study before the test, including a rudimentary vocabulary and sample test questions. Such efforts have boosted grassroots interest in both acquiring Hakka language skills and demonstrating proficiency in those skills through taking the certification test. This is particularly true in the case of the basic level of the certification test. Figures (CHA, 2010) indicate that over 15,000 people took the basic level in 2010, with a passing rate of 70%. The test population of the basic level was composed of a wide range of examinees, including students at various educational stages, housewives, senior citizens, and the general public. The higher levels of the test were taken by approximately 6,000 people. Among them, 60% passed the high-intermediate level.

Taiwanese Southern Min Language Certification

The development of the official Taiwanese Southern Min language certification examination began relatively late, in 2007. Unlike the other L1 certification examinations, the Taiwanese Southern Min language certification system aims to align with an international language proficiency framework, namely the Common European Framework of Reference for Languages or CEFR (Council of Europe, 2001). To accomplish this, the official test of Taiwanese Southern Min divides Taiwanese language proficiency into six levels in accordance with the CEFR levels (A1, A2, B1, B2, C1, and C2), despite the fact that the test is more norm-referenced in nature (see below) and that there have been debates about the use of the CEFR beyond Europe

Table 125.1 Relationship between scores of the test of Taiwanese proficiency and CEFR levels

CEFR	A1	A2	B1	B2	C1	C2
Total score (X)	151 < X ≤ 220	221 < X ≤ 290	291 < X ≤ 340	341 < X ≤ 380	381 < X ≤ 430	431 < X ≤ 500

(e.g., Weir, 2005; Wu & Wu, 2010; Byram & Parmenter, 2012). The alignment of this test with the CEFR is a response to a 2005 Ministry of Education policy that recognizes the CEFR as a common yardstick to interpret language proficiency.

Despite the intention to develop a criterion-referenced test, the test is nevertheless norm-referenced, with test items across all six levels tested within one individual test paper. The examinees' Taiwanese Southern Min language proficiency level can be identified by referencing their scores on the test. The relationship between the test scores and the CEFR levels is shown in Table 125.1.

The total score is 500 points. The test consists of four sections: reading, listening, dictation, and speaking. School teachers and teaching assistants are encouraged to take the test, and those who reach CEFR B2 level in the test are certified as qualified Taiwanese Southern Min teachers. To attract more school teachers to language certification, their test fees are waived. With this incentive, the first test in 2010 was taken by 4,100 people, of whom more than 1,700 were school teachers (Ministry of Education, 2011). Approximately 1,600 examinees attained the certificate at B2 level, making up 40% of the total test population.

The use of a norm-referenced measurement which provides examinees with criterion-referenced information in the current official test of Taiwanese Southern Min seems to be an economic solution. The NLC offered two reasons for this design: First, the budget and resources were insufficient to develop a certification system in six levels; second, the test needed to be launched as quickly as possible. Whether this well-intentioned effort can be justified is one of the important L1 assessment issues explored in the following section.

Issues and Challenges

Retrospectively, the return of L1s to the mainstream in Taiwan has been a long journey. With years of hard work, significant tasks have been undertaken to support L1 teaching through the implementation of the nationwide formal tests in the indigenous, Hakka, and Taiwanese Southern Min languages. It is exciting to see the new area of assessment of L1s in Taiwan being explored and developed. Yet, from the testing practices described earlier, several problems are apparent.

The problems are mainly associated with the notion of usefulness, a well-established concept in the testing literature (e.g., Bachman & Palmer, 1996). Underlying the concept of usefulness, a test should perform a useful function within an educational and social context, achieving a balance of essential test qualities: reliability, validity, practicality, and positive impact. Therefore, to demonstrate the usefulness of the tests of L1 proficiency newly developed in Taiwan, there is an urgent need to enhance these qualities in the new L1 tests.

This section discusses key issues that have emerged from the new context, broadly categorizing these into two areas: test production and procedure, and test validation.

Test Production and Procedure

Creating a new test is a complicated process that requires careful research through a rigorous process of item writing, editing, pretesting, and iterative reviews of test construction. However, there is no clear information about how the official tests of L1 proficiency in Taiwan are constructed. Having been involved in the development of the Indigenous Peoples Language Skill Certification for many years, Huang (2003) strongly recommended that a systematic approach to test production be undertaken to ensure test quality. Similarly, Jiang (2008) suggested that the current administrative procedure for producing the L1 tests in Taiwan is problematic, putting the tests at risk. He further explained that at present the test production for each test operation is commissioned to a task force representing a university or an academic institution selected through a bidding process. In other words, task forces bid on the project, and the winner produces the test. As a result, the process and procedure of test production could vary significantly depending on which task force undertakes the project, potentially reducing the reliability and validity of the tests.

To improve the situation, it is important for the government in Taiwan to change the current approach to producing L1 tests and to consider commissioning the work as a long-term project undertaken by a professional testing institution. The General English Proficiency Test (GEPT), Taiwan's first country-wide high stakes test of English proficiency, has provided a model of how this could occur. In the case of the GEPT, the Ministry of Education funded the Language Training and Testing Center (LTTC), a reputable institution having provided language training and testing services in Taiwan for six decades, to carry out the project. The LTTC administers various tests, including those developed by itself and those administered on behalf of other institutions, and maintains a high quality testing service through ongoing research and development (Kunnan & Wu, 2009). Having developed rigorous processes for producing the GEPT test papers and procedures for GEPT test administration, the LTTC has administered the GEPT in a consistent and reliable manner to over 5.2 million EFL learners in Taiwan since it launched in 2000 (Roever & Pan, 2008; Wu, 2012).

Test Validation

It is also important to ensure that the L1 tests are accurate, relevant, and fair by iterative reviews of the tests before and after they are administered. Test validation with support of both quantitative and qualitative evidence must be undertaken. With the test of Taiwanese language proficiency, for example, the claim of the relationship between the test scores and CEFR levels is questionable. No empirical evidence to support the claim has yet been reported, and it is unclear how the judgment on the relationship between these two was made. Given that the scores are interpreted in terms of the CEFR levels, it is highly important to conduct

empirical qualitative and quantitative investigations into the claimed relationship, with reference to the approach recommended in the manual published by the Council of Europe (Council of Europe, 2003).

Although there are no claims that the scores of the other two L1 tests are related to the CEFR levels, the meaning of these tests' scores also need to be validated. One of the pressing issues about these two L1 tests seems to be how various versions of the tests, using different dialects, can be validated. However, no validation of any of the L1 tests has yet been reported. Given that the major purpose of the L1 tests is to certify qualified L1 teachers, the critical question is to what extent the test is a valid assessment of the level of L1 proficiency that qualified L1 teachers are expected to possess. In answering the question, validation studies need to be carried out to provide credible evidence to demonstrate the reliability of scores derived from the test and to support valid uses and interpretations of the test scores.

The information released by all three L1 tests gives only the number of test takers and the number of passing test takers, providing a very general picture of the test administration. Such information is inarguably important, yet it is rather limited. For the sake of transparency and test fairness, the information about reliability should also be reported. Moreover, given that human judgments are involved in the assessment of writing and speaking skills, it is necessary to provide statistics on inter-rater and intra-rater reliability as evidence to support score validity.

Lastly, considering that the results of the L1 tests are high stakes, test impact is another important area which should not be overlooked. It is necessary to understand the impact of each of these L1 tests, both intended and unintended, on the stakeholders involved in the assessment process, for instance test takers, test users, school administrators, students and their parents, and other professionals working on Taiwan's L1 education. The feedback received from stakeholders can help to identify areas in Taiwan with greater need for L1 assessment.

Conclusion

In Taiwan, L1 education has received increasing attention from the government as well as from society at large. In order to preserve and promote these languages and their cultures, and to meet the need for qualified L1 teachers, with government support, formal tests assessing the languages of indigenous peoples, Hakka, and Taiwanese have been administered regularly and are gradually gaining in importance. It is hoped that this chapter will provide useful insights into L1 assessment in Taiwan. By sharing observations of key issues and problems affecting Taiwan's L1 assessment, it is also hoped that this chapter will spark an interest in conducting more research into Taiwan's L1 testing and assessment, both by test developers themselves and by external researchers, to enhance test usefulness.

Assessing Korean

Chungsook Kim

Korea University, Republic of Korea

Junho Lee

Gyeongin National University of Education, Republic of Korea

Introduction

Korean is a unique language written in Hangeul, the Korean alphabet, and the official language of the Republic of Korea. Morphologically, it is an agglutinative language and is a member of the Altaic language family. It is the main language used on the Korean Peninsula and most of the islands in the area, including Jeju Island. As of 2011, there were around 77 million speakers of Korean around the world, making it the 13th most widely spoken language in the world. Regionally, Asia has the most speakers of Korean followed by North America and Europe. The number of students studying Korean as a foreign or second language has continuously risen with the Republic of Korea's economic development and growth in international status. In 2010, the number of international students in Korea studying Korean or studying in Korean rose to over 83,000, which represents a 680% increase from 2003. Further, the number of people taking the Test of Proficiency in Korean (TOPIK), an exam which assesses the proficiency of learners of Korean as a foreign or second language, has increased by over 20 times, and has reached about 104,000.

Assessing Korean as a First Language (L1)

History of Assessment of Korean as L1

Assessment of Korean as a mother tongue can be traced back to the time when Korea was established on the Korean Peninsula. However, education and assessment in the modern sense of the words started on the Korean Peninsula in the late 1800s, with the establishment of modern schools and the Korean language as

a school subject in 1885. A brief description of the time periods in which the Korean language and Korean education were developed is presented below.

The Time of Enlightenment (1895–1910) and the Japanese Colonial Era (1910–45) The time of enlightenment covers the period around 1900 when Korea opened its doors to Western influence and began its journey to becoming a modern society. During this time, the Joseon Dynasty, the last dynasty of Korea, lost a great deal of power. Korea's educational system was modernized during the time of enlightenment and a school education system similar to today's took effect. According to Cheon Kyeong-rok (2005), we can presume that Korean language assessment during this time was carried out based mainly on the contents of Korean language education. The semester exams of government primary schools comprised topics which were based on reading and writing skills such as reading, calligraphy, and composition. Middle school entrance exams also covered the reading and writing of Korean and Chinese characters. Assessment methods such as essay tests and an interview method called "mundae" were used, but there were no multiple choice tests. However, this assessment system faced a serious crisis in August 1910, when the Korean Empire was destroyed after it lost national sovereignty. Japanese colonial rule was imposed on the Korean Peninsula until independence was achieved on August 15, 1945. This period is called the Japanese colonial era. During this time, the focus was on Japanese language education and assessment rather than Korean. Korean language education withered and was excluded from assessment systems.

Syllabus: First Curriculum (1945–63) and Second and Third Curriculum (1963–81) These two periods were times when Korean assessment was revived and a base for progress was prepared. According to Noh Myeong-wan et al. (2011), this was a time when a huge amount of effort was used to reclaim a lost language. Also, a syllabus which described the general goals of Korean language education was announced directly after liberation, and this was fine-tuned during the First Curriculum period. Noh Myeong-wan, Shin Heon-jae, Park In-gee, Kim Chang Won, and Choi Yeong-hwan (2011) surmise that the goal of Korean language education at the time was experience centered and aimed to increase students' ability to use Korean and to contribute to its practical use in everyday life. Assessment was generally done through question and answer exams in which students read texts for comprehension.

The Second and Third Curriculum periods utilized content from the First Curriculum period but were more elaborate. Assessment was also more advanced than during the First Curriculum period and received a lot of influence from the Tyler evaluation model, in which teachers give instruction after setting goals and then evaluate the students, providing feedback. The focus of assessment was mainly ability in reading, language knowledge (grammar), and literature. This is probably because of the influence received from preliminary exams given by the state and the college entrance exam system based on *bongosa* (principal exam) tests given by each university (Cheon Kyeong-rok, 2005).

Fourth and Fifth Curriculum (1982–92) and Sixth and Seventh Curriculum (1992–Present) During these two periods, there was rapid progress in Korean language

assessment, and the present Korean language assessment system was established. Expressions and comprehension, language, and literature were the three parts of Korean language education during the Fourth Curriculum period. During the Fifth Curriculum period, expressions and comprehension was broken down into speaking, listening, reading, and writing, making a total of six parts. Guidelines regarding assessment also began to be mentioned more often. In the Sixth and Seventh Curriculum periods, assessment was stressed more in the curriculum. This was also the time when achievement standards, assessment standards, examples of assessment tool development, etc. for elementary, middle, and high school Korean language courses were formulated. According to Cheon Kyeong-rok (2005), the Seventh Curriculum brought about an emphasis on the functions of formative assessment and deepened diagnostic assessment for remedial education.

Assessment Systems for Korean as L1

Classroom-Based Korean Language Assessment Current assessments of Korean language classes for elementary, middle, and high schools, carried out according to the Seventh Curriculum, are linked closely to the curriculum and teaching and learning content, and directly reflect assessment plans, management policy, and utilization methods suggested in the curriculum. In order to understand the current Korean language assessment system, one must first examine the fundamentals of the current Korean language curriculum.

In the current Seventh Curriculum, Korean education is split into the basic curriculum of "Korean" and the optional curriculum of "Korean 1, Korean 2, speech and composition, reading and grammar, literature, and classics." "Korean" is part of the National Common Basic Curriculum, and it provides the nature and goals of elementary, middle, and high school Korean language courses and ultimate achievement standards that must be reached through elementary, middle, and high school studies. The common curriculum states that Korean courses should have three main characteristics. First, they should cultivate ability to use proper and effective Korean, a language which is ingrained in the lives of Koreans. Second, they should contribute to the progression of Korean and the development of Korean language culture through creative use of Korean. Third, they should foster a healthy national psyche and future-oriented community spirit through building up honest and hardworking characteristics through correct language use.

These educational characteristics are reflected in the content structure of each category. The content structure for "Korean" courses is largely split into "listening and speaking, reading, writing, grammar, and literature." Each of these categories' content structures attains a structured aspect focused mainly on the "practicality" of that category's language activities and other related items. "Listening and speaking," "reading," and "writing" are composed of "practicality, knowledge, function, and attitude." "Grammar" is composed of "practicality, knowledge, and research and application," and "literature" is composed of "practicality, knowledge, and taking in and production attitude."

Large-Scale Standardization Tests *Language (Korean) Section of the College Scholastic Ability Test:* After the college entrance exam from 1982 to 1993, the "Achievement

Test," was criticized for encouraging simple memorization of exam contents, in 1994, the College Scholastic Ability Test was created to better gauge thinking skills. This exam is divided into five sections: language, mathematics, foreign language, inquiry (social inquiry, scientific inquiry, vocational inquiry), and a second foreign language or Chinese characters. The language (Korean) section of the test strives to measure language skills needed to study effectively in college. This section tests whether the student efficiently understands interdisciplinary Korean materials using language functions such as listening, writing, and reading. The goals of the language section are to reflect the Seventh Korean Language Education Curriculum while emphasizing factual, inferential, critical, and original thinking skills and including vocabulary and grammar, to write according to the contents and standards of the Seventh Korean Language Education Curriculum while using interdisciplinary topics. Language categories such as listening, writing, and reading can be used independently for questions or combined to form questions. (Korea Institute for Curriculum & Evaluation, 2004).

In other words, assessment of the College Scholastic Ability Test is based on the Korean language education curriculum, but tests basic language skills needed in college studying and is interdisciplinary and multifunctional. As mentioned previously, the Korean language curriculum is composed of "listening and speaking, reading, writing, grammar, and literature," and the assessment contents for each section include the needed Korean knowledge and factual, inferential, critical, and original thinking skills. Similarly, the assessment content for the language section of the College Scholastic Ability Test is separated into contents and activities. Content is used to evaluate "listening," "reading," and "writing." The goal of assessment of "listening" is to evaluate both listening and speaking skills. Therefore, speaking is evaluated indirectly in the "listening" section. Activities are used to evaluate skills related to "vocabulary and grammar," "factual thinking," "inferential thinking," "critical thinking," and "creative thinking."

KBS Korean Proficiency Exam: The KBS Korean Proficiency Exam is a Korean language assessment developed and supervised by the Korea Broadcast System (KBS), a public broadcasting system in Korea. The KBS Korean Proficiency Exam's home page (*n.d.*) states the following:

KBS feels it has a leading mission and responsibility to preserve Korean language beautifully through the correct and sophisticated use of Korean. Therefore, KBS eventually executed the KBS Korean Proficiency Exam in order to contribute to the raising of citizens' ability to use Korean and the progression of Korean language culture.

However, the scale of usage of this test, as stated on its Web site, is related closely to employment fields such as government, military and the police force, teachers and instructors, media, and office work. This causes the test to be used mainly as a Korean proficiency test for employment purposes.

This test, which is recognized as a state registered test, was first held in August 2004. There have been a total of 24 tests, the most recent being held in January 2012. It is currently given four times a year. According to Ji Young-seo (2004), the questions of the test are made up of the following skills: "grammar, comprehension,

expressions, originality, and language culture." Grammar skills are again split into vocabulary and grammar. Comprehension skills are made up of (a) a listening section in which test takers must solve problems after listening to various types of spoken language such as lectures, speeches, news, discussions, conversations, and interviews and (b) a reading section in which test takers read literary, academic, or practical texts and then are measured as to their factual, inferential, and critical understanding of the text. Expression skills are split into writing and speaking, but, because the test is large scale, it is multiple choice and accordingly evaluated indirectly rather than directly. Questions for the writing section are focused on writing processes like choosing a topic, collecting information, writing an outline, writing, revision. The speaking section includes questions regarding various speaking situations such as presenting, discussing, negotiating, persuading, proving, standard speaking (lingual manners, use of titles or designations, etc.). There are also questions on standard pronunciation. Finally, the Korean language culture section tests the ability to understand sophisticated common sense related to the Korean language. Knowledge of Korean linguistics and literature is considered to be part of high Korean language culture and is accordingly tested here.

Assessment of Korean as a Foreign Language

Although the assessment of Korean as a foreign language may have started at the same time as Korean education itself, an assessment that considered communication abilities as well as proficiency did not start until the latter half of the 1990s when the principles and standards of Korean education as a foreign language were implemented. An effort to develop a proficiency test in Korean occurred only after the American Council on the Teaching of Foreign Languages Oral Proficiency Interview (ACTFL OPI) and Test of Proficiency in Korean (Kim Chungsook & Won Jin Sook, 1993) were introduced into Korean education. Even so, Korean assessment as a foreign language is only in its early stages and there are still many issues that need to be solved.

Classroom-Based Assessment of Korean as a Foreign Language

There are currently over 100 universities in Korea that have courses in Korean as a foreign language. Each individual educational institution has a unique assessment method that follows its educational goals and teaching methods. Classroom-based assessment is divided into two major sections, placement and achievement assessment, and both show the different characteristics of these institutions. According to Lee Junho (2009a), there are many differences in evaluation method and the method of constructing results between institutions. As for the method of evaluation, every institution holds interviews, which shows that spoken language ability is considered a major evaluation component. But methods of constructing results include using interview results as the primary component, using interview results as supporting material, and using interview results and written test results as a total, which shows how spoken language ability is valued differently.

Korean Proficiency Assessment

The very first Korean proficiency assessment is the Japan-Korean Performance Testing Association Supervision. But this test was developed to measure the Korean language abilities of those who considered Korean as their L1 and, when considering its assessment content and categories, it is hard to say that this test met the requirements of being a proficiency assessment. Strictly speaking, the very first test that fulfilled the requirements of a proficiency assessment is the Test of Proficiency in Korean (TOPIK).

Test of Proficiency in Korean (TOPIK): TOPIK is run by the Ministry of Educational Science and Technology and is supervised by the National Institute for International Education. It was designed for foreigners and Koreans living abroad who do not consider Korean as their first language. TOPIK has quantitatively and qualitatively achieved great progress for 15 years, from its first examination in 1997 to its most recent (25th) on January 25, 2012. It firmly gained its status at national level as the assessment that measures Korean proficiency objectively, and is widely used as proof of Korean proficiency for academic and employment purposes in Korea.

In terms of assessment levels and its distribution method, TOPIK uses a rating system that ranges from levels 1 through 6. The test taker needs to choose the level of test that is appropriate for their proficiency. In the early stages of TOPIK (first to ninth), each level had a different set of questions to distribute the levels accordingly, but starting from the 10th test (2006), the questions were divided into three levels (beginner, intermediate, advanced) to distribute the levels based on the results.

Currently, TOPIK is only carried out in the form of a written test but a plan to adopt the methods of computer-based testing (CBT) and Internet-based testing (IBT) is being discussed. A hundred points are allocated for each category, with the total possible points being 400. Vocabulary and grammar, listening, and reading tests consist of 30 multiple choice questions. The writing part of the test consists of 10 multiple choice questions (40%) and 4–6 descriptive questions (60%), which are made up of 3–5 questions on sentence making or completing, and one composition question (150–300 words for beginner level, 400–600 words for intermediate level, and 700–800 words for advanced level).

Employment Permit System-TOPIK (EPS-TOPIK): EPS-TOPIK is an exam administered by the Human Resources Development Service of Korea, affiliated with the Ministry of Employment and Labor. It assesses command of the Korean language and understanding of Korean society for those foreigners who wish to be employed in Korea. The exam is held in 15 nations across Asia. The test takers are assessed on their communication abilities used in everyday life, industrial settings, and on their understanding of the Korean work environment. The level of the exam corresponds to TOPIK's beginner level, but some technical terminology may be from a higher level. It is composed of 25 listening questions (30 minutes) and 25 reading questions (40 min), all being multiple choice. The test is open to the public in order to promote basic learning and to minimize the cost of studying.

Others: Other than the two exams mentioned above, there are Hangeul Performance Testing (한글능력검정시험) administered by the Hangeul Performance

Testing Association of Japan, the Defense Language Proficiency Test IV (DLPT IV), the Korean Language Exam, superintended by the Defense Language Institute, Foreign Language Center of the USA, and the Korean Language Ability Test (KLAT), superintended by the Korean Educational Testing Service of Korea.

Current Issues and Future of Assessment of Korean

The current issues of Korean assessment as L1 include establishing an assessment system at a national standard. First, Korean evaluation at the national level within elementary to high schools must be established. Currently, there is no systematic assessment system for basic public education on a national scale. But according to Jeong Koo-hyang (2005), establishing a systematic assessment system on the national scale will promote learners' achievements and be the foundation for managing quality of education. A systematic assessment system will also help in finding out which program in what standard is needed to help an underachieving student. For this to be possible, the concept of Korean language proficiency needs to be elaborately formulated. Choi Yeong-hwan (2003) pointed out that current research on Korean education assessment is leaning towards the development of assessment tools rather than the essence of Korean education. Also, according to Jeong Koo-hyang (2005), assessment in Korean language without the concept of Korean language proficiency being established will lead to criticism that it will not meet the demands of changing society and times.

Second, in order for assessment of Korean as L1 to grow significantly, an assessment system at national level for elementary to high school Korean is needed. This is because the method of assessment is heavily criticized, especially written assessments or multiple choice assessments. Third, classroom assessments influenced by the College Scholastic Ability Test are causing a problem. Korea's current high population density and enthusiasm for education causes unavoidable fierce competition for college entrance. This has grossly standardized assessment of the College Scholastic Ability Test. It also causes the education and assessment at schools to fall short of the goals on education and assessment specified by the current curriculum. A large part of the current assessment system and method in the College Scholastic Ability Test depends on multiple choice response format assessment. Although such entrance exams may be ideal for selecting and ranking learners, they influence and hinder classroom assessment, which requires authenticity and application of feedback, causing a problem that needs to be solved.

The current issues of assessment of Korean as an L2 include the following. First, there is a need to develop an "Academic TOPIK" that can academically assess Korean language ability, since the majority of Korean learners are pursuing Korean for academic purposes. Although the current TOPIK does include a section to evaluate Korean learners with an academic purpose, it will ultimately need to determine the concept of Korean with an academic purpose, and to devise a method to decide constructs of academic Korean ability by means of reviewing and analyzing the validity of content to those subjects.

Second, a change from the rating system to a point system is required for long-term growth, and the question pool must be re-evaluated in order to increase the

test's practicality and the efficiency of its execution. The current system, with its problems with examination equalization and the appropriateness of each difficulty level, is causing unavoidable criticism. But the coming plan to implement a self-rating system for beginners and use TOPIK mainly to assess intermediate to advanced learners will need a point system to create an assessment with a single format. Also, to secure the convenience and fairness of the questions and execution, the method of using an item bank will need to be positively examined. But TOPIK underwent trial and error in developing an item bank, so the integration of a question pool method will be favored when supported by long-term planning and research.

A research study that analyzed the construct of TOPIK found a similar problem to the one mentioned above. In Yang Kil Seok, Min Kyung Seok, and Park Jung Jin (2012), empirical studies on each area of construct analysis and question formation was done to point out that the areas with high relativity, such as vocabulary and grammar and writing, need question formation reconsidered.

Such changes to TOPIK could lead to the growth of classroom assessments that extend to achievement assessments. Also, when a nationally accredited oral assessment test is developed, there is a possibility that a large part of its rating system or assessment standard will be applied to classroom assessments. Lee Junho's (2009a) investigation of the current situation of achievement assessment at the five largest Korean educational institutions uncovered the following problems.

In the case of Korean classroom assessment, performance assessments were not carried out properly and only assessed the learners' knowledge of the language rather than their ability. This is the result of evaluating their achievements based on a written test. In other words, performance assessments in Korean education are not actively carried out. Fourth, there is a tendency to exclude the learners' learning process from the assessment subject and to depend on formal assessments like midterms and final examination. This means practical learning activities that have a communication purpose and require the use of procedural knowledge are not being appropriately utilized.

Other problems include the lack of authenticity of an integrated assessment that promotes the overall use of language areas and skills, and assessments focused on a discrete-point test that measures every factor of language separately.

Conclusion

To summarize, assessment of Korean as L1 in the Republic of Korea emphasizes authentic use of the language as its basis along with the assessment of factual, inferential, critical, and creative thought processes for college entrance examinations. Assessment of Korean as a foreign language focuses on complete and full-scale communication assessments rather than fragmentary knowledge of the Korean language in terms of listening, speaking, reading, and writing.

Viphavee Vongpumivitch

National Tsing Hua University, Taiwan

Debi Jaratjarungkiat

Chulalongkorn University, Thailand

The Thai Language

Thai, also known as Siamese, is spoken by approximately 65 million people in Thailand. The Thai language focused on in this chapter is the dialect of Bangkok, the capital of the country. This dialect is the official language used by all government sectors, schools, and universities throughout Thailand, although regional dialects are spoken in various parts of the country.

Genetically, Thai is a language in the Southwestern branch of the Tai language family. It is a tonal language with 5 tones, 21 consonants, and 9 simple vowels. Typologically, Thai is a subject–verb–object language which places adjectives after head nouns in noun phrases and prepositions before noun phrases in prepositional phrases. There is no grammatical tense. The time of events is recognized from situational or textual context with the aid of time markers such as temporal nouns or adverbials.

Thai has its own alphabet. The letters are written from left to right, with vowel signs being placed above, below, or to the right or left of the consonants and tone signs being written above. There are no breaks between words or syllables, and one has to know the words to read correctly. Figure 126.1 illustrates a Thai phrase written in Thai which may be read in two ways, meaning either ‘too many cases’ or ‘passed closely away’, depending on where one places the word boundaries.

The Learning and Teaching of Thai

Thai as Mother Tongue

Thai is the language of instruction in all school subjects, except for English classes in some schools. Thai language courses are compulsory throughout the 12 years

The Companion to Language Assessment, First Edition. Edited by Antony John Kunnan.

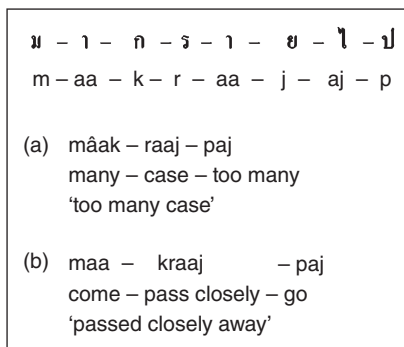

Figure 126.1 An illustration of a written phrase in Thai with two readings

of primary and secondary education (Curriculum and Instruction Development Section, Thai Ministry of Education, 2001, 2008). The goal of teaching Thai at school is to build students' ability to communicate effectively and think soundly. There seems to be some misunderstanding about the appropriateness of using group activities to enhance language skills which need to be practiced individually. A 2006 report by the Ministry of Education (Office of the Basic Education Commission, 2006) thus revealed that Thai students taking the national examination test did quite poorly in Thai writing and reading, proving that being a native speaker is no guarantee that one is a skilled user of the language. Yet, despite these disturbing test results, Thai language instruction receives no serious government support for either teaching or assessment in comparison to the teaching of English as a foreign language, and there is a particular shortage of good Thai language teachers in the provinces, where Buddhist monks and patrol policemen are occasionally forced to act as Thai language teachers by necessity.

Thai as a Foreign Language (TFL)

Thai is taught as a foreign language in several countries. Currently, the largest number of TFL learners is in the People's Republic of China (PRC), where Peking University was the first institute to offer Thai as a foreign language in 1946 (Fu, 2002). Since then, approximately 12–15 institutes in the PRC have started offering courses in Thai. In the southern part of China where Tai (not Bangkok Thai) is one of the minority languages, around 1,500–2,000 students learn Thai as a foreign language, a large number at Guangxi University of Minorities in Nanning and a smaller number in other institutes. Each institute that offers Thai as a foreign language prepares its own courses, textbooks, and achievement tests. Japan is another country where a significant number of people, both students and non-students, are studying Thai and could be interested in taking a test of Thai as a foreign language (Pojsatienkul, 2010; Japan–Thai Language Education Center, JTLEC, 2011). In other countries, such as the USA, Russia, several European countries, Southeast Asian countries, and Australia, Thai is studied as a foreign language to fulfill the requirements for tertiary education. In these countries, it is likely that only a small number of students take Thai with real interest.

Assessing Thai

Achievement Tests of Thai

In Thailand, achievement tests of Thai are given to measure whether a school student's proficiency in the Thai language is sufficient to allow him or her to move on to the next level. These tests cover knowledge of and ability in Thai literature, Thai grammar, and general language use. They are created by teachers in each school independently and therefore vary both in content and in standards. At the end of elementary school (6th grade), junior high school (9th grade), and senior high school (12th grade), students in all schools must take the national examinations in Thai language and literature developed by the Ministry of Education (MOE) (Curriculum and Instruction Development Section, 2001). As a part of these examinations, students' skills in reading and writing Thai are assessed. Due to the large number of students and the limited time allotted for grading, the examinations make use of multiple choice and short answer questions, which likely means that students' abilities to communicate effectively in written Thai are not being assessed accurately. This seems to be confirmed by the results of the Thai language proficiency tests given annually to first year students at Chulalongkorn University, which show that, of the three skills assessed—reading, writing, and listening—writing is the poorest, followed by listening and reading (Sirindhorn Thai Language Institute, 2005–10).

Assessment of the Thai language is given importance during university admission. Thai is a required subject for entry into all departments (Association of University Presidents of Thailand, AUPT, *n.d.*), therefore, the test of Thai receives serious attention from students. The contents of the entrance examinations reflect the MOE curriculum for the 10th–12th grades. Public opinion is that the entrance examinations devalue the regular learning in high schools, where several achievement tests have already been given. As a result, a number of ways for the school achievement test results to receive more weight have been suggested. However, until the school achievement tests are standardized for reliability and validity, the MOE “entrance examination” will have to be used as the preferred method for selecting university students.

Outside Thailand, where Thai is offered as a foreign language, achievement tests are given independently by each institute. Tests usually focus on speaking, listening, and writing, in that order. In some institutes, writing is only assessed via word dictation, that is, at the level of spelling.

Proficiency Tests of Thai

In contrast to achievement tests, proficiency tests of Thai have come to the attention of Thai academics only recently. The tests can be divided into proficiency tests for native and non-native speakers. It can be said that there were no proficiency tests for native speakers of Thai before the development of the Thai proficiency test by the Sirindhorn Thai Language Institute in 2008 (Sirindhorn Thai Language Institute, 2008). Similarly, proficiency tests for non-native speakers or for TFL learners are offered by very few universities offering Thai as a foreign language outside of

Thailand, for example, at the New York University School of Continuing and Professional Studies (NYU SCPS), USA (NYU SCPS, *n.d.*). In Japan, Thai proficiency tests are given by few private institutions such as the Association for Thai Language Certification (JTLEC, 2011). In Thailand, Thai proficiency tests for non-native speakers are, to our knowledge, given officially only by the Sirindhorn Thai Language Institute at Chulalongkorn University and by the Ministry of Education.

Thai Proficiency Test for Native Speakers of Thai The Sirindhorn Thai Language Institute can be said to be the first and the only institute which officially offers proficiency tests for native speakers of Thai. This “native test” takes approximately three hours and is a criterion-referenced test that covers listening, reading, and writing. It targets high school graduates, university students, and university graduates. In the listening test, test takers listen to three listening excerpts of various lengths from 2 to 10 minutes. The listening prompts range from monologues to interviews and group discussions. Multiple choice and short answer questions are used to assess ability to grasp important details and to identify main points and speakers’ purposes, attitudes, and opinions. Similarly, the reading test consists of 3 or 4 reading passages varying from 2–5 short paragraphs to 1–2 pages. The test takers are assessed on their ability to identify main points and important details and to read between and beyond the lines. Questions about important details are multiple choice. Questions assessing the ability to read between and beyond the lines make use of multiple choice and short answer formats. The writing test is in two parts and takes about one hour to complete. The first part, taking 20 minutes, assesses the test taker’s vocabulary level and ability to organize ideas. The second part consists of two writing tasks. The first task is to summarize the main ideas of a given text of approximately 120–150 words in length. The second involves writing an essay of approximately 300–450 words in length, expressing opinions on a topic provided. Two examiners grade each writing task using the following rubrics: task fulfillment, range of vocabulary and structures, organization and cohesion, register and formal features.

Results of past assessments indicate that test takers generally lack ability in identifying main ideas and significant details when reading texts, particularly more complexly structured texts. In writing, average performance on the rubrics for cohesion of ideas and selection of exact words to express ideas lies below level 3 out of a possible 5. Although the total score covering all three language modalities is used to gauge the test taker’s proficiency level, separate scores for each modality can be provided upon request. The scoring over the past four years indicates that, of the three modalities, writing is at the lowest level, followed by listening and reading (Sirindhorn Thai Language Institute, 2005–10).

The Sirindhorn Thai Language Institute is developing additional proficiency tests for native speakers in which each modality is examined independently. This is because most employers in Thailand only require certification of writing ability. This newly developed writing test includes two writing tasks at two different levels. The first task assesses the ability to write objectively, such as writing an instructional passage or a report. The second task assesses the ability to write persuasively or to present opinions convincingly. This type of writing assessment takes two and a half hours.

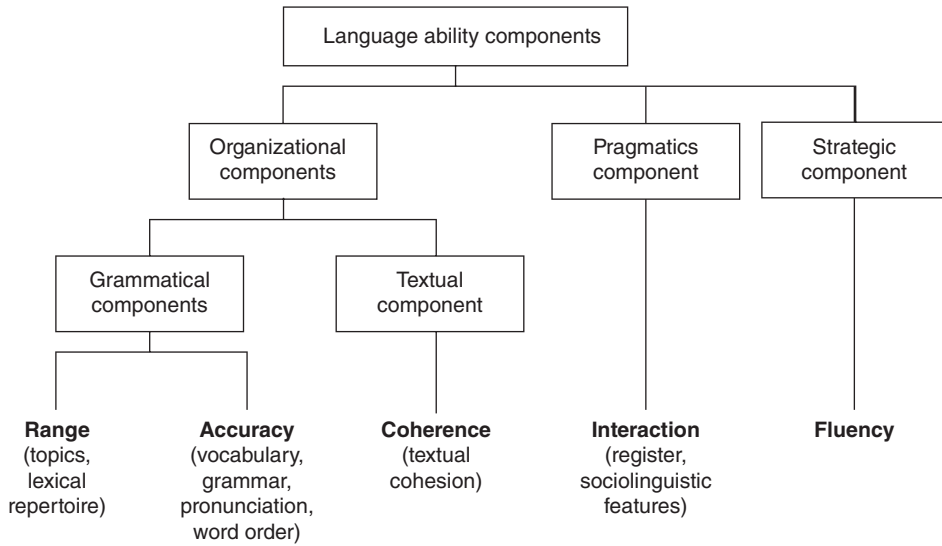

Figure 126.2 Components of language ability in the Sirindhorn Thai Language Institute’s Proficiency Test modified from Bachman’s (1990) model of language ability

Thai Proficiency Tests for Non-Native Speakers of Thai at the Sirindhorn Thai Language Institute: This is a criterion-referenced test covering all four modalities: speaking, reading, listening, and writing. Speaking is assessed separately and takes around 20–40 minutes depending on whether the test taker is allowed to take the second and third tasks of the test. The speaking test has been developed within the frameworks of the Interagency Language Roundtable (ILR) and Foreign Service Institute (FSI) (ILR, *n.d.*) and the American Council on the Teaching of Foreign Languages (ACTFL, *n.d.*). It measures the speaking modality via three selected communicative tasks: engaging in a face-to-face conversation, reporting opinions on a selected topic, and eliciting information about a selected topic in an interview and briefly summarizing the information at the end. These communicative tasks are used to reveal the test taker’s ability in five areas: range—the ability to speak on a variety of topics with suitable control of vocabulary repertoire; coherence—the ability to speak coherently and at length; accuracy—the ability to speak with accurate pronunciation and correct grammar; interaction—the ability to interact with ease; and fluency—the ability to speak fluently (see Figure 126.2). Using an analytical scale addressing each aspect, a holistic score is assigned to assess the test takers’ abilities at five levels: novice, intermediate, advanced, superior, and distinguished. A “plus” sublevel is assigned if performance in some abilities is at a higher level.

In the past four years, the majority of test takers have been Chinese students studying both in Thailand and in their own country. They take Thai as a foreign language and usually have the opportunity to stay in Thailand for three to six months. Most of them are fluent in face-to-face conversation and usually get rated only at the advanced level. This is probably due to their programs’ aim to produce competent tour guides.

The reading and listening proficiency tests take one hour each and are in the form of multiple choice questions assessing the ability to identify main ideas, to infer, to read or listen between and beyond the lines, and to comprehend abstract and complexly structured texts. Ability is also graded on a five-level scale with “plus” sublevels.

The writing proficiency test consists of two sections. The first part assesses the test taker’s ability to write a short letter or short notes using information provided. In the second part, the test taker writes an essay giving opinions on a certain topic. Ability is again graded on a five-level scale with “plus” sublevels.

The Thai Proficiency Test Issued by the Thai Ministry of Education: The National Institute of Education Testing Service under the MOE offers a Thai proficiency test called the “Test of Thai as a Foreign Language” (Bureau of Academic Affairs and Educational Standards, 2011). The test is given once a year and only to foreigners living in Thailand. It assesses four modalities: listening, reading, writing, and speaking. The listening test contains 48 multiple choice questions to be completed in 40 minutes; the reading test consists of two sections, general reading and academic reading, also in a multiple choice format and contains 48 items to be finished in 50 minutes. The writing test contains two parts, general writing and academic writing, to be finished in 50 minutes, and the speaking test consists of a 10-minute interview. Each part in this four-part test is scored separately with six possible levels. The first level, beginning, indicates a basic ability level with problems in communication. The second level, approximating lower elementary education, indicates limited ability in all four skills, probably at a survival level. The third level, approximately equivalent to upper elementary education level, shows limited command of grammar but fair communication skills. The fourth level is characterized by considerable communicative ability in Thai although mistakes are still made. The fifth level indicates a strong ability to use the language with command of situationally appropriate register. The sixth and highest level signals native-like ability.

Some Observations About the Sirindhorn Thai Language Institute’s Proficiency Test for Non-Native Speakers

In this section, certain points in the Sirindhorn Thai Language Institute’s Proficiency Test for Non-Native Speakers are presented in the hope that they will be useful for developers of proficiency tests for less commonly taught languages, where attempts to design such tests may not seem worth the effort and expense due to the small number of test takers.

Target Test Takers

The target group of the Sirindhorn Thai Language Institute’s proficiency test are non-native speakers of Thai regardless of academic background; test takers may be foreigners learning Thai in Thailand or elsewhere. At the lowest level, novice, test takers can hardly communicate using any language modality, while test takers at the highest level, distinguished, can communicate like an average educated native speaker using any modality.

Language Ability Specification

At the start of test development, Bachman's (1990) model of language ability was studied while generating the institute's language ability specifications. These components of language competence (Bachman, 1990, p. 87) were modified to form the general language ability framework of our tests.

Proficiency Levels

Our decision to grade test performance at five levels, novice, intermediate, advanced, superior, and distinguished, with a "plus" sublevel at each level except the highest, was influenced by the ILR/FSI and ACTFL scales. The comparison charts of the institute scale with the ACTFL and ILR/FSI scales show our attempt to set the established performance levels.

Table 126.1 Comparison charts between the Sirindhorn Thai Language Institute's proficiency levels and ACTFL scales and between the Sirindhorn Thai Language Institute's proficiency levels and ILR/FSI scales

<i>Sirindhorn Thai Language Institute's proficiency levels</i>	<i>ACTFL scale (2012)</i>
Distinguished	
Superior	Superior
Advanced	Advanced High Advanced Mid Advanced Low
Intermediate	Intermediate High Intermediate Mid Intermediate Low
Novice	Novice High Novice Mid Novice Low
<i>Sirindhorn Thai Language Institute's proficiency levels</i>	<i>ILR/FSI scale (2011)</i>
Distinguished	5 (functionally native proficiency) 4+ (advanced professional proficiency, plus) 4 (advanced professional proficiency)
Superior	3+ (general professional proficiency, plus) 3 (general professional proficiency)
Advanced	2+ (limited working proficiency, plus) 2 (limited working proficiency)
Intermediate	1+ (elementary proficiency, plus) 1 (elementary proficiency)
Novice	0+ (memorized proficiency) 0 no proficiency

Note. A plus sub-level is given if performances in some ability areas are higher than the base abilities of the same proficiency levels. For example, *Novice*plus* means that performances in the ability areas of the Novice level are not consistently high.

The test results report presented to test takers in both English and Thai includes descriptions of each proficiency level. An individual report is given for each modality.

Reliability and Validity Checks

As suggested in Brown (2005), measurement errors may arise from the testing environment; administrative procedures; scoring procedures; clarity, quality, and security of test tasks; and test-taker characteristics. The institute minimizes the first and second sources of error variance in test scores by standardizing the administration procedures and making sure that the testing environment is well equipped and suitable for testing performance in each modality. An administrative handbook has been created with a checklist of steps to be accomplished in the pretest, test, and post-test phases for each assessment. Also, for the speaking assessment, the whole test is recorded for quality control and future training uses. Additionally, to ensure clarity of task instruction, all test takers receive a Thai-English bilingual brochure that explains the purpose of each skill assessment. Then, before each test begins, test takers are questioned to make sure they understand what they are supposed to do.

To increase reliability of the scoring procedures, two raters trained in speaking and writing assessments first score the tasks independently based on the institute's rubrics and then discuss their scores to determine the test taker's proficiency level together.

In the reading and listening assessments, the score of each test section and the total score of the whole test are taken into account when determining the performance level of each test taker, to guard against the possibility of wild guessing in answers to multiple choice questions. If the two types of scoring disagree, the scores of the lower test sections in which performance is consistent are taken as decisive indicators of the test taker's final performance level. To ensure content validity, trialing of items is conducted to check all test items for bias, appropriateness for different proficiency levels, and item difficulty. Then, each assessment is followed by a validity evaluation and test item modification before the test items are placed in the test bank. Finally, at the end of every five-year period, a group of experts who are not on staff at the institute perform a crosscheck of content validity.

Rater Training

Standardization in testing and grading across raters and consistent performance by each rater are given a great deal of importance since they affect test reliability and validity. This is particularly important for speaking and writing assessments, where rater subjectivity is to be expected. At the Sirindhorn Thai Language Institute, testers and examiners involved with the speaking test and two raters in the writing test have to undergo a training program in which they learn techniques for elicitation when administering speaking tests and for grading both by total impression and by rubrics of both the speaking and writing assessments. They

must be certified by institute raters before they can do the rating. The certification is valid for three years, after which raters must undertake recertification.

Conclusion

Experience reveals several limitations in developing Thai proficiency tests for non-natives. Because Thai is a less commonly taught language, a relatively small number of people take the tests annually. This affects test development. In the first place, there are restricted resources to perform pretest procedures for each modality. Second, one cannot wait for test takers to come to Thailand to start giving the test. Examiners need to practice to achieve rating consistency. Also, the tests have to be put in use so that feedback is available for refining the tests, scoring rubrics, and scoring procedures. Content validity must also be checked for improvement. The Sirindhorn Thai Language Institute decided to utilize resource locations in other countries. This necessitated supporting budget and cooperation from partner organizations abroad. These limitations were the first hurdle for the Institute to overcome. In the long run, the Institute will have to offer online testing.

The most difficult aspect of developing the reading and listening tests was selecting suitable texts. Many texts were proposed but rejected because, although they were genuine and interesting, they did not provide for sufficient test items. An hour-long test in reading and listening cannot include too many texts. Genuine texts for listening tests that have clear acoustic effects and contents that are neutral with respect to test takers' cultural backgrounds are not easy to find. For the writing and speaking assessments, raters must be trained to avoid bias for or against a test-taker's fluency and ignoring to check his or her competence in other language knowledge.

In a developing country where the native language is a less commonly taught language, serious pursuit of first language or foreign language assessment is not usually considered worth the effort in terms of either expense or time, even if the benefits of such assessment for education are recognized. In Thailand, interest and financial support fluctuate from government to government. To develop standardized language test forms in such a situation requires a great deal of courage, continuing effort, and unflinching determination on the part of the development team. The experience of the Sirindhorn Thai Language Institute's assessment development team is that, despite the hardship, the effort was worthwhile since it has inspired a group of young Thai academics to learn by doing how to develop "reliable and valid tests." If this interest and determination do not fail, it can be hoped that the assessment of Thai will flourish in the land where it is needed most.

Assessing Mandarin Chinese

Luxia Qi

Guangdong University of Foreign Studies, China

Kai Zhang

National Education Examinations Authority, China

Introduction

Chinese, the official language of China and one of the official languages of Singapore, is spoken in mainland China, Taiwan, Hong Kong, Macao, and Singapore. It is also spoken by people who learn Chinese as a second language all over the world. In all these Chinese-speaking areas, it is assessed for educational purposes and in the workplace as a first language (L1) or a second language (L2). This chapter gives a short introduction to teaching and assessing Chinese both as L1 and as L2, but focuses on the assessment of Mandarin Chinese as a first language in mainland China because L1 speakers form the largest group of Mandarin learners. A brief description of the language along with its teaching, learning, and assessment is presented, followed by a discussion of assessment issues and challenges.

Description of Mandarin Chinese

Chinese (*Hanyu*) is one of the many branches of the Sino-Tibetan family of languages. It consists of regional dialects that are mostly mutually unintelligible in the spoken form, but its writing system, using characters rather than an alphabet, unifies speakers of various dialects. The common dialect that serves as the lingua franca is Mandarin or *Putonghua*, a standardized variety of Chinese developed from the northern dialect, one of the major dialects of Chinese spoken in the areas north of the Yangtze River. The phonological system of Putonghua is based on the Beijing dialect and the grammar is standardized in conformity with the literary works written in modern Chinese.

The basic phonological unit of Putonghua is the syllable, which consists of an initial consonant, a vowel, and a final consonant in some cases; and the tone,

Introduction

Chinese, the official language of China and one of the official languages of Singapore, is spoken in mainland China, Taiwan, Hong Kong, Macao, and Singapore. It is also spoken by people who learn Chinese as a second language all over the world. In all these Chinese-speaking areas, it is assessed for educational purposes and in the workplace as a first language (L1) or a second language (L2). This chapter gives a short introduction to teaching and assessing Chinese both as L1 and as L2, but focuses on the assessment of Mandarin Chinese as a first language in mainland China because L1 speakers form the largest group of Mandarin learners. A brief description of the language along with its teaching, learning, and assessment is presented, followed by a discussion of assessment issues and challenges.

Description of Mandarin Chinese

Chinese (*Hanyu*) is one of the many branches of the Sino-Tibetan family of languages. It consists of regional dialects that are mostly mutually unintelligible in the spoken form, but its writing system, using characters rather than an alphabet, unifies speakers of various dialects. The common dialect that serves as the lingua franca is Mandarin or *Putonghua*, a standardized variety of Chinese developed from the northern dialect, one of the major dialects of Chinese spoken in the areas north of the Yangtze River. The phonological system of Putonghua is based on the Beijing dialect and the grammar is standardized in conformity with the literary works written in modern Chinese.

The basic phonological unit of Putonghua is the syllable, which consists of an initial consonant, a vowel, and a final consonant in some cases; and the tone,

namely, the way the sound goes up or down, which conveys meaning and differentiates the many homophonic words in Chinese. For example, in Putonghua, which has four tones (high level tone, rising tone, low-falling-rising tone, and falling tone), the syllable *ma* pronounced in the four tones can mean “mother”, “rough”, “horse”, and “scold” respectively. But the tones of words are not fixed and they change in utterances according to the adjacent words.

The basic unit of the vocabulary system in Chinese is the word, which comprises one or more morphemes. Monomorphemic words can be used freely or as a composing part of compound words (Cao, 2003). For example, the word *meihao* “really good” consists of two morphemes, *mei* and *hao*, which can be used separately as two words: *mei* “beautiful” and *hao* “good”. Most of the basic words in Chinese are monosyllabic with a single morpheme or disyllabic with two morphemes. Many multisyllabic multimorpheme words are proper nouns like *zhonghua renmin gonghe guo* “the People’s Republic of China” or loanwords like *bishengke* “pizza hut”.

In terms of grammar, Chinese differs from inflectional languages like English, one distinctive feature being that it has no inflectional changes, that is, no morphological changes occur no matter what grammatical function the words serve (Zhu, 1985). For instance, the Chinese verb *pao* “run” has no change in its form in a sentence or utterance, no matter whether the subject is one person or two people or whether they run every day or they ran yesterday. Therefore, as in English, word order is important in Chinese because it indicates grammar and meaning differences. The basic word order is similar to that in English, that is, subject–verb–object and modifier–modified. However, in some cases word order in Chinese is flexible. For instance, the sentence “I don’t eat mutton” can be uttered in two different word orders in Chinese, *wo bu chi yangrou* “I don’t eat mutton” or *yangrou wo bu chi* “Mutton I don’t eat” (Zhu, 1985, p. 2). Another way of indicating grammatical differences in Chinese is the use of individual words. For example, to indicate that something has already been done or has happened, the word *le* is used in Chinese while in English the main verb has to be in the form of the present perfect tense.

Written Chinese uses characters as its basic building blocks which are composed of strokes like the horizontal stroke (一), the vertical stroke (丨), the hook (丿) and so on. Each character represents one syllable of spoken Chinese that may be a word or a component of a polysyllabic word.

In the 1950s, *pinyin*, an alphabet based on Roman letters, was developed in mainland China with the purpose of popularizing Putonghua. The Chinese pinyin system, consisting of 26 letters, overlaps with the English alphabet, the only difference being that pinyin does not have the letter *v*, but includes an umlaut letter, *ü*, that is not found in English. With the help of pinyin, speakers of Chinese can learn the pronunciation of unfamiliar characters and words.

Teaching and Learning Mandarin

L1 Teaching and Learning in Mainland China

In mainland China, Chinese as L1 education is divided into the basic phase and the higher phase with the former covering the stages of primary and middle school education (12 years) and the latter higher education (4 years). Throughout

the country, Chinese courses in schools are designed according to the National Chinese Curriculum issued by the Ministry of Education (2004) in Beijing. The goal of teaching is twofold: first, to help students master the language as a tool for communication and, second, to help them develop as a whole person with a good moral character and a positive outlook on life. Accordingly, the teaching objectives are centered on this twofold goal. For example, in the module “reading and appreciation,” students learn to read not only for obtaining information but also for appreciating great works in Chinese and world literature. They read texts of all genres, including descriptions, instructions, essays, novels, and poems. It is hoped that through reading students will learn to appreciate the cultural legacy of China and the world and cultivate their ability to find truth and pursue the ideal of beauty.

Another module is “expressing and communication,” in which students learn to develop their oral and writing skills. They are required to write or speak not only to pass on information but also to express their own ideas and thoughts. To sum up, Chinese courses are not restricted to the teaching of the linguistic system (sound, characters, vocabulary, and grammar). They are designed to help students develop the ability to use the spoken and written language to communicate effectively and the capacity to think logically, analytically, and critically.

In the higher phase of Chinese education, there is no unified curriculum. Each college or university designs its own courses, but they are all called College Chinese and are taken by all students as a general course distinguished from Chinese courses offered to students who major in Chinese. The College Chinese course in most colleges and universities teaches classical and modern Chinese literature as well as world literature, with the purpose of furthering students’ communicative skills and accomplishments in Chinese.

L2 Teaching and Learning in China and Other Countries

Chinese is taught to speakers of other languages as a second or foreign language in China and in other countries. In China, it is taught to students of minority nationalities whose native language is not Mandarin. It is both a school subject and medium of instruction. For example, in the Xinjiang Uyghur Autonomous Region, students start to learn Chinese in the first year in primary schools, and in the third year they start to learn some subjects like math and physics in Chinese while learning other subjects in their native language (Li & Cao, 2009). The teaching objectives and content are similar to those of teaching Chinese as L1 (see the section above). However, there are some differences, one of which is that listening and speaking are emphasized in Chinese teaching as L2 whereas such skills receive less emphasis for L1 students. Another group of students who learn Chinese as L2 in China are foreigners who come to learn Chinese or other subjects at universities in China. For these students, the main teaching objective is to help them develop the ability to communicate in Chinese.

Outside China, Mandarin Chinese is offered as a school subject and as a university major or minor in local schools and universities in some countries. It is also offered as a language course in Confucius Institutes and Confucius Classrooms run jointly by Chinese universities and local universities in many countries.

By the end of 2010, there were 322 Confucius Institutes and 369 Confucius Classrooms in 96 countries (Hanban, *n.d.*).

Assessment of Mandarin

L1 Assessment in Mainland China

Assessment of Mandarin Chinese for educational purposes includes classroom-based assessments like midterm and final examinations as well as large-scale standardized tests such as those conducted at the end of junior and senior middle schooling. The results of these large-scale tests are used, together with tests in other subjects like math and English, to make decisions concerning whether a student will go on to senior secondary school or university. Such tests are highly competitive because only those students whose scores rank high among the test takers can meet the requirements of being promoted to a higher grade in education. As for classroom-based assessment, the National Chinese Curriculum prescribes use of formative assessment like portfolios as a supplement to traditional quizzes and tests. At the tertiary level, no unified assessment of Chinese is conducted. Instead, assessment is based on what is taught in the Chinese courses offered at individual colleges and universities.

The most important standardized test of Chinese in mainland China is considered to be the University Entrance Chinese Test (UECT). With differences in content and format, different versions of the test are administered in the country. One version used in 15 provinces is developed by the National Education Examinations Authority (NEEA) under the Ministry of Education in Beijing. Other versions are produced by the local educational exam authority of provinces and metropolises (e.g., Beijing, Shanghai) for their own use. Because of limited space, only the NEEA version is described here. This test measures test takers' knowledge of pronunciation, grammar, and vocabulary as well as reading and writing skills. Knowledge is tested by true-or-false and multiple choice items. The reading comprehension section includes texts in both classical and modern Chinese and comprehension is tested through multiple choice items, short answer questions, and translation from classical to modern Chinese. Test items in the writing section include gap-filling, sentence writing, and essay writing. Prompts for the essay writing can be a topic, a situation, or a picture. In the 2010 test, a picture is employed. It depicts four cats sitting at a table eating fish. One of them is trying to catch a passing mouse and another says contemptuously to the other two, "It still tries to catch a mouse when it has fish on its plate." The instructions read, *yuedu xiamian de tuhuacailiao, genju yaoqiu xie yipian bushaoyu 800 zi de wenzhang*. "Look at the picture below and write an essay of at least 800 characters based on it." The students are allowed to choose a genre and give a title themselves (National Education Examinations Authority, 2011).

In the workplace, a large-scale Chinese test in mainland China is the Putonghua Shuiping Ceshi (Standard Spoken Chinese Proficiency Test), whose purpose is to popularize Standard Chinese and to provide certification for some professions, such as teachers and radio or TV announcers. The test lasts for 15 minutes during which a test taker reads aloud some Chinese words and texts, makes a short speech on a certain topic, and makes judgments on the correctness of some words

and phrases in front of two examiners. Test results are reported as levels, including Level 1-A (the top), Level 1-B, Level 2-A, Level 2-B, Level 3-A, and Level 3-B (the lowest). Different professions might require a certificate of different levels. For a TV announcer, for example, a certificate at Level 1-A is required.

L2 Assessment in Mainland China and Other Countries

Chinese is assessed as L2 in schools or at universities where students learn it as a second or a foreign language. Such assessment is classroom based and students are assessed on what they learn in the courses. Distinct from classroom-based assessment, there are four standardized Chinese tests for L2 learners. The first is the L2 Chinese Test for University Entrance (L2CTUE) taken by students of minority nationalities at the end of senior middle schooling. This is the equivalent to the University Entrance Chinese Test (UECT) for L1 students. As such, these two tests share the same purpose and have similar content and test methods, though some differences exist.

The second standardized Chinese test is the Hanyu Shuiping Kaoshi (HSK), a proficiency test of Mandarin Chinese designed for non-native speakers of Chinese. It is managed jointly by the China National Office for Teaching Chinese as a Foreign Language (Hanban) and Confucius Institute Headquarters. Having gone through several reforms, the current HSK consists of two tests, a written test and an oral test. The former has six levels, Level 1 being the lowest and Level 6 the highest. Each of these levels has a can-do description of what candidates at this level can be expected to do with Mandarin, which is comparable to the levels in the Common European Framework of Reference (CEFR). For example, HSK-1 is equivalent to A1 in CEFR while HSK-6 is equivalent to C2. The oral test has three levels: elementary, intermediate, and advanced (Hanban, *n.d.*). This test is administered at 180 test centers in 60 countries around the world (Hanban, *n.d.*). The purpose of HSK is to provide a certificate of Mandarin proficiency which can be used for applying for university studies in China or for employment purposes by any L2 speaker of Mandarin. Therefore, in some provinces or minority nationality autonomous regions, this test is used as an alternative to L2CTUE. In other words, middle school graduates in those regions can choose to take either the L2CTUE or the HSK-3 when applying for higher education in China.

The third standardized Chinese test is the Business Chinese Test (BCT), developed by Peking University under the auspices of Hanban to assess the Chinese proficiency of non-native speakers who are engaged in business. The fourth test is the Youth Chinese Test (YCT), a standardized test of Chinese language proficiency for primary and secondary school students who learn Chinese as a second language. This test is developed and managed by Hanban.

Language Assessment Issues Related to Assessment of Mandarin Chinese

Some key issues related to assessment of Chinese are similar to assessment issues in other languages such as English. These have to do with whether a test or a task measures what it is intended to measure (validity), whether rating of

assessment performances like speaking and writing is consistent and accurate (reliability), and whether assessment exerts a positive or negative influence on teaching and learning (washback) (Hughes, 2003). These issues are discussed in this section.

Indirect Assessment of Productive Skills

In mainland China, most discussion about assessment quality involves large-scale tests. For instance, scholars question using multiple choice items to test standard word pronunciation and the correct writing of characters in the UECT. They doubt whether correct choice necessarily means the test taker can pronounce the word correctly or write it in the correct way (Lu, 2006; Huang, 2011). This raises the validity issue of an indirect test format, or selected response items, like true-false, matching, and multiple choice employed to test productive skills. It is generally believed that more direct testing or constructed response assessments like short answers, speaking, and writing are better options to “measure productive language use as well as the interaction of receptive and productive skills” (Brown & Hudson, 1998, p. 661). In the above case, asking the test takers to actually speak and write the characters would provide a more valid measure of their capacity to do so. Thus, some scholars go to the extreme and claim that the best way of assessing Chinese is essay writing and that alone suffices for a Chinese L1 test (Wang, 2010).

As for the HSK, even more multiple choice items are used. In HSK-6, for example, the test paper consists of 100 multiple choice items assessing knowledge of Chinese as well as listening and reading skills and only one summary writing task intended to assess the ability to write in Chinese. Thus the validity of that test is also questioned (Gao, 2012).

Keeping a balance between selected response items and constructed response items is necessary as both types have their advantages and disadvantages. One disadvantage of the constructed response items is that rating can be difficult, especially for large-scale assessment.

Rating Problems

Rating of constructed response items in Chinese assessment proves to be problematic. The rating of the UECT, for example, is a demanding job every year because of the limited time allowed, about 10 days, and the huge population of test takers, approximately 9,330,000 in 2011 (NetEase, 2011). Each year after the test, all the answers are scanned into computers and those to the selected response items are marked by computer while those to the constructed response items are marked by human raters onscreen. Since inaccurate and inconsistent rating cannot be avoided in human rating, and will affect reliability, various means have been used to reduce it. With rating guidelines, raters receive training before rating. Each constructed response is double marked and the central system monitors the rating process for quality control. Harsh or lenient raters or raters whose scores are not normally distributed are retrained. Some extremely poor raters have been fired. In spite of this, problems still exist. It was found that some raters did not rate

according to the guidelines as they were not familiar with them even after training (Cai & Lou, 2008). This is not unique to the UECT, as discrepancies between scores for the same test taker given by different examiners were also found in the Standard Spoken Chinese Proficiency Test (Song, 1998). Thus, how to ensure that the score given to each response is fair and accurate remains a key issue in assessment of Chinese in mainland China.

Influence of Assessment on Teaching and Learning

Whenever assessment results are used to make important decisions and have serious consequences, tests or other forms of assessments exert influence or washback on teaching and learning (see Chapter 68, Consequences, Impact, and Washback). This is true of the UECT in mainland China because the results determine whether test takers will receive higher education and are often used by schools to evaluate teachers as well. Therefore, starting from Senior One in the middle schools teachers teach toward the test and students will learn for the purpose of getting a high score in the test (Lu, 2006; Li, 2011). This, in consequence, narrows the curriculum and restricts teaching methods and learning activities. Furthermore, it makes students lose interest in learning Chinese (Lu, 2011). Such test-oriented teaching and learning have aroused heated debates and severe criticism of the university entrance tests including the UECT in mainland China, which is considered to be an obstacle to quality education by some authors (Pan, 2005).

In the case of assessing Chinese as L2, although not much discussion about washback is found in the literature, some scholars have noted the issue. Yan and Zhao (2000) doubt the effectiveness of teaching and learning if they are targeted just to what is required by the HSK.

Challenges

Possibility of Automated Scoring of Constructed Response Items

One big challenge for Chinese assessment remains the formidable task of rating constructed responses, especially essays. The same is true of essay rating in English assessment. To increase rating efficiency and reliability, various automated English essay-scoring systems have been developed (Valenti, Neri, & Cucchiarelli, 2003). Similarly, in the Chinese assessment context, research on automated essay scoring is also conducted. Chang, Lee, and Chang (2006) tried a new method of including Chinese figures of speech as a distinctive feature to score essays, and found it increased the efficiency of the Chinese automated essay-scoring system. Applying Latent Semantic Analysis to automated scoring of Chinese essays by senior middle school students, Cao and Yang (2007) found that the scores by computer and by human raters achieved a correlation of 0.55. Although there is still insufficient research, it is hoped that in future Chinese automated essay scoring systems might serve as a supplement for human rating to enhance the efficiency and accuracy of rating in Chinese assessment.

Narrowing the Gap Between Teaching Objectives and the Content of Assessment

Another challenge is the gap between the objectives of Chinese teaching and what is assessed in Chinese tests at various levels in the education system. As mentioned previously, the objectives of Chinese teaching include helping students to develop as a whole person with a good moral character and a positive outlook on life. It is not clear thus far whether assessments have been effective in finding out how successful Chinese teaching is in achieving these objectives. Furthermore, the National Chinese Curriculum prescribes the components of assessment, which include learning processes and methods, and feelings and attitudes towards learning, among others. Scholars doubt whether these components can be assessed accurately and reliably (Tu, 2009). Thus, it is advocated that some of the components, like feelings and attitudes towards learning, should be assessed through formative assessment such as continuous assessment and portfolio assessment rather than standardized tests and examinations (Tu, 2009).

In fact, in recent years formative assessments like portfolios of Chinese have been practiced and experimented with in more and more schools in mainland China. Although there exist numerous problems, such as being time consuming, adding extra burdens to teachers and students, insufficient and inappropriate means being taken to implement them, and so forth, it is believed that with more research and practice formative assessment can be improved and applied to the assessment of some objectives of Chinese courses which cannot be assessed through traditional tests (Zhang, 2011). It is to be hoped that testing and formative assessment will complement each other to enhance the quality of assessment of Chinese both as L1 and as L2 in China and around the world.

This chapter was supported by a grant (12&ZD224) from the China National Social Sciences Funding Program.

Assessing Australian and New Zealand Indigenous Languages

Gillian Wigglesworth
University of Melbourne, Australia

Peter Keegan
University of Auckland, New Zealand

Introduction

Despite their close proximity, there are substantial differences between the indigenous populations, and the indigenous language situations, in Australia and New Zealand. The 2006 census in Australia reports that the indigenous population makes up 2.3% of the total population, that it is younger (median age 21) than the general population (median age 37), and more likely than the general population to live in remote or very remote locations (25% of Australians living in remote locations are indigenous). Conversely indigenous Australians make up only 1% of the urban population (Australian Bureau of Statistics, 2012). As discussed in more detail below, Australia once played host to a great diversity of languages, many mutually comprehensible, and many spoken by only small numbers of people.

In contrast, the Māori population (around 14% of the total population) is more predominantly urban, with 85% now living in urban areas (Statistics New Zealand, 2007) and the majority domiciled outside their traditional tribal regions. Those still living in rural areas usually have high contact with their “city cousins” and, in most cases, travel to urban areas is not difficult and does not take a great deal of time. Unlike Australia, New Zealand’s small size and well-developed transportation and communications network mean that small rural Māori communities can no longer be regarded as isolated. Māori is and was the only indigenous language spoken throughout the two islands.

It is to a great extent these differences that contribute to the very different linguistic environments we find in each country.

Description of the Languages

Australia

Indigenous Australians live either on the mainland (Aboriginal people) or in the Torres Strait (Torres Strait Islanders). At the time of European settlement, Australia boasted over 250 distinct indigenous languages from two distinct language families: Pama Nungyan and non-Pama Nyungan. Many of these languages were spoken by only a few hundred people, while others were spoken by larger groups. Two hundred years later, it is estimated that only around 20 of these are being learned by children as a first language with the remainder either having become extinct or being in the process of extinction. McConvell and Thieberger (2001) suggest that by 2050 no indigenous languages will be spoken in Australia. Even the languages with the most speakers have fewer than 3,000 speakers. Assessing language endangerment is therefore a critical issue for Australia.

Although Australian languages exhibit many different grammatical features, there are also some similarities across languages. Australian languages tend to be morphologically complex, agglutinating languages. In other words, grammatical information is expressed within words rather than through separate grammatical items, such as articles, prepositions, and auxiliary verbs; nouns inflect for many cases (Koch, 2007), so that word order becomes less important compared to European languages where word order frequently determines the grammatical relations.

Australian languages manifest similarities with each other at the phonological, syntactic, and lexical level. Phonologically, Australian languages have either three or five vowels, and lack voicing contrasts and fricative phonemes (Koch, 2007). Grammatically, in addition to the features outlined above, these languages tend to be either suffixing or prefixing with a highly inflected noun phrase; number expressed as singular, dual (inclusive or exclusive), or plural (again inclusive or exclusive); and a complex verbal system. Lexically, Australian languages have extensive vocabularies, and in particular they have a wide range of reference with respect to environmental terms, kinship terms, and terms denoting space and direction, which reflects the importance of these concepts.

In Australia today, intergenerational transmission occurs in only around 20 communities, and many indigenous people now speak a new mixed language or a variety of an English-lexified creole (often labeled Kriol),¹ Australian Aboriginal English, or Standard Australian English. Particularly in the more rural communities, either the traditional language (where spoken) or a form of Kriol is the language of everyday use.

New Zealand

In stark contrast, New Zealand has only one indigenous language, Māori (with little dialectal variation). Together with English and New Zealand Sign Language, Māori is an official language of New Zealand. As a result, the linguistic ecology is significantly different from that of Australia, with Māori the second most widely spoken language in New Zealand apart from English.

Recent estimates of the number of speakers of Māori consist of the 1996 national census, which included a question on “what language(s) could you have a conversation about a lot of everyday things.” The question was repeated in 2001 and 2006. Tragically, a major earthquake in Christchurch in March 2011 resulted in the postponement of the 2011 census until 2013. The 2006 census reported the number of speakers of Māori as 157,110 (approximately 28% of the 565,329 people who identify as Māori).

Two national surveys of Māori language commissioned by Te Puni Kōkiri (Ministry of Māori Development) were undertaken in 2001 and 2006. These surveys involved administered questionnaires on all four areas of language use (speaking, writing, reading, and understanding). The 2001 national survey involved a sample of approximately 5,000 adults (those 15 years and over) and in 2006 the sample was 3,858. The 2006 national survey suggested that 14% of the Māori population were able to speak Māori very well (i.e., were very fluent speakers of Māori).

Other important indicators of the health of the Māori language include the number of students attending Māori-medium programs in early childhood education (ECE) and the compulsory school sector. The number of *kōhanga reo* (ECE centers based on Māori culture and using Māori as the medium of communication) and students peaked in the mid-1990s, with some 14,000 students (approximately 40% of all Māori students in ECE) attending 819 *kōhanga reo*. There has been a steady decrease since then to around 9,300 students and 470 *kōhanga reo* in 2010 (approximately 25% of all Māori students in ECE). The number of students in Māori-medium education in the compulsory school sector peaked in 1998 at 28,962 (approximately 15% of all Māori students). The number has slightly decreased since then to 27,532, students (approximately 14% of all Māori students).

Teaching–Learning Contexts

Australia

Children growing up in indigenous communities in Australia, particularly in remote areas, are not necessarily exposed to English until they enter the formal school system. In their early years, children receive a variety of language inputs in their communities, which are often multilingual and may to varying degrees include the local indigenous language, several indigenous languages, one of the new mixed languages, Kriol, Australian Aboriginal English, and Standard Australian English. When children begin to enter the school system, they enter a system in which Standard Australian English (SAE) is the language of instruction, and they often enter a system which has very limited awareness of the children’s language knowledge and assumes that they will speak SAE. There is often limited recognition of the complexity of their language background and a lack of cultural understanding (Moses & Wigglesworth, 2008). While indigenous children may not have fluent SAE when they enter school, they are likely to speak fluent Kriol or, in a few communities, the traditional language (Kelly, Nordlinger, & Wigglesworth, 2010). By not understanding the extent to which children can

use their indigenous language, we are far from understanding the extent of their language knowledge in general, and the importance of language for cultural identity cannot be underestimated. As Klenowski (2009) argues, even when the language is no longer being passed on from one generation to the next, elements of the language are incorporated systematically into the spoken language and this serves to distinguish its speakers linguistically and culturally, and to enhance their group identity and to retain their distinctiveness as has occurred with many varieties of Kriol across northern Australia.

In the context of the Australian educational system, the fate of indigenous languages has been subject to various government policies which have changed over time, with policy makers seeing bilingual education as leading to a lack of fluency in Standard Australian English. In 1972 the government recommended the preservation of indigenous languages and cultures (Rhydwen, 2007). There was a small increase in the number of bilingual schools after this but, in 2008, Northern Territory government policy effectively banned bilingual teaching by declaring that the first four hours of schooling in each school day should be conducted exclusively in English. This was based on the claim that children in bilingual schools were not reaching levels of English commensurate with indigenous children in English-only schools as measured through the NAPLAN (National Assessment of Proficiency in Literacy and Numeracy) test, introduced in 2008 and mandated across the country at Grades 3,5,7, and 9. Although this policy has now been overturned, it has had deleterious consequences for bilingual education in the Northern Territory.

Over 80 indigenous languages are taught in Australian schools, with around 16,000 indigenous student enrolments and 13,000 non-indigenous student enrolments between 2006 and 2007 (Parliament of Australia, 2012, p. 52). At the tertiary level, there is only very limited teaching of indigenous languages. Yolngu Matha is taught at Charles Darwin University; Pitjantjatjara can be taken intensively at the University of South Australia, and a one-semester unit in Gamilaraay is offered at the University of Sydney.

New Zealand

Māori language has been well established in the New Zealand education system. It has a long history of being taught as a subject from primary to tertiary level. The Māori-medium education sector, noted above, is well known internationally. The compulsory school sector has Māori-medium curriculum statements which are equivalent to those used in the English-medium sector. Curriculum support materials are funded by New Zealand's Ministry of Education. Māori is taught as a subject in all New Zealand universities and *wānanga* (modern Māori tertiary institutes focusing on Māori learners and Māori content).

There are community-based initiatives, such as the well-known Te Ataarangi movement, which began in 1979 and offers courses throughout New Zealand. Many tribal groups have a long history of teaching Māori to tribal members during the weekends and school holidays, both in urban areas and in traditional tribal regions requiring members to travel back to their traditional tribal homelands.

Assessment Practices

Australia

The assessment of indigenous language can take two quite different forms. The first relates to the health of the indigenous languages as a whole with a view to determining whether and to what extent the indigenous language/s is/are endangered. The second is related to the first, but involves the assessment of the indigenous language knowledge of individual members of a community for academic content or job skills. While the latter type of assessment may be carried out through a variety of means, it occurs only minimally in Australia.

Assessing the health of a language means determining how many people and what age groups speak that language. Self-report (e.g., through the census or some other means) is frequently used, but the results are in part determined by the question which is asked. For example, as McConvell and Thieberger (2001, pp. 40–1) point out, the question “Does the person speak a language other than English at home?” (with a space for the language name to be written after the question) may elicit quite a different response from “Can you speak an indigenous language?” The question used in the New Zealand census is likely to elicit yet another response: “In which language(s) could you have a conversation about a lot of everyday things?” (New Zealand Census, 2006).

McConvell and Thieberger (2001, pp. 53–4) propose a relatively straightforward scale for assessing the degree of endangerment of a language and suggest that a more elaborate instrument could be developed once more systematic data on the language proficiency of its speakers were available (see Table 128.1).

Clearly, assessing the degree of endangerment of a language is a complex process. The UNESCO report on language vitality and endangerment (2003) suggests there are nine factors which need to be taken into account in order to assess the vitality of a language. First, the language must be passed from one generation to the next. Second is the importance of the absolute number of speakers, which should be compared to the transmission factor and to the third factor, the proportion of speakers in the total population. The fourth factor concerns language use—where, with whom, and for what purpose the language is used. The remaining factors revolve around how languages respond to new domains, the availability of resources for language and literacy education, community and government attitudes and policies related to the language, and the extent and quality of the

Table 128.1 Recommended language endangerment indicator (McConvell & Thieberger, 2001, p. 54)

Age	<i>Strong</i>	<i>Endangered (early stage)</i>	<i>Seriously endangered</i>	<i>Near-extinct</i>	<i>Extinct</i>
5–19	Speak	Don't speak	Don't speak	Don't speak	Don't speak
20–39	Speak	Speak	Don't speak	Don't speak	Don't speak
40–59	Speak	Speak	Speak	Don't speak	Don't speak
60+	Speak	Speak	Speak	Speak	Don't speak

language documentation. In sum, the assessment of language vitality ideally takes into account a wide range of factors, all of which contribute to developing a picture of the extent to which a language may or may not be endangered.

At the individual level, there are many reasons for developing ways of assessing indigenous language knowledge. McGroarty, Beck, and Butler (1995) point out that the assessment of such skills has the potential to raise the prestige of indigenous languages in the formal educational system, and well as providing a method for determining language skill and ability which may otherwise be overlooked. In the Australian context, children often have some limited knowledge of their local indigenous language, but they may not be fluent speakers or speakers who use the language on a daily basis (although there are, as noted above, some communities where the indigenous language is being transmitted across generations). In addition, indigenous languages often do not have a tradition of literacy instruction. In such situations, assessing the oral knowledge of the indigenous language may be useful both for determining the strength of the language and for identifying what is known about it for the purposes of revitalization programs in the language. However, as Jones and Campbell Nagari (2008) argue, assessment is not straightforward and is often more complex than assessing language in a non-indigenous context. As they point out, children will often have only a passive knowledge of the indigenous language and so the assessment of comprehension, rather than production, becomes important. Testing comprehension is not trivial because the child's response to each item has to be inferred, and this may have implications for the reliability and validity of the item (Jones & Campbell Nagari, 2008). However, to date the assessment of indigenous language knowledge remains very limited.

New Zealand

Māori children growing up in New Zealand are all exposed to New Zealand English (NZE). For the majority, this is their dominant language and exposure to Māori is largely through Māori-medium education programs, ECE and the compulsory school sector (Year 1 to Year 13), and the media, including Māori TV. New Zealand linguists agree that some Māori (and in some cases non-Māori) speak a variety of NZE termed Māori English, which is reported to be increasing. Although there are differences in phonology, pragmatics, lexicon, and rhythm (Maclagan, King, Gillon, 2008), differences are not sufficient to hinder communication or understanding.

The first attempt at assessing the language ability of students in Māori-medium education was the 1984–5 New Zealand Council for Educational Research evaluation of eight nascent bilingual schools set up in the late 1970s and early 1980s (Benton, 1985). Five tests were used to obtain a comparative measure of how well the students could speak, read, and write Māori. These consisted of a Māori picture vocabulary test, a listening comprehension task, a short oral question and response test, an oral reading task, and a storytelling task using a set of pictures as a stimulus. The students at the original bilingual school, Rūātoki, performed much better (on the basis of their median score) than those of other schools. Benton (1985, p. 11) suggested that this was due to a higher level of community support

for Māori language and more intensive use of the language in the classroom as a medium of instruction.

The Ministry of Education developed and standardized a Māori version of the School Entry Assessment (SEA) or *Aro Matawai Urunga-a-Kura* (AKA), consisting of three tools: Checkout/*Rapua* (numeracy), Concepts about Print/*Ngā Tikanga o te Tuhi Kōrero* (literacy), and Tell Me/*Ki Mai* (oral language) in both English and Māori (Ministry of Education, 1997a, 1997b).

Since the 1990s, a number of language assessment instruments have been developed locally by practitioners, research groups, and providers of professional learning for the Māori-medium sector (Rau, 2005, 2008; May & Hill, 2008). The University of Waikato has developed a test battery to measure the Māori language proficiency of 150 Year 5 and Year 8 students in Māori-medium education (Crombie, Houia, & Reedy, 2000). The test has become known as the *kaiaka reo* or “language proficiency” project, and consists of four parts: listening, reading, writing, and speaking.

Edmonds, Roberts, Keegan, and Houia (2011), under contract to the Ministry of Education, have revised the *kaiaka reo* speaking task and rating scale using a further sample of over 170 Māori-medium students in Years 1 to 8, collected in early 2010. This involved 70 Māori-medium teachers participating in a series of marking workshops (i.e., rating samples of students’ oral language).

AsTTle (assessment tools for teaching and learning) is a computer-based educational resource for assessing reading, writing, and mathematics through the medium of both Māori and English. This tool was developed for the Ministry of Education by the University of Auckland. AsTTle’s Māori-medium assessment items were developed within the framework of the Māori-medium curriculum. Test items were trialed from 2001 to 2004. The Māori-medium sample consisted of over 8,000 Māori students in Years 4 to 11. This was the largest sample of data ever gathered on Māori-medium students. All test items were developed and trialed by Māori-medium teachers.

Recent larger-scale developments such as asTTle and *kaiaka reo* have used sufficiently large samples to permit test statistics to be calculated using item response theory (i.e., modern test theory approaches). Issues such as reliability and validity have been examined, and the tasks used have been developed by experienced Māori-medium teachers and Māori language experts cognizant of the need to work in relevant Māori cultural frameworks and modern communicative approaches to language assessment.

Future Directions

Australia

Assessment of indigenous languages in Australia is in its infancy, but there is increasing interest in ways of assessing this language knowledge. Indigenous people themselves want to know how much of their traditional language is being learned by children, and there is a need to better understand how and why some languages are still being transmitted while others are not. Speech pathologists are

recognizing the importance of assessing all aspects of a child's language—not how much English they speak and understand. There is increasing awareness of the importance of using qualified interpreters in formal situations, particularly with indigenous Australians. It is to be hoped that the future will see increasing focus on assessing indigenous languages.

New Zealand

Assessment of Māori in New Zealand consists of a small number of standardized tools and a number of practitioner-based initiatives for students in Māori-medium education (i.e., in the school sector), all of which would benefit from further development and refinement. There is a dearth of assessment resources for second language learners and adult learners of Māori. It is widely recognized that assessment tools will be very beneficial to ongoing efforts to revitalize Māori and ensure its future survival.

Assessing Māori Indigenous Language Learners

Cath Rau

Kia Ata Mai Educational Trust, New Zealand

Introduction

In early 2008, the Ministry of Education in Aotearoa/New Zealand released *Ka Hikitia—Managing for Success* (Ministry of Education, 2009a), a Māori education strategy that prioritized the actions required for the ensuing four years in order to achieve better outcomes for Māori learners than those learners (and their predecessors) have experienced in the school system to date. Aotearoa/New Zealand has an international reputation for providing a high quality education system. The education system in this country, however, also produces academic outcomes that are less equitable for particular groups of students, including Māori learners.

In 2009, the newly elected National Party Government made good on their promise to introduce national standards in Aotearoa/New Zealand on the premise that these would set clear expectations of performance, provide the basis for clear and plain language reporting to parents and, as a consequence, raise student achievement.

National standards (NS) for reading, writing, and mathematics were developed for year 1 to 8 students (kindergarten to grade 7–8) learning either primarily or exclusively from the New Zealand Curriculum in English. A year later (Ministry of Education, 2010) the development of the Māori-medium expression of national standards—*Ngā Whanaketanga Rumaki Māori* (NWRM) began. NWRM are derived from *Te Marautanga o Aotearoa* (Ministry of Education, 2008), the curriculum designed specifically to support learning and teaching in Māori-medium classrooms. NWRM have created both opportunities and challenges for Māori-medium educators in referencing the performance and achievement of year 1 to 8 learners in Māori language programs against national expectations in *Pānui* (reading), *Tuhituhī* (writing), *Kōrero* (speaking), and *Pāngarau* (mathematics).

Description of the Language

An independent panel convened by the Minister of Māori Affairs in 2010 was tasked with inquiring into and reporting on the state of the Māori language. Referring to the scale of language development provided by UNESCO in 2009, the panel positioned the Māori language somewhere between definitely endangered and severely endangered, using intergenerational transmission as the defining criterion. The nature of the interruption to the generational transmission of the Māori language and the compensatory measures to address this language crisis are such that the numbers of children with proficiency in *Te Reo Māori* to ensure its survival are not adequately replacing the quickly diminishing numbers of senior native language speakers.

Coinciding with the panel's inquiry was the release by the Waitangi Tribunal of a pre-publication chapter of the *Wai262* report in October 2010. It declared that the government's agenda to support the growth and development of the Māori language was no longer working. This finding was attributed to falling numbers participating in state-funded Māori language initiatives in both the noncompulsory education sectors (early childhood and tertiary) and compulsory sectors (primary school—kindergarten to 11th grade.)

The Waitangi Tribunal (2011) in the full *Wai262* report acknowledge that an overreliance on schools, education, and the state to rescue the language will not secure its future and an upscaling in localized responses by Māori is required. *Iwi* (tribal groups) need to mobilize their efforts and focus on dialectal protection and revitalization because dialect is central to identity and expressions of that identity. A scan of the tribal landscape indicates that *iwi* are not yet giving priority to nor adequately investing the time, energy, expertise, and funding required even when they have the fiscal means to do so, as a result of settlements with the Crown involving substantial monetary compensation.

The most recent statistics, collated from the July 1, 2010 school roll returns, reveal that Māori represent just under one quarter (23.2% or 110,229 students) of the total student population (475,114 students) in schools from years 1 to 8. The vast majority of Māori students (90,184 or 82%) are in English-medium programs while the balance, 18% (or 20,045 Māori students), are in some form of Māori-medium education. Four levels of immersion or bilinguality are defined in the Aotearoa/New Zealand context based on the percentage of time the teacher instructs in the Māori language rather than the percentage of time students might be using the Māori language in the classroom (see Table 128.1). Of note is the fact that for most learners (and teachers for that matter) the Māori language is a second language.

Teaching and Learning Contexts

A diverse range of programs in various settings has evolved in Aotearoa/New Zealand. Some of these programs reflect different philosophical positions about language, culture, and education (Hohepa & Rau, 2011). These include *Kura*

Table 128.1 Number and percentage of students in Māori-medium education in 2010

<i>Programme description</i>	<i>Level of immersion in Māori</i>	<i>No. of Māori students enrolled in 2010</i>	<i>% of Māori in Māori-medium education</i>	<i>Total %</i>
Immersion	Level 1 (81–100%)	3,753	18.0	33.7
	Level 2 (51–80%)	3,273	15.7	
Bilingual	Level 3 (31–50%)	3,910	18.8	66.3
	Level 4 (0–30%)	9,908	47.5	

Kaupapa Māori, established under Section 155 of the Education Act (1989), where programs are based on *Te Aho Matua* philosophy (a particular set of Māori principles, perspectives, and values); *Kura a iwi*, established under Section 156 of the Education Act (1989), where the philosophy is based on the practices, language, and history of particular *iwi* or tribal groups; and *Kura Māori*, which under the same section of the Act, are recognized as special (Māori-medium) character schools.

Most level 1 (81–100%) Māori immersion programs deliver the curriculum by providing instruction exclusively in Māori in year 1 (kindergarten grade) and then introducing English language instruction later in year 4 (grade 3) or beyond. *Te Reo Pākehā* (formal English language instruction) appears as a learning area in the current Māori-medium curriculum (*Te Marautanga o Aotearoa*) for the first time. Where previously the provision of formal English language instruction has been voluntary, its inclusion in the Māori-medium national curriculum now makes it a requirement.

In level 2 (51–80%) immersion programs, English and Māori tend to be used interchangeably within the same classroom by the same teacher. This might occur within a lesson (English and Māori), or across lessons (English or Māori). These immersion classes are usually situated within English-medium schools and teachers are often trying to navigate two distinct curricula and assessment schedules to meet the sometimes competing expectations of non-Māori school managers and Māori parents.

The limited use of the Māori language for instruction in level 3 and 4 bilingual programs means students do not become sufficiently proficient in the Māori language to carry out academically demanding tasks in that language but can (and do) experience an increased sense of (Māori) identity and improved attitude to school and learning. Most assessment practices in these classrooms measure performance in the English language (Rau, 2009).

Assessment Practices

The most active area in assessment and achievement development in Māori language schooling is the compulsory sector catering for years 1–8 (kindergarten to 7th grade), precipitated by the recent implementation of national standards in 2010. This is reflected in the Ministry of Education's current work program,

Mātaiako (Ministry of Education, 2011a), which is concerned with providing mechanisms for schools teaching from the Māori-medium curriculum *Te Marautanga o Aotearoa* (and therefore referencing student performance against NWRM) to enable them to build richer evidence bases to support teaching and learning than has hitherto been possible. A number of initiatives are being rolled out to support the *Mātaiako* agenda, including the alignment of assessment tools which may include further iterations of current assessment tools and the development of new ones.

National standards in Aotearoa/New Zealand differ in important and fundamental ways from international approaches to standards-based accountability policies and practices. In the USA, the 2001 No Child Left Behind Act (NCLB), while designed to make schools more accountable for student learning and, by implication, to raise educational performance, has left indigenous (heritage) language programs vulnerable. National testing is exclusively carried out in English, thereby penalizing those indigenous students for whom academic competence is best demonstrated in their indigenous (strongest) language. According to McCarty (2009, p. 7), NCLB has proven to be “one of the most problematic education reforms in US history,” in many cases intensifying doubts about the need for instruction in native language and culture (Wyman et al., 2010) and, at worst, providing an argument for their elimination. There is little evidence that improved learning, either tangible or “illusionary,” for indigenous students has occurred as a result of the introduction of NCLB (McCarty, 2009). Conversely, where fewer concessions and compromises to indigenous language revitalization efforts occur, the results for students are far more promising, as evidenced in the Hawaiian (McCarty, 2009) and the Alaskan examples (Wyman et al., 2010).

While the US example is characterized by reliance on a single achievement measure (in English), in contrast a strong assessment for learning focus means that the Ministry of Education in Aotearoa/New Zealand and the teaching fraternity at present deems (singular) national testing as inappropriate.

Furthermore, where students are primarily learning in the Māori language (albeit for most their second language), the expectation is that assessment practices should capture performance in the language of instruction (which is Māori). Strong advocacy for multiple sources of evidence to be used when referencing performance against either NS or NWRM requires that teachers make an overall judgment by collapsing the information they gather from a variety of sources in order to arrive at a singular, discrete judgment in relation to benchmarked performance. Moderating teacher judgment becomes necessary for consistency and reliability, a practice that is still relatively novel for teachers of year 1 to 8 students in Māori-medium settings and will, for the short term at least, stretch professional capabilities because of its “newness” and attendant workload issues.

NS and NWRM also differ from international examples because the genuine intention is to distribute resources (monetary or in the form of expertise and resourcing, or both) to assist and support schools and ultimately learners to achieve rather than to impose penalties for underperformance.

There are also fundamental differences between NS and NWRM. A literal translation of *Ngā Whanaketanga* is “progressions”, signaling that a value-added component is as important (if not more important) in determining whether a student has reached an acceptable level of performance. While NS has set bench-

marks based on age that are highly aspirational and do not necessarily reflect what most students can do, NWRM use a time in immersion measure which directly accounts for the opportunity a student has had to engage with the Māori-medium national curriculum and the likely performance based on that engagement.

Challenges

A criticism leveled at national standards is that they could become the default curriculum in English-medium and Māori-medium settings, with teaching efforts focused on narrowed sets of skills and knowledge from the NS and NWRM. This might lead to the wider sets of skills and knowledge required to function well in the mathematics and literacy learning areas being treated too lightly or ignored altogether, with the added possibility that other important learning areas such as *Toi* “arts”, *Tikanga a Iwi* “social sciences”, *Pūtaiao* “science”, etc., will become casualties. Narrower definitions of what constitutes achievement and success are a real possibility.

The “hard” evidence-based culture that has quickly developed around national standards and assessment in general will make it more difficult for Māori-medium educators to validate the use of “intuitive and sensory information,” a practice that is being argued for a draft Aromatwai position paper commissioned by the Ministry of Education (2011b).

The potential for national testing using a single test, like the US example created from the NCLB policy could still become a reality, particularly if educators, and teachers in particular, do not manage well the use of multiple sources of information to make judgments about performance. In many ways this has to work because the alternative is even more unacceptable, and the current government is unlikely to abandon national standards.

The Ministry of Education has stipulated that programs based on the New Zealand Curriculum report against NS while programs based on *Te Marautanga o Aotearoa* report against NWRM. These guidelines haven’t necessarily made the decision about which to use any clearer for teachers in some level 2 Māori-medium programmes. The suggestion is that one or the other be used but, in some level 2 immersion classes, the literacy programme is delivered in the Māori language from *Te Marautanga o Aotearoa* while the mathematics programme is delivered in English from the New Zealand Curriculum. Confusion about what (if any) derivations from the guidelines are possible has yet to be addressed. The expectations in NWRM are also based on the performance of students who have been learning in level 1 in immersion programmes. The extent to which the same expectations apply for students who differ from this profile (i.e., students in level 2 immersion programmes or students who are late enrollments into level 1) is untested.

Future Directions

Prior to the advent of NS, and coinciding with the implementation of NWRM, two important policy documents (both in draft) have been developed. They are

important because they attempt to contextualize assessment using a Māori frame. *Te Tīrewa Mātai* (Ministry of Education, 2009b) proposes a framework for describing student achievement in Māori-medium settings on a national scale that is far more expansive than is possible in a development such as NWRM and far more ambitious than earlier attempts at monitoring achievement in these settings. The framework re-emphasizes that any national monitoring of achievement in Māori-medium settings should be sensitive and responsive to linguistic issues, contribute to fulfilling Māori aspirations for language regeneration and cultural transmission, and value *matauranga Māori* (Māori knowledge, Māori epistemology).

The draft position paper on *Aromatawai* (Ministry of Education, 2011b) argues that the Māori term *aromatawai* is not synonymous with the English term “assessment”, and that understandings and practices around *aromatawai* and assessment are shaped by the respective learning, linguistic, and cultural contexts for which and from within which they function. An *aromatawai* approach means applying and making use of all of the senses to understand and connect with the learner, and not just assessing what the learner knows or can do. This creates leverage for Māori-medium educators to explore and further validate these ways of “knowing” learners.

Provision for the development of localized curricula gives schools and their communities license to select and co-construct learning contexts and experiences that give the national curriculum relevancy for their children. Likewise graduate profiles give expression to the values and attributes those communities desire for their children that schools are also expected to nurture. These are important levers that are yet to be fully explored so that much richer and broader profiles of achievement are possible than those reflected in current assessment practices including national standards. Both *Te Tīrewa Mātai* and the draft *Aromatawai* position paper emphasize the potential for families and school communities to contribute valuable assessment information in this broader approach.

All of these developments signal new challenges but, more importantly, new directions and opportunities in assessment and teaching and learning for Māori-medium settings that mean the overarching aim expressed in the education strategy *Ka Hikitia*—where Māori enjoy success as Māori—can be realized.

Assessing Armenian

Rubina Gasparyan

American University of Armenia, Armenia

Mirtsa Halajyan

Assessment and Testing Center, Armenia

Introduction

Armenian is one of the oldest languages in the world and the state language of the young Republic of Armenia (RA). It has two variants: Eastern Armenian and Western Armenian. Eastern Armenian is spoken in the RA. Western Armenian is the language of the large Armenian diaspora, which is spread all over the world—mostly in Russia, Europe, and the United States.

Armenian is a required subject in schools and colleges in the RA and is assessed regularly. Since the state language of the Republic of Armenia is Eastern Armenian, this chapter concentrates on the description and assessment practices of Eastern Armenian as the language of the home country of all Armenians. An overview of the assessment practices of Armenian in educational programs and in real-world settings is provided.

The chapter also addresses the imperative of creating new school tests in general and the high stakes Unified School Leaving and University Entrance (USL&UE) test of Armenian in particular. The reason for this choice of emphasis is the importance of the USL&UE test, in areas and respects that will be explained further. The authors also discuss the challenges of assessing Armenian and give recommendations on the basis of research conducted by the Assessment and Testing Center (ATC) of the RA.

Description of Armenian

Armenian is one of the oldest languages in the world. It is classified as an independent branch of the Indo-European language family. Many scholars claim that it evolved from this common ancestral language in the third millennium BC

(Mikaelian, *n.d.*). The history of written Armenian started in the fifth century AD, namely in 405, when Mesrop Mashtots created the Armenian alphabet. After that date, Armenian scholars and writers have left a very rich written heritage. Some of the oldest manuscripts are kept in Matenadaran, an institute and museum of ancient manuscripts in Yerevan.

The history of Armenian as a literary language is divided into three periods: old Armenian, from the 5th century to the 11th; middle Armenian, from the 12th century to the 16th; and modern Armenian, from the 17th century to the present. Due to historical circumstances, in the 19th century Armenia was divided between the Ottoman and Russian empires. This resulted in the development of two linguistic variants: Western Armenian and Eastern Armenian. In addition to these two variants, Modern Armenian recognizes some 40–60 living dialects. It must be noted that native speakers of Armenian face no difficulty in understanding written or oral production either in the two main variants or in the dialects.

To understand the structure of the Armenian language, it is important to briefly describe Armenian phonology, orthography, lexicology, morphology, and syntax. In some cases we will draw comparisons with the English language in order to provide a better understanding of some aspects of Armenian.

Armenian has 36 phonemes and 39 letters. The alphabet is phonetic—in other words each letter corresponds to a phoneme. There are only three exceptions: *n* [vo]; *Է* [ye]; and *և* [yev]. In these three cases the letter denotes two or three phonemes. The direction of writing is from left to right. All the letters have capital and small letters. The phonetic system has 6 vowels—*u*, *o* (*n*), *ու*, *ը*, *է* (*t*), *ի* [*a*, *o*, *u*, *ə*, *e*, *i*]*—*and 30 consonants—*լ*, *ր*, *ն*, *յ*, *ւ*, *ն*, *բ*, *գ*, *դ*, *ա*, *զ*, *վ*, *զ*, *ղ*, *պ*, *կ*, *տ*, *ս*, *ժ*, *ւ*, *չ*, *խ*, *հ*, *փ*, *ք*, *թ*, *գ*, *չ* [*l*, *r*, *rr*, *y*, *m*, *n*, *b*, *g*, *d*, *dz*, *j*, *v*, *z*, *zh*, *d*, *p*, *k*, *t*, *ts*, *tj*, *f*, *s*, *sh*, *kh*, *h*, *ph*, *kh*, *t*, *ts*, *ch*].

Over the centuries, orthographic rules evolved as a result of phonetic modifications. Since there are words that sound different in many dialects, unified spelling rules are employed, in an effort to streamline orthographic rules with traditional forms.

The Armenian stress is stable and always falls on the last syllable of the word in its basic, dictionary form. However, when suffixes or endings are added and modify that form, the stress remains on the same syllable, which is now the penultimate one. The stress may fall on all the vowels except for [ə].

Modern Armenian has approximately 300,000 words. According to Ajaryan (Աճարյան, 1979), the main borrowings of the Armenian language are from Persian, Greek, Arabic, Assyrian, Turkish, Georgian, and Russian. However, according to Sukiasyan (Սուկիասյան, 1989), thorough analyses show that most of the borrowings either have become obsolete or have been replaced by Armenian equivalents.

Modern Armenian is considered overall a synthetic language, though it also has many inflected forms. It has ten parts of speech: nouns, verbs, pronouns, adjectives, adverbs, numerals, conjunctions, connectors, interjections, and modal words.

Semantically, the Armenian noun can be divided into the following categories: proper and common; definite and indefinite; personal and nonpersonal; animate and inanimate. It has the grammatical categories of number (singular and plural) and case (nominative, genitive–accusative, locative, ablative, and instrumental).

It must be noted that the definite article (English *the*) is expressed in Armenian by *ը* [ə], added to the end of the noun in nominative and genitive only. The indefinite article (English *a*) is expressed by the zero article. Armenian has no grammatical gender.

Adjectives have two types: qualifying and classifying. Qualifying adjectives have degrees of comparison. Adjectives have no grammatical categories unless they are used as nouns. They are usually placed before the noun.

There are four types of numerals: ordinal (first, second); cardinal (one, two), distributive (one by one, in fives), and fractional (one fifth). Numerals have no grammatical categories unless they are used as nouns. Neither the adjective nor the numeral changes form as a result of agreeing with the noun in case and number; as in English, they remain unchanged.

The main types of the Armenian pronouns are: personal, demonstrative, reciprocal, relative–interrogative, definite, indefinite, and negative.

The verb is the only part of speech that has unity of form. All the indefinite forms end either in *-ել* [-el] or in *-ալ* [-al], and changes during conjugation are conditioned by the endings of the verb. Armenian has regular and irregular verbs, and the verb has three voices: neutral, active, and passive. The passive is formally characterized by the passive suffix, which differentiates this voice from the other two.

The verb has independent and dependent participles with different functions in a sentence. For example, an independent participle can be used as a subject or an object of the sentence, while the dependent participle is used with the auxiliary verb “to be” to form a verbal predicate. Some tense forms are formed with the help of the auxiliary verb “to be,” which determines the person and number. Other tense forms require no auxiliary verb and are formed by adding an ending to the root of the verb. For example, the Armenian past simple takes no auxiliary and shows not only the tense, but also the person and the number. Consider the verb “to go” (*gnal*): in the past simple tense, its forms are *gnatsi*, *gnatsir*, *gnats*, *gnatsink*, *gnatsik*, *gnatsin*, whereas the past indefinite of the same verb is formed with the help of the participle and the auxiliary “to be”: *gnum ei*, *gnum eir*, *gnum er*, *gnum eink*, *gnum eik*, *gnum ein*. In the past indefinite the person and the number are shown by the auxiliary verb.

The remaining parts of speech, namely adverbs, conjunctions, connectors, interjections, and modal words remain unchanged in form.

Unlike the English sentence, the Armenian sentence has a free word order. The main syntactic rules governing the Armenian sentence are as follows. The predicate has to agree with the subject in number; the declension of the object is conditioned by the meaning and/or the voice of the verb.

Teaching, Learning, and Assessment of Armenian in Schools, Colleges, and the Workplace

Teaching and Learning Armenian

The importance of the Armenian language is twofold. It is not only a compulsory subject in schools and colleges and a required component for admission to many universities and departments. It is also regarded as the means that helped

Armenians to maintain their identity through difficult historical periods and pass their cultural heritage to generations. Today the importance of Armenian is emphasized by the fact that knowledge of it is assessed both in educational programs and in real-world settings.

The educational system in Armenia is undergoing certain developments, one of them being the transition from an 11-year school system to a 12-year one. In schools, Armenian is taught in grades 1 through 12, in accordance with the document called State Curriculum and Standards of the Armenian Language and Literature, developed by the National Institute of Education. Learners are taught and tested on the rules of orthography and phonology, word formation and meaning, morphology and syntax. They also learn how to write compositions and reproductions. Armenian literature, which includes the rich heritage of both Western and Eastern Armenian, is taught in grades 7 through 12.

Assessment of Armenian in Schools, Colleges, and the Workplace

As Bachman (2004) states, the results of assessment in educational programs “are most commonly used to describe the processes and outcomes of learning for the purposes of diagnosis or evaluating achievement, or make decisions that will improve the quality of teaching and learning of the program itself” (p. 6). The tests of Armenian in schools are designed in an attempt to meet these requirements.

A brief account of the assessment practices employed in making judgments about learners’ proficiency levels in Armenian is provided below, with an emphasis on assessment in schools.

Assessment types in schools differ on the basis of the grade and requirements of the curriculum. Students are tested on their knowledge of Armenian throughout the whole period of schooling and take achievement tests at the end of every grade of elementary school (grades 1–4), middle school (grades 5–9), and high school (grades 10–12). They take both formative and summative tests, which range from quizzes and multiple choice tests to essays and compositions.

In schools, Armenian is assessed both internally and externally. For internal assessment, teachers create tests according to the set guidelines and samples provided by the ATC. At the end of each term and school year, students are evaluated on the basis of their daily oral answers, quizzes, and tests. The tests, ideally, should reflect the school curriculum of Armenian developed by the National Institute of Education (for more information, see www.aniedu.am).

External assessment is conducted through centralized tests developed by the ATC. These tests are administered in all the grades, as a tool for making decisions about the curriculum and the ways it is taught and tested. In addition, the purpose of external assessment is to supervise the process of grading in schools, as the results of these tests are correlated with the students’ grades. The test results, however, do not count toward the grades obtained at the end of the year but serve mostly as research tools for the ATC.

Below are some examples of how different language elements are tested in schools. The usual techniques employed to test orthography are multiple choice,

gap-filling (c-tests), or dictations that test spelling in general. (A c-test is a test where a certain number of letters are missing in some of the words and the student has to fill in the gaps on the basis of context.)

Teaching lexicology includes word formation, meaning (direct and figurative), synonyms, and antonyms. This knowledge is tested mostly indirectly, through written production. As Armenian is rich in phraseological units, it is important to differentiate between the use and meaning of phrases and the use and meaning of word combinations. This is tested through multiple choice items and the weight given to the item may vary depending on its difficulty and the number of steps taken to answer it.

The knowledge of syntax and morphology is tested either orally, through discussions of theoretical aspects, or in written form, through multiple choice items or written production. Multiple choice items may include questions that test either application or theory.

Writing ability is tested through guided or independent compositions and is an integral part of the school curriculum of Armenian. The ATC is currently developing samples of rubrics for written production tasks, in an attempt to introduce uniformity in grading productive skills. Such types of tasks, however, are not included in the USL&UE test for several reasons, which will be explained in the next section. Instead, issues related to meaning, cohesion and coherence, or organization, are tested through multiple choice questions of the following type: "Which of the following sentences contradicts the information in the text?"

It must be mentioned that, although the testing of literature is mainly done orally, to assess students' ability to analyze literary text and characters, this ability is also tested through multiple choice items.

This very brief presentation shows that school tests employ a variety of techniques that, hopefully, allow test developers to create items that address a wide variety of language elements. Besides, these tests help learners to get practice with different types of assessment tools, develop critical thinking skills, meet the challenge of the high stakes USL&UE test, acquire better knowledge of Armenian, and, eventually, be ready for college and real-life tests.

It must be noted that there is no centralized approach to teaching or testing Armenian in colleges or universities. The depth of teaching Armenian in those institutions is conditioned by the requirements of a particular department. Armenian is taught more thoroughly in languages and humanities departments. The forms of assessment are not streamlined and may vary.

The need to have good knowledge of Armenian is currently being emphasized by a recent requirement that tests be taken in some governmental institutions and banks of Armenia: in those institutions both employees and new applicants need to submit themselves to an examination. Since this practice is new, no relevant research has been conducted and no official results have been revealed. One could, however, assume that the measure is dictated by the need for employees to pay more attention to their productive skills, especially writing, because the ability to write reports in Armenian is in very strong demand in many institutions.

Assessment Practices

The USL&UE Test of Armenian

The USL&UE test of Armenian is developed by the ATC established in 2004 as a step toward meeting international standards in the field of education in general and of testing and assessment in particular. The responsibilities of the ATC include creating assessment tools that are relevant to the school curriculum, piloting those tools, and conducting research on the basis of the results.

The USL&UE test of Armenian, which replaced the centralized state admissions examination in 2007, has set new standards for formative and summative assessment practices in schools. It is a high stakes test, and it is taken for admissions purposes in most educational institutions of Armenia. Therefore it is important to discuss some of the difficulties and challenges encountered in the process of developing the test, as well as the solutions adopted on the basis of analyses conducted by the ATC. This discussion is also intended to function as an awareness-raising tool, given that, except for brief and superficial accounts in the media or in ATC short reports that have not been open to the public, no attempt has yet been made to address the issue of the USL&UE test of Armenian.

The USL&UE test consists of two sections: section A, which is a graduation requirement for all school leavers; and section B, which, together with section A, is an admissions requirement for a number of higher educational institutions. Section A is an achievement test with 50 items addressing different aspects of Armenian language and literature covered in school. Section B includes 30 complicated items that test the test taker's overall proficiency in all those aspects.

One of the important conditions stated by the ATC and the Ministry of Education and Science of Armenia (MoES) for the USL&UE test was objectivity; and it was eventually agreed to secure objectivity through multiple choice items and scoring machines, and thus by eliminating human involvement or judgment. Guidelines for the test have been published every year since 2007; these guidelines reflect all the changes made on the basis of research conducted by the ATC. The sample tests are constantly being piloted and moderated, and only afterwards are parallel tests being developed for admissions purposes. To understand the developments and challenges of the test, it is worth comparing the results obtained from 2007 until 2010.

The statistical data of the research on the USL&UE exams of Armenian in 2007–10 reveal a high reliability coefficient for all the tests (see Table 129.1):

Table 129.1 Statistical data of the tests of Armenian for the period 2007–10

<i>Year</i>	<i>Number of test takers</i>	<i>Mean (out of 20)</i>	<i>Test reliability coefficient</i>
2007	14862	14.4	0.90
2008	13814	13	0.93
2009	12378	11.4	0.91
2010	10754	11	0.89

It may be observed that the mean score was lower in 2010 than in all other years. The comparison between the data related to the mean and the data related to test difficulty shows that, if the tests were relatively easy in 2007, when the test difficulty coefficient was 0.72, they were of medium difficulty in 2010, which had the test difficulty coefficient of 0.55 (ATC report, 2010).

One of the most important outcomes that the various analyses of the tests have led to is related to item writing. This is in fact a very important issue, as test developers gradually began to attach more importance to the theory behind item-writing practices. During these four years, some types of MC (multiple choice) items proved to work well, others needed more elaboration. To understand this, let us discuss a few examples.

The initial decision envisaged that section B should be a more complex reflection of the school curriculum and should include items that tested the applicants' overall proficiency; in consequence, the test developers have been in constant search of ways of securing the difference between sections A and B. In 2007 the decision was to give five options in each item, thus reducing the percentage of guessing to 20%. However, according to the ATC report of 2007, distractor analyses and item discrimination showed that several items in the tests contained very weak distractors and did not discriminate adequately between high and low scorers (Գնահատման և թեստավորման կենտրոն, 2007). This came to prove that it was very difficult to write plausible distractors and that very often the fifth distractor simply did not work. The claim that the "optimum number of response options for foreign/second language testing should be four" (Coombe, Folse, & Hubley, 2007, p. 25) may hold true for native language tests as well.

As a result of the 2007 analysis, the number of options for section B was established as four for the tests of the period 2008–10. However, a different type of item was introduced, as the test developers believed that complicated tasks eliminated the opportunities to guess by negation and allowed test takers to think critically. For example, section B, item 58 of the Unified School Leaving and University Entrance Test of the Armenian Language and Literature in 2009 (*Հայոց լեզու և գրականություն*, 2009) asks: "To how many of the words provided can the given suffix be added to form a new word?" Ten words are provided. The student has to count the words that can take that suffix and mark the option they consider to be the correct answer in the answer sheet (e.g., 1 five words; 2 six words; 3 all the words; 4 four words). If the student has all the correct answers except one, instead of receiving a point for each correct answer, he/she will lose a whole point for only one incorrect answer in the row. To put it simply, if the student chooses option (1) because he/she knows five words formed with the help of a given suffix, yet according to the key there are six words, the student will receive no score, even if he/she knows five of the words. According to the ATC report of 2009, items similar to this one did not meet the purpose of eliminating guessing, even though they could not be answered by negation. The data revealed that those items did not discriminate appropriately between high-scoring and low-scoring students. Therefore, to make such items serve their purpose, a change was proposed: the words had to be enumerated, and the stem should ask the test taker to write the correct word number in the space provided in the answer sheet. In this way the test taker would receive a point for each correct answer.

The test also included several items of the following type: “In the suffix of which of the following words is there a sound interchange?” The test taker had to find the suffix, then find the sound interchange, and then choose the best answer among those provided in the options. The fact is that such items, with multiple steps, create artificial difficulties. What is more, they do not eliminate guessing.

Although according to the USL&UE report of 2010 the test had medium difficulty (0.55) and high reliability (0.89), there are many instances of items that need serious consideration and improvement. Even though the general understanding is that MC tests seem to serve their primary purpose—that is, objectivity—and in this particular case they show high reliability, the test developers believe that some serious changes need to be introduced. This judgment is based on several considerations discussed below.

Challenges and Future Directions

Since the discussion above was mostly related to school tests and to the USL&UE test of Armenian, this section formulates several challenges that teachers, educators, and test developers face in regard to assessing Armenian. Some of those listed below may seem simple. However, taking into consideration the relatively young history of testing practices in Armenia, their importance can hardly be overestimated.

First of all, the MoES and the ATC need to put in considerable effort in streamlining school tests and the USL&UE test of Armenian. Although school programs may still employ assessment types that include production, high stakes tests such as the USL&UE test of Armenian employ MCQs (multiple choice questions) whose main goal is objectivity. However, taking into account the shortcomings of MCQs—which test knowledge only at the recognition level, restrict the choice of what can be tested, or facilitate cheating (Hughes, 1989)—this technique should not be the dominant one in a test. Items that test productive skills should be included, appropriate rubrics should be developed, and types of training designed to establish rater reliability need to be organized.

Second, interesting and detailed though the ATC reports on the USL&UE test of Armenian may be in terms of reliability, item discrimination, and distractor analyses, they include no discussions or data on validity in general and on content validity in particular. Hence judgments about the match between assessment content and instruction content have no solid evidence to support them.

Further, to streamline assessment practices, ATC could develop alternative and traditional assessment forms not only for schools, but also for colleges and other institutions. This would give learners of Armenian a clear understanding of what the main goals and requirements of learning and assessing Armenian as L1 are.

Last, but not least, it is important to gather information about practices of assessing Armenian in the large Armenian diaspora and to join the efforts of all the stakeholders toward better tests, better assessment, productive teaching, and effective learning.

Assessing Finnish

Mirja Tarnanen

University of Jyväskylä, Finland

Eija Aalto

University of Jyväskylä, Finland

Introduction

Increasing migrant numbers and general language policy across Europe have influenced Finnish language planning and legislation. For instance, language proficiency requirements for different purposes, such as citizenship, the labor market, and education, have been set according to national language proficiency scales linked to the Common European Framework of Reference for Languages (CEFR) scale. This applies not only to the official languages, Finnish and Swedish, but also to foreign language education at all education levels where the CEFR principles have been widely applied (Tarnanen & Huhta, 2008).

At the same time, the Finnish school system has aroused interest across the world because of its excellent Programme for International Student Assessment (PISA) results. Finns achieved high scores in the literacy test in 2000 and 2009. These results are explained by social and instructional factors, such as the fact that the national core curriculum stresses the strategic skills of reading and writing, there is a wide choice of learning materials and long-term collaboration with libraries, newspapers, and magazines in Finnish schools. Teachers have a university master's degree and they are fairly free to choose teaching methods and materials. But the small number of migrant students has also been raised as a reason (Väljjarvi et al., 2007).

In this chapter, we look behind these factors through Finnish as a second language (L2). We first provide a short overview of the Finnish language. Next, we look at L2 teaching and learning at different educational levels, followed by an introduction to pedagogical and test-oriented assessment practices. Finally, we discuss the challenges of assessment culture and practices in Finland.

Description of the Language

Finland has two official languages, Finnish and Swedish, as specified in the Constitution. About 92% of the Finnish population of 5.4 million speak Finnish as their first language, 5.5% speak Swedish, and the rest some other language (Statistics Finland, 2010). The most widely spoken of these is Russian, whose speakers form the majority of migrants (25%), the next most commonly spoken languages by migrants being Estonian, English, Somali, Arabic, Kurdish, Chinese, and Albanian. In addition to Finnish and Swedish, three other languages with minority language status are mentioned in the Constitution: Sámi, Romani, and (Finnish) Sign Language, which can be the language of instruction in certain schools (Basic Education Act, 628/1998; Ministry of Justice, 2006). All these five languages can be taught as a mother tongue. Other languages are also taught as L1 but, with no constitutional basis, their status is different. Language demographics in terms of bi- and multilingualism should be considered with reservation as it is possible to register only one mother tongue in Finland.

Finnish is mainly spoken in Finland, but also in Sweden and other countries by emigrant Finns. Finnish belongs to the Finno-Ugric group of languages, part of the Uralic family, and as such is fairly close to Estonian and distantly related to Hungarian. Finnish is a synthetic language using suffixes to express grammatical relations and to derive words. Finnish is also characterized by a rich system of word inflexion (e.g., 15 cases for nouns and a wide set of verb forms). Finnish has borrowed words from many languages over an extensive period of time. Old loanwords are no longer recognized as loanwords, as they have been borrowed at some point from contemporary languages and many have been adapted to the Finnish phonetic system.

Teaching and Learning Contexts

Considering the learning and teaching of Finnish as L2 at the macro-level, integration, according to Finnish integration policy, is a two-way process: It concerns not only migrants but also the Finnish population. Accordingly, national policy aims to promote a multicultural society and enable participation in Finnish society. The most common reason for coming to Finland is family ties, such as marriage to a Finn, or family members of individuals who have already moved to Finland. However, the number of migrants coming to work in Finland is steadily increasing, not least because of the aging population. These so-called voluntary migrants are mainly Russians and Estonians, while most Somalis, Vietnamese, and Afghans, for example, arrived as refugees.

Integration education is provided for adult migrants who have been granted permanent residency and who are unemployed or outside the labor market. Integration education covers learning Finnish or Swedish, Finnish society, learning strategies, and work-related skills and knowledge including practical training. The length of integration education is approximately 11 months except in the case of illiterate migrants, for whom it can take longer. Education aims at improving

migrants' position in the labor market and facilitating their employment. However, integration education has been criticized for not achieving its goals as the unemployment rate for migrants exceeds that of native Finns. The goal of language proficiency in integration education is B1 on the CEFR scale (3 on the National Certificate scale); however, in 11 months, this is not reached by all migrants nor in all subskills, particularly writing. Among authorities, employers, and educators, language proficiency level B1 appears to be considered a threshold level for working and vocational education. Naturally, migrants with lower Finnish or Swedish language proficiency can be hired, especially for jobs requiring little or no training.

In basic education, pupils whose native language is not Finnish, Swedish, or Sámi receive instruction in Finnish as a second language to replace, either entirely or partially, the Finnish as a mother tongue and literature syllabus. There may be considerable variation in the time pupils in the same grade have lived in Finland and studied at school. Thus, they are in varying phases in their Finnish language learning and it is not possible to define an extensive syllabus and set criteria for assessment for each grade, but individual learning paths need to be supported. The starting point for instruction is the pupil's skills in Finnish, not the grade in which she or he is studying. Therefore, the objectives and core contents are described in fairly general terms covering situations and subject areas, knowledge of language, reading and writing, literature, speaking and interaction skills, cultural skills, and language study skills.

Another complicated watershed is the borderline between the syllabi of Finnish as a mother tongue and Finnish as L2. Finnish as a second language is intended for pupils whose proficiency in Finnish is not native-like in any of the language skill areas. However, it is difficult to define native proficiency and the timing of the syllabus change to Finnish as L1. Decisions on changing the syllabus are often complicated, and the National Board of Education (NBE) has not provided clear instructions or tools for guiding and supporting teachers' decision making. It is obvious that the criteria used vary and are not always determined on the basis of the skills needed in studying school subjects, for instance ability to read abstract study-book texts, adequate vocabulary, and writing skills.

Compared to teachers in some other countries, Finnish teachers are exceptionally free to make choices of their own as regards teaching practices and materials. Despite this freedom, textbooks are seemingly assigned an unquestioned key role in determining classroom activities (Luukka et al., 2008). This probably applies equally to teachers of Finnish as a second language, although they do not have as wide a selection of materials available as teachers of other subjects. Unlike foreign language textbooks intended for basic education, the teachers' guides for Finnish as L2 do not customarily contain tests and instructions for assessment. However, the situation seems to be changing as a recent series of textbooks for basic education contains assessment practices described in the teacher's guide and teachers are provided with ideas for pedagogical assessment and tests, feedback forms, and guidelines for assessment in all language skill areas (Aalto, Tukia, Taalas, & Mustonen, 2008). Particular attention is paid to enabling learners to proceed on their individual learning paths and designing teaching and learning activities based on in-depth understanding of an individual learner's learning, skills, and

needs. Assessment is seen as an inseparable part of pedagogical decision making—not as the final point of a course. Assessment practices are designed to support the learner on his or her learning path and not just to show their place on the assessment scale. To that end, the descriptors of the CEFR assessment scale are explored from a pedagogical viewpoint: What kind of skills, learning processes, and activity types might best lead the learner from the current stage to the next? Typically, teachers' underpinning idea of progress is related to learning new grammar and more vocabulary. This idea is powerfully challenged when skill development is examined thoroughly.

Finnish as L2 is also taught in other educational institutions, such as vocational schools, polytechnics, universities, and on various types of voluntary language courses. A number of assessment packages and supportive tools are available for teachers (e.g., Kokkonen, Laakso, & Piikki, 2008; Tani, 2008). In these materials, teachers are guided in the use of criteria-referenced assessment and provided with concrete examples of task types for all language skills and benchmarks for concretizing the assessment scale used widely in basic and adult education (based on the CEFR scale, see above).

Assessment Practices

As mentioned above, the curriculum for basic education takes a functional approach to language learning and encourages educators to promote it with a broad range of assessment practices, especially self-assessment. In basic education pupils receive a yearly report at the end of each school year. During the school year, schools usually issue two to five intermediate reports. The assessment scale is from 4 (weak) to 10 (excellent). Verbal reports can also be used throughout the school, except in the final assessment. Pupils' performance level is assessed in relation to the objectives of the curriculum.

Final assessment is intended to be nationally comparable and to treat pupils equally. The final mark for a subject is based on a pupil's performance in the eighth and ninth grades. The national core curriculum contains the descriptions of good performance (grade "good" = 8) in all common subjects in grades 5 and 9. These descriptions are the teacher's tools in making a final assessment in grade 9. Assessment is expected to be based on diverse evidence, not only on tests. Generally, continuous assessment of work skills, activity, and learning motivation is emphasized and incorporated into the grade for the subject. Failing to meet some criteria can be compensated for by exceeding the standard in another criterion. If a pupil studies according to an individualized syllabus (diagnosed need for special support), his or her performances will be assessed on the basis of the individual objectives defined in the individual educational plan—not in relation to the final assessment criteria defined in the National Core Curriculum.

In the National Core Curriculum, Finnish as a mother tongue consists of five areas to be assessed: interaction skills, reading, writing, literature, and language. Each area includes objectives, core contents, and descriptions of good performance (grade "good" = 8) in grades 1–2, 3–5, and 6–9. Consequently, assessment of L1 is guided by use of continuous and summative assessment in terms of

descriptions of objectives, core contents, and the criteria of good performance. Otherwise, L1 teachers are free to choose how they assess students in practice, for example what kind of tests or portfolio type of assessment they use, how often and what kind of self- and peer assessment they apply, and what kind of feedback practices they prefer.

The current national curriculum (NBE, 2004) has made use of the Common European Framework of Reference with its view of language, proficiency scales, and criterion-referenced assessment, and this has important implications for assessment in foreign languages and in Finnish as L2 (Hildén & Takala, 2007; Tarnanen & Huhta, 2008). The Finnish application of the CEFR scale included in the curriculum is an adaptation of the original six-point scale. Its content is slightly modified and each CEFR level is divided into sublevels (e.g., A2 into A2.1 and A2.2) to provide learners and teachers with more quickly attainable targets. The scales cover all four subskills: listening, speaking, reading, and writing. Teachers are required to refer to the proficiency levels when grading students, which is challenging because target setting and level-referenced assessment are novel activities for most teachers and students. Another challenge is to combine absolute levels of proficiency and the traditional grading of achievement during a term or a course, which, furthermore, often relies on comparing students with each other (Tarnanen & Huhta, 2011). In Finnish as a second language education, assessment takes into account all areas of language proficiency, and it should be based on individual achievement throughout comprehensive school, up to final assessment. At the end of the grade 9 (final assessment) criteria for a grade of 8 (=good) are set at B1.1 on the curriculum language proficiency scale.

On the whole, the assessment tradition in Finnish schools is not testing-oriented as there is only one large-scale high stakes test, the Matriculation Examination, at upper secondary level, and some low stakes Teachers Association tests used on a voluntary basis at the end of lower secondary level. In addition, there are two large-scale tests of Finnish as L2 for adults (see below). The Matriculation Examination is the oldest and largest national examination in Finland. It is based on legislation and organized by an independent board under the supervision of the Ministry of Education. The annual number of candidates ranges from over 30,000 in the mother tongue test to a few hundred in some optional languages. The number of examinees in Finnish as L2 was 419 in 2010. The mother tongue test is arranged in Finnish, Swedish, and Sámi. The Finnish and Swedish tests have two parts: a textual skills section measuring the candidate's analytical skills and linguistic expression and an essay focusing on the candidate's general level of education, development of thinking, linguistic expression, and coherency. The weighted sum of points determines the candidate's grade on the mother tongue test. The Finnish as L2 examination tests reading comprehension, writing, structures, and vocabulary, whereas other foreign language examinations also include listening comprehension. The target level of Finnish as L2 instruction in upper secondary school is B2 on the CEFR scale (Matriculation Examination Board, 2010).

Although teachers could apply a broad range of assessment practices in their classroom, language education has traditionally taken a formal approach to language learning. This emphasizes the role of grammar as the core of language teaching, the writing of school texts, and the use of summative exams as an

indication of learning (Tarnanen & Huhta, 2011). This is also supported by the results of a large-scale survey conducted in the research project "Towards Future Literacy Pedagogies—Finnish 9th Graders' and Teachers' Literacy Practices in School and Out-of-School Contexts." Language 1 and 2 teachers ($n = 740$) and students (1,720) were asked who, in general, carries out assessment in grade 9 and how often (often; sometimes; only seldom; never). According to the results, almost all teachers placed themselves in the highest response category (often). Also the majority of students (83%) estimated that their teachers carried out assessment often. Although the teacher has the main role in assessment, over 90% of teachers and 63% of students reported that students did self-assessment at least sometimes. However, when teachers and students were asked whose assessment determines the grades and to what extent (a lot; to some extent; only a little; not at all), all teachers and 87% of students reported that the teacher's assessment influences grades a lot (Huhta & Tarnanen, 2009). Finnish assessment culture is, however, gradually changing as self-assessment is widely applied in primary education. This will develop a basis for a reflective approach to learning and promote sustainable practices providing support throughout schooling and also in working life.

There are two national language examination systems for adults based on legislation: the civil servants' language examination and the National Certificates. The civil servants' language examination, dating from 1922, is intended for civil servants to demonstrate their command of the second national language (Finnish or Swedish). There are three examination levels: "satisfactory," "good," and "excellent." The test consists of speaking, listening, writing, and reading. The candidate can choose whether to take the comprehension or productive skills subtests or all four. The annual number of candidates is falling, as the most common way to fulfill the civil servants' language proficiency requirements is to complete tertiary education; completed Finnish and Swedish courses are equal to the "satisfactory" and "good" levels (Tarnanen & Huhta, 2008).

The National Certificates (NC), established in 1994, cover several languages: English, Finnish, French, German, Italian, Russian, Sámi, Spanish, and Swedish. Finnish Sign Language will probably be included in the NCs by 2015. In this sense, the NCs represent national language policy and aim to encourage language studies, also in less frequently taught languages. The NCs are based on a six-level scale linked to the CEFR with three test levels: basic (levels 1–2), intermediate (levels 3–4), and advanced (levels 5–6). All the tests at all levels include a subtest in reading, writing, listening, and speaking. The tests are based on a functional view of language and assessed by trained raters according to the same criteria. Finnish tests are taken by migrants and Swedish-speaking citizens, and certificates are used mainly for job or citizenship applications.

Both these examinations are acceptable ways of demonstrating language proficiency in applying for Finnish citizenship. According to the current Nationality Act, citizenship requires a certain age (18 or older), period of residency in the country, satisfactory economic standing, absence of criminal record, permanent address, and Finnish or Swedish language proficiency at a certain level (Nationality Act, 579/2011). Language proficiency can be shown in any of the following ways: (a) obtaining a level 3 in the NC, (b) passing the satisfactory level tests of

oral and written skills in the civil servants' examination, (c) completing basic education in Finnish or Swedish, or (d) through other school education. The NC is the most used way of demonstrating language proficiency as its content and topics better represent daily language use than the more specific civil servants' examination.

Challenges

Assessment is an inseparable element of learning and teaching, and it impacts on L2 learners' self-esteem and identity. Thus, assessment culture and teaching practices should be based on transparent and ethical principles and encourage applying assessment practices that support and promote the learning process. In Finland, curricula largely take into account the changing needs of the modern world and rely on a socioconstructivist view of learning. In addition to the achievement of cognitive and knowledge-related goals, they emphasize growth of the students' personality, importance of self-assessment and ongoing feedback, and sharing assessment criteria with students and parents (NBE, 2004). However, in practice, these principles and objectives do not seem to be followed consistently by language teachers.

Assessment culture and practices change slowly, but when a change takes place it should be systematic and holistic. For example, self-assessment applied merely technically does not necessarily promote learning as intended. In the case of Finland, major developments are required in the range of assessment practices and in sharing the responsibility for assessment as well as in teachers' ability to assess learners' language proficiency. Besides assessment, this involves a wide range of competencies, such as understanding the learning of Finnish, the ability to articulate learning goals, and communicating pedagogically with learners. According to national surveys, teachers of Finnish as L1 have a disparate understanding of the content they teach, and partly because of this their assessment at the end of primary and lower secondary level is inconsistent (Lappalainen, 2008, 2010). This has aroused discussion about the need for more national large-scale tests—which seems very unlikely as the tradition is strongly against a testing-centered orientation. As mentioned above, improving the situation requires efforts from different stakeholders, institutions, and experts, including teachers and learners themselves. The Ministry of Education and Culture, National Board of Education, teacher educators, researchers, and schools should work together toward a shared vision.

Learning a language is a life-long process. Assessment can provide useful tools to be applied in different contexts and phases of life. At its best, assessment forms a continuum throughout the education path and supports the development of self-reflection and learning skills.

Assessing French

Eve Ryan

Avant Assessment, USA

Introduction

French¹ is the official or co-official language in 29 countries spread over the American, African, and European continents. It is also commonly spoken in countries where it is not the official language, such as Tunisia or Mauritius. In a report released by the International Organization of Francophony, it was estimated that there are over 220 million Francophones in the world who are able to understand and communicate in French, and that there are about 116 million learners of French, half of whom study it as a foreign language (Organisation internationale de la francophonie, 2010). French is one of the official languages of the United Nations (UN), of the North Atlantic Treaty Organization (NATO), and of the European Union (EU).

This chapter deals with the assessment of French both as a first language and as a second or foreign language. A brief history and a short description of some salient features of the language are given, followed by a description of teaching trends and an explanation of assessment practices. The chapter concludes by identifying challenges and suggesting directions for future research.

History of French

French is of Indo-European origin. Very little of today's French bears any resemblance to the language spoken by the Gauls, the Celtic people who inhabited France before the Roman invasion in the third century. Instead, the Vulgar Latin of the region was strongly influenced by the subsequent invasions by Germanic tribes, such as the Franks in northern France. A broad distinction was made during the Middle Ages between the two major language groups in France: the *langue*

d'oc in the south and the *langue d'oïl* in the north, from which Modern French is derived. With the 1539 landmark Ordinance of Villers-Cotterêts, François I, the king of France, replaced Latin with French as the official language of administration and court proceedings. A period of unification and standardization ensued, which culminated in the creation of the Académie française in 1634.

The Académie tried to control neologisms but “it did not itself innovate—in fact after its initial successes of raising the prestige of French letters of the 17th century, it quickly became a conservative body that inhibited innovations of any sort” (Schiffman, 1996, p. 86). To this day, the main objective of the Académie is to keep track of the ongoing changes in Standard French.

In practice, the Académie has tended to follow the evolution of Standard French rather than drive it. The lasting influence it has had has been in two areas. First, in orthography, where its conservative approach, favouring the existing tendency towards etymological spellings . . . has been accepted. . . . Second, where the Académie’s influence on standard literary French has been very strong, at least until recently, is in its officially sanctioned dictionary. (Battye, Hintze, & Rowlett, 2000, p. 23)

French language policy took a turn after the 1789 French Revolution, laying the ground for the dominance of French throughout the country. Laws were passed to reinforce the status of French. However, these centrally made decisions had very little effect at the local level and most countrymen only spoke a local vernacular (*patois*) or regional language (e.g., Corsican, Alsatian, Breton). Costa and Lambert (2009) identify three events that subsequently accelerated the spread of French throughout the country, namely: “the 1870 defeat against Prussia, the advent of the Third Republic, and compulsory schooling” (p. 17). Indeed, under Napoleon, the concept of centralization thrived; France was to encompass its linguistically diverse groups in a common nation with a common language. Little by little, *patois* lost their influence, so much so that “today, regional language transmission in the homes is a very rare phenomenon” (Costa & Lambert, 2009, p. 17). Today, France endeavors to preserve its language, and feels particularly threatened by the political and cultural ascent of American English since World War II:

[French speakers] think of the French language not just as a vehicle of French culture, but as its highest embodiment. And since they see language and culture as strongly linked, they also fear that the spread of English will bring with it cultural values that they dislike. (Schiffman, 1996, p. 80)

Interestingly, this reticence toward English is also found in Quebec, where despite the “status and use of French as the majority language . . . , many Francophones still feel that French is threatened by English” (Montreuil & Bourhis, 2001, p. 701). French language has traditionally been controlled by a centralist government and one may question whether this will be challenged by current trends, such as the dominance of the Internet, the globalization of the economy, the ascendancy of the EU, and so on.

The linguistic heritage left by France in its former colonies takes different forms. French still remains the lingua franca in former African colonies, especially in West

Africa. This is partly explained by the fact that French was the major vector through which assimilation was to happen, “of course to the detriment of the local language” (Sonaiya, 2007, p. 434). On the other hand, French has lost its prime in former French colonies in Southeast Asia. As for the West Indies, French is still used as the language of the education system, but creoles, dialects, or pidgins are spoken by the local population.

Description of French

Below is a short description of some of the salient features of Standard French that are similar to or different from English:

- **Phonology:** The French sound system makes some distinctions that the English system does not make, including the differentiation of 17 vowels (although only about 10 are used in common practice), four of which are characteristically nasal vowels.
- **Grammar:** Unlike English, French has two grammatical genders (masculine and feminine). French also has literary grammatical forms that are rarely used, even by native speakers (e.g., past tense subjunctive).
- **Vocabulary:** Most French words derive from Vulgar Latin, or were constructed with Latin or Greek roots.
- **Orthography:** Just like English, French orthography is not strictly phonetic, making its mastery tricky for native and non-native speakers alike. For example, orthographic conventions of conjugation, which rely heavily on silent letters, are a focus of the dictation tasks that are so common in French primary education. Indeed, dictation features in school examinations all the way to high school, demonstrating the emphasis put on orthographical skills.

Below are but a few illustrations of language variety in French:²

- **Canadian French:** By comparison to Standard French, the lexis in Canadian French is at times characterized by archaisms (e.g., *poudrerie* instead of *tempête de neige*), neologisms, and anglicisms (e.g., *chum* instead of *petit ami*) (Blanc, 1993, p. 245).
- **Belgian French:** “Word final consonant devoicing (WFCD) has for some time been described as one of the main features characterizing French spoken in Belgium” (Hambye, 2009, p. 28). An example of a written form where the final consonant is made voiceless would be *belge* written *belche*.
- **Popular Ivorian French:** Sonaiya (2007) describes some of the salient features of the French spoken in the Ivory Coast. The imperative uses the infinitive as the stem, except for verbs ending in *-er* (e.g., *découvririez* instead of *découvrez*). Unlike Standard French, in popular Ivorian French, “qualifiers tend to have a single form, such that the phonetic differences indicative of number and gender are obliterated” (p. 442). Also, popular Ivorian French uses imagery whose meaning would be unclear in Standard French (e.g., *C’est versé* instead of *C’est chose courante*).

Teaching and Learning Context

The educational system of France is centralized. The Ministère de l'éducation nationale is responsible for the curriculum, budget, legislation, appointment of teachers, and supervision of both public and private schools, including at the preschool level (*école maternelle*), the elementary school level (*école primaire*), the junior high school level (*collège*), and the high school level (*lycée*). The Ministère de l'enseignement supérieur et de la recherche is responsible for the budget, legislation, and supervision of public universities at the postsecondary level.

Standards are not the same for teachers of French as a first language (L1) and teachers of French as a foreign language (FL) in France. Indeed, to be able to teach French as an L1 at the post-elementary level, a teacher has to be certified, by passing either the Certificat d'aptitude au professorat de l'enseignement du second degré (CAPES) or the notoriously more difficult Agrégation de lettres modernes. Both tests can only be taken after obtaining a master's degree. Certified teachers enjoy the advantages associated with their status as civil servants. By contrast, there is no certification for teachers of French as a FL. Most teachers have studied the teaching of French as a FL at university level, but the centers that recruit them have their own hiring criteria. Similarly, while the curriculum of French as an L1 is determined by the Ministère de l'éducation nationale, the curriculum of French as a FL is not standardized. This point is interesting given that assessments of both French as an L1 and French as a foreign language are standardized. In 2006, a commission between three ministries created the "label qualité français langue étrangère" (Label qualité français langue étrangère, *n.d.*), a label that guarantees the abundance by predetermined standards of practice by institutions that teach French as a FL. However, its scope remains limited, not only because it only targets postsecondary teaching centers in France, but also because accreditation is obtained on a voluntary basis.

France allocates significant resources to maintaining the status of its language abroad. In their report on French cultural diplomacy, Wyszomirski, Burgess, and Peila (2003, France section, p. 3) note that

France promotes the French language [abroad] through a network linking 300 schools and their 150,000 pupils, of whom 60,000 are French. France's cultural presence is also reinforced by approximately 130 cultural organizations in 56 countries, which give French lessons to 140,000 adults and teenagers. In addition, the Alliance Française [the primary institution responsible for the teaching, learning, and assessment of French abroad] centers teach French to 320,000 students in 138 countries.

These efforts seem to pay off, since the number of students of French keeps increasing, albeit mostly in the African region (Organisation internationale de la francophonie, 2010).

The educational systems in many former French colonies are similar to that in France. In former French colonies in Africa, French—once the language of the colonizers—remains the major language of education and African languages are rarely used in the education system (Sonaiya, 2007).

In Quebec, the Ministère de l'éducation, du loisir et du sport is responsible for the curriculum, budget, legislation, and supervision of schools. The Charter of the French language stipulates that all students in the public system must attend French language schools, except if their parents attended an English school or if they did most of their studies in an English-speaking school in Canada. "In Québec, courses in French as a second language are available free of charge in several formats. Financial aid is granted by the Ministère de l'Immigration et des Communautés culturelles (MICC) under certain conditions" (Government of Quebec, *n.d.*).

Assessment Practices of French as a First Language

Assessment of French as an L1 in France is conducted at several educational levels. At the elementary school level, students are evaluated based on participation in the classroom and performance on homework, as well as progress and achievement tests designed by the teacher. Two midstakes proficiency tests are given at the national level, at the end of CE1 (grade 2) and CM2 (grade 5). The tests are graded by the student's own teacher and aim to monitor the progress of the student. The skills tested are reading, writing, vocabulary, orthography, and grammar (Ministère de l'éducation nationale, *n.d.a.*).

At the junior high school level, students are also evaluated based on participation in the classroom and performance on homework, as well as progress and achievement tests designed by the teacher. A midstakes proficiency test called the Diplôme national du brevet is given in 3ème (grade 9). The final score is determined by combining the grades obtained by the student throughout the school year with the grade obtained on the end-of-the-year national test, which is graded anonymously. The latter consists of a writing task, a dictation task, and a reading comprehension task (Ministère de l'éducation nationale, *n.d.b.*). Students go on to high school regardless of their performance on the Brevet.

Finally, the Baccalauréat serves "both as a high school exit exam and a university entrance exam" (El Atia, 2008, p. 143). It is a high stakes large-scale national assessment that is scored anonymously. The Baccalauréat de français is taken in the junior year of high school and aims at assessing several skills in French, including reading comprehension, writing, knowledge of literary history and concepts, and argumentation building (Ministère de l'enseignement supérieur et de la recherche, *n.d.*).

Assessment Practices of French as a Second and Foreign Language

Unlike assessments of French as a first language, assessments of French as a second and foreign language are not always tied to a standard curriculum. A distinction is made between tests and diplomas of French as a FL:³ test scores are considered valid for a limited period of time, whereas diplomas are granted for life. These assessments are all developed based on the Common European

Table 131.1 Major tests of French as a foreign language

<i>Name</i>	<i>Intended audience</i>	<i>Skills being assessed</i>
Test de connaissance du français (TCF)	Learners who wish to have their French proficiency tested for professional or personal reasons	<ul style="list-style-type: none"> • Listening • Reading • Grammar
Test d'évaluation de français (TEF)	Learners who wish to have their French proficiency tested for professional or personal reasons	<ul style="list-style-type: none"> • Listening • Reading • Writing • Speaking • Grammar • Vocabulary

Framework of Reference or CEFR (Council of Europe, 2001). Unless otherwise specified, French spoken in France is the norm that is being tested.

Table 131.1 provides an overview of the major tests of French as a FL. The TCF, commissioned by the Ministère de l'éducation nationale and the Ministère de l'enseignement supérieur et de la recherche, was created with a view to becoming the French equivalent of the TOEFL. It is offered in centers in Europe, Asia, Australia, North and South America, and Africa, with a computer-based version available. Items on the TCF are developed and calibrated by the Centre international d'études pédagogiques (CIEP). The results of the TCF are considered valid for two years. Several versions of the TCF are available for different situations. The TCF DAP is a three-hour exam for aspiring students at French universities. It includes sections on listening comprehension, reading comprehension, writing, grammar, and lexicon. Applicants for French naturalization have to demonstrate their proficiency in French, and can thus take the TCF nationalité française. The latter consists of 30 listening comprehension questions, and an individual interview to assess speaking proficiency. Applicants for immigration to Quebec can demonstrate their proficiency in French by submitting their score on the TCF Québec. The latter consists of 30 listening comprehension questions and an individual interview to assess speaking proficiency.

The TEF is for adult learners who wish to immigrate, study, or work in a French-speaking country. It is administered by the Chambre de commerce et d'industrie de Paris (CCIP), and a computer-based version is available. The TEFAQ is for learners who wish to gain admission to a university in Quebec, or who wish to immigrate to Quebec. It tests listening comprehension and speaking proficiency. Applicants for French naturalization have to demonstrate their proficiency in French, and can thus take the TEF épreuves orales, which focuses on listening comprehension and speaking proficiency.

Table 131.2 provides an overview of the major diplomas for learners of French as a FL. The DELF is a well-known diploma granted to learners of French as a FL and it is officially recognized by the French Ministère de l'éducation nationale. It assesses the four skills of reading, writing, speaking, and listening and reports scores from level A1 to B2 on the CEFR scale. It can be used for entrance into a

Table 131.2 Major diplomas for learners of French as a foreign language

<i>Name</i>	<i>Intended audience</i>	<i>Skills being assessed</i>
Diplôme d'études en langue française (DELF)	Learners of French as a FL	<ul style="list-style-type: none"> • Speaking • Writing • Listening • Reading
Diplôme approfondi de langue française (DALF)	Advanced learners of French as a FL who want to work or study in a Francophone environment	<ul style="list-style-type: none"> • Speaking • Writing • Listening • Reading
Diplôme initial de langue française (DILF)	Beginner learners of French	<ul style="list-style-type: none"> • Speaking • Writing • Listening • Reading
Diplômes de français professionnel (DFP)	Learners who wish to work in a Francophone environment	<ul style="list-style-type: none"> • Reading • Listening
Diplômes d'université (DU)	Learners of French at French universities	

French university. DELF Prim is for young language learners. DELF Junior is for learners who are in a secondary school. DELF Pro is for specific purposes: It targets learners who wish to work in a French-speaking environment. The DALF is the direct continuation of the DELF, in that it targets learners at levels C1 and C2 on the CEFR scale. The DILF, by contrast, is for beginner learners who are at level A1 on the CEFR scale.

Other diplomas that measure French for specific purposes are the various DFPs, which are administered by the *Chambre de commerce et d'industrie de Paris*. They present learners with certificates in specific areas, such as tourism, law, and medicine. They report scores from level A2 to C2 on the CEFR scale.

Lastly, the DUs are delivered by private or public institutions of higher education and vary in their focus. Some DUs assess French for specific purposes, while others assess general French proficiency. They report scores from level A1 to C2 on the CEFR scale.

Challenges

There are several challenges inherent to assessing French, both as an L1 and as a FL. First, the status of the *Baccalauréat* as a landmark test that symbolically marks the passing into adulthood has been questioned by many. Not only are its preparation, development, administration, and grading lengthy and costly, but also its role as both an exit and an entrance test raises questions. A major debate concerns its pass rate, which was historically low (until the 1960s) and which is now relatively high (usually above 80%). "Throughout its 200-year history, governments have toyed with this double function, either a gate-keeping exam with few students passing it or a high school degree with large passing rates" (El Atia, 2008,

p. 143). What's more, the fact that the test is high stakes means that many students resort to complementary help in the form of private tutoring, a solution which less privileged families cannot necessarily afford.

Second, the fact that French is an international language poses the question of whose norms should be assessed. Too often, Standard French spoken in France is held as the absolute norm for testing. Local varieties are taken into account only in the case of Quebec (TCF Québec and TEFAQ). This leaves out other varieties of French as it is spoken in postcolonial communities. This situation is oblivious to the fact that many French speakers reside outside of France.

Finally, the status of some French-speaking countries as host countries for immigrants means that there has been an increase in the number of speakers whose first language is not French. This pattern is similar to that of other countries whose languages are rapidly expanding in terms of use, such as English and Spanish. For students who speak a language other than French at home, lack of or partial knowledge of the language of instruction might impede their school performance, an issue that remains under-researched. Even if language classes are offered to incoming immigrants (e.g., recently arrived immigrants in secondary schools may attend *classes d'accueil* for less than a year in France), the fact that the student population is increasingly linguistically heterogeneous and the potential effects on student performance remain underestimated.

Future Directions

With regard to the Baccalauréat, several issues remain on the agenda. First, research should be conducted on the effects of the test on teaching (washback). There is no official publication describing the development and validation of the test, which should be remedied. Also, given the lengthy and costly preparation, development, administration, and grading of the test, a call for modernization can be made (e.g., make certain sections of the exam computer-based).

Second, a call should be made to broaden the standards of French in language assessment so as to be more inclusive of local norms. The reality of language variation in French should be acknowledged and taken into account in assessment practices.

Those of us who are responsible for assessing language ability need to be able to account somehow for language variation within the model of linguistic or communicative competence underpinning our test. We need to consider how language variation affects the validity, reliability, practicality and impact of the test we offer. At the very least we need to keep our policy and practice on language variation under review and maintain a clear rationale for why we do what we do in relation to the inclusion, or non-inclusion, of more than one linguistic variety in our tests. (Taylor, 2008, pp. 279–80)

With regard to assessments of French as a foreign language, there is a lack of publications describing the development and validation of the various assessment tools, as well as their linking to the CEFR levels, which should be remedied.

Similarly, there should be more public domain information made available regarding the naturalization tests and their impact.

Finally, the recent demographic changes in some French-speaking countries suggest that, in some instances, the monocultural and monolingual educational systems have to be revised. Research should be conducted to uncover potential gaps in educational achievement for student groups based on their ethnic, cultural, economic, and linguistic background. Similarly, the status of French as a second or foreign language in these French-speaking countries should be improved to make the plight of multilingual citizens more visible.

Assessing German

Michaela Perlmann-Balme

Goethe-Institut, Germany

Introduction

German is of Indo-European origin. It is the most widely spoken mother tongue (L1) in the European Union, with at least 90 million L1 users. It is the official language in Germany, Austria, Liechtenstein, Luxemburg, and parts of Switzerland, has the status of a protected minority language in South Tyrol (Italy), parts of Belgium and southern Denmark, and is considered a regional language in Alsace-Lorraine (France), Poland, Romania, states of the former Soviet Union, and many other states in the world (see Glück, 2000, p. 148).

Description of German

The codification of written Standard German (*Hochdeutsche Standardsprache*) began with Martin Luther's bible translation in 1534 and was later defined in Johann Christoph Adelung's (1781) and Jacob and Wilhelm Grimm's (1854) dictionaries. Standardization of German spelling started with Konrad Duden's *Orthographisches Wörterbuch der deutschen Sprache* (1880, last revised in 2006).

Due to the "pluricentric" constitution of German, there are three national standard varieties of German. They are considered as "standard" in Germany, Austria, and Switzerland and they share a rather large common core. Variants are mainly lexical, for instance words for food (*Kartoffel*, German vs. *Erdapfel*, Austrian: "potato") and everyday objects (*Fahrrad*, German, vs. *Velo*, Swiss: "bicycle"). Additionally, there are differences in pronunciation, grammar, and spelling as well as in conventions of politeness, such as the use of academic titles in Austria (see Ammon, 1995; Glaboniat, Müller, Rusch, Schmitz, & Wertenschlag, 2005, pp. 79–80). The Austrian standard variety is recognized by law and was standardized via a

dictionary in 1951 (see Back, Benedikt, & Blüml, 2009). Swiss Standard German (see Bickel & Landolt, 2012), referred to by the Swiss as *Schriftdeutsch*, is mainly written and rather less often spoken. Apart from these standard varieties there are a number of local and regional dialects, used in informal situations in all countries; German-speaking Swiss use Swiss German (*Schweizerdeutsch* or *Mundart*), which comprises a number of local dialects that represent the everyday language in the German-speaking part of Switzerland.

In Standard German there are eight vowels—*a, e, i, o, u*, and the umlauts *ä, ö, and ü*, which are, in notation, orthographical particularities of German—next to four diphthongs: *au* (as in *Haus*, “house”), *ei* (*Heim*, “home”), *äu* (*Häuser*, “houses”) and *eu* (*Eule*, “owl”). Nouns have three genders—masculine, feminine, and neuter—and follow a four-case system: nominative, genitive, dative, and accusative. The agreement of articles and adjectives with the noun they qualify is affected by that noun’s gender and case: *Sie gibt mir ein weißes Blatt, einen bunten Stift und eine schwarze Mappe* (“She gives me a white sheet of paper [=neuter], a colored pen [=masculine], and a black folder [=feminine]”). It is especially this inflected structure of gender and case that makes German difficult for learners of other languages.

Nouns can be connected to form long compounds (e.g., *Bundesangestelltentarif*, “tariff for employees of the federal government”), while syntactic structures are flexible in German, as in *Die Elbphilharmonie ist leider noch nicht fertig* (“The Elbe Philharmonic Hall is unfortunately not yet ready”), which can also be expressed as *Leider ist die Elbphilharmonie noch nicht fertig* (“Unfortunately the Elbe Philharmonic Hall is not yet ready”). German sentences are well known for their complexity: *Die Elbphilharmonie, jenes elegante Bauwerk, das im Hamburger Hafenviertel seit sechs Jahren gebaut wird und den Steuerzahler inzwischen Unsummen gekostet hat, ist immer noch nicht fertig* (“The Elbe Philharmonic Hall, this elegant building that has been under construction in the dockland of Hamburg for six years and has cost the taxpayer an enormous sum, is still not ready”). Over the last decades the German lexicon has been rather open to borrowings, particularly from English: especially IT-related and technical terms (e.g., *Adapter, Keyboard*) are either borrowed directly or integrated into German orthographically (*die Maus* < mouse) and morphologically: *Hast du ihn auf Facebook geaddet?* (“Did you add him on Facebook?”). Despite being controversial in social discourse, this trend has not led to new legislation against it.

Testing German as a Foreign Language

In 2010 there were 14 million learners of German as a foreign language (GFL) around the world (Goethe-Institut, 2010). Particularly in Eastern Europe, GFL still plays a significant role in schools and in business and there is a growing demand for certification. The following overview shows the most well-known GFL exams developed by German, Austrian, and Swiss institutions and administered worldwide by the following exam boards: the Goethe-Institut (GI), the Austrian–German language diploma (Österreichisches Sprachdiplom Deutsch, ÖSD), the telc GmbH (The European Language Certificates), the TestDaF-Institut (Test institute for German as a foreign language for study purposes), the German

Table 132.1 Examinations for German as a foreign or second language

Chamber of Industry and Commerce (Deutscher Industrie und Handelskammertag, DIHK), and the Central Department for German Schools Abroad (Zentralstelle für das Auslandsschulwesen, ZfA); all this is part of the Federal Office of Administration (Bundesverwaltungsamt) and is done on behalf of the Standing Conference of the Ministers of Education and Cultural Affairs of the Länder in the Federal Republic of Germany (Kultusministerkonferenz, KMK). Table 132.1 gives a summary of the most well-known German examinations for different target groups and purposes provided by the major examination boards in Germany and Austria.

Target Groups, Teaching–Learning Contexts, and Assessment Practices for Native Speakers

Children acquire the “difficult” features of German mentioned above within the first years of their lives. In kindergarten and at preschool, the use of dialect is widely accepted, while Standard German is the language of instruction in primary school; here written language and its text types come into focus, which involves the teaching of new words, grammar, spelling, reading, writing, and speaking. Secondary education places more emphasis on the development of writing skills. For reading, literature of all genres is central, and emphasis is placed on textual analysis and the interpretation of different text types rather than on the extraction of information from different sources. Rhetorical competency is trained through oral presentations.

Mediocre results in the international educational study *PISA 2000* in Germany and Austria (see Baumert et al., 2001) led to a reorientation in educational politics and to a shift from input to output. In foreign language instruction there was a shift from language knowledge in grammar and vocabulary to task-based teaching and learning. Different curricula for an increasing number of school types in the 16 states (*Bundesländer*) were now considered a problem, and therefore collaboration was furthered and national educational standards that described the competencies to be attained were introduced. At secondary level, centralized tests to monitor the development of mother tongue competency were implemented (see Sekretariat der Ständigen Konferenz der Kultusminister der Länder in der Bundesrepublik Deutschland, 2004).

German Tests for Young Learners

To motivate younger learners to show their German skills outside the school and its context, the exams *Fit in Deutsch 1* and *Fit in Deutsch 2* (Austrian alternatives: *ÖSD-KIDS 1* and *ÖSD-KIDS 2*) are being used. They are administered in *PASCH* (partner school initiative) schools in many countries and in young learners language summer schools, holiday courses, and language institutes worldwide.

A demand for internationally recognized certificates administered within the national school system first emerged in the late 1990s. In the *Progetto Lingue 2000* in Italy, GFL (alongside English, Spanish, and French) examinations for levels A1 and A2 were developed for middle schools; these examinations were *Fit in Deutsch 1* and *2*. They were based on the Common European Framework of Reference (CEFR), published in German in 2001 (Europarat, Rat für kulturelle Zusammenarbeit, 2001, Section E). The CEFR was instrumental because it defined levels of proficiency suitable for the different age groups and school types. The two new exams tested all four skills—reading, writing, speaking, and aural comprehension—by using group and pair formats in the oral component. Critics of this kind of international exams felt that there was too much testing in schools already and saw no need for large-scale tests administered by external authorities. They were concerned that the phenomenon of “learning to the test” would prompt pupils to

neglect subjects that had no attached tests. Supporters, however, pointed out that washback studies had shown that tests can be shortcuts to reform of the content and to design of language courses (Hawky, 2006). The exams indeed had a positive influence on task selection in classrooms, and teachers found in them a clear definition of goals. In 2005 a French government initiative aimed at revitalizing foreign language learning in the national school system led to the introduction of DSD 1, the German Language Certificate of the Conference of the Ministers of Education and Cultural Affairs of the Länder in the Federal Republic of Germany (Deutsches Sprachdiplom der Kultusministerkonferenz)—a scaled exam on levels A2 and B1, as an addition to the already existing DSD 2 (on levels B1 and B2/C1). DSD 2 had long been administered predominantly in German schools worldwide and still plays a role in opening access to German universities. Both DSD 1 and DSD 2 test the four skills. Test versions are developed by the ZfA in Cologne. The analysis of results is done centrally, the administration is done by the schools locally. Students at the end of secondary school receive a certificate signed by a German government body.

Adult Learners

Modern GFL testing started in the 1960s. While English tests had been in use in the US and the UK since the beginning of the century, in German-speaking countries the behavioristic approach to empirical testing methods was predominantly met with skepticism. Due to the humanistic tradition in the German education system and to its emphasis on learners' personalities, German testing preferred open-ended questions and refused the use of automatically marked item types, like multiple choice items, until the late 1960s.

The first GFL exams were developed and administered in 1960 by the Goethe-Institut (GI), which had been founded ten years earlier and given the mission to rebuild the image of the German language and to foster its learning worldwide. The textbook *Deutsche Sprachlehre für Ausländer*, published by H. Schulz and W. Sundermeyer in 1929 (Schulz, Sundermeyer, & Thies, 1935) was reissued under the authorship of Dora Schulz and Heinz Griesbach in a new format and used in German courses (Schulz & Griesbach, 1955). Soon the certification of language proficiency for foreign students at universities became necessary. This need was met in 1960, when the Ludwig-Maximilians-Universität Munich engaged in a collaboration with the GI to develop the tests Kleines Deutsches Sprachdiplom (KDS) and the Großes Deutsches Sprachdiplom (GDS). For both, literature was the basis for reading comprehension and writing. They remained in use almost in their original formats until 2011, serving as teacher qualification in several countries. The testing format was much like that of L1 German testing, featuring mainly open-ended questions, essay writing, transformation exercises (grammar), and dictations (listening comprehension). Marking was done centrally in Munich by native German-speaking raters.

German testing thus started at the highest possible level. Soon a demand for qualification below university level arose, once the language needs of a growing number of immigrants to West Germany (*Gastarbeiter*) came into focus in the 1960s

and 1970s (Council of Europe, 2001, Section E). Under the auspices of the German Adult Education Association (Deutscher Volkshochschul-Verband, DVV), the so-called Volkshochschul-Zertifikate (adult education center certificates) were developed, establishing serious language courses with a curricular basis, clearly defined learning objectives, and a communicative approach as their theoretical basis. Beginning in 1971, the DVV in cooperation with the GI developed and issued the Zertifikat Deutsch als Fremdsprache (certificate of German as a foreign language) (Deutscher Volkshochschul-Verband, 1972), introducing into German testing multiple choice questions, pretesting, the statistical analysis of candidates' responses, and the automatic marking sheets. Featuring recordings of everyday dialogues, it was the first German test based on the audiolingual method. The exam had five components: the four skills and one section on grammar and lexis. In 2000, the revised exam (developed by GI, DVV, ÖSD, and the University of Fribourg) was published in a new format as "German certificate," Zertifikat Deutsch (ZD), now also offering Austrian and Swiss varieties next to *Bundesdeutsch* (Western German; see Weiterbildungs-Testsysteme GmbH, Goethe-Institut, Österreichisches Sprachdiplom Deutsch & Schweizerische Konferenz der kantonalen Erziehungsdirektoren, 1999, Section B).

In the 1970s the exams Zentrale Mittelstufenprüfung (ZMP) and the Zentrale Oberstufenprüfung (ZOP) filled the portfolio of exams on the (upper-)intermediate levels. Originally developed as achievement tests for language courses, they tested the four skills, with sections on grammar and lexis attached. But, as the need for certification on the job market was growing, these too came soon to be considered certificates of proficiency levels. Both granted foreign students university access in the German-speaking countries. In 2007 the ZMP was revised and two new exams were published under the names Goethe-Zertifikat B2 (Goethe Certificate B2) and Goethe-Zertifikat C1 (Goethe Certificate C1). Due to necessary adjustments after the German adaptation of the CEFR (see Europarat, Rat für kulturelle Zusammenarbeit, 2001, Section E), ZOP, KDS and GDS were replaced by Goethe-Zertifikat C2: Großes Deutsches Sprachdiplom in 2012.

In the mid-1990s Austrian federal ministries started to establish cultural institutes abroad that offered language courses focusing on Austrian cultural specificity. In 1992 a suite of exams matching this curriculum and modeled closely on the GI exams were developed. The Austrian German language diploma (Österreichisches Sprachdiplom Deutsch, ÖSD) was set up as a project headed by H.-J. Krumm at the University of Vienna in 1994. The crucial difference from the "Goethe exams" was that test items included Austrian and Swiss varieties. The first ÖSD examinations were held in 1995. A collaboration between Austrian, Swiss, and German experts led to a new ZD, first administered in 2000.

German for Specific Purposes

During the 1980s German was offered at universities around the world in combination with courses in business administration. To cater for this demand, the International Examination of Business German (Prüfung Wirtschaftsdeutsch International, PWD) was developed in the late 1980s by the GI in the United States.

The PWD was the first GFL exam for specific purposes. After 1989, this test was in demand in Eastern European countries, which used it to prepare candidates for work in joint ventures and in companies specialized in international trade. The PWD, offered in cooperation with the DIHK, catered both for university students and for practitioners in middle management. It placed a high demand for knowledge of special lexis in marketing and international business relations. This trend to create special tests for the need of business continued during the 1990s and led to the development of a diploma in vocational German (Zertifikat Deutsch für den Beruf, ZDfB; see Deutscher Volkshochschulverband & Goethe-Institut, 1995). With its mixture of open and closed task types and a curriculum less specific than that of the PWD, the ZDfB was tailored more for the needs of the lower management levels. In the late 1990s German universities attracted fewer and fewer foreign students, mainly as a result of the language barrier. In 1998 the German Academic Exchange Service (DAAD) commissioned the creation of a new exam, to be adapted to the needs of participants worldwide interested in studying in Germany and to be taken in their home countries: TestDaF (test for German as a foreign language for study purposes) (see Bolton, 2000). Designed to measure the candidates' ability to meet the demands of academic communication, TestDaF tests the four skills separately and is marked centrally in Bochum, Germany. The model for the tape-mediated oral test was the Simulated Oral Proficiency Interview (SOPI); reading and listening were tested with closed/semi-closed item types. An alternative to TestDaF is the Deutsche Sprachprüfung für den Hochschulzugang ausländischer Studienbewerber (DSH) (language test for admission of foreign students to German universities), developed and marked individually by each university. To facilitate mutual recognition of these tests, the Professional Association of German as a Foreign Language (Fachverband Deutsch als Fremdsprache) has issued a framework (*Rahmenordnung*) of common aims that registers all DSH versions. Another alternative is the UNICert system, which was developed by the association of language centers, language teaching institutes, and institutes of foreign languages (Arbeitskreis für Sprachenzentren, AKS) and is also based on a contract between German universities. Access to universities in Austria and in German-speaking Switzerland is not standardized to the same extent (Glaboniat, 2010).

Current and Future Directions

Accessibility

In recent years test accessibility for persons with disabilities has become a new challenge on the agenda of testing organizations. Observing the UN Convention on the Rights of Persons with Disabilities, which was signed by over 60 states and ratified at the domestic level, the GI, for example, can today claim to fulfill the conditions set in Article 10 of the ALTE Minimal Standards (ALTE, 2010): GI tests are available in Braille, and films featuring sign language are also available for persons with hearing disabilities. Finally, accessibility to practice materials is granted insofar as they are available on the GI Internet sites.

International Testing

The influence of international concepts and standards on testing German has manifested itself in two waves. First, the foundation of the Association of Language Testers in Europe (ALTE) in 1991 advanced international cooperation among several European language exam institutions. In 1994 this association defined 17 self-imposed acceptable standards as well as an audit system to control the adherence to the Minimal Standards (ALTE, 2010). The classical test criteria (quality, validity, reliability, impact, and practicability) were transformed into standards for development, administration, marking, analysis, and communication of results.

A second wave came with the publication and reception of the CEFR, developed from 1998 to 2000 by the Council for Cultural Cooperation, Modern Languages Division, and published in 2001 (Council of Europe, 2001). Defining learners' linguistic and communicative abilities in six levels (A1 to C2), the CEFR was received with special interest by European language testers, as a yardstick for identifying levels of competence. A common "currency" for the recognition of language certificates, it introduced more transparency in language testing. From 2001 onwards, new language exams in German were labeled with the targeted CEFR level. The CEFR's reception brought the introduction of methods of standard setting and benchmarking. The Council of Europe published illustrative samples of proficiency levels in different languages, including German (Bolton, Glaboniat, Lorenz, Müller, Perlmann-Balme, & Steiner, 2008).

Exams for Migrants

In 1974 the GI's unit *Deutsch für Ausländische Arbeitnehmer* (German for Foreign Employees) was founded, which elaborated a theoretical basis for teaching German to the growing number of immigrant workers (*Gastarbeiter*), mainly Southern European and Turkish, who were coming to Germany. One effect of the fall of the Berlin Wall in 1989 and of the ensuing geopolitical changes was the increase in the number of immigrants from Eastern Europe—so-called *Aussiedler* (ethnic German immigrants)—who resettled and became legally integrated into German society. State-funded German courses lasting up to ten months (1,000 units) were organized for them and administered mainly by the language centers of the GI and of the *Volkshochschulen* (colleges of adult education). At the same time, German courses for the *Gastarbeiter* were sparse. A survey initiated by the government to evaluate the effectiveness of the language courses for both groups made it clear, however, that the factor responsible for many participants' insufficient preparation for the job market was the lack of learning objectives. A standardized language test was suggested as a learning goal; it would also motivate participants and measure the quality of the courses.

Two exams below ZD-level were developed from 1999 to 2002 by the GI and the DVV: *Start Deutsch 1* and *Start Deutsch 2*. Only *Start Deutsch 1* was introduced, in 2007, as a pre-entry test for spouses and for family reunion purposes. In 2005 new legislation on immigration in Germany prompted a scheme of almost fully tax-funded language courses under the name of "integration courses" (*Integrationskurse*), for all groups of immigrants with the German test for immigrants

(Deutsch-Test für Zuwanderer); the integration course was first administered in 2009, as an achievement test; the language level was set at B1. Critics have judged this to be an ambitious level for migrants, some of whom had only a few years of schooling in their country of origin. For those not reaching B1 at the end of the language course, A2 was defined as also acceptable; it entitled participants to another 300 units of language course after an initial 600. The theoretical basis for this exam was a curriculum adding descriptors to the CEFR so as to serve the needs of migrants.

Assessing Greek

Spiros Papageorgiou

University of Michigan, USA

Introduction

Modern Greek is the official language of Greece and one of the two official languages in the government-controlled areas of the Republic of Cyprus (the other language being Turkish). It is also spoken in the Greek and Cypriot diaspora in many countries, primarily the USA, Canada, UK, Germany, and Australia.

Description of the Language

Greek, which has a history of 3,500 years, belongs to the Indo-European family of languages. The first examples of language use come from the Mycenaean civilization in the 16th century BC (Horrocks, 2010). Greek is noted for its continuity from ancient and Byzantine Greek to modern Greek, primarily concerning lexical aspects of the language (Browning, 1983). Standard modern Greek is largely based on the Peloponnesian vernacular; this is due to social and political circumstances in the 19th century, when the first Greek independent state was established (Pavlou & Papapavlou, 2004). In 1976 the Greek government abolished *Katharévoussa*, the “purified” language, which was used for official and formal purposes, and it established through the constitution *Demotikí* or *Koine*, the “common” language, as the official language of Greece; this political decision ended centuries of diglossia in the country (Papatzikou Cochran, 1997). Numerous dialects exist in Greece, for example Pontic and Cretan, whereas in Cyprus Cypriot Greek and Standard modern Greek are used in different domains, for example the former at home and the latter at school (Yiakoumetti, 2006, p. 298).

Standard modern Greek is written in the Greek alphabet and, as Papaefthymiou-Lytra (1987) points out, it is quite different from languages such as English in the following areas:

- Phonology. The modern Greek vowel system makes fewer distinctions than the English vowel system, whereas spelling is phonetic, with an almost one-to-one correspondence between sounds and letters.
- Grammar. Although there are many similarities between modern Greek and English, such as singular and plural forms and active and passive voice, there are also numerous notable differences. Modern Greek, for example, is a highly inflected language (e.g., articles, nouns, pronouns, and adjectives have four cases), and grammatical gender (masculine, feminine, or neuter) does not have any relationship with meaning.
- Vocabulary. There are words in English that are loans from Greek, and at the same time Greek has borrowed many words from English. However, false friends (e.g. “to sympathize,” understood in English as meaning “to like”) and the lack of words with equivalent meaning across the two languages (e.g., the lack of Greek verbs equivalent to the English “know,” “learn,” and “study”) might cause confusion.

Teaching and Learning Context

The educational systems of Greece and Cyprus are centralized. In Greece, the Ministry of Education, Lifelong Learning, and Religious Affairs is responsible for the appointment of teachers and for the curriculum, the budget, and the legislation of the regional educational directorates, which it supervises. Education is compulsory for all children between 6 and 15 years of age. Children first attend *demotiko* (elementary school) for six years, then *gymnasio* (lower secondary school) for another three years. Upon completion of the compulsory education, students can choose between a general upper secondary school (*enieto lykio*) and a technological vocational school (TEE). For students who work full time, evening classes are offered. Students can also enroll in vocational training institutes (IEK), which are postsecondary, nontertiary institutions. Approximately 1.1 million students were enrolled in public and private compulsory education during the school year 2009/10, the vast majority of them (94%) attending public schools (European Commission, 2010a). The national curricula for all subjects in primary and secondary education are developed by the Pedagogical Institute and approved by the Ministry. Higher education consists of universities and technological educational institutions (TEI), which are exclusively public, as dictated by the constitution. Private institutions offer postsecondary degrees that are not recognized by the Greek state as equivalent to university degrees, despite the fact that these degrees are issued by, or in cooperation with, universities outside Greece. Admission to public tertiary education is primarily determined by scores on the centrally organized, nationwide examinations referred to as *Panelladikes* or *Panellinies* (Pan-Hellenic); these scores are obtained at the end of upper secondary education. University entrance examinations are very competitive, as the number of applicants is larger than the number of places they apply for (Giamouridis & Bagley, 2006, p. 9).

As a result of the fierce competition, almost all students enroll in after-school preparatory classes in private institutions called *frontistiria* or attend one-on-one

private classes. Almost all students in Greece also attend *frontistiria* for foreign languages, despite the fact that languages are taught in public schools—as discussed by Tsagari (2009), who provides detailed insights into the learning and teaching context of these institutions. A major motivation for attending additional foreign language classes is probably the desire of students and parents to obtain foreign language certification from international and local examination agencies (see a list of such agencies in Papageorgiou, 2009, p. 199). Tsagari's (2009, pp. 190–202) study shows that this desire is not only motivated by future professional or educational plans (for example to enhance a CV or to study abroad), but also by personal reasons and aims, in particular to acquire the self-esteem that results from belonging in the group of “successful” students (i.e. those who pass a language exam).

In Cyprus the Ministry of Education and Culture is responsible for the administration, organization, and allocation of financial resources. As in Greece, compulsory education in Cyprus includes six years of elementary school (*demotiko*) and three years of lower secondary school (*gymnasio*); in addition to these, one year of kindergarten has been made compulsory since 2004. Postcompulsory education includes general upper secondary schools (*eniao lykio*), technical and vocational upper secondary schools (*techniki scholi*), and the “apprentice scheme” (*sistima mathitias*) for students who have not completed compulsory education successfully and want to train to enter the job market. Approximately 95,000 students were enrolled in public and private compulsory education during the school year 2008/9, and the vast majority of them (87.5%) were attending public schools (European Commission, 2010b). The national curricula for all subjects in primary and secondary education are decided by the Council of Ministers, following suggestions by the Ministry of Education and Culture. Higher education in Cyprus is provided by state and private universities, as well as by state and private non-university institutions. Students are generally admitted to state universities and to most private universities upon taking the national (Pan-Cypriot) examinations (European Commission, 2010b, p. 29).

Modern Greek is a school subject in primary and secondary education and the language of instruction in Greece and Cyprus. Other languages include Turkish, which is used in schools for the Muslim minority that resides in the region of Thrace, Greece (to be further discussed in later sections of this entry) and in public universities in Cyprus (European Commission, 2010a, 2010b). English is the language of instruction in some private universities in Cyprus and in international schools in both Cyprus and Greece. In both countries, university departments specializing in foreign languages employ English, French, German, Italian, and other languages for instruction.

Outside formal schooling contexts, modern Greek is learnt as a foreign or second language, not only by non-native speakers but also by repatriated citizens in both Greece and Cyprus (Pavlou & Christodoulou, 2001). On the basis of Pavlou and Christodoulou's classification of learners of Greek as a second or foreign language in Cyprus, the following groups can be distinguished:

- Students in universities in Greece or Cyprus where Greek is the language of instruction. Students either attend these institutions to obtain a degree or they

complete classes as part of an exchange program such the Erasmus program of the European Union.

- Foreign nationals who live and work in Greece and Cyprus and need to learn Greek for professional reasons and to be part of the local society.
- Repatriates from traditional countries of immigration such as the USA, UK, Canada, Australia, Germany, and countries of the former Soviet Union. Repatriated Greeks and Greek Cypriots may vary as to their knowledge of the Greek language and as to the difficulties they face in the four language skill areas (Pavlou & Christodoulou, 2001, p. 80).

Classes in Greek as a second or foreign language are offered in public and private institutions in Greece and in Cyprus, such as the Modern Greek Language Teaching Center at the University of Athens, the School of Modern Greek Language at the Aristotle University of Thessaloniki, the Language Centre at the Cyprus University of Technology, and the Hellenic American Union in Athens. A comprehensive list of institutions offering Greek classes in Greece, in Cyprus, and abroad is held at the Center for the Greek Language (www.greek-language.gr).

Assessment Practices

As in most school subjects, there are diverse practices in the assessment of modern Greek in Greece and Cyprus, depending on the educational level and the use of test scores.

In primary schools in Greece, students are evaluated on the basis of participation in the classroom and performance on homework and projects in grades 5 and 6. Although officially a school grade can be repeated if performance is not satisfactory, this rarely happens, as remedial teaching is provided for students with learning difficulties (European Commission, 2010a, p. 22). In secondary education assessment is based on day-to-day participation in the classroom, compulsory tests designed by teachers and administered without prior notification, projects, and an end-of-year achievement examination (in May or June) for which a 20-point scale is used. All types of assessment count toward promotion to the next grade. If students have not met the minimum performance requirements in order to be promoted, they can repeat the end-of-year examination. Students completing compulsory secondary education receive a certificate and can attend noncompulsory secondary education (European Commission, 2010a, p. 29). After receiving a school-leaving certificate from a noncompulsory secondary school, a student may enter higher education or may attend a vocational institute. Admission is determined by the student's score in the national university entrance examinations, the student's order of preference of university departments, and the number of students admitted by each academic department. The 2011 modern Greek exam papers for students graduating from regular and evening noncompulsory secondary schools are available from the Web site of the Ministry of Education, Lifelong Learning, and Religious Affairs (see Ministry of Education, Lifelong Learning, and Religious Affairs, 2011a and 2011b). Modern Greek is compulsory for all students, irrespective of their field. The exam consists of a two-page passage, adapted from

publicly available sources such as newspaper articles. Students must summarize the passage and answer open-ended questions that test comprehension of the lexical content, syntax, and author's intention. Students also have to write a 500- to 600-word essay.

In Cyprus primary school students are evaluated on the basis of their classroom participation, results of oral and written tests designed by the teacher, and work done in the classroom and at home, including project work. A student may repeat a school grade because of unsatisfactory performance. A school-leaving certificate is issued at the end of primary education, and students can enroll in compulsory secondary education (European Commission, 2010b, p. 21). Assessment in compulsory and noncompulsory secondary education involves quizzes, revision tests and individual or group projects, and internal end-of-year examinations, for which a 20-point scale is used. A certificate indicating successful completion of the school grade is the sole requirement for enrollment in the next grade. The national examinations serve both as final examinations for the last year of non-compulsory education and as entrance examinations for the public universities of Cyprus and Greece (Greek universities reserve admission offers for citizens of the Republic of Cyprus). On the basis of national and school scores, a school-leaving certificate is issued upon successful graduation (European Commission, 2010b, p. 29). The 2011 modern Greek exam paper in Cyprus is available from the Web site of the Ministry of Education and Culture (see Ministry of Education and Culture, 2011) and is almost identical in terms of content and focus to its counterpart in Greece.

Learners of Greek as a foreign or second language can take examinations offered by state institutions both in Greece and Cyprus. The Certificate of Attainment in Greek, designed by the Center for the Greek Language to assess all four language skills (reading, writing, speaking, and listening), is probably the most widely known examination of Greek as a foreign or second language, as it is offered in centers in Europe, the USA, Canada, South America, Africa, Asia, and Australia. It is also a high stakes examination, because the examinees' meeting requirements for practicing various professions in Greece, for registering at a Greek institution of higher education, and for being employed by the civil service will depend on the proficiency level they achieve in this examination (Antonopoulou, Tsangalidis, & Mourtzi, 2008). Since 2011, the Certificate of Attainment in Greek consists of a suite of six exams aiming to test proficiency at levels A1 to C2 on the Common European Framework of Reference (CEFR; Council of Europe, 2001). An earlier standard-setting study (Papageorgiou, 2008) was carried out to set cut scores on the CEFR levels for the initial suite of four exams. Sample items for all six levels are available from the Web site of the Center for the Greek (see Center for the Greek Language, 2011).

Challenges

Social, political, and economic developments, especially in the last two decades, have contributed to a significant increase in the number of speakers of languages other than modern Greek who now reside in Greece and Cyprus. Greece, for

example, changed from a country of origin for immigrants, as it was in the 1950s and 1960s, to a host country for immigrants—particularly since the late 1980s, when immigrants from Eastern Europe, together with ethnic Greeks from Albania and countries of the former Soviet Union, started to settle in Greece (Lytra, 2007, pp. 3–4). Naturally, demographic changes have been observed in schools, as 10% of the student population in Greek public schools in 2006/7 consisted of repatriated and foreign students (Zachos, 2009, p. 142). For these students, partial knowledge of the language of instruction, or even lack of it, might have a negative effect on performance on subjects other than modern Greek. Although educational authorities offer language support classes to students as well as to adults (European Commission, 2010a, p. 54), the change from a linguistically homogeneous student population to a population with diverse cultural and language backgrounds remains a challenge, and the success of various reforms has been questioned (Zachos, 2009, p. 142). The assessment of Greek language proficiency in public schools and the effect that proficiency in Greek has on performance on other school subjects remain largely unexplored areas of the Greek and Cypriot educational contexts.

The Greek Muslim minority in the region of Thrace, Greece, which comprises speakers of Turkish, Pomak, and Romany, has been studied by educational researchers and sociolinguists for its use of languages other than Greek. Because only Turkish is written, it enjoys a special status as language of instruction, along with Greek, in bilingual minority schools (Sella-Mazi, 1997, p. 84). Research suggests that measures designed to increase the participation of minority school students in postsecondary education have not been effective (Zachos, 2009, p. 146), and the minority school students' proficiency level in modern Greek varies significantly across and within age groups (Tzeveleku et al., 2005, p. 18).

The linguistic context of Cyprus makes another interesting case study for the learning and assessment of modern Greek, because of the political issues that surround it. Standard modern Greek is one of the two official languages and the language of instruction, although Cypriot Greek is spoken at home. Applied linguists describe this situation as "bidialectalism" (Pavlou & Christodoulou, 2001; Pavlou & Papapavlou, 2004), and Cypriot Greek is generally perceived as a dialect of Standard modern Greek. Nevertheless, some linguists argue that Cypriot Greek is actually a linguistic variety, that is, a language that can be considered a single entity, and that the diglossic situation of Cyprus is denied because of the link between language and ethnicity (Arvaniti, 2006): Cypriots define themselves as ethnic Greeks (Hellenes) on the basis of language. Yiakoumetti (2006, p. 299) argues that educational language policy in Cyprus treats Standard modern Greek as the students' mother tongue and excludes their actual dialectal mother tongue.

Future Directions

This chapter's discussion of the educational contexts of Greece and Cyprus and of the assessment issues related to modern Greek points to potential directions for research. The increasing number of students from different social, cultural, and

educational backgrounds strongly suggests that future studies need to address concerns formulated in the literature (Sella-Mazi, 1997, p. 100; Giamouridis & Bagley, 2006, p. 14; Zachos, 2009, p. 146) and related to:

- the school system structure, which remains strictly monocultural;
- school textbooks, which continue to promote an old-fashioned image of the superiority of anything Greek;
- inequalities in the educational achievement of student groups, which are due to these students' social, economic, geographical, and ethnic background;
- restricted access to higher education for minorities on account of their low proficiency level in modern Greek;
- restricted access to all levels of education, primarily higher education, to children who were born, raised, and educated in Greece but are not eligible for citizenship because their parents are not Greek citizens.

There is also a need for more research and for validation for the tests of Greek as a second or foreign language, especially for those tests whose scores are used to make important decisions. For example, statistical analyses of test reliability, item difficulty, and item discrimination for the Certificate of Attainment in Greek (Papageorgiou, 2008, pp. 31–2) suggest that there is room for improving the psychometric quality of these items—which is essential, given the high stakes nature of the test scores.

Assessing Italian

Giuliana Grego Bolli

Università per Stranieri di Perugia, Italy

Introduction

In writing about language assessment in Italian, it is worth starting with a broad and updated definition of assessment that is suitable for the aim and the content of this paper: “all methods and approaches to testing and evaluation whether in research studies or education context” (Kunnan, 2004, p. 1). With regard to this definition, there has been little in-depth study of the assessment of Italian, either as a mother tongue, or as a second language. There is no specific academic discipline dealing with it, which confirms the fact that there is neither real scientific interest, nor a research tradition in the field. Consequently, there are few Italian scholars who work on the type of research that language testing has been contributing to internationally over the last 60 years. The reason for this is basically a cultural one: the empiricist research methods, that draw on observation, experiment, and data collection on which language testing heavily relies, have not been part of the research tradition in linguistic sciences as far as the Italian context is concerned, which instead has been more focused on historical and philological aspects.

Description of Italian

Italian is a neo-Latin or Romance language, like Portuguese, Spanish, French, Provençal, and Romanian. However, the history of Italian differs from that of the other Romance languages, in that for centuries in Italy there was no collective force, either political or religious, to impose the establishment of a regional language or dialect at a national level. The fundamental linguistic structures of Italian (phonology, morphology, many aspects of syntax, basic vocabulary) come from

the Florentine dialect of the 14th century, as it was elaborated in a literary form by the “three crowns” of Italian literature: Dante, Petrarch, and Boccaccio. Later on, in the 16th century, grammarians adhering to the prevailing line of thought in the Renaissance language debate headed by Pietro Bembo used this as a model for written Italian. The very literary and classical origins of the language, that were exclusively linked to the written form, explain why, in contrast to other languages, Italian has not undergone a structural evolution, which would have allowed it to develop and change, as happened for other Romance languages. Up until the unification of Italy in 1861, Italian was used mainly for writing, sometimes alternating with Latin. Not being connected to the spoken language of daily life, it therefore assumed similar characteristics to those of a dead language, like Latin itself. As such, while the vast majority of the population spoke in dialect, the Italian language remained conservative, largely unchanged and consequently unsuited to modern forms of writing, particularly scientific writing, essays, and novels.

Clearly the problem was not only a linguistic, but also a political and, above all, a cultural one. Alessandro Manzoni understood the importance of dealing with the issue when in 1821 he started to work on *I Promessi Sposi*. This book was written at a time when the problem of a national identity was beginning to come to the fore, in a country that was still divided into many different states with little sense of national unity. It was to Manzoni’s great credit that he realized there could be no national identity or culture without having a common language. With good reason *I Promessi Sposi* is not only considered to be the first great Italian novel, but also the first real piece of writing in the unified language.

The unification of Italy in 1861 opened up new political, linguistic, and socio-cultural scenarios. In relation to this, D’Achille (2010) observed the following:

For various reasons, the use of Italian has progressively increased since unification, meaning less use of dialects. Some of these reasons include the gradual spread of literacy following compulsory education, internal and external emigration, urbanization, the change in social, economic and cultural conditions of the population, closer dealings that most people have with the State, (the army, bureaucracy etc.), and lastly the development of mass media (newspapers, cinema, radio, television, advertising up to the so-called new media). (p. 26)

However, the actual process of establishing Italian as the only language used by the whole nation has been both long and gradual, and did not result in a sudden and complete disappearance of dialects.

Today the scenario has changed and Italian is the language of communication, both in the social and work environments. The evolution of Italian society and history is the basis for the progressive disuse of dialects and the consequent adoption of a common language (De Mauro, 1963, p. 50). In addition, the language spoken on a daily basis has influenced written Italian, leading to some restructuring of the linguistic system, introducing new features, regional elements, and simplifications.

To summarize, for centuries, Italian was a language of literature and not of common usage. This fundamental characteristic helps to further clarify the

historical and conceptual background that has led to the development of a greater part of linguistic research in Italy.

Current Situation of Italian in Italy and Abroad

Even today, Italy remains one of the most historically rich countries in Europe for languages and dialects. There are about 15 languages other than Italian that are protected by a special state law which is part of the Italian Constitution (law n. 482, 1999, for the protection of minority languages). Among these languages are Sardinian, Albanian, Ladin, Catalan, Friulian, Slovenian, German, and Austrian dialects. Recently added to these historical minority languages are other new or minority languages, spoken by immigrant communities in Italy, the most numerous being Romanian, Albanian, Moroccan, Chinese, Ukrainian, Tagalog, Indian, Polish, Moldavian, and Tunisian. In addition, there are hundreds of dialects, which cannot be considered varieties of Italian because, as Lepschy (1988, p. 13) pointed out, “they differ from each other and from the national language.”

To this panorama, Italian spoken abroad both by emigrants (see Vedovelli, 2011) and by those studying it as a foreign language can also be added. The great migratory movements that have affected the population of Italy started in the second half of the 19th century, and continued up until the 1970s, affecting around 25 million Italians. For most of these migrants, their mother tongue was a dialect rather than Italian, although their ability in Italian has increased continually over the years. However, Italian has never managed to take foothold as a proper “ethnic language” (see Bertini Malgarini, 1994), nor has there ever been the support of a national policy to encourage it. Consequently, the language has been supplanted by the much more powerful languages of the host countries: English in the USA, Australia, and Canada (as well as French), Spanish in Argentina, Portuguese in Brazil, French in France and Belgium, German in Switzerland.

Nowadays, studying Italian does not appear to be very popular within the education systems across the European Union. Very recent data revealed by the European survey into language competence carried out by a European project funded by the European Commission (SurveyLang, *n.d.*) fully confirm this. Italian is not the most commonly taught language in the higher secondary schools in any of the 14 countries (Belgium, Bulgaria, Croatia, England, Estonia, France, Greece, Malta, Netherlands, Poland, Portugal, Slovenia, Spain, Sweden) who agreed to take part in the survey, and only in Malta was it tested as a second foreign language. Italian was, in fact, the official language of Malta until 1934 and still remains very popular due to the country’s proximity to Italy.

Assessment of Italian

Assessment of Italian as a First Language: Context and Issues

The assessment of Italian as a mother tongue (L1) within the state school system in Italy has to follow the national legislative framework and national curricula and programs, and is formally under the supervision of the Istituto Nazionale

per la Valutazione del Sistema Educativo di Istruzione e di Formazione (INVALSI) (INVALSI, *n.d.*).

INVALSI is monitored by the Ministry of Education, which periodically identifies the strategic priorities, on the basis of which the Institute plans its activities. Broadly speaking, by evaluating the skills acquired by the students, INVALSI evaluates the overall quality of programs, education activities, and practices within the school system. INVALSI also has the task of conducting research on education, based on the analysis of the assessment results, using both qualitative and quantitative methods. The Institute takes part in various national and international projects in this field, such as the Organisation for Economic Co-operation and Development-Programme for International Student Assessment (OECD-PISA) Project.

To help the reader understand the context in which INVALSI operates, it might be useful to offer a brief outline of the Italian education system. The system is subdivided into:

- primary school (five years),
- lower secondary school (middle school) (three years),
- higher secondary school (five years).

The higher secondary school system differs depending on subject orientation: classical, scientific, or technical-professional. We may also refer to the first cycle of education, which encapsulates primary and lower secondary school, and second cycle, meaning higher secondary school.

The teaching of Italian as mother tongue in all types of schools today is very different from that taught several decades ago. Nowadays the national curricula and programs are based not only on the literary language, on structural and stylistic knowledge, but also on the ability to use it for communicative purposes in different contexts and situations. In this relatively new context, INVALSI is responsible for both formative and summative assessment and for preparing suitable tests for both sectors. INVALSI has the task of preparing and developing the final exams for both lower and higher secondary schools.

INVALSI (2010–11) provides an example of an exam at the end of lower secondary school. The components of the exam have been elaborated following a specific framework of reference for Italian INVALSI (2011) that provides the specifications needed. According to the framework, mastery of the language consists in the knowledge of the language itself and the ability to use it, and is achieved in three different areas:

1. oral interaction (oral communication in different contexts),
2. reading (understanding and interpreting various written texts),
3. writing (producing various types of text for differing communicative aims).

Due to the technical difficulty in standardizing the marking process of both oral interaction and writing across the national territory, the assessment is focused on reading, which includes not only comprehension of explicit or implicit meaning, depending on the school level, but also textual competence, as well as lexical and

grammatical knowledge. The testing methods most commonly used are multiple choice with four options and open-ended questions. The framework provides fairly comprehensive descriptions of competences and procedures, as well as the types of text to be used for assessment at different school levels.

Another framework is provided for the assessment of writing in Italian at the end of the second cycle: (INVALSI, 2009–10). This framework has been elaborated by INVALSI jointly with Accademia della Crusca, one of the leading institutions worldwide in the field of research on the Italian language (Accademia della Crusca, *n.d.*).

In addition to the tests provided and administered by INVALSI, teachers in the state system are also free to use less formal tests, throughout the school year, in order to assess their pupils' skills in Italian. These tests may be created by individual teachers or by a group within each school.

The work done by INVALSI and the tests they administer for supervision in schools are not always well received by the teaching staff in the state schools. There could be various explanations:

- The result of an evaluation of learning may be taken to imply assessment for the teacher, that is, if the teaching has had the desired results or “success.”
- Despite the fact that the assessments provided by INVALSI follow the Ministry of Education guidelines, they are often found quite difficult by both teachers and students and are not always consistent with what is effectively taught.

The first reason is part of the often conflicting relationship between teaching–learning and assessment, especially when the assessment is carried out by an institution other than the one in charge of teaching. The second, however, may depend on the (principally objective) testing methods used by INVALSI. Perhaps not enough importance is given to how the students' preparation and their familiarity with the methods can affect their performance. More generally, what is missing is an effective form of communication and a more systematic exchange of experience and competences, between external experts in assessment and teachers within the school system.

Generally speaking, there is the unresolved problem of the relationship between the national curricula, teaching, and assessment in pedagogy (see Cumming, 2009). It would be opportune to question whether teaching and assessment, particularly formative, should be solely dependent on national curricula, or should students' needs and their characteristics be taken into greater consideration. Despite the presence of INVALSI and the work it has done concerning the assessment of Italian as a mother tongue within the state school system, it is still necessary to make the relationship between national programs, teaching activities, and assessment more coherent and systematic, just as it is still necessary for Italian teachers to receive more specific and systematic training in language assessment.

Assessment of Italian as a Second Language: Contexts and Issues

Nowadays, when dealing with Italian as L2, it is important to distinguish between Italian as a second language, meaning learned where it is used for everyday

communication and social interaction, that is, in Italy, and Italian as a foreign language, meaning learned where it is not used for everyday communication, that is, abroad. Different problems also emerge from the two different learning contexts, in terms of assessment. This is not only because the mental processes activated in the two situations differ, but most of all because, today more than ever, the learners involved in the two contexts tend to differ in terms of sociocultural and cognitive characteristics, as well as in their objectives and needs; if this is not taken into consideration, problems can emerge in terms of the fairness of the assessment, consequently having a social and educational impact.

Assessment of Italian as a Second Language (L2) The assessment of Italian as a second language is, nowadays, mainly linked to the immigration context. Increasingly very complex concepts, such as social inclusion and integration, are involved with language assessment, and particularly with formal assessment. As a result of large migratory movements which have affected Italy, particularly over the last 10 years, the problem of reception, inclusion, and integration of immigrants is being taken ever more seriously. Inclusion and integration depend on various factors: personal, social, political, economic, and cultural. An important contribution to immigrants' inclusion, both social and in the work environment, can be made by providing education opportunities and, more specifically, language training. Knowing the language of the country you live in facilitates access and opportunity for study, for better jobs, as well as making it easier to take part in public life in its various forms. Accordingly, assessment could be included in language courses, providing some form of acknowledgment of the study and effort involved, which could lead to further opportunities.

In contrast, Italy, like most of the European Union member states, has seen the official introduction of a test for linguistic qualification as a requirement for a long-term residence permit. Although this permit, according to the new legislation, can also be obtained by attending training courses or by providing proof of other studies or qualifications (such as attending a language course with an exam at the end, language certificates in Italian, secondary school diplomas obtained within the Italian education system, attending a university course or a postgraduate course), the quickest and most economical way is through the test.

There are various risks when such formal tests for language requirements are included in a context of immigration: first, they can easily be improperly used to control the flow of immigration (see Shohamy, 2001, 2008; Kunnan 2009; Shohamy and McNamara, 2009) and to exclude the weaker, less educated migrant; second, they can draw attention away from more important issues that the state should be dealing with, namely education: introducing systematic training courses, including language courses, designed to encourage inclusion as much as possible. In addition, the use of such language tests in order to obtain fundamental rights is an example of how language assessment, with its basic characteristic of "decision making," can be used as a political tool. This distorted use poses not only important ethical considerations, but also practical and theoretical ones for those who develop and produce language tests in such a delicate situation.

The new law approved in December 2010 requires the passing of an A2 level (Common European Framework of Reference, CEFR) test in order to obtain a

long-term residence permit. The test is focused on reading, listening, and writing: no assessment of speaking is provided at the moment. On the basis of a framework agreement between the Ministry of Interior and the Ministry of Education, the tests are to be administered and organized by Centri Territoriali Permanenti (CTP)—state schools which have worked in the field of adult continued education since the end of the 1990s. Therefore, from now on, it will officially be these state schools that have to deal with the assessment of language skills of adult immigrants in Italy. The law, however, also recognizes language certificates awarded by the Italian institutions involved in the certification of Italian and recognized by the Foreign Ministry and Ministry of Education since 1993 (Università per Stranieri di Perugia, Università degli Studi Roma Tre, Università per Stranieri di Siena, Società Dante Alighieri) as equally valid. In addition, the Ministry of Interior and the Ministry of Education have delegated to the four above-mentioned institutions the task of preparing a syllabus and specific guidelines to be used as a basis and reference point for test construction, administration, and rating procedures. Nevertheless these guidelines have already been partially changed by the Ministry of Education. There are various issues that this Italian solution poses and that should be addressed, among which are the monitoring of the overall test production process, the training of both item writers and examiners, and the impact of the test on the immigrant population.

Passing to another context, within the Italian state school system nothing has yet been formalized for the assessment of language abilities of foreign pupils, except for language certificates produced by the certification institutes previously mentioned and aimed at these users. It is important to stress that in this field the most pressing problem is related to the inclusion of foreign pupils (about 629,000 in 2008/9, compared to 574,000 in 2007/8, according to the official data provided by the Ministry of Education) into the Italian school system, and the resulting need for specific actions and courses to support such inclusion effectively. Particularly when dealing with minors who are likely to be future citizens, the school, and more generally the education system, can play a fundamental role in creating real opportunities to foster a process of reciprocal and mutual knowledge and understanding between the immigrant communities and the hosting one, which is the basis for inclusion and for long-term integration.

Despite official documents and regulations provided by the Ministry of Education and various declarations by policy makers that go in this direction, the only useful and concrete initiatives in this field have been organized at regional level, involving local councils, or even individual schools and teachers. Little has been done systematically at a central level to train teaching staff either to cope with the new situations and conditions in Italian schools, or the resulting language emergency caused by the growing presence of immigrant pupils.

Assessment of Italian as a Foreign Language Over the last 20 years the most important and significant event in the area of the assessment of Italian as a foreign language has been, without doubt, that related to the work on language certification carried out by the four Italian institutions previously mentioned. There are four certificates of Italian:

- the Certificato di Conoscenza della Lingua Italiana (CELI) certificate, awarded by the Università per Stranieri di Perugia;
- the Italiano (IT) certificate, awarded by the Università degli Studi Roma Tre;
- the Certificazione di Italiano come Lingua Straniera (CILS) certificate, awarded by the Università per Stranieri di Siena;
- the Progetto Lingua Italiana Dante Alighieri (PLIDA), awarded by the Società Dante Alighieri.

Each certificate has its own internal specifications, depending on the type of user, general language, or language for specific purposes and levels.

The work of the four institutions in the field of language certification officially started in 1993, with the signing of a framework agreement by the four institutions and the Ministry of Foreign Affairs, which assigned to them the function of certifying knowledge of Italian. Wanda d'Addio Colosimo (1986a, 1986b), and her team, were the first to write about language certification in Italian, making concrete proposals and highlighting aspects and implications to deal with both in terms of theoretical and practical issues.

Nowadays each of the four certification systems has its own specific theory and methods to refer to, a difference that over the years has attracted different test users. Different offers can more easily satisfy different demands. Vedovelli, Barni, Bagna, and Machetti (2009) explain in some detail how the systems differ and how they are similar in terms of the overall testing process. In addition, specific publications by each institution describe their respective certification systems, the work done in this area, the projects realized, and the research carried out (Società Dante Alighieri, *n.d.*; Università degli Studi Roma Tre, *n.d.*; Università per Stranieri di Perugia, *n.d.*; Università per Stranieri di Siena, *n.d.*).

Despite their differences, the work that the four Italian institutions involved in the certification of Italian have carried out in the last 20 years has undoubtedly contributed enormously toward

- promoting the study and knowledge of the Italian language worldwide, offering language qualifications that can be used in the workplace, tailored from the very basic to much more complex learning objectives;
- introducing language testing in the Italian context;
- promoting a more systematic approach toward the assessment of language competence in Italian, based on the principles of good practices introduced by scientific and professional associations such as the International Language Testing Association (ILTA), the European Language Testing Association (EALTA), and the Association of Language Testers in Europe (ALTE);
- encouraging the development of specific competences and experiences in the field of language assessment and specifically of language testing, opening up to international collaboration;
- contributing to the training of teachers of Italian as L2 in this specific sector, providing special courses in language testing;
- promoting research into this particular field within the Italian context.

Challenges and Future Directions

Historical and cultural reasons, closely linked to the history of Italian language and of the related research, lie behind the low interest that language assessment and, hence, language testing holds within the academic community in Italy. More empirical research and more studies in this specific field still have to be conducted. For this reason, it is of vital importance to foster interest amongst university students in this field, in order to create a scientific community with appropriate competences. To reach this objective it is necessary to introduce language testing as a subject to be taught at university level, which, at present, has been limited to the three universities involved in language certification. At the same time, as has been previously stressed, what is lacking is a more detailed and systematic training of teachers of Italian as L2 in assessment, in order to help them develop language assessment as a part of their professional competence. The four Italian institutions involved in the certification of Italian L2 and, in particular, the three universities, are working in this direction, having set up regular training courses for teachers, item writers, and examiners, but much remains to be done.

Finally, the impact of assessment, both in society and in education, is an area of research and investigation that needs to be addressed in more depth, especially in order to find a responsible way of dealing with the social emergency emerging from the political use of language assessment in the context of migration.

There are therefore many challenges still to be faced in the field of language assessment in the Italian context. Despite this, the work and contribution of INVALSI and the four Italian institutions involved in language certification, international collaboration in this area, and the input it can offer, are destined to remain of great importance in the future, in order to promote a more systematic, theory-based approach to language assessment.

Assessing Norwegian

Cecilie Carlsen

University of Bergen, Norway

Eli Moe

University of Bergen, Norway

Introduction

Norway is a small language community with slightly fewer than 5 million inhabitants. With the exception of a modest population of Samis, totalling approximately 40,000 individuals, Norway was a relatively homogeneous society until the 1970s. During the last four decades Norway has, however, witnessed a growing population of immigrants from every corner of the world. Today the immigrant population amounts to approximately 550,000 individuals, corresponding to 11.5% of the total population. There is broad political agreement that a good command of the majority language, Norwegian, is a key factor for successful integration. The government therefore considers it beneficial for all parties to offer to the immigrant population courses in Norwegian language and knowledge of society as well as language tests at various levels of proficiency.

Even though Norway is a small language community, it has two official languages: Norwegian and Sami. What makes the language situation even more complex is the fact that Norwegian has two written forms, Norwegian Bokmål and Norwegian Nynorsk, and all public documents are published in both forms. Norway is also widely known for its many dialects, or more correctly, for its high tolerance for dialectal variation (Trudgill, 2002, p. 31). Norwegians speak their local varieties in all contexts, and are normally very proud of their dialect.

In this chapter we will describe the Norwegian language and how it is taught and assessed in Norway, with respect to the majority as well as the minority population and with regard to children and adolescents as well as adults.

Description of the Norwegian Language

Norwegian is a North Germanic language. This language branch of the Indo-European tree can be further divided into subgroups (Figure 135.1).

Figure 135.1 North Germanic languages

Since Norwegian, Swedish, and Danish are the national languages of Norway, Sweden, and Denmark, they are defined as different languages. They could, however, just as well be viewed as dialects or varieties of the same language, Scandinavian, as Norwegians, Swedes, and Danes experience only minor problems communicating with one another using their distinct national languages (Kloss, 1978, pp. 23–30).

The Norwegian alphabet has 29 letters, 26 of which are identical with those of the English alphabet. In addition it has the three letters æ, ø, and å. As for pronunciation, the front or central rounded vowels /y/, and /ʉ/ are secondary to the unrounded /i/, while /ø/ is secondary to /e/. In Norwegian, there is a significant distinction in pronunciation and meaning between rounded and unrounded front and central vowels. Since frontal rounded vowels are typologically rare, pronunciation of these vowels is particularly difficult for many second language (L2) learners of Norwegian. As regards morphology, Norwegian has become gradually less synthetic than Old Norse, yet modern Norwegian still has a relatively rich morphology with inflections of pronouns, nouns, verbs, and adjectives. Syntax plays a more important role in modern Norwegian than it did in Old Norse. Like English, Norwegian is a subject–verb–object (SVO) language. Variations to the SVO order do occur, but these are considered less basic. Like all the other Germanic languages (with the exception of modern English), Norwegian syntax obeys the verb second (V2) word order rule, which requires a finite verb to be the second constituent of a declarative main clause, as illustrated in Table 135.1.

Table 135.1 Norwegian SVO patterns

1	2 <i>finite verb</i>	3	
Han	kjøpte	en bil i går.	“He bought a car yesterday.”
I går	kjøpte	han en bil.	* “Yesterday bought he a car.”
En bil	kjøpte	han i går.	* “A car bought he yesterday.”
* I går		han kjøpte en bil.	“Yesterday he bought a car.”

Historically, most Norwegian words derive from Old Germanic or Latin. Modern Norwegian, however, is largely influenced by English. While some English loanwords are translated into Norwegian, for example, “home page” to

hjemmeside and “memory stick” to *minnepinne*, other English words are used in their original form, for example, “hat trick” (from football) and “food processor”. As Norwegian is a rather orthophonic language, there is a tendency for English loanwords to be spelled in accordance with Norwegian pronunciation, for example, *jus* “juice”.

The year 1814 marked the end of the Danish–Norwegian Union, which had lasted for 400 years, during which Danish had been the official written language in Norway. After 1814, the Norwegians wanted an official Norwegian written language as a manifestation of the new nation and to strengthen Norwegian identity. Two options were considered: to use the Danish written standard as a starting point and gradually try to “Norwegianize” it by changing typical Danish features (orthographical, morphological, lexical, etc.) with more Norwegian features; or to start from scratch and build a new written standard based on Norwegian dialects (considered more purely Norwegian than the Danish standard at the time).

As people were unable to decide which would be the better, both strategies were applied. This is the background for the two official written standards of Norwegian today. Norwegian Bokmål has its historical roots in Danish while Norwegian Nynorsk was developed on the basis of Norwegian rural dialects. Since 1885, both forms have held an equal status as official Norwegian written standards, that is, used in public administration, radio and television, schools, etc. Pupils learn to write both standards in school, but they choose one of them as their primary written language.

Another special characteristic of the Norwegian language community is the lack of a spoken standard considered more correct or suitable than the others. This means that people also speak their local dialect in official contexts, for instance in parliament, on television, when teaching at university, etc. The question as to whether this linguistic diversity poses problems to learners of Norwegian as a second language, has not been the focus of much research interest so far (Blommaert, Leppanen, & Spotti, 2012).

Teaching and Learning of Norwegian as L1 and L2

Norwegian L1 is considered a core subject in school. It covers not only Norwegian language, but training in writing, reading, oral presentation, text and literature study, etc. The Norwegian language curriculum is based on the underlying belief that learning to express oneself in the mother tongue, both in speaking and writing, along with the reading of literary works, forms pupils’ identity and develops their learning and thinking skills (Ministry of Education and Research, 2010a). The curriculum aims at developing pupils’ identity and 21st-century skills, and at promoting “cultural understanding, communication, education and development of identity” (2010a, authors’ translation).

A strong guiding principle for the school policy in Norway is that the educational system should contribute to wiping out social difference and inequality and strive for social equality and mobility. In line with this thinking, pupils in primary and lower secondary education have the right to individually adapted education. Language minorities lacking sufficient proficiency of the Norwegian

language have the right to receive differentiated courses in Norwegian. A new curriculum for the teaching of Norwegian for minority children and adolescents to be used in primary and lower secondary school as well as in upper secondary education was implemented in the school system in 2007–8 (Norwegian Directorate for Education and Training, 2007). The curriculum should only be used in a transitional phase, and once the pupils have acquired a sufficient level of proficiency in Norwegian, they are to follow the regular curriculum of Norwegian. The basic Norwegian curriculum is therefore not based on age, but on levels of proficiency as described in the Common European Framework of Reference (CEFR) (Council of Europe 2001). Compared to the Norwegian first language (L1) curriculum, the Norwegian L2 curriculum has a narrower perspective, focusing primarily on pupils' language skills. The Norwegian Directorate for Education and Training has developed mapping material to help teachers decide when their pupils have reached a sufficient level of Norwegian to follow the ordinary curriculum of Norwegian. Once this decision has been made, the pupils follow ordinary classes of Norwegian and sit for the ordinary exams alongside mainstream pupils.

The teaching of Norwegian to newly arrived adult immigrants is governed by the Introduction Act of 2003, amended in 2005 and 2012 (Ministry of Children, Equality and Social Inclusion, 2012), which guarantees specific groups of immigrants (refugees, persons granted residency on humanitarian grounds or collective protection, and persons granted family reunification with a member of the mentioned categories or with a Norwegian citizen) 250 lessons (of 45 minutes each) of tuition in Norwegian and 50 lessons of social studies, free of charge. If necessary, immigrants in these categories may get up to 2,700 additional lessons. Immigrants from outside the European Economic Area-European Free Trade Association (EEA-EFTA) area with a work permit, or persons granted family reunification with people of this group, may also follow these classes, with the important difference that they have to pay for their tuition. It is important to note that Norway does *not* at present require a specific language test for citizenship. However, for immigrants who want to apply for a permanent residence permit or Norwegian citizenship, 250 lessons of Norwegian tuition and 50 lessons of social studies are compulsory.

The language courses are further regulated by the National Curriculum in Norwegian Language and Social Studies for Adult Immigrants (Ministry of Education and Research, 2012) based on the CEFR. The competence goals in the curriculum are described at four levels, from the lowest level, A1, up to level B2, but training free of charge stops at level B1.

Assessment Practices, Norwegian as L1 and L2

In primary school (1st to 7th grade), pupils are assessed only formatively, that is, they are not formally graded in any subject, and there are no exams. Grading starts only in lower secondary school, in the 8th grade. In secondary school, pupils receive overall achievement grades in all subjects. These grades are based on the teachers' overall assessment of the students' knowledge and performance in a

subject during the school year. In lower secondary school, as well as in general secondary education, teachers give each student a distinct overall achievement grade in each of the following: first choice form of Norwegian (i.e., Bokmål or Nynorsk), second choice form of Norwegian, and oral Norwegian (assessment of the student's oral activity and involvement in the subject, including their knowledge of specific literary texts and Norwegian literature in different historical periods). In the school system, only a few exams are compulsory. Students must take a certain number of exams during their school careers in order to satisfy the requirements for a matriculation certificate. The exams they take are chosen at random by the school authorities. The system of deciding which exams are to be taken, and when, is called *trekkfag*. In lower secondary school, exams in first and second choice forms of Norwegian and oral Norwegian are *trekkfag*. In upper secondary school, all pupils take a written exam in their first choice form of Norwegian, while the second choice form and the oral exam are *trekkfag*. The written exams are produced and administered centrally while the oral exam is developed and scored locally, giving schools freedom to a certain extent. In lower secondary schools, pupils can choose to have a group exam or an individual exam. These exams resemble real-life situations where people often have the possibility to prepare presentations in advance and sometimes also to make joint presentations. Some people are critical of the way oral exams are administered, questioning the purpose, validity, and reliability of these exams (Norwegian Directorate for Education and Training, 2010).

Until 2000, teacher education did not include the topic of language assessment. Primary school teachers of Norwegian assessed their pupils formatively guided by curriculum aims and experience. Secondary school teachers in addition had the oral and written exam standards and system supporting their formative assessment. In the last 10–15 years, courses in language assessment have been introduced at some universities and teacher-training colleges.

Since 2004, national tests in Norwegian reading (as well as national tests in mathematics and English) have been administered to pupils in the 5th and 8th grades. These tests are low stakes for the pupils as no important decisions concerning their future are based on the results. The introduction of national tests was met with strong negative public reactions as the tests were considered to contradict traditional Norwegian educational values of equality and late differentiation (Moe, 2009; Carlsen, 2010). Since 2004 the negative reactions against national testing have more or less vanished, and people seem to have accepted the new testing system. What is more, many say the tests make teachers and schools administrators reflect upon assessment issues and how to improve learning. In addition, studies based on data from national testing appear at regular intervals, adding information on learning outcomes, factors of success, opinions of stakeholders, etc. (Bonesrønning & Vaag Iversen, 2008, 2010).

When the policy makers decided to develop national tests for school children, they did not, however, propose to develop national tests of Norwegian as a second language. Minority children therefore have to take the same national tests as those in the majority. National tests of Norwegian L2 for school children could have been a useful tool in mapping the skills of this group and a supplement to the mapping material used in relation to the Basic Norwegian Curriculum.

In contrast, testing of Norwegian as a second language for *adult* immigrants has reached a high level of standardization and professionalization in Norway. There are standardized and officially recognized tests developed according to assessment theory and international assessment practice at several levels: *Norskprøve 2* (Norwegian Test 2 for adult immigrants) at the A2 level, *Norskprøve 3* (Norwegian Test 3 for adult immigrants) at the B1 level, and *Test i norsk—høyere nivå* (Test in Norwegian—advanced level, AL-test) at the B2/C1 level. All tests are based on the CEFR and developed by Norsk språktest (Folkeuniversitetet/University of Bergen) which has been a member of the Association of Language Testers in Europe (ALTE) since its beginning in 1990. Norsk språktest was assigned the task of developing, validating and administering Norskprøve 2 and Norskprøve 3 by Vox, Norwegian Agency for Lifelong Learning, which is an agency of the Ministry of Education and Research responsible for the tests of Norwegian for adult immigrants. The theoretical construct of all three tests is communicative competence, and they measure the five language skills: reading, listening, oral interaction, oral production, and writing. The oral and written tests are administered separately, so that candidates may take the tests at different levels in line with their profile of proficiency. In addition, there is a test at the A1 level: *Norskprøve 1* (Norwegian Test 1 for adult immigrants) which is used for diagnostic purposes only and mostly for the groups of learners with a very limited school background. The AL-test measures language proficiency at the B2/C1 level. This test is used for admission to higher education in Norway for foreign students who otherwise meet the minimum requirements for entrance to higher education. The test is recognized by every higher education institution in Norway. All tests are administered three times a year at more than 50 different test centers around the country and marked centrally in accordance with standardized assessment criteria and assessment routines. It should be mentioned that most universities and university colleges offer courses in Norwegian for immigrants, mainly restricted to their foreign students and employees. The final exam, *Trinn 3-eksamen*, also gives admission to higher education, and therefore fulfills much the same purpose as the AL-test. An important difference between the two is that *Trinn 3-eksamen* is an achievement test developed and scored locally, while the AL-test is a proficiency test developed and scored centrally.

Challenges and Future Directions

There are many challenges related to assessment in Norway. First, there are no exams and no grades in Norwegian primary schools. In secondary education, pupils receive grades and have to take a few compulsory exams. Even though this is a well-established system with a great deal of support, it is to some extent also a political issue, as some political parties are in favor of grades in primary school and more compulsory exams both in primary and secondary education. Second, there is no well-developed formative assessment system (i.e., assessment is traditionally not part of teacher education or in-service courses, and few guidelines are provided) to support teachers. Many changes have taken place in the Norwegian educational system over the last 10–15 years. In 2012, there is still some way to

go before a system of formative assessment is up and running. In teacher education, courses on language assessment are gradually being introduced, and since 2010 the Norwegian Directorate for Education and Training (2010) have been encouraging schools and teachers to be involved in assessment for learning projects, thus developing their competence in the field.

As in many other countries, the traditional Norwegian educational system has had great faith in teachers' natural ability to assess pupils' competence. As exam results are getting more important in society, we see that ministries, directorates, schools, and teachers to a greater extent need to document that the grading system, exams, and results are fair, valid, and reliable. Little by little, different stakeholders see that measures have to be taken. Ensuring valid and reliable formative, as well as summative, assessment will be very important in the years to come.

The assessment of Norwegian L2 for young learners and adolescents is an area in need of improvement. There is a lack of standardized measures of young learners' L2 proficiency in the school system today. As mentioned above, a national test of Norwegian L2 has not been developed, and the mapping system to be used together with the Basic Norwegian Curriculum is not of a high enough standard (Ministry of Education and Research, 2010c, p. 184). Another problem is that teachers may choose not to use the mapping material and evaluate the minority pupils with other tools. Many adolescents from minority groups as well as professionals call for a separate exam in Norwegian as L2 in upper secondary school, as used to be the case until 2007. Norwegian L1 is an extensive school subject covering so much more than just proficiency in Norwegian. For many minority population adolescents, it is challenging to pass the same exam as native speakers of Norwegian (Ministry of Education and Research, 2010c, p. 216).

The standard of the tests of Norwegian for adult immigrants is high according to an international evaluation of *Norskprøve 2* and *Norskprøve 3* carried out by an external ALTE auditor in 2007. The main challenge with respect to the tests of Norwegian for adult immigrants lies, as we see it, in the way the tests are used: In 2010, more than 8,000 candidates passed the written test of *Norskprøve 2* or *Norskprøve 3*, and more than 12,000 passed the oral tests, yet these tests open few doors in practice. It would have been an advantage if the job market recognized these tests as proof of language proficiency to a greater degree, instead of assessing their skills themselves. Assessing a person's language competences is a professional skill, and not all employers are equally capable of making valid judgments.

Another problem in the area of assessment of adult learners is the lack of standardization of tests for university entrance. A study from 2006 revealed that the distinct *Trinn 3-examen* were quite different, and the rating scale of higher education (European Credit Transfer and Accumulation System, ECTS, grading scale, A–F) is used quite differently across education institutions (Andersen, 2006). The correlation between the tests developed locally and the standardized test at advanced level developed at *Norsk språktest* was found to be poor. A later study investigated the language requirements for university entrance, which was decided by the Norwegian Association of Higher Education Institutions (*Universitets-og høyskolerådet, UHR*) for the *AL-test* and for the *Trinn 3-examen*.

The results of this study show that the pass score for the AL-test is stricter than that for the Trinn 3-examen (Carlsen, 2008).

Finally, there is an ongoing discussion between different political parties about whether or not citizenship should be linked to language skills. In 2009, the Ministry of Labor proposed the introduction of a test of Norwegian and knowledge of society for citizenship (Ministry of Labor, 2009). The proposal was, however, not taken further after the public hearing, but several political parties are in favor of such thinking which is in line with the policy seen in many European countries during the last few years (Extra, Spotti, & Van Avermaet, 2009; Little, 2010). The authors of this chapter would warn against a policy where democratic rights are linked to skills and knowledge, as this may undermine the very idea of a democratic society and equal rights for all citizens.

Assessing Polish

Jo Lewkowicz

University of Warsaw, Poland

Marcin Smolik

Maria Curie Skłodowska University, Poland

Introduction

Polish is the official language of the Republic of Poland, the first language of approximately 97% of the country's population, which is around 35 million. Partly as a result of the redrawing of the country's borders after World War II, it is also the home language of many families living in neighboring Belarus, Lithuania, Ukraine, and the Czech Republic. Poland has experienced numerous waves of emigration, notably in the 19th century, in 1956, in 1968, and after 2004; as a result there are large Polish-speaking populations in Western Europe (Great Britain, Germany, France), in North and South America (the USA, Argentina, Brazil), and also in Israel. This situation raises the number of Polish speakers to approximately 44 million. Poland's chequered history, and in particular the Partitions of Poland (1772–1918)—during which period Prussian and Russian conquerors attempted to eliminate Polish identity—have impacted on attitudes toward the country's language and culture, and consequently on attitudes to the teaching of these subjects (for a detailed history of Poland, see, e.g., Davies, 2005).

Description of the Language

Polish is an Indo-European language, the largest within the West Slavic group and the second most widely spoken Slavic language, after Russian. Polish is spoken in a virtually uniform manner throughout the country, the differences between the few broad dialects being slight. Like many other European languages, Polish exhibits numerous influences from Latin, which was the official language in Poland in the past. Other languages that have exerted an influence on Polish include French, German, the languages of the bordering countries, most pro-

nouncedly Russian and Czech, and, more recently, English, from which there are countless borrowings.

In linguistic typology, Polish would be classified as a synthetic language, its synthetic nature resulting mostly from the highly complex inflectional system. Nouns, pronouns, and adjectives have seven cases and two number classes, while verbs are inflected, roughly, according to person and number; they also have three tenses, three moods, and three voices. Polish is also characterized by a complex gender system that combines features from three categories: gender (masculine, feminine, neuter), personhood (personal, nonpersonal), and animation (animate, inanimate). Polish is a highly inflected language; nouns alone are classified into as many as 19 declensions or inflectional groups, depending on the grammar consulted. Owing to this, word order is relatively free. The dominant sentence pattern is subject–verb–object; it must be stressed, however, that this may be a source of confusion for non-native speakers (NNSs) as precise meaning depends on proper word forms. For example, the three lexical elements *pies*, *gryźć*, *człowiek* (“dog,” “bite,” “man”) may be used to form either of the following sentences: *Pies ugryzł człowieka* / *Psa ugryzł człowiek*. The order of the elements is identical, yet the different word forms change the meaning completely: “A dog bit a man” versus “A man bit a dog” (for a detailed description of contemporary Polish, you may wish to consult <http://polish.slavic.pitt.edu/grammar.pdf>).

Polish is generally considered to have a shallow orthography, with a relatively straightforward phoneme–grapheme correspondence, although its numerous consonant clusters often prove a challenge for NNSs of the language, both in terms of spelling and in terms of pronunciation. In addition, some sounds appear in more than one written form; for instance, the phoneme /u/ has two corresponding graphemes: *u* and *ó*, an issue that many native speakers of Polish find problematic. While the orthographic system is largely based on Latin, some diacritics are also used. Polish is considered a syllable-timed language with rule-governed pronunciation: stress is typically placed on the penultimate syllable.

Teaching Polish as L1

Although last reformed in 1999, the educational system in Poland is currently undergoing further developments, the completion of which is predicted for 2015. We therefore focus here on some of the key points concerning teaching and assessing Polish as an L1, as they are envisioned to be once the reform process has been finalized.

Poland has a fairly uniform educational system, which is centrally regulated with respect to expected academic outcomes. The outcomes are set forth by the Ministry of Education in a series of documents jointly referred to as *podstawa programowa kształcenia ogólnego*, “the national core curriculum” (NCC) (MEN, 2009). The NCC consists of four sets of content- and skills-related standards, for all school subjects, couched in the language of student-centered curricular objectives (called “requirements,” *wymagania*), specifying what a student is expected to know and be able to do at the end of each of the four stages of education, after 3, 6, 9 and 12 years, respectively. The NCC provides only a systematic presentation

of the knowledge and skills to be mastered by students, leaving the methodological application of the objectives to coursebook writers and teachers. The degree of mastery of curricular objectives is measured after 6, 9 and 12 years of education, at the end of primary, lower secondary (*gimnazjum*) and upper secondary education (*liceum* or *technikum*), respectively, by means of standardized nationwide assessments developed and administered by the Central Examination Board (Centralna Komisja Egzaminacyjna—CKE) in cooperation with eight regional examination boards (*okręgowa komisja egzaminacyjna*).

For each educational stage, the NCC divides the curricular objectives for all school subjects into two categories: general and specific requirements. For Polish, general requirements comprise three broad areas, namely (1) text reception and use of information, (2) analysis and interpretation of texts of culture, and (3) text production. Specific requirements, on the other hand, consist of a series of increasingly fine-grained objectives, all being an elaboration of the general requirements, and they include, among other issues, the four language skills, language awareness, self-learning, and analyzing, interpreting, and evaluating literary texts. With respect to literature, the NCC either lists (fragments of) literary masterpieces that should be discussed with students or only provides names of key literary figures, leaving the final selection of texts to teachers. As a school subject, thus, Polish embraces the teaching and learning of language subsystems; it also encompasses broadly understood communicative competence, literature—mainly written in Polish, but also some translations of major works of world literature—and cultural studies; and it extends to other educational goals, for instance patriotic education.

As emphasized by the authors of the NCC for Polish (e.g., Żurek, 2009), the document should be seen more as a continuation and harmonization of, rather than an opposition to, what was done prior to 2009. Indeed, the influence of the NCC on the everyday classroom teaching of Polish as an L1 has not been dramatic thus far. Practicing reading and writing skills has remained prioritized over developing speaking skills, so that L1 listening is hardly being practiced at all. Furthermore, contrary to ministerial intentions, teachers still tend to devote most classroom time to literary studies, to the detriment of purely language-related work. The literary canon, set forth in the NCC, appears to be the only NCC-related subject of relatively intense academic debates, widely reported in the media primarily due to its underlying ideological nature. All other debates remain largely confined to staff rooms. The only area where the NCC has had a profound effect is assessment, as the NCC requirements have become the de facto examination construct.

Assessing Polish as L1

Students are assessed on their knowledge of and skills in Polish as L1 in the classroom—through continuous, mainly formative assessment—as well as by external bodies using standardized tests. Classroom-based assessment has always been a vital part of L1 education, where teachers regularly question and grade students on the content of previous classes and set various assignments, both in

class and as homework. Interestingly, the introduction of standardized nationwide exams in 2002 contributed significantly to diminishing the value of and prestige associated with classroom-based assessment—a trend opposite to what has been observed in the USA, for example (Niemierko, 2009). Despite the heavy criticism they have received over the decade since they were established in Poland, standardized tests are regarded by many as the “proper” assessment (Niemierko, 2006).

The standardized assessments in Poland should be viewed as both criterion- and norm-referenced. Criterion referencing concerns the test content—all assessments are NCC requirements-based, while norm referencing pertains to the way exam scores are interpreted and used. This mixture, characterizing a number of state-wide government-regulated assessment systems, is rather unfortunate, if only for the reason that a lot of potentially useful feedback for students regarding their achievements vis-à-vis the NCC requirements is simply lost as the overwhelming majority of stakeholders appear to be primarily interested in the scores rather than in the qualitative information that they carry.

As of 2015, students’ mastery of Polish as L1 will be assessed three times in the course of their education. At the end of primary school (grade 6) there will be a test (called *sprawdzian*) of reading, writing, and making use of information. While the *sprawdzian* has already been administered for more than a decade, the precise form of the 2015 exam is currently being developed. Until 2014 students will continue to take a general competencies test, which includes questions from a number of school subjects, including Polish, maths, art (sample papers for *sprawdzian* and other exams discussed in this section are available on the CKE Web site; see “Suggested Readings” below). Just like in the current format, however, no fail/pass threshold will be set. All primary school students will be required, as they are now, to sit the test, yet their results will not be taken into account in the lower secondary school admission process.

At the end of lower secondary school (*gimnazjum*; grade 9) students will take a five- or six-module exam (called *egzamin gimnazjalny*), Polish being one of the modules. This exam, introduced in 2012, will place emphasis on reading and understanding cultural texts, as well as on essay writing. Unlike the *sprawdzian*, *egzamin gimnazjalny* in Polish will contain elements of literature and culture, and the essay may require students to refer to one or two literary works to support their views. The scores students obtain on the test will be among other criteria taken into account in the secondary school admission process.

In contrast to the *egzamin gimnazjalny*, the exam that secondary school students sit upon graduation (grade 12), called *matura*, is not compulsory. In theory it is for those wishing to pursue tertiary education, yet in reality it is taken by approximately 95–97% of all secondary school students. The exam of Polish consists of two parts: an oral test, internal to the school, and a written test, external and standardized. In the oral exam students make a speech on a topic of their choice, for which they have done research for approximately nine months (see further, “Challenges”). The written part has two levels: a basic level and an extended level; and all students taking the *matura* exam are required to select one of these. The extended level is only a requirement for some university applicants, depending on the course they wish to pursue. The basic level currently consists of two

subtests: the former tests reading comprehension of cultural texts as well as essay-writing skills; the latter always asks students to refer to selected literary works in their discussion. The extended level is an entirely literature-oriented exam. The pass/fail threshold of 30%, set only for the basic level, is achieved by approximately 95% of all candidates. Just like the *sprawdzian*, the *matura* will change in 2015. However, the precise direction of the changes is not yet known.

It is worth emphasizing that, for all three external exams, separate papers are also prepared for students with special educational needs. Various accommodations are available for a number of different groups of students, for example the blind or the deaf, with some variation between particular exams.

Teaching Polish as Foreign Language

After World War II, many émigré communities offered Polish language and culture classes for their children, hence the common phenomenon of in situ “weekend schools” and, later, summer holiday language camps in the homeland. However, the widespread and systematic teaching of Polish as a second or foreign language is a comparatively recent phenomenon, which has come about for a number of reasons. Poland’s emergence on the political and economic scene, its joining NATO in 1999 and the European Union in 2004, have raised interest in Polish, which is one of the 23 official languages of the EU. The opening up of the Polish market has caused a rise in the number of foreigners working, settling, and studying in the country. Many are required to produce evidence confirming their proficiency in Polish, hence their interest in learning the language either before they arrive in Poland or once they are there. Yet perhaps it was the introduction, in 2004, of certificate exams in Polish as a foreign language that had the greatest impact, as these exams have not only stimulated interest in learning the language and in gaining a recognized qualification, but have also systematized the teaching of Polish, shifting the focus from language accuracy and a knowledge of culture to communicative ability. It is currently estimated that there are roughly 10,000 people learning Polish, one third of whom reside in Poland (Biuro Uznanalności Wykształcania i Wymiany Międzynarodowej [BUWiWM] / Bureau for Academic Recognition and International Exchange): www.buwiwm.edu.pl).

Assessing Polish as FL

The introduction of Polish as a foreign language (PFL) certificate exams was an integral aspect of the country’s language policy of promulgating and promoting the language toward the end of the 20th century. The planning and development of the exams took approximately 10 years prior to their full introduction in 2004. Since then, the exams have been conducted three times a year in Poland and twice a year in centers abroad (where there are at least 12 candidates registered).

The aim of the certificate exams is to determine candidates’ proficiency in Polish regardless of where they have studied PFL (www.certyfikatpolski.pl). The exams are currently offered at three levels—B1, B2, and C2 of the Common European

Framework of Reference for Languages (CEFR) scale—and work is underway on the remaining levels (A1, A2 and C1), though it is still unclear when these will be available. The structure of the exam at the three existing levels of difficulty is identical. Each is made up of five sections of equal weight: listening comprehension, grammatical accuracy, reading comprehension, writing, and speaking.

The tests are set by a team of experienced test writers drawn from university departments in Poland that offer PFL but are responsible to the State Commission for the Certification of Proficiency in Polish as a Foreign Language, which was established in 2003 (its official Web site is at www.certyfikatpolski.pl). The reading, listening, and grammar sections are made up of closed and limited response items, while the writing and oral, being open-ended, involve subjective marking by two trained examiners. The pass mark is 60%, and candidates are required to gain at least 60% for each section of the exam (compare the pass mark for the *matura* exam of 30%). The demands of the C2 certificate exams are attested to by a study comparing the performance of 145 Polish final year upper secondary school students across Poland with 65 PFL students on the 2005 C2 exam (Miodunka & Przechodzka, 2007). The Polish students not only commented on the difficulty of the exam, but they performed overall only minimally better than the PFL students, and the PFL learners outperformed the Polish students in the writing subtest.

The certificate exams are the only state document confirming a person's proficiency in PFL. They have been developed in accordance with Council of Europe standards and recommendations. The *Common European Framework of Reference for Languages: Learning, Teaching and Assessment* (Council of Europe, 2001), was translated into Polish (Martyniuk, 2003) to facilitate this process. A recent Association of Language Testers in Europe (ALTE) audit in 2008 has confirmed that the system of certification works well, though the audit recommended some changes, such as: extending the time of the reading test; greater flexibility in determining the pass/fail rate, allowing candidates to fail one of the sections (with the exception of grammar accuracy), on condition that the overall mark totals 60%; requiring from the candidates who fail to repeat only the sections they failed rather than the entire exam; establishing a number of accredited examination centers within and outside the country (Dąbrowska, 2010). To date, however, these recommendations have not been implemented.

The number of candidates for the certificate exams is steadily rising. In 2004, when the exams were first introduced, there were 106 candidates, while in 2010 500 candidates sat the exams, with the overall total reaching 2,361 over the 7 years (Miodunka, 2011). Although there has been insufficient time to determine through rigorous empirical studies the effect of the exams, there is evidence of positive washback. The exams seem to have impacted on the materials and coursebooks developed for teaching PLF, bringing them into the 21st century (Mazur, 2006). They have also brought about changes in the teaching techniques utilized both within and outside Poland and, as Miodunka (2011) highlights, a new generation of teachers of Polish seems to be emerging that is much more conversant with a variety of up-to-date teaching techniques. Furthermore, student motivation has also been affected, as demonstrated in a small-scale study at the Tokyo University of Foreign Studies: it revealed that, since students have been offered the

opportunity of sitting for the certificate exams as part of their undergraduate studies in Polish, and thus they have something tangible to aim for, they are more motivated (Horbatowski, 2011).

Challenges and Future Directions

Experts need to face a whole array of challenges as far as teaching, learning, and assessing Polish as an L1 is concerned. First and foremost, there is the pressing issue of providing NCC-related help for both preservice and in-service teachers and teacher educators. Considerable work must be done to help these groups translate ministry documents into useful and usable classroom practices, as many NCC objectives are believed to be imprecise or ill defined, if not both. This calls not only for providing teachers with suitable teaching aids, but also for developing new classroom-based assessment instruments, closely linked to and reflecting the requirements specified in the core curriculum.

Substantial effort must also be channeled into developing new external exams, so that their impact on teaching and learning Polish as L1 may be as beneficial as possible. This concerns the written tests just as much as the oral *matura* exam, which has up until now suffered from bad press due to its many shortcomings—and these are not limited to unethical examinee and examiner behaviour (e.g., Ślósarz, 2006). The necessary work has already been undertaken by the Central Examination Board, and it only remains to be hoped that everything possible will be done to bridge the gap between what should be taught, what actually is taught, and what and how it is assessed.

It would appear that the greatest challenge for the testing of PFL is to complete the work on developing the remaining three levels of certificate exams, so that the whole spectrum of proficiency may be covered. Given the still limited number of candidates and the premise that the certificate exams were to be income-generating (Dąbrowska, 2010), other challenges include the continued funding of the development program, to allow for periodic validation and subsequent revision of the exams, for the training of test writers, and for the in-service preparation of teachers, so that the progress achieved so far can be maintained.

Assessing Portuguese

Michele Back

George Mason University, Fairfax, USA

Introduction

Portuguese is one of the fastest growing Western languages, especially in southern Africa and South America. With approximately 240 million speakers, it is the 6th most spoken native language and the 13th most taught language worldwide (Carvalho, Luna, & Da Silva, 2010). Assessing competent speakers of the language is therefore critical, yet challenging for several reasons. First, Portuguese has two standard varieties—European and Brazilian—and several unofficial varieties. Second, learners of Portuguese as a foreign language (PFL) have different assessment needs depending upon their backgrounds and knowledge of other languages, such as Spanish.

In this chapter I discuss various approaches to assessing PFL. After a description of the language, I discuss different teaching and learning contexts, focusing on international efforts by Portugal's Instituto Camões and Brazil's Centros de Estudos Brasileiros. I then compare and contrast the methods and content of the standardized tests from these organizations and US-specific assessments. I conclude with special assessment issues, including computer-mediated and self-assessments as future directions for assessing PFL both in and outside the classroom.

Description of the Language

Originating from spoken Latin on the western coast of the Iberian Peninsula in the areas currently known as Portugal and Galicia (Spain), Portuguese became similar to its current variant around the 16th century (Ilari & Basso, 2006).

Portuguese colonizers disseminated the language in the 15th and 16th centuries to Brazil, western and southeastern Africa, East Timor, Goa (India), and Macau (China), where it acquired some features of local languages. As a Romance language, it is similar to Spanish, with important vocabulary and grammatical differences. Phonetically, Portuguese is a stress-based language, which is often difficult to grasp for Spanish speakers accustomed to a syllable-based system. Portuguese's vowel system is also more complex, with 12 vowel sounds compared to Spanish's 5.

Portuguese retains two official varieties: Brazilian and European. Although there are significant lexical and syntactical differences (see Baxter, 1991, for more details), the most salient difference is pronunciation. European Portuguese has a greater tendency toward the loss of unstressed vowels, while Brazilian Portuguese speakers tend to raise these vowels. These differences can lead to difficulty in mutual comprehension. The 2007 orthographic reform signed by member countries of the Community of Portuguese Language Countries (CPLP) has made steps towards eliminating most differences in the written language varieties. The Ministry of Foreign Relations in Portugal, the Ministry of Education in Brazil, and the CPLP actively promote the two standard varieties worldwide with traditional and online courses and international advocacy events.

Portuguese plays varying roles in the everyday lives of the former colonies. While Portuguese is both an official and a majority language in Portugal and most of Brazil, it is used infrequently in nonofficial contexts in the African nations of Angola, Cape Verde, Guinea-Bissau, Mozambique, and São Tomé e Príncipe, where indigenous languages and creoles take precedence in everyday situations. Although primary and secondary education remains in Portuguese in these nations, English is encroaching upon Portuguese's presence in official contexts, as seen by Mozambique's membership in the UK's Commonwealth of Nations.

In Asia, Portuguese shares co-official status with local languages. In East Timor, Leach (2007, p. 1) stated, "Portuguese was always far more important as a signifier of difference from Indonesia tha[n] as a means of communication," although this has changed as people become more accustomed to its co-official status with Tetum. In Macau, Portuguese shares co-official status with Cantonese until 2049, when China assumes total control of the region. It is difficult to predict what will happen to the language then; currently there is some disconnect between the Chinese government's enthusiasm for promoting the language and Macau residents' view of English as a more important international language (Leach, 2007; Pacheco, 2009).

This brief description shows that, from its modest origins on the Iberian Peninsula, Portuguese has evolved into a global language with two standard varieties and several creolized and regional variants. Though the language is infrequently used in nonofficial contexts in most former colonies, the increasing importance of Brazil as a global and economic power, as well as continued ties with Portugal, continue to motivate Portuguese instruction in these areas and around the world. In the section to follow I discuss several contexts in which the teaching and learning of Portuguese are taking place.

Teaching and Learning Contexts

As mentioned above, the governments of both Portugal and Brazil have made great efforts to promote the teaching and learning of Portuguese. Portugal's Instituto Camões works with 294 postsecondary institutions and international organizations in 69 countries, particularly in Europe, Africa, and Asia. Additionally, the Institute operates 57 standalone Portuguese language centers (Centros de Língua Portuguesa, CLP) and the Centro Virtual Camões, which offers online activities for learning Portuguese and links to distance-learning courses for both general and specific purposes.

Brazil's Ministry of Culture operates 21 Brazilian studies centers (Centros de Estudos Brasileiros, CEB), principally in Latin America, that promote PFL and Brazilian culture. The CEBs operate independently, rather than in collaboration with postsecondary institutions in Latin America. Both the CLP and the CEB offer PFL courses primarily for adult learners.

Portuguese is also taught in over 200 postsecondary institutions in the USA, with enrollment in PFL having increased by 10.8% between 2006 and 2009 (Furman, Goldberg, & Lusin, 2010). Carvalho et al. (2010) attributed part of this boost to the increase in PFL courses for Spanish speakers. These authors also noted that 100 US public schools offer Portuguese courses, mainly for the approximately 85,000 children who speak Portuguese as a heritage language.

PFL courses are also widely available online. In addition to the Centro Virtual Camões, there are several resources for learners of Portuguese of all levels, from basic vocabulary and conversation to podcasts aimed specifically at Spanish speakers.

In sum, Portuguese is taught on nearly every continent to a variety of learners, from primary school students in Portugal's former colonies to heritage speakers to business professionals. Within these contexts, the Portuguese and Brazilian governments have created the most recognized proficiency assessments, while US-based institutions and organizations use their own instruments. In the section to follow I compare these practices and their assessment philosophies.

Assessment Practices

The Instituto Camões in Portugal and the CEB in Brazil are the administrators of two recognized avenues for adult (age 14 and up) proficiency certification in PFL. The Portuguese government's Centro de Avaliação de Português Língua Estrangeira (CAPLE) administers exams for the Certificação de Português Como Língua Estrangeira (certification in Portuguese as a foreign language). CAPLE is responsible for producing, delivering, and evaluating exams, while the Instituto Camões and its centers administer the exams and grade the oral interview component. Brazil's Certificado de Proficiência em Língua Portuguesa para Estrangeiros (Celpe-Bras) (certification of proficiency in Portuguese for foreigners) is administered by Brazil's Ministry of Education in Brazil and the CEB abroad. Both exams assess reading comprehension, listening comprehension, and written and

oral production through the use of real-life materials (e.g., radio programs and authentic texts) and a 10–20-minute interview between an examiner and candidates.

According to the CAPLE's Web site, the goal of the exams is for a candidate to "prove his/her competence in the Portuguese language for educational, professional or other reasons." There are five levels of certification available, from initial (A2 on the Common European Framework, corresponding to novice mid to high on the American Council on the Teaching of Foreign Languages [ACTFL] scale) to university level (C2, or ACTFL's advanced mid to high). ALTE has a description of each certification on their Web site, including its correspondence to the Common European Framework and the tasks that successful candidates are expected to complete.

The CAPLE exam is approximately two hours long. At the lower levels, the exams test candidates using multiple choice, true or false, or matching questions on the prompts, as well as short writing exercises. At more advanced levels, the exam assesses grammar skills; a section on "structural competence" asks candidates to edit, transform, and expand texts based on prompts for different complex sentence constructions (e.g., the use of mood and idiomatic expressions). The oral production component involves both free conversation and role play between the examiner and one or two candidates; it is expected that candidates will interact in this part of the exam.

In Brazil, the Celpe-Bras exam assesses non-native speakers' competence in the language before their admission to postsecondary schools. Outside of Brazil, the certificate is accepted by businesses and educational organizations in Latin America as proof of competence in Portuguese. The Celpe-Bras is conferred at four levels: intermediate, high intermediate, advanced and high advanced. Although these levels are not tied to any other framework, the Celpe-Bras candidate manual outlines what is expected at each level (Sobrinho et al., 2006).

The principal goal of the Celpe-Bras is to assess "uso adequado da língua para desempenhar ações no mundo" (adequate use of the language to perform actions in the world; Sobrinho et al., 2006, p. 3). As such, the exam simulates real-life situations in both written and oral sections. Assessment is conducted in an integrated way through several short projects that simultaneously assess various skills. An example of this integrated assessment is an exercise in which candidates listen to a short radio program on workplace safety and write an employee notice that incorporates information learned from the program. The oral production component of the Celpe-Bras employs both free conversation and a conversation stimulated by visual prompts (Sobrinho et al., 2006). Similar to the CAPLE exams, the Celpe-Bras oral component is evaluated by local examiners, while specialists at the Ministry of Education in Brazil evaluate the written portion.

Looking at these two exams, there is an effort by both organizations to assess PFL using situations and prompts as close as possible to real life. Though materials for both exams state their interest in testing proficiency and the ability to interact in real-life situations, the CAPLE does emphasize more grammar testing, especially at the higher levels. This may be due to its integration with the Common European Framework for languages, which emphasizes proficiency for business and academic contexts, both of which demand mastery of more complex grammar

constructions. Unlike the Celpe-Bras, the CAPLE provides certification at more elementary levels of proficiency. Although the two exams have been in existence for roughly the same amount of time (the Celpe-Bras exam was first given in 1998 and a version of the CAPLE through the University of Lisbon in 1999), there is much more literature available on the Celpe-Bras, including a candidate manual, sample tests, and related research (e.g., Scaramucci, 1995; Sobrinho et al., 2006). This may be because the CAPLE was just recently established as an independent entity, and has only recently posted sample exams and other materials on their Web site.

US-based assessment in Portuguese, such as the ACTFL Oral Proficiency Interview (OPI) and Simulated OPI (SOPI), tests by the Defense Language Institute and the Foreign Service Institute, the ACTFL's Writing Proficiency Test (WPT) and Business Writing Test (BWT), and the American Association for the Teaching of Spanish and Portuguese (AATSP)'s National Portuguese Exam, are described in Cowles, D'Oliviera, and Wiedemann (2006), and more generally in this volume's relevant chapters (see Chapter 9, *Assessing Speaking*; Chapter 20, *Government and Military Assessment*). As Cowles et al. (2006) state, "Both the OPI and the SOPI measure proficiency, follow a standardized structure based on the ACTFL/ILR guidelines, and are valid and reliable tools for assessing Portuguese" (p. 125). Although many questions have been raised regarding the suitability and construct validity of the OPI as a measure of oral proficiency (see Johnson & Tyler, 1998; Chalhoub-Deville & Fulcher, 2003), the OPI and SOPI do follow a level of standardization similar to the CAPLE's ties with the Common European Framework, and thus are similar measures for determining proficiency. Like the CAPLE and Celpe-Bras exams, US-based proficiency exams adhere to standardized structures as determined by their relevant organizations or partner organizations.

These most recognized exams are clearly only a small part of the assessment activities that take place in the schools, universities, and language centers teaching Portuguese around the world. It would be impossible to list all of these activities in the space permitted; one important concern mentioned by Furtoso (2010) and others is a need for ongoing, integrated assessment in PFL contexts, as well as a greater focus on usage versus form. These concerns highlight the importance of addressing the needs of individual learners from varied backgrounds with varied language-learning goals. In the next section I discuss challenges related to these concerns.

Challenges in Assessing Portuguese

One assessment issue specific to PFL is how to assess different varieties of the language. Although movements like the orthographic reform mentioned above have attempted at some level to erase these differences, Portuguese in its spoken form still has two distinct standard varieties. Cowles et al. (2006), stating that the goal of proficiency assessment "is to better standardize the evaluation of language speakers," muse, "this [standardized evaluation] appears not to have been done for Portuguese" (p. 130). I would argue that, even if standardized evaluation were the goal of all proficiency tests (which in itself is doubtful, given that assessment

instruments should reflect learner environments), this goal should not hold for Portuguese. One valid critique of the OPI and other oral proficiency exams is that the native speaker norm is viewed as the ideal proficiency level. However, this is not necessarily the goal of many learners of Portuguese and other languages, who may desire different levels of proficiency. Moreover, given the varieties of Portuguese, what exactly is a “native speaker norm”? Is it a Lisbon native, a person from Rio de Janeiro, or a resident of Salvador, Bahia, where a more stigmatized variety is spoken? Is it a Mozambican who speaks Portuguese as well as Ronga, Shangana, and English? Though individual examiners are aware of different varieties, without proper guidance they might not be able to evaluate particular written and oral productions in the variety with which they are least familiar. Instead of pursuing further standardization of PFL evaluation, more effort should be made in the USA to develop instruments that at least assess the two standardized varieties in a distinct manner.

Similarly, examiners for US standardized tests, as well as the CAPLE and Celpe-Bras exams, may not recognize the assessment needs of particular PFL learners. Spanish-speaking learners, for example, are a growing population that, depending upon their goals, have different assessment needs. While previous research has highlighted the two languages’ lexical similarities (up to 85%; Ulsh, 1971), this similarity can lead to a false perception of competence. Among the sticking points for Spanish learners of Portuguese are pronunciation, false cognates, and idiosyncratic expressions and registers, all easily detectable in real-life interactions but not usually evaluated with currently available assessment methods. Jensen (1989), for example, argued that the ACTFL OPI would assess most Spanish-speaking learners of Portuguese as intermediate low speakers, despite their having had no prior contact with Portuguese. Scaramucci (1995) raised similar concerns with respect to the Celpe-Bras and its applicability to Spanish speakers. These concerns imply a disconnect between standardized oral proficiency exams and what Spanish speakers may be faced with in a Portuguese-speaking community of practice. On the other hand, given the high level of similarity between the two languages, this interference may not be a concern for Spanish learners or their Portuguese interlocutors in many contexts. We must ask, then, what exactly is being assessed with respect to Spanish-speaking learners of Portuguese, and whether or not a better instrument could be developed that reflects the mastery of Portuguese language skills that are particularly difficult for Spanish speakers. Jensen (1989), for example, advocated achievement tests that show “careful adaptation to the needs” of Spanish speakers, including vocabulary items unique to Portuguese or false cognates with Spanish, and grammar items such as the future subjunctive (pp. 120–1).

Heritage speakers of Portuguese are also often ignored with respect to proficiency-based methods of assessment. There are approximately 731,000 speakers of Portuguese or Portuguese Creole in the USA, particularly in the northeast region of the country (US Census, 2012). Given the uptick in global migration, heritage Portuguese speakers are surely also present in significant parts of the Americas, Europe, and Asia. Portuguese heritage learners have particular assessment issues, including some disconnect between oral proficiency and literacy skills and, for some populations, interference with creole varieties (Ferreira, 2007). Ferreira also noted that there are significant differences in proficiency among

Portuguese heritage learners themselves, depending on whether or not they are second or third generation speakers of the language, with the former performing “much better than expected” on writing tasks (2007, p. 13). For these reasons, standard proficiency assessments may not work well for heritage speakers whose acquisition of literacy skills and standard varieties has not yet taken place.

Though both Spanish speakers and heritage learners will possess a higher level of commonly interpreted proficiency than other PFL learners, evaluative instruments should take into account the common pitfalls that these learners might face. One way to address this is by placing them in higher levels of PFL courses, where more explanations on the more subtle aspects of form and usage are available. Another way is to develop courses and instruments that directly address the needs of these learners. In the final section of this chapter I describe alternative methods of assessment that might be helpful for these and other learners.

Future Directions

Traditional methods of assessment are valuable tools to determine at an official level the ability of Portuguese learners to function in a variety of contexts in the language. For many learners, however, alternative methods might be more appropriate ways to determine their own proficiency. In this section I discuss available resources in computer-mediated and self-assessment as valid alternatives for PFL learners, and offer a final word on evaluative instruments for Spanish and heritage speakers.

Computer-mediated assessment methods have become popular in recent years as improvements in technology offer increased possibilities for assessing skills in an adaptive and accurate manner. In Portuguese, several assessment exams are available either online or on CD-ROM. They mostly consist of multiple choice questions that assess grammar, vocabulary knowledge, and reading comprehension. Some assessments also include audio clips to assess listening comprehension. Most computer-mediated exams in PFL are either meant to supplement in-class instruction or to offer an abbreviated assessment of proficiency. Some, such as the Brazilian Portuguese entrance and exit exams, developed by Simões (2003b, 2003c), specifically address placement and proficiency pre- and post-instruction in Portuguese. Computerized adaptive placement tests are particularly helpful resources for Spanish-speaking and heritage learners of Portuguese, as they allow these learners to be placed in a more appropriate level of coursework for their needs.

One computer-mediated assessment in Portuguese is also a self-assessment. Developed by Simões (2003a), the Brazilian Portuguese Self-Assessment Test asks candidates to evaluate their knowledge of Brazilian Portuguese language and culture. The 48 test questions cover a wide variety of content areas, including culture and civilization. Though some may argue that the inclusion of these topics in a language exam is construct irrelevant, the integration of linguistic forms and cultural knowledge is a hopeful future direction towards more inclusive assessments of language use.

With respect to Spanish-speaking and heritage learners, aside from placement in advanced courses, developing particular instruments that directly address

these learners would be a step in the right direction. For Spanish-speaking learners, instructors and examiners might take as a point of departure Grannier and Carvalho's (*n.d.*) list of critical points to be addressed when evaluating Spanish speakers of Portuguese. Carvalho et al. (2010) also recommended the inclusion of authentic texts due to Spanish speakers' "early advanced reading skills" which "make the gap between authentic and textbook language unnecessary and counterproductive" (p. 73). For heritage learners, more emphasis should be placed on evaluating different varieties of Portuguese and writing skills.

Recent years have brought an increase in the popularity of PFL. While standardized methods such as the CAPLE and Celpe-Bras exams worldwide and the ACTFL exams in the USA continue to serve as official methods of certification, concerns have been raised with respect to their validity for particular groups of learners. Methods of assessment that emphasize a standard native speaker norm may not be adequate for assessing different varieties of Portuguese. Meanwhile, computer-mediated and self-assessment are gaining footholds as alternative assessment methods for those not seeking official certification. Despite the availability of these resources, much research remains to be done on the various methods of assessing Portuguese, as well as the development of instruments for Spanish-speaking and heritage learners.

Assessing Russian

Irshat Madyarov

American University of Armenia, Armenia

Introduction

Before the collapse of the Soviet Union in 1991, its vast territory embraced 15 independent republics spread out across the Baltic region, Eastern Europe, Transcaucasus, Central Asia, and Russia itself. These are now independent countries, often referred to as the Former Soviet Union (FSU). A decade ago, Cubberley (2002) reported some 150 million speakers of Russian as a first language (L1) in FSU, 1 million speakers of Russian as a second language (L2) across FSU, and another 500,000 speakers in other countries around the globe.

Russian is a state language of the Russian Federation according to the Russian constitution. The Russian republics (e.g., Bashkortostan, Dagestan, Tatarstan, and 18 others) have the right to establish their own state languages. Russian is taught in all the schools, but the number of hours may differ at the school district level (Хлебников, 2008). In FSU the status of Russian differs from country to country.

In this context Russian is taught and assessed as a native language in Russian schools and as L2 for speakers of other languages. In the past several years Russia has taken a path of streamlining assessment of Russian as L1 and L2. This involves efforts of standardizing the assessment psychometrically and procedurally, and in some cases of handing over all the decisions to a federal department.

This chapter discusses current developments in the assessment of Russian as L1 mostly within the Russian territory and of L2 within Russia and in the FSU region.

Description of Russian

The Russian language belongs to the Slavic group of Indo-European languages. Some other Slavic siblings of Russian are Belarusian, Bosnian, Croatian, Czech, Macedonian, Polish, Serbian, and Ukrainian (Slavic Languages, 2011).

Table 138.1 Sampling of declensions of nouns and adjectives

	<i>Большой стол (big table) masculine</i>		<i>Большое поле (big field) neuter</i>		<i>Большая кровать (big bed) feminine</i>	
	<i>singular</i>	<i>plural</i>	<i>singular</i>	<i>plural</i>	<i>singular</i>	<i>plural</i>
Nominative case	большой стол	большие столы	большое поле	большие поля	большая кровать	большие кровати
Genitive case	большого стола	больших столов	большого поля	больших полей	большой кровати	больших кроватьей

Russian uses Cyrillic script, which comes with 33 letters representing 10 vowels, 21 consonants, and two pronunciation signs—the hard sign and the soft sign, which mark the pronunciation of sounds at the segmental level (Розенталь, Голуб, & Теленкова, 2008).

According to Timberlake (2004), two major pronunciation-related challenges for non-native Russian speakers and learners are stress in vowels and palatalization in consonants (i.e. their softening). At the suprasegmental level there are a total of seven basic contours: four for communicative functions and three for affective functions (Cubberley, 2002).

Russian grammar often presents difficulties to speakers of other languages. Russian nouns change their grammatical forms by taking morphemes to express gender (feminine, masculine, and neuter), number (singular and plural), and one of six cases. Russian nouns are also categorized into three declensions, which adds yet another layer of complexity to noun endings. Adjectives agree with nouns in gender, number, and case. Table 138.1 (adapted from Розенталь et al., 2008, pp. 204–5) offers a few examples of noun and adjective endings in boldface. The word *стол* “table” belongs to the first declension; *поле* “field” belongs to the second; and *кровать* “bed” belongs to the third:

Verbs are conjugated; this modification is achieved through inflection and through changes in the verbal stem (Timberlake, 2004). The form of verbs varies according to several grammatical categories: aspect (perfective or imperfective), mood (indicative, imperative, and subjective), tense (present, past, and future), voice (active or passive), gender (feminine, masculine, and neuter), person (first, second, and third) and number (singular or plural) (Timberlake, 2004; Розеунталь et al., 2008).

Recent years have witnessed rapid changes in Russian vocabulary, grammar, orthography, phonology, and pragmatics (Балыхина & Косарева, 2007; Степыкин, 2011). Below is a sampling of recent changes observed in modern Russian (Балыхина & Косарева, 2007):

- phasing out of certain categories of vocabulary: e.g., *колхоз* “collective farm” (in Soviet times);
- emergence of new words and phrases: e.g., *креативность* “creativity”;
- new words formed by means of derivational affixes: e.g., *подписант* “signatory,” formed with the suffix *-ант*;

- gender changes: e.g., the word кофе (“coffee”) is now neuter, so when “coffee” is accompanied by an adjective like “hot,” we now say горячее кофе (“hot coffee”), in the neuter.

While these changes could be amusing, others cause serious concerns among the public, members of the government, and scholars. Examples include overuse of vulgar words (Offord & Gogolitsyna, 2005) and evidence for sloppy and inaccurate use of words and structures. To address these and other needs, the Russian Ministry of Education and Science formed an Advisory Committee on the Russian Language. Over the past several years the Russian government has also been earmarking funds to help preserve and develop the Russian language in Russia and abroad. According to media reports, the most recent investment was around \$70,000,000 for the period 2011–15.

Teaching, Learning, and Assessment of Russian

Assessing Russian as a Native Language

Native speakers of Russian are taught Russian from grade 1 through grade 11. Some tertiary institutions continue giving Russian courses during the first and following years of their curricula, depending on the students’ specialization. Middle school students leaving after grade 9 and all high school graduates recently started taking a standardized test of Russian. The State Final Attestation—Gosudarstvenya Itogovya Attestatsia (GIA)—is still in the piloting phase throughout Russia. The Unified State Examination—Ediny Gosudarstvenny Ekzamen (EGE) for high school graduates—was introduced in full in 2011. This chapter limits its discussion of the assessment of Russian as L1 to EGE, because this type of exam has received the greatest amount of attention in the literature and is having a strong impact on many stakeholders.

As of 2009, all high school graduates in Russia and those graduating from Russian high schools abroad have been tested on a number of school subjects: two required tests in math and Russian, and a few others in subjects selected by students on the basis of the requirements of colleges and universities they plan to apply to. Tertiary educational institutions accept EGE results as part of their admission requirements. Some are able to specify additional admission conditions, including examinations developed in house.

The EGE examination of Russian consists of three parts and lasts for three hours. Part 1 comes with 30 multiple choice questions. Part 2 has eight short answer questions. Part 3 is a written response to a supplied text. The test covers the following content areas, which high school graduates are expected to have learned as part of their curriculum (Федеральная служба по надзору в сфере образования и науки РФ, 2011a):

- lexicology and phraseology;
- word formation;
- morphology;

- syntax;
- orthography (spelling);
- punctuation;
- textual analysis;
- linguistic norms;
- expressiveness of the Russian language;
- composition skills.

Much of this content is tested across all three parts of the exam. Below are a few examples of test items (Федеральная служба по надзору в сфере образования и науки РФ, 2011b, pp. 4, 14–15).

Part 1 (closed questions):

Select the word that has the right vowel stress:

- (1) красИвее “more beautiful”
- (2) Агeнт “agent”
- (3) нАчав “having started”
- (4) торты “cakes”

Part 2 (short answer questions):

(Based on a supplied text) Find a complex sentence with a subordinate clause of measure and degree from among Sentences 12 through 20 of the text. Write down the number of the sentence.

Part 3 (An essay question based on a reading text):

- Read the supplied text and write a response based on it.
- State one of the problems identified by the author and comment on it (avoid quoting too much).
- State the author’s (narrator’s) position and whether you agree or disagree with the author’s view?
- Explain your answer.
- Your arguments should be based on your reading experience and knowledge as well as your daily experience (the first two arguments will be scored).
- Write at least 150 words.
- A response that does not address the content of the reading text will not be marked.
- If the response simply summarizes the reading text, or it has been copied verbatim without any original comments, it will be given zero points.
- Please use legible handwriting.

The three parts of the test offer some variety in the format, from multiple choice items to essay writing.

Assessment of Russian for Speakers of Other Languages

Russia has taken a path of streamlined standardized testing of Russian as L1. A similar trend has developed in the assessment of Russian as L2. According to

Cubberley (2002), Russian lost its long-standing status around the world dramatically after the Russian government suffered a political fiasco in 1991, and this came as a severe blow on the economy of the entire region of the FSU. Many Slavonic schools in Russia and across the FSU had to be closed down or reduced in size in order for costs to be absorbed. Over time, this precarious position of Russian in the FSU has improved.

Today learning opportunities for speakers of other languages are growing throughout Russia. Courses and schools offer a wide range of options for international college-bound applicants and for people wishing to obtain Russian citizenship.

The pedagogy of Russian as L2 followed about the same course of development as that of second languages in the rest of the world. The 19th century was marked by the predominance of grammar translation, which continued throughout the first half of the 20th century (Капитонова, Москвин, & Щукин, 2008). At the end of the 19th century, the Berlitz direct method came in handy after the historical coup in 1917, when the Communist Party took over the government and a number of international students had to be prepared for Russian-medium universities in the Soviet Russia. Then came the contrastive–comparative method, the audiolingual method, suggestopedia, and later the communicative language method (among others). Some teaching methods were developed by Russian scholars; such was Galperin’s method, which was based on Leontev’s and Vygotsky’s theories of learning, and the conscious practical method (сознательно-практический метод). Today there is a sense of agreement in the L2 Russian literature that in most cases sticking to any particular language-teaching method would not be justified (Капитонова et al., 2008).

Soon after the collapse of the Soviet Union, the assessment of Russian as L2 started to move gradually to the top of the federal agenda. In 1998 the Russian Testing Center launched the Test of Russian as Foreign Language (TORFL), which is aligned with the Common European Framework of Reference (CEFR) (see Table 138.2).

All applicants for Russian citizenship are expected to have a minimum of A2. International college-bound applicants at the undergraduate level are expected to score B1. Graduate school applicants are required to be at Level B2 or C1, depending on their area of specialization. To be able to teach Russian, a non-native speaker should be at Level C2.

Table 138.2 Test of Russian as a Foreign Language in the CEFR framework (adapted from Балыхина, 2006)

<i>CEFR level</i>	<i>Russian as a Foreign Language Test</i>
A1	Elementary Level of Russian
A2	Basic Level of Russian
B1	TORFL—1—first certificate level
B2	TORFL—2—second certificate level
C1	TORFL—3—third certificate level
C2	TORFL—4—forth certificate level

All six proficiency levels (Table 138.2) are consistent in format and have five parts: (1) written test of vocabulary and grammar, (2) reading comprehension, (3) writing, (4) listening comprehension, and (5) speaking. The tests take anything from 230 to 285 minutes, depending on the proficiency level, and are administered within one day, with five-minute breaks between the parts. For lower proficiency levels, dictionaries are allowed for some parts of the tests.

Below are a few sample items followed by translation:

TORFL 1—Listening (Гончар, Федотова, & Юрков, 2005, p. 14):

Select the correct answer from those given below:

Сначала Вова не хочет есть, потому что суп (“First, Vova does not want to eat because the soup is”)

- А) холодный (“cold”)
- Б) теплый (“warm”)
- В) горячий (“hot”)

TORFL 2—Vocabulary and Grammar (Капитонова et al., 2007, p. 5):

Ребенок боится . . . (“The child is afraid of”)

- А) темноты (“the dark” in the genitive case)
- Б) темнотой (“the dark” in the instrumental case)
- В) темноту (“the dark” in the dative case)
- Г) темнота (“the dark” in the nominative case)

TORFL 2—Vocabulary and Grammar (Капитонова et al., 2007, p. 63)

Татьяна хотела поехать в Грецию, но потом . . . (“Tatiana wanted to go to Greece, but then she”)

- А) придумала (derivative of the verb “think” equivalent to “thought of”)
- Б) выдумала (derivative of the verb “think” equivalent to “invented”)
- В) задумала (derivative of the verb “think” equivalent to “planned”)
- Г) передумала (derivative of the verb “think” equivalent to “changed her mind”)

Apart from general Russian proficiency tests, the Russian Testing Center also offers tests for Russian for specific purposes, such as business Russian, Russian for mass media, other Russian for vocational purposes, and academic Russian (Балыхина, 2006).

Russian Assessment Issues

This section offers an evaluation of the two tests of Russian described above: the Unified State Examination of Russian (EGE on Russian) for high school-graduating native speakers and the Test of Russian as a Foreign Language (TORFL). Given the lack of reliable literature in academic sources on the assessment of Russian, it is hard to obtain any conclusive evidence. Therefore many of the arguments in this section remain tentative.

Issues of Assessing Russian as a Native Language

EGE has created much turmoil and harsh rhetoric in the government, in the public, and among educators. In 2011 some of the most covered news on TV, in print, and online included cases of corruption—such as test answers leaking out and being sold online and in person—and cheating—for instance, college students taking EGE for high school graduates for money, or teachers helping their students during exams; complaints from test takers and their parents; and public addresses condemning cheating and corruption, delivered by Russian President Medvedev, Russian Minister of Education and Science Andrei Fursenko, and Head of the Russian Orthodox Church Patriarch Kirill.

According to Avanesov (2006), professor and editor of the Russian journal of *Pedagogical Measurements*, the root of the EGE saga lies deep in the Russian political, economic, and educational systems. EGE is supposed to address several problems in Russian education. It is a unified measuring tool with the help of which key stakeholders could be informed of the achievement of high school graduates throughout Russia. EGE is also meant to perform a dual function, as an exam for high school-leaving students and as an admission exam for tertiary schools. Given all this, the government has placed high hopes on EGE for reducing corruption in Russian education. Finally, unified EGE scores should presumably open the doors of top-ranking universities to applicants from remote areas of the country, who otherwise would not dare to travel that far to take admission exams.

The original idea was to use EGE results in order to identify the top applicants to tertiary institutions, so that the government could offer grants to cover their tuition expenses, while those scoring lower would have to pay. However, economically this model did not work (Avanesov, 2006). Once it was implemented, the government realized it could not give out grants to all those who qualified to be at the top, and the original plan was abandoned.

From a political standpoint, Spolsky (2011, July 2) argues that high stakes testing exerts a lot of power, and he cautions educators and other key decision makers not to place this power in the hands of a federal department. Instead, assessment decisions should be mandated to educational institutions or to third party entities. Many Russian educators voice similar concerns (e.g., Avanesov, 2006; Хлебников, 2008; Самарин, 2011).

Apart from economic and political concerns, there could be some concerns with test validity. EGE is a norm-referenced test that measures both high school graduates' achievement on the curriculum and college applicants' competitiveness, since EGE is also used as an entrance exam to tertiary institutions. Vladimir Khlebnikov, the former director of the Federal Testing Center under the Minister of Education and Science of Russia, suggests that, while the norm-referenced approach would be justified for a college admission exam, it would not be a good choice for a high school graduate exam, where performance should be measured against specific objectives, hence a criterion-referenced test would be called for (Хлебников, 2008). Clearly different purposes are lumped into one test, an issue also raised at the 2004 International Conference on Assessing Educational Achievements at the State Level.

Let us now turn to the more specific discussion of the EGE of the Russian language. The exam targets a list of specific objectives that are weighted in the test specifications. It includes both open-ended responses and closed ones, which presumably tap into the target skills more directly. However, a closer look reveals a potential problem.

The grading rubric for the open-ended question, which is a written response of 150 words to a given text, looks overly mechanistic. It comes in a number of categories, such as statement of the problem, argumentation of personal opinion, cohesion and coherence, precision of thoughts, spelling, and punctuation. There are a total of 12 such criteria. Scores are assigned on how many errors a test taker has made (e.g., one to two grammar errors result in a deduction of one out of two points; making one logical error and offering two instances of improper division of paragraphs result in zero points).

Apparently the authors of the EGE have tried to address the potential problem of subjective assessment of open-ended responses by regimenting the scoring procedures at this level. It is puzzling that, instead of channeling their efforts into calibrating and rater training for a more holistic assessment, a practice that is empirically tested and commonly accepted worldwide, the EGE test developers took this new path. No data or empirical evidence seem available to validate this original take on open-ended responses. Larisa Novikova (Новикова, 2008), a professor of Russian, raises similar and many other concerns regarding the validity of Part 3 of the EGE Russian exam.

Psychometric results on EGE on any subject including Russian are hard to obtain. It is impossible to judge its reliability, validity, practicality, fairness, and overall impact on stakeholders without empirical evidence. Avanesov (2006) suggests that reliability measures on EGE are very poor, and that is why they are not made available.

Issues of Assessing Russian for Speakers of Other Languages

The test of Russian for L2 users seems to have a more solid grounding, but even there the situation can only be guessed indirectly, from the Association of Language Testers in Europe (ALTE) Web site. Direct evidence from published literature does not seem to be available, either in Russian or in English.

The Russian Language Testing Consortium, which includes the Moscow State University for International Education and the Russian Language Testing Center for Foreigners in Saint-Petersburg, is a formal member of ALTE. ALTE follows a quality assurance model published on its Web site (Association of Language Testers in Europe, 2005). According to their quality management system (QMS), ALTE members are expected to be continuously self-evaluating and improving their tests, while ALTE provides external collaboration for member institutions and is able to influence their work. The QMS approach takes into account major psychometric evidence as well as ethical aspects of language assessment.

So far, compared to EGE for L1 users, the test of Russian for L2 users seems to have more credibility due to its affiliation to an internationally recognized lan-

guage-testing organization. However, in both cases, direct solid evidence is drastically lacking, as was discussed earlier in this chapter.

Challenges and Future Directions

Over the last decade, Russia has made major strides toward a more standardized assessment of Russian as L1 and L2. From the literature available to date, one forms the impression that the assessment of Russian as L1 (EGE) has caused more controversies than expected. EGE is challenged on many grounds by the academic and professional community. In terms of its validity, there are concerns as to its ability to measure performance, both that of high school graduates and that of applicants to tertiary institutions. Predictive validity studies with accepted college students are in order to identify this trend. The same holds for the validity of the results when these are compared to the specific Russian-learning objectives of the high school curriculum. Whether this area of inquiry is on the federal research agenda for the near future remains to be seen.

EGE is also challenged in relation to the lack of transparency in scoring procedures. The final converted scale ranges from 0 to 100. Scores are converted by using a Rasch model, but according to some reports data do not seem to be consistent with the assumption of this statistical analysis for its valid application. For the end user, these converted scores are hard to interpret, too (Чельшкова & Шмелев, 2004). Some open discussion is underway, and perhaps the future will see positive changes in this direction.

Perhaps one of the hottest topics discussed in public media is the integrity of EGE, and of the test of Russian in particular. With federally controlled tests cheating still occurs, and this seems to happen on a large scale. Unexpectedly high results on Russian tests sometimes come from regions and small rural areas where Russian is not typically taught as well as in capital cities. The government now endorses independent third party observers during test administration, which will hopefully shed more light on this issue.

Finally, there is an ongoing discussion of potentially handing over EGE to a nongovernmental agency. This has been identified by educators and scholars as one the major drawbacks of EGE (Avanesov, 2006; Хлебников, 2008; Самарин, 2011), yet according to some news reports the government seems to be considering this option for the future.

There is less to be said about the challenges and future directions for the test of Russian for L2 users, and this, once again, is due to the vacuum registered in the literature. Some authors state that computerized approaches to testing constitute one of the major agenda items (Бальхина, 2006). Such approaches may include the development of computer-adaptive tests, or perhaps the computerized scoring of open-ended written responses.

Assessing Spanish

José Ramón Parrondo Rodríguez

Instituto Cervantes, Spain

Language Overview

Spanish, referred to as *español* or *castellano*, is a Romance language. It evolved from common Latin, which established itself over other European indigenous languages as a lingua franca during the expansion of the Roman Empire. The fall of the Empire gave way to the domination by Germanic tribes over the former Roman provinces. Visigoths dominated the Iberian Peninsula until the eighth century AD, when Muslim armies from North Africa brought most of the land under their rule.

For nearly 800 years, the Christian kingdoms to the north sustained a military struggle with their Muslim neighbors for control of the land. This resulted in intense contact between early Castilian speakers (a local version of Vulgar Latin that had evolved in the central northern region of the peninsula) and Arabic speakers. The evolution of the language must be considered also in terms of its geographical context: a natural bridge between Africa and Europe, the westernmost point of the Mediterranean, was a springboard from which to explore the Atlantic Ocean, a necessity brought on by the interest in finding alternative trading routes to Asia in the 15th century. The colonial enterprise of the Crown of Castile in the Americas meant the expansion of the language throughout a vast territory. It also came into contact with a large number of American languages, which contributed to its makeup, mostly in terms of lexical additions.

Spanish has more than a single standard. There are, broadly, two strands that can be found in Europe and America, conservative (in northern Spain, central Mexico, and the Andes) and innovative (in the Caribbean, southern Spain, the Canary Islands, and Argentina). Dialectologists generally distinguish eight varieties of Spanish: Castilian, Andalusian, and Canarian in Spain (Moreno Fernández & Otero Roth, 2007, p. 33); Caribbean, Meso-American, Andean, Chilean, and

Argentinian in America. Geolectal varieties manifest themselves especially in phonology (cf. *seseo*), and in the use of certain personal pronouns, which affect verbal forms (cf. *voseo*).

Spanish is a flexive language—grammatical agreement marks the relationship between words—but it is also a hybrid as it uses prepositions, sometimes essential for marking the arguments of transitive and intransitive verbs. Nouns and adjectives are number and gender marked; personal pronouns additionally distinguish case; verbs have different forms according to tense, mood, aspect, and voice. Sentence construction is more complex than in other similar languages—subordinate clauses are regulated by the use of the indicative or subjunctive moods. One of the most characteristic of its graphemes is “ñ,” phonetically /ɲ/. Spanish employs other graphic symbols which are not found in other European languages (e.g., the opening marks that signal questions or exclamations (“¿” and “¡”).

A History of Language Policy and Practice

Antonio de Nebrija’s Spanish grammar (1492), the first of any modern European language, was intended as a normative tool, and it included a section for learners of Spanish. By the 17th century, Spanish had become consolidated as a modern language and was being taught systematically, though with methods based on learning classical Latin: grammar rules and translation of literary texts. Other practical approaches (phrase books and conversation guides) were also produced for those who wanted to learn the language to travel, trade, or evangelize. Until the 20th century, most language-learning materials were created outside Spain by non-native speakers (Sánchez Pérez, 1992). Official language policies ranged from encouraging the learning of local languages for evangelization purposes to imposing a metropolist model and establishing norms authoritatively, often to the detriment of other vernacular languages.

The Real Academia Española (Spanish Royal Academy, RAE), founded in 1713 with the mission of “purifying, setting norms and enhancing the grandeur” of the language, has had a profound influence in teaching and assessment practices to this day. It has propagated the view that language use should be norm regulated—in a prescriptive approach—and that sanctioning such norms is the prerogative of the learned elite and the literary masters. On the other hand, it has been largely responsible for the structural cohesiveness of modern Spanish. Spelling, for instance, which over time has been simplified in accordance with phonological criteria, has remained uniform. The RAE has inventoried and authorized lexical items—especially the adoption of foreign words—through dictionaries; it has produced normative grammars and it has expanded into 21 corresponding academies, representing each of the countries where Spanish is spoken, including the USA.

Throughout the 19th century, the emancipation of the Spanish American colonies coincided with the birth of universal schooling systems, whose contribution to the standardization of the written language has been considerable. The new constitutional frameworks in the American republics ensured that written language standards were maintained in the educational and legal systems, and in the media. Written Spanish is consequently a highly standardized language.

The RAE's outlook has changed considerably over the past decades, becoming less prescriptive and more sensitive to the demography of speakers. Its new motto—"unity and diversity"—reflects modern political trends without renouncing its primary function: the preservation of standards. The *Diccionario Panhispánico de Dudas* (Real Academia Española, 2005) is an exponent of a change of paradigm, whereby the principle of polycentric standards is materialized through a more descriptive and inclusive approach to language norms.

Over the past two decades global media, the entertainment industry, and Internet have probably contributed more to the standardization of the language than official policies. The tendency, as speakers become less distanced from unfamiliar variants thanks to worldwide access to media, is towards "neutralization," so that products are accessible to a greater audience.

Outside Spanish-speaking countries, language learning has, until recently, been confined to universities, where any manifestation of the language that was not strictly literary was frowned upon. Teaching favored Peninsular Spanish and written literary texts. The traditional view is that learning modern languages should not be easy. Consequently, assessment is based on knowledge and application of grammatical rules in translation tasks, with examiners focusing on formal errors. Thus, Hispanic studies graduates are typically able to quote Cervantes, but unable to use more sophisticated pragmatic tasks.

Official language policies from Spanish-speaking countries did not materialize until the 20th century:

- The Spanish Escuela Oficial de Idiomas (EOI), set up in 1911, started to issue proficiency certificates as early as 1927. Examinations contained a translation component, but certificates had considerable social prestige, because the tests were "very hard" and a meagre percentage of students managed to pass the "Reválida" examination. EOIs filled a gap that universities were neglecting. The focus of their programs was on language, rather than literary texts alone, and their standardized tests can be taken without enrolling in courses.
- In 1989, the Spanish Ministry of Education started to administer standardized language examinations outside Spain, the diplomas in Spanish as a foreign language (DELE). An act of parliament led to the creation of the Instituto Cervantes in 1991. Both initiatives were indebted to the convergence of several factors: the emergence of a younger, more professional, cadre of teachers of Spanish at the EOIs, the rise of communicative language teaching, and the integration of Spain in the European Union, which gave the language a political dimension.
- The Universidad Nacional Autónoma de México established the Centro de Enseñanza para Extranjeros in 1921, in order to cater for the language needs of its international students. The development of the Examen de Posesión de la Lengua Española (EPLE) examination in 1997 and the existence of a proprietary network of offices in the USA allowed for the internationalization of the certification scheme, which is now also run in Asia.
- Cuba has been a provider of language teachers through a network of university departments around the world since the 1970s.

- In Argentina, with a focus primarily on Brazil, a consortium of universities has developed language-teaching programs and international examinations (Certificado de Español Lengua y Uso, CELU, *n.d.*).

Most Spanish-speaking universities have developed initiatives to supply language services in the wake of the formidable demand for Spanish in the educational systems of Europe, America, and Asia. It is estimated that the world population of students of Spanish has increased fivefold from 1997 to 2007, and stands at over 14 million (Instituto Cervantes, *n.d.*).

Teaching, Learning, and Assessing Spanish Today

In school systems where Spanish is taught as a first language assessment practices may vary significantly. Regulations are open ended and allow individual teachers a considerable amount of freedom to design and implement procedures. Where practical orientations are given, teachers are advised to integrate assessment into their teaching but are not told how, nor are they given coherent indications (Morales Gálvez, Arrimadas Gómez, Ramírez Nueda, López Gayarre, & Ocaña Villuendas, 2000). Specific criteria, rubrics, or other technical tools are absent from most official directives, and so teachers use a mixture of common sense and received tradition.

At the heart of the problem lies the lack of attention given to assessment in most teacher-training programs, which concentrate on learning theories and on how to teach different subjects, but where the knowledge and skills necessary for assessing learning are generally absent. Moreover, there has always been a tendency to teach and assess language in conjunction with literature, and constructs are further contaminated by attitudinal features (e.g., attendance, punctuality in completing assignments) and crosscurricular elements (e.g., culture).

There is an all too apparent contradiction in advocating student-centered approaches, communicative language teaching methodologies and formative assessment, while ignoring the impact that proficiency testing has at certain points in the curriculum. How high stakes examinations impact learning outcomes is underestimated and is largely responsible for turning out students who can carry out a syntactical analysis of a complex sentence, or recite verbal conjugations, but who struggle to speak out coherently in a public debate or write a formal letter. This situation is paradoxically more acute in countries like Spain, with supposedly high—or almost full—literacy levels.

In Central America, it is worth highlighting the work carried out by agencies such as the United States Agency for International Development (USAID) in the context of cooperation programs with local governments to improve literacy levels among school populations. The systematic use of modern measuring methods is feeding back into teacher-training programs and raising awareness of assessment as a language policy tool.

In regions of Spain, Central America, Colombia, Paraguay, or Chile, Spanish is also taught as a second language, often in the context of bilingual programs that have materialized in the last 30 years. As many as 400 different ethnolinguistic

groups coexist with Spanish in the Americas alone. The impact of certain modern policy trends, such as plurilingualism, political concepts such as the empowerment of minorities and the preservation of heritage languages, and significant demographic shifts caused by migration, have contributed to the diversification of language teaching. Although this has triggered a prolific production of educational materials and teaching programs, assessment procedures—if they exist at all—remain for the most part unstandardized and, with the exception of some Peninsular languages such as Basque, Catalan, or Galician, examination systems are not deployed beyond the confines of teaching institutions or limited geographical areas.

This is not the case in the USA, where Spanish is taught as a second language in a whole variety of contexts and programs, but where there is also a long tradition of standardized testing; placement, diagnosis, and proficiency are some of the uses of the array of commercially available tests for school and professional use (Del Vecchio & Guerrero, 1996), albeit fashioned on the basis of existing English language tests.

In 2010, a survey was carried out by the Instituto Cervantes on certification systems in the Spanish-speaking world, in the context of devising working plans for the international certification system of Spanish as a foreign language (SICELE), an initiative designed to introduce quality management systems to language-testing activities among its 140 member institutions. More than 200 organizations were canvassed and the results were analyzed in order to obtain a picture of the current situation.

Independent, standardized foreign language testing in Spanish—outside the context of higher education institutions—took off in the early 1990s and has now become an industry that turns out an estimated quarter million certificates annually. Although as much as 20% of the market share is held by the Spanish Education Ministry DELE examinations, modeled on other European assessment systems such as the Cambridge English for speakers of other languages (ESOL) suite of exams, other initiatives from Argentina (CELU examinations) and Mexico (EPLE examinations) are worth mentioning, but the best part of this activity is carried out in non-Spanish-speaking countries. The National Spanish Exam—a norm-referenced assessment system aimed at secondary schools—has had a long tradition in the USA and attracts 100,000 candidates a year; the Casa de España in Tokyo, Japan—an independent organization—promotes Spanish language examinations sat by 10,000 people every year; other language service providers in Europe and North America include Spanish language certification schemes for which demand is on the increase.

Although most of these certification systems are related to general proficiency, some schemes address specific professional purposes, such as the Examen de Español de los Negocios, sponsored by the Madrid Chamber of Commerce and the University of Alcalá, or the Educational Testing Service (ETS)'s Examen de Admisión a Estudios de Posgrado™ (EXADEP)—aimed at Latin America. For the most part, these tests are criterion referenced, and some of them claim to be linked to the most popular referent—the Common European Framework (CEFR)—although little or no evidence has been published to support these claims.

The majority of the estimated 1 million plus discrete language certificates in Spanish which are issued annually worldwide, however, are linked to specific courses of study and are unstandardized. Users of these certificates, most of which are valid indefinitely, range from employers to immigration officers, and their impact is greater in geographical areas such as the Mediterranean Basin, Central and Eastern Europe, and Brazil, although demand is growing in the Far East. The existence of a considerable number of commercially available standardized Spanish tests in the USA—especially for second language use—has meant that other assessment systems promoted by foreign institutions, whose focus is on foreign language learners, hardly have a presence in social and educational spheres.

Issues Related to the Assessment of Spanish

In the assessment of Spanish as a first language, which takes place almost exclusively in regulated schools, one of the major issues is that most educational programs are based on the acquisition of metalanguage, the memorization of language rules, and the reading of literary texts, with little time devoted to developing writing skills, speaking, or putting language to use in practical applications of everyday life.

Consequently, the assessment systems that prop up these programs are based on tasks such as dictation (to monitor spelling mistakes), syntactical and morphological analysis of clauses, and the occasional questionnaire on compulsory reading material. Testing instruments are mostly based on discrete-point items which are graded dichotomously, and there is little recourse to rubrics or proficiency scales for the grading of open-ended questions. Thus, an eight-year-old might reasonably be expected to carry out a syntactical analysis of a simple clause and answer questions on the conjugation of a specific verb form, but their production skills are seldom tested and therefore of little interest in classroom practice. Pedagogical and evaluation materials seldom differ from one another, since the general belief is that educational and testing practices are thus consistent.

Reports on school students' skills across Europe have highlighted the interest of standardized testing instruments for comparing student populations and educational systems. In terms of the first language, these tests usually measure reading comprehension, so their scope is limited even as they focus on practical language use. A side effect has been that textbooks and classroom practice make provision for such tasks, although the tendency to use literary materials as a basis for developing reading and writing skills still remains.

In the second and foreign language sectors, however, and in spite of a shorter tradition, the philosophy and practices are more modern, perhaps because epistemological sources for most professionals in the field are closely connected to the development of applied linguistics in English language teaching (ELT), as well as the general acceptance of communicative approaches, and latterly the popularization of the CEFR. As a result, proficiency and achievement tests are developed to measure other dimensions than grammatical accuracy, but the scholastic traditions are still prevalent in most placement and diagnostic tests provided by educational institutions.

Testing does not figure prominently in postgraduate programs or training courses aimed at future language teachers, for there is still little awareness that this crucial aspect of an instructor's professional career requires specialized preparation. As a result, most classroom-based assessment is unstructured and unsystematic. The teachers' lack of technical skills for norming and standardizing testing instruments disables concurrent validation with other assessment procedures, and the appraisal of external or independent certification systems is impeded by the lack of critical judgment skills. One case in point is the intense assessment and certification activity that takes place in the Instituto Cervantes' 70-center educational network, largely linked to the teaching services it provides. Here, there is no common standardized procedure for placement, progress monitoring, achievement, or proficiency testing of its over 100,000 annual students.

Large-scale standardized testing still needs further development. Where claims are made by test providers that their products are linked to an external reference framework (notably the case of the Spanish DELE exams and the CEFR), evidence needs to be provided. Where no such claims are made (the Argentinian CELU, the Mexican EPLE, or Centro Nacional de Evaluación [CENEVAL] exams), rubrics, scales, benchmarks, and more elaborate descriptors of the model of language competence being tested need to be put forward.

It is worth noting that in the majority of first language teaching and assessment contexts the geolectal variety of language tested tends to be quite homogeneous, though this contributes to validity problems. In second and foreign language situations, however, where test takers can be multifarious in terms of the variety of the language learned, establishing a Spanish language standard by which the learners' ability is measured can be elusive. It is difficult to develop a Spanish language test that will not place some candidates at a disadvantage because of the variety of Spanish they have learned (Del Vecchio & Guerrero, 1996) or even because of the variety that the rater uses. A possible solution would be to label the examination appropriately (e.g., "assessment of Argentinian Spanish"). DELE exams appeal to the global user: input texts in multiple varieties and output allowed in any variety, provided it is consistent, although the bias towards the Peninsular variety is evident in the subtests that measure grammatical and lexical competence.

The results generated by such proficiency tests may be suspect due to the complexities involved in norming them throughout the Spanish-speaking world. Nonetheless, there is probably more cause for concern in the fact that some varieties may be stigmatized a priori by certain foreign language learners, and that any variety that a learner uses may be potentially subject to biased evaluation by a prejudiced rater.

A common thread can also be identified in the nature of language-testing practices that take place in most contexts. Virtually all of the instructors and testers involved—whether they teach Spanish as a first, second, or foreign language—come into the profession through rigid university programs (philological studies) still anchored in the humanities tradition, and where more prominence is given to diachronic language study and the authority of renowned literary masters than to applied linguistics, pedagogical training, or the use of empirical quantitative and qualitative research methods.

Until more interdisciplinary and specialist programs are devised and implemented, and until awareness of the dimensions and consequences of language-testing activities is shared, most practitioners will continue to apply and defend traditional testing and certification solutions, based solely on the historical prestige and academic acumen of the institutions that sponsor them.

Future Challenges

The popularization of external frameworks (Association of Language Testers in Europe, ALTE, from 1990 to 2001; CEFR, from 2001) in Europe, was largely due to the need for a transnational recognition of language certificates, central to the mobility of labor. Not a single product or service connected with the language sector today fails to relate to the CEFR. This has given way to criticism that not all claims are founded on real research evidence and that many service providers are simply taking advantage of a trend that has gone beyond Europe's political borders. Some have advocated the need to regulate the language assessment sector so that claims can be challenged if they are not properly substantiated, an initiative which could be considered in the context of consumer protection legislation, although so far no significant moves have been made in that direction. Instead, associations such as ALTE have chosen to set up self-regulatory schemes by developing quality management systems designed primarily to communicate with the stakeholder and provide assurance that tests comply with certain standards. Similarly, the SICELE initiative addresses the same issues in the Spanish-speaking world, although so far no outcomes are apparent, beyond a well-worded declaration of intent and a fairly elaborate working plan.

It would not be impossible to envisage future supranational agencies that would carry out independent test audits, issuing certificates of compliance as appropriate, much in the same manner as other industries are regulated, so that competitiveness would depend on the standards of excellence achieved. In the short term, it would be desirable to see high stakes Spanish language examination providers address certain unresolved validity issues (language norm, evidence of linkage to external frameworks) and thus become more economically, socially, and politically accountable to users. It would also be useful to undertake a review of current training programs for language professionals in order to instill more empirical, scientific approaches to testing, as well as an awareness of the importance of this activity and its consequences. The abandonment of deep-seated beliefs that the quality of an exam is determined by the historical prestige of the institution that promotes it, rather than on modern industry standards and evidence-based approaches, must also figure.

Spanish testing will expand and diversify throughout the world, especially in the foreign and second language segments, both in terms of the volume of activity and in the number of service providers. The currency of certificates will also increase, as they become essential access keys to the labor market and to geographical mobility. What remains to be seen is whether providers and practitioners will rise to the challenge of making their activity more professional, more sustainable and more responsible.

Assessing Welsh

Emyr Davies

CBAC-WJEC, Wales

Introduction

Welsh is a Celtic language, spoken primarily in Wales, a country within the UK. At the time of the census in 2001, there were 582,000 Welsh speakers, representing 20.8% of the population of Wales (see Figure 140.1). This was an increase of 2.1% from the figure of 1991 which was 18% (Welsh Language Board, 2011), the first census in history to record an upturn. The results of the 2011 census have yet to be analyzed. The population map (Figure 140.1) shows a higher percentage of speakers in the rural north and west, though demographic patterns have changed and are changing, with young people migrating from the traditional “heartland,” and in-migration of older people to the same rural areas. This change has had a negative impact on the number of speakers, as well as the use of Welsh as the medium of social interaction in these areas.

There are some key milestones in legislation which may account in part for the overall increase in numbers, and a change to a more positive attitude toward the language. Welsh has been compulsory in schools in Wales since the 1988 Education Act, and children must now learn Welsh either as a first or second language from the ages of 5 to 16. Another key milestone was the Welsh Language Act of 1993 which gave Welsh and English equal status. This was followed by the establishment of the National Assembly for Wales in 1998, to which certain areas of responsibility were devolved from the UK parliament, including education. This in turn follows decades of benign neglect on the part of government, and before that, openly negative attitudes. It is difficult to ascribe the sea change in attitudes within government and within the general population to these measures, and some would claim that the legislative changes have only come about following political pressure and the increased willingness to assert a linguistic identity and to campaign for Welsh-medium education, bilingual signs, and official documents

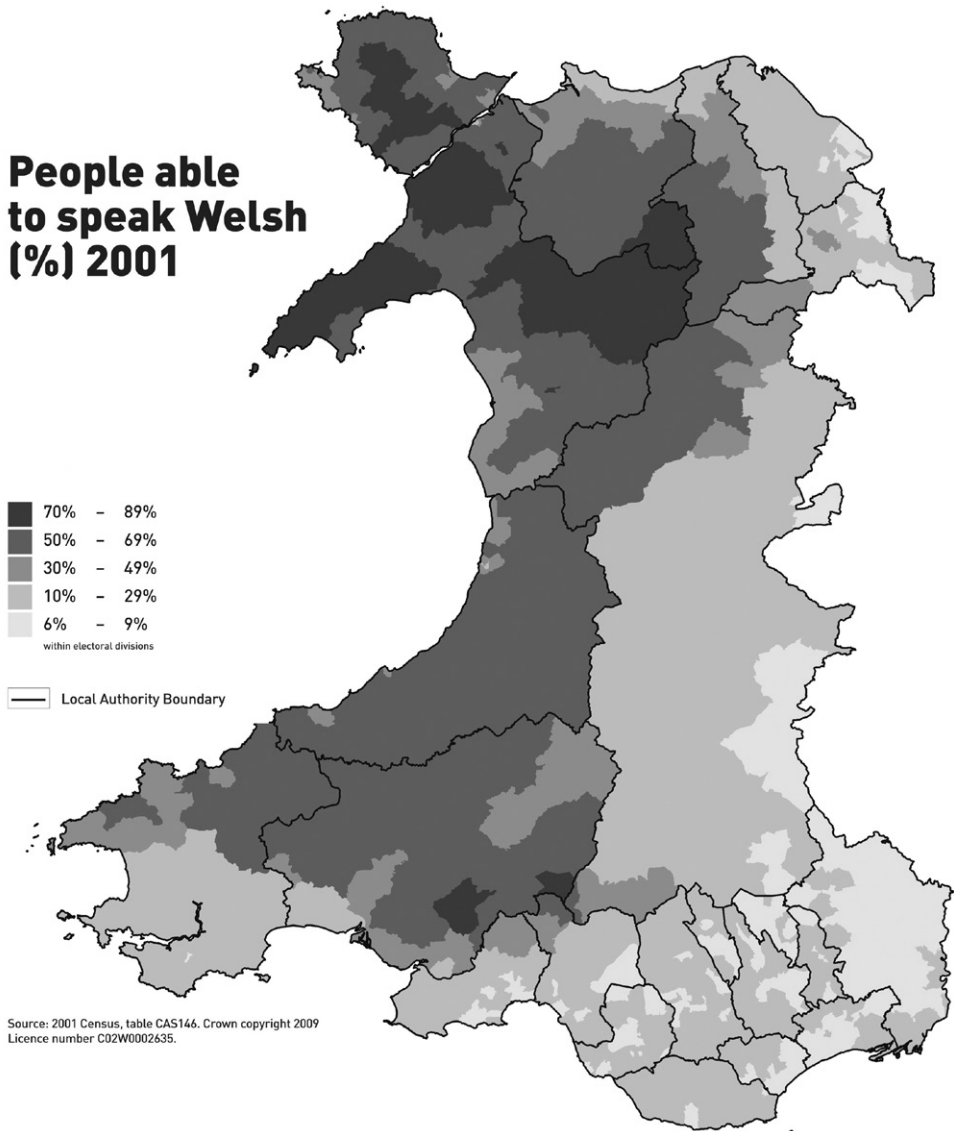

Figure 140.1 People able to speak Welsh in Wales (2001 census). © Welsh Language Board

in Welsh. One of the most striking manifestations of this change in attitude is the demand for Welsh-medium schools in the more anglicized southeast. This has led to a mushrooming of new schools following vocal protests by parent groups. Another feature relevant to this chapter is the increase in Welsh learning among adults. Formerly the preserve of academics (and eccentrics), fluent former learners are far more visible in the media and society generally.

There are other positive aspects to this change in attitude to Welsh which should be mentioned. Welsh language media, including a dedicated television channel

and Welsh language radio, provide a variety of programming. The media industry has given high quality employment for many, though this has been concentrated in the Cardiff area. From a teaching and assessment perspective, the availability of authentic audio and audiovisual material has been valuable, and, more importantly, provides a constant source of language input into learners' homes. Newer technologies have also been embraced by Welsh language speakers, including Web-based resources, apps, and social media. The impact of these is still being realized, but the importance of being perceived as a modern and useful communication tool cannot be overestimated. Welsh is no longer perceived as old-fashioned, culturally quaint, and shrouded in Celtic mysticism.

Description of the Language

Welsh is a Celtic language and has certain linguistic features in common with the other languages in this group, which contrast with English. Syntactically, Welsh has verb-initial (VSO) word order, for example:

Darllenodd Twm y cylchgrawn
 Read Tom the magazine
 'Tom [did] read the magazine'

There is a system of initial consonant mutation, driven partly by phonology and partly by syntax. The most common "soft" mutation (mainly voicing of unvoiced stops) can be triggered by different contexts, for example, following the definite article (feminine nouns only); following certain prepositions; being the direct object of an inflected verb, and many more, for instance:

Darllenodd Twm *gylchgrawn*
 Read Tom a magazine
 'Tom [did] read a magazine'

In the second example, the direct object of the inflected verb is not preceded by a definite article and, therefore, the first consonant is "softened" (voiced, in this case). There is no indefinite article in Welsh. Other complexities include responses to closed questions, that is, yes/no answers, which vary according to tense, person, and emphasis.

Phonologically, Welsh has some distinctive consonant sounds, including fricatives, for example, "Ll" as in *Llangollen*; "Ch" as in *Chwech* (six), similar to German "ch." These features can present difficulty for learners of Welsh as a second language, though accuracy in vowel and diphthong placement is in fact more problematic for learners. Difficulty in pronunciation has implications for assessment, and features in assessment criteria to different degrees.

Welsh is an Indo-European language, and has a number of historical Latin loanwords, and loanwords from English. For example, words like *fffenest* 'window', *pont* 'bridge', and *braich* 'arm' are clearly derived from Latin loanwords. More recent loans from English are many, and may be easily adapted, for example,

by addition of a suffix. For example, *banc* 'bank' is changed into a verb-noun by the addition of a verbal suffix: *bancio* 'to bank'. However Welsh and English are linguistically very distant cousins, and familiarity with other, "larger," European languages is of little help to learners and candidates. Nouns can be masculine or feminine, though there is some variation in gender across dialects. There is a wealth of dialect variety in Wales, usually generalized into south and north, though there are many rich, more localized forms. Mutual intelligibility is not the problem it once was, and familiarity with different accents, lexis, and minor differences in syntax is well established, thanks to television and radio. Issues around dialect often arise in teaching and assessment, as language classes which focus on colloquial forms will of course vary, and teachers will either be in favor of more localized forms, or more "standardized" forms. Efforts to standardize a written representation of the spoken language have had mixed results (Davies, 1988). However, it should be noted that Welsh orthography is comparatively consistent in its phonemic representation, which facilitates reading. Children find learning to read in Welsh far easier than in English (Ellis & Hooper, 2001).

In speech, Welsh speakers frequently code switch and include English words and phrases in spoken Welsh, adding to the confusion of learners. With regard to the sociology of Welsh, Welsh learners often have difficulty accessing Welsh-speaking circles. The reasons for this are difficult to isolate. First language speakers often feel a sense of inferiority regarding their own language, and are therefore unwilling to speak to learners whom they regard as speaking "proper Welsh." First language speakers may also feel uncomfortable if an interlocutor is struggling or if communication breaks down, and will then switch to English. Other reasons for this switch have been suggested, for example, the difficulty of establishing a "social identity" for Welsh learners (Trosset, 1986).

The only context where learners or candidates may not necessarily be fluent English speakers is in Patagonia, Argentina. Hundreds of Welsh emigrants arrived there in the nineteenth century, and there remains a Welsh-speaking community, or rather a bilingual Spanish–Welsh community, who are the descendents of the original migrants (BBC Wales History, 2008). A small number of candidates take the Welsh for adults assessments annually (between 10 and 20 candidates at different levels), and Welsh language teachers from Wales are supported there by the British Council.

Teaching–Learning Contexts

Teaching and Assessment in Schools

Welsh language assessment provision is an ever-changing picture. The main provider of qualifications in Wales, since its establishment in 1948, is CBAC-WJEC (Cyd-Bwyllgor Addysg Cymru-Welsh Joint Education Committee). Other awarding organizations can provide qualifications to schools in Wales, though they may be based in England. Schools can choose different awarding organizations for different subjects. Although education is a devolved area of responsibility, there are good reasons why the qualifications framework is shared across England, Wales,

Table 140.1

<i>GCSE (General Certificate of Secondary Education) Qualifications attained at the end of compulsory education at age 16</i>	<i>Number of takers in 2010</i>
Welsh Literature (First Language)	4,167
Welsh Language (First Language) (including a revised pilot version of the same qualification)	5,444
Welsh Language (Second Language) (including a revised pilot version of the same qualification)	10,311
<i>GCE (General Certificate of Education—Advanced) Qualifications attained at age 18</i>	
Welsh First Language	363
Welsh Second Language	503

and Northern Ireland. GCE (or General Certificate of Education qualifications, commonly known as “A levels” in the UK), are high stakes, and are used by universities as entry requirements, based on a points system. Welsh language qualifications count equally in this regard, and conform to the requirements of regulators in England and those for Wales. Table 140.1 shows the number of candidates for the various levels in 2010 for the main Welsh qualifications available.

Full details and information about results are available on the WJEC Web site (WJEC, *n.d.*). Children must learn Welsh until the age of 16 either as a first or second language, and the end of program assessment at age 16 is known as GCSE. For first language students at this level, qualifications are divided into Welsh Language and Welsh Literature. The language qualification includes part internal assessment, that is, assessment within the school by a teacher, and part external examination. The external examination involves reading comprehension, text production based on the text and an element of “use of language,” which is an error correction exercise. Speaking is assessed internally by a structured discussion and prepared presentation of a topic from a prescribed list of themes. There has always been a strong bias toward literature in teaching first language speakers, which reflects a general unstated view that studying Welsh should prepare students for studying Welsh literature in higher education. This focus is more apparent in the GCE or advanced qualifications for first language speakers, though there is a “use of language” strand to the assessment.

As seen in the figures for 2010 in Table 140.1, the number of candidates for Welsh Second Language is nearly double that for Welsh First Language. The distinction between “first language” and “second language” is not as clear cut as it may first appear. Many children come from homes where neither parent speaks Welsh, and yet will have attended Welsh-medium education from the age of four, and be classified as “first language.” This can be a contentious issue when schools enter students as “second language” simply in order to achieve higher grades. At GCSE (end of compulsory education), Welsh Second Language also involves internal and external assessment. Skills are weighted equally, and speaking is

assessed by group or pair discussion on a prescribed topic. Samples of speaking performance are sent to external moderators to ensure reliability. At GCE (advanced level), there is a focus on literature including drama, poetry, and film. Also included is a “mediation” task, whereby candidates are required to summarize an article in Welsh, with the source article being in English. This development reflects the bilingual context, and the fact that people often mediate between languages in this way, that is, discussing sources which are in English through the medium of Welsh.

Teaching and Assessment of Adult Welsh Learners

Teaching Welsh to adult learners is well established in Wales, and is the largest adult education program area. There are a number of providers: higher education universities, further education colleges, education departments of local government, and others. These providers are directed by six regional centers, which have responsibility for training, quality management, and coordinating assessment. Over 20,000 students join adult education classes annually, not counting the many independent learners, those who learn by association with Welsh speakers, and learners outside Wales.

Teaching Welsh to adults is well developed, and has grown both in terms of learner numbers and in the amount of resources available for the language classroom and heuristic learning. The approach to teaching has been eclectic, and has drawn from different methodologies. In the main, course designers have adopted a structural view of language, building sentence patterns in an ordered fashion via language drills. The learner is thus enabled to engage in more communicative activities and tasks, leading to more autonomy. Certainly, the communicative approach has been influential, but was not adopted wholesale. The focus in teaching has always been on speaking, and spoken interaction. Writing is viewed mainly as a reinforcement, or confirmation, of speaking skills, and this is reflected in the weighting for the different skills in the Welsh for adults assessment regime. Learners on Welsh for adults courses and, by extension, candidates undergoing assessment, rarely join courses in order to be able to write in the target language. Adults are motivated, often highly educated learners, and have a positive attitude to learning and the Welsh language, which is not always the case for school-age learners. Adults also choose to undergo formal assessment, whereas this is compulsory for school-age learners. The vast majority of learners speak English as a first language, or speak English fluently. This is an important consideration in teaching, and affects outcomes in many ways. The success of a learner cannot be measured in terms of surviving in a monolingual target language environment. In any context where Welsh can be used, that activity can be achieved through the medium of English, and learners must therefore look for opportunities to use their Welsh language skills. Even where the density of Welsh language speakers is highest, there is no social necessity for non-Welsh speakers to learn. Adults join classes for different reasons, but the majority will not pursue a language course for utilitarian reasons. Although candidates state that they may undertake formal assessment to “help their work prospects,” even here the majority take examinations for personal, formative reasons.

Table 140.2

<i>Level</i>	<i>Number of candidates in 2010</i>
Mynediad/Entry (A1)	1,105
Sylfaen/Foundation (A2)	445
Canolradd/Intermediate (B1)	209
Uwch/Advanced (B2/C1)	56

There is a suite of five qualifications for adult Welsh learners, provided by WJEC, and supported financially by the Welsh government. Two of these examinations have been in existence since 1990, but the decision was made to develop a wider suite of examinations at more levels in 2001. The first cohort of candidates took the new levels in 2003, and the whole suite has been in continuous development since then. In 2001, CBAC-WJEC became a member of the Association of Language Testers in Europe (ALTE), and the support provided by ALTE, including a thorough auditing process, has been a valuable development tool. The examination suite was revised using the Common European Framework of Reference (CEFR) (Council of Europe, 2001), as a guide, but maintaining the close link with the existing course provision and teaching materials. There is a broad correspondence between the levels of the Welsh for adults examinations and the CEFR, certainly at the lower levels. The number of candidates has grown steadily, and the figures for 2010 are given in Table 140.2.

The fifth level (Proficiency) is not included in Table 140.2, as it has attracted few candidates. More than half the candidates are at A1 level and there is a tendency for candidates to take a lower level than they could achieve. The population is self-selecting; that is, candidates will not opt to do an exam if they are unlikely to pass. So, the pass rate is very high, for example, 95% at Mynediad/Entry level. The assessment is criterion-referenced, and no fixed proportion of candidates must achieve any particular grade. Skills are tested separately and, as mentioned, weighting is heavily in favor of spoken interaction, for example, at Mynediad/Entry level, skills are weighted as follows: Speaking (55%), Listening (20%), Reading (15%), and Writing (10%). The effects of examinations can be far reaching, and the washback on teaching is a main consideration in the development of these examinations. A greater bias toward writing could possibly encourage tutors to spend scarce classroom contact time on developing writing skills which learners are unlikely to need. Speaking tests are held one-to-one with a trained interlocutor, and all are recorded and assessed externally.

Specifications are available (WJEC, *n.d.*), but it would be useful to draw attention to examples of various task types in the examinations, as they relate to the linguistic and sociolinguistic context. Responding to closed questions (answering “yes”) is an immediate problem for learners, and one task within the speaking test in the Sylfaen/Foundation examination requires candidates to give the appropriate “yes” answer to questions and to agree with statements, using the correct “yes” form. The response depends on a number of variables such as person, tense, number, the main verb, and others, for example, *Ydw* is the ‘yes’

response in the first person singular, present tense, responding to an inflected form of *bod* 'to be'. Essentially, this is a grammar component, and although it accounts for only five percent of the total, candidates have expressed positive views about this part, as it obliges them to concentrate on an often neglected, but important aspect of grammar. At B1, in the Canolradd/Foundation exam, candidates are required to fulfill a prerecorded oral task, whereby they are required to record a five-minute conversation with a fluent speaker. The candidate must direct the conversation, and assessment includes the candidate's ability to interact with the fluent speaker, to ask questions, as well as the grammatical accuracy of their input. It is hoped that such a task will encourage learners to engage in interaction with fluent speakers, and to establish links and norms which may continue after the examination process has ended. Given the difficulties that learners have in accessing Welsh-speaking circles, this is a case where the impact and washback effects are as important as the primary purpose of the examinations: assessment. From the feedback forms returned by candidates, the views expressed toward the examinations are overwhelmingly positive. This suggests that their impact is a positive one.

Challenges and Future Directions

There are many other positive aspects to the renewed interest in the Welsh language, and much investment has been made in its future. However, many challenges are faced by educators and those with responsibility for assessment. In schools, it can be difficult to persuade 16-year-olds that learning Welsh has any value or interest. Attitudes can be indifferent or even hostile, and the problem of getting learners to integrate with Welsh speakers outside the school boundaries has no easy answers. Much investment and work have gone into providing out-of-school activities in which learners can participate through the medium of Welsh. Welsh as a subject competes with other subject areas for time in an already full curriculum, and this can make teaching this age group difficult. Also, the successes of teaching at a primary level are not always continued at secondary level, after the age of 11. Adult learners are at least motivated and positive but, even in this sector, getting learners to integrate with Welsh speakers in all areas, including Welsh "strongholds," is always a challenge.

Assessment is a means to an end, and the aim across sectors is to increase the number of confident Welsh speakers. This is in fact the stated aim of the Welsh government. A recent publication states the government's intention of creating "the right conditions in which the Welsh language can grow and flourish in all aspects of Welsh life" (Welsh Assembly Government, 2003). Assessment, and the impact of assessment practices, must surely play a part in this policy, if it is to succeed.
